1819.
MONSTER, in Anatomy and Physiology, a creature in whom the body in general, or some large and conspicuous part of it, deviates remarkably from the accustomed formation. The union of the two eyes into one, with deficiency of the nose, the want of the brain, and of its membranous and bony coverings, the various more or less complete junctions of two bodies, &c. come under this description. A considerable deviation from the ordinary form or structure of a particular part or organ is often called a monstrous formation.

Considerable variation is observed in the form, size, and relative position of the nerves, vessels, muscles, bones, &c. All the smaller parts, particularly the blood-vessels, differ in almost every two bodies; so that it would be very difficult, if we defended into minutiae, to settle precisely what ought to be regarded as the most frequent, and therefore the natural structure. These aberrations from the accustomed type are generally called by anatomists varieties, and frequently lyphas natures, as if they owed their origin to nature being in a sportive mood. No very accurate line can be drawn between them and monsters; nor can we assign any very rigorous meaning to the latter term, which is generally used in a loose and popular manner. "Monstrum vox," says Haller, "ex ipsa lingua natura videtur deignare aberrationem animalis a confidenti fuso speciei fabrica adeo evidentem, ut etiam ignarorum oculos ferat. Nobis vis vocis perinde videtur indicare fabricam, etiam grandium & confpicuum partium, alienam a folia." De Monstris, lib. i. cap. 1.

In the present article we propose to consider the subject of unusual formations in a general view, without confining ourselves to those called monsters. When we speak of natural or unnatural formations, we only mean, by the former, the organic arrangements, which are the most common; by the latter, the deviations from the standard.

In the following account of unusual formations of the body in general, or of its parts, we shall adopt the following divisions, without attempting to draw very accurately the line of distinction between varieties and monstrous formations, which differ rather in degree than in kind.

I. Varieties which are for the most part not incompatible with the right performance of the natural functions.

1. General Observations. 2. Unusual formations of the skin; comprising, a, deviations from the natural colour; b, patches of hair; c, porcupine men; d, marks existing at birth; e, horns. 3. Varieties in the viscera; including, a, transpositions; b, varieties in the intestinal canal; c, in the kidneys and uterus; d, in the heart.

II. Monsters. 1. With unnatural formation of some parts; a, hare-lip; b, malformation of the urinary and generative organs; c, united eyes; d, spina bifida; e, imperforations; f, imperfect extremities; g, general malformation; h, resemblances of animals. 2. With unnatural position of parts. 3. With deficiency of parts; a, want of the brain and its coverings, and of the spinal marrow; b, of the heart; c, of various other parts. 4. With supernumerary parts; a, supernumerous parts in bodies otherwise perfect, as fingers, limbs, heads, lower half of the body, and more or less complete body; b, united fetuses; compound head; fetuses double above and joined below; double below and joined above; two perfect bodies united; c, fetuses included in the bodies of others.

III. Considerations on the production of these unusual formations.
there is no reason why nature should not sometimes deviate from her ordinary plans. Accordingly, we find that there is much variety in animal structure, but this does not commonly affect the functions. Under this restriction, the variety is so great in the appearances of every part, that it is almost impossible to examine any two animals of the same species without remarking many differences. In the articular extremities of bones there is little variety; because a particular shape is best adapted to a particular kind of motion. In other parts, as the foramina, depressions, ridges, and futures, there is great variety. Examples of this are seen in the ossa triquetra of the skull, which are sometimes absent, sometimes prefixed, and in the latter case vary greatly in size and number; in the suprarenal foramen of the frontal bone, which sometimes is deficient, its place being supplied by a notch; in the suprascapular notch, which may be deep or shallow, or not exist at all; or there may be a complete foramen instead of it, &c. &c. There may be twenty-six ribs, or fix lumbar vertebrae.

The same general rule will apply to the varieties of muscles. The principal object is a certain infection near a joint, whereby the motion produced has a determined direction. These infections, comparatively speaking, vary very little; but there is a great difference in the bodies and connections of the muscles, which have no share in the regulation of the motion. The biceps flexor cubiti has often an additional flip from the humerus; and the latissimus dorsi from the angle of the scapula. The palmaris longus and the planglairus are often entirely absent; but the other flexors of the wrist and extensors of the ankle supply their place. The same observation applies to the pyramidalis of the abdomen. The number of processes, to which the muscles of the spine are affixed, varies considerably.

In no part of the body are the arrangements less confined to a particular model than in the distribution of the blood-vessels. The object is, that blood should be conveyed to every part of the body, and brought back again to the heart; it is of no importance whether the fluid pases by one route or another. Thus, instead of three, we sometimes have two, and sometimes four, or even more numerous branches from the arch of the aorta: the artery of the upper extremity may divide into its radial and ulnar branches in the axilla, the arm or fore-arm; the order, in which the principal arteries come off from the subclavian and internal iliac trunks, is by no means constant, &c. There may be four, or only two valves instead of three, at the orifices of the great arteries. The great arterial trunks of the body and limbs, however, are not exposed to these varieties, because they generally occupy situations, in which they are most effectually protected from external injury. We have to remark, also, that the arteries of the upper are much more liable to varieties than those of the lower limbs. The latter are almost constant in their distribution, while those of the fore-arm and hand are hardly alike in any two subjects taken together. We do not see on what principle this difference can be accounted for.

We shall mention two other infirmities of varieties in the blood-vessels, which are sufficiently remarkable to deserve notice. There were no internal carotid arteries in the case of a nobleman lately examined by Mr. Wilton, lecturer on anatomy at Windmill-street: the vessels were usefully large, and the communicating branches of the posteriores cerebri of the bulbar run forwards to take the situation of the internal carotids. A woman had laboured under a difficulty of swallowing from her infancy, gradually increasing as she advanced in years, and relieved by regular bleedings, at monthly or shorter intervals: she became at left from her incapability of taking down sufficient nourishment, that she could not provide for her own maintenance, and was admitted into a parish work-house. For the last twenty years of her life she could scarcely mutter up resolution to force down food enough to prevent her from starving. The obstruction seemed to be opposite to the first bone of the sterno: there was violent palpitation of the heart when she swallowed. Nothing was found after death to account for these circumstances, except a variety in the course of the right subclavian artery; which arose from the left side of the arch of the aorta, and then passed between the esophagus and trachea. Memoirs of the London Medical Society, vol. ii. p. 275. We have several times seen this variety, but in infirmities where we know nothing of the previous history of the individual.

It cannot be at all important to the function of a viscus, whether it be in one mafs or in separate portions: the structure being the same, the same actions will take place. Hence we often find the two kidneys united into one mafs; and, not unfrequently, two or three small spleens besides the common one. Neither is it of consequence that a viscus should always be of the same shape, because its functions depend not on this circumstance, but on structure; accordingly we find much variety in this particular.

Many viscera are connected together in their functions, or by the medium of large blood-vessels, in such a way as to require a certain relative situation to each other; this also becomes necessary, in order to preserve the general shape of the animal. Accordingly we find, that when any important viscus is changed in its situation, it affects other viscera, requiring in them a similar change. In the infall of the transposed visce, which will be related afterwards, the change in the situation of the heart and liver was accompanied with a corresponding change in the stomach, spleen, pancreas, in short in all the visce of the abdomen and thorax. So great a deviation as this changes almost the whole vital system, and happens very rarely. The functions cannot be affected, as they depend on structure and situation, both of which are preferred. Hence the individual alluded to arrived at the age of maturity, and might have continued to live to an extreme old age. The human machine might have been constructed in this way commonly; and under such circumstances, what is now called the natural situation of parts would have been as singular as the appearances which we shall mention.

There is less variety in the nervous system of animals of the same species, than in most parts of the body. Scarcely any differences are observed in the appearances of the brain, and much fewer in the distribution of the nerves than of the blood-vessels. Yet varieties have been seen even in the brain, of which a remarkable instance is recorded in the Transactions of a Society for promoting Medical and Surgical Knowledge, vol. i. p. 212. The falk cerebri was deficient, and, instead of the usual fissure dividing the two hemispheres, there was merely a depression for the superior longitudinal sinus. "No pain could be found in the situation of the natural chit; a transverse fiction was made through the cerebrum, keeping above the level of the corpus callosum, but left no vestiges of membrane, or of eminent subarachnian, or of previous inflammation and adhesions, to be found." There is also very little variety in the organ of sense; perhaps the mechanism in both there is nicer, so that a considerable deviation would interfere with their peculiar functions.

2. Unusual Formations of the Skin:—Deivation of Colour.

—Deviations from the accustomed structure in this organ are more conspicuous in the coloured than in the white races.
of mankind. One of the most striking is the entire absence of colouring matter, constituting the Albino, which was first noticed in the negro: this peculiar formation, however, occurs also in the white races, and in various genera both of mammalia and birds. The individuals are remarkable, not only for the whiteness of the skin, but also for that of the hair (feathers and fur in animals), and redness of the eyes. See INTEGUMENTS, ALBINO, and MAN.

Individuals of the black races are sometimes marked by spots of white, of various size and number, without any thing like disease of the skin. This circumstance occurs most frequently in negroes, and generally begins in early infancy; the individuals are called spotted or piebald negroes, in French, negri-plies. Blumenbach has described a man of this kind, whom he saw in London; he was servant to the person who kept the animals at Exeter Change. He was a young man, perfectly black, excepting the umbilical and hypogastrical regions of the abdomen, and the middle of the lower limbs, including the knees and neighbouring parts of the thighs and legs, which were of a clear and almost snowy whiteness, but spotted with black, like the skin of a panther. His hair was of two colours; on the middle of the front of the head, from the vertex to the forehead, where it ended in a sharp point, there was a white spot, with a yellowish tinge than those on the trunk and legs. The hair covering this was white, but resembled the rest in other respects. On comparing the picture of this man with three others (a boy and two girls), he observes, that the white spots occupied the abdomen and thigh, never appearing on the hands and feet, which parts with the grins are the first to turn black in the newly-born negroes; and that the arrangement of the white parts was symmetrical. Both the parents of this man, and of the others, of whom Blumenbach had collected accounts, were entirely black, so that Buffon's conjecture of this variety being produced by the cohabitation of a negro with an albino is groundless. Representations of spotted negroes may be seen in Blumenbach's Abbildungen Naturhistorischer Gegenstände, 3d part, and in Buffon, Supplement, t. iv. p. 565, tab. 2. See also Byrd in Phil. Trans. vol. xix. p. 781, for an instance, in which the spots began in the fourth year, and increased in size; and Morgan, in Transactions of the Philosophical Society at Philadelphia, t. ii. p. 392.

These spots, in which the epidermis is perfectly healthy, and which are distinguishable from the rest of the skin, only by their whiteness, are not to be confounded with diseases of the organ, where the cuticle becomes scaly or branny, which are frequent in some of the black races. Nor are they peculiar to the dark-coloured races. Blumenbach has seen two instances in Germans, one of a youth, and the other of a man 60 years old. They both had a rather tawny skin, marked here and there with various sized spots of the clearest white. They appeared first in the former in infancy, and in the latter at the age of manhood.

b. Hairy Coverings.—Patches of the skin are sometimes thickly covered with hair, like that on the head. Such occurrences have given occasion to reports of persons having hides like animals. Buffon (Supplement, v. iv. p. 571.) Wunschf (Kolpeilengleichen unterhaltungen, pt. 3.) and Laves (Physiognom. fragments, pt. 4. p. 68.) have given figures and descriptions of A. M. Herrngh, a woman of Triers, said to have the skin like a deer, and shewn in many parts of Europe. Sombiering saw this person, and found the peculiarity to consist of numerous and large elevations of the skin, covered by thick and strong hairs. They were of the nature of the moles, often seen on the face of very fair persons, and generally giving origin to hair; he could not discover a single hair resembling that of a deer. Beschreibung einiger Mißgeralten, &c. p. 32.

c. The Porcupine Men.—In the English family of the porcupine men, a very singular structure of the skin is observed. At nine weeks after birth, this remarkable peculiarity first began to show itself. The skin of the whole body, except the head and face, the palms and soles, is covered by hard wart-like prominences. "It was not easy to think of any sort of skin or natural integument, that exactly resembled it; some compared it to the bark of a tree; others thought it looked like felt-skim, others like the hide of the equid, or the skin about the legs of the rhinoceros; and some took it to be like a large wart, or a number of warts uniting and overgrowing the whole body. The brightly parts, which were chiefly about the belly and flanks, looked and ruffled like the bristles or quills of a hedgehog, torn off within an inch of the skin." The person enjoyed good health; every thing connected with his excrections was natural; he derived no inconvenience from the state of his skin, except that it would crack and bleed after very hard work. (Philos. Trans. N. 424, with views of the skin.) In a subsequent account, after an interval of 24 years, the man is said to continue the fame. "The covering seemed most nearly to resemble an innumerable company of warts, of a dark brown colour, and a cylindrical figure, riling to a like height (an inch at their full size), and growing as close as possible to one another, but so stiff and elastic, that when the hand is drawn over them, they make a rustling noise." They are shed annually in the autumn or winter months, and succeeded by young ones of a paler brown. The person had the small-pox, and had been fialvated twice; the tubercles disappeared on these occasions, but were reproduced. The health continued good. He had fix children with the same peculiarity, beginning, as in himself, about nine weeks after birth. One only of these survived, and was eight years old, when the account was written. Phil. Trans. v. xix. p. 21, with a figure of the hand. Edwards's Gleanings of Natural History, v. i. pl. 212. A description of them at a later period has also been given by Blumenbach, in Voigl's Neue Magazin, v. iii. pt. 4, which we have not seen.

There is an instance somewhat analogous recorded, of a man whose skin was covered in various places with warts of different size and form. See Historia Pathologica singularis Cutis turpitudinis, J. G. Rheinhardi viri 50 annumor. Lips. 1753, fol.

d. Marks Existing at Birth.—The various appearances of the skin, comprehended under the name of nevi materni, and commonly supposed to be produced by the influence of the mother's imagination, are natural varieties in the structure of this organ. The colour of these is generally red, livid, or brownish; they sometimes consist of considerable masses of subcutaneous tissue, or may be quite superficial; they are smooth or irregular on the surface. Numerous ramifications of blood-vessels are generally visible in them. We have seen one occupying nearly the whole forearm; but often they are not larger than a pin's point. They are frequent about the face. They appear to consist of a congeries of vasa formed most innumerable communications, and correspond nearly to what Mr. J. Bell has described by the name of "aneurism from anatoormosis." See N E V I and A N E U R I S M.

e. Hora.—The formation of hard subcutaneous lumps, described under the name of horae, on the human head, is not a very uncommon occurrence. These cannot be regarded in the same point of view with the varieties in formation of different parts, as they are not originally formed; and they may be classed rather with the productions of disease, although
they are free from pain, and attended with no inconvenience when undisturbed. The term horn is applied to them from their hardness and colour; for they bear no resemblance in their development and growth to the parts of animals called horns. (See Horn, in Comparative Anatomy.) Yet productions from the skin, resembling true horns, have been seen in animals. A sheep, about four years old, had a large horn, three feet long, growing on its flank. It had no connection with bone, and appeared to be only attached to the external skin. It dropped off in consequence of its weight having produced ulceration in the soft parts to which it adhered. On examining it, there was a flabby substance, five inches long, of a fibrous texture, filling up the cavity on which the horn had been formed. (Home on Horny Excrecences; Phil. Trans. vol. lxxi.) In the following work, vol. xlix. p. 183, is another example of a very regularly shaped horn of 26 lbs. in weight, growing from the neck of a sheep.

The growths, which have been called horns, in the human subject, have taken place from excised tumours, which have burst, and discharged a thick gummy fluid; the cysts have then collapsed, and the new substance has gradually grown from the bottom. It is at first pliable, and afterwards attains nearly the colour and hardness of horn. The lining of these cysts approaches to the nature of cuticle, and hair has sometimes been found among their contents. The horn then is simply a secretion of cuticular substance from the surface of the cyst, becoming dry and hard in consequence of its exposure. Such horns may be produced in any situation of the body.

In the case of a middle aged woman related by Mr. Home, a movable tumour grew on the side of the head, in the course of four or five years, to the size of a pullet's egg, when it burst, and discharged a thick gummy fluid. A small soft substance of a reddish colour was produced from the centre of the tumour; it increased in length and thickness, and continued pliable for about three months, when it first began to put on a horn-like appearance. It attained the length of five inches, being about one inch in circumference at the ends, and rather less in the middle. It was curled, like a ram's horn, and resembled illusory in colour. Three others formed successively in this individual.

Batholin, in his epistles, mentions a woman who had a tumour under the scalp, covering the temporal muscle. This gradually enlarged, and a horn grew from it, which had become 12 inches long in the year 1646, when he first saw it. There is a horn-like excrescence in the British Museum, 11 inches long, and 24 in circumference at the base, or thickest part, produced from a wen on the head; it began in the 4th year of the woman's age, and was four years in reaching the above-mentioned size. See Mr. Home's paper in the Phil. Trans. quoted above.

3. Varieties in the Viscera.—A. Transposition of the Viscera.

A very complete account of such an arrangement has been given by Dr. Baillie, in the seventy-eighth volume of the Philosophical Transactions: the particulars ascertained by his dissection are there very minutely detailed. The anterior mediastinum inclined obliquely to the right; the left lung was divided into three, and the right into two lobes. The apex of the heart pointed to the right side, nearly opposite to the fifth rib, and its cavities, as well as the large vessels, were completely transposed. The right auricle and ventricle were situated on the left, and the left cavities on the right side. The pulmonary artery ascended towards the right side, and the arch of the aorta also passed to the right, while the superior and inferior cava were turned into their auricle on the left side of the spine. The right subclavian vein crossed the chiel in front of the arteries that arise from the arch of the aorta; the artery innominata produced the left carotid and subclavian, while the right arteries came off separately. The descending aorta was on the right, and the vena azygos on the left side of the spine; the thoracic duct opened into the right subclavian vein.

The ordinary course of the right and left recurrent nerves was interchanged. The liver was placed on the left side of the epigastric region; its ligaments and blood-vessels, the gall-bladder, and the biliary ducts bearing the same relations to it in this new situation as they do in the ordinary one. The duodenum communis cholecodochus terminated on the fore part of the duodenum. The spleen was placed in the right hypochondrium, and the pancreas corresponded to the altered course and situation of the duodenum. The great omentum was inclined obliquely from right to left. The iiium terminated in the great intestine on the left side, and the cecum was placed on the left pons magnus and iliacus internus muscles. The arch of the colon passed from the left to the right side of the body, and the sigmoid flexure crossed over the right pons, to get into the cavity of the pelvis. The renal vessels were transposed.

The aorta in the abdomen continued on the right side of the spine, and its branches were altered from their natural course in accommodation to the peculiar situation of the vifcera. The inferior vena cava was placed on the left of the vertebral column, and perforated the left side of the tendinous centre of the diaphragm.

Dr. Baillie adds, that "the person seemed to have used his right hand in preference to his left, as is usual in cafes, as was readily discovered by the greater bulk and hardness of that hand, as well as the greater fleshiness of the arm. It was not indeed to be expected that he should be left-handed. The person, while alive, was not conscious of any unusual situation of his heart; and his brother has his heart pointing to the left side, as in ordinary cafes. Indeed there was little reason to expect that we should meet with any thing particular in the account of his life. His health could not be affected by such a change of situation in his vifcera; nor could there arise from it any peculiar symptoms of disease. Still less could there be any connection between such a change and his dispositions or external actions."

In the body of a child ten months old Mr. Abernethy found the heart pointing to the right side of the chest, and the liver in the middle of the epigastric region, extending equally into each hypochondrium. The great blood-vessels of the chest, and the other abdominal organs, were not transposed in this case. Phil. Trans. vol. lxxxii.

There are several other minute and well authenticated accounts of similar transpositions. Myer found all the parts of the abdomen and chest in this inverted state in a soldier who died at the age of 72; and has left a very exact narrative of the dissection. See the Recueil des Anciens Mémoires de l'Acad. t. x. 1733. p. 374. Another instance is recorded by Riolan, in his Dissertation de transpositiones partium naturalem et vitalum in corpore humano; see his Opuscula anatomica, 1652; and another by F. Hoffman, in his Cardiologiae, seu cordis inverto memorabilis, observata a collegio medicorum Halleanis, in anatomia cadaverum tumulis; Leipsic, 1671. Numerous references to other instances may be seen in Halber's Opera minora, tom. iii. p. 16.
b. Varieties in the Intestinal Canal.—Short processi, terminating in blind extremities, and called diverticula, are sometimes found in the small intesline. (See INTESTINE.) A more remarkable deviation from the ordinary structure of these parts was met with by Mr. Abernethy. In the well-formed body of a boy, four feet three inches in length, he found a small intesline only two feet long, with a large one of four feet. Phil. Trans. vol. lxxxiii.

To the unusual formation of the intestines belongs also the want of the opening at the anus; the rectum ends in a cul-de-sac. Sometimes all the external openings are deficient; those of the urethra and vagina as well as of the large intestine. The mouth or nose may also be closed.

c. In the Kidneys and Uterus.—Among the abdominal viscera, the kidneys are frequently subject to varieties in number and arrangement. There may be only the right or left; or the two may be joined together, so as to represent a crescent; or they may be united into one large rounded mass. (Haller, Op. Minor. t. iii. p. 34. p. 40. et seq.) In these cases there are considerable deviations from the ordinary number and arrangements of the renal vessels.

Inflations are not very uncommon of two uteri; see the article GENERATION, in the description of the uterus, and Haller de Monfris, lib. i. cap. g.

d. In the Heart.—In many of the cafes which we have just been considering, the functions are still perfectly executed; the change of position in the transposed viscera, or of size and figure in the united kidneys, leaves these organs just as capable of answering their usual purposes as when the ordinary arrangement is observed. But the heart is often the seat of deviations from the accustomed structure, which essentially affect its functions, and therefore exert such an influence on circulation and respiration, as to give a very peculiar character to the whole state of the individual, and generally to shorten very considerably the term of existence. In animals which breathe, the passage of the blood through the lungs produces a remarkable change in its properties and appearances; the right performance of the various vital processes requires that the organs of the body should be supplied with blood that has undergone this change; and this object cannot be accomplished unless the cavities of the heart holding the two kinds of blood, are kept perfectly free from all communication with each other. In many inflations the heart is so formed that the two sides constantly communicate; this is of no consequence so long as the fetal existence continues, in which the blood is all of one kind; but afterwards it produces a mixture of the arterial and venous bloods, and the greatest disturbance of respiration and circulation. The body, particularly its extremities, is cold and livid; the slightest exercise produces anxiety, and often a suffocating sensation, accompanied with fits of insensibility; the growth is impeded, and the whole being so altered, that the individual is unfit for any active employment, and has a truly miserable appearance. Sometimes the two ventricles form but one cavity; or there may be a larger or smaller opening in the partition between them, with the aorta rising over it, and the pulmonary artery having a very small communication with its ventricle, &c. (See HEART.) The black and red bloods will be more or less completely mixed in these cases, according to the degree of malformation, and the individual will either die very soon after birth, or exit in a state of languor, suffering, and constant prospect of death, for a few weeks, months, or even years.

II. Monsters.—We proceed to consider those imperfect organizations which are commonly called monsters, and shall describe them under the four divisions generally adopted; viz. 1. Unnatural formation. 2. Unusual position of certain organs. 3. Deficiency. 4. Redundance of certain parts. Some of the examples may not, perhaps, be deemed sufficiently striking deviations from the accustomed form to deserve the name of monsters; but we take up the term in its most extensive meaning. Neither are the kinds of monstrosity kept distinct in each case; they may all be united in one specimen, and the want of one part is often attended with an unnatural position of another, &c.

1. Monsters with unnatural Formation of certain Parts.—The hare-lip is one of the most striking examples of vicious formation of parts; this may either be but a simple fissure in the lip, or it may be complicated with more or less extensive division and deficiency of the bony and soft palates, so that often the nose and mouth form but one cavity. (See HARE-LIP.) When this mal-formation exists in a very considerable degree it rendersucking impossible.

b. The urinary and generative organs in both sexes are frequently the seat of unnatural arrangements. The anterior part of the urinary bladder and the integuments covering it may be wanting; the posterior portion being protruded through the recti abdominis muscles, and forming by its mucus lining a soft, red, sensitive protuberance on the surface of the lower part of the abdomen, contiguous at its circumference with the common ilin, with the ureters opening on it, and constantly allowing the passage of the urine. The osa pubis do not come together in these cases, but are separated by an interval of an inch or two; hence the recti muscles are unusually separated, and allow the projection of the back of the bladder. So extensive a mal-formation could not exist in this part of the body without disturbing the arrangement of the generative organs, particularly in the male. The wide separation of the osa innominata occasions an unusually long portion of the penis to be concealed under the integuments; hence the looie portion of the organ is very long. It deviates again very widely from its ordinary appearance in consequence of not being perforated by an urethra; or perhaps we may say that the urethra, like the urinary bladder, is laid open. The scrotum is divided into two lateral folds, each containing its testis. In the female, the labia are wide apart, instead of being joined by the usual comm. &c. the hymen detached, &c. We shall give a description of the appearances, in the case of a male and a female, which will serve as specimens of the structure; the same description, in all essential circumstances, will apply to the other inflations.

Mr. A. Cooper has described the external appearances and the disposition of a female in the Edinburgh Medical and Surgical Journal, vol. i. p. 129, with a figure: another plate, representing the external appearances, is given at p. 42. This person had from birth a fungous tumour at the lower part of the abdomen, from which the urine was discharged involuntarily; this infirmity disabled her from gaining a subsistence in service, and drove her to the necessity of begging in the streets of London, where she died, at the age of twenty-two, from the effects of want, and exposure to the severity of the weather. The fungous, forming three projections, occupied the region of the pubes, extending as far as the usual situation of the lymphatics. It was red, pony, and very vascular, extremely sensitive, and it blist upon the slightest irritation. The urine is frequently trickled from the lower part of the tumour; and if anything was given her to drink, the urine began to flow by drops in a few minutes; but if she made any considerable effort with the abdominal muscles, a small stream of urine spouted from each side of the surface of the tumour. The openings, through which it was discharged, were sufficiently large to admit the introduction of a small probe, and were situated,
situated, one on each side of the tumour, near to its junction with the skin, and towards its lower edge. Just above the tumour a cicatrix was observed, which was the only appearance of umbilicus; so that the umbilical vessels had puffed through the patieties of the abdomen near the fungus, instead of at the umbilical place. The labia pudenda receded from each other more than usual; the nymphae and meatus urinarius were wanting, the lower part of the fungus occupying the usual situation of the meatus and glans clitoridis. The vagina had its usual situation. The bones of the pubis were separated to the distance of an inch and a half or two inches from each other. The urinary bladder appeared from the abdomen as if forced through the aperture of the skin and abdominal muscles, with the anterior portion wanting, so that the fungous surface on the abdomen was the back of the bladder, with the ureters terminating in it. It adhered firmly to the margin of the abdominal muscles and skin, and appeared from within puckered at its edges. The ureters, which opened through the lower part of the fungus, were uncommonly large, equal in size indeed to the rectum, and had served the purpose of refervoirs. The kidneys were also more than double the usual size, owing entirely to their pelvis and infundibula being enlarged, for the secreting part did not appear altered.

The influence, which we shall relate of the mals, is described by Dr. Ballie in the transactions of a Society for the Improvement of Medical and Surgical Knowledge, vol. i. p. 189. Immediately above the usual situation of the symphysis pubis, there was a vascular pulpous mass of about two inches by one and a half. It was seated in a deep bed, scooped out, as it were, from the lower part of the skin and muscles of the abdomen, and covered thickly with a vivid mucus. At the upper edge of this mass the skin was in one part firmer than is natural, and a little puckered; this was all the appearance of navel. The ureters opened on two projecting tubercles. At the lower edge of the pulpous mass, and about its middle, were two distinct rounded orifices, the openings of the vasa deferentia and vesiculae feminales. A little above their level was a considerable canal, large enough to admit a goose-quill, and leading to the substance of the prostate gland. About half an inch below the vascular mafs the penis was seen, of the common size with respect to the transverse diameter, and a little more than an inch in length. The whole of its upper surface was somewhat hollowed, and had a finer skin than the common covering. Near its extremity, the canal corresponding to the urethra opened by a pretty large oval orifice. Under the glans there was a loose fold of skin corresponding to the prepuce, and a chord like the fraenum. There were two considerable elongate swellings at the grom, covered with hair, and terminating below in a corrugated skin forming the frenum.

On the inside, corresponding to the situation of the vascular mafs, there was a projection, resembling the back of the urinary bladder, consisting of an arrangement of muscular fibres similar to that of the bladder, and perforated by the ureters. The latter tubes were larger than usual. The umbilical vessels terminated at the fine puckered film above the vascular mafs. On each side of the faubrance, corresponding to the bladder, the rect muscles passed, to terminate in the offa pubis, at nearly four inches distance from each other. The prolate and vesiculae were about one-third of the ordinary size. There was a canal corresponding to the urethra, in the corpus spongium. The testes were of the usual size and structure. In the front of the pelvis there was a deficiency of bone for nearly four inches, filled by a broad ligamentous membrane.

For numerous references to the other recorded cases of this kind of malformation, see two papers by Dr. Duncan, jun. in the Edinburgh Medical and Surgical Journal, vol. i.

It has been observed much more frequently in the male than in the female subject. Many of the individuals have exhibited themselves for money, and have often been duped to be hermaphrodites; a suppofition which they have encouraged for the purpose of increasing public curiosity. On this subject, as well as on all those unusual formations of the sexual organs, which have given rise to the notion of a mixture of the two sexes, see the article Generation, under the head of Hermaphrodism.

These cases prove to us clearly, what we should have duped a priori; viz., that the urinary bladder is not a part essential to the body, but subfervient only to our convenience and comfort, by retaining the urine, and preventing its constant discharge. A perfon may exist in perfect health and strength, although the urine should run off as it is secreted.

e. United Eyes.—An union of the two eyes into one, which is placed under the middle of the forehead, in the situation of the nose, which is deficient, is not an uncommon kind of monstrosity: it seems to realize the ancient fables of the Cyclops. This single eye is large, and has generally the appearance of being composed of two confounded together. Thus, each lid is composed of two, united in the middle by their extremities, and having their respective Meibomian glands, &c. In one instance there were two optic nerves joined into one, two lacrimal glands, and one crystalline lens. In another an iris almost double, a simple lens, two lacrimal glands. Indeed, in all the instances there have been more or less plain marks of the apparently single organ being composed of the parts of two eyes.

This kind of formation is not uncommon in animals. Haller described a cyclopian lamb; the upper eye-lid was composed of two, the lower deficient. There was a single optic nerve, and one set of muscles. All the parts of the eye were simple, but unusually large. De Monfris, lib. i. cap. 12. For other examples, see Sommersing, p. 31, in the pig; Memoires de l’Acad. des Sciences, 1703 and 1744, in the dog; Philos. Trans. No. 456, in the sheep; Buffon, Dier. du Cabinet du Roi, t. xiv. p. 592—594, in the dog and pig; Hill, Naturelle, t. vi. p. 58, in the cat. See also the description of the middle eye in the double head described by Sommersing in the latter part of this article.

d. Spina Bifida.—A division sometimes occurs in the posterior part of the vertebral canal, formed by the fainous prococles of the vertebrae, and is attended with a tumour, caused by a protrusion of the membraneous lining of the canal, and filled with fluid. We have seen the fainous procoles deficient through the whole vertebral column. See Spina Bifida.

e. Imperfections.—The termination of the rectum in a cul-de-sac, where the anus is deficient; the termination of the esophagus in a similar way; the confusion of the bladder, uterus and rectum into one mass, without any external opening, all belong to this class.

f. Imperfect Extremities.—The extremities present various imperfect arrangements, which do not, of themselves, occasion the tatuins, in whom they occur, to be called monsters. The club-feet, in which the foot is turned inwards or outwards on the leg, are of this kind. (See Foot, Distortion of.) The fingers or toes may be united together by the skin, the bones, muscles, &c. being perfect. Hailer saw a girl born at the sixth month, with both hands unnaturally curved (manus utrnsa cortocalcata). The thumb was crooked and not well formed; there were three other fingers united into one mass, with distinct nails; the middle of these
MONSTER.

there was twice as large as the others. In the feet, the great toes were well formed; the four other toes were arranged in the natural direction, and perfectly formed, but united laterally by the skin. (Opera Minora, t. iii. p. 37.) These unions of the fingers are not rare, and they do not affect the essential structure, as the parts, when artificially separated, can execute all the usual motions.

Sometimes the limbs are quite mis-shapen, and end in one or two small and ill-formed parts, holding the place of fingers.

g. General Malformation.—A very considerable malformation is described by Dr. Clarke, in the Philosophical Transactions, vol. 83. After the birth of a healthy child, another substanee contained in the umbilical membrane, and connected with a placenta, was expelled: it had an oval figure, and was covered by common integuments. There were two projections, each ending in three imperfect toes, and another like a finger. It consisted internally of a homogeneous fleshly and vascular substance, without any muscular fibres, and leaving the umbilical vessels distributed through it. It contained an os innominatum, os femoris, tibia and fibula. At the upper part, and towards the inside of the os innominatum, was placed a little portion of small intestines, loosely connected by their mesentery to the posterior edge of that bone, and covered by peritoneum. No other parts could be traced in this production; there was not the least vestige of either brain or nerves.

Another remarkable instance of general malformation occurs in the child contained in the body of another, described in the latter part of this article.

We might carry this enumeration to a much greater length, by collecting what has been observed by various authors, but the enumeration would be very tedious, and not instructive. We refer therefore on this subject to Haller’s work De Monstris, contained in the 3d vol. of his Opera Minora, lib. i. § 8. We may state, in general, that where any principal organs are wanting, or any great deviation occurs in leading points, there is always great confusion in the subordinate parts. In the case just quoted from Dr. Clarke, the want of the viscera produced a disturbance of the whole fabric; and in other examples, where there has been no heart, all the rest of the body has been very irregularly framed.

h. Refemblances of Animals.—The numerous examples of resemblances to animals must be referred to the imagination of the observer, as more exact modern observation does not at all confirm them. We find figures described with the face of a monkey, as dog, hare, goat, calf, sheep, cock, skate, lizard, locust; with the head of a cat, horse, or calf; with the penis of a dog, or horie, &c. &c. &c. To the same class belong the calves, sheep, and pigs, with human heads, &c. &c. &c. See Haller, lib. supra.

2. Monsters with unnatural Position of Parts.—The second is the least common kind of monsters. We cannot include under this description the transpositions of the viscera, as the external appearance is natural, and the functions are performed regularly; nor can we arrange in the class of monsters the examples of perforations in the diaphragm, where a greater or smaller proportion of the abdominal contents passes into the cavity of the thorax. In the latter case the viscera may have taken the unnatural situation before birth, and then death follows birth very quickly, from the impediment to the free action of the lungs, or they may not pass into the thorax until some subsequent period of life. For references to several cases of this kind, see Lawrence’s Treatise on Ruptures, p. 482, note.

Protrusion of the abdominal vices at the navel may more justly be regarded as a monstrous formation. This exists in very various degrees, from a small tumour, holding a few turns of intestine, to a large pouch, containing the liver, stomach, spleen, and all the movable viscera of the abdomen. Sometimes these organs are all completely uncovered, lying on the surface of the body, without any abdominal muscles at all; and the same formation may extend to the chest, leaving the heart and lungs bare. Hence the particulars of the whole anterior and lateral parts of the abdomen and chest are deficient. See the Treatise on Ruptures quoted above, chap. viii. sect. 1, and Haller, De Monstris, lib. i. cap. 5.

The same kind of protrusion of the abdominal viscera at the navel, is said by Haller to be frequent in the common fowl, and not to be uncommon in other animals. We have seen a calf with the abdominal and thoracic viscera completely uncovered.

In a monster delineated by Soemmerring, tab. 8, two ill-formed fingers projected from the left breast: the os humeri, and a bone connected with it, were under the integuments; the scapula and clavicle in their natural situation. Abildung und Beschreibung einiger Missgeburtten, &c.

Where there has been only one eye, a kind of monstrosity that has occurred in the human subject, and in some animals, as the pig, sheep, and calf, it has been placed under the middle of the forehead, in the situation of the nose.

3. Monsters with deficient Parts.—a. Want of the Brain and its Coverings, and of the Spinal Marrow.—An entire want of the brain, and of the coverings which ordinarily belong to it, is a very common occurrence; and it constitutes what has been commonly called acephalous (headless) fextures. All the upper convex portion of the frontal bone, the whole of the parietal bones, the fquamous parts of the temporal bones, and the greater part of the occipital bone, behind the foramen magnum, are deficient in these cases. Instead of the brain, there is an ill-shaped mass of bone, the basis cranii, covered by a thin membrane; the latter forms sometimes a considerable soft mass, covering the basis of the skull; behind this there is an opening, leading into the vertebral canal. The soft vascular membrane is united at the edge of the cranium with the common integuments, and hair grows on the latter in this situation, although there is none in the corresponding part, nor within some distance of it, in individuals naturally formed. The neck is remarkably short, so that the head seems to lie on the shoulders, and sometimes there is a continuity from the chin to the chest. (See Soemmerring, tab. 3.)

In one instance, Haller found only five cervical vertebrae. The eyes, viewed in connection with the retiring surface of the head, give to the whole a striking resemblance to the head of a cat; so that these fextures have been called in Germany cats’-heads (katzen-köpfe). The body is well formed in every other respect, and generally reaches the full size. The medulla spinalis, and the different nerves of the brain begin at the openings, by which they usually go out of the head, and are perfectly formed in all respects. It has been observed by Soemmerring and Morgagni, that most of the acephalous monsters are females. Hewan, Mielck, and Soemmerring found in many instances, that the renal capsules were very small in these brainless children. Soemmerring, p. 7.

These children generally die very soon after they come into the world; but they have sometimes lived many hours, cried, sucked, &c.

In one case, where the bones were wanting, but an imperfect cerebrum seemed to exist, the child lived six days. The child
MONSTER.

child was perfectly formed, excepting the head, and of the usual size. It took no food, and had no evacuation. Respiration went on naturally: it did not cry, but often made a hideous whining noise. When the soft fulblance at the top of the head was touched, general and violent convulsions took place. No signs of voluntary motions appeared, and the mother had left feeling of the child in utero, than in her former pregnancy.

See the work of Soemmerring already quoted, and Sandifort’s Anatomie infantis cerebro delititii, Lugd. Bat. 1784.

Want of the spinal marrow is sometimes observed in the same fetuses which have no brain. We have seen an instance in which the whole of the spino-pine processes were deficient, so that the spinal canal was completely exposed; the place of the medulla spinalis was supplied by a vascular membrane, like that covering the basis cranii in acephalous monsters, united in the same way to the surrounding skin. A similar deficiency was observed by Soemmerring, p. 21.

b. Want of the Heart.—The instances in which there has been no heart are not very rare. Mr. Brodie met with an example in a fetus nearly of the natural form and size. There was no communication between the trunks of the arteries and veins. The vena cava of the fetus was continued to form the umbilical vein, and the internal iliac artery of one side was reflected to form the umbilical artery. There were defects in several other parts of this fetus: the fingers and toes were not perfect, nor in the right number; the palate was divided, the liver deficient, and the oesophagus terminating in a cul-de-sac. Other cases of left perfect fetuses without hearts, are mentioned in the Memoires de l’Acad. des Sciences for 1720 and 1740. Phil. Trans. for 1767. There were also two in Dr. Hunter’s collection. See Mr. Brodie’s paper in the Phil. Trans. for 1809. We have seen one instance in which there was no heart; the brain and medulla spinalis were also deficient. The formation of the body and the size of the limbs were for the most part natural, but the fingers and toes here were below the ordinary number. The extraordinary malformation described above from Dr. Clarke’s, belongs also to the present division, as exhibiting an instance of want of the heart and brain; also that of the fetus found in the body of a child delivered towards the end of this article.

Monsters, in which considerable parts are wanting, seem peculiarly likely to afford in the prosecution of physiological researches. If we never saw animals, except in a perfect state, we could not form just ideas of the comparative importance of the different organs. And if we attended only to the complicated structure of the more perfect animals, we should probably conclude that the connection of parts found in them was essential to the execution of vital functions. Of these parts, the brain and nerves, the alimentary canal and its appendages, the heart and lungs seem to be of such importance in the machine, that we should probably conclude the functions of life could not go on without them. But, in the simple animals, which compose the lower orders, many of the parts are not found; although they are capable of performing the most important animal functions. This great fineness of structure is found chiefly when the body is homogeneous, not confining of parts so different from each other as skin, viscerae, muscles, bone, &c. We may, therefore, still suppose, that all the complicated mechanism, found in the more perfect animals, is essential to the construction of such heterogeneous sublunacies, as those of which they consist. The monsters just described prove that this is not the case; they shewed us that cartilage, bone, ligament, cellular sub-

flance, membrane, intestine can be formed where no brain or nerve or heart exists, and where there is nothing further than the actions of the vascular system; and they lead us to conclude that the formation and nutrition of our organs are the functions of the blood-vessels only. At all events they exclude the brain, nerves and heart from all participation in this process.

The nature of fetal existence is considerably elucidated by these monsters. Superficial observation will convince us that the life of the fetus is very different from that of the animal which is born. The former is the most simple kind of vitality: it includes merely the development and growth of parts, which, although useless to the animal in this state of its existence, are essential afterwards. That the lungs are of this kind, is generally admitted; we must adopt the same conclusion concerning the heart. A little reflection shews us, that the brain and nerves are equally inessential to the fetal existence. The nerves transmit impressions from without; the brain perceives, reflects and wills; the nerves again convey the influence of the brain to the muscles. Although we cannot clearly prove the point, we think there is very little reason for hesitation, in affirming that none of these processes take place in utero; consequently, that the brain and nerves are completely inactive. The alimentary canal, and the organs connected with it, the urinary apparatus, which disposes of the residue of nutrition, are fitted to the subsequent stage of existence, and bear an obvious relation to the mode in which the body is nourished after birth; they are dormant while the animal remains in utero, during which time the materials of its nourishment and growth are drawn from the mother, through the placenta and umbilical chord. It is hardly necessary to say anything of the generative organs, as they are not called into action until many years after birth, and are then not very closely connected to the rest of the system; at least their absence or inaction does not produce any consequences that endanger the existence of the animal. We should infer then, that the whole growth and formation of a fetal body depend on the actions of the vascular apparatus, which appear from Dr. Clarke’s case to be fully equal to the talk.

That beings so imperfectly formed are incapable of executing the functions necessary for the continuance of existence after birth, is very clear. Respiration is performed by muscles deriving their power from the brain, and, consequently, cannot take place where there is no brain. If, in any instance, life and respiration have been kept up for a short time, there has probably been an imperfect brain; as in the case related above, where the child lived six days. All our observations on living animals, too, concur in the sing that the heart’s action is essential to life. Without the alimentary canal, no supply of nourishment can be received.

The acephalous monsters shew us the independence of the nerves on the brain. So far as their formation goes; and they evince very clearly the independence of the formation and growth of the organs in general on the brain. For these individuals are perfect in the size and form of all the parts; any organ or limb could not be distinguished from that of the most regularly constructed fetus with a brain.

If the anatomy of the vessels were well known in cases where there has been no heart, and if the circulation could have been observed, we could not fail to derive some important elucidating information: hitherto we know too little on these points to enable us to draw any inferences applicable to the physiology of the circulation after birth.

c. Want of other Parts.—The examples of deficiency of less important parts are numerous. Where there has been only
only one eye, the nose has been wanting: the ears have sometimes been deficient. We have heard of a child, in whom the skin was smooth and not perforated in the situation of the ears, who had the sense of hearing. We met with a fetus, in which the soft palate did not exist, and the tongue had passed into the nose, having a deep impressions on its surface, corresponding to the septum narisum. This child must have died immediately after birth, as it could not have breathed.

Various deficiencies occur in the extremities, from the want of some fingers or toes to the entire want of the whole limbs. Individuals have been born without either arms or legs. (Haller D. Monstris, lib. i. cap. 10.) We have seen a cat without fore legs, and a similar deficiency has been noticed in the dog and horse. (See Haller, lib. i. cap. 10.) The want of the usual abdominal and thoracic coverings we have already mentioned.

The irregularities in the deficient of the teftis have sometimes been noted as monstros formations. See the description of the deficient of the teftis in the article Generation. When one teftis only has descended, the individuals have been called monorchides; and where both have been retained in the abdomen, aororchides: as if there had been original deficiency.

4. Monsters with supernumerary Parts.—In the last division of monsters we shall consider, under separate heads, instances of some additional parts connected to bodies otherwise perfect, of united fustes, and of fustes involved in the bodies of others.

a. Supernatural Parts in Bodies otherwise perfect. Supernumerary Fingers.—Supernumerary fingers and toes hardly constitute a sufficiently striking deviation to define the name of monstrosity; there may be five fingers, or a small additional thumb in the hand; and fix toes in the foot. In some instances this variety has existed in several individuals of the same family, and has been transmitted through two or more generations, both by the father and mother. See the article Generation, towards the end, on the theories concerning that subject; also Haller D. Monstris, lib. i. cap. 9.

Analogous appearances have been noticed in animals, as the dog, pig, sheep, and common fowl. Supernumerary horns sometimes exist in the cow, sheep, and deer; and in the ovis polycetera this variety seems to have become permanent.

The existence of hernia and other tumours in the ferotum has given rise heretofore to the notion of supernumerary teftes: hence the trioorchides, pentorchides, &c. There are never more nor fewer than two teftes naturally.

Supernumerary Extremities are by no means uncommon in animals. Haller dissected a dog, in which there was a large broad bone between the two offa innominata, supporting a leg, to the lower end of which two feet were connected. In a chicken, which he examined, there were two rumps, with a bone placed between them and supporting a supernumerary leg. Ibid. c. 15.

Morand dissected a full-grown and perfectly well-formed sheep, in which there were two additional lower extremities projecting between the hind legs. The anus and penis were double. An unusual bone was placed between the two offa pubis, and had acetabula for the supernumerary thighs. The bones of these additional limbs were regular; but there were no muscles. The ileum divided into two tubes, each of which was continued into a large intestine; the kidneys, testes, &c. were doubled. The aorta and vena cava bifurcated; one branch going in the usual course, and the others being distributed to the supernumerary parts. (Mem. de l’Acad. des Sciences, 1733, p. 141.) For a similar instance in a cow, where the additional parts adhered to the spine, see the Philos. Transact. vol. xlxxv. p. 193.

Examples of these additional limbs in all the domesticated animals, as the horse, dog, cat, cow, sheep, pig, goat, also in the hare; in the common fowl, duck, goose, parrow, dove, goldfinch; and in the frog, are mentioned in the work of Haller.

Additional Head.—Examples of any other parts, besides the limbs, being thus attached to bodies otherwise perfect, are less common: an ox is mentioned in the Philosophical Transact. of the Philos. Transact. vol. xlxxv. with an additional head attached under the lower jaw; and a cow attained its full size with two heads and necks.

Some instances have occurred, in the human species, of a more or less considerable portion of another individual adhering to some part of the body. The Indian child with a double head, described by Mr. Home in the Philosophical Transact. vol. xxxiv. is a rare example of this kind.

The child lived to the age of two years, when it died from the bite of a cobra de culeb. The woman, who acted as midwife, terrified at the strange appearance of the double head, endeavoured to destroy the infant by blowing it out on the fire, where it remained long enough to have one of the eyes and ears confiderably burned. The body was naturally formed, but the head appeared double, there being, besides the proper head of the child, another of the same size, and to appearance almost equally perfect, attached to its upper part. This upper head was inverted, so that they seemed to be two separate heads united together by a firm adhesion between their crowns, but without any indentation at their union, there being a smooth continued surface from one to the other. The face of the upper head was not over that of the lower, but had an oblique position, the centre of it being immediately above the right eye. When the child was six months old, both heads were covered with black hair in nearly equal quantity. The neck of the upper head was about two inches long, and the upper part of it terminated in a soft tumour like a small peach. The eyes of both heads moved at the same time, but those of the superior wandered in different directions. The irides of the upper contracted on exposure to light; its eyelids were never completely shut, remaining a little open, even when the child was asleep. Tears flowed almost continually from them, but never from the eyes of the lower head, except when crying. The superior head appeared to sympathize with the child in most of its natural actions. When it felt the mother, it was in the mouth of the superior head, and the falva flowed more copiously than at any other time; for it always flowed a little from it. When the child smiled, the features of the superior head sympathized in that action. When the skin of the superior head was pinched, he seemed to feel little or no pain, at least not in the same proportion as was felt from a similar violence being committed on the lower head or body. No pulsation could be felt at the age of six months in the situation of the temporal arteries in the upper head; but the superficial veins were very evident.

The monstrous head was brought from the East Indies to this country, and deposited in the museum of Mr. John Hunter. The two skulls are nearly of the same size, and equally complete in their ossification. The frontal and parietal bones, instead of being continued over the top of the head, meet each other, and are united by a circular future. The two skulls are almost equally perfect at their union; but the superior skull, as it recedes from the other, becomes imperfect.
imperfect, and many of its parts are deficient. The number of teeth is the same in both. There is no septum of bone between the two crania, so that the two brains must have been contained in one bony cafe.

Winflow mentions an Italian, whom he saw in 1698, who had another head, much less than his own, connected to the chest, below the cartilage of the third rib. This had been separated separately from the other. It adhered by the lower half of the right side of the face and head; so that the right ear and surrounding parts were not seen. All the rest of the head and face, with the hair, and molk of the neck, the eyes, nose, mouth, teeth, and chin, were very distinctly visible. This Italian felt whatever affected the additional head. Mem. de l'Acad. des Sciences, 1773, p. 366.

**Imperfect Portion of another Body attached to a perfect one**—The same anatomist saw a girl, twelve years old, well formed, and of the acculturated face, with the abdomen and lower extremities of another body hanging from the left side of the epigastric region. This second body was small; it had a row of vertebrae connected to the sternum of the larger, and faces were discharged from it. The formation of the parts composing it seemed natural in every respect.

The child perfectly whatever touched this additional body. Winflow found, on dissection, that the ileum bifurcated, and each branch went into a corresponding large intestine. The latter, in the little filter, terminated in a common receptacle with the ureters. There were no sexual organs. The bones of the filter were well-formed, but there were no muscles; the interval between the skin and bones being filled merely with fat, blood-vessels, and nerves. In this instance, there was a doubt whether the child should be considered as one or two; and Winflow was sent for, not only to afford his medical assistance, but also to consider whether extreme unification should be administered to the little filter, as well as to the entire body. Mem. de l'Acad. 1773. p. 366.

A more remarkable instance, in which at least the additional being was more perfect, was seen and described by Bartholin, who viewed it, as he says, with great astonishment (cum supra), and Zacchias; and was exhibited in many of the principal cities of Europe.

The individual, named Lazarus Colloredo, was 28 years old, well-formed, and of the usual stature: he had a deformed twin brother hanging by the chest from the lower part of the ileum, who was christened by the name of Johannes Baptista. The latter had two arms, with three fingers only on each hand, and one imperfect lower extremity. The head was larger than that of Lazarus, but not well-formed; it was well covered with hair, and there was no beard; the trunk seems, from the figure, to have been very imperfect. The eyes were apparently closed, the mouth open, and yielding a constant flow of saliva. Respiration was hardly perceptible: there was a pulsation in the chest. The hands, ears, and lips could be moved. John Baptista was nourished by the food taken by Lazarus (Hillor. Anat. cent. i. Hift. 66, Stealzo Zacchias, Quell. Medico-Legal. lib. vi. tit. i. quell. i. 3.) The latter author, who was chief physician in the ecclesiastical states, enters into a dissection whether John Baptista had a rational soul, which he determines in the negative; and hence seems to have doubted whether it was right for him to have undergone the holy rite of baptism. "Scio hunc humanem scirem un perfectum baptram: an requia: an secundum re nom substr auctum, neque affirmo, neque nemo: quod non cum ecclesia catholica in hac determinet, expetio, cur et in hoc et in estra omnium humiliter me subjicio." Ibid. quell. 4. He determines that the additional beings in these cases are "additamenta ex luxuriantie semine enata, et quod nullum, ne per formium quidem rationalis anima potentiam fortunament."  

Ambrose Paré relates an instance of a similar description, where another man, with all his parts, excepting the head, was attached to an individual forty years old. (Lib. xxii. cap. 3.) Amatus Lusitanus has an example in a well-formed boy of six years old, from whose navel another imperfect being, without a head, was suspended. Curat. Medicin. cent. iii. hist. 57.

In the later volume of the Philosophical Transactions, there is an account of a handsomely and well made Gento boy, of good figure and figure, who has a little brother suspended from his parts, and consisting of pelvis and lower limbs. He feels perfectly what is done to the brother, but cannot move the legs and feet, which are cold.

These are the most detailed and authentic cases; references to others, both in the human subject, and in animals, may be seen in Haller, ut supra, cap. 20. These approach very nearly to the double fetuses, in which there appears to be an union of two, originally distinct.

b. United Fetuses.—These form a very numerous class of monsters, both in the human subject and in animals, and we meet with this kind of unnatural arrangement in almost every possible degree, from the flight indications of a head composed of two joined together, to two bodies, apparently perfect in all their parts, adhering at some point to each other. We might form a series, having at one end a body naturally formed, and at the other two natural bodies joined, in which the intermediate gradations should be filled by individuals differing almost imperceptibly from each other. Part of such a series, in that kind of monstrosity in which there is a double head, is exhibited in the work of Soemmerring, tab. 2. 7.

In all these specimens, the parts placed at the point of union are the most worthy of notice; they are not like the organs of a natural body, but exhibit unions of the parts of two bodies in various degrees and shapes. If it were possible for two heads, from each of which one-third or one-fourth had been cut away, to be joined and grow together by the cut surfaces, we should have the appearances exhibited in these cases. In the same way, two tracheas or oesophagi, coming from the two halves of a double head, are united below into one tube, or the small or large intestines from two distinct upper portions of a body are joined into one canal, or the blood-vessels united in the same way, or the skeletons joined in various manners; or, on the contrary, the organs may be simple above, and bifurcated downwards, to produce double parts for double bodies. In all such instances, organs are formed, for which there is no model in the common structure; the points of bifurcation, or division of the various canals mentioned above, are like nothing in the naturally formed body. We shall proceed to notice a few particulars.

**Fetuses with compound Head.**—The slight deviation from the common structure in this direction is exhibited in Soemmerring's second plate. The head is very broad; there are only two eyes, placed far apart; and the nose and upper lip are divided by a considerable fissure. On each side of this fissure there are about two-thirds of a nose. The third plate represents a head of such size and form as would result from joining two two-thirds heads. The halves of this double head are symmetrical, and resemble each other in all respects; the features are exactly alike, and each upper lip has a cleft.

In the following instance the same close resemblance of the features is observed, and in one there is a bare lip on both sides, yet the right is rather larger and better formed than
than the left side; and the same circumstance is noticed in the other instances represented by this author; and he conceives that it admits of explanation by the circumstance of the right half being nearer to the heart. In the middle of this broad head, of which each lateral cavity contains its eye, nose and mouth, there is a large unnaturally turned eye. Each lid is manifestly composed of two, united by their outer extremities, instead of joining corresponding extremities of the lower lids to form external angles; the opposite ends of these lids are joined and form two angles turned towards the noes of the two halves of the head. The globe, observed externally, seems composed of two two-thirds united together; two optic nerves enter it behind, and the number of muscles exceeds that of a single eye. There were two lens, two choroid cent, and irises. A sharp projecting edge of the sclerotics, corresponding to an external deprefion, formed the back of a septum dividing the interior of the globe; the two choroids, lying in contact, continued this partition, but it did not reach to the cornea. The two irises were united, and formed one large pupil; a pointed projection in the middle of the upper and lower edge of this, as well as its breadth, showed that it was made of two joined together. Under this large eye, there was a broad surface composed of the two cheeks and chins united; a deprefion showed the division of the right and left cheeks. The ãœosphagi and trachee of the two halves joined at the bottom of the neck. In the feto, represented in the fifth plate, the face is composed of two three-quarter faces. There are four well-formed eyes; the outer angles of the two middle eyes exhibit the ordinary appearance, but are united in the middle of the head. The fifth plate exhibits a still nearer approach to two heads. The two inner eyes are apart from each other; a deprefion above marks the distinction of the two heads, and the bottom of this is filled by an irregularly formed external ear, appearing as if it had been made by blcnding the opposed ears of the two heads. In the preceding instances there had been only two ears; here there were three, two of the ordinary structure and a third compound one. A still more complete division of the head into two lateral heads is fown in the 7th plate. There are in this four ears, and the two middle ones are in contact at their convex surfaces. From this part a deep deprefion runs to the breast, marking the distinction of the cheeks and chins.

The cafes in which the head is fingle, but composed of two imperfect heads united, are followed by others, in which there are two completely distinct heads, joined higher or lower in the neck; if we add to those already described the three following cafes, the series will be complete; Sahler Diff. de Feto bipetiti, Defil. 1786; Prochaska Annot. Academ. fæticic. tab. 1. tab. 6. Monro on the Nervous System, tab. 8.

A feto with two Heads, joined in the Trunk.—The double parts of the body are continued farther down in this than in the preceding cases. There are two heads and necks and two arms; the double parts join in the chest, and the body is fingle below. See Hall, de l’Acad. des Sciences, 1745, p. 39.

Or the union may take place lower down in the chest, or in the abdomen or pelvis; there are three or four arms in such cafes, and two lower limbs. In a feto described by Duverney, Comm. Acad. Petropol. t. iii. p. 188, there were two imperfect arms between the two necks. The two inner rows of ribs joined together, and did not run on to the sternum; there were three cavities in the thorax, a right and left proper, and a middle common one, and two hearts. In another there were two perfect lateral upper extremities, and a middle imperfect one; a double spine as far as the loins; two hearts, and aorta, which united below the diaphragm. (Phil. Trans. N° 158.) In one examined by Lemery, there were two vertebral columns, and trachee, double lungs, a single heart composed of one auricle and ventricle, two aortæ joined in the back, two flomachs and duodenae, which united into one intifline. (Mem. de l’Acad. des Sciences, 1724, p. 63.) In another the vertebrae were joined in the back; there were two ãœosphaguses and one flomach, a double heart, and large vessels united in the loins. (Haller, Opera Minora, p. 85.) A child with two heads and chests, and four upper limbs; one pelvis and penis, and two lower limbs is described in the Journal des Savans, 1684, p. 27. For an account of a much greater number of these cafes, and numerous references, see Haller De Monstris, lib. i. cap. 1. 28.

A feto, double below, and united above.—There is a clas of fetouses different from the former, in which a single head is united to a double body. Haller has given a very detailed account of a pig of this kind. The face and upper part of the cranium were single in this animal, the lower portion of the cranial cavity, and all the organs thence downwards were double. The two bodies, which in size and form corresponded to the ordinary model of the species, adhered together from the navel upwards. All the parts towards the face of the head were single. There were two occipital bones, divided by an additional petrous bone; they rested in front against a single ãœosphoid. Two additional occipital bones were joined into a pentagonal piece resting on the additional petrous portion. The occipital bones were supported by their respective atlantes, and there were two clefts from this point downwards, differing from the ordinary arrangement only in the ãœcal. Each of these received a row of ribs of each body; that is, to one ãœcalum were attached the right ribs of one chest, and the left of the other, and vice verâ. The cerebrum was single, with furrured medulla oblongata, two cerebella, two medullaæ spinæs, two basillary arteries, and two pituitary glands. The nerves were single from the first to the sixth pair; there were four auditory nerves and paria vaga, and a single ninth pair for the single tongue. There were two larynges, with one pharynx and ãœosphagus between them. Above the navel the abdomen was single, and double below; there was one flomach and small intestine; the latter bifurcated towards its end, and the canal from this part was double. There were two livers, spleens, and pancreases. The thorax was single in the middle, and extended on each side into two cavities resembling each a single thorax; and containing the lungs as usual. There were two hearts, one of which received the veins of the left body, and sent an aorta to the right, while in the other these relations were reversed. Just behind the arches, the aortae were joined by a large but short transverse communicating branch. (Haller, ut supra, cap. 16, with five figures.) In the name place a multitude of examples of this formation in animals, as the dog, cat, goat, horse, hare, rabbit, fowls, &c. is quoted. There are also many instances in the human subject; see cap. 18.

Two complete Bodies united.—Through the preceding classes there is a gradual approach, from the single body to the union of two, in other respects, perfect bodys. The most complete dissection of a double child is furnished by Haller. The mother had brought forth three well-formed children, and carried this double production the full time. It consisted of two well-formed girls, of the ordinary size, with abundant hair, perfect nails, and rather elegant features. The chests and epigastria were united, the two bodies being free
MONSTER.

free in every other part. The labour was very difficult and tedious, and attended with the death of the children, which, but for this reason, might probably have survived, their organization seemed so perfect in all respects. The umbilical chord contained four arteries and one vein; the abdomen was single above the navel, and double below; it contained one liver, to which there were attached two gall-bladders. The greater diaphragm was simple, and terminated below into two appendices for the two bodies. A large single heart was placed in the middle of the chest; but all the blood-vessels were double. The pulmonary veins of one body opened into the superior cavae, while in the other there were two superior cavae, and the pulmonary veins had distinct openings in the heart. The latter organ consisted of one atrium, receiving the terminations of all the veins, and of two ventricles, one of which was no doubt a ventricle and a pulmonary artery arose. All other parts were double; indeed there were two bodies almost entirely distinct. The two femora were both common to the two bodies; each receiving a series of ribs from each child, and a clavicle of each, (loc. cit. cap. 29,) with several figures. In the 30th, 31st, and 32d chapters, Haller has collected a great number of instances of similar monsters both in animals and in the human subject from authors. Generally there has been only one heart, but sometimes two; in some cases there have been four cavities, with the usual blood-vessels, but often fewer. The liver in almost all instances single.

The formation of the bodies is so perfect in many of these cases, that we can discern no reason why they should not continue to live after birth; probably the violence to which they are exposed in parturition, and the duration of that process consequent on this difficulty, may be the cause of their destruction. They have lived for a longer or shorter time in a few instances. Two children joined by the abdomen, double above, and having one pelvis and penis, and two lower limbs, but no rectum, lived seven days, and died within a quarter of an hour of each other. (Journal des Savans, 1684, p. 27.) Another is mentioned in the same work, p. 346, who lived to the age of 28, under James IV. in Scotland; one of the bodies died four days before the other.

The most extraordinary instance of this kind is that of the united twins born at Szony, in Hungary, in 1701, publicly exhibited in many parts of Europe, and among others in England, and living till 1723, when they were buried in the convent of the nuns of St. Ursula, at Prague. They were joined at the back, below the loins, and had their faces and bodies placed half sideways towards each other. They had one anus, and one vulva. The vaginae were all double, except that the two vaginae united into one towards the external aperture, and the two recta were joined in the same way. There were two bladders and urethra opening separately. The two fauces were blended into one, and had a single or cecygis connected to the lower end. The two orae were joined into one tube before the division into the sides; and the inferior orae were united to the same part. They were not equally strong nor well made; and the most powerful, (nor they had lepares wills,) dragged the other after her, when she wanted to go any where. At six years one had a paralytic affection of the left side, which left her much weaker than the other. There was a great difference in their functions in health and disease. They had different temperaments. Neither the lungs nor the urinary evacuations were always performed at the same time by both infants; they usually happened at different times, one having them a week or more after the other; sometimes one, sometimes the other would be most disordered at such periods; when one was asleep, the other was often awake; one had a desire for food, when the other had not, &c. They had the small-pox and measles at one and the same time, but other disorders separately. Judith was often convulsed, while Helen remained free from indisposition. One of them had a catarrh and a colic, while the other continued well. Their intellectual powers were different; they were brisk, merry, and well bred: could read, write, and sing very prettily; could speak several languages, as Hungarian, German, French, and English. They died together. Phil. Trans. vol. i. G. C. Dreschel historia magnae legationis cæsareæ, &c. p. 41. Haller, lib. i. cap. 28, and lib. ii. cap. 26, where some other instances are quoted.

c. Fœtuses included in the Bodies of others—Being included in the bodies of others are the most uncommon kind of monstrosity; yet we have some well authenticated cases.

In the Gentleman's Magazine for December, 1748, mention is made of a child, born with a large bag extending from the fundament to the toes. It burst a few days after birth, and exposed an irregular mass of florid flesh, in which a hand and foot with perfect fingers and toes could be distinguisished. There was no other visible distinction of parts or sex. The child fed heartily.

A fœtus was lately discovered in the abdomen of a boy fourteen years old in Paris: we have seen no detailed account of this occurrence, which is mentioned in the Bulletin de l'Ecole de Médecine, in the Gazette de Santé, 1804, No. 1, and the Journal de Médecine, an. 13.

But the instance recorded by Mr. G. Young in the Mémoire-Chirurgical Transactions, vol. i. with four plates, is the most minutely described, and the best authenticated, as the parts were seen at the time by the principal medical men in London. A tumour was perceived nearly from the time of birth in the abdomen of a child, and gradually increased to its death, which took place at the age of nine months. A firm and for the most part thick clyst was placed in front of the abdominal aorta, between the roots of the celiac and superior mesenteric arteries, attached to the left crus of the diaphragm, and covered in front by the mesentery and duodenum, pancreas, and its duct, and transverse portion of the colon. It contained 38 ounces of a limpid fluid, and a rudely formed human fœtus adhering to its surface, by a fleshy cone proceeding from the umbilicus, and measuring one inch and seven-tenths at one end, and half an inch at the other. This production was covered by integuments of the natural appearance, on which there was fibrous matter, such in all respects as is often met with on the limbs of infants recently born. The extremities were distinctly recognizable, and in many respects tolerably well formed, so much so as to have distinct fingers and toes with nails, but exceedingly short and stout. There was something corresponding to the biceps cranii, and a considerable portion of the spine, some short ribs, scapum, and osa innominata, and some bones and joints of the limbs well formed. Very little mucilaginous substance was found in this creature; none on the trunk, a little about the hips, and none in the remainder of the limbs, which consisted of adipose substance. There was neither brain nor spinal marrow, but a distinctplexus of nerves just within the umbilicus, about the commencement of the intestines, to which numerous branches were distributed. There were two loops of hair just below the part corresponding to the head. It had no heart nor lungs, and no abdominal vasa, except a few inches of naturally formed intestine, with mesenteries. Two kinds of vessels were distinguished in this production; but it was not practicable
MONSTER.

practicable to ascertain clearly the nature of their connection with the cyst. There was a very distinct ferum and penis.

III. Considerations on the production of these unusual formations.

There is a very important ground of dissection, in conformity to which, on the first view, we separate them into two classes; those which are, and those which are not, capable of supporting life after birth. To the former belong all varieties, and few of the monstrous formations: to the latter most of the monsters, as the headless and heartless children; those with imperfect arms, with communication between the trachea and oesophagus, with uncovered viscera. In the former, there is another dissection between the inclinations, in which the natural functions are all perfectly executed, and those in which life is continued for a certain length of time with inconvenience and suffering, and then prematurely ended. The varieties of a lighter kind, and in important organs, belong to the first of these divisions; malformations of the heart, and of the urinary organs, pina bifida, &c. to the second. Again, in some kinds of malformation, the vital powers seem as perfect as in the ordinary formation, but the mechanism is imperfect, as in club-feet and other erroneous organizations or deficiencies of the limbs.

It is very clear that the great deviations from the accustomed standard, producing monstrosities, are generally incapable of life; and we can understand the reason of this in many cases, where the heart or brain is deficient, &c. But in other instances, where no such satisfactory cause is apparent, experience shews us that these monsters are generally cut off. We have already observed, in the article Exanuno, when speaking of the fetus, that it is often ill-formed, smaller than it should be, deviating from the usual proportions, or monstrous, in abortions; so that the vital powers in monsters do not seem adequate to maintain the comparatively simple existence of the fetal state; if, however, they get over this danger, the hour of birth is with them generally the hour of death. There are many possible arrangements, differing from the ordinary type, in which the functions would have been all preferred; but this would interfere with another principle, which seems to prevail extensively in the operations of nature, viz. preservation of uniformity in the species.

We should observe, in the next place, that these deviations are not confined to the human subject: they are very frequent in animals. All the kinds of monstrosity have not, we believe, been noticed in the latter; we find no instances recorded of hare-lip, of want of brain and heart, of spina bifida, of malformed urinary organs, nor of such general malformation as is exhibited in the case of Dr. Clarke, and in the fetus dissected by Mr. Young. But united features, supernumerary limbs, and unnatural arrangements about the eyes and nose, are very frequent.

We observe further, that such monstrous productions are almost, if not entirely, confined to domesticated animals; at least nearly all the recorded instances justify this assertion. Out of very numerous monstrous animals, of which the descriptions are referred to in the work of Haller, we find very few that can be at all suspected to have been in a state of nature. There are some hares, and one instance of double males cited from Valisneri. He refers to three instances of frogs with five feet. Examples of serpents with two heads have been very uncommon; the same formation has been seen in the turtle and lizard. (See Haller de Monstris, l. cap. 23.) True hermaphrodites, or individuals possessing perfect male and female organs, are not rare among fishes. We have read somewhere, that if the spawn of a fish be placed in a small vessel, about the time that it begins to be evolved, all kinds of unnatural unions will take place, exhibiting monsters of every description, but we cannot now refer to the place.

Monstrosities are very frequent in the pig; we believe that they are entirely unknown in the wild animal. That domestication should have this effect is not more surprising, than that it should affect the number of young produced. The wild sow brings forth only once a year, and thus has fewer young than the tame one, which farrows twice.

The circumstances just mentioned: the great abundance and numerous kinds of monsters found in the human subjeet, their comparative rarities and fewer species in the domestic animals, &c. their probable entire absence in wild animals, lead us to suspect that they owe their origin to something connected with our peculiar mode of existence in this respect; in short, they resemble our diseases, which we believe to be altogether unknown to animals in a state of nature, and to exist in greater number in proportion as they are more and more completely domesticated and rendered artificial. At the top of the scale, whether we regard the number, the complication, or the severity of his diseases, stands the lord of the creation; if he boasts that his arts have subdued both animate and inanimate nature, the nonsensically, unfolding his long and appalling catalogue, loudly proclaims that he is diseased, checks his triumph, and convinces him that he has paid too dear a price for empire.

Generation is a function not differing in its essential characters from the other processes of the animal economy. The production of a new being seems, on a superficial view, so much like creation, according to the notions which men have assumed themselves with framing on that subject, that they have conceived it to require some preternatural agency. Regarding this business then as the work of God, and having already affirmed that all his works are perfect, we maintain that the young animal is originally perfect, and degenerates into a monster through the action of external forces. More accurate observation discloses to us in this affair merely the operation of secondary causes, and exhibits effects in the production and development of the fetus as the result of vital action in secretion and nutrition; in short, however his pride may be offended at hearing it, the simple truth is, that on confidered at the epocha of his first formation, and with respect to his corporal frame, is a fiction.

The function of generation is not more exempt from the operation of disturbing causes than any other in the animal economy. Any violent and sudden impetion interrupts it at once by causing abortion; but minor causes, although, their effects are not seen, are not to be deemed inoperative. Particular bodily formations, particular mental characters, and dispositions to certain diseases, &c. &c. are transmitted to the offspring. Indeed, how can we expect, that, when all the rest of the being is artificial and vitiated, this one part should be undisturbed; we ascibe then the aberrations from the usual form and structure of the body, which produce monsters, to an irregular operation of the powers concerned in generation, and place them on a level, with respect to their causes, with unhealthy executions of the nutritive, secretory, or exhalant functions. We on y mean, by these observations, to refer the aberrations of the formation proper to the same general principles, as the other deviations from the healthy execution of functions, and to protest against the confiding them as forming a peculiar cafe out of the common rules applying to organized beings.

It would not be right, however, to pass unnoticed the commonly
MONSTER.

commonly entertained opinions, although we entirely reject them; we shall, therefore, make a few observations on some of these.

Physicians for a long time believed, and mankind in general are still firmly convinced, that the mind of the mother exerts a very potent influence on the formation of the child; and that her imagination, or some peculiar mental state, is capable of producing even very signal deviations from the accustomed formation, after the natural development and growth have been very considerably advanced. It has been supposed that a sudden fright will cause a resemblance to the animal or object producing it, and that a violent desire or longing for any thing, particularly if it be not gratified, will cause a resemblance of the thing to be marked on some part of the child’s body. The names given to the marks, sometimes observed in newly-born children, shew how generally the opinion has prevailed; viz. nati materni, in Latin; muttermahl, or muttermelchen (mother’s spots), in German; envie (longing), in French. Matrons and nurses, the hereditary priates of Venus and Lucina, and the great authorities, to the uninitiated, on all the mysteries of generation, often contrive to keep a mother, doubly anxious for herself and her offspring, in a state of alarm throughout her pregnancy, lest the sight of something frightful or disgusting, the longing after some object, &c. should convert the child in her womb into a monster.

In the first place, monstrous productions are often brought forth, when the mother has been conscious of no caufe during her pregnancy, that could be thought likely to produce them. The strong desire, common indeed to both sexes, of being thought capable of executing the generative functions perfectly, and the unceasing accompanying any suppressed failure, induce midwives, where a monster is brought forth, to conceal it from the mother’s knowledge, which, as they generally die after birth, is easily done. If, however, the should learn the occurrence, the recals to her recollection whatever has happened in her pregnancy, and can hardly be at a loss for some longing, or averion, or fright, to which she refers what might otherwise bring into question her fitines for these important functions. How are the nati, and other unnatural formations to be accounted for, when no mental caufe is remembered, or, when the monstrosity not being known to the mother, she never mentions any such occurrence?

A knowledge of the different kinds, and of the anatomical structure of monsters, affords very strong, and indeed incontrovertible proofs of the absurdity of the common notions. The moit zealous advocates of the opinion, which indeed only makes the matter more obscure, will hardly contend that the imagination of the mother can annihilate one-third or one-fourth of a head, and adapt to it an exactly corresponding piece of another head, resembling it so exactly in size, form, features, &c. If it should not be difficult enough to account for the production of this symmetrical double head, a harder task remains; viz. to explain how the imagination of the mother changes nearly half the body; for the vertebral column may be double, the breast consequently broader, &c. in such an example.

We shall again ask how longing or fright can dispose of the brain, membranes, face, &c., as in the acephali? How can it flop up the anus? or destroy the fore-arm and place the fingers at the end of the arm? or annihilate the nose; and bring together and confound in one the two eyes?

Do pigs, horses, hares, &c. long? are pigeons and fowls given to these fancies? or does the same effect arise from one cause in men, and from another in animals? How does the explanation apply to trees, and other vegetables, in which monstrous productions are not rare?

That the vulgar, who know only the surface of things, and are contented with the most dilatant resemblances and the loofest analogies, should ascribe the harelip to the fight of a hare, is not very strange but we should hardly believe, if it were not before our eyes in print, that Heister (Observ. Med. Miscell. obf. 14.) describes a sincipital fatus with divided lip as the result of such a caufe. The mother of a similar child described by Sandfort ascribed the deformity to a fright caused by a monkey. Now what resemblance is there between a hare or a monkey and such a child? What between a hare and a monkey? All the monsters of this description are remarkably alike; in our judgment they do not bear the most remote resemblance, either to a monkey or a hare; and we have already mentioned that they have gained the common name in Germany of cat’s-heads. If we go back into times a little more remote, as 1670, we shall meet with children resembling devils. Kerkring (Stiepel. Anat. obs. 24.) gives us a figure, with the following inscription: "Monstros similes pueris qui temporibus ultimorum in medico perserant, hodie namque in medico perserant, hodie namque in monstros similes pueris qui temporibus ultimorum in medico perserant."

The fingers in the engraving have something of the character of claws; and the mother fancied that she had a monstrous child, and her acquaintance used to ridicule her. The goats were thought the child like an imp; and Kerkring found it in no respect like a human being, but rather like an ugly monkey: "Caput nihil habebat, quod hominem referret. Facies fimilis, etque deformi similissima."

Is it not very clear that the imagination is much more powerful, and in the good people, than in the poor mothers? Devils, apes, hares, and cats are all alike to them. It is difficult to contend against such advancies: if they are driven from their monstrosities and hares, they conjure up the phantoms of their brains, and array against us imps, blue devils, and old nick himself.

In cafes of harelip, the parts do not resemble the nout of a hare, but are formed in quite an opposite way. The upper jaw-bones are drawn apart, and the face conformation more than usually broad, instead of being narrow and standing forwards, as in the hare. The lip of the hare is not hareliped; but merely notched, and covered with long hair, and bristles. The failure of the lip is often the smallest part of the deformity in the human subject; there is a division through the whole of the bone and soft palate, to which a hare’s head has nothing analogous.

The productions of the skin, which are compared to strawberries, mulberries, raspberries, &c. are so obviously unlike those objects, that it would be a waste of time to say anything on the subject. Let it be observed, too, that hare-lips and other monstrous productions are seen in countries, where there are no hares, no raspberries, cherries, &c. to cause them.

Women generally refer to frights, longings, or other mental impressions, in the latter months of pregnancy; at earlier periods they do not feel the fear of such occurrences. New monstrous features are seen at all times of tero-gestation, from the first recognizably existence of the child; and the fetus is formed or monstrous in a large proportion of abortions, which occur for the most part before the time at which their apprehensions begin.

The child does not participate in most of the bodily affections of the mother, and apparently is uninjured in many very serious and extensive disorders: at least strong and well-formed children are brought forth by mothers, after going through such ill effects. It is reasonable to suppose that the fright of an animal, or the mere wish for an article of food, should have no effects which the much more serious causes do not.
not produce. We know that if a pregnant woman has a limb broken or amputated, the will nevertheless produce an entire child; yet we are gravely told that if the foes such things in another, her child will suffer.

But it is needless to pursue further a question, on which all rational persons well acquainted with the circumstances are already unanimous; to explain that there is not a single fact even approaching to a proof, that the mother's imagination ever had any effect on the form of any child; that none of the numerous monsters refemble, in any essential character, the objects to which they are compared, and most of them, as the brain-leafs and those without hearts, the double fetuses, those with redundant parts, as the two-headed, &c. correspond to no archetype in nature; and that, when deception is employed, unnatural arrangements of important organs, like nothing else in heaven above or the earth beneath, are found in abundance. This belief in the power of imagination, like the belief in witchcraft, is greater or less, according to the progress of knowledge, which in truth differs greatly in different countries and heads. We know that many enlightened men are fully convinced of its absurdity, while foolish philosophers are still found to support it.

The production of monsters has been explained mechanically by some physicians: they have supposed that deficient parts are destoyed by external pressure or violence; that superfluous parts are remains of another fetus becoming adherent to a perfect one, and that compound fetuses are made of two growing together. This is a perfectly gratuitous hypothesis, and is repugnant to all our knowledge concerning the animal economy. By what facts are we justified in believing, that the ribs of two fetuses, and the clavicles, can detach themselves from their respective sterna, and become fixed, each to the sternum of the other, as in the skeleton of the double fetuses: that two perfect hearts, if the chest could be thus metamorphosed, could be united with one auricle only, and with two ventricles, of which each produces a pulmonary artery and an aorta; that a new communicating channel should be formed between the two aortae, as in the double bodied pig already described. If we could believe all these wonders, it would not be sufficient; for monstrosities occur, when there has been no violence inflicted during pregnancy. We cannot help being surprised that Haller, who knew how inadequate this explanation is to the solution of the phenomena in most of the monstrous births, should admit it in any case. Yet he considers it as perfectly applicable to most of the unnatural positions of parts; to some unnatural formations; to the absence and division of organs, and to some cases of preternatural unions. He refers the hare-lip to a want of the cellular substance, that should unite the superior maxillary bones, and conceives that the parting of the bones lacerates the lip. (Lib. ii. cap. 13.) He attributes the appearances in the accephali to accidents during utero-gestation destroying the brain and its cafe. The respect due to the name of Haller, a name so dear to all who interest themselves in physiological pursuits, leads us to believe on these opinions a degree of notice which they would not otherwise gain from us. Let us allow, what is not supported by a shadow of proof, that a force can be applied to the child in utero, capable of causing such extensive destruction; how does it happen that the head should be destroyed in all cases just so far as the orbits? it must either take place suddeley or gradually. The former cannot be the case, for the brain and its membranes could not be annihilated without killing the child: moreover, in the frequency of these cases how does it happen that the head is never found in this bruised condition? If it be the consequence of gradual pre-
MONSTERS, Vegetable. There are also monstrous productions in the vegetable world: such, e. g., are what some botanists call nudae.

Florists also give the denomination monsters, or monstrous flowers, to those flowers which are not only double, but double potted; or when, instead of one flower, there are two or three rising one above another from a single stalk.

MONSTERAS, in Geography, a town of Sweden, in the province of Smaland; 25 miles N. of Calmar.

MONSTER. See Moutier.

MONSTRANS DE Dreux. in Lact., a writ issuing out of chancery, or the exchequer; for restoring a person to lands or tenements that are his in right, though on some occasion found in possession of another lately dead.

MONSTRAVERUNT, a writ which lies for a tenant who holds by free charter in ancient demesne, upon his being displeased for the payment of any service or imposition contrary to the liberty he does or ought to enjoy.

MONSTRELET, ENGUERRAND, DE, in Biography, a chronicler of the fifteenth century, was descended from an ancient family in Cambray, of which city he died governor in 1452. He left a history, in French, of his own times, commencing with the year 1309, and carried down to 1457, but the last fifteen have been added by another hand. The first edition of that of Paris, in two folio volumes, 1572: its title is "Chronique d'Enguerrand de Montrelet, gentilhomme, jadis demeurant à Cambrai en Cambrésis." It gives a faithful, but, as might be expected, a prolix narrative of the wars between the houses of Orleans and Burgundy, of the capture of Normandy and Paris by the English, and their expulsion, and of all the memorable events in France and other countries during that period. It occupies the space between the histories of Froissart and Comines, and is valuable on account of the number of original documents which it contains. Moreni.

MONT, HENRY DU, a voluminous ecclesiastical compiler of music, and maître de chapelle to the king of France. He published at Paris, in 1652, Cantica sacra; and in 1681, motets in four parts, five vols., and other motets for the Chapelle royale in 1686, sixteen vols.

He was born at Lige in 1610, was a great organ player, and the first, says M. Laborde, who introduced the lute, Garci, or thorough-bass, into France. His style is now become extremely dry and uninteresting; and never was equal to that of many Germans and Netherlanders, his contemporaries.

MONT, in Geography, a town of Perú in the province of Segedan; 90 miles N. W. of Zareng.

MONTAUBAN, a town of Germany, in the principality of Nassau, in the extensive huildie of which silver mines are found: 11 miles E. of Coblenz.

MONTAFIA, a town of France, in the department of the Tamaro; 11 miles N. W. of Ait.

MONTAGNA, a department of Italy, E. of lake Como, containing about 165,432 inhabitants, who elect 12 deputies; the capital of which is Lecce.

MONTAGNAC, a town of France, in the department of the Dordogne, and chief place of a canton, in the district of Bergerac; nine miles N. of Bergerac. The place contains 1,620, and the canton 10,865 inhabitants, on a territory of 977 square kilometres, in 19 communes. — Also, a town of France, in the department of the Herault, and chief place of a canton, in the district of Beziers; 24 miles W. S. W. of Montpellier. The place contains 3,106, and the canton 11,162 inhabitants, on a territory of 212 square kilometres, in 12 communes.

MONTAGNANA, Antonio, in Biography, an Italian opera singer, with a powerful base voice, and great abilities, who arrived in England during the latter part of Handel's opera regency, as successor to Bolchi.

He first performed in Sofarnos, in the grand air, "Fra l'ombre poror." In this air Handel displayed all the power, depth, and mellowness of his voice, and the peculiar accuracy of his intonation in hitting distant intervals. This air will ever be admired, among base songs, by real judges of composition, and heard with delight by the public, whenever it shall be executed by a singer whose voice and ability shall equal those of Montagnana. He sung for Handel in Faramond and Xerxes, from whom he apostatized, and went over to the opposition, and performed with Farinelli in the operas of Porpora.

MONTAGNANA, BARTHOLOMEW, a native of Padua, was a distinguished professor of medicine in the university of that city, in the middle of the fifteenth century; and was succeeded by his son, of the same name, who held a still higher reputation as a scholar, though he was left distinguished as a practical physician. The latter left Padua, and took up his residence in Venice, in the year 1528, where he practiced his profession until his death, in 1575. The first Montagnana left a collection of opuscules, which were first printed at Venice in 1597, and afterwards frequently republished, with the title of "Selecitorum Operum, &c. Libri unus et alter." And the second published, "Retrosa repurpanda, conservandaque sanitati palatia dignissima:" and "De Pedilantium ad Adriamum Pont. Maxim.

But the family of Montagnana produced several medical and surgical professors for two or three successive generations, the son and two grandsons of the second Bartholomew having taught these sciences, and published each one or two works of little note. A tract of Bartholomew, the son, "De Morbo Gallico," is printed in the Venice collection upon that subject. The grandsons, Marc Anthony and Peter, who were successively professors of surgery at Padua, published, the one a treatise, "De Herpete, Phagedeum, Gangan, Phacelo, et Camero," Ven. 1559; and the other two essays, "De Uramis," and "De Vulvibus et Urethribus, curorum remedii," both in Latin and Italian. Eloy Dict. Hist. de la Med.

MONTAGNA, in Geography, a town of Italy, in the Paduan; 18 miles S. W. of Padua; N. lat. 43° 14'. E. long. 11° 34'.—Also, a town of Italy, in the duchy of Modena.

MONTAGNE, or MONTAGNE, MICHAEL, DE, in Biography, a celebrated essayist, was born in 1513. His early attention to the studies of youth led his father, lord of Montagne, in Perigord, and mayor of Bordeaux, to cultivate his talents with the greatest care. He was exceedingly well grounded in the ancient and some of the modern languages. At the age of thirteen he had completed his course of education at the college of Bordeaux, where he had enjoyed the benefit of the instructions of Muret and Buchanan. He was intended for the legal profession, and followed it some time, but became dissatisfied with its dry forms, and devoted his talents and time to the study of men and books. After the death of his friend Etienne de la Boëtie, who bequeathed to him his library and manuscripts, he published "The Remains" of that friend in prose and verse. In 1569 he printed a translation of "The Natural Theology of Raymond de Sebond," a learned Spaniard. On the death of his father he acquired possession of the estate and seat of Montagne, and being now at ease, in that retreat, he began to collect materials for his Essays. In the hope of enlarging
larging his sphere of observation on men and manners, he travelled through France, and visited Germany, Switzerland, and Italy. At Rome he was honoured with the privilege of citizenship. In 1581 he was chosen mayor of Bordeaux, an office which he held four years, in the course of which he was delegated by his fellow citizens on some public business to the court. During a residence at Paris he contracted that intimate friendship with Madame de Gournay, which continued as long as he lived. He was not inclined much to the political speculations which disturbed France during the reign of Charles IX., but was subject to temporary dangers from the military parties, which at that period seemed to make no difference between friends or foes. He died in 1592, leaving an only daughter. His literary reputation is founded on his "Effays," which were at one time extremely popular, and which are still read with pleasure by a numerous class of persons. They embrace a great variety of topics, are lively and entertaining manner, but without much accuracy or depth. Their style is neither pure nor correct, but simple, bold, lively, and energetic. La Harpe says of him, "As a writer, he has impressed on our language (the French) an energy which it did not before possess, and which has not become antiquated, because it is that of sentiments and ideas. As a philosopher he has painted man as he is: he praises without compliment, and blames without malice and example." The best editions of Montague's Effays are those of Colle, in three volumes, quarto, 1725, with additions, and a supplemental volume, quarto, 1740, reprinted in six volumes, 12mo.; and that of Brussels, three volumes, 1759. In 1772, Montague's "Travels" were published by M. de Queurou, in one volume, quarto, and three volumes, 12mo. Moreri.

This modern Democritus, in travelling through Italy and Germany about 12 years before his death, seems to have attended to the ecclesiastical music of those times and countries, with more interest than we have reason to expect from the general tenour of his life and occupations. In 1582, at Kempton in Bavaria, he says, "after the Catholic church of this city, which is Lutheran, is well served; for on Thursday morning, though it was not a holiday, mass was celebrated in the abbey, without the gates, in the same manner as at Notre Dame, in Paris, on Easter-day, with music and organs, at which none but the priesthood were present."

At the church of the Lutherans, Montague heard one of the ministrants preach in German to a very thin congregation, "when he had done. a psalm was sung, in German likewise, to a melody a little different from our's. At each stroke of the organ, which had been but lately erected, played admirably, making a kind of response to the singing." This is an early instance of the use of interludes in accompanying psalmody on the organ. "As a new-married couple," continues Montagne, "went out of the church, the violins and tabors attended them." This circumstance is mentioned to prove, that the violin was then a common instrument in Germany.

At Lauenberg, the same author tells us, that "the town clock, like many other's in this country, struck quarters, et dit-on que celui de Nuremberg fonce les minutes," This is likewise an early proof of chimes, in Bavaria, whence they are said to be brought into the Low Countries.

It is here that this author gives an account of the cantor or chanter, who directs the singing in Lutheran churches. "Two seats are placed, one for the ministrant, and one for the preacher, when there is one, and another below for the person who leads off the psalm. After each verse, the congregation waits till he has pitched and begun the next; then they all sing together, peste melo, right or wrong, as loud as ever they can."

MONTAGRIER, in Geography, a town of France, in the department of the Dordogne, and chief place of a canton, in the district of Riberac; six miles N.E. of Riberac. The place contains 1850, and the canton 9175 inhabitants, on a territory of 1924 square miles, in 13 communes.

MONTAGU, Lady Mary, in Biography, the eldest daughter of Evelyn, earl of Kingston, afterwards marquis of Dorchester, and then duke of Kingston, and of lady Mary Fielding, daughter of William, earl of Denbigh, was born at Thoreby, in Nottinghamshire, about the year 1690. The first dawn of her genius, led her parents to pay the strictest attention to her education. She acquired the elements of the Greek, Latin, and French languages in the company of the most celebrated of her time, and was afterwards taught by her famous preceptors as were employed in the education of her brother, lord viscount Newport. After she had made considerable progress in her classical studies, she came under the care of bishop Burnet, who formed her superior talents with every expression of dignified praise. She gave an extraordinary proof of her erudition, in her twentieth year, by a translation of the Enchiridion of Epictetus. She was enabled to acquire so much learning by living a very retired life, spending her time chiefly at Thoreby, and at Aiton, near London, in the society of a very few friends. The charms of her person and understanding seem to have been little known to the world till after her marriage, which took place in the year 1712, with Edward Wortley Montagu, a relation of the earl of Halifax, who will be shortly noticed.

For three years after her marriage, and till the return of lord Halifax to the ministry, at the accession of George I., introduced Mr. Wortley (for he is usually called) to a place in the treasury, they lived privately; but on this change in his circumstances he thought proper to bring his wife to London, and place her in the sphere of the court. Here she attracted that admiration which beauty and elegance, joined to wit and all the charms of conversation, could not fail to inspire. She became familiarly acquainted with Addison, Pope, and other distinguished writers of that period, and was fully equal to maintain her rank among the votaries of polite literature. In 1716, Mr. Wortley obtained the appointment of ambassador to the Porte, and was accompanied to Constantinople by his lady, who took great delight in the opportunity which such a journey offered her of viewing foreign countries and manners. They passed through Germany to Vienna, and thence across Hungary, and the northern provinces of Turkey to Adrianople. Her natural talents, joined to her acquired knowledge, singularly fitted her for taking advantage of her situation, both in the course of travelling, and in her residence as ambassador's wife. On many occasions she displayed a mind superior to common prejudices and weak fears; but in none so happily as in adopting the Turkish practice of inoculation for small-pox, then unknown in Christian Europe. For her own son, at Pera, in 1718. This practice, it must be mentioned to her high honour, she was the principal means of introducing into England by the ministration of Mr. Maitland, the medical attendant on the embassy, and thereby she has rendered herself one of the greatest benefactors of her country. "This merit alone," says one of her biographers, "justly entitles her memory to a high degree of gratitude, not only from this nation, but from all others which have followed the example of Great Britain in taking advantage of so fatal a invention, and even if it should hereafter be super-

D
founded by a newer discovery (vaccination), fill the medical system of Europe must be considered as indebted to her for rendering familiar the general idea of inoculation." Mr. Wortley returned in 1718, by the way of the Archipelago, to Genoa, and thence to Turin, Lyons, and Paris; so that lady Mary's tour comprised a larger and more varied circuit, than has often been performed by a female traveller; and few have ever been better, or, indeed, half so well able to adapt themselves to foreign manners, or have displayed more firmness of mind in circumstances of difficulty and hazard. On her return she was received at court with the distinction due to her great talents and splendid accomplishments, and the renewed her connection with the wits, among whom, Pope was one of the most highly favoured. With this poet the afterwards quarrelled, and this has been regarded as a memorable epoch in her life. If lady Mary were the "Sappho" of that poet's satirical pieces, which few will doubt, though he positively denied the fact, he is chargeable with a grooser insult than could be endured by any woman. The lines particularly referred to are to be found in the imitation of Horace's first satire in the second book. In writing to lord Hervey in vindication of himself, he says, "In regard to the right honourable lady, your friend, I was far from designing a perfon of her condition by a name so derogatory to her as that of Sappho, a name prostituted to every infamous creature that ever wrote verse or novels. I protest, I never applied that name to her in any verse of mine, public or private, and I firmly believe not in any letter or conversation. Whoever could invent a falsehood to support such an accusation I pity; and whoever can believe such a character to be her's, I pity still more."

Lady Mary retaliated upon the fatirist, by joining lord Hervey in a very severe copy of verses, addressed to him. She was thenceforth courted by other wits of the time, and retained her place in the circles of fashion and literature till the year 1759, when she quitted her country and family, and, for a long series of years, established her residence on the continent. Her health was made the pretext of this change of place, but there were probably other reasons for her determination. It is certain she had her husband's consent, from the liberal allowance he made her, and for which she expresses her acknowledgments. It has been thought it was through his injunctions that she left England; this is rendered probable by her returning immediately after his death. But the strain of her letters to him, during this period, betrays neither repentment nor humiliation. Venice, Aix, Avignon, and Chambery, were at different times her residence, but she usually spent her summers at Louverne, in the Venetian territory, famous for its mineral waters. There she occupied an old palace, which she put into habitable condition, amusing herself with her garden, her fow: and the little society which the place afforded. She perfectly accommodated herself to the manners and way of living in that country, and passed her time in tranquillity. On the death of Mr. Wortley in 1761, she complied with the solicitations of her daughter, the countess of Hulse, and after an absence of twenty-two years returned to England, where she died in the following year.

Lady M. W. Montagu has obtained a considerable reputation among the literary characters of her own country, as a poetess and epistolary writer. Her chief works in poetry are "Town Elegies," meant as a kind of parody upon the common pastoral elegies, and a vehicle of some fashionable satire. As an epistolary writer, this lady's fame stands much higher, and is not surpassed by that of any person of either sex, whose letters have in this country been given to the public. In proof of what we assert, we refer to the edition in five volumes, published in 1803, to which a biographical memoir is prefixed, from whence the foregoing facts have been chiefly collected.

Montagu, Edward Wortley, only son of lady Mary, and Mr. Wortley Montagu, was born about the year 1714. He was, from a very early period, remarkable for eccentricity of character, and ran away three times from Westminister school. It is said, that in the first of these escapements he exchanged his clothes with a chimney-sweeper, and followed the looting occupation for some time. He next associated himself with low fishermen, and cried fish through the streets: after this he failed as cabin-boy in a vessel bound to Spain, on his arrival in which country he deserted the ship, and hired himself as a mule-driver; at length he was discovered by the English confidant, who sent him back to his friends, and they put him under the care of a private tutor. How long he remained under the instructions of this gentleman we cannot ascertain, but the next time we hear of him is in the West Indies, where he continued some time. He was fond of adventures, and was almost perpetually seeking something new. Of himself he says in a letter to a friend, "I have conversed with the nobles of Germany, and serv'd my apprenticeship in the science of horsemanship at their country-feasts. I have been a labourer in the fields of Switzerland and Holland, and have not disdained the humble occupations of poet, physician and ploughman. I am, at Paris, the ridiculous character of a petit-maitre. I was an abbé at Rome. I put on at Hamburg the Lutheran ruff, and with a triple chin and a formal countenance, I dealt about me the word of God, so as to excite the envy of the clergy."

In the more regular and serious part of his life, he was member of the house of commons in two successive parliaments, and was rather an affidious attendant upon various literary societies. His expensive habits, and consequent necessities, obliged him again to quit his native country, and from this time he became a wanderer upon earth for long as he lived. As an author he published, in 1759, "Reflections on the Nile and Fall of the Ancient Republics," which work contains an elegant and concise summary of the histories of Greece, Rome, and Carthage, with allusions to the state of Great Britain. It acquired for the author a considerable degree of reputation for learning, ingenuity, and taste, but in a pamphlet published almost thirty years afterwards, under the title of "An authentic Detail of Particulars relating to the late Dukes of Kingdon," it is affirmed, without any hesitation, that Mr. Montagu had no share in the composition, but that it was wholly written by Mr. Welis, his private tutor, afterwards chaplain to the dukes. In 1763, Mr. Montagu communicated to the Royal Society, in two letters from Turin, "Observations on a sunpowered antique basil in the King of Sardinia's Collection." In the Transactions of the Royal Society of London, for the year 1765, there is a letter from Mr. Montagu, giving a curious account of his journey from Cairo to the mountains in the desert of Sinai; and in the following year he transmitted to the society some new observations on Pompey's pillar at Alexandria. These articles," says his biographer, "put out that among the Oriental countries which was the source of his most distinguished singularities." As a professor of religious opinions and doctrines he quitted the Protestant church, in which he had been educated, for that of Rome, which he afterwards abandoned to become a follower of the Arabian prophet. He is said, by Mr. Sharp, in his "Letters from Italy."
Italy," to have appeared with a very long beard and an Armenian head-dress. "His bed was the ground, his food rice, his beverage water, his luxury a pipe and coffee." A more particular account has been given of his mode of living at Venice, by count de Lamberg, in the "Memorial d'un Mondon." "He riles," says the count, "before the sun, says his prayers, and performs his ablutions and bedwiiz according to the Mahometan ritual. An hour after he wakes his pupil, a filthy emigrant of Abyfliana, whom he brought with him from Rosetta. He instructs his dirty negro with all the care and precision of a philosopher, both by precepts and example: he lays before him the strongest proofs of the religion he teaches him, and catechizes him in the Arabian language. That he may not omit any particular, in the most rigorous observance of the Mahometan rites, Mr. M. dines at a low table, sitting cross-legged on a fopha, while a Moor, on a cushion still lower, is gaping with avidity for his master's leavings. It is this negro who supports the white mantie that makes a part of the Turkish garb of his master, who is always preceded, even at moon-day, by two gondoliers, with lighted torches in their hands. The usual place of his residence is Rosetta, where he lives, his wife lives, who is the daughter of an inn-keeper at Leghorn, and whom he has forced to embrace the Mahometan religion. During the most intense cold he performs his religious ablutions in cold water, rubbing at the same time his body with sand from the thighs to the feet: his negro also pours fresh water on his head, and combs his beard, and he also pours cold water on the head of the negro. To smite the religious ceremony, he returns his pipe, turns himself to the wall, masters some prayers, walks afterwards for half an hour, and drinks coffee." With respect to his wife, it may be observed that he married very early in life, a woman of mean birth and in almost the lowest ranks of society, with whom he never cohabited, but to whom he allowed a separate maintenance. "He afterwards assumed all the Mahometan licence with respect to the lex, and in several countries of his residence had a harem of women of various nations and complexes." Dr. Moore, who saw a good deal of Mr. Montague on the continent, describes him, in his "View of Society, &c. in Italy," as extremely acute, communicative, and entertaining, and blending in his discourse and manner the vivacity of a Frenchman with the gravity of a Ciceronian. Mr. Montague displayed his singularity of conduct to the laft. Upon the death of his lawful wife, being devious of leaving an heir to his estate, which he was aware would otherwise fall to the Bute family, whom he disliked, he conunitted a friend in England to advertise for a descrete young woman already pregnant, who would be willing to marry him. One of the many applicants was fixed on, and he was on the point of returning to England, to form the alliance, when he was seized with an illness which terminated his life in the year 1776. Gent. Mag. Gen. Bic.

MONTAGUE, Richard, a learned prelate, was born about the year 1577, and having received the elements of good classical education he was sent to pursue his matuer studies at King's college, Cambridge, of which he became a fellow. He very soon obtained preference in the church, for the duties of which he had been expressly educated. In 1616, he was appointed dean of Hereford, and in 1621 he published a learned answer to Selden's "History of Tythes." He was afterwards engaged in a controversy with the Pains, and wrote a work "Appello Cæfarëm," by which he gave offence to the government, and was ordered to appear at the bar of the house of commons in the first parliament of Charles I., on a charge of maintaining Armenian and Popilish errors. He was afterwards made bishop of Chichester in 1628, from whence he was translated to Norwich in 1638. This see he held about three years, when he died. His chief work was an "Ecclesiastical History," in Latin, in which his learning and talents are said to appear to great advantage. Biog. Brit.

MONTAGUE, Edward, earl of Sandwich, a celebrated English admiral, the only surviving son of Sir Sidney Montague, was born in July, 1625. He married, before he was eighteen years old, the daughter of Mr. (afterwards lord) Crewe, and being thought warmly in the interest of the parliament, he received a commission, in 1643, to raise and command a regiment. This colonel Montague performed, and even took the field, in six weeks. He was present at the storming of Lincoln in May, 1644, which was one of the hottest actions in the course of the whole war. He was, likewise, in the battle of Marston-moor, where he so highly distinguished himself, that on the capitulation of the city of York, he was appointed one of the commissiours for settling the articles, though then only in his nineteenth year. He took an active part in the battle of Nafely, and also at the storming of Bristol, in the months of July and September, 1645. After this he entered into the fore-runner, and was engaged, in 1656, with admiral Blake in the Mediterranean, and for his succés at that time he was exceedingly censured by the protector, and received the thanks of parliament. On the death of Cromwell, he, like many others who had been zealous in the protector's service, was ready to sacrifice his principles to join the royal party, which was supposèd to be the stronger. He was, indeed, in the councils of Charles while he held a commission under the authority of parliament. His conduct became suspected, and he was ordered to attend at the bar of the house to answer for himself. After an examination he was dismissed from his command, which he probably took as a very lenient punishment, knowing, as he must, that he had been guilty of high treason against the exiling government. "After such an escape," says Campbell, "he withdrew to his estate in the country, with a design to enjoy, in privacy and peace, the remainder of his life;" his real motives were probably to watch the opportunity of enlisting again under the banners of the king, or the commonwealth, according as the one or other obtained the upper hand. He was quickly enabled to leave his retirement, and had the honour, as he then thought it, of conveying his majesty to England, who within two days of his landing lent him the riband and George of the most noble order of the Garter, which were presented to him in his ship, then riding in the Downs. In July, 1663, Charles, grateful for his assistance, created him baron Montague, vicount Hinchinbrooke, and earl of Sandwich, in Kent; he was at the same time sworn of his majesty's most honourable privy-council, made master of the king's wardrobe, admiral of the narrow seas, and lieutenant-admiral to the duke of York, as lord high-admiral of England.

Lord Sandwich has been accused of being an adviser of the measure for giving up Dunkirk, and notwithstanding what Campbell and others have said in his vindication, there seems little doubt that he was privy to the bargain, and offered reasons to bring over those who were against it.

He was in the great battle fought in June, 1665, in which the Dutch lost their admiral, Opdam, and had eighteen of their men of war taken, and fourteen destroyed: the honour of this victory was chiefly due to the earl of Sandwich. The last action in which he was engaged, was on the 28th of May, 1672, which is thus described by Campbell: "The earl of Sandwich, in his fine ship the Royal James, which carried one hundred pieces of cannon, and about 800 men, began the fight, and fell furiously on the squadron of Van D 2..."
Ghent: this he did, not from a principle of distinguishing himself by an act of heroic valour, for he knew that his character was too well established to need that: his view was to give the rest of the fleet time to form, and in this he carried his point. Captain Brakel, in the Great Holland, a fifty-gun ship, depending on the assistance of his squadron, attacked the Royal James, but was soon disabled, as were several other men of war; and three fine ships were sunk. By this time most of the admiral's men were killed, and the hulk of the Royal James was so pierced with shot, that it was impossible to carry her off. In this diftrese he might have been relieved by his vice-admiral, sir Joseph Jordan, if that gentleman had not been more folicitous about affilting the duke: when, therefore, he faw him fail by, he declared of the condition in which he lay, he said to those that were about him, "There is nothing left now but to defend the ship to the last man;" and those who knew him readily understood, that, by the last man, he meant himself. When a fourth fire-ship had grappled him, he begged his captain, sir Richard Haddock, and all his fervants, to get into the boat and fave themselves, which they did; yet some of the failors would not quit the admiral, but ftiad and endeavoured to put out the fire, which in fpite of all their efforts they could not do, and fo they perifhed together." Other writers, following the Dutch account, fay, that when he faw his fhip on fire, he jumped out into the sea and was drowned. This noble lord, it has been reported, occupied his leisure moments in engraving. His Letters and Negotiations have been printed in two volumes. He translated from the Spanish a work on "The Art of Metals." His lordship's body was found nearly a fortnight afterwards, and being brought home the highest funerals were paid to it. He is described by the Dutch biographer, Gerard Brandt, as a man equally brave, knowing, and of a most engaging behaviour, one who had rendered his sovereign the greatest services, not only in the field, but in the cabinet, and as an ambassador in foreign courts. His own countryman, bishop Parker, says "he was capable of any business, full of widom, a great commander at sea and land, and also learned and eloquent; affable, liberal, and magnificent." Notwithstanding these encomiums, and we might transfer to many others, equally strong and honourable to the character and talents of the earl of Sandwich, still it cannot be denied that he possessed a large portion of worldly widom, by means of which he attained to the most distinguishing honours, while others, who had acted in the fame caufe, but who were fteady to their principles, were doomed to the severest sufferings, to the penalties of confiscation of property, and of death. Campbell's Lives of the Admirals. Walpole's Noble and Royal Authors.

Montague, Charles, earl of Halifax, an eminent statesman, and illuftrious as a patron of letters, was the fourth son of George Montague, a younger son of the earl of Mancheftcr. He was born in 1661, at Horton, in Northamptonshire, and having laid in a flock of grammatical knowledge in the country, he was at the age of fourteen sent to Westminster school, then under the care of Dr. Bulby. He remained in that femyuary till he had attained the age of manhood, when he was admitted of Trinity college, Cambridge. Here, besides purfuing the studies of the place, he cultivated a talent for poetry, of which he gave specimens in an ode on the marriage of the princes Anne to prince George of Denmark, and a copy of verses on the death of Charles II. The latter piece attracted the notice of the earl of Dorset, who introduced the author to the royalty of the day. He took a part in the parody of Dryden's Hind and Panther, entitled "The Country and City Muse," which proved his zeal for the liberties of his country, and which he farther manifested by signing the invitation to the prince of Orange. He was elected a member of the convention which declared the throne vacant on the abdication of king James; and by the recommendation of the earl of Dorset, a pension of 500l. was settled on him by the king, till some promotion should offer. In the house of commons he distinguished himself on many important occations, particularly in promoting a bill which allowed counsel to perfons accused of high treafon. In pleading the caufe of humanity, he felt embarrafsed, and for a fhort interval was unable to proceed in the argument, upon which he exclaimed "If I, Mr. Speaker, who stand here, a member of this house, innocent and unaccufed, am fo awed by the view of a wife and illuftrious assembly, as to lofe the powers of utterance, what must be the condition of a man obliged to plead in a public court for his life.'" He was introduced to feveral places of great honour and trule, as a commiffioner of the treasury, a member of the privy-council, and chancellor of the exchequer. In 1695, he undertook the arduous task of receiving all the silver-money of the kingdom, which had become, at that time, more than ever neceffary; this scheme he completed in the course of two years. He also procured the establishment of a general fund, which was the parent of the finking fund. For thefe, and for other services, he had a grant of lands in Ireland. In 1698, he was made firft commiffioner of the treasury, and during his majefly's abfence abroad he was appointed one of the lord juifices. In 1700, he was called to the house of peers by the title of baron Halifax. Scarcely had he taken his feat in this afsemblcy before he was impeached, by the lower house, of high crimes and misdemeanours. The articles againft him referred to the grants which he had obtained from the crown, and to his polifling at the fame time offices that were inconsistent with each other, as commiffioner and chancellor of the treasury, and auditor of the exchequer. The charges, being heard, were difmissed by the house of lords, and he continued in the king's favour till the death of that sovereign. He was again attacked upon fimilar grounds after the afeeencion of queen Anne, and though ftruck out of the lif of privy-counfellers, he was protected by the lords. He took a very active part in all the political questions that were agitated at this period, and, in 1706, was appointed one of the commiffioners to negotiate the union with Scotland. When the act passed for the naturalization of the Hanover family, and the fecurity of the Protestant feceffion to the crown, he was appointed to carry it over to the electoral court. He vigorously maintained the struggle of the Whig party to retain a share of power, and after their entire defeat, he was the ferviceous oppofite of the treaty of Utrecht; and a fecdualf supporter of the honour and interefl of the duke of Marlborough. In 1714, he exerted all his powers to ward off the danger that feemed to threaten the Hanover feceffion, and by his contrivance procured a writ for calling the electoral prince to the houfe of peers. On this account he was, after the afeeencion of George I., rewarded by an advancement to the earldom of Halifax, with the order of the Garter. His prospects now were extensive and flattering, but death stopped his career, in May, 1715, at the age of 54. The patronage which lord Halifax afforded to polite literature was reaped by the eulogies of many of the moft eminent writers of the time, among whom were Addison, Congreve, Steele, and Tickell. Of Addison he was the particular friend and patron. Steele dedicated the fourth volume of the Tatler to his lordship, and mentions him as having "given a new era to wit and learning; by his
patronage to have produced those arts which before flunmed
the commerce of the world, into the service of life, and to
have been the cause that the man of wit has turned himself
to be a man of business." Biog. Brit. Johnson's Lives of the
Poets.

MONTAGUE, ELIZABETH, the daughter of Matthew Ro-
binson, esq. of Horton in Kent, was educated under the
direction of the celebrated Dr. Conyers Middleton. In
1742 she married Edward Montague, son of Charles, fifth
son of Edward, the first earl of Sandwich. By his wife she had
a son, who died when he was about two years old. She
became a widow in early life, and was left with an ample for-
tune and honourable connections. In 1769 she published
"An Essay on the Writings and Genius of Shakspere," which
obtained for the author a considerable degree of re-
putation. She formed a literary society, which, for some
years, was the topic of much conversation, under the name
of the "Blue Stocking Club." We have heard many ac-
counts of the origin of the title, but believe it arose from
the circumstance of a perfon excusing himself from going to
one of its very early meetings, on account of his being in a
deahbille, to which it was replied, "No particular regard to
dress is necessary in an assembly devoted to the cultivation of
the mind; so little attention, indeed, is paid to the dress of
the parties, that a gentleman would not be thought very outre who
should appear in blue stockings." This lady was,
for many years, noticed for the benevolent peculiness of
giving an annual dinner on May-day to all the little climbing boys, apprentices to the chimney-sweepers of the metropo-
lis. Perhaps in attention to these, too frequently difflcated children, led to those humane regulations, which, through
the exertions of Mr. Jonas Hanway, were determined on by
parliament. Lord Lyttelton was a warm admirer of Mrs.
Montague, and was afflled by her in the composition of his
and Private Communication.

MONTAGUE, in Geography, a townshifp of Hampshirle
county, Massachusetts, on the E. bank of Connecticut
river; about 18 miles N. of Northampton, incorporated in
1753, and containing 1222 inhabitants. —Also, the
northernmost township in New Jersey, situated in Sussex
county, on the E. side of the Delaware; 17 miles N.
of Newtown. —Also, the largest of the small islands in Prince
William's Sound, on the N.W. coast of North America,
about 50 miles long and 10 broad. N. lat. 50° to 60° 30'.'
W. long. 147° to 148°. —Also, a township in Upper Canada,
partly in the county of Greenville, and partly in Leeds,
washed by the river Radeau. —Also, a small island in the
Florida stream. N. lat. 24° 43'.' W. long. 81° 43'.' —Also,
one of the New Hebrides, in the South Pacific ocean. S.
lat. 17° 26'. E. long. 168° 15'.

MONTA_INA, a small island on the E. side of the gulf
of Bothnia. N. lat. 65° 39'. E. long. 24° 44'.

MONTAIGNE, a township of France, and principal place
of a district, in the department of the Vendee; 16 miles S.S.E. of Nantes. The place contains 1011, and the can-
ton 10,696 inhabitants, on a territory of 265 square
kilometres, in 10 communes. N. lat. 47°. W. long. 1° 14'.

MONTAIGU, or SHERPENHEUvel, a township of France,
in the department of the Dyke, raised from a hamlet to a
place of importance by the multitude of people who an-
nually resort hither to pay their respect to a miraculous
image of the Virgin, placed in a chapel, richly adorned.
Johannes Lutius has published an account of the miracles
performed by this image; three miles W. of Dritt.

MONTAIGUT, a town of France, in the department
of the Puy-de-Dome, and chief place of a canton, in the
district of Riom; 21 miles N.N.W. of Riom. The place
contains 1400, and the canton 6875 inhabitants, on a territo-
y of 197 square kilometres, in 10 communes. N. lat. 46° 12',
E. long. 2° 53'. —Also, a town of France, in the depart-
ment of the Lot and Garonne, and chief place of a canton,
in the district of Agen; 18 miles N.E. of Agen. The place
contains 4182, and the canton 8513 inhabitants, on a
territory of 165 square kilometres, in eight communes. N. lat.
44° 30', E. long. 1° 07'.

MONTALEGRE, a town of Portugal, in the province
of Tras-os-Montes; 22 miles N.E. of Braga. N. lat.
41° 45'. W. long. 7° 38'.

MONTALTA, a town in Spain, in the province of
Catalonia; seven miles E.N.E. of Urgel.

MONTALTO, a town of the marquisate of Ancona,
the fee of a bishop, suffragan of Fermo; 12 miles S.W.
of Fermo. N. lat. 42° 56'. E. long. 13° 38'. —Also, a town
in the duchy of Caltro, on the Fiora; 43 miles N.W.
of Rome. N. lat. 43° 21'. E. long. 11° 33'.

MONTALVAN, or MONTALBAO, a town in Spain,
in the province of Aragon; 30 miles S.E. of Daroca. —
Also, a town in Spain, in the province of Cordova; five
miles N.W. of Montilla.

MONTALVAO, a town of Portugal, in Alentejo, on
the borders of Spain, near a small river, which pilies not
far from it into the Tagus; 96 miles N.E. of Lisbon. N.
lat. 39° 30'. W. long. 7° 12'.

MONTALYA, a town of Portugal, in Esfarandura;
28 miles N.W. of Beja.

MONTAMEUF, a town of France, in the de-
partment of the Charente, and chief place of a canton,
in the district of Confolens; seven miles N.E. of La Roche-
couft. The place contains 947, and the canton 10,548
inhabitants, on a territory of 185 square kilometres, in six
communes.

MONTANARI, in Biography, a great performer on
the violin at Rome in the middle of the last century; when
a favourite pupil of Tartini, Paqualina Bini, arriving in
that city very young, practised with such affability, that in
three or four years time he vanquished the most difficult of
his master Tartini's compositions, and played them with
greater force than the author himself. All the professors
at Rome were so astonished by his performance, particu-
larly Montanari, at that time the principal performer on
the violin in the capital of the world, that he is supposed
to have died of grief and mortification at being so much ex-
celled in talents by the young Bini.

MONTANARI, Geminiano, a celebrated Italian natural
philosopher and mathematician, was born at Modera in
the year 1643. He lost his father while he was very young,
but his mother, well aware of the great importance of a
good education, had him carefully instructed in the clas-
sic-rhetoric, and philosophy, in his native city, and afterwards
sent him to Florence, where he studied with much success
in civil and ecclesiastical jurisprudence. Having completed
his studies, he settled in the profession of the law at Vienna,
and was previously to this admitted to the degree of doctor
at Salzburg. At Vienna he formed an acquaintance with
Paul de Buono, a considerable mathematician, which proved
the means of diverting his attention from legal pursuits, and
of reviving in him a strong inclination for the study of ma-
thematics and natural philosophy. Till now he had been a
disciple of the philosophy of Des Cartes, but by con-
versing with Buono, he adopted the theory of Galileo.
In 1657 he accompanied his friend in visiting the mines in Stizia,
Bohemia, and Hungary, and attended diligently to those
scientific pursuits connected with mineralogy. At length,
their proceedings awakened the jealousy of the Hungarians, and they were obliged to take refuge in one of the royal palaces, which affected Buono so tenderly that he fell sick and died. Upon this event Montanari came back to Vienna, which he very soon after quitted, and returned to Italy. His necessities now obliged him to practice at the bar of Florence, in order to furnish himself with the means of subsistence; still, however, his philosophical studies occupied the greatest share of his attention. After this he was patronized by duke Alphonso IV. of Modena, and by the marquis Malvina of Bologna, by whose recommendation he was elected professor of mathematics at the university of Bologna. During 14 years he discharged the duties of his office with unwearied diligence, made a vast number of observations on the celestial bodies, and performed experiments on the nature of different bodies. When the salaries of the professors were reduced, Montanari determined to obtain a settlement elsewhere, and was elected professor of astronomy at Padua. Here he continued to prosecute his observations and experiments, and published various useful and curious works. The Senate, likewise, frequently availed themselves of his advice in matters relating to hydraulics, fortification, the art of war, and the management of the mint. He died at Padua in 1587, in the 55th year of his age. He was author of a number of works, of which the titles, in a very long list, is given in the "General Biography:" and to him is attributed the discovery of the method of determining the heights of mountains by means of the barometer, to which he was accidentally led in the course of his travels.

MONTANARO, in Geography, a town of the dechy of Piacenza; seven miles S.S.E. of Piacenza.

MONTARCHES, a town of Spain, in Etramadura; 17 miles N. of Merida.

MONTANER, a town of France, in the department of the Lower Pyrenees, and chief place of a canton, in the district of Béarn. The place contains 918, and the canton 8549 inhabitants, on a territory of 116 kilometres, in 10 communes.

MONTANERA, a town of Italy, in the department of the Mincio; five miles S. of Mantua.

MONTANINI, in Biography. See PERUGINO.

MONTANISTS, in Ecclesiastical History, ancient heretics so called from their leader Montanus, who acted the prophet, and had his prophetesses.

Montanus was an obscure man, without any capacity or strength of judgment, who lived in a Phrygian village, called Poepuzio, towards the close of the second century. It is generally supposed, that he was born at Ardaia in Mydia, which is either a part of Phrygia, or lay contiguous to it; it is said, that he was but a new convert to Christianity, when he had the vanity to assume the character of a prophet. The rise of Montanism is generally placed by learned moderns about the year 151, agreeably to Eusebius in his "Chronicle," who refers it to the 11th year of Marcus Antoninus. Some, however, as Parchon and Beaulobre, are of opinion, that it appeared in the year 156 or 157, and Barretier refers it to the year 126. Euphianus, whose chronology is not always accurate, intimates, that Montanus set up his pretensions in the 19th year of Antoninus Pius, or about the year of Christ 156. But the most probable account is that of Eusebius. Although Irenaus has not expressly mentioned the Montanists, he is supposed to refer to them. They were twice mentioned by Clement of Alexandria; and they were for some time coun-temned by a bishop of Rome. They inhabited a good while; for the Cata-phrygians are expressly mentioned in Conflantius's edicts against heretics. Epiphanius says, they were then in Cappadocia, Gallatia, and Phrygia, and numerous in Cilicia, and at Constantinople. Auguline, Sozomen, and Theodoret speak of them as fabricating in their times.

Montanus, no less weak than arrogant, gave out, that he was the paraclete, or comforter, which the divine Saviour at his departure from the earth promised to send to his disciples to lead them to all truth. Some have affected that Montanus pretended to be the Holy Ghost. But others have observed, with greater reason, that he made a distinction between the paraclete, promised by Christ to his apostles, and the holy spirit: understanding by the former a divine teacher, who was to perfect the gospel by the addition of some doctrines omitted by our Saviour, and to cast a full light on others which were expressed in an obscure and imperfect manner: according to he pretended to be this divine teacher. Under this character, he added to the laws of the gospel many aulterite decisions; inculcated the necessity of multiplying fasts; prohibited second marriages as unlawful; maintained that the church should refuse absolution to those, who, after baptism, had fallen into the commission of enormous sins, and that such persons should not be admitted to full communion, though they repeated; and condemned all care of the body, especially all nicety in dress, and all female ornaments. He threw the same averton to the noblest employments of the mind, that he did to the innocent enjoyments of life; and gave it, as his opinion, that philosophy, arts, and whatever favour of polite literature, should be mercilessly banished from the Christian church. He looked upon those Christianians as expulsive of a most heinous transgression, who saved their lives by flight from the perpetuating sword, or who reformed them by money from the hands of their cruel and mercenary judges. He added many other precepts equal to these in severity and rigour: and, in many-predictions concerning the disasters that were to happen in the empire, and the approaching destruction of the Roman republic, which rendered him obnoxious to the governing powers. Montanus was, therefore, first by a decree of certain assemblies, and afterwards by the unanimous voice of the whole church, solemnly separated from the body of the faithful. However, he had many patrons and adherents, the principal of whom was Tertullian, and his cause spread abroad through Asia, Africa, and a part of Europe. Eusebius speaks of Aleibiades and Theodoutus as joined with Montanus from the beginning. But the persons most frequently mentioned as his affilants and prophetesses are two women, named Prisca, or Priscilla, and Maximilla. Besides these, there were other women, who were supposed to possess the gift of prophecy. Some of the prophetesses of these persons were preferred in writing. Nevertheless, it is observed by several ancient writers, that the people made no boast of any prophecies among them after Montanus and his two women: Maximilla expressly declared that there would be none after her. Although the followers of Montanus held him to be an inspired person, they did not think that his inspiration was equal to that of the apostles, as it did not relate to the great articles of faith, but chiefly to matters of external order and discipline. When they delivered their pretended prophecies, they seemed to be for some time deprived of their reason. As for the resurrection of the body and other great articles of the Christian religion, no doubt seems to have been entertained with regard to their belief of them. Some of them, however, have been charged with not holding the right doctrine concerning the Trinity; and it is probable, says Lardner, that these were in the Sabellian
Sabellian or Unitarian scheme. Tertullian evidently intimates, that they were Millenarians. Several writers of the fourth and fifth centuries inform us, that they had certain mysteries among them, in which they practised both cruelty and infanticides; and two writers, one Tertullian and Cyril of Jerusalem, charge them with magic, killing of infants, lewdness, and idolatry. But reports of this kind have been deemed fictions and calumnies. Eusebius and his authors do not warrant this account of them; and if it had been true, Tertullian would certainly have had no concern with them. We have no reason for doubting, that they received all the scriptures of the Old and New Testament in common with other Christians, and with like respect; and it appears that they had their separate assemblies, in which every part of Christian worship was performed. Mos. Eccl. Hist. vol. i. Lardner's Works, vol. ix.

The Montans are the same with what were otherwise denominated Phrygians, Cataphrygians, and Quintiliani, which see.

MONTANUM VERD. See Verd.

MONTARAN ISLANDS, in Geography, a cluster of small islands in the East Indian sea. S. lat. 2° 25'. E. long. 98° 48'.

MONTARGIL, a town of Portugal, in Estremadura; 28 miles S.E. of Santarem.

MONTARGIS, a town of France, and principal place of a district, in the department of the Loiret. The place contains 6,934, and the canton 15,135 inhabitants, on a territory of 225 square kilometres, in 15 communes. N. lat. 47° 59'. E. long. 2° 48'.

MONTASORO, a town of Naples, in Principato Cita; nine miles N. of Salerno.

MONTASTRUC, a town of France, in the department of the Upper Garonne, and chief place of a canton, in the district of Toulouse; nine miles N.E. of Toulouse. The place contains 11,521, and the canton 64,546 inhabitants, on a territory of 1,524 square kilometres, in 14 communes. Alto, a town of France, in the department of the Gers; 10 miles N. of Auch.

MONTAUBAN, a town of France, in the department of the Ille et Vilaine, and chief place of a canton, in the district of Montfort; five miles N.W. of Montfort. The place contains 27,555, and the canton 81,187 inhabitants, on a territory of 137,583 square kilometres, in eight communes. Alto, a town of France, and principal place of a district, in the department of the Lot, on the Tarn; before the revolution the fee of a bishop. Its principal trade consists in woollen stuffs. This town was built in the year 1144 by Alphonso, count of Toulouse. In 1562, the inhabitants became Protestants, who fortified it in such a manner, that Louis XIII. besieged it without success in the year 1621, nor was he able to reduce it till the year 1629, when its fortifications were demolished.

The place contains 21,859 inhabitants: the western part includes 12,851, and its canton 13,257, on a territory of 387 square kilometres, in three communes; and its eastern part contains 9,088 inhabitants, and its canton 10,438, on a territory of 821 square kilometres, in two communes. N. lat. 44° 39'. E. long. 1° 20'.—Alto, a town of France, in the department of the Drome; 16 miles E. of Nîmes.

MONTAUK POINT, the eastern extremity of Long Island, belonging to the state of New York. A tract called Turtle Hill has been ceded to the United States for the purpose of erecting a lighthouse upon it.

MONTAUSIER, Charles de Sainte Maure, in Geography, duke of, a peer of France, born in 1610, was educated a Protestant, but afterwards conformed to the established religion. He obtained some considerable posts under government. His high character for strict purity of morals, and unshaken loyalty, caused him to be chosen to preside over the education of the dauphin, son of Lewis XIV., and it was his perpetual care to inculcate on his pupil the principles of virtue, and to accustom him to the truth. He always kept from him all court flatterers, who were likely to corrupt his heart and injure his moral habits. He wrote a short history of his own life, and was on the point of taking his leave, he said to the prince, "Sir, if you are a man of worth, you will love me; if otherwise, you will hate me, and I shall confide myself." The duke was so infamous for avarice, morality, and sincerity in his conduct and actions, that Moliere's character of the "Misanthrope" was thought to be modelled after him. Some enemies of the poet infuriated this to the duke, and he went to see the poet. Moliere, leaving the theatre-exclaimed, "Would to God that I really resembled Moliere's Misanthrope!" He was accustomed to speak bold truths even to Lewis XIV. He died at the age of 80, in the year 1690, regretted by all men of real worth. Gen. Biog.

MONTAUTO, in Geography, a town of Naples, in Principato Uftra; five miles N. of Benevento.

MONTAWE, a town of Prussia, in Pomerelia; eight miles S.W. of Marienburg.

MONTABARD, a town of France, in the department of the Côte d'Or, and chief place of a canton, in the district of Semur; nine miles N. of Semur. The place contains 21,185, and the canton 10,875 inhabitants, on a territory of 287 square kilometres, in 26 communes. N. lat. 47° 36'. E. long. 4° 23'.

MONTABRE, a town of France, in the department of the Jura, and chief place of a canton, in the district of Dôle. The place contains 43,342, and the canton 67,279 inhabitants, on a territory of 187 square kilometres, in 14 communes.

MONTBAZAN, a town of France, in the department of the Indre and Loire, and chief place of a canton, in the district of Tours; seven miles S. of Tours. The place contains 950, and the canton 13,766 inhabitants, on a territory of 547 square kilometres, in 15 communes.

MONTBAZENS, a town of France, in the department of the Aveyron, and chief place of a canton, in the district of Villefranche. The place contains 1026, and the canton 9,175 inhabitants, on a territory of 195 square kilometres, in 13 communes.

MONTBELIARD, Philibert-Gueneau, in Biography, was born in 1720, at Semur, in Auxois. He spent the early part of his youth at Dijon, and afterwards came to Paris, where he made himself known as a man of science. He continued with reputation, the "Collection Académique," a periodical work, which gave a view of every thing interesting contained in the "Mémors" of the different learned societies in Europe. He was chosen by Buffon to be his associate in his great work on natural history, and the compilation of his ornithology was committed to him. He was described by the great French naturalist, "(Of all men, the person whose manner of seeing, judging, and writing was most conformable to his own," when the clasps of birds was finished, Montbeliard undertook that of insects, rel
tive to which he had already furnished several articles to the New Encyclopædia, but his progress was cut short by his death, which took place in 1735. 

MONTBELTRAN, in Geography, a town of France, in the department of the Upper Rhine, and chief place of a canton, in the district of Porentroy; 32 miles W. of Bâle. The place contains 3,593, and the canton 7,665 inhabitants, on a territory of 102½ square miles, in 20 communes. Before the revolution, it was the capital of a principality, which, though inhabited in France, was considered as belonging to Germany. Its situation is pleasant, at the foot of a hill, and it is watered by the river Halle, which runs into the Doubs. The adjacent soil is fertile, and the air is salubrious. The inhabitants have a considerable trade in linen, leather, flockings, and cutlery. In its vicinity are vineyards, and a productive iron mine. The principality was about 30 miles long, and 24 in its greatest breadth. The inhabitants were chiefly Protestants, confiding of Swiss, Germans and French. By the peace of Lunéville, the whole was ceded to France. 

N. lat. 47° 38'. E. long. 6° 44'.

MONT-BENOIT, a town of France, in the department of the Doubs, and chief place of a canton, in the district of Pontarlier; 7 miles N.N.E. of Pontarlier. The place contains 94, and the canton 7,039 inhabitants, on a territory of 183½ square miles, in 18 communes.

MONT-BLANC. See Blanc.

MONTBOZON, a town of France, in the department of the Upper Saône, and chief place of a canton, in the district of Véfoul; 10 miles S.E. of Véfoul. The place contains 592, and the canton 9,698 inhabitants, on a territory of 277½ square miles, in 38 communes.

MONTBRISON, a city of France, and capital of the department of the Loire, celebrated for its medicinal waters; 31 miles S.S.W. of Lyons. The place contains 4,703, and the canton 12,222 inhabitants, on a territory of 295 square miles, in 21 communes. N. lat. 45° 36'. E. long. 4° 9'.

MONTBRON, a town of France, in the department of the Charente, and chief place of a canton, in the district of Angoulême; 15 miles E. of Angoulême. The place contains 520, and the canton 11,612 inhabitants, on a territory of 32½ square miles, in 14 communes.

MONTBRUN, a town of France, in the department of the Drôme; 18 miles S.E. of Nions.—Alfo, a town of France, in the department of the Upper Garonno; 9 miles S. of Rieux.

MONT-BUET, a mountain of Switzerland, said to be 10,000 feet above the level of the sea.

MONT-CAVITA, a town of the island of Cuba; 20 miles E. of Villa del Principe.

MONT-CAYO, a branch of the Pyrenees, which extends to the province of Aragon, in Spain, and one of the highest in that kingdom: it is situated between Aragon, Catalonia, and Navarre. The Norms which collect on this mountain are said to be the terror of the adjacent country, to the extent of 20 miles.

MONTCHANIS, a town of France, in the department of the Sãone and Loire, and chief place of a canton, in the district of Autun; 10 miles S.S.E. of Autun. The place contains 1,069, and the canton 9,913 inhabitants, on a territory of 290 square miles, in 14 communes.

MONTCHIU, a river of Thibet, which runs into the Sânpoo, 13 miles W. of Kimbu.

MONT-DAPPHIN, a town of France, in the department of the Higher Alps, seated on a rock, and almost surrounded by the Ière: the residence of a governor and garnison; 3 miles N. of Embrun.

MONT-DE-MARSAN, a town of France, and principal place of a district, in the department of the Landes; 56 miles S. of Bordeaux. The place contains 2,666, and the canton 11,986 inhabitants, on a territory of 305 square miles, in 26 communes. N. lat. 43° 53'. E. long. 0° 26'.

MONTDIDIER, a town of France, and principal place of a district, in the department of the Somme; 18 miles S.E. of Amiens. The place contains 4,049, and the canton 13,923 inhabitants, on a territory of 224 square miles, in 33 communes. N. lat. 50° 5'. E. long. 2° 30'.

MONTDOUBLEAU, a town of France, in the department of the Loir and Cher, and chief place of a canton, in the district of Vendôme; 30 miles N.N.W. of Blois. The place contains 1,749, and the canton 9,793 inhabitants, on a territory of 247½ square miles, in 14 communes.

MONTÉ, Giambattista Da, in Biography, (or latinized Montanus,) a learned and distinguished physician of the 16th century, was descended from the noble family of Monte, in Tuscany, and born at Verona in the year 1508. His tutors in Greek and philosophy were Mufuro and Ponzazzotto, and on quitting their tuition, he was sent to Padua, with the view of studying jurisprudence, being intended by his father for the profession of the law. His talent, however, was not directed to this study, but led him to that of phyic, which he commenced, notwithstanding the displeasure of his father, who even withdrew from him the means of support, in consequence of his disobedience. Nevertheless he perjured himself in following the bent of his mind, and truited to his own abilities and industry for subsistence, while he visited several of the principal towns in Italy; especially Naples, Rome, and Venice, where he practised his profession, and distinguished himself by his classical skill. It is probable, indeed, that, in addition to his professional knowledge, his classical talents were put in employment for the means of subsistence; since Ghilini mentions that, at Naples, he explained the poems of Pindar. In the course of his residence at these places, he gained high reputation, and numerous illustrious friends, and at length acquired such ease of circum stance, that he retired to Padua, with the intention of enjoying repose, in 1559. But after residing there about four years, he was called upon to exert his talents as a teacher in that school, being first appointed professor of the practice of medicine, and subequently of the theory: he was also for some time professor of anatomy in the same university. As his reputation advanced, his emoluments were also augmented, and ultimately surpased those of any other Italian physician of his time. His disciples were exceedingly numerous, and many of them attained to great eminence. He had been professor eleven years, when his extensive reputation brought him very liberal offers from the emperor, Charles V., Francis I. of France, and the grand duke of Tuscany, and urgent solicitations to settle at their respective courts. But nothing could induce him to quit the chair, which he filled with so much benefit to his pupils, and satisfaction to himself. He was afflicted with calculous complaints, however, under which he at length suffered so severely, that he was compelled to retire to his estate at Terazzano, in the Venetian territory, where he died in May, 1571.

Montanus was held in high estimation by his contemporaries, and his name was deemed of great authority in the Italian schools for a long period. His works, however, which were exceedingly numerous, and mostly published by his disciples, were principally comments upon the ancients, and
illustrations of their theories; and have therefore ceased to be of importance, since the originals have lost their value. He translated into Latin the works of Aëtius, which he published at the desire of cardinal Ippeolito de Medici. He also cultivated poetry, and translated into Latin verse the poem of Meneus: he is said likewise to have made translations of the Argonauts attributed to Orpheus, and of Lucian's Tragopodagra. Eloy Dict. Hist, de la Med. Gen. Biog.

Monte, Guidobaldo, Marquis del, a Venetian nobleman, an able mathematician, who flourished in the 16th and 17th centuries, but of whom little is known, more than that he spent his whole life in retirement, devoted to abstruse and difficult mathematical studies. In 1600 he published his "Treatise on Perspective," and in 1608 an edition of his "Astronomical Problems" was published by his son, from which it appears that he was then dead. The treatise on perspective, already referred to, is the first in which that science was completely established upon mathematical principles. He also published "A Theory of the Planisphere;" and he drew up "A Reformed Calendar." He was author of commentaries upon the two treatises of Archimedes "On Centres of Gravity," and "On the Screw-pump for drawing Water." Gen. Biog.

Monte, II. in Geography, a town of the island of Corfica; 18 miles S. of Baffia.

Monte-Acuto, a town of Sardinia; 40 miles E.N.E. of Alghieri.—Alfo, a town in the district of Urbino; 15 miles N.W. of Urbino.

Monte-Agnone, a town of Naples, in Principato Cita; 9 miles N.E. of Sierno.

Monte-Albano, a town of Naples, in the province of Oranto; 6 miles W. of Otranto.—Alfo, a town of Naples, in Bigliatica; 4 miles N.E. of Puri.—Alfo, a town of Sicily, in the valley of Demona; 17 miles S.W. of Melazzo.

Monte-Alcino, a town of Etruria, anciently Monte Altino, the see of a bishop, suffragan of Sienna. The most excellent wine of Italy, called "Mailatello di Monte-Alcino," is procured in its vicinity; 15 miles S.S.E. of Sienna.

Monte-Almaya, a town of Etruria; 9 miles N. of Florence.

Monte-Alto, a town of the marquisate of Ancona, the see of a bishop, suffragan of Fermo; 10 miles N. of Ascoli.

Monte-Alverino, a mountain of Etruria, near the source of the Tiber, celebrated for a convent, which is a sanctuary; 14 miles from Florence.

Monte-Aperto, a town of Naples, in Principato Ultra; 9 miles S. of Benevento.

Monte-Baldo, a mountain of Italy, between the river Adige and lake Garda, separating the Venetia from the Trentin.

Monte-Barbaro, a mountain of Naples, on the sea-coast, near Pozzoli.

Monte Barone, a town of Naples, in Capitanata; 13 miles S.S.W. of Vieille.

Monte Beluto, a town of Naples, in Calabria Ultra; 10 miles S. of Reggio.—Alfo, a town of Naples, in Abruzzi Cita; 2 miles S.E. of Ranciano.—Alfo, a town of Naples, in Abruzzi Ultra; 15 miles E.N.E. of Aquila.—Alfo, a town of Italy, in the Vicentin; 13 miles S.W. of Vicenza.

Montebourg, a town of France, in the department of the Channel, and chief place of a canton, in the district of Valognes; 4 miles S.E. of Valognes. The place contains 3,351, and the canton 10,478 inhabitants, on a territory of 145 square kilometres, in 25 communes.

Monte-Brandone, a town of the marquisate of Ancona; 15 miles E.N.E. of Ascoli.

Monte-Braulio, a mountain of the Rhenish Alps, between the Grisons and the Tyrolese; 10 miles N. of Bornio.

Monte-Bruno, a town of the Ligurian republic; 15 miles N.E. of Genoa.

Montecalm, Louis Joseph de St. Veran, Marquis de, in Biography, a celebrated general, was born of a noble family at Candia, in 1712. He entered early into the army, and distinguished himself gallantly in many battles, particularly in that of Piacezza, in 1746. In 1756 he became a field-marshall, and was appointed to command the French army in Canada, where he opposed Lord Loudoun with skill and success. He afterwards defeated Abercrombie, his lordship's successor, but in the famous battle at Quebec, in 1759, he received a mortal wound, at the same time when the brilliant Wolfe was slain.

Monte-Calvo, in Geography, a town of the duchy of Urbino; 4 miles N. of Urbino.—Alfo, a town of Naples, in Principato Ultra; 10 miles E.N.E. of Benevento.

Monte-Campeolo, a town of Spain, in Galicia; 7 miles N. of Ferrol.

Monte-Carlo, a town of Etruria; 24 miles W.N.W. of Florence.

Monte-Carotto, a town of the marquisate of Ancona; 8 miles W. of Jefi.

Monte-Casino, a town of Naples, in the province of Caserta, situated on a mountain of the same name, with an abbey in which Benedict is said to have founded his order. This monastery became so famous, that monarchs resided in their crowns in order to end their days here; 13 miles S.S.E. of Sora.

Monte-Catino, a town of Etruria; four miles W.S.W. of Volterra.

Monte-Catinus, Anthony, in Biography, an Italian professor of philosophy, was born in the year 1550, at Ferrara, where he read public lectures, and in process of time was elected the first professor of philosophy. He obtained also the appointment of governor of the city of Reggio, the chief magistrate of Ferrara, and frequently was entrusted with the whole management of affairs under the duke. He died at Ferrara in 1599, at the age of 63. He is chiefly known as an author by his "Commentary on Aristotle's Politics," to which he added some of Plato's works.

Monte-Cecce, in Geography, a town of Naples, in the county of Molife; 20 miles N.N.E. of Molife.

Monte-Tech, a town of France, in the department of the Upper Garonne, and chief place of a canton, in the district of Calet Sarrazin; 7 miles E. of it. The place contains 2,019, and the canton 10,482 inhabitants, on a territory of 71,215 square kilometres, in 10 communes.

Montechal, Charles de, in Biography, a learned French prelate, who flourished in the 17th century, was educated at the college of Autun, at Paris, and rose from step to step to the post of principal of that institution. He also rose to the rank of archbishop of Toulouse, and obtained a high reputation for piety, as well as for his acquaintance with history, the civil and canon law, and the Greek and Hebrew languages. He died in 1651. His principal work was entitled "Memoirs of M. de Montechal, archbishop of Toulouse, containing particulars of the life and ministry of Cardinal Richelieu," in two volumes, 12mo. Montevideo.
a town of the duchy of Piacenza; 13 miles S.W. of Piacenza.

MONTECHIO, a town of Italy, in the department of the Mela, on the Oglio; 5 miles S.S.W. of Bres.

MONTECHIO Maggiore, a town of Italy, in the Vicentin; 11 miles S.W. of Vicenza.

MONTE-CHRISTI, a cape, bay, town, and river, on the N. side of the island of St. Domingo. The cape is a high hill, situated in lat. 15° 34' 50", and long. 74° 9' 30" W. of Paris. The bay is formed by Cape La Grange on one side, and Pointe des Dunes on the other, about 6,000 fathoms apart; this bay is about 1,000 fathoms deep, and its widening is nearly four leagues. The town stands at 800 fathoms from the sea-side, and rises in the form of an amphitheatre on the side of the coast. It was founded in 1513, abandoned in 1606, and is now become a poor place.

The town and its territory contain about 30,000 souls. The land round the town is sandy and barren; and the river contains a great number of crocodiles. To American smugglers this port is well known, and carries on a great commerce, on account of its vicinity to the French plantations.

—Also, a chain of mountains, extending parallel to the N. coast of the island of St. Domingo, from the bay of Monte-Christi to the bay of Samana on the E. Two rivers rise and flow in opposite directions, along the southern side of this chain. The river Monte-Christi or Yaqué runs in a W. by S. direction, and Yuna river in an E. by S. course to the bay of Samana. Both rise near La Vega, and have numerous branches.—Also, a town of South America, in the audience of Quito, and jurisdiction of Guayaquil, built at first near the Pacific ocean, and called "Manz." Its commerce was then considerable, by means of vessels passing from Panama to the ports of Peru; but being pillaged by foreign adventurers, who frequented these seas, the town was removed to the foot of a mountain, where it is now situated, and from which it has its name; 110 miles N.W. of Guayaquil.

MONTE-CIRCELLO; a mountainous cape of Italy, near the sea, called by the ancients an island, and rendered famous as the supposed habitation of Circe, the sorceress, who used to transform her lovers into brutes. On the promontory there was once a town called Circeum. On the ruins of the town was built a fortress, which served as a place of retreat, and safety for the popes in times of danger. Nothing now remains but a castle called "St. Felice," erected by pope Celestine II., in the 12th century. An ancient tomb is shown as the sepulchre of Elpenor, one of the companions of Ulysses, who, in a state of intoxication, fell from the top of a house into the street. N. lat. 41° 17'. E. long. 12° 57'.

MONTECCLIERE, Michel de, in Biography, a French musician, who published several useful elementary treatises on his art; but began his career as a serious opera composer in the year 1716, among those who tried their force with little success, after the decease of Lully.

MONTE-CORVINO, in Geography, a town of Naples, in Principato Citera, formerly the see of a bishop, but united to Vulturara in the year 1433; nine miles E. of Salerno.

MONTECUCCOLI, Count Sebastian, in Biography, an Italian gentleman, who was introduced at the French court, and became cup-bearer to the dauphin Francis, son of Francis I. He was accused of having poisoned the young prince of Valence, and being put to the torture, confessed that he was hired to do the deed by the partisans of Charles V. The friends of the emperor, however, full refuted the abominable charge, and threw it back upon Catherine de Medicis, wife of Henry II. brother to the dauphin. This circumstance occurred in 1536.

MONTECUCULI, Raymond de, prince of the holy Roman empire, and a celebrated general in the service of the house of Anjou, was born in 1608, at Montecuccoli, the seat of his family, in the Modene. Having received a liberal education, he took arms at an early age, under his uncle Ernol Montecuccoli, general of artillery in the imperial service. The wars in Flanders were his first scene of action, and in that school he acquired the skill and experience which raised him into notice. The first contest in which he distinguished himself was in the year 1644, when at the head of 2,000 men he surprised 10,000 Swedes, whom he compelled to abandon their baggage and artillery. He was himself afterwards defeated and made prisoner by the Swedish general Bannier, and was detained in captivity two years. This time, which to most young men would have been lost to themselves and the world, our youthful Roderick employed in literary and scientific pursuits. On returning to his profession, he defeated the Swedes, in Bohemia. After the peace of Wilmphalia, he travelled into different countries, and was sent once in a diplomatic character to Stockholm. He was very honourably received by queen Christina, who afterwards admitted him to her correspondence, and imparted to him her secret intention of abdicating the throne. In 1657 he was appointed field-marshall, and sent to the relief of John Calvin, king of Poland, who was attacked by the forces of Sweden, and the prince of Transylvania. After defeating the latter, he took Cracow from the Swedes, and gained several splendid actions, which produced a peace. He next served against the Turks, and drove them out of Transylvania, for which he was made president of the Imperial council. In 1673 he was sent against the French, to oppose the celebrated Turenne; these great masters in the art of war exhausted every stratagem in their science; but while the game was in a state of balance, it was brought to a conclusion by the death of Turenne, from a cannon-ball, as he was reconnoitring with a design to attack. He afterwards acted with great courage and skill against the prince of Conde. After this he refused to contend with generals of inferior reputation. He died in 1681. He was attached to literature, and left behind him a work entitled "Memorie delle Arti della Guerra."

MONTE-DE-BUCHAR, in Geography, a cape on the W. coast of North America. N. lat. 35° 19'. E. long. 239° 29'.

MONTE-DELL-CASALE, a town of Naples, in Ba[ilicata; 12 miles N.W. of Turi.

MONTE-FAGARIA, a mountain of Sicily, in the valley of Noto; seven miles W.N.W. of Calabro Giovanni.

MONTE-FALCO, a town of the duchy of Spoleto, on a mountain near the Clitummo; 12 miles W.N.W. of Spoleto.

MONTE-FALCONE, a town of Naples, in the county of Molfi; 18 miles N.E. of Molfi.—Also, a town of Itaria; 16 miles W. of Treville.

MONTE-EGATESE, a town of the republic of Luca; 12 miles N. of Luca.

MONTE-ELICICE, a town of the duchy of Urbino; 12 miles N.W. of Urbino. N. lat. 43° 56'. E. long. 22° 16'.

MONTE-FIASCONO, a town of Italy, the see of a bishop, formerly belonging to the patronage of the pope; and supposed by some to be the ancient "Falerum," or "Falerii,"
MONTE-IGNOSO, a town of the republic of Lucca; 20 miles W. of Lucca.

MONTEJICAR, a town of Spain, in the province of Granada; 13 miles N.W. of Guadix.

MONTEJO, a town of France, in the department of Marenco; 12 miles E.S.E. of Chavasso.

MONTEITH, a district of Scotland, in the S. part of the county of Perth.

MONTELIEU, a port of Burgundy wine.

MONTEILMART, in Geography, a town of France, and the principal place of a district, in the department of the Drôme, situated on the Robion; in which are some manufactures of wool, silk, and leather. The place contains 6320, and the canton 10,598 inhabitants, on a territory of 2125 kilometres, in 11 communes. The people of this town, it is said, were the first in France who embraced the doctrines of the reformation. N. lat. 44° 33'. E long. 4° 49'.

MONTELLA, a town of Naples, in Principato Citra; 12 miles W. of Conza.

Monella, or Montilla, a light, white Spanish wine from Andalusia.

MONTEMOR o Novo, in Geography, a town of Portugal, in the province of Alentejo, on the Cama; containing four parishes, and above 4000 inhabitants; 50 miles E. of Líbion. N. lat. 38° 36'. W. long. 8°.

MONTEMOR o Velho, a town of Portugal, in the province of Beira, on the Mondego, containing six parish churches, a convent, several hospitals, and above 1900 inhabitants; the residence of a military commander, with 24 companies of regular troops, quartered in the town and vicinity; 90 miles N. of Líbion. N. lat. 40° 7'. W. long. 8° 33'.

MONTENDRE, a town of France, in the department of the Lower Charante, and chief place of a canton, in the district of Jonzac; seven miles W. of Montluçon. The place contains 852, and the canton 7471 inhabitants, on a territory of 285 kilometres, in 19 communes.

MONTENERO, a town of France, in the department of the Stura; five miles N.N.E. of Coni.

MONTENSES. See AGONISTIC, CAMPIST, and DONATISTS.

MONTE-NUOVO, the New Mountain, near Puzzolli, in the Neapolitan territory. It was raised in the night, in September 1538, by the agency of a subterranean volcano, which ejected such an immense quantity of earth, stones, and ashes, that in the course of 48 hours it attained the height of 2100 feet.

MONTEPULCIANO, a very fine red Tuscan wine from Stiano, in the district of Scarperia. It is exported in barrels.

MONTER, Fr., in Musæ, to rise, ascend in the scale by a series of notes from the grave to the acute.

MONTEBEAU-FAUT-YONNE, in Geography, a town of France, in the department of the Seine and Marne, and chief place of a canton, in the district of Fontainebleau, at the junction of the Seine and Yonne; 12 miles N.E. of Nemours. The place contains 3435, and the canton 8999 inhabitants, on a territory of 1075 kilometres, in 14 communes.

MONTEREY, a town of Spain, in Galicia; 18 miles S.E. of Orense.

MONTEREY, or MONTEREY, a Spanish settlement or presidio on the coast of California, founded, according to La Perouse, on the third of June 1770, which by exact Spanish observations in 1791, is in N. lat. 36° 35' 45" and long. 115° 47' 30" W. of Cadiz. We shall here observe, that with the Spaniards, "presidio" is a general name for all forts, both in Africa and America, placed in the middle of
of a country of indolents, and implying, that there are no
other inhabitants besides the garrison which refides within
the citadel. The principal Spanish garrison is that of Mon-
terey, and the lieutenant-governor, who refides at Mon-
terey, is governor of both the Californias. The soil of the
adjacent district is tolerably fertile and productive; for La
Perouse observed maize, barley, and peas; and by his
account, the climate is mild though foggy. But according
to the Spanish writers, whose account is more likely to be
just than that of Peroufe, who visited this coast at a particu-
lar season, the climate of California seems to be divided
between excessive cold and torrents of rain, while water-
spouts and hurricanes are not unfrequent, and thick fog
serve to diversify these vicissitudes. The soil seems also to
display a great variety of barrenness. The chief product
is derived from the fur of foxes and other animals. From
the account of the late California in 1794, given by
Elalla, we learn, that the missionaries have planted olives,
figs, pomegranates, vines, and peaches, all of which yield
an abundant produce. The most common plant is the "Me-
calce," which covers the mountains and valleys, and like
the "Maguey" of the south, supplies the savages with food,
drink, and clothing. Although the land be generally
barren, it is an abundant, and some of the shells are ex-
quisitely beautiful. From Monterey, and even from the
Red river, to Mendocino, the country is covered with
immense forests of pines and other trees. The Spaniards
have begun to carry on a fair-trade with China; in this respec-
to following the example of the Russians, who for this pur-
pose had availed themselves of their settlements on the north-
western coast of America, who fitted their settlements in Cal-
ifornia furnished them with an abundant supply of skins,
chiefly of the sea-otter, as it is called by the Spaniards,
the fur being black, and equal to the finest beaver. The
manner of catching the sea-otters is so peculiar to the
Indians, that the English, Dutch, and Spaniards, have not
been able to imitate their skill. In small canoes, constructed
of wood, or a kind of flag, and capable of holding only
one person, they venture out to sea; and provided with a
long rope furnished with two hooks, the boatman advances
towards the otter, the females being surrounded with their
young, whom they teach to swim. On the approach of the
canoes, the female plunges under water, and the Indian fixes
the hooks in the foot and leg of one of the young. He
then retires and gives out rope, which he occasionally pulls,
and then giving pain to the young animal, it roars so as to
bring the dam to its assistance, who, in endeavouring to ex-
tricate the young one, is often herself entangled by the hooks;
upon which the hunter arrives and kills her by a sharp blow
on the head.

The mining faction of St. Ann, near the mission of All-
Saints, at 24, the silver of which is remarkably pure, has
been abandoned on account of the cruelty of the savages,
who massacred the workmen. However, in some parts of
the country, the natives are more mild and docile than in
others. The women are enticed with the care of pro-
viding food, and other means of subsistence, while the men,
lke other savages in general, walk about like idle vagabonds;
and this hobnails is often very laborious. They are obliged
to submit to this fatiguing drudgery, as death might prob-
elly be the end of any objection or demur. Hence
it happens, that murders are very frequent among them,
and they are committed on the slightest occasions. Their
food is very simple, consisting of hawks, wild fritters, a kind
of rabbit, venison, with vipers, snakes, rats, lizards, and
the like. In fishing the Californians are very skilful; and
they are also very dextrous in the chase. The Californians
are easily infligted either to good or evil; they will often
learn the principles of the Christian faith in a fortight, and
as soon forget them; sometimes crowding to the missions,
and prefently abandoning them. They receive favours with
coolness, and treat their benefactors with neglect. Al-
though they appear bold, they are in reality cowardly, and
soon yield under the apprehension of danger or chastisement.
They have scarcely any government, or disposition to affil-
iate, or to fix in any place; they only unite in the dance,
the feast, and their petty wars. Their huts or hovels are
generally two or three together, about 14 yards square,
having roofs formed of branches, and covered with a little
earth, and very low, so that they are always full of smoke.
They indulge their appetites without restraint; and they are
all naked except the women, who wear a small mantle of the
fibres of a plant, and a skin of some animal over the bosom.
The latter is also worn by the chiefs. The head-dress of
the ladies is a little helmet of rushes, while the men wear
feathers. They nfe necklaces made of little shells, and some
of the men wear caps made of clay. Their complexion is
generally dark, though some of the women are tolerably
fair. They paint themselves with various colours; some
cut off a piece of the ear, some pierce the under lip, others
the noluids, and wear as ornaments maces, lizards, shells,
&c.; and it is evidently their design in painting, to render
themselves terrible to their enemies. The furniture of their
hovels consists in a little net to keep feeds, some wild tobacco,
with a pipe of clay, quiver for arrows. Two pieces of wood
to light a fire, in rubbing which against each other, so as to
produce it, they are very dextrous; a bow and arrows, a
card to kill rabbits, and some cords and hooks for fishing.
A person who polleth these articles is reckoned rich, but
there are many who have nothing. When they wish to
move, the man bears the bow and arrows, and the woman
all the rest. The missionaries have discovered one district
in which polygamy is not permitted, but regarded as unhappy,
and tending to a speedy death. But, in general, a man
may keep, under the title of cooks, as many women as he
can maintain. Although adultery be common, it is an ob-
ject of chastelement, and the husband may repudiate or kill
his wife. The mother will sometimes kill or Abound her
infant, without being subject to any account. Many of the
Indians seem to have no knowledge of religion or a first
con; they have neither temples, nor idols, nor altars, nor
do they worship the sun or moon. Some, however, have
confused notions both of a creator, and of a kind of pro-
vidence. They have a sort of magicians, called "Quamas,"
who supply the want of priests, and are regarded as oracles.
These magicians pretend to cure diseases by ridiculous cer-
emonies and gufferies, and they greatly impede the progres-
of Chirilitanity, because they jallily regard it as destructive
to their profession. These magicians distinguished themselves
at the festrivals, which are merely allegories of men and women
to gratify all their appetites. They have also wrestling
matches, in which the victor becomes the favourite of the
women, while the vanquished feel to mortified that they some-
times put themselves to death. The magicians display their
influence on occasion of funerals, in a variety of ridiculous
ceremonies. The natives of this country, whatever difference
there may be in the statements by various authors as to the
salubrity of the climate, are generally temperate, and enjoy
very good health; but the number of savages, particularly among
the Peruvians in the southern part of the peninsula, that have
fallen victims to the vpera, dfei, is very great, so that
this particular tribe is almost extinguished.

The bay of Monterey, formed by New-Year's day (An-
na no meso) point to the northward, and Cyprus or Fir

(Par6)
(Pinos) point to the southward, is eight leagues across; at its entrance in that direction, and nearly five in depth to the westward, where the lands are low and sandy. The sea rolls in to the very foot of the eminences of sand, with which the coast is skirted, with a noise which may be heard at about the distance of a league. The lands to the northward and southward of this bay are elevated and covered with trees. Ships intending to put in here must keep the S. shore aboad, and after doubling this point, which stretches out to the northward, they will see the "predica," and may drop anchor in ten fathoms water within, and behind this point, which sheltered them from the sea-breezes. The Spanish ships that lay for a long time at Monterey, approach within one or two lengths of a cable to the shore, in six fathoms water, where they moor to an anchor buried in the sand of the beach; they are thus sheltered from the S. winds, which are sometimes very strong, though not dangerous, as they blow off shore. At full and change of the moon it is high water at half past one, and the tide rises seven feet. The whales in this bay are very numerous, and, as Peroufe says, very familiar. They were continually blowing at the distance of half a pintol's shot, and occasioned a very disagreeable smell in the air.

The coasts of Monterey bay are covered by almost eternal fogs, which render it difficult of approach, though in other respects there scarcely exists a bay more easily entered. The sea is covered with pelicans, which never go above five or six leagues from land; and, therefore, navigators who perceive them during a fog, will be certain that they are within that distance. These birds are very common on the whole coast of California, and are called by the Spaniards "Alcatras." M. Momeron, who visited this harbour in December, 1736, observes that the land about it, though dry, seems adapted for advantageous cultivation. European grains grow here both fine and abundant, and the butchers' meat is of the best quality. It is therefore certain, he adds, considering the commodiousness of the harbour, that if this settlement should ever flourish, a better port for one or more vessels could not be found in any part of the world. For further particulars, we refer to the articles New Albion, and California.

MONTEROSO, a town of Sicily, in the valley of Noto; 29 miles N.N.W. of Noto. N. lat. 36° 48'. E. long. 14° 55'.

MONTESA, a small town and ruined castle of Spain, in Valencia; nine miles S.W. of St. Felipe. The town is built in the form of an amphitheatre, on a mountain which stands forward detached from the chain. This was the seat of the military order of that name. Most of the monks perished there by an earthquake, which happened on the 23rd of May, 1748; the rock on which the castle was built being split open, so that parts of it fell off. A great part of the castle still remains of a long rectangular form, the walls of which are flanked with towers and pierced with loop-holes.

MONTESA, Order of. See St. George of Alfaraz.

MONTEQUIEU, CHARLES DE SECONDAIT, Baron de, in Biography, an eminent magistrate and writer, descended from a distinguished family in Guienne, was born in 1689. At a very early period in life he manifested a propensity to deep and solid thinking, and in his twentieth year he began to make collections for his most celebrated work. He was appointed to the office of president a mortier in the parliament of Bourdeaux in 1716, and in 1722 he was deputed by that body to make remonstrances on account of a new impost, when he employed his eloquence with so much force as to obtain its suppression. He had already published his "Perianc Letters," which give a fictitious representation of the manners and sentiments of the country, under the assumed character of a foreigner. These letters serve as a vehicle of free sentiments concerning politics and religion, which the author was one of the first to render popular in France. They gave him a degree of literary reputation which induced him to become a candidate for a place in the French academy; but the liberties which he had taken with the church and state were represented in so fierce a light to the minifter, the cardinal Fleury, that he had reason to fear exclusion, through the interference of authority. He, however, surmounted this obstacle, and was admitted into the academy in the year 1728. He now resolved to devote his time and talents to the instruction of his fellow creatures as a writer: with this view he thought it was necessary to study national characters upon the spot, and accordingly set out on his travels. He visited Germany, Hungary, Italy, Switzerland, and Holland, and finished with a residence of nearly two years in England. Of this country, he said "it was the hell to think in," and here he was honoured with the regards and attention of queen Caroline, and of the most distinguished literary characters of the day. He paid a marked attention to the English constitution, of which, upon the most profound reflection, he thought most highly. On his return to his native country he put the last hand to his work, entitled "Sur la Caufe de la Grandeur et de la Decadence des Romains," which was published in the year 1734. This excellent performance is celebrated for the energy of its style, the force of its deprivations, and the depth of the author's remarks. His love of liberty is the animating spirit of the whole. In 1743 he published, in two volumes quarto, his "Efrps des Lois." On this he had spent very many years of his life; its principles are founded on the radical diversities of mankind, owing to climate and other causes, and it discusses at large the nature of different forms of government, from which laws emerge, and to which they ought to be adapted. Voltaire, in speaking of this work, which is far from faultless, says, "if it does not always instruct the reader, it never fails to make him think." And M. de la Harpe, in comparing Montefiquieu and Roufseau, says that the system of the latter was a work of more imagination; but the "Efrps des Lois" was produced by long labour and meditation, and it seems as if one should, like a novel, be read for amusement, and the other for information and improvement. Montefiquieu's lively and ingenious explications, in which is displayed the imagination of Montagne, have particularly contributed to the great reputation of the "Efrps des Lois." The same things said even by a more learned man would not have been read. Few works are to be met with in which there are more pronounced ideas, more bold thoughts, or more matter for instruction. It has a claim to be ranked among the original productions which adorned the age of Lewis XIV., and which has no model in antiquity. For several parts of his work the author drew upon himself certain confusions, and among his critics was M. Dupin, a farmer-general, who wrote an answer to it; but after a few copies of the critique had been distributed, Montefiquieu made his complaint to madame Pompadour, who sent for the writer, and told him she took the "Spirit of the Laws," and its author, under her protection: in consequence of this, Dupin was obliged to submit, and the whole edition of his answer was confounded to the flames. This was not to the credit of Montefiquieu, who should have learnt a different lesson from the country in which he had been excited to thought and reflection.

He died of a pulmonary complaint in February, 1795, in the sixty-fifth year of his age. His last hours were disturbed.
turbed by the Jésuits, who were anxious to get from him something like a retraction of his sentiments concerning religion. His private character is represented as having been highly amiable and estimable. Though habitually frugal, he was capable of great generosity, and an instance of his beneficence in giving his purse to a young boatman at Marseilles, and secretly confining a sum of money to a banker to redeem the youth’s father from slavery in Africa, has been the subject of a pathetic drama. In temper he was mild, cheerful, and equal, free from ambition, simple, and unaffected. After his death was published a collection of his works in three volumes quarto, in which were some pieces that had not before appeared. Of these the principal was “Le Temple de Guise,” a kind of profe poem. This was at first read with great avidity, but was soon considered as an effusion unworthy of the author. The president had a son, John Baptiftra Sefcordat, counsellor of the parliament of Bourdeaux, who died in that city in 1795, at the age of seventy-nine. He was author of many works; particularly of “Observations de Phyficque et d’Hiflorie Naturelle fur les Eaux Minerales de Pyrenees,” 1750; “Confidérations fur la Commerce et la Navigation de la Grande Bretagne,” 1740; “Confidérations fur la Marine Militaire de France,” 1756. He reided a considerable time in London, and was elected a member of the Royal Society.

MONTESQUIEU, in Geography, a town of France, in the department of the Upper Garonne, and chief place of a canton, in the district of Muret; four miles N.W. of Villefranche. The place contains 2802, and the canton 9401 inhabitants, on a territory of 227½ kilometres, in 15 communes.

MONTESQUIOU, a town of France, in the department of the Gers, and chief place of a canton, in the district of Mirande; four miles N.W. of Mirande. The place contains 1874, and the canton 9547 inhabitants, on a territory of 272½ kilometres, in 19 communes.

MONET, a town of France, in the department of the Allier, and chief place of a canton, in the district of Moulins; six miles N.W. of Montmerault. The place contains 450, and the canton 10,544 inhabitants, on a territory of 3275 kilometres, in 14 communes.

MONTEVERDE, Claudio, in Biography, a native of Cremona, was one of the most eminent composers of the period now under consideration. He first distinguished himself as a performer on the tenor viol; and being taken into the service of the duke of Mantua, applied himself to the study of composition under the direction of Marcantonio Ingegneri, of Cremona, maestro di capella of that court, and a considerable composer for the church. Soon after he went to Venice, where the republic appointed him maestro di St. Mark’s church, a place which has been always filled by professors of great abilities. Here, in 1652, he published madrigals for three, four, and five voices, in the style of the times; but his courage increasing with experience, in his subsequent productions he dared to violate many rules of counterpoint, which, having been long established, were held sacred by orthodox professors. He had, therefore, many opponents, who treated him as an ignorant corruptor of the art. Among these, the principal was Gio. Maria Artusi, of Bologna, who, in the first part of his tract “On the Imperfection of Modern Music,” published in 1660, as well as in the second, which appeared in 1663, inveighed with great alacrity against Monteverde. Musicians entered the lists on both sides, and the war became general. Monteverde defended himself in prefaces and letters prefixed to his works; but his best defence was the revolution he brought about in counterpoint; for his licenes, pleasing the public ear, were soon adopted not only by dilettante, but professors.

As the innovations of Monteverde form a memorable epoch in the history of the art, it seems necessary to acquaint the musical reader in what they consisted. The laws of harmony, like those of tragedy, comedy, and epic poetry, when once established, check invention, and frequently impede men of real genius to become imitators. Unluckily musicians had not such perfect models before them, as antiquity has furnish’d to poets in the dramatic works of Sophocles, Euripides, and Terence, or the epic poems of Homer and Virgil. In the infancy of musical composition, men few but a little way into the latent resources of harmonic combinations; rules were formed upon few and narrow principles, derived from monotonous and insipid compositions, where timidity was feeling its way in the dark, and every deviation from the practice of the first contrapuntists was thought licentious. However, men were too great friends to the pleasure of the ear, not to encourage such happy licences as those with which Monteverde was charged; and since that time, every fortunate breach of an old rule seems to be regarded as the embellishment of a new; by which means, the code is fo enlarged, that we may now almost pronounce everything to be allowable in a musical composition, that does not offend cultivated ears.

Monteverde was the first who used double discords, such as the 3, 5, and 7, as well as the flat fifth, and the seventh unprepared; and as he was pofticated of more genius and science than the prince of Venetia, his innovations were not merely praised, and then avoided, but abused, and adopted by other composes.

But it was not only by the use of these discords that he improved music, for by quitting ecclesiastical modulation in his secular productions, he determined the key of each movement, smoothed and phrased the melody, and made all his parts sing in a more natural and flowing manner than had been done by any of his predecessors. In the first set of Monteverde’s madrigals the composition is not only correct and simple, but to dry and fancifl, as to threaten no attempts at such new harmonies and effects, as would bring about a revolution in the art. And it seems to have been by design, and in his dramatic experiments at the expression of words, that he ventured to violate ancient rules, and militate against prejudice and pedantry: for neither his church music, nor the two first books of his madrigals, contain any licences that would offend or surprize orthodox ears, even in the fifteenth century. But in his fifth and last book of madrigals, almost every species of discord and modulation is hazarded, for the sake of which the boldest composers of modern times have been often thought licentious.

Something so free, facile, and similar to music of much later times appears through all the trammels of fugue and complication, in the melody, harmony, and modulation of his latter madrigals, that we are forry not to be able to allow room in our plates for a specimen, which, however, curious inquirers into the progress of the art, may see in Burney’s History of Music, vol. iii. p. 237, &c.

Monteverde may be regarded as a man who formed an era in the history of his art: he freed himself from many severe and narrow rules which impedied all experiment, and consequently improvement. His new and bold use of discords opened a career, which, but for him, a great number of celebrated composers would never have been heard of.

He had acquired great reputation in 1620, and was admitted that same year into the academy at Bologna with great solemnity. His madrigals were printed at Venice from 1582 to 1651. Another collection of his pieces appeared
at Venice in 1640, for one, two, three, four, five, six, seven, and eight voices.

He was one of the first cultivators of recitative, and set the following operas: "Proserpina Rapita," 1630; "Ariadne," 1640; "Adonis," with the title of a musical tragedy, 1642; and "L’Incoronazione di Poppea," all for Venice. With respect to these operas, the learned Gio. Bat. Doni says: "Claudio Monteverde, at present maestro di capella to the republic of Venice, has received great applause at the performance of his Ariadne: he afterwards published the principal part of this production, which is the Lamentation of Ariadne, and perhaps the most beautiful composition of the kind which our times have produced."

Montevideo, in Geography, a bay and town of La Plata, or Paraguay, in South America, situated on the N. side of La Plata river: it lies E. of Buenos Ayres, and has its same from a mountain which overtops it, about 20 leagues from Cape Santa Maria, at the mouth of the Plata. S. lat. 34° 30'.

Montey, a town of Switzerland, and seat of a bailiff, in the Valais; nine miles N. of Martigny.

Montejo, a town of Portugal, in the province of Beira; 15 miles S.W. of Guardia.

Montezuma, in Biography. See Mexico.

Montfaucon, Bernard de, a celebrated antiquary and philologus, was born in 1653, at the castle of Saultage, in Languedoc. In early life he entered into the military service, and served in two or three campaigns. By the death of his parents, and some other circumstances, he was so much impressed with a desire of the world, that he formed the resolution of adopting a monastic life. In 1675, he entered among the Benedictines of St. Maur, and devoted himself to the pursuits of literature. In conjunction with two of his friends, he published "Analefta Graecæ, Græc. et Lat. cum notis." In 1699, he published a small tract, entitled "La Verité de l’Histoire de Judith," in which he gave some elucidations of the history of the Median and Assyrian empires. After this he was occupied a few years in preparing a new edition of the works of St. Athanasius, which appeared in three volumes folio, dedicated to pope Innocent XII. This work was published in 1698, and was preceded by a new life of that father, and by several learned dissertations. In the same year he undertook a journey to Italy, for the purpose of consulting libraries and examining manuscripts relative to the inquiries in which he was engaged. Having been from home about three years he returned to Paris, where, in 1702, he published an account of the observations made in this tour under the title of "Diarium Italicum, aum Monumentorum veterum Bibliothecarum, Mufoeumen, &c." During his residence at Rome, he printed a defence of the edition of St. Augustin, published by the fathers of his order, against various attacks which it had undergone. In 1706, he published "A Collection of Ancient Greek Ecclesiastical Writers," in two volumes, with translations, notes, and dissertations: but one of his most learned and important works appeared in 1708, with the title of "Palaeographia Graecæ, five de Ortu et Progresi Literarum Graecarum, et de variis omnium Seculorum Scripturis Graecarum generibus, &c." This work has effect, with respect to the ascertainment of the age of Greek MSS., that which the work of Mabillon, "De Re Diplomatica," has done with regard to the Latin. In 1710, he was nominated a supernumerary honorary member of the Academy of Inscriptions and Belles Lettres, and in the same year he published, in Latin and French, his celebrated work, "L’Antiquité expliquée et representée en Figures," Paris, ten volumes folio. A supplement to it appeared in 1724, in five volumes. This stupendous collection of the monuments of antiquity contains 1200 plates, comprising between 50 and 40,000 figures. Between the years 1729 and 1731, he published "De la Confession de Monarchie Françoise," five volumes folio, with a great number of figures. And in 1739, he gave the public his concluding work, entitled "Bibliothéca Bibliothecarum Monumenterorum nova," in two volumes folio. He died at the abbey of St. Germain des Prés in 1741, at the age of eighty-seven, leaving, it is said, preferred his faciencies to entire, that nearly to the termination of his career he employed eight hours a day in study. He was author of many other works besides those that have been already noticed. He was not less estimable for his piety, candour, and goodness, than for the extent of his erudition. Morei.

Among the voluminous works of this learned and indefatigable writer, there is in his "Trefor d’Antiquitez sacrées," a dissertation on the music of the ancients, and particularly of the Hebrews, which merits some consideration as a musical article.

The antiquity of the sacred writings is now so remote as to throw into the regions of conjecture almost every thing concerning the Hebrews that is not in the Bible. After an eulogy almost enthusiastic on the music of the ancients in general, and of the Hebrews in particular, up to Tubal Cain, this pious Benedictine proceeds to describe their music and musical instruments, with as much firmness as if he had seen and heard them but yesterday.

He allows, however, that there was no musical establishment, even in the celebration of religious rites, till the time of the royal psalmist, David, when he constituted it a part of prierly study. So that they had it all to learn.

The author then describes the musical establishments of David and Solomon for the service of religion; which were indeed the most numerous and splendid upon record. When David first regulated these establishments, it appears that not only the select band of singing men and singing women, but 4000 Levites were appointed to praise the Lord with instruments; and the number of those that were instructed and cunning in song, is said to be 288.

But all this sudden cultivation of music does not reflect any great honour on the Hebrews as inventors of the art: for the learned writer says that they had their music from the Chaldeans and the Egyptians, and never pretended to the honour of invention. The rabbins enumerate 34 different musical instruments which they seem to have had in use, and which, perhaps, surpasses the Grecian lute. But after examining the names of these instruments, he found it necessary to retract 14 of them at once; as there did not appear among them any term which indisputably signified an instrument of music; so that the number is reduced to 20, of which he has given engravings; but every one of these is demonstrably Grecian, and copied from ancient sculpture, known to be Greek. The reverend father, indeed, does not seem deeply read in musical history, or he would never have asserted that several of these ancient instruments were played with a bow instead of a plectrum. But it has not been proved by any of the most curious and pernicious antiquaries, that the use of the bow was ever known to the ancients, nor can it be demonstrated of higher antiquity than 500 years.

Montfaucon, in Geography, a town of France, in the department of the Nievre, and chief place of a canton, in the district of Montmedy; 10 miles N. of Clermont. The place contains 1024, and the canton 9194 inhabitants, on a territory of
of nine kilometres, in 18 communes. — Also, a town of France, in the Upper Loire, and chief place of a canton, in the district of Yenne; nine miles S.E. of Monistrol. The place contains 683, and the canton 9172 inhabitants, on a territory of 187,5 kilometres, in 7 communes. — Also, a town of France, in the department of the Maine and Loire, and chief place of a canton, in the district of Beaupréau; nine miles W. of Cholet. The place contains 477, and the canton 10,053 inhabitants, on a territory of 2671 kilometres, in 12 communes.

MONTFERRAND, a town of France, in the department of the Puy-de-Dome, and chief place of a canton, in the district of Clermont, one mile N. of Clermont. The place contains 5522, and the canton 13,334 inhabitants, on a territory of 72,540 kilometres, in 6 communes.

MONTFERRAND, a fine port of red Bourbon wine, the produce of Clermont-Ferrand, in Auvergne. It is principally sent to Holland, Germany, and the north of Europe.

MONTFERRAT, Duxy of, in Geography, lately a principality of Italy, bounded on the W. and N. by Piedmont, on the E. by the duchy of Milan, and on the S. by the republic of Genoa; lying in N. lat. 45°, and in E. long. 8° 20', and being upwards of 63 miles from N. to S., and from 30 to 38 from W. to E. Consisting of mountains and fruitful valleys, it abounds in corn and multhead wine; and contains about 200 market-towns, villages, and seats. It was erected into a duchy by the emperor Maximilian II., but was entirely ceded to Sardinia, A.D. 1758. It is divided into Upper and Lower; the former containing the provinces of Alba and Acqui, and the latter those of Cafal and Trino. Cafal is the capital of the duchy. This duchy is now united to France, and included in the departments of the Tanaro and Marengo.

MONTFERRAT Wines, a common kind of Italian wines in the Piedmontese territory.

MONTFLANQUIN, in Geography, a town of France, in the department of the Lot and Garonne, and chief place of a canton, in the district of Villeneuve-d’Agen; 19 miles N. of it. The place contains 5173, and the canton 12,377 inhabitants, on a territory of 225 kilometres, in 12 communes. N. lat. 44° 32'. E. long. 0° 52'.

MONTFORT, Simon de, in Biography, a famous commander in the 13th century, was descended from a noble family, the lords of Montfort, a town in the district of Paris. He was remarkable for the magnitude and strength of his body, and distinguished himself on various occasions in combat against the Germans and English, and in an expedition beyond sea. In 1269 he conducted the crusade against the Albigenses, on which occasion he rendered himself infamous by the cruelties which he perpetrated; of these too many instances are given on the page of history; we shall record but one, which of itself is insufficient to hand his name down to posterity with execration. After the capture of Lavau, he called the lady of the place to be thrown into a well, her brother to be hanged, several gentlemen to be massacred in cold blood, and 400 heretics to be burnt, while the kind-hearted clergy, of that barbarous period, were singing a hymn to the Holy Ghost. Montfort gained a victory, in 1213, over Peter, king of Aragon, but was himself killed, at the siege of Toulouse, in 1218, by a stone hurled from a machine, of peculiar construction, by the hand of a woman. He obtained the reputation of one of the greatest captains of the time, and was a champion of the Catholic faith. Moreri. Universal Hist.

MONTFORT, Simon, earl of Lancaster, son of the preceding, settled in England in 1236, and obtaining the favour of the king, Henry III., he was created earl of Leicester, and was permitted to marry the countess dowager of Pembroke, sister to the monarch. He was afterwards appointed lieutenant-general of Gascony, but his government having excited great discontent among the people, he was recalled, tried, and acquitted of the charges exhibited against him. The king, however, was satisfied of his guilt, and called him a traitor to his face, an affront which the earl returned by giving him the lie direct: and though an outward reconciliation took place, yet they never afterwards appear to have borne good-will for each other. The extortions and tyranny of Henry having excited discontents at home, Montfort began to entertain ambitious projects, by dishonouring a zeal for reform, and by fomenting public dissatisfaction. He even went so far as to call a secret meeting of the most considerable barons, and concerted with them a plan for reforming the government. In 1258, Henry having convoked a parliament for the purpose of obtaining supplies for the conquest of Sicily, the crown of which the pope had conferred on his son, the barons entered the hall completely armed, and boldly remonstrated with him upon his errors. The king now found it was too late; it were, a prisoner in the hands of his subjects, and the power, which was, probably, at first, necessary for security against the sovereign’s usurpations, was soon abused and made subservient to the private interest of the barons, of whom Leicesters was the chief mover. He soon obtained various successe, and at length got possession of the king’s person. He now made use of the superiority which his valour had won, without any regard to the dictates of moderation, and at length contrived to have the whole authority committed to himself, the bishop of Chichester, and the earl of Gloucester. He employed various methods of extort to fill his coffers, of which some were so oppressive, that they drew upon himself the hatred of the people, and a junction was expected to be formed between the royalists and the discontented barons. To oppose this he summoned a parliament in January 1265, composed not only of the two knights sent from every shire, but of representatives from the boroughs, for the first time on record. The dread of Leicesters’ unbounded power detached from him the earl of Gloucester, who retired to his estate and garrisoned his fevdal estates. Leicesters proclaimed him and his adherents traitors: a civil war commenced, in which Leicesters was slain, with one of his sons; another of his sons was taken prisoner, and the ruin and expulsion of his whole family were the result of this defeat. Hunt. Henry.

MONTFORT, in Geography, a town of France, and principal place of a district, in the department of the Ille and Vilaine; 30 miles S. of St. Malo. The place contains 11,15, and the canton 13,420 inhabitants, on a territory of 1771, in 11 communes. N. lat. 48° 3'. E. long. 1° 52'.—Also, a town and ruinous castle, where the ancient counts of Fuld Kirch refurred, and from which they took their title, forming, as it has been said, a separate county; 12 miles S. of Bregranz.—Also, a town of Holland, situated on the river Ijssel. It is a well-built town, and fortified, but not strong; 23 miles S. of Amsterdam.—Also, a town of France, in the department of the Languedoc, and chief place of a canton, in the district of Dax; nine miles E. of Dax. The place contains 14,10, and the canton 11,585 inhabitants, on a territory of 225 kilometres, in 22 communes. — Also, a town of France, in the department of the Sarthe, and chief place of a canton, in the district of Meaux; nine miles E. of Meaux. The place contains 763, and the canton 12,666 inhabitants, on a territory of 247,5 kilometres, in 18 communes.
MONTCARTER-sur-Risle, a town of France, in the department of the Eure, and chief place of a canton, in the district of Pontandemer; seven miles S.E. of it. The place contains 542, and the canton 9275 inhabitants, on a territory of 1342534 kilometres, in 15 communes.

MONTGISCARD, a town of France, in the department of the Upper Garonne, and chief place of a canton, in the district of Villefranche; 7 miles N.W. of it. The place contains 1100, and the canton 9789 inhabitants, on a territory of 165164 kilometres, in 20 communes.

MONTGOLFIER, in Biography. See AEROSTATION.

MONTGOMERY, GABRIEL DE. Count of, a celebrated French nobleman, was born of an ancient Scotch family. In 1559 he had the misfortune to kill Henry II. by accidentally wounding him in the eye as they were tilting at a tournament given by that monarch, on occasion of the marriage between his daughter Elizabeth and the king of Spain. After this unfortunate disaster, Montgomery went to Italy and other countries. till the civil wars recalled him to France, where he attached himself to the Protestants, and became one of their principal chiefs. He defended Rouen in 1563, against the royal army, and when the city was taken by assault he escaped to Havre. In 1569 he raised the siege of Beaune, in Navarre, then closely pressed by the Catholics; after which he followed the besiegers to Othe, which he took by assault.

Montgomery was at Paris at the time of the massacre of the Protestants in 1572, but escaped, though closely pursued.

With his family he retired to Jersey, and from thence to England. In 1573 he returned to Normandy, where he was joined by some of the Protestant nobility at St. Lo, at which place he was besieged by Matignon, lieutenant-general in Lower Normandy. But Montgomery escaped from thence, and went to Dumfront, whither he was followed by Matignon, who after a long combat made him prisoner. This gallant nobleman was beheaded at Paris in 1574.

MORET.

MONTGOMERY, in Geography, a county of America, in the upper district of Georgia, on the N.E. side of Altamaha river, containing 3180 inhabitants, and divided into 12 towns,—Alfo, a county of New York, first called Tryon, but changed into Montgomery in 1784, by an act of the legislature. It contains 24,483 inhabitants. Its chief town is Johnston.

—Alfo, a township in Ulster county, New York, W. of New Windsor and Newburgh.—Alfo, a township in Franklin county, Vermont; watered by Trout river, and containing 36 inhabitants.—Alfo, a township in Hampshire county, Massachusetts; 15 miles from Bolton; incorporated in 1780, and containing 560 inhabitants.—Alfo, a county in Pennsylvania, 13 miles long, and 17 broad; N.W. of Philadelphia. It is divided into 18 townships, and contains 24,150 inhabitants. Its chief town is Norristown.

—Alfo, a township in the last mentioned county.—Alfo, a township in Franklin county.—Alfo, a county in Salisbury district, North Carolina, containing 7577 inhabitants, including 1973 slaves.—Alfo, a county of Virginia, S. of Botetourt county; about 100 miles long, and 44 broad. It has some lead mines. It contains 8765 free inhabitants, and 968 slaves. Its chief town is Christiansburg.—Alfo, a county of Maryland, on Patowmac river; containing 15,658 inhabitants, including 6288 slaves.—Alfo, a county in Tennessie state and Merlo district. This and Robertson county are the territory formerly called Tennessie country, the name of which ceases since the State has taken that name. It contains 2891 inhabitants.—Alfo, a county of Kentucky, containing 6999 inhabitants, of whom 749 are slaves.
history. Indeed it still retains convincing proof of its strength; one side of the ridge on which it was erected being extremely lofty, and almost perpendicular in acclivity; while the others, which are less steep, have the defence of four large fosses cut out of the solid rock, over which drawbridges have been thrown.

The town of Montgomery is pleasurably situated on an eminence of inferior height to that on which the ruins of the castle appear. It is clean and neatly built, and still bears evident marks of its having been anciently surrounded by a wall. In Leland's time great part of this wall was standing; and that writer mentions four gates then in ruins, called "Kedewen gate, Chirbury gate, Arthur's gate, and Kerry gate," and also four remains "of broken towers," of which the white tower was "the most notable;" only a few traces of these are now left. This town is governed by a high steward, two bailiffs, and twelve capital burgesses, or common councilmen, and was erected into a free borough in the reign of Henry III. It sends one representative to parliament, who is elected by the burgesses, and returned by the bailiffs. Llandyblodig, Welsh-Pool, and Llanfyllin formerly possessed a share in this privilege, but they have been totally debarred from it since the year 1728, on the authority of a parliamentary decision. The guildhall here is a very handsome edifice, at which all the public business of the town is transacted; and near the site of the castle a large county gaol has been lately erected. The church is built in the form of a cross, and contains several monuments of the Herbert family. That in honour of Richard Herbert, esq. father of the celebrated lord Herbert of Cherbury, is particularly distinguished for the remains of former magnificence, which are yet apparent.

A market is held on Saturdays here: here are held the quarter sessions, and the petty sessions for the lower division of the hundred. According to the parliamentary returns of 1801, the population of the parish amounted only to 992 persons, viz. 493 males, and 499 females.

On the same side of the town with the castle, but at a short distance, is a stupendous encampment, which probably has been a British fort. The situation is on the summit of a lofty hill, sufficiently defended on one side by its abrupt ascent; and on the more accessible parts by deep fosses which run directly across it. The approach was further defended by four shorter fosses, having two entrances communicating with the main work. In the vale between this hill and that on which the castle stands, are the remains of a small fortification, which Mr. Evans conjectures to have been the site of the fortres built by Sir Baldwin, because "a par-taking of the Norman manner in design and shape." Chirbury priory stands about two miles from the town on the road to Shrewsbury. This edifice was founded in the reign of king John for monks of the order of St. Bennet; and at the general dissolution was granted to Edward Hopton and his wife Elizabeth; but the scutage and parlagry were both soon afterwards bestowed on the grammar-school at Shrewsbury. The mountain, Myndd, or Cefn-Digoll, about five miles to the north-east, on the confines of Shropshire, is distinguished in the military history of Wales as the scene of a desperate engagement, in which Madoc, prince of that country, was defeated and slain. Pennant's Tour in Wales. Beauties of England and Wales, vol. xvii.

MONTGOMERYSHIRE: one of the counties of North Wales, is bounded on the E. and N. E. by the county of Salop in England; on the S. W. by Radnorshire; on the W. and S. W. by Merionethshire and Cardiganshire; and on the N. by Denbighshire. It extends, according to the most accurate surveys, 35 miles in length, from the farthest point of Llangurig, on the borders of South Wales, to Pityll-Rhaiadr, a noted cataract in the Berwyn hills; and in breadth, from the town of Montgomery to that of Machynlleth, 30 miles. The superficial area is variously stated; Templeman making it to comprise 444,800 acres, while by other computation it is fixed as high as 560,000; and again, in a very recent survey, at 491,500. Of this extent only 60,000 acres are under cultivation, and 18,000 laid down in pasture; the remainder of the country is either in a waste condition or is appropriated to woodlands.

The first inhabitants of this district, of whom mention is made in history, were a portion of the Ordovices, or Ordovices, whose territories extended at one time over the whole fix counties of North Wales, with the exception of a small part of Flintshire, which belonged to the Carnabs. This people, naturally brave, and defended by the lofty hills and almost impassable ravines, with which their country abound, contrived, notwithstanding their deficiency in military skill, to battle; for a period of two centuries, all the efforts of Roman discipline and courage to subdue them. Julius Agricola, the celebrated general of Domitian, however, at last effected, by his concentrate and indefatigable condens,
MONTGOMERYSHIRE.

mountains, commonly distinguished by the title of "the back-bone of Montgomeryshire and Merionethshire," commence in the south-western district, and running nearly through the whole shire, in a curvilinear direction, enters the county of Merioneth near Aran Fowddy. The Freiddin, or Briddin, and the Long mountain, near their lofty heads on the eastern side of the county, and form a natural boundary throughout their extent, between it and Shropshire. The Biga mountains are seen on the north, stretching themselves along the northern side of the valley of the Severn, till they reach a collateral ridge of Plinium. Besides these there are numerous inferior ranges, usually separated by long narrow vallies and a few isolated hills, which rise to a very considerable height, like artificial mounts, in the centre of a level tract of country. The habitra of these hills vary, but not so much as in the adjacent counties. Lime-tone rarely enters into their composition, except in the vicinity of Llangyme and Porthwaun, at both of which places a considerable quantity of lime is wrought, chiefly for the purposes of manure. Slate flata, on the other hand, are very abundant, and indeed constitute the principal portion of all the mountains in the county, which are not pre-eminently lofty. Many quarries have been opened in different districts for the manufacture of this material, but the principal ones are confined to the hills around Llangynam, where the slate flates, perhaps in England, are procured. From the elevated situation of these quarries, the conveyance of the slate from thence to the plain below is a task of considerable difficulty and hazard. The method in use here to accomplish that object is not a little remarkable, and to an observer unaccustomed to the fight, must appear fraught with extreme danger. The slate is placed on a small sled, adapted to the work, which is fastened to the shoulders of a man who has the care of delivering the cargo at the base of the mountain, by means of a rope, of which he lays fall hold with both hands, and then turning his face towards the load, he begins to move, gradually receding backwards till he reaches the bottom. Apparently dangerous, however, as this operation is, long experience has rendered it so familiar to the workmen in general, that accidents are very uncommon; and to many of them it is equally easy of conducting a common wheel-barrow on level ground. The other mineral productions of this county are coal, silver, lead and copper. The coal mines are only found, in any considerable quantity, at Coedware, on the borders of Salop. Silver is most plentiful at Esgair-hir, where, as well as at Graigue-Mwyn, near Pityll-Rhaiadr, Dolodyan west from Llanbrwyn-Mair, and Llanidyce, lead mines have been opened. The only copper mine is situated in the vicinity of Esgair-hir, on the confines of Cardiganshire.

Montgomeryshire is abundantly supplied with rivers; indeed it may justly be said that more streams take their rise in this county than in any other of similar extent in Great Britain. Of these rivers the principal are the Severn, the Wye, the Vyrnwy, and the Tanat. The Severn, rising on the side of Plinium hill, runs in a north-easterly direction through a very considerable portion of the county, and during its course receives the waters of several auxiliary streams. The Wye, which likewise has its source from the same ridge, taking a south-east direction, is joined by the Bedw rivulet at Llangoer; whence flowing more to the south it soon enters Radnorshire. The Vyrnwy rises near Brech-y-Groes, and after a very changeable course, during which it is joined by the Tanat, falls into the Severn near Llandrinio. This river is remarkable for the multiplicity and variety of fish which frequent it. Of the rivers which pass through the county, but have their springs in another, the principal are, the Maw, the Traethbach, the Cierig, the Dee, and the Dovey: all of which will be found more particularly noticed in our account of the respective counties to which they seem more properly to belong, under their appropriate names.

The climate of this county varies in different districts. In those parts which have been mentioned as more elevated than the rest, it is extremely cold and bleak; and in the narrow vallies the wind is almost constantly high, and very frequently boisterous. The westerly winds are prevalent during nine months of the year, and the easterly the remaining three. These last are usually accompanied with wind and rains, but seldom blow so strongly as those from the S.W. or N.W., which commonly prove fatal to the fruit both on the higher grounds and in the vallies. The soil of the mountains here, partaking of the nature of their substrata, is for the most part of a felhisfie kind; that in the vales was doubtless originally of the same description, but in consequence of cultivation now approaches very nearly to a clayey sublance.

It has already been observed, that not above one-half of Montgomeryshire is in a state of cultivation, the rest being either covered with wood, or lying in a waste condition; but the cultivated lands, about one-third has been mentioned as arable; the other two-thirds being usually laid down with grass. The most common arable crops are oats, barley, wheat and rye. Hemp is likewise grown in considerable quantity in the eastern division of the county; almost every cottage having what is called a hemp-yard attached to it. Of the grass lands only a small portion, compared with their extent, are sufficiently fertile to be adapted for fattening cattle. Indeed that object is seldom attempted, except in some particular spots in the vales of the Severn, and of the Vyrnwy. The woodlands comprehend several very valuable and extensive plantations. Montgomeryshire, in fact, is still by far the belt wooded county in Wales, and was formerly regarded as a valuable deposit of oak for the use of the navy. Within the last fifty years, however, large quantities of that noble tree have been felled; and for little care taken to replace them, that the county has nearly lost all its importance in this respect. The waffle lands here are chiefly appropriated to the grazing of oxen, sheep, and horses. The oxen are of different breeds, each of which have their provincial peculiarities. Those of the native breed, which are usually termed the finch-backed kind, are of a brindled colour, short in the leg, and of great depth in the carcass. Those originally from Devonshire have, on the other hand, long legs, and a more compact body, and are consequently better fitted for agricultural purposes than the native front. A kind from Hereford, distinguised by their white faces, have of late years become very prevalent in the eastern district. Of sheep there are two kinds; the one peculiar to the Kerry hills, and the other chiefly bred on the ridge called Long-Mountain, and some other hills on the borders of Shropshire. The first of these breeds is supposéd to be the only variety in Wales which produces perfect wool; that of the other breeds being usually more or less debased by the intermixture of coarse long hairs, denominated by dealers kemp. Its discriminating characteristics are large wide checks, covered with wool, a bunchy fore-head, delitute of horns, white woolly legs, and a broad beaver-like tail. The second kind also affords wool of a superior quality, but in much less quantity. Herds of very different sizes and properties are reared in Montgomeryshire. The hilly districts are remarkable for a race of small ponies, called merlins, which being left to range over the mountains, as well during winter as summer, till at least three years old, are in consequence a very hardy race. These are chiefly used as beasts of burden, by numerous packmen who traverse the country to collect the manufactured
manufactured articles, or to sell others which the inhabitants may require. For this purpose they are extremely well fitted, custom having taught them to climb the rugged and slippery ascents with a firm and steady tread; and it is on that account much to be lamented, that the neglected state in which they are allowed to remain has materially deteriorated the breed. A larger kind of horse, apparently a cross between the merlyn and the English breed, is likewise a native of the hilly districts in Montgomeryshire. The most sizable of these animals are admirably adapted for the team on the higher grounds, where heavier horses would be egregiously misapphed; and the lighter ones make good roadsters with a light weight. A third breed, of a very superior quality to either of these, is so reared in the more fertile vales here, which some say was introduced from Spain by Robert, earl of Shrewsbury. Queen Elizabeth is further stated to have greatly assisted in perpetuating this breed, by keeping a famous stud of horses and brood mares at Park, in this county.

The chief, or rather the only, manufactured production of Montgomeryshire, is flannel; for though hemp, as has been already said, is grown here in considerable quantity, it is seldom made into any article of use, till it has passed into the hands of the manufacturers of other districts. In former times, the only machinery employed in the manufacture of the flannel was the common weaving machine; all the processes of carding the wool, and spinning into thread, having been executed, in the most literal sense of the term, by the tedious operation of the hand, by farmers and cottagers in their own houses. Of late years, however, the powerful aid of more complicated apparatus has likewise been reformed to; and there are now upwards of forty carding, and several spinning machines, driven by water, in different parts of the county. The most extensive manufactories for weaving are those at Newtown, Berhiew, Wllih-Pool, and Dolytrian; and one on the Dulas Stream, near Machynlleth, at which, however, cloths are made as well as flanne's. Of these fall the finer pieces generally measure about 132 yards, and the inferior ones 110: and as 500 pieces of either kind are frequently sold at the weekly markets, it does not seem to be exceeding truth to average their amount at 320, thereby making the whole annual produce fold out of the county 7500 pieces; which, calculated at the low average of 5s. a piece, gives the sum of 62,500l. as the total profit arising therefrom, including the value of wool, which may be supposed worth something more than 18,000l.

The roads in this county are, perhaps without exception, the worst within the limits of North Wales, especially in the valleys; but this deficiency does not arise so much from any neglect on the part of the proprietors in their formation or repair, as from the want of suitable materials for the purpose; there being no granite or other indurated rock here, as in the other counties, which could be employed to render them firm and compact. They are consequently most commonly formed of the shale and slate stones, of which it has been remarked that the mountains are chiefly composed; and these soft and friable substances become reduced, by the pressure and friction they necessarily sustain, to their primitive clay. Hence the roads, even in summer, are often mud and slippery, and in winter are too hard and hardy, as to be nearly impervious for carts of a heavy burden. But to the honour of the county, though the roads are thus invariably of a bad texture, the bridges are generally excellent, and more numerous than those of any other county in the principality, when considered in reference to the comparative extent of its cultivated lands.

Many interesting remains of antiquity of various description have been discovered or traced, at different periods within the limits of Montgomeryshire. The Roman station, Mediolum, is fixed by several able antiquaries in the vicinity of Meifod, or Meivid, which, as noticed above, afterwards became the residence of the Powysian monarchs. The station Maglost is likewise, with great probability, placed at or in the vicinity of Machynlleth, as many vestiges of walls, and the remains of two forts evidently Roman, are still distinctly visible there. Many Roman coins have also been dug up at this place; and two miles from it is a spot, yet retaining the appellation of Cefn Caer, or the back part of the city. Machynlleth afterwards became a town where the celebrated Owen Glendwr assembled the estates of Wales in 1402, when his title to the principality was solemnly acknowledged. The fountain house, in which this convocation was held, is now degraded, by being converted into a stable; but its spacious door-way sufficiently evinces its occupancy to have been once more honourable. (See Machynlleth.) At Montgomery are the ruins of the celebrated castle of that name; and close to it is a British and a Saxon encampment, the former remarkable both for its strength and extent. On the west side of the road from this town to that of Newtown stands the ancient fortress of "Dolforwyn-Castle," said by Dugdale to have been the work of Dafydd-ap-Llewelyn, a prince who reigned from the year 1240 to 1246; but referred by a Welsh writer, John Dafydd Rhys, to a much earlier date. Caer-Sws, or Caer-goose castle, on the north bank of the Severn, is considered by some to have been a Roman station, though not mentioned in any of the Itineraries. Extensive traces of buildings, ranged in streets intersecting each other at right angles, have been discovered in the fields, adjacent to the village. Two encampments are situated at a little distance, where some inscribed bricks have been dug up; and close to them appear considerable vestiges of a Roman road, running in a direction from Caer-Sws to Meifod. Several encampments, both Roman and British, are likewise discovered in the neighbourhood of Llanfair and Wlhih-Pool. Near the latter town was situated the abbey of Ystrad-Marchell, founded in 1170, for monks of the Cistercian order. A mile from hence is Powis castle, a venerable mansion, constructed of red sand-stone, and standing on the ridge of a lofty rock. This castle makes a considerable figure on the pages of history, and is now the chief seat of the noble family of Clive, to which the adjoining village gives the title of marquis. (See Wlsen-Pool.) Besides these, many other relics of antiquity in Montgomeryshire might be noticed, would the limits of an article like the present allow of greater digression; but as that cannot be permitted, we shall only further mention the "Dyke of Olfa," which runs nearly through the whole eastern side of the county, and which is justly ranked among the most extraordinary efforts of human labour in Great Britain.

Montgomeryshire, in a political point of view, is divided into nine hundreds, comprising forty-nine parishes, one borough-town, Montgomery, and six market-towns, viz. Wlhih-Pool, Llanilili, Llanfair, Machynlleth, Newtown, and Llanydloes. The names of the hundreds are Llanilili, Denbog, Pool, Cowse, Mathrafal, Machynlleth, Llanilili, Newtown, and Montgomery. This county sends two representatives to parliament, one as knight of the shire, and another as burgesses for the borough. Its honourable distinctions are confined to two families; that of Clive, already mentioned, and that of Herbert, which holds the dignity of earls of Pembroke and Montgomery. By the returns made to parliament in 1801, the amount of its population was 47,558 persons, viz. 22,394 males, and 25,164 females;
Males; of which number, 623 were reported as employed in the various departments of trade and manufacture, and 13,683 in the labours of agriculture. The money raised here for the use of the poor, in 1833, amounted to the sum of 22,088L. In respect to ecclesiastical jurisdiction, the whole county is included within the province of Canterbury, but is divided among the three dioceses of Bangor, Hereford, and St. Asaph. Davie’s Agricultural Report of North Wales, 8vo. Beauties of England and Wales, by Mr. Evans, vol. xvi. Wynn’s History of Wales.

MONTGUYON, a town of France, in the department of the Lower Charente, and chief place of a canton, in the district of Jonzac. The place contains 1298, and the canton 8847 inhabitants, on a territory of 37252 kilometres, in 14 communes.

MONTH, in the Computation of Time, the twelfth part of the year.

Among the ancient Greeks, the year was divided into twelve months, which contained thirty and twenty-nine days alternately; but so as the months of thirty days always went before those of twenty-nine; the former were termed μενενή, full, and ἠμένη, as ending on the tenth day; the latter were called αμένη, hollow, and from their ending on the ninth day, ἡμένη.

In order to understand their method of reckoning the days of the month, it must be considered that every month was divided into τετάρτη, or three decades of days; the first decade they called the μενενή ἡμένη, or ἡμένη μενενή; the second, μενενή μενενή, or μενενή μενενή; the third, μενενή μενενή, or μενενή μενενή; or ἡμένη μενενή. Whence the territory of the month was called ἡμένη, as falling upon the new moon, and μενενή, as being in the first day of the first decad; the second day was termed μενενή ἡμένη, and so on to the τετάρτη ἡμένη.

The first day of the first decad, which was the eleventh day of the month, was called τετάρτη μενενή, or τετάρτη ἡμένη; the second of this decad, τετάρτη μενενή, or τετάρτη ἡμένη, and so on to the τετάρτη, the twentieth, which was the last of the first decad.

The first day of the third decad was termed τετάρτη ἡμένη, the second, τετάρτη ἡμένη, and so on to the τετάρτη, the tenth. Sometimes they inverted the numbers of this decad, the first being called τετάρτη ἡμένη; the second, τετάρτη μενενή; the third, τετάρτη μενενή; and so on to the tenth day of the month, which was called τετάρτη δεκατή, Decim, from Demetrius Polliocees; before whole time, particularly in Solon’s law, it was called me dia, the old and new; because the new moon falling out on that day, part of it belonged to the old moon, and part to the new. It was also called τετάρτη, the thirtieth; and that not only in the months which contained of thirty days, but also in those of twenty-nine: for in these, according to some accounts, the twenty-second day was omitted; or, according to others, the twenty-ninth: but which day forever was omitted in computation, the thirtieth was constantly retained. Hence, according to Thales’s first scheme, all the months were called months of thirty days; though, by Solon’s regulation, half of them contained only twenty-nine; and the lunar year of Athens was called a year of three hundred and fifty-six days; though really after Solon’s time, it consisted of no more than three hundred and fifty-four. Vide Pott. Archæol. Gr. lib. ii. cap. 26.

The names of the months being various in different parts of Greece, it will be sufficient particularly to consider those of Athens, barely mentioning those of others that correspond with them, 1. Hekatombaeon, or Echatombeon. 2. Metagenion. 3. Boedromion. 4. Mazaedereion. 5. Pyanep-

As the Roman months were the same with those now in use among the Europeans, we shall only refer to the articles Calendar and Calends, where the manner of their computation is explained.

The Hebrew months were originally reckoned in order, as the first, second, &c. but after the Babylonish captivity, the Israelites borrowed the names of their months from the Chaldeans and Persians: and they were distinguished in the sacred and civil year as follows. In the sacred year Nisan, answering to our March, Ikar to April, Sivan to May, Thammuz to June, Ab to July, Elul to August, Tizri to September, Marhchevan to October, Calef to November, Theteb to December, Sebat to January, and Adar to February. In the civil year, Tizri corresponding to September, Marhchevan to October, Calef to November, Theteb to December, Sebat to January, Adar to February, Nisan to March, Ikar to April, Sivan to May, Thammuz to June, Ab to July, and Elul to August.

Time, we have observed, is duration marked out for certain uses, and measured by the motions of the heavenly bodies.

Hence result divers kinds of years and months, according to the particular luminaries by whose revolutions they are determined, and the particular purposes they are designed for; as solar months, lunar months, civil months, astronomic months, &c.

MONTH, Solar, is the space of time in which the sun moves through one entire sign of the ecliptic.

Hence, if regard be had to the sun’s true motion, the solar months will be unequal; since the sun is longer in passing through the summer signs, than through those of the winter.

But as he constantly travels through all the twelve in 365 days, 5 hours, and 49 minutes, the quantity of a mean month will be had by dividing that number by 12. On this principle, the quantity of a solar month will be found 30 days, 10 hours, 29 minutes, 5 seconds.

MONTHS, Lunar, are either synodical, periodical, or illuminative.

M O NTH, Lunar synodical, called also, absolutely, lunar month; and lunation, is the space of time between two conjunctures of the moon with the sun; or between two new moons. (See SYNODICAL Month, and LUNATION.) The quantity of the synodical month, is 29d 12h 44m 3s 11". See Moon.

MONTH, Lunar periodical, is the space of time in which the moon makes her round through the zodiac; or in which she returns to the same point.

The quantity of this month is 27d 7h 44m 3s.

The ancient Romans made use of lunar months, and made them alternately 29 and 30 days; and they marked the days of each month by three terms, viz. calends, nones, and ides.

MONTH, Lunar illuminative, is the space from the first time of the moon’s appearance after new moons, to her first appearance after the new moon following.

Hence, as the moon appears sometimes sooner after the new moon, and sometimes later; the quantity of the illuminative month is not always the same. By this month the Turks and Arabs reckon.

MONTH, Astronomical or Natural, is that measured by some exact interval corresponding to the motion of the sun, or moon.

Such are the lunar and solar months above mentioned.
MONTHLY

M. Monti

Where note, that these months can be of no use in civil life, where it is required that the months begin and end on some certain day. For this reason, recourse is had to another form of months.

MONTH, Civil or Common, is an interval of a certain number of whole days, approaching nearly to the quantity of some astronomical, either lunar or solar, month.

Civil months are various, according to the astronomical month to which they are accommodated.

MONTHS, Civil lunisolar, are to consist alternately of 29 and 30 days. Thus will two civil months be equal to two astronomical ones, abating for the odd minutes; and, consequently, the new moon will be thus kept to the 21st day of each civil month for a long time together. However, to make them keep conflux pace with the civil months, at the end of each 945 months, a month of 29 days must be added; or else every 33rd month must consist of 30 days.

This was the month in civil or common use among the Jews, Greeks, and Romans, till the time of Julius Cæsar.

MONTHS, Civil solar, are to consist alternately of 30 and 31 days, excepting one month of the twelve, which for every fourth year should consist of 30 days, and for the other years of 29. The form of civil months was introduced by Julius Cæsar.

Under Augustus, the sixth month, till then from its place called Sextilis, was denominated Augustus in honour of that prince; and, to make the compliment yet the greater, a day was added to it; so that it now consisted of 31 days, though till that time it had only consisted of 30; to make up for which, a day was taken from February: so that hereafter it only consisted of 28 days, and every fourth year of 29; though before it had consisted of 30 days. And such are the civil or calendar months which now obtain through Europe. See CALENDAR.

MONTH, Philosophical, among Alchemists, is the space of forty days and nights.

MONTH, Draconic, Embolistic, Fence, Twelve. See the adjectives.

MONTH Climate. See CLIMATE.

MONTH, Paris in Geography, a town of France, in the department of the Ardeches, and chief place of a canton, in the district of Mézières; 9 miles N. of Charleville. The place contains 1415, and the canton 5750 inhabitants, on a territory of 1375, kilometres, in 11 communes.

MONTHLY COURSES. See MENS.

MONTHHOIS, in Geography, a town of France, in the department of the Ardennes, and chief place of a canton, in the district of Vouziers. The place contains 610, and the canton 6606 inhabitants, on a territory of 195 kilometres, in 21 communes.

MONTHMET, a town of France, in the department of the Aude, and chief place of a canton, in the district of Carcassonne. The place contains 2760, and the canton 4354 inhabitants, on a territory of 3774, kilometres, in 18 communes.

MONTHUREUX-SUR-SAONE, a town of France, in the department of the Vosges, and chief place of a canton, in the district of Mirecourt; 4 miles S.S.W. of Darny. The place contains 1351, and the canton 7316 inhabitants, on a territory of 255 kilometres, in 15 communes.

MONTI BAY. See Port MELGRAVE.

MONTIA, in Botany, named by Micheli in honour of a very meritorious author, Joseph Monti, professor of Botany at Bologna, who flourished early in the last century. In 1719, he published an account of the grasses in his neighbourhood, and this treatise is one of the earliest attempts to illustrate the characters of this curious but difficult tribe of plants. Scheuchzer, Micheli, and Monti, devoted their several labours to this subject much about the same period.—Mich. Nov. Gen. 17. Linn. Gen. 41.

Gen. Ch. Col. Perianthus inferior, of two, ovate, concave, obtuse, erect, permanent leaves. Car. of one petal, cloven into five segments, of which the three alternate ones are smaller, and each bearing a filaments. Stem. Filaments three, capillary, the length of the corollas, and inserted into it; anthers small. Petl. German superior, top-shaped; styles three, hairy, spreading; frigates simple. Perie Capítulo top-shaped, obtuse, inclines by the calyx, of one cell, and three valves. Seeds three, roundish.

Obv. The calyx is frequently found with three leaves instead of two, in which case there are often five filaments.

Eff. Ch. Calyx of two leaves. Corolla of one irregular petal. Capulus with one cell, three valves, and three stamens.

—Found chiefly in wet places, on the gravelly parts of heaths where the water stagnates in winter; also in rivulets and marithes. It flowers in the spring, and ripens its seeds in June. Root annual, fibrous. Stem much branched from its very base, prostrate in the lower part, and frequently taking root at the joints, leafy, tinged with red. Leaves opposite, ovate, entire. Flowers stalked, in terminal clusters, white, expanding only in the brightest sunshine, at other times nearly closed; whence we presume its vulgar appellation. Blinks.—Seeds kidney-shaped, large, rough, black.

—The whole herb is smooth and somewhat succulent, much resembling Elatine Hydrophyllar in its general aspect. Dr. Smith observes that "Micheli's name of Montia was retained by Linnæus, in preference to Camararia previously given to this genus by Dillemius, because Plomer had already given the latter name to an American plant, more worthy to commemorate so great a botanist as Camararia."

Monticelli, Angelo Maria, in Biography, first appeared on the opera stage at Rome in the year 1720, and having a beautiful voice and figure, began in that city, where no women are allowed to mount the stage, by representing female characters. His voice was clear, sweet, and free from defects of every kind. He was a fluent performer, and never hazarded any difficulty which he was not certain of executing with the utmost precision. To his vocal excellence may be added the praise of a good actor; so that nothing but the recent remembrance of the gigantic talents of Farinelli, and the grand and majestic style of Senebino, whom immediately preceded him, could have left an English audience any thing to wish.

He was invariably perfect as a singer and actor in every part in which we saw and heard him perform; but in the opera of Olimpie, set by Pergolesi, whose music, in 1742, was heard in England for the first time, in the parting scene between Megacco and Acrilea, his singing and acting were exquisite, particularly in the aria parlante, "Se cerca fe dice..."

He arrived here with Amorevoli and the Vicoconti, and remained in England in great and just estimation, till the rebellion broke out in 1745, when popular prejudice running strong against foreign performers, who were Roman Catholics, the Lyric theatre was shut up till the next year, 1746, when...
Monticelli performed in Gluck's opera of "La Caduta de' Giganti," and in "Artamise."

He sung in an opera composed by Bononcini in Vienna, at the peace in 1748; went to Venice the next year; then quitting that city, he went to Dresden, where he died in 1758.

MONTICEILLO, in Geography, a town of Corsica; 10 miles E.N.E. of Calvi.  

MONTIEL, a town of Spain, in New Castile, formerly the see of a bishop; 18 miles W.S.W. of Alcazar.

MONTIERS-SUR-SAUX, a town of France, in the department of the Meuse, and chief place of a canton, in the district of Bar-sur-Oise; nine miles W. of Gondrecourt. The place contains 1271, and the canton 1723 inhabitants, on a territory of 200 kilometres, in 14 communes.

MONTIERENDER, a town of France, in the department of the Upper Marne, and chief place of a canton, in the district of Waffly; 12 miles S. of St. Dizier. The place contains 1478, and the canton 8133 inhabitants, on a territory of 2724 kilometres, in 15 communes.

MONTIERRA, a town of the island of Sardinia; nine miles E.S.E. of Bosa.

MONTIFRINGILLA, in Ornithology, the name of a bird, known in English by the name of the Bramble, Brambling, or Mountain-Finch; and called by the ancients, Opposita. It is a species of Fringilla; which fee.

MONTIGNAC, in Geography, a town of France, in the department of the Dordogne, and chief place of a canton, in the district of Sarlat; 12 miles N. of Sarlat. The place contains 3000, and the canton 12688 inhabitants, on a territory of 245 kilometres, in 14 communes. N. lat. 45° 3' E. long. 1° 34',

MONTIGNY-SUR-ARTIB, a town of France, in the department of the Côte-d'Or, and chief place of a canton, in the district of Chatillon; nine miles N.E. of Chatillon. The place contains 690, and the canton 7860 inhabitants, on a territory of 3223 kilometres, in 16 communes.

MONTIGNY-SOURCE-MENDE, a town of France, in the department of the Upper Marne, and chief place of a canton, in the district of Langres; 12 miles W.N.W. of Bourbounais. The place contains 1061, and the canton 5714 inhabitants, on a territory of 1921 kilometres, in 15 communes.

MONTILLA, a town of Spain, in the province of Cordova, containing two parishes, seven convents, and about 4000 inhabitants; 18 miles S.S.E. of Cordova. N. lat. 37° 4' 56", W. long. 4° 30'.

MONTINIA, in Botany, named by Thunberg in honour of his much esteemed friend Dr. Laurence Montin, a distinguished pupil of Linnaeus, who died in 1785, aged 62. This gentleman was the maternal uncle of the late learned Mr. Dryander, so well known to all the botanists of this country, and who published various botanical works in the Stockholm Transactions. His inaugural dissertation, published under the presidency of Linnaeus, March 28th, 1750, is a learned treatise on the genus Spaladium, with various botanical remarks made in a journey to Lapland, undertaken at the perusion of his great preceptor. This dissertation is printed in the second volume of the Amoenitates Academicae. —Thunb. Nov. Gen. 27; Linn. Suppl. 69, Schreb. 681. Mart. Mill. Dict. v. 3. Jull. 318. Lamarck Illust. t. 868. Gurt. t. 33. —Chas and order, Tetrandria Menogynia. Nat. Ord. Calycanthes. Linn. Onagra. Jaff.

Ohh. This genus was originally referred to the class Dioces, where it is to be found in all the authors above quoted. We think it most convenient however to place it in Tetrandria, whether it has been referred by Dr. Smith, who found both flamin and pistils, or at least their rudiments, in every flower which he examined.

MONTJOYE, in Geography, a town of France, in the department of the Poitou, and chief place of a canton, in the district of Aix-la-Chapelle. The place contains 2912, and the canton 15,522 inhabitants, in 27 communes.

MONTJOUET, a town of France, in the department of the Dordogne; 10 miles S.E. of Auln.

MONTJOY, L.A., a town of France, in the department of the Lot and Garonne; eight miles S.E. of Nérac. N. lat. 44° 4'. E. long. 1° 30'.

MONTIRA, in Botany, so named by Aublet, after Montf. de Monti, member of the Superior Council of Cayenne, one of his patrons, on whose estate at Aourora the plant was found. —Aubl. Guian. v. 2. 637. Juss. 122. Lamarck Illust. t. 523. —Chas and order, Didynamia Angiosperma. Nat. Ord. Peronates. Linn. Stropharius, Juss.

Gen. Ch. Cal. Perianth inferior, of one leaf, in five deep, lanceolate, acute, spreading, nearly equal segments. Cor. of one petal, funnel-shaped; tube much longer than the calyx, twining upwards, slightly inflated, incurved; limb spreading, in five deep, roundish, acute, equal lobes. Stem. Filaments four, much shorter than the tube, inserted into its lower part, thread-shaped, smooth, two of them longest; anthers oblong, simple, of two cells. Pftl. German superior, of two round lobes, seated on a glandular disk; style cylindrical, the length of the flamin; stigma capitate, furrowed. Peric. Capsule of two round lobes and two cells, with four valves, separating longitudinally at the outer side. Seeds very numerous, very minute, attached to the inner angle of the cells.

1. M. guianensis. Aubl. t. 257. —Inhabited by Aublet in a cotton-field, at the place above-mentioned, and no where else, flowering in June. Root fibrous, probably annual. Stem leaven or eight inches high, slightly forkted, leavy, smooth, with four sharp angles. Leaves opposite at each joint, slitile,
MONTIÈRE, in Geography, a town of France, in the department of the Mela; seven miles S. of Brecia.

MONTIVILLIERS, a town of France, in the department of the Lower Seine, and chief place of a canton, in the district of La Havre; six miles N. of Havre. The place contains 4000, and the canton 14,695 inhabitants, on a territory of 1224 kilometres, in 20 communes. N. lat. 49° 35’ E. long. 0° 17’. MONTLIEU, a town of France, in the department of the Lower Charante, and chief place of a canton, in the district of Jonzac; 33 miles S.S.E. of Saintes. The place contains 655, and the canton 8972 inhabitants, on a territory of 1074 kilometres, in 15 communes. N. lat. 45° 15’ W. long. 0° 11’.

MONT-LOUIS, a town of France, in the department of the Eastern Pyrenees, and chief place of a canton, in the district of Prades; 15 miles W.S.W. of Prades. The town is well laid out, and fortified with a citadel, arsenal, magazines, &c. The place contains 418, and the canton 6150 inhabitants, on a territory of 350 kilometres, in 17 communes.

MONTLUC, Blaise de, in Biography, a celebrated French general, was born in 1500, of a noble family near Condé. He rose through the different ranks in the army to that of marshal in France. His first services were in Italy, and at the battle of Pavia, in 1525, he was taken prisoner. In the wars of Picardy he served with great reputation; and in 1546, he recovered Boulogne from the English. The city of Sienna in Tuscany, having driven out the imperial garrison, and solicited the protection of France, Montluc was appointed to command the forces sent thither in 1554. He sustained a siege of eight months against the imperial army commanded by the marquis of Marigny, who was obliged, after several attacks, to retreat from the siege into the blockade. It was not till the garrison and inhabitants had endured the utmost extremity of famine, that the place capitulated, when Montluc and his troops marched out with the honours of war. He commanded in Guienne, during the wars which ravaged France on account of religion, and defeated the Calvinists in several actions. But he was guilty of great cruelties to the vanquished. At the siege of Rages, in 1570, he was febrifugous, wounded in the face, and obliged always to wear a mask to hide his deformity. He died on his estate in 1573. At the age of 75 he wrote the history of his own life, printed at Bourdeaux, in 1592, folio, and several times since. Morier.

MONTLUTEYON, in Geography, a town of France, and principal place of a district, in the department of the Allier; 33 miles E. of Gueret. The place contains 4420, and the canton 13,784 inhabitants, on a territory of 315 kilometres, in 16 communes. N. lat. 45° 25’ E. long. 2° 40’.

MONTLUCON, a town of France, in the departement of the Allier, and chief place of a canton, in the district of Autun. The place contains 9141, and the canton 11,328 inhabitants, on a territory of 185 kilometres, in 15 communes.

MONTMARTRE, a town of France, in the department of the Allier, and chief place of a canton, in the district of Montluc; 22 miles S.W. of Moulins. The place contains 895, and the canton 9976 inhabitants, on a territory of 355 kilometres, in 19 communes. N. lat. 49° 17’ E. long. 3° 2’.

MONTMARTIN-SUR-MEN, a town of France, in the department of the Channel, and chief place of a canton, in the district of Coutances; four miles S.W. of Coutances. The place contains 1168, and the canton 12,776 inhabitants, on a territory of 137½ kilometres, in 11 communes.

MONTMEDDY, a town of France, and principal place of a district, in the department of the Meuse; situated on the river Cher, and divided by it into Upper and Lower; 21 miles N. of Verdun. The place contains 1896, and the canton 11,491 inhabitants, on a territory of 245 kilometres, in 27 communes. N. lat. 49° 28’ E. long. 5° 26’.

MONTMEILLON, a pleasant French muscadet wine, from the neighbourhood of Riez, in Provence.

MONTMELIAN, in Geography, a town of France, in the department of Mont-Blanc, and chief place of a canton, in the district of Chambery; situated near the Isère, and containing one church and two convents; the adjacent country is agreeably diversified with hills and mountains, and for six miles about it covered with vine, which yield good wine. The fortress is on an eminence, and inaccessible except towards the town, and is well garnished with means of security and defence. The castle is the residence of the governor. The importance of this place depends upon its being the key of the whole country, and therefore it is usually well garrisoned; seven miles S.S.E. of Chambery. The place contains 1165, and the canton 11,239 inhabitants, on a territory of 1724 kilometres, in 18 communes.

MONTMIRAIL, a town of France, in the department of the Marne, and chief place of a canton, in the district of Epernay; 12 miles N.W. of Sezanne. The place contains 2298, and the canton 8909 inhabitants, on a territory of 2674 kilometres, in 25 communes.——Also, a town of France, in the department of the Sarthe, and chief place of a canton, in the district of Mame; 24 miles N.E. of Le Mans. The place contains 804, and the canton 7431 inhabitants, on a territory of 140 kilometres, in 10 communes. N. lat. 48° 52’ 8” E. long. 3° 32’ 16”.

MONTMIRAIL, Célestin de, a town of France, in the department of the Tarn, and chief place of a canton, in the district of Gaillac. The place contains 2522, and the canton 9715 inhabitants, on a territory of 1624 kilometres, in 15 communes.

MONTMIREY-LE-CHATEAU, a town of France, in the department of the Jura, and chief place of a canton, in the district of Dole; seven miles N. of Dole. The place contains 416, and the canton 6594 inhabitants, on a territory of 120 kilometres, in 19 communes.

MONTMOREAU, a town of France, in the department of the Charents, and chief place of a canton, in the district of Barbezieux; 12 miles E.S.E. of it. The place contains 411, and the canton 9449 inhabitants, on a territory of 220 kilometres, in 16 communes.

MONTMORENCI, Anxe de, in Biography, second son of William, lord of Montmorency, representative of one of the most illustrious houses in France, was born in the year 1493. He received the female christian name Anne from his godmother, queen of France. He was brought up at the court of Francis I., and was present at the battle of Marignan, in 1515. He was one of the train of that king, at the celebrated interview with Henry VIII., between Guise and Arche, and was afterwards sent to England to prevent the machinations of Charles V. He was made marshal of France in 1522, and in the following year oblied the confidant of Bourbon to raise the siege of Marilcks. For his great services the government of Languedoc was conferred upon him, and in 1525 he was made prisoner with his king at the battle of Pavia. After his liberation he was employed...
employed on many important occasions, and contributed to the ruin of the army with which the emperor, in person, had invaded Provence. By his sovereignty, Francis, he was entrusted with the sword of confidant in 1538, whom he accompanied to Nice, where a truce was signed between the two rival monarchs, in the presence of the pope. When Charles V., on occasion of the revolt of the people of Ghent, had requested a passage through France, under promise to restore Milan, Montmorency advised his sovereign to rely on his own strength, which afterwards excited the displeasure of Francis against his confidant, who was banished from court, and not permitted to return till the accession of Henry II. By this prince he was treated with every respect and confidence, and was sent by him, in 1548, to Guinette to suppress an insurrection on account of the tax on salt, on which occasion he treated the people of Bourdeaux with great severity. After this he was again disgraced by the intrigues of Catherine de Medicis, Charles IX. recalled him, and he served against the Calvinists, disfiguring their assemblages, and burning the pulpits of their ministers; but in the year 1562 he was taken prisoner by them at the battle of Dreux, which battle was remarkable for the capture of the opposing generals Condé and Montmorency. Being liberated the following year, he took Havre-de-Grace from the English. On the renewal of hostilities between the two religious parties, he attacked the army of the prince of Condé at St. Dennis, in November 1567, and lost his life in that action. He received eight wounds, of which the last was a pistol-shot in his loin, but he still retained strength enough to beat out the teeth of his assailant with the hilt of his sword. Finding himself mortally wounded, he began to prepare for his last moments: a monk offered to affix him in this important business, on which the dying general said, "Do you think that a man who has lived four-score years with honour does not know how to die in a quarter of an hour?" Almof within that period he expired, at the age of 74, and was interred with great honours at Paris. He was one of the most illustrious characters of the age in which he lived, and was accounted very pious, though his religion was much more that of a father than a Christian. Nevertheless he has obtained the title of a "Christian hero." He never omitted the repeating of his paternal prayers, but in the midst of them he would frequently order his soldiers to be flogged, or shot, or whole villages to be burnt, and then proceed in his prayers with the most perfect fang froide. The political maxim by which he was governed was "One faith; one law; one king," and he readily supported the royal authority amidst all the turmoils and vicissitudes of faction. Moreni. Hisk. of France, 1790.

MONTMORENCY, Henry, Duke of, grandson of the preceding, was born in 1505. He was, in early life, distinguished for a fine person, joined to the splendid qualities which attract general admiration. He was raised to the office of high admiral of France at the age of sixteen, and served with great courage and success against the Protestants in Languedoc, and other places. For the important services which he performed, he was rewarded with the title of marshall, added to the government of Languedoc, and he might have attained the highest honours in the way of his duty, when disappointment of the office of confidant rendered him a most contented man, and brought on his ruin. He excited an insurrection, and put himself at the head of a body of forces, with which he encountered marshall Schomberg. In the action he was surrounded and taken prisoner. Knowing the rigour of Richelieu's government, he, from that hour, had no hopes of a pardon. He was brought to trial, and convicted; and on being advised to appeal to a higher court, he said, "I will not use any chicanery even to save my life." His guilt was clear, but no criminal was ever more pitied, and no one for whom more intercession was made. He died with that humility and resignation which a sense of religion inspires; and, leaving no issue, the principal branch of the house of Montmorency terminated with him. Though he had not been faithful as a husband, yet his wife cherished his memory with so much affection as to quit the world, and retire into a convent. Moreni.

MONTMORENCY, Matthew de, called the Great, a distinguished general, who signalized his valour at the battle of Pont a Bouvines in 1214, and the year following was employed against the Albigenes in Languedoc, for which services he received the sword of confidant of France, and was made general of the army. He afterwards took several places from the English. Louis VIII. committed his son to the care of the confidant, who, by his prudence, dissolved a league which had been formed against the queen mother, during the minority of Louis IX. He died in 1230. Moreni.

MONTMORENCY, in Geography, a town of France, and seat of a tribunal, in the department of the Seine and Oise; seven miles N. of Paris. N. lat. 48° 59'. E. long. 2° 24'.

MONTMORENCY, a river of Canada, which, after pursuing an irregular course through a woody and rocky country, runs into the river St. Laurence, about seven miles below Quebec. It descends into the St. Laurence from the brink of a precipice in an uninterrupted and nearly perpendicular fall of 240 feet, fars Mr. Weld, or as others have laid, 264 feet. The breadth of the river at the top, from bank to bank, is about 50 feet. In its fall, the water has the appearance of snow, as when thrown in heaps from the roof of a house, and it seemingly descends with a very slow motion. The spray at the bottom is considerable, and when the sun happens to shine bright in the middle of the day, the prismatic colours are exhibited in it in all their variety and splendour. At the bottom of the precipice the water is confined in a fort of bains, as it were, by a mass of rock, extending nearly across the fall, and out of this it flows with a gentle current to the St. Laurence, which is about 300 yards distant. The banks of the Montmorency below the precipice are nearly perpendicular on one side, and on both inaccessible, so that if a person be desirous of getting to the bottom of the fall, he must descend down the banks of the St. Laurence, and walk along the margin of that river, till he comes to the chasm through which the Montmorency flows. To a person falling along the St. Laurence, and passing the mouth of the chasm, the fall appears in great beauty. Weld's Travels, vol. i, p. 57.

MONTMORENCY, a town of Lower Canada, on the forementioned river. It was on some eminences near this town, that general Wolfe began his attack on the French at Quebec, which was unsuccessful; five miles N.E. of Quebec.

MONTMORILLO, a town of France, the principal place of a district, in the department of the Vienne, on the Gartempe; 22 miles S.E. of Poitiers. The place contains 3056, and 3025 inhabitants, on a territory of 335 kilometres, in nine communes. N. lat. 46° 26'. E. long. 0° 57'.

MONTMORIN, a town on the N. bank of Ohio river, 18 miles below Pittsburg, situated on a beautiful plain, very fertile, and abounding with coal.

MONTMORET, Peter Raymond de, in Biography, an able mathematician, was born at Paris in the year 1678. He was intended for the profession of the law, to enable him to qualify for a place in the magistracy. Finding his difficulty to
to this plan insuperable, and that his father would not relax in his intentions, he withdrew into England, whence he sailed over into the Low Countries, and travelled into Germany, where he resided with a near relation, M. Chambon, the preludium of France at the Diet of Ratisbon. He returned to France in 1699, and in a very short time his father died, leaving him an ample fortune, and at perfect liberty to pursue the bent of his inclinations. From this time he devoted his talents to the study of philosophy and the mathematics, under the direction of the celebrated "father Malebranche," to whom he had, some years before, felt greatly indebted for the conviction of the truth of Christianity, by perusing his work on "The Search after Truth." In 1700 he went a second time to England, and on his return resumed the ecclesiastical habit, and succeeded to a canonry in the church of Notre-Dame, at Paris, on the resignation of his younger brother. About this time he printed, at his own expense, the works of M. Guicciarelli on "The Application of Algebra to Geometry," and that of Newton on the "Quadrature of Curves." In 1703 he published his "Analytical Essay on Games of Chance," which was most favourably received by men of science in all countries, and contributed greatly to increase the number of his acquaintance and correspondents. A second edition of the "Games of Chance," enlarged and improved, he published in 1714. In the following year he paid a third visit to England, for the purpose of observing a solar eclipse, which was to be total at London, and during his stay in the metropolis of England he was elected a fellow of the Royal Society, to which learned body he soon afterwards transmitted an important treatise on "Infinite Series," which was inserted in the Philosophical Transactions for the year 1717. He was elected an associate of the Royal Academy of Sciences at Paris in 1716, and died at the early age of forty-one, of the small-pox. He sustained all the relations of life in the most honourable manner, and though subject to fits of passion, yet his anger soon subsided, and he was ever ashamed of the irritability of his temper. He could resolve the most difficult problems in company, and among the noise of playful children. He was employed several years in writing "A History of Geometry," but he did not live to complete it. Moreiri.

Montmort, in Geography, a town of France, in the department of the Marne, and chief place of a canton, in the district of Epernay. The place contains 622, the canton 7075 inhabitants, on a territory of 2874 square miles, in 25 communes.

Montare, a town of France, in the department of the Loire and Cher, and chief place of a canton, in the district of Vierdome. The place contains 2260, and the canton 11,475 inhabitants, on a territory of 2424 square miles, in 20 communes.

Montona, a town of Ilulia; 16 miles E.S.E. of Umbria.

Montona, an excellent sort of white wine, the produce of Alcamia, in the island of Majorca.

Montone, in Geography, an island in the gulf of Venice, near the coast of Friuli. N. lat. 45° 50'. E. long. 31° 9'.—Allo, a river of Italy, which rises in the Apennines, and runs into the Adriatic below Ravenna.

Montong, a town of Africa, near cape Lopez Gonzales; 10 miles N. of Olibato.

Mont pour, a mountain of France, in the department of the Puy de Dome, about 1500 toises above the level of the earth, abounding in curious plants and mineral springs.

Montorio, a town of Italy, in the Veronese; four miles E. of Verona.—Allo, a town of Naples, in Abruzzo Ultra; six miles S.S.W. of Ternano. N. lat. 42° 53'. E. long. 13° 51'.

Montoro, a town of Spain, in the province of Cordova.

Montour, a town of Hindostan, in Oude; 35 miles W. of Currah.

Montoyto, a town of Portugal, in Alentejo; 13 miles E. of Evora.

Montagnote, the lost of the invulnerable, an emience chosen without the reach of the cannon of a place besieged: where curious persons poll themselves to see an attack, and the manner of the siege, without being exposed to danger.

Montpenn, in Geography, a town of France, in the department of the Aveyron; 12 miles S. of Millau.

Montpelier, in Geography, a city of France, and capital of the department of the Herault. This city was built on a hill near the river Lez, after Charlemagne had demolished Maguelone, the asylum of the Saracens in their depredations, and the bishop's see was established in this city. An univerity for the study of medicine was founded here in 1180, and an academy of sciences was instituted in 1736. The streets of this city are narrow, but the houses good; the citadel commands the town and its vicinity. The chief manufacture of this place is verligris, and its trade, which is considerable, confits of this article, and wool brought hither from the Mediterranean; and also wine, aqua vitae, Hungarian water, cinnamon water, capillaire, essence of bergamot, lemons, cec. and great quantities of woollen carpets, stuffs, and silk flossings. These commodities are conveyed by the canal to Cotte, which is the sea-port of Montpelier. The city is divided into three sections; occupying a territory of 270 kilometres; the first contains 15,000, and its canton 15,000 inhabitants, in one commune; the second section contains 13,419, and its canton 14,990 inhabitants, in 5 communes; and the third section contains 15,049, and its canton 15,296 inhabitants, in 11 communes. The environs of this city are delicious and highly ornamented, and its aqueduct is extensive: it has been particularly celebrated for the fertility of its air, and its ancient school of medicine. The prospect is singularly extensive and interesting; as it embraces the Pyrenees on one side, and on the other the grand summits of the Alps. Its temperature, according to the estimate of Kirwan, from 1777 to 1781, was 69.87. The standard temperature being 59°, Montpelier is 1.87 warmer. Its distance from the Atlantic is 260 miles, by which it should be cooled 1.6, but its temperature is governed chiefly by that of the Mediterranean, which, lying to the south of it in still warmer latitudes, communicates its temperature to it both summer and winter; but winters, during which evilly winds from the mountains of Savoy and Piedmont prevail, must be much colder. The soil on which Montpelier stands, which is sandy and rocky, must contribute much to its heat. N. lat. 43° 36'. 29'. E. long. 3° 51'. 45'.

Montepell, a pottle of America, in Caledonia county, Vermont, on the N.E. side of Onion river; 43 miles W. from lake Champlain.

Montpellas, a town of France, in the department of Mont Blanc; 7 miles E.N.E. of Chambery.

Montpensier, Anne Marie Louisa, Duchesse de, in Biography, the daughter of Gallon, duke of Orleans, brother of Louis XIII., was generally known by the name of Madame, and took the part of Condé in the civil wars. She caused the cannon of the Baltic to be fired on the French troops, and flew on many occasions a most impetuous spirit. After trying in vain to elpeue several foreign
reign princes, among the rest Charles II. of England, she
secretly married the count de Launay, who used her with
great disrespect and cruelty. She died in 1693. Made-
moiselle wrote her memoirs, which are curious, and full of
anecdotes, 8 vols. 12mo.; she was also the author of two
books of devotion. Moreri.

Montpensier, in Geography, a town of France, in the
department of the Puy-de-Dôme; 9 miles N.N.E. of
Riom.

Montpezat, a town of France, in the department
of the Ardèche, and chief place of a canton, in the district
of L'Argentière; 16 miles W. of Privas. The place con-
tains 2115, and the canton 7709 inhabitants, on a territory
of 235 kilometres, in 7 communes. — Also, a town of
France, in the department of the Lot, and chief place of a
canton, in the district of Montauban; 14 miles N.N.E. of
Montauban. The place contains 2684, and the canton
7091 inhabitants, on a territory of 140 kilometres, in 9
communes. N. lat. 44° 14'. E. long. 1° 34'.

Montpont, a town of France, in the department of
the Artois and Loire, and chief place of a canton, in the
district of Louhans; 7 miles S.S.W. of Louhans. The
place contains 2146, and the canton 5974 inhabitants, on a
territory of 175 kilometres, in 5 communes. — Also, a town
of France, and seat of a tribunal, in the department of the
Dordogne; 16 miles N.W. of Bergerac. N. lat. 44° 59'.
E. long. 0° 14'.

Montquillet, a town of Perpignan, in the
N. coast of the Perisan gulf; 120 miles S.S.W. of
Schipras.

Montrachet, one of the choicest forts of white
Burgundy, the produce of Beaune, in Poligny. It is much
esteemed both in France and abroad.

Montreal, in Geography, a town of France, in
the department of the Aude, and chief place of a canton,
in the district of Carcassonne; 9 miles W. of it. The
place contains 3103, and the canton 6585 inhabitants, on a
territory of 140 kilometres, in 9 communes. — Also, a town
of France, in the department of the Gers, and chief place
of a canton, in the district of Condom; 7 miles W. of
Condom. The place contains 5565, and the canton 11,090
inhabitants, on a territory of 237½ kilometres, in 12
communes. N. lat. 43° 58'. E. long. 0° 16'. — Also, a town
of France, in the department of the Sarre; 17 miles W. of
Coblentz.

Montreal, a town of America, reckoned the second
city in rank in Lower Canada, situated on an island in the
river St. Lawrence; and deriving its name from a very high
mountain, about the middle of it. It lies on the opposite
side of the river to La Prairie; the two towns being 9 miles
apart, and the river about 24 miles wide. The current of
the river is here very strong, so that vessels encounter im-
mense difficulties in arriving at Montreal; hence it is that
the passage from Quebec to Montreal is generally more
tedious than that across the Atlantic, and therefore those
ships which trade between Europe and Montreal never
attempt to make more than one voyage in the year. Not-
withstanding the rapidity of the stream, the channel of the
river is very deep, and particularly opposite to the town;
so that the largest merchant-vessels can there lie close to
the banks, which are in their natural state, that they may
be nearly touched with the hand from the shore. This town
was laid out in pursuance of the orders of the emperors of
France, which were, that a town should be built as high
up on the St. Lawrence as it were possible for vessels to go
by sea; and his commands were strictly observed. The
town at present contains about 1200 houses, of which 500
only are within the walls, the rest being in the suburbs,
which commence from the N., E., and W. gates. The
houses in the suburbs are mostly built of wood, but the
others are all of stone; none of them are elegant, but many
of them are comfortable habitations. In the lower part of
the town, towards the river, where most of the shops stand,
they have a very gloomy appearance, and look like so many
prisons, as they are all furnished, at the outside, with iron
shutters to the doors and windows, which are regularly
closed towards the evening, in order to guard against fire,
from which the inhabitants have often suffered; and, there-
fore, as an additional security they cover the houses with
tin-plates instead of shingles. By law they are obliged to
have one or more ladders, in proportion to the size of the
house, always ready on the roofs. The streets are all very
narrow, three of them run parallel to the river, and
these are intersected by others at right angles, but not at
regular distances. On the side of the town, farther from
the river, is a small square, called "La Place d'Armes," de-
signed originally for the military to exercise in it; though
not now used for that purpose. On the opposite side
of the town, towards the water, is another small square,
in which the market is held. In Montreal there are four
churches, one for English Episcopalians, one for Presby-
terians, and four for Roman Catholics. The cathedral
church, belonging to the latter, is a very spacious building,
containing five altars, all of which are very richly decorated.
Almost all the shrines, marriages, and burials of the
Roman Catholic inhabitants are performed in this church,
on which occasions, as well as before and during the masses,
they always ring the bells, which are five in number, to
the annoyance of those who are not fond of discordant sounds.
The funerals are conducted with great ceremony; the corpse
being always attended to the church by a number of
priests chanting prayers, and by little boys in white
robes and black caps, carrying wax-lights. In Montreal
there are also four convents. The barracks are agreeably
situated near the river, at the lower end of the town; they
are surrounded by a lofty wall, and calculated to contain
about 300 men. The walls round the town are generally
mouldering, and some of them are in ruins; although the
gates are quite perfect. The walls were erected as a de-
fence against the Indians, and they have been found useful
even so late as the year 1760. They were also useful on
occasion of the large fairs held in Montreal, to which the
Indians from all parts resorted with their furs; because they
enabled the inhabitants to flut them out at night, when
danger might have attended their remaining in a flate of
intoxication, to which they are much addicted. However,
Montreal has been always an easy conquest to regular troops.
The greater number of the inhabitants consists of perfons
of French extraction; all the eminent merchants, however,
and the principal people of the town, are English, Scotch,
Irish, or their descendants, all of whom pass for English
with the French inhabitants. The French retain, in a great
measure, the manners and customs, as well as the language,
of their ancestors. The people of this town are, in general,
remarkably hospitable and attentive to strangers; they are
fondable among themselves, and extravagantly fond of con-
vivial amusements.

The island of Montreal is about 28 miles in length, and
16 in breadth. Its soil is luxuriant, and in some parts much
cultivated, and thickly inhabited. It is agreeably diversified
with hill and dale, and towards its centre, in the vicinity of
the town, there are two or three mountains. The base of
the highest, at the distance of a mile, from which the town
is named, is surrounded with neat country houses and
gardens;
of a district, in the department of the Straits of Calais, about six miles from the sea. This town is fortified, lies on an eminence, and contains several churches. The place includes 3534, and the canton 14,129 inhabitants, on a territory of 210 kilometres, in 25 communes. N. lat. 56° 28'. E. long. 1° 51'.

MONTECHU-Pelloy, a town of France, in the department of the Maine and Loire, and chief place of a canton, in the district of Saumur; 7 miles S. of Saumur. The place contains 1614, and the canton 16,811 inhabitants, on a territory of 210 kilometres, in 25 communes.

MONTECHU-Roisin, a town of France, in the department of the Vienne, in which was formerly a mint for coinage; 9 miles S.W. of Poitiers.

MONTRICHARD, a town of France, in the department of the Loire and Cher, and chief place of a canton, in the district of Blois; 15 miles S. of Blois. The place contains 1814, and the canton 10,836 inhabitants, on a territory of 245 kilometres, in 14 communes. N. lat. 47° 20'. E. long. 1° 16'.

MONTROSE, a royal borough and sea-port town, situated on the northern ocean, in the parish of Montrose, and county of Forfar, Scotland, is one of the first provincial towns of its size in that kingdom, or perhaps in the whole island. It consists of a fine spacious main street, with bye-lanes, the houses of which are in general well built, but, like the Flemish towns, have their gables turned towards the street. This place is more distinguished for its gaiety, and as the residence of persons of opulence and fashion, than for its commerce and industry. It has a theatre, monthly assemblies, and other pleasures of amusement; and, during the last twenty years, has been remarkable for its well attended races. In the middle of the principal street stands the prison, formerly the old town-hoose. The new town-hoose is a new edifice, having piazzas below, and rooms for public business above. The parish church, a large edifice of late erection, is finished with great elegance. The episcopal chapel, situated in the Links, to the eastward of the town, is a neat building; as is likewise the Lunatic hospital, erected in 1779, not only for the reception of lunatics, but also of indigent sick, or as a dispensary for the relief of out-patients. The public schools here are remarkable both for the accommodation they afford, and for the excellent mode of education adopted in them. In 1785 a public library was established by subscription, on a most liberal plan, which now contains several thousand volumes, by the best authors. Many improvements have been made in this town within these few years; in particular, a handsome bridge has been thrown over each of the two rivers, the North and South Esk, which flow on either side of it. From the bridge over the South Esk a new street now extends to the middle of the main one, which was formed by cutting through a considerable hill, called the Port-hill. The harbour of Montrose is very commodious, and capable of receiving ships of large burden; and there is, besides, a safe anchorage in the river, a little below the town. A considerable number of vessels belong to this port, most of them employed in the coaling and Baltic trade. There are here a dry and wet dock, for building and repairing ships. The principal manufactures are of linen yarn and thread, fleeting, and fail-cloth.

Montrose is governed by a provost, three bailies, a dean of guild, and a treasurer, assisted by thirteen councillors. It unites with Aberdeenshire, Birnie, Brechin, and Arbroath, in electing a representative in the imperial parliament. The resident population here, according to the parliamentary returns of 1801, amounted to 7074 persons, 3880

Gardens: on the side towards the river is an old monastery, with extensive enclosures walled in; and the open park is covered with a rich verdure, and it is encircled by woods, among which perfumes may roam about for miles, shaded by the lofty trees from the rays of the sun. The wine from hence, says Mr. Weld, is good beyond description. A prodigious expanse of country is laid open to the eye, with the noble river St. Lawrence winding through it, which may be traced from the remotest part of the horizon, and which, flowing in, pales down the tremendous rapids above the town, when it is precipitated over huge rocks, with a noise that is heard even up the mountain. On the left below appears the town of Montreal, with its churches, monasteries, shining spires, and the flaming under its old walls; several little islands in the river near the town, partly improved and partly overgrown with wood, add greatly to the beauty of the scene. La Prairie, with its large church on the distant side of the river, is seen to the greatest advantage, and beyond it is a range of lofty mountains, which terminates the prospect.

The trade chiefly carried on at Montreal is that of fur; and here the greatest quantity of the furs is shipped, which are sent from Canada to England. For an account of the fur trade, as it is carried on by the Hudson's Bay company, and by the N.W. company, see the article Fur-trade.

Montreal, a river which runs north-westward into Lake Superior, in Upper Canada, on the southern side of the lake.

Montreal Bay, a bay that lies towards the E. end of Lake Superior, having an island at the N.W. side of its entrance, and N.E. of Caribou island. N. lat. 47° 9'. W. long. 84° 50'.

Montreal Isle, a small island on the E. end of Lake Superior, situated between the mouths of the rivers Montreal and Charrion, and near the shore.

Montredon, a town of France, in the department of the Tarn, and chief place of a canton, in the district of Castres. The place contains 4558, and the canton 5725 inhabitants, on a territory of 120 kilometres, in four communes.

Montrejeau, a town of France, in the department of the Upper Garonne, and chief place of a canton, in the district of St. Gaudens; 6 miles E. of St. Gaudens. The place contains 2515, and the canton 8788 inhabitants, on a territory of 2273 kilometres, in 16 communes.

Montresor, a town of France, in the department of the Indre and Loire, and chief place of a canton, in the district of Loches; 9 miles E. of Loches. The place contains 760, and the canton 8586 inhabitants, on a territory of 410 kilometres, in 12 communes.

Montret, a town of France, in the department of the Sarthe and Loire, and chief place of a canton, in the district of Laval. The place contains 811, and the canton 5758 inhabitants, on a territory of 130 kilometres, in 16 communes.

Montrevaulet, a town of France, in the department of the Meuse and Loire, and chief place of a canton, in the district of Boupé; 13 miles N.N.W. of Cholet. The place contains 492, and the canton 9373 inhabitants, on a territory of 195 kilometres, in 10 communes.

Montrevel, a town of France, in the department of the Ain, and chief place of a canton, in the district of Bourg; 8 miles N.N.W. of Bourg. The place contains 1242, and the canton 13,659 inhabitants, on a territory of 192 5/16 kilometres, in 13 communes. N. lat. 46° 10'. E. long. 5° 13'.

Montreuil, a town of France, and principal place of a district, in the department of the Straits of Calais, about six miles from the sea. This town is fortified, lies on an eminence, and contains several churches. The place includes 3534, and the canton 14,129 inhabitants, on a territory of 210 kilometres, in 25 communes. N. lat. 56° 28'. E. long. 1° 51'.
The river South Eik, immediately above the town, expands into a beautiful circular sheet of water, nearly three miles in diameter, called the bason of Montrofe. This basin is perfectly dry at low water; but at high water, vessels of 60 tons can run up to its upper end without hazard. Valuable salmon fisheries are established on this river, as well as on the North Eik, and form a considerable branch of commerce with England. Beauties of Scotland, vol. iii.

MONT-ROTIER, a town of France, in the department of the Rhône and Loire; 15 miles W. of Lyons.

MONTSQUIOUES, a town on the west part of the island of St. Domingo, at the head of the bight of Leogane; 5 leagues S.E. of St. Mark.

MONTS, a town of France, in the department of the Vienne, and chief place of a canton, in the district of Loudun; 4 miles S.S.E. of Loudun. The place contains 689, and the canton 6185 inhabitants, on a territory of 277½ square kilometres, in 15 communes.

MONTSAIN-BERNARD. See St. Bernard, Guineen.

MONTSAIN-ELOY, a town of France, in the department of the Straits of Calais; 6 miles N.W. of Arras.

MONTSAIN-JEAN, a town of France, in the department of the Côte-d’Or; 12 miles S. of Semur-en-Auxois.

MONTSAIN-MICHEL, a town of France, in the department of the Channel, about six miles from the sea, with a caffle upon a rock, about a quarter of a mile in circumference, in the midst of a sandy plain, covered by the sea twice in 24 hours; and as the sands are shifted by the waves, the ships are obliged to take guides for directing their course. Before the revolution, this caffle was a Benedictine monastery, and the prior was governor of the town. It gave name to an order of knights, founded by Lewis XI.; 6 miles S.W. of Avanches. N. lat. 46° 36’. W. long. 1° 27’.

MONTSAIN-VINCENT, a town of France, in the department of the Seine and Loire, and chief place of a canton, in the district of Châlons-sur-Saône. The place contains 700, and the canton 6446 inhabitants, on a territory of 227½ square kilometres, in 12 communes.

MONTSALVY, a town of France, in the department of the Cantal, and chief place of a canton, in the district of Aurillac; 15 miles S. of Aurillac. The place contains 834, and the canton 10,021 inhabitants, on a territory of 252½ square kilometres, in 14 communes.

MONTS-SAUCHE, a town of France, in the department of the Nievre, and chief place of a canton, in the district of Chateauneuf-Chinon; 11 miles N. of it. The place contains 1308, and the canton 11,117 inhabitants, on a territory of 473½ square kilometres, in 10 communes.

MONTS-SEGUER, a town of France, in the department of the Gironde, and chief place of a canton, in the district of La Roque; 7 miles N.E. of La Roque. The place contains 1440, and the canton 7804 inhabitants, on a territory of 136 square kilometres, in 15 communes.

MONTS-SENI, a mountain of Spain, being a branch of the Pyrenees, and the most lofty in Catalonia: its summit is always covered with snow.

MONTSERRAT, one of the Leeward Chararbeit islands, in the West Indies; discovered at the same time with St. Christopher’s, viz. in 1493, and deriving its name from a supposed resemblance which Columbus perceived in the face of the country to a mountain of the same name near Barcelona. This island, though named by the Spaniards, was planted by a small colony from St. Christopher’s, detached in 1632 from the adventurers under Warner. This colony consisted chiefly of natives of Ireland, of the Romish persuasion; they were joined, soon after the first settlement, by many persons of the same country and religion, so that they thus created a white population, which it has ever since preserved, and which amounted, at the end of 16 years, according to Oldmixon’s account, to upwards of 1000 white families, constituting a militia of 600 effective men. In 1712 Montserrat was invaded by a French force, and suffered so much, that an article was inserted in the treaty of Utrecht, for appointing commissioners to inquire into the damages; but these were never made good to the sufferers. It was again invaded in a subsequent war, and, with most of the other islands, captured by the French, and restored with the rest.

The island is about three leagues in length, and as many in breadth, and is supposed to contain about 30,000 acres of land, of which almost two-thirds are very mountainous or very barren.

The land in cultivation is appropriated nearly as follows. In sugar, 6000 acres; in cotton, provisions, and pastureage, 2000 each. None other of the tropical staples are raised. Its average crop, from 1784 to 1798, was 2757 hogheads of sugar of 1600 weight, 1100 puncheons of rum, and 275 bales of cotton. The exports of 1787, for Montserrat and Nevis, and their value at the London market, will appear in the following table:

The articles above enumerated are produced by the labour of 1500 whites, and almost 10,000 negroes.

The government is administered in this, as in the other islands, by a legislature of its own, under the captain general...
The council consisted of six members, and the assembly of eight, from each of the four districts into which it is divided; and the proportion which Montserrat contributes to the salary of the captain general is 400l. per annum. N. lat. 16° 45'. W. long. 61° 6'. Edwards's History of the West Indies, vol. i.

Montserrat, a mountain of Spain, in Catalonia, famous for its height and hermitage, to which pilgrims resort, to improve the protection of the Virgin before her miraculous image. The whole extent of this mountain is supposed to be about 24 miles in circumference, comprising chiefly of round limestone, firmly conglutinated with a yellow calcareous earth and sand, with a further addition of round white quartz, streaked with red, as well as touch-stone, all cemented together, and forming one solid mass. In the course of time, however, torrents of rain have washed away the earth, formed by decomposition, and have split the mountain into clefts and precipices of the most grotesque and frightful figures; while other parts consist of immense rocks, bare and blanched, in form of cones, pillars, and jagged fragments, apparently sealed upon one another to the height of upwards of 3500 feet above the level of the sea. On the summit of this lofty mountain the prospect is extensive and splendid. The lower part of the mountain, having been decomposed sooner than the upper parts, and converted into soil, produces corn, vines, and olives; while the shelving rocks facilitate a passage to the summit, and exhibit to the curious botanist above 250 sorts of trees, shrubs, and plants, that seem to shoot up spontaneously. The direction of this mountain is from east to west, rather visibly inclining to the west; 25 miles N.W. of Barcelona.

Montserrat, a town of Brazil, in the government of St. Paul; 35 miles N.W. of St. Paul.

Montsols, a town of France, in the department of the Rhone, and chief place of a canton, in the district of Villefranche; 15 miles N. of it. The place contains 1253, and the canton 10,476 inhabitants, on a territory of 200 kilometres, in 12 communes.

Mont-Surs, a town of France, in the department of the Mayenne, and chief place of a canton, in the district of Laval; 9 miles E.N.E. of Laval. The place contains 1100, and the canton 6803 inhabitants, on a territory of 195 kilometres, in 10 communes.

Mont-Tonnere, one of the thirteen departments of the region of France, called the United Country, formerly a portion of the electorate of Mayence, of Hunsrück, of the Palatinate, of the bishopric of Spire, and of the duchy of Deux-Ponts, separated from Germany on the north and east by the Rhine, in N. lat. 49° 35'. This department contains 6015 kilometres, or 277 square leagues, and 34,316 inhabitants. It is divided into 4 districts or circles, 37 cantons, and 685 communes. Its circles are Mayence, containing 11,468 inhabitants; Spire, 12,191; Kaiserslautern, 50,135; and Deux-Ponts, 55,088. Its capital is Mayence. Its contribution, in the year 1775, was 3,165,473 francs, and its expenses 304,100 francs. This department is hilly, but abundantly fertile in grain, wine, tobacco, timber, and excellent pastures. In the circle of Kaiserslautern are mines of anthracite, coal, sulphur, mercury, coal, &c.

Montucla, John Stephen, in Biography, a celebrated mathematician, was born at Lyons in the year 1725. His father wished to bring him up to trade, in which he himself was engaged; but the youth gave early indications of a love of learning, and was placed under the instructions of the Jesuits, who carefully cultivated his opening genius. In their seminary, he acquired an intimate acquaintance with the ancient and modern languages, and made a considerable progress in the mathematics. When he left the Jesuits' college, at the age of sixteen, having loft both his parents, he went to Toulouse to study the law, and was, in due time, admitted an advocate, though without much intention of practising at the bar. Having completed his studies, he went to Paris, cultivated his acquaintance with the most distinguished literary characters, and attended all the meetings at which scientific men were accustomed to meet, to promote the interests of knowledge. At these meetings he formed an intimacy with Diderot, d'Alembert, and other learned men; and it was owing to his intercourse with them, that he was stimulated to the grand undertaking for which his name is rendered illustrious, viz. his “History of the Mathematical Sciences.”

Before he engaged in the actual composition of this great work, he employed himself in giving new editions, with additions and improvements, of several mathematical treatises, which were already held in the highest estimation. The first of these was “Mathematical Recreations,” by M. Ozanam, which has been since translated into English, and published in London, in 4 vols. 8vo. To all the works which he edited, after Ozanam's, he gave the initials of his name. While thus occupied, he contributed his affinities for some years to “The French Gazette;” and in 1755 he was elected a member of the Royal Academy of Sciences at Berlin. In the following year, when the experiment of inoculation was about to be tried on the first prince of the blood, Montucla translated from the English an account of all the recent cafes of that practice, which had been sent from Constantinople, by lady Mary Wortley Montagu. This translation he added to the memoir of De la Condamine on the subject. Previously to this publication, he had given to the world his “History of Inquiries relative to the Quadrature of the Circle.” The encouragement which this met with from very able judges of his merit, afforded him great encouragement to apply with ardor to his grand design, “The History of the Mathematicians.” The talk he proposed to himself was comprehensive and laborious. “He had to trace the progress of the human mind from age to age, and nation to nation; from one transcendent genius to another; to mark the gradual development of important truths, and their dependence on each other; to pass in review all the celebrated characters who have adorned the annals of science, to appreciate their merits, to compare their respective pretensions, and to refer discoveries to their real authors; to illustrate the nicest theories, the most profound systems, and the most abstruse analyses; to extract materials from an indefinite number of books, in almost all languages, ancient and modern; and to amalgamate the whole into a narrative style, which should, if possible, interest the reader by his historic form, and infinitely initiate him into all the mysteries of the mathematics.”

In the year 1758 he published his “History,” in two volumes, 4to., which terminates with the close of the 17th century. It answered the expectations of all his friends, and of the men of science in all countries, and the author was instantly elevated to a high rank in the learned world. His fame was widely diffused, and he was pressed from all quarters to proceed with the mathematical history of the 18th century, which he had announced for the subject of a third volume, and for which he had made considerable preparations; but he was diverted from his design, by receiving the appointment of secretary to the Intendance at Grenoble. Here he spent his leisure hours chiefly in retirement, and in scientific pursuits. In 1764, Turgot, being appointed to establish a colony at Cayenne, took Montucla with him as his
his "secretary," to which was added the title of "astronomer to the king." In about fifteen months he returned, without attaining any particular object with regard to the astronomical observations, for which he went out; but the voyage afforded him the opportunity of collecting some valuable tropical plants, with which he enriched the king's hot-houses at Versailles. Soon after his return, he was appointed chief clerk in an official department, similar to that known in this country by the name of the "Board of Works." In the immediate belief of the appointment he devoted himself most affidiously for the space of 26 years, till the place itself was abolished in 1792. During this long period, his progress in the "History of Mathematics" was exceedingly slow; but he was continually rising in the esteem of the learned world, and was offered a seat in the Royal Academy of Sciences, which he declined, from a persuasion that the duties of his business would not allow him sufficient leisure for filling it in a proper manner. By the revolution in 1789 he was, as we have seen, deprived of his office, and reduced to considerable pecuniary embarrassments. Under the pressure of these circumstances, he began to prepare a new and much enlarged edition of his "History," which he presented to the world in 1799, in two volumes, 4to. In this edition are many important improvements; and many facts, which were barely announced in the former impression, are largely detailed and illustrated in this. After the publication of these two volumes, the author proceeded with the printing of the third; but death terminated his labours, when he had arrived at the 335th page. The remainder of the volume, and the whole of the fourth, were printed under the inspection of Lalonde. Montucla had been a member of the National Institute from its original establishment. He had obtained various employments under the revolutionary government, though he was but meanly paid for his labour, and had to struggle with many difficulties to furnish his family with the bare necessaries of life. At length he was reduced to seek the scanty means of support by keeping a lottery-office, till the death of Sauffure put him in the possession of a pension of about $100. per annum, which he enjoyed only four months. He died in December 1799, in the 75th year of his age. He was, says his biographer, "model to a degree, which, when his exalted merits are considered, cannot but excite our admiration; and he was distinguished by acts of generosity and liberality, which will appear equally extraordinary, when the smallness of his means is recollected. He was a warm friend, a lively cheerful companion, and his manners and behaviour were simple, innocent, and virtuous." See Hilt. of the Mathematicians, vol. iv.

MONTVILLE, in Geography, a township of America, in New London county, Connecticut, about 10 miles N. of New London; containing 2231 inhabitants.

MONTUOSA, a small island in the Pacific ocean, near the coast of Mexico. N. lat. 8° 15'. W. long. 85° 30'.

MONTUYRI, a very ancient town of the island of Majorca, which has a parish church and a bauxit royal. Its vicinity affords neither well nor fountain, so that the inhabitants are obliged to procure water from wells and cisterns. The land produces corn, wine, and pasture for cattle.

MONTWILISZKI, a town of Samogitia; 14 miles E.S.E. of Rofienie.

MONTZBURG, a town of Saxon, in the margraviate of Meissen; 9 miles N. of Dresden.

MONTZEN, a town of the duchy of Limburg; 7 miles N. of Limburg.

MONUMENT, an edifice raised to preserve the memory of some eminent person, or designed to perpetuate some remarkable event.

Monuments were at first made of stones erected over the tombs of the deceased, on which were engraved the names and frequently the actions of the person to whose memory they were reared.

Monuments received different names among the ancients, according to their figure. When the base was square, and the fold erected thereon a prism, the monument was called flës; when square pillars or attic columns are supposed to be derived. When the base was circular, and the fold erected thereon a cone, the monument was called pyramis. Thosè monuments that were square at the foot, and tapering therefrom in planes to a point in which the planes ended, were called pyramids. Others which had triangular bases, and their sides ending in a point, were called obelisk, being constructed in imitation of the instruments or spits used in roasting sacrifice.

MONUMENT, The, absolutely so called among us, denotes a magnificent pillar, designed by Sir Christopher Wren, erected by order of parliament, in memory of the burning of the city of London, anno 1666, in the very place where the fire began.

This pillar was begun in 1671, and finished in 1677. It is of the Doric order, fluted, 222 feet high from the ground, and fifteen feet in diameter, of solid Portland stone, with a pillar-cake in the middle of black marble, containing 345 flaps. The lowest part of the pedestal is 28 feet square, and its altitude 40 feet; the front being enriched with curious baffle relieves. It has a balcony within 32 feet of the top, where is a curious and spacious blazing urn of gilt brass.

MONUMENT Bay, in Geography, a bay of America, on the E. coast of Massachusetts, formed by the bending of Cape Cod: it is spacious and convenient for the protection of shipping. The cape in this bay is called "Monument Point." N. lat. 41° 55'. W. long. 70° 31'.

MONUMENT Island, one of the New Hebrides, which appeared to be a rock of a pyramidal form, accessible only to birds; N. of Montague island.

MONUSCAT, a town of Curdlan; 50 miles W. of Belisi.

MONYCHA, formed of mones, fingle, and ovos, hoof, an epithet applied by naturalists to those animals whose hoofs are single and undivided; such are the horse and the like.

MONZA, IL CAVALLIERE, in Biography, a judicious and excellent opera composer, in the service of the court of Milan in 1770. A man in music of his composition, which we heard performed at a church in that city, excited hope and expectation that he would soon be ranked among composers of the first clafs: and we were not disappointed: for in 1777 he composed two operas for Venice, "Nitetti," and "Cajo Major," which established his reputation.

The first air which Pachieretti sung on our stage in the piazzetta of opera of "Demofoonte," was "Miferer pergoletto," by Monza, a capital production, in which the composition was masterly, the melody touching, the accompaniments clear and full of effects in painting parental affection and diftrust, and the motive and general conduct of the air grand and judicious.

The late Mrs. Sheridan was so much struck with this composition, that he eagerly sought and procured all the productions of Monza that could be found.

MONZA, in Geography, a town of Italy, in the department of the Olona, on the river Lambro, chiefly deferving notice on account of the treasury of John the Baptist, where, among
among other articles, is the iron crown with which the ancient Italian kings, and afterwards the emperors of Germany, were crowned, whenever they asserted their rights as kings of Lombardy. It takes this name from an iron ring within it, though the crown itself is of gold and enriched with jewels. Charlemagne was crowned here in 774, after taking prisoner Desiderius, king of Lombardy; 8 miles N. of Milan.

MONZAMBANO, a town of Italy, in the department of the Mincio; 14 miles N.W. of Mantua.

MONZE, CAPE, a cape on the coast of Sind, W. of the Indus. N. lat. 24° 43'. E. long. 65° 46'.

MONZINGEN, a town of France, in the department of the Rhine and Mofelle; 42 miles E. of Treves. N. lat. 49° 48'. E. long. 7° 30'.

MONZKUTH, a district of Pomerania, forming a peninsula in the S.E. part of the island of Rugen.

MOO, a town of Sweden, in Weft Gothland; 26 miles N.W. of Uddevalla.—Alto, a town of Sweden, in Welf Bothnia; 30 miles N.W. of Tornes.

Moo Ors, a small island in the East Indian sea, near the W. coast of the island of Niasu. S. lat. 2° 53'. E. long. 99° 45'.

MOOB DA, a town of Hindooflan, in Oude; 12 miles W. of Lucknow.

Mood, or Mode, in Logic, called also Syllogism Mood, is a proper disposition of the several propositions of a syllogism in respect of quantity and quality.

By proper disposition, we mean such in which the antecedent being true, the consequent, in virtue of the form, cannot be false. So that all those moods or manners of syllogism are at once excluded, where no conclusion formally follows; or where the antecedent being true, a false conclusion may be drawn from it.

There are two kinds of moods; the one direct, the other indirect.

Mood, Direét, is that in which the conclusion is drawn from the premises directly and immediately; as, every animal is a living thing; every man is an animal; therefore every man is a living thing.

Mood, Indirect, is that in which the conclusion is not inferred immediately from the premises, but follows from them by means of a conversion; as, every animal is a living thing; every man is an animal; therefore some living thing is a man. There are fourteen direct moods; of which four belong to the first figure; four to the second; and six to the third. See Figure.

They are denoted by so many artificial words framed for that purpose: viz. 1. Barbara, celarent, darii, ferioque. 2. Baralip, calanters, dabii, fefpame, fieroquin. 3. Celare, celanters, ferio. 4. Darapri, deflant, defmalis, datif, locard, ferio. The use and effect of which words lie wholly in the syllables and the letters of which the syllables consist. Each word, e. g. consists of three syllables, denoting the three propositions of a syllogism; viz. major, minor, and conclusion. Add, that the letters of each syllable are either vowels or conjonants: the vowels are Α, which denotes an universal affirmative proposition; Ε, an universal negative; Ι, a particular affirmative, and Ε, a particular negative.

Thus, baralip is a syllogism or mood of the first figure, consisting of three universal affirmative propositions: baralip, of the fourth figure, consisting of two universal affirmative premises, and a particular affirmative conclusion. The conjonants are chiefly of use in the reduction of syllogisms.

Mood, or Mode, in Grammar, is used to signify the different manners of conjugating verbs, agreeably to the different actions or affections to be expressed; as viewing, commanding, wishing, &c.

Hence arise five moods; viz. the indicative, imperative, optative, subjunctive, and infinitive; which see.

Some grammarians reckon but four moods, confounding the optative with the subjunctive; and make some fix, dividing the optative into potential and optative.

The Greek have five moods of verbs different in termination; but the Latins have only four. In English the terminations are the same in all the moods.

With respect to the origin of moods, it may be observed, that verbs are of that kind of words which signify the manner and form of our thought; of which the principal is affirmation. Verbs are also formed to receive different inflexions, as the affirmation regards different persons and different times; whence arise the tenses and persons of verbs. See Verb.

But, besides these, men have thought fit to invent other inflexions, to explain what passeth in their minds still more difficultly; for, in the first place, they considered, that besides the simple affirmations, as he loves, he loved; there were others modified and conditional, as if he loved, though he should love: and the better to distinguish these affirmations from the others, they doubled the inflexions of those tenses or times; making some forms for simple affirmations, as, I love, he loved; and referring the rest for affirmations that were modified, as, if he should love, might he have loved. Yet they kept not steadily to their rules; but sometimes made use of simple inflexions to express affirmations that were modified: as, ester, estes, for esse vereat. And it is from this kind of inflexion, that grammarians have formed the mood they call subjunctive.

But farther, besides the affirmation, the action of our will may be taken for a mood, or manner of our thought; and men have found themselves under a necessity of expressing what they will, as well as what they think. Now we may will a thing in several manners; of which there are three that may be considered as the principal. First, then, we sometimes will things which do not depend on ourselves; and in that case we only will them by a bare wish, which the Latins express by the article vultum; and we by pleat God. Some languages, for instance the Greek, have invented particular inflexions for this end; whence the grammarians have taken occasion to call this the optative mood, and there seems something like it in the French, Italian, and Spanish tongues, as there have a kind of triple tenses; but in Latin, English, &c. the same inflexions serve for the subjunctive, and for the optative. For this reason, one may very well retract this mood from the Latin conjugations; because they are the different inflexions that make moods, not the different manners of signifying, which may be varied to infinity.

We sometimes will in another manner: as when we are content a thing should come to pass, though we do not absolutely desire it; as when Tereus says, profundis, purdior, pereat, let him perish, sink, perish. Men might have invented a particular inflexion to express this movement, as in Greek they have done to express a simple desire: but they have not done it; and, in lieu of it, they make use of the subjunctive.

In English, we add the particle let, him perish, &c. Authors call this the potential, or concessive mood.

The third manner of willing is, when what we desire depends on another person, of whom we can obtain it, and we signify our will that he do it. This is the motion we use, when we command or pray; and to express this motion, was invented
invented the mood we call imperative; which has no first person in the singular, because a man, properly speaking, cannot command himself; in some languages it has no third person, because, in strictness, a man cannot command any person, but him to whom he speaks and addresses himself. And because the command or prayer always relates to what is to come, it happens that the imperative mood, and the future tense, are frequently used for each other (especially in the Hebrew): as, non occides, thou shalt not kill, for do not kill. Hence some grammarians place the imperative among the number of futures.

Of all the moods we have mentioned, the oriental languages have none but the lait, which is the imperative; and, on the contrary, none of the modern languages have any particular inflexion for the imperative. The method we take for it in English, is either to omit the pronoun, or transpose it; thus, I love, is a simple affirmation; love, an imperative; we love, an affirmation; we, an imperative. An infinitive verb is sometimes used by the poets to express a command; the imperative verb being understood.

In explaining the origin of moods, the ingenious Mr. Harris observes, that the soul's leading powers are those of perception and volition; and that all speech or discourse is a publishing either a certain perception or volition. Hence then, according as we exhibit it either in a different part, or after a different manner, the variety of moods. If we simply declare or indicate something to be, or not to be, whether a perception or volition, this constitutes the declarative or indicative mood. If we affect of something possible only, and in the number of contingents, this makes the potential mood. When this is subjoined to the indicative, and used, as it mostly is, to denote the end or final cause, it is the subjunctive. When we address others, in order to have some perception informed, or some volition gratified, we form new modes of speaking: if we interrogate, it is the interrogative mood; if we require, it is the requisitive, which, with respect to inferiors, is imperative; and, with respect to equals and superiors, imperative or optative. The indicative, potential, interrogative, and requisitive moods, have their foundation in nature; and, therefore, certain marks or signs of them have been introduced into language, that we may be enabled by our discourse to signify them to one another; so that moods are, in fact, no more than so many literal forms, intended to express these natural distinctions. All these moods, with their respective tenses, the verb being considered as denoting an attribute, have always reference to some person or subsistence. But there is another mood or form, under which verbs sometimes appear, where they have no reference at all to persons or subsistences: these, from their indefinite nature, are called infinitives. Hermes, p. 140 &c.

Mood, or Mode, in our old Mufic, was a term only applied to the divisions of time or measure, which was so embarrassing a fludy, that a very considerable portion of Morley's treatise is bel owed on that subject. Previous to the use of bars, all measures, however complicated, were determined by the modal signs placed after the clef of every composition. These signs were circles, semicircles, pointed, or without points, followed by the figures 2 or 3 differently combined. See Mode, Modal, and Prolation.

Roueffe gives twelve examples of ancient characters of quantity; but as these were characters referred to notes now out of use, as the maxima, the long, and the breve, these explanations can be of little consequence but to those who are ambitious of knowing the flat of measured music at every period of its cultivation.

Mood, in Philosophy and Mufic. See Mode. Vol. XXIV.
as above stated from M. de la Lande, is the arithmetic mean between the greatest and least diameters; the diameter at the mean distance is $31^\circ 7^\prime$. When the moon is at different altitudes above the horizon, it is at different distances from the spectator, and, therefore, there is a change of the apparent diameter; which is inversely as the moon's distance. The diameter of the moon may be measured, at the time of its full, by a micrometer; or it may be measured by the time of its passing over the vertical wire of a transit telescope, which must be done when the moon passes within an hour or two of the time of the full, before the visible disk is sufficiently changed from a circle. The moon's surface contains $14,898,750$ square miles, and its solidity $5,498,240,000$ cubical miles. The mean eccentricity of the moon's orbit is $0.02503568$ of her mean distance, which is equal to about $13,500$ miles; and this makes a considerable variation in that mean distance. This eccentricity, however, is subject to a variation, the greatest variation from the mean being $0.00986$; the excentricity being increased whilst the apsides move from quadratures to syzygies, and decreased whilst they move from syzygies to quadratures. (See the annexed table.) The corresponding greatest equa-

The revolution of the moon is $32^d 43^h 7^m$; hence the mean solar motion of the nodes when quadratures is $16^d 21^h 32^m$, in an elliptic orbit, and in a circular orbit $10^d 35^m 16^s$. The mean annual regression of the nodes is $19^d 23^m$. Allowing for the inclination of the orbit, this motion will be about $4^d 10^m$; and we may, therefore, suppose the mean annual motion to be $19^d 10^m$. Mayer makes the mean annual motion of the nodes to be $12^d 10^h 43^m$. The motion of the nodes is not affected by the excentricity of the orbit, as Sir Isaac Newton supposed.

The motion of the apogee in one mean periodic revolution of the moon is $3^d 7^h 39^m$; hence, $27^d 7^h 43^m = 365^d 6^h 0^m$; $3^d 7^h 39^m = 40^d 40^h 20^m$ the mean pro-

To determine the mean motion of the apogee, find its place at different times, and compare the difference of the places with the interval of the time that had elapsed between them. For this purpose, compare, first, observations at a small distance from each other, in order to prevent being deceived in a whole revolution, and then we may compare those at a greater distance. The mean annual motion of the apogee in a year of $365$ days, is thus found to be $40^d 39^m 50^s$, according to Mayer. Horrox, long ago, from observing the diameter of the moon, found the apogee subject to an annual equation of $12.5$. The following table shews the times of the revolutions of the moon, of its apogee, and as determined by M. de la Lande.

N.B. The preceding table is taken from Dr. Halley's "Astronomical Tables;" the argument, called the "annual argument," is the distance of the Sun from the mean place of the apogee corrected by its annual equation.
MOON.

Moor, Course and Motion of the. Though the moon finishes its course in 27 7/10 43 5/8', which interval we call a periodical month, yet the is longer in passing from one conjunction to another; which space we call a synodical month, or a lunation. The reason is, that while the moon is performing its course round the earth in its own orbit, the earth and moon are making their progress round the sun, and both are advanced almost a whole sign towards the east; so that the point of the orbit, in which the former position was in a right line passing through the centres of the earth and sun, is now more easterly than the fun; and, therefore, when the moon is arrived again at that point, it will not yet be seen in conjunction with the fun; nor will the lunation be completed in less than 29 days and a half, or 29 12 25 43 5/8.

The moon's periodical and synodical revolution may be familiarly represented by the motions of the hour and minute hands of a watch round its dial-plate, which is divided into 12 equal parts or hours, as the ecliptic is divided into 12 signs, and the year into 12 months.

Let us suppose these 12 hours to be 12 signs, the hour-hand the fun, and the minute-hand the moon; then the former will go round once in a year, and the latter once in a month; but the moon, or minute-hand, must go more than round from any point of the circle where it was last conjuncted with the fun, or hour-hand, to overtake it again; for the hour-hand being in motion, can never be overtaken by the minute-hand at that point from which they started at their last conjunction. The first column of the annexed table shews the number of conjunctions which the hour and minute-hand make whilst the hour-hand goes once round the dial-plate; and the other columns shew the times when the two hands meet at each conjunction. Thus, suppose the two hands to be in conjunction at XI, as they always are; then, at the first following conjunction it is 5 minutes 27 seconds 16 thirds 21 fourths 49 5/7 fifths part 1, where they meet; and at the second conjunction it is 10 minutes 54 seconds 32 thirds 43 fourths 38 3/5 fifths part II; and so on. This, though an easy illustration of the motions of the fun and moon, is not precise as to the times of their conjunctions, because, while the fun goes round the ecliptic, the moon makes 12 1/2 conjunctions with him; but the minute-hand of a watch or clock makes only 11 conjunctions with the hour-hand in one period round the dial-plate. But if, instead of the common wheel-work at the back of the dial-plate, the axis of the minute-hand had a pinion of 6 leaves turning a wheel of 7 4/7, and this last turning the hour-hand, in every revolution, it makes, round the dial-plate, the minute-hand would make 12 5/7 conjunctions with it; and so would be a pretty device for shewing the motions of the fun and moon, especially as the lowest moving hand might have a little fun fixed on its point, and the quickest a little moon.

</table>

Were the plane of the moon's orbit coincident with the plane of the ecliptic, i.e. were the earth and moon both moved in the same plane, the moon's way in the heavens, viewed from the earth, would appear just the same with that of the fun; with this onl difference, that the fun would be found to describe his circle in the space of a year, and the moon her's in a month. But this is not the case; for the orbits of the two planets cut each other in a right line, passing through the centre of the earth, and are inclined to each other in an angle of about five degrees eighteen minutes.

Suppose, e.g. A B (fig. 7) a portion of the earth's orbit, T the earth, and C E D F the moon's orbit, in which is the centre of the earth; from the earth C the plane of the ecliptic, describe another circle C G D H, whose semi-diameter is equal to that of the moon's orbit. Now these two circles, being in separate planes, and having the same centre, will intercept each other in a line D C, passing through the centre of the earth. Consequently, C E D, one-half of the orbit of the moon, will be raised above the plane of the circle C G D H, towards the north, and D F C, the other half, will be sunk below towards the south. The right line D C, in which the two circles intercept each other, is called the line of the nodes, and the points of the angles C and D, the nodes of which that where the moon ascends above the plane of the ecliptic, northwards, is called the ascending node, and the head of the dragon; and the other D, the descending node, and the dragon's tail.
MOON.

The interval of time between the moon's going from the ascensional node, and returning to it, is a synodic month.

If the line of the nodes was immovable, that is, if it had no other motion but that by which it is carried round the sun, it would still look towards the same point of the ecliptic; i.e. it would always keep parallel to itself; but it is found by observation, that the line of the nodes constantly changes place, and shifts in situation from east to west, contrary to the order of the signs; and, by a retrograde motion, finishes its circuit in about nineteen years; in which time each of the nodes returns to that point of the ecliptic whence it before receded.

Hence it follows, that the moon is never precisely in the ecliptic, but twice each period; viz. when she is in the nodes. Throughout the rest of her course she deviates from it, being nearer or farther from the ecliptic, as she is nearer or farther from the nodes. In the points $F$ and $E$, she is at her greatest distance from the nodes; which points are therefore called her limits of north and south latitude.

The moon's distance from the nodes, or rather from the ecliptic, is called her latitude, which is measured by an arc of a circle drawn through the moon, perpendicular to the ecliptic, and intercepted between the moon and the ecliptic. The moon's latitude, when at the greatest, as in $E$ or $F$, never exceeds $5$ degrees and about $15$ minutes; which latitude is the measure of the angles at the nodes.

It appears by observation, that the moon's distance from the earth is continually changing; and that she is either drawing nearer, or going farther from us. The reason is, that the moon does not move in a circular orbit, which has the earth for its centre; but in an elliptic orbit (as represented in fig. 8.), one of whose foci is the centre of the earth: $A$ represents the greater axis of the ellipse, and the line of the apsides; and $C$ the eccentricity; the point $A$, which is the highest apsis, is called the apogee of the moon; and $P$, the lower apsis, is the moon's perigee, or the point in which she comes nearest the earth.

Besides, there is reason to believe, that the moon is somewhat nearer the earth now than she was formerly; her periodic month being shorter than it was in former ages. For our astronomic tables, which in the present age shew the time of solar and lunar eclipses to great precision, do not answer so well for ancient eclipses.

If the moon's orbit had no other motion but that with which it is carried round the sun, it would still retain a position parallel to itself, and always point the same way, and be observed in the same point of the ecliptic; but the line of the apsides is likewise observed to be moveable, and to have an angular motion round the earth, from west to east, according to the order of the signs, returning to the same situation in the space of about nine years.

The irregularities of the moon's motion, and that of her orbit, are very considerable. For 1. When the earth is in her aphelion, the moon is in her apsides; in which case she breakfasts her pace, and performs her circuit in a shorter time; on the contrary, when the earth is in its perihelion, the moon is too slow, and then she slackens her motion; and thus she revolves round the earth, in a shorter space, when the earth is in her aphelion than when in her perihelion; so that the periodical months are not all equal.

2. When the moon is in her syzygies, i.e. in the line that joins the centres of the earth and sun, which is either in her conjunction or opposition, she moves swifter, ceteris paribus, than when in the quadratures. According to the different distances of the moon from the earth, in its semapho' from opposition to conjunction, she changes her motion: in the first quarter, that is, from the conjunction to her first quadrature, she abates somewhat of her velocity; which in the second quarter she recovers; in the third quarter she again loses; and in the last she again recovers. Hence the areas described are accelerated and retarded; and the mean place differs from the true. This inequality was first discovered by Tycho Brahe, who called it the moon's variation. At different distances of the earth from the sun, the disturbing forces vary, and, therefore, the equation, called the "variation," being first calculated for the mean distance of the earth from the sun, will be subject to a variation from the variation of that distance; and hence some new equations will arise.

4. The moon moves in an ellipsis, one of whose foci is in the centre of the earth, round which the deferent describes areas proportional to the times, as the primary planets do round the sun; whence the motion in her perigee must be quickest; and it must be slowest in the apogee.

5. The very orbit of the moon is changeable, and does not always preserve the same figure; its eccentricity being sometimes increased, and sometimes diminished: it is greatest, when the line of the apsides coincides with that of the syzygies; and least, when the line of the apsides cuts the other at right angles.

The moon's orbit being dilated or contracted as the earth approaches to or recedes from the sun, its motion will accordingly be diminished or increased; and hence arises an annual equation, assigning the difference between the mean motion at the mean distance of the earth from the sun, and the mean motion at any other distance of the sun. The variation depending on the true distance of the sun from the moon, will produce several other equations, arising from the different corrections that are made. The change of the eccentricity causes a change of the equation of the centre, called the equation, and hence new equations must be applied. See these terms respectively and eccentricity.

6. Nor is the apogee of the moon without an irregularity; being found to move forward, when it coincides with the line of the syzygies; and backward, when it cuts that line at right angles. Nor are this progress and regress in any measure equal: in the conjunction or opposition, it goes bricly forward; and in the quadratures it moves either slowly forward, or stands still, or goes backwards. Upon the whole, however, the motion of the apogee is progressive. Hence arises an equation of the motion of the apogee, which depends upon its distance from the sun; and there is also a smaller annual equation, arising from the disturbing forces being different at different times of the year.

7. The motion of the nodes is not uniform; but when the line of the nodes coincides with that of the syzygies at right angles, they go backward, from east to west; and this, if Isaac Newton shews, is at the rate of $10^\circ 19'' 24''$ in an hour. See the preceding part of this article, and Notes.

The only equable motion the moon has, is that with which she turns round her axis exactly in the same space of time in which she revolves round us in her orbit; whence it happens, that she always turns the same face towards us.

For as the moon's motion round its axis is equal, and yet its motion, or velocity, in its orbit, is unequal, it follows, that when the moon is in its perigee, where it moves swiftest in its orbit, that part of its surface, which, on account of its
its motion in the orbit, would be turned from the earth, is not to entirely; by reason of its motion round its axis. Thus some parts in the limb or margin of the moon, sometimes recede from the centre of the disc, and sometimes approach towards it; and some parts, that were before invisible, become conspicuous; which is called the moon's libration.

Yet this equability of rotation occasions an apparent irregularity; for the axis of the moon not being perpendicular to the plane of her orbit, but a little inclined to it; and this axis, maintaining its parallelism, in its motion round the earth; it must necessarily change its situation, in respect of an observer on the earth; to whom sometimes the one, and sometimes the other pole of the moon becomes visible; whence it appears to have a kind of wavering, or vacillation. See libration.

The irregularities above enumerated, and some others of a similar kind, have been urged as objections to the Newtonian theory of gravity, though they were anticipated by the illustrious author, who not only enuncied their consistence with it, but suggested the explication of them which might be deduced from that theory, properly understood and applied. Sir Isaac Newton having found, in the manner which we shall presently explain, that the moon was retained in its orbit by a force, which, at different distances from the earth, varied inversely as the squares of the distances, and concluding from analogy that the same law of attraction might take place between all the bodies in the system, applied this theory to compute the effect of the sun's attraction upon the earth and moon, so far as it might affect the relative situation of the latter as seen from the former; and hence he discovered, besides the irregularities already mentioned, other smaller inequalities of the moon's motion, which were also found to agree with observations. From this, and other applications of his theory, he was confirmed in his conjectures concerning the principle of universal gravitation; and the further investigation of the same principle, and the discovery that it produced conclusions conformable to observation, served firmly to establish his theory. M. Clairaut, indeed, in the year 1747, published a memoir which was read before the Academy of Sciences at Paris, and urged as an objection against it, that it would not account for the motion of the moon's apogee, but that this motion, deduced from it by his calculations, was only one-half of what was found to be by observations. But soon after discovering his mistake, and posseisng coudour enough to acknowledge it, he was the first who gave a complete theory of the moon, in which he showed that Sir I. Newton's law of gravity would not only account for the motion of the moon's apogee, but also for all the other irregularities of the moon. M. Euler also retracted his own erroneous opinion, in deference to the judgement of M. Clairaut; and concurs with him in doing ample justice to the Newtonian theory. "After most tedious calculations," says Euler, "I have at length found, to my satisfaction, that M. Clairaut was in the right, and that this theory is entirely sufficient to explain the motion of the apogee of the moon. As this enquiry is of the greatest difficulty, and as those who hitherto pretended to have proved this nice agreement of the theory with the truth, have been much deceived, it is to M. Clairaut that we are obliged for this important discovery, which gives quite a new lufre to the theory of the Great Newton; and it is but now that we can expect good astronomical tables of the moon." Others, and particularly Mr. Masch and M. Frie, have prosecuted a similar investigation of this theory, and contributed to establish it. What Euler led astronomers to expect, they have now actually obtained in Mayer's tables, as corrected by Dr. Mascltyne, which, founded upon a very elegant theory conformable to observations, are the most correct, and do not err more than half a minute in longitude. See longitude and lunar observations.

Moon's Motions. Physical Cause of the. The moon, we have observed, moves round the earth by the same laws, and in the same manner, as the earth and other planets move round the sun. The solution, therefore, of the lunar motions, in general, comes under those of the earth and other planets.

As for the particular irregularities in the moon's motion, to which the earth, and other planets, are not subject, they arise from the fun, which acts on, and disturbs her in her ordinary course through her orbit; and are all mechanically deducible from the same great law by which her general motion is directed; viz., the law of gravitation and attraction.

Other secondary planets, e. g. the satellites of Jupiter and Saturn, are, doubtless, subject to the like irregularities with the moon; as being exposed to the same perturbing or disturbing force of the sun; but their diérance secures them from our observation.

The laws of the several irregularities in the syzygies, quadratures, &c. see under syzygies, quadratures, &c.

It would not be consistent with the limits or nature of this work to investigate, by tedious and elaborate procedures of an analytical and geometrical kind, the various equations that have been explored for the illustration of these laws, and for furnishing a complete theory of the moon. Much has been done in this way by several learned mathematicians, and of late by professor Vince, who is eminently qualified for the undertaking; and we shall therefore refer the reader, who may be desirous of farther information, and who has no access to a variety of other publications, to the second volume of Vince's Complete System of Astronomy, chap. xxxii.

We shall, however, in this place, introduce a general view of the Newtonian theory of gravity, as it is applied to the solution of the irregularities of the moon's motion.

We have already, under the article gravitation, illustrated and confirmed the Newtonian theory of gravity, as it regards the moon and the other planets; but as the subject is of importance, and as it is immediately connected with what follows, we shall here give a concise statement of the leading facts by which the identity of the centripetal force, as it respects the moon, and that of gravity, was originally explained and established, referring for a more detailed account to the article just cited.

It is well known, and universally allowed, that the planets are retained in their orbits by some power which is continually acting upon them; that this power is directed towards the centres of their orbits; that the efficacy of this power increases upon an approach to the centre, and diminishes by its reeds from the same; and that it increases according to a certain law, viz., that of the squares of the distances, as the distance diminishes; and that diminishes in the same manner as the distance increases. Now by comparing this centripetal force of the planets with the force of gravity on earth, they will be found perfectly alike. This we shall illustrate in the case of the moon, the nearest to us of all the planets. The rectilinear spaces described in any given time by a falling body, urged by any powers, reckoning from the beginning of its descent, are proportionable to those powers. Consequently the centripetal force of the moon, revolving in its orbit, will be to the force of gravity on the surface of the earth, as the
space which the moon would describe in falling any little time, by her centripetal force towards the earth, if she had no circular motion at all, to the space which a body near the earth would describe in falling, by its gravity towards the same. By a very easy and obvious calculation of these two facts the will find, that the force of them in the former case, is to the force of the moon revolving in her orbit to the force of gravity on the surface of the earth, as the square of the earth's semidiameter to the square of the semidiameter of the orbit, which is the same ratio as that of the moon's centripetal force in her orbit to the force of gravity near the surface of the earth. The moon's centripetal force is, therefore, equal to the force of gravity. These forces, consequently, are not different, but they are one and the same; for if they were different, bodies acted upon by the two powers conjointly, would fall towards the earth with a velocity double to that arising from the sole power of gravity. It is evident, therefore, that the moon's centripetal force, by which she is retained in her orbit, and prevented from running off in tangents, is the very power of gravity of the earth, extended thither. This reasoning may be farther illustrated and confirmed in the following manner. Let RAE (Plate XVII. Astronomy, fig. 9) represent the earth, T its centre, V the orbit of the moon, and LC a part of it described by the moon in a minute, which is equal to the double of the circumference of the orbit of the moon's semidiameter of a foot; because the moon completes her whole course in 27 days, seven hours, 43 minutes, or in 30343 minutes. Moreover, the circumference of the earth, according to M. Picard's measurement, is 123496000 Paris feet, and therefore its semidiameter TA = 19014800 feet; and TL, the semidiameter of the moon's orbit, will be 11764800 feet, or 60 times T A; and the veridical L D of the arc LC = 33° 3', computed by means of tables, or BC, will be 15° 3', nearly; or LD may be found without tables thus: The whole circumference of the moon's orbit, or 60 x 123246600, is equal to 7394976000, which divided by 30343, will give the arc LC = 187961 feet; but by a well-known theorem in geometry, supposing the arc LC, which is a very small part of the moon's orbit, to be rectilinear, L C = L D \times 2 LT, i.e., L D = L C \times 2 L T, or the square of 187961, which is 35320317521, divided by 2353860000, will give 15.013, &c. It may be here observed, that a dilance of the moon somewhat greater than 60 times the diameter of the earth would afford a more exact result; and the force by which the moon is restrained in its orbit should also be increased in the proportion of 177° to 178°, in order to have the exact centripetal force of the moon, such as it would be undiminished by the action of the sun, and with this correction the above number 15.013, &c. will become 15.047, &c. or 15° 3' very nearly. (See Newton's Principia, lib. i. prop. 45. cor. 2. and lib. iii. prop. 3.) In either way of calculation it appears that the force, by which the moon is drawn off from the tangent LB, or retained in its orbit, impels it towards the centre of the earth about 15° 3'. Paris feet in one minute; but this force, being known from the elliptic figure of her orbit to be proportionally equal to the square of the distance, would impel the moon, supposing to be at the surface of the earth, through a space equal to 60 x 60 x 15° 3' feet in one minute. But bodies, impelled by the force of gravity, fall near the surface of the earth through the space of 15° 3' Paris feet in one second, and the spaces being in the ratio of their times, through 60 x 60 x 15° 3' in a minute. Consequently, as the force by which the moon is retained in its orbit, and the force of gravity, produce the same effects in the same circumstances, and tend towards the same point, they are the same force. The moon, therefore, gravitates towards the earth, and the earth reciprocally towards the moon; and this law is further confirmed by the phenomena of the tides. See Tides.

The like reasoning might be applied to the other planets. For, as the revolutions of the primary planets round the sun, and those of the satellites of Jupiter, Saturn, and the Georgium Sidus, round their primaries, are phenomena of the same kind as the revolution of the moon round the earth; as the centripetal powers of the primary are directed towards the centre of the sun, and those of the satellites towards the centres of their primaries; and, lastly, as all these powers are reciprocally as the squares of the distances from the centres; it may safely be concluded, that the power and caufe are the same in all. Therefore, as the moon gravitates towards the earth, and the earth towards the moon, do all the secondaries to their respective primaries; the primaries to their secondaries; and so do, also, the primaries to the sun, and the sun to the primaries, &c. Newton's Princ. lib. iii. prop. 4, 5, 6. Gregory's Astr. lib. i. § 7. Prop. 47.

In obedience the irregularities of the moon's motion, according to the theory of gravity, previously established, it must first be considered, that if the sun acted equally on the earth and moon, and always in parallel lines, the action would force only to restrain them in their annual motions round the sun, and no way affect their actions on each other, or their motions about their common centre of gravity. But because the moon is nearer the sun, in one half of her orbit, than the earth is, and farther in the other half of her orbit, and the power of gravity is always greater at a less distance, it follows, that in one half of her orbit the moon is more attracted than the earth towards the sun, and in the other half less attracted than the earth; and hence irregularities necessarily arise in the motions of the moon; the excels, in the first case, and the defect, in the second, of the attraction, becoming a force that disturbs its motion; and besides, the action of the sun on the earth and moon, is not directed in parallel lines, but in lines that meet in the centre of the sun.

In order to understand the effects of these powers, let us suppose that the projectile motions of the earth and moon were destroyed, and that they were allowed to fall freely towards the sun. If the moon was in conjunction with the sun, or in that part of her orbit which is nearest to him, the moon would be more attracted than the earth, and fall with greater velocity towards the sun; so that the dilance of the moon from the earth would be increased in the fall. If the moon was in opposition, or in the part of her orbit which is farthest from the sun, she would be less attracted than the earth by the sun, and would fall with less velocity towards the sun than the earth, and the moon would be left behind by the earth; so that the dilance of the moon from the earth would be increased, in this case also. If the moon was in one of the quarters, then the earth and moon being both attracted towards the centre of the sun, they would both directly defend towards that centre, and, by approaching to the same centre, they would necessarily approach at the same time to each other, and their dilance from one another would be diminished, in this case. Now, wherever the action of the sun would increase their dilance, if they were allowed to fall towards the sun, there we may be sure the sun's action, by endeavouring to separate them, diminishes their gravity to each other; wherever the action of the sun would diminish their dilance, there the sun's action, by endeavouring to make them approach to one
one another, increases their gravity to each other: that is, in the conjunction and opposition, their gravity towards each other is diminished by the action of the sun; but in the two quarters it is increased by the action of the sun. To prevent mistaking this matter, it must be remembered, it is not the total action of the sun on them that disturbs their motions, it is only that part of its action, by which it tends to separate them, in the first cafe, to a greater distance from each other; and that part of its action, by which it tends to bring them nearer to each other, in the second cafe, that has any effect on their motions, with respect to each other. The other, and the far more considerable part, has no other effect but to retain them in their annual curve, which they perform together about the sun.

In considering, therefore, the effects of the sun's action on the motions of the earth and moon, with respect to each other, we need only attend to the excess of its action on the moon above its action on the earth, in their conjunction; and we must consider this excess as drawing the moon from the earth towards the sun in that place. In the opposition, we need only consider the excess of the action of the sun, on the earth, above its action on the moon, and we must consider this excess as drawing the moon from the earth, in this place, in a direction opposite to the former, that is, towards the place opposite to where the sun is; because we consider the earth as quiescent, and refer the motion, and all its irregularities to the moon. In the quarters, we consider the actions of the sun as adding something to the gravity of the moon towards the earth.

Suppose the moon setting out from the quarter that precedes the conjunction, with a velocity that would make her describe an exact circle round the earth, if the sun's action had no effect on her; and because her gravity is increased by that action, she must descend towards the earth, and move within that circle: her orbit, there, will be more curve than otherwise it would have been: because this addition to her gravity will make her fall farther at the end of an arc below the tangent drawn at the other end of it; her motion will be accelerated by it, and will continue to be accelerated, till she arrives at the ensuing conjunction; because the direction of the action of the sun upon her, during that time, makes an acute angle with the direction of her motion. At the conjunction, her gravity towards the earth being diminished by the action of the sun, her orbit will be less curve there for that reason; and she will be carried farther from the earth, as she moves to the next quarter; and because the action of the sun makes then an obtuse angle with the direction of her motion, she will be retarded by the same degrees by which she was accelerated before.

Thus she will descend a little towards the earth, as she moves from the first quarter towards the conjunction, and ascend from it, as she moves from the conjunction to the next quarter. The action which disturbs her motion will have a like, and almost equal effect upon her, while she moves in the other half of her orbit, that is, that half of it which is farthest from the sun: she will proceed from the quarter that follows the conjunction with an accelerated motion to the opposition, approaching a little towards the earth, because of the addition made to her gravity, at that quarter, from the action of the sun; and receding from it again, as the gravity from the opposition to the quarter, from which we supposed her to set out. The areas described in equal times, by a ray drawn from the moon to the earth, will not be equal, but will be accelerated by the conspiring action of the sun, as she moves towards the conjunction or opposition from the quarters that precede them.

and will be retarded by the same action, as she moves from the conjunction or opposition to the quarters that succeed them. Newton has computed the quantities of these irregularities from their canons. He finds, that the force added to the gravity of the moon, in her quarters, is to the gravity with which she would revolve in a circle about the earth, at her present mean distance, if the sun had no effect on her, as 1 to 1757. He finds the force subducted from her gravity, in the conjunctions and oppositions, to be double of this quantity, and the area described in a given time in the quarters, to be to the area described in the same time in the conjunctions and oppositions, as 10973 to 11075. He finds, that in such an orbit, her distance from the earth in her quarters, would be her distance in the conjunctions and oppositions, as 70 to 69. This is the variation of the form of the orbit arising from the force of the sun, supposing that the orbit would have been a circle without that disturbing force. And as the orbit of the moon is an ellipse, having the earth in its focus, and approaching nearly to a circle, the same cause must produce very nearly the same effect in the moon's orbit. Dr. Halley first took notice of this contraction of the lunar orbit in syzygies, from the phenomena of the moon's motion, and made the ratio of the diameter as 44:5:45:5 from observation.

From the alteration of the form of the orbit and from the acceleration of the areas, there will arise two corrections to be applied to the mean motion of the moon, in order to give the true motion; and the joint effect of these two constitute an equation, called the 'variation.'

As to the effect of the action of the sun on the nodes, and, consequently, on the inclination of the moon's orbit to the ecliptic, see Nodes, and the preceding part of this article.

Moreover, the action of the sun diminishes the gravity of the moon towards the earth, in the conjunctions and oppositions, more than it adds to it in the quarters, and, by diminishing the force, which retains the moon in her orbit, increases her distance from the earth and her periodic time; and because the earth and moon are nearer the sun in their perihelion than in their aphelion, and the sun acts with a greater force there, so as to subduct more form the moon's gravity towards the earth; it follows, that the moon must revolve at a greater distance, and take a longer time to finish her revolution in the perihelion of the earth, when her orbit is dilated, and she moves slower, than in the aphelion, when her moon's orbit is contracted, and she moves faster. The annual equation, by which this inequality is compensated, is nothing in aphelion and perihelion; and at the mean distance of the sun it is $12^55''$, according to professor Vincen's determination. Sir Isaac Newton makes it $11^50'$; according to Mayer, it is $11^60'$; M. d'Alembert makes it $12^57''$: Halley makes it about 13': according to M. de la Lande, it is $11^80.6''$; and this also is conformable to observation.

There is another remarkable irregularity in the moon's motion, that also arises from the action of the sun: which is the progressive motion of the apsides. The moon describes an ellipse about the centre of the earth, having one of the foci in that centre. Her greatest and least distances from the earth are in the apsides, or extremities of the longer axis of the ellipse. This is not found to point always to the same place in the heavens, but to move with a progressive motion forwards, so as to finish a revolution round the earth's centre in about nine years.

To understand the reason of this motion of the apsides, we must consider, that, if the gravity of a body decreased less as the distance increases, then according to the regular
M O O N.

course of gravity, the body would descent sooner from the higher to the lower apsis, than in half a revolution; and therefore the apsis would recede at this pace, for it would move in a contrary direction to the motion of the body, meeting it in its motion. But if the gravity of the body should decrease more, as the distance increases, than according to the regular course of gravity, that is, in a higher proportion than as the square of the distance increases, the body would take more than half a revolution to move from the higher to the lower apsis; and, therefore, in that case, the apsides would have a progressive motion in the same direction as the body.

In the quarters, the fun's action adds to the gravity of the moon, and the force it adds is greater, as the distance of the moon from the earth is greater; so that the action of the sun hinders her gravity towards the earth from decreasing as much as the distance increases, as it ought to do according to the regular course of gravity; and, therefore, while the moon is in the quarters, her apsides must recede. In the conjunction and opposition, the action of the sun subducts from the gravity of the moon towards the earth, and subducts the moon the greater her distance from the earth is, so as to make her gravity decrease more as her distance increases, than according to the regular course of gravity; and, therefore, in this case, the apsides are in a progressive motion. Because the action of the sun subducts more in the conjunctions and oppositions from her gravity, than it adds to it in the quarters, and, in general, diminishes more than it augments her gravity; hence it is that the progressive motion of the apsides exceeds the retrograde motion; and, therefore, the apsides are carried round according to the order of the signs. The annual equation of the apsides, according to Sir Isaac Newton, is 10' 43". See Macaulay's Account of Sir Isaac Newton's Phil. Difcl. lib. iv. c. 4. We have some observations and tables concerning the moon's motion, by Mr. Richard Dunthorn, in the Philosophical Transactions, N. 482. lefl. 15, where he gives 100 observed longitudes of the moon compared with the tables, viz. 25 eclipses of the moon, taken (except the first) from Flamstead's Historia Coelestis, the Philosophical Transactions, and the Memoirs of the Royal Academy of Sciences; the two great eclipses of the sun in 1700 and 1715; 25 felen. places of the moon, from Flamstead's Historia Coelestis; and 48 of those longitudes of the moon, computed from Flamstead's Observations by Dr. Halley, and printed in the first edition of the Historia Coelestis.

Theory of the Moon's Motions and Irregularities.—The tables of equation, which serve to solve the irregularities of the fun, do likewise serve for those of the moon. But then those equations must be corrected for the moon, otherwise they will not exhibit the true motions in the fixyges. The method is thus: Suppose the moon's place in the zodiac, required in longitude, for any given time; here, we first find, in the tables, the place where it would be, supposing its motion uniform, which we call mean, and which is sometimes faster, and sometimes slower, than the true motion; then, to find where the true motion will place her, which is also the apparent, we are to find in another table at what distance it is from its apogee; for, according to this distance, the difference between her true and mean motion, and the two places which correspond thereto, is the greater. The true place thus found, is not yet the true place; but varies from it, as the moon is more or less remote both from the fun, and the fun's apogee; which variation respecting, at the same time, those two different distances, they are to be both considered and combined together, as in a table apart. Which table gives the correction to be made of the true places first found. That place, thus corrected, is not yet the true place, unless the moon be either in conjunction, or opposition; if then be out of these, there must be another correction, which depends on two things taken together, and compared, viz. the distance of the moon's corrected place from the fun; and of that at which she is with regard to her own apogee; this last distance having been changed by the first correction.

By all these operations and corrections, we at length arrive at the moon's true place for that instant. In this, it must be owned, there occur prodigious difficulties: the lunar inequalities are so many, that it was in vain the astronomers laboured to bring them under any rule, before the great Sir Isaac Newton; to whom we are indebted both for the mechanical causes of these inequalities, and for the method of computing and ascertaining them: so that he has given us a world, in a great measure, of his own discovering, or rather subduing.

From the theory of gravity he shews, that the larger planets, revolving round the sun, may carry along with them smaller planets, revolving round themselves; and shews also, a priori, that those smaller must move in ellipses having their umbilici in the centres of the larger; and must have their motion in their orbits variously disturbed by the motion of the sun; and in a word, must be affected with those inequalities which we actually observe in the moon. And from this theory, he argues analogous irregularities in the satelites of Saturn.

From the same theory he examines the force which the sun has to disturb the moon's motion, determines the horary increafe of the area which the moon would describe in a circular orbit by radii drawn to the earth—her distance from the earth—the horary motion in a circular and elliptic orbit—the mean motion of the nodes—the true motion of the nodes—the horary variation of the inclination of the moon's orbit to the plane of the ecliptic. Lastly, from the same theory he has found the annual equation of the moon's mean motion to arife from the various dilatation of her orbit; and that variation to arife from the sun's force, which being greater in the perige, diftends the orbit; and, being lefs in the appoge, fuffers it to be again contracted. In the dilating orbit the motion moves more slowly; in the contracted, more swiftly; and the annual equation, whereby this inequality is compenfated in the appoge and perige, is nothing at all; at a moderate dilatation from the fun, it amounts to 11' 50'"; and in other places it is proportional to the equation of the fun's centre, and is added to the mean motion of the moon, when the earth proceeds from its apogee to its perihelion; and subtracted when in the opposite part.

Thus, supposing the radius of the orbit magius 1000, and the earth's eccentricity 16'; this equation, when greatest, according to the theory of gravity, comes out 11' 49'.

He adds, that in the earth's perihelion, the nodes move fweatier than in the apheion, and that in a trirratic ratio of the earth's distance from the fun, inversely. Whence arise annual equations of their motions, proportionable to that of the centre of the fun. Now the fun's motion is in a duplicate ratio of the earth's distance from the fun inversely, and the greatest equation of the centre which this inequality excites, is 1' 50' 26", agreeable to the fun's eccentricity 16'. If the fun's motion were in a trirratic ratio of its distance inversely, this inequality would generate the greatest equation 2' 56' 0"; and therefore the greatest equations which the inequalities of the motions of the moon's apogee and
and nodes occasion, are to 2° 56' 9", as the mean diurnal motion of the moon's apogee, and the mean diurnal motion of her nodes, are to the mean diurnal motion of the fun. whence the greatest equation of the mean motion of the apogee comes out 19° 42'; and the greatest equation of the mean motion of the nodes 9° 27'. the former equation is added, and the latter subtracted, when the earth proceeds from its perihelion to its aphelion, and the contrary in the opposite part of its orbit.

from the fame theory of gravity, it also appears that the sun's action on the moon must be somewhat greater when the transverse diameter of the lunar orbit pales through the fun, than when it is at right angles with the line that joins the earth and fun; and, therefore, that the lunar orbit is somewhat greater in the first case than in the second. hence arises another equation of the mean lunar motion, depending on the situation of the moon's apogee with regard to the fun, which is greatest when the moon's apogee is in an octant with the fun; and none, when the fun arrives at the quadrature, or syzygies; and is added to the mean motion, in the paffage of the moon's apogee from the quadrature to the syzygies, and subtracted in the paffage of the apogee from the syzygies to the quadrature.

this equation, which sir isaac calls femellis, when greatest, viz. in the octants of the apogee, rifes to 3° 45"; at a mean distance of the earth from the fun; but it increases and diminishes in a triplicate ratio of the fun's distance inversely; and therefore, in the fun's greatest distance, is 3° 34"; in the smallest, 3° 56", nearly. but when the apogee of the moon is without the octants, it becomes les, and is to the greatest equation, as the line of double the distance of the moon's apogee from the next syzygy, or quadrature, to the radius.

from the fame theory of gravity it follows, that the fun's action on the moon is somewhat greater when a right line, drawn through the moon's nodes, passes through the fun, than when that line is at right angles with another joining the fun and earth; and hence arises another equation of the moon's mean motion, which he calls secunda semellis, and which is greatest when the nodes are in the fun's octants, and vanishes when they are in the syzygies, or quadratures; and in other situations of the nodes, is proportionable to the line of double the distances of either node from the next syzygy, or quadrature.

it is added to the moon's mean motion while the nodes are in their paffage from the fun's quadratures to the next syzygy, and subtracted in their paffage from the syzygies to the quadratures in the octants.

when it is greatest, it amounts to 47", at a mean distance of the earth from the fun; as it appears from the theory of gravity; at other distances of the fun, this equation in the octants of the nodes is reciprocally as the cube of the fun's distance from the earth; and in the fun's perigee is 45°; in his apogee nearly 49°.

by the fame theory of gravity the moon's apogee proceeds the faster when either in conjunction with the fun, or in opposition to it; and is retrograde when in quadrature with the fun. in the former case, the excentricity is greatest, and in the latter smallest. these inequalities are very considerabe, and generate the principal equation of the apogee, which he calls semellis, or semellimal. the greatest semellimal equation is about 12° 18'.

horrox first observed the moon to revolve in an ellipsis round the earth placed in the lower umbilicus; and halley placed the centre of the ellipsis in an epicycle, whose centre revolves uniformly about the earth: and from the motion in the epicycle arise the inequalities now observed in the progress and regrefs of the apogee, and the quantity of the excentricity.

suppose the mean distance of the moon from the earth divided into 100,000; and let t (plate xvii. astronomy, fig. 12.) represent the earth, and tc the mean excentricity of the moon 5505 parts; produce tc to b, that cb may be the line of the greatest femellimal equation 12° 18', to the radius tc; the circle bda, described on the centre c, with the interval cb, will be the epicycle wherein the centre of the lunar orb is placed, and wherein it revolves according to the order of the letters bda. take the angle bcd equal to the annual argument, or double the distance of the true place of the fun from the moon's apogee once equated, and ctd will be the femellimal equation of the moon's apogee; and td the excentricity of its orbit tending to the apogee equated a second time. from hence the moon's mean motion, apogee, and excentricity, as also the greater axis of its orbit 200,000, the moon's true place, as also her distance from the earth, are found, and that by the most common methods. in the earth's perihelion, by reason of the greater force of the fun, the centre of the moon's orbit will move more swiftly about the centre c than in the aphelion, and that in a triplicate ratio of the earth's distance from the sun inversely. by reason of the equation of the centre of the fun, comprehended in the annual argument, the centre of the moon's orbit will move more swiftly in the epicycle bda, in a duplicate ratio of the distance of the earth from the fun inversely.

that the fame may still move more swiftly in a triplicate ratio of the distance inversely from the centre of the orbit d, draw de towards the moon's apogee, or parallel to tc; and take the angle edc equal to the excess of the annual argument, above the distance of the moon's apogee from the fun's perigee in consequence; or, which is the same thing, take the angle cdf equal to the complement of the true anomaly of the fun to 26°; and let df be to dc as double the excentricity of the orbitis magnus to the mean distance of the fun from the earth, and the mean diurnal motion of the fun from the moon's apogee, to the mean diurnal motion of the fun from its own apogee, conjunctly, i.e. as 33° is to 1000, and 52° 27" 16" to 58° 8" 16", conjunctly; or as 3 to 100. conceive the centre of the moon's orbit placed in the point f, and to revolve in an epicycle, whose centre is d, and its radius df, while the point d proceeds in the circumference of the circle dadf; thus the velocity, with which the centre of the moon's orbit moves in a certain curve, described about the centre c, will be reciprocally as the cube of the fun's distance from the earth.

the computation of this motion is difficult; but it will be made easy by the following approximation: if the moon's mean distance from the earth be 100,000 parts, and its excentricity tc 5505 of those parts, the right line cb or cd will be found 1172; and the right line df 35°. this right line, at the distance of the fun's perigee, is parallel to the earth, which the transferring of the centre of the orbit from the place d to f generates in the motion of this centre; and the same right line doubled, in a parallel situation, at the distance of the upper umbilicus of the moon's orbit from the earth, subdends the same angle, generated by that translation in the motion of the umbilicus; and at the distance of the moon from the earth subtends an angle, which the same translation generates in the motion of the moon; and which may therefore be called the second equation of the centre.

this equation of a mean distance of the moon from the earth, is as the sine of the angle contained between the right
line $DF$, and a right line drawn from the point $F$ to the moon, nearly; and when greatest, amounts to 2° 25′. Now the angle comprehended between the right line $DF$ and a line from the point $D$, is found either by subtracting the angle $EDF$ from the mean anomaly of the moon, or by adding the moon's distance from the sun to the distance of the moon's apogee from the apogee of the fun. And as radius is to the sine of the angle thus found, so is 2° 25′ to the second equation of the centre; which is to be added, if that line be less than a semicircle; and subtracted, if greater: thus we have its longitude in the very fyzynges of the luminaries.

If a more accurate computation be required, the moon's place thus found must be corrected by a second variation. The first and principal variation we have already considered, and have observed it to be greatest in the octants. The second is greatest in the quadrants, and arises from the different action of the sun on the moon's orbit, according to the different position of the moon's apogee to the fun, and is thus computed; as radius is to the versed sine of the distance of the moon's apogee from the fun's perigee, in consequence, so is a certain angle $P$ to a fourth proportional. And as radius is to the sine of the moon's distance from the fun, so is the fun of this fourth proportional and another angle $Q$ to the second variation; which is to be subtracted, if the moon's light be increasing; and added, if diminishing.

Thus we have the moon's true place in her orbit; and by reduction of this place to the ecliptic, we have the moon's longitude. The angles $P$ and $Q$ are to be determined by observation in the mean time, if for $P$ be assumed 2, and for $Q$ 1, we shall be near the truth.

The results of computations of this kind are rendered more accurate, in consequence of modern discoveries; and the labour of them is in a great measure superceeded by the valuable lunar tables, which the astronomer has now in his possession. We shall therefore refer for these tables to the Nautical Almanack, and to Vince's Complete Astronomy, vol. iii.

Moon's Path with respect to the Sun, Figure of the. The path of the moon is concave towards the fun throughout.

In other secondary planets, as the satellites of the superior planets, that part of the path of these satellites which is nearest the fun, is convex towards the fun, and the rest is concave. And we often find in elementary treatises of astronomy, the moon's path represented in the same manner; that is, as partly convex, and partly concave towards the fun; but this is a mistake. For it is to be observed, in general, that the force which bends the course of the satellite into a curve, when the motion is referred to an immovable plane, is, at the conjunction, the difference of its gravity towards the fun, and of its gravity towards the primary. When the former prevails over the latter, the force that bends the course of the satellite tends towards the fun; and, consequently, the concavity of the path is towards the fun; and this is the case of the moon. When the gravity towards the primary exceeds the gravity towards the fun, at the conjunction, then the force which bends the course of the satellite tends towards the primary, and therefore towards the opposition of the fun; consequently the path is there convex towards the fun; and this is the case of the satellites of Jupiter. When these two forces are equal, the path has, at the conjunction, what mathematicians call a point of rectitude; in which case, however, the path is concave towards the fun throughout.

If, indeed, the earth had no annual motion, the moon's motion round the earth, and her track in open space, would be always the same. But as the earth and moon move round the fun, the moon's real path in the heavens is very different from her visible path round the earth; the latter being in a progressive circle, and the former in a curve of different degrees of concavity, which would be always the same in the same parts of the heavens, if the moon performed a complete number of lunations in a year, without any fractions.

Mr. Ferguson has suggeted the following familiar idea of the earth's and moon's path. Let a nail in the end of a chariot-wheel represent the earth, and a pin in the nave the moon; if the body of the chariot be propped up, so as to keep that wheel from touching the ground, and the wheel be then turned round by hand, the pin will describe a circle both round the nail, and in the space it moves through. But if the props be taken away, the horses put to, and the chariot driven over a piece of ground which is circularly convex; the nail in the axle will describe a circular curve, and the pin in the nave will still describe a circle round the progressive nail in the axle, but not in the space through which it moves. In this case, the curve described by the nail will resemble in miniature as much of the earth's annual path round the fun, as it describes whilst the moon goes as often round the earth as the pin does round the nail; and the curve described by the nail will have some resemblance to the moon's path during so many lunations.

Let us now suppose that the radius of the circular curve, described by the nail in the axle, is to the radius of the circle, which the pin in the nave describes round the axle, as $33\frac{1}{3}$ to 1; which is the proportion of the radius or semidiameter of the earth's orbit to that of the moon's; or of the circular curve $A_1 B_1 C_1 D_1 E$, &c. (Plate XVII. Astronomy, fig. 10.) to the little circle $a$, and then, whilst the progressive nail describes the said curve from $A$ to $E$, the pin will go once round the nail, with regard to the centre of its path, and, in so doing, will describe the curve $a b c d e$. The former will be a true representation of the earth's path for one lunation, and the latter of the moon's for that time. Here we may let aside the inequalities of the moon's motion, and also the earth's moving round its common central of gravity, and the moon's: all which, if they were truly copied in this experiment, would not sensibly alter the figure of the paths described by the nail and pin, even though they should rub against a plain upright surface all the way, and leave their tracks visible upon it. And if the chariot was driven forward on such a convex piece of ground, so as to turn the wheel several times round, the track of the pin in the nave would still be concave towards the centre of the circular curve described by the pin in the axle; as the moon's path is always concave to the fun in the centre of the earth's annual orbit.

In this diagram, the thickest curve line $ABC\grave{D}E$, with the numeral figures set to it, represents as much of the earth's annual orbit as it describes in 32 days from west to east; the little circles at $a, b, c, d, e$ show the moon's orbit in due proportion to the earth's; and the smallest curve $a b c d e$ represents the line of the moon's path in the heavens for 32 days, accounted from any particular new moon at $a$.

The fun is supposed to be in the centre of the curve $A 1 2 3 4 5 6 7 B$, &c. and the small dotted circles upon it represent the moon's orbit, of which the radius is in the same proportion to the earth's path, in this scheme, that the radius of the moon's orbit, in the heavens, bears to the radius of the earth's annual path round the fun; that is, as 240,000, to $1,500,000$, or as 1 to $33\frac{1}{3}$.

When the earth is at $A$, the new moon is at $a$; and in the seven days that the earth describes the curve $1 2 3 4 5 6 7$, the
the moon, in accompanying the earth, describes the curve \( ab \); and in her first quarter at \( b \), when the earth is at \( B \).

As the earth describes the curve \( BS1011121314 \), the moon describes the curve \( bc \); and is at \( c \), opposite to the fun, when the earth is at \( C \).

Whilst the earth describes the curve \( 1516171819202122 \), the moon describes the curve \( cd \); and is in her third quarter at \( d \), when the earth is at \( D \).

And, lastly, whilst the earth describes the curve \( D23242526272829 \), the moon describes the curve \( de \); and is again in conjunction at \( e \) with the fun, when the earth is at \( E \), between the 29th and 30th day of the moon's age, accounted by the numeral figures from the new moon at \( A \).

In describing the curve \( abcde \), the moon goes round the progressive earth as really as if she had kept in the dotted circle \( A \), and the earth continued immovable in the centre of that circle.

And thus we see, that although the moon goes round the earth in a circle, with respect to the earth's centre, her real path in the heavens is not very different in appearance from the earth's path. To shew that the moon's path is concave to the fun, even at the time of change, it is carried on a little farther into a second conjunction, as to \( f \).

The moon's absolute motion from her change to her first quarter, or from \( a \) to \( b \), is so much greater than the earth's, that she falls 240,000 miles, (equal to the semi-diameter of her orbit) behind the earth at her first quarter in \( b \), when the earth is in \( B \); that is, she falls back a space equal to her distance from the earth. From that time her motion is gradually accelerated to her opposition or full at \( c \), and then she is come up as far as the earth, having regained what she lost in her first quarter from \( a \) to \( b \). From the full to the last quarter at \( d \), her motion continues accelerated, so as to be just as far before the earth at \( d \), as she was behind it at her first quarter in \( b \). But from \( d \) to \( e \) her motion is so retarded, that she looses as much with respect to the earth, as is equal to her distance from it, or to the semi-diameter of her orbit; and by that means she comes to \( e \), and is then in conjunction with the fun, as seen from the earth at \( E \).

Hence we find, that the moon's absolute motion is slower than the earth's, from her third quarter to her first; and swifter than the earth's, from her first quarter to her third; her path being less curved than the earth's in the former case, and more in the latter. Yet it is still bent the same way towards the fun; for if we imagine the concavity of the earth's orbit to be measured by the length of a perpendicular line \( CG \), let down from the earth's place upon the straight line \( hbd \), at the full of the moon, and connecting the places of the earth at the end of the moon's first and third quarters, that length will be about 640,000 miles; and the moon, when new, only approaching nearer to the fun, by 240,000 miles, than the earth is, the length of the perpendicular let down from her place, at that time, upon the same straight line, and which shews the concavity of that part of her path, will be about 400,000 miles.

The gravity of the moon towards the fun has been found to be greater, at her conjunction, than her gravity towards the earth, so that the point of equal attraction, where those two powers would fulfill each other, falls then between the moon and earth; and since the quantity of matter in the fun is about 250,000 times as great as the quantity of matter in the earth, and the attraction of each body diminishes as the square of the distance from it increases; it may be easily found, that this point of equal attraction between the earth and the fun, is about 70,000 times nearer the earth than the moon is at her change; whence foine, and particularly Mr. Baxter, author of Mathis, have apprehended, that either the parallax of the fun is very different from that which is signified by astronomers, or that the moon ought necessarily to abandon the earth; because the is considerably more attracted by the fun than by the earth at that time.

This apprehension may be removed easily, by attending to what has been shewn by Sir Isaac Newton, and is illustrated by vulgar experiments concerning the motions of bodies about one another, that are all acted upon by a third force in the same direction. Their relative motions not being in the least disturbed by this third force, if it act equally upon them in parallel lines; as the relative motions of the ships in a fleet, carried away by a current, are no way affected by it, if it act equally upon them; or as the rotation of a bullet or bomb, about its axis, while it is projected in the air; or the figure of a drop of falling rain, are not at all affected by the gravity of the particles of which they are made up towards the earth. The moon is far nearer the earth, and both of them so far from the fun, that the attractive power of the fun may be considered as equal on both; and, therefore, the moon will continue to circulate round the earth in the same manner as if the fun did not attract them at all. It is to the inequality of the action of the fun upon the earth and moon, and the want of parallelism in the directions of these actions, only, that we are to ascribe the irregularities in the motion of the moon.

But it may contribute farther towards removing this difficulty to observe, that if the absolute velocity of the moon, at the conjunction, was less than that which is requisite to carry a body in a circle there around the fun, supposing this body to be acted on by the same force which acts there on the moon, (i.e. by the excess of her gravity towards the fun, above her gravity towards the earth,) then the moon would, indeed, abandon the earth. For, in that case, the moon having less velocity than would be necessary to prevent her from descending within that circle, she would approach to the fun, and recede from the earth. But though the absolute velocity of the moon, at the conjunction, be less than the velocity of the earth in the annual orbit, yet her gravity towards the fun is so much diminished, by her gravity towards the earth, that her absolute velocity is still much superior to that which is requisite to carry a body in a circle there about the fun, that is acted on by the remaining force only. Therefore, from the moment of the conjunction, the moon is carried without such a circle, receding continually from the fun to greater and greater distances, till she arrives at the opposition; where, being acted on by the fun of those two gravities, and her velocity being now less than what is requisite to carry a body in a circle there about the fun, that is acted on by a force equal to that fun, the moon thence begins to approach to the fun again. Thus she recedes from the fun, and approaches to it by turns, and in every month her path hath two apidies, a perihelion at the conjunction, and an aphelion at the opposition; between which she is always carried in a manner familiar to that in which the primary planets revolve between their apidies.

The planet recedes from the fun at the perihelion, because its velocity there is greater than that with which a circle could be described about the fun, at the same distance, by the same centripetal force; and approaches towards the fun from the aphelion, because its velocity there is less than is requisite to carry it in a circle, at that distance, about the fun.

If we suppose the earth to revolve in a circular orbit round the fun as its centre, and the moon to revolve round the earth in the same manner; the planes of their orbits to coincide; the diameters of their orbits to be as 340 to 1; and the moon to perform 13,768 revolutions to every single revolution of the earth; it is easy to investigate the nature and
and description of the curve generated by the centre of the moon; and to determine whether this curve, in one lunation, be any where convex towards the sun.

Let S (fig. 11.) represent the sun; E the earth; E a an arc of the orbit of the earth passed over by its centre, in one lunation of the moon; the circumference of the circle E A = the concentric arc A a; then, (because 13568 - 1 = 13567) the number of lunations in the year, or one revolution of the earth, and therefore SA : EA :: 13568 : 1, when the moon is in conjunction with the sun, the distance between the sun and moon will be greater than the distance or radius SA. Now the curve, described by the centre of the moon, is the same as that described by a point M (EM being the semi-diameter of the moon's orbit), carried round by the rotation of the circle E A F on the arc A a; it is therefore of the cycloidal kind, having a point of inflexion, if any cycloid, described by a point within the generating circle, is affected, as well upon a circular as upon a rectilinear base.

To determine which,

Put S b A or SR = a, E A or r = b, E M or e m = c, RM = r, RD = s; and let MC be the radius of curvature at any point m, which, it is evident, must pass through the point of contact R. Suppose the point n indefinitely near to m; then, R r and R being the indefinitely small contemporary arcs with m n, and, consequently, the triangles R m n and R n r equal in all respects; if we consider the said little arcs R n and R r as right lines perpendicular to the radius e r and S r, we shall have the <m n r = <r n r (because the angles e r and S r r, added to either side of the equation, make two right angles) <e r + <S r r. Now SR = e r :: <S r r, and S R : S R + : <R e r : R e r + <S r r, that is, a : a + b :: <R e r :: <m n r = a + b <R e r. Again, in any triangle, as d m r, if the angles m d r, m r d, and R m r, the complement of the obtuse angle to two right angles, be indefinitely small, they will be proportional to the opposite sides m r, m d, and d r; that is, d r :: m r :: <m r r : <d r r, and d r :: <m r r :: <d r r; that is, m n r : d R :: <R d r : <R m r, or, r : s :: <R e r :: <m n r = 2 r <R e r. And again, <R C n :: <R n C :: <R C

RC, that is, <m n r :: <R n r :: <R m r :: R m.

RC, or (a + b - r) : 2 r :: <R e r :: <R r :: R C

= a r + 2 b r - r = 2 a r + 2 b r - a s = r - a s = r - a s = 2 a + 2 b curvature at any point m.

Now, it is evident, that, at the point of inflexion, the radius of curvature must be infinite; or that, on one side of the said point, the expression for the radius of curvature must be affirmative, and on the other negative; therefore, r must be more than a s 2 a + 2 b on one side of the said point, and on the other less; and, consequently, at the point of inflexion, r = a s 2 a + 2 b ; which, substituted for r, makes (d M x m R = ) r s - r = 2 a b / 2 a + 2 b (because d M x m R = f m x m a) = b 2 - c 2 ; from which equation we have s = b 2 - c 2 / 2 a b + a 2 . Or, to find r, say 2 a r + 2 b r = a s, or t = 2 a r + 2 b r / a ; then (d M x m R = ) r s - r = a r + 2 b r / a = (f m x m a) = b 3 - c 2 ; which equation gives r = b 2 - a c / a + 2 b, when the point becomes a point of inflexion.

Now, as m R (r) must, by the nature of the circle, always be greater than ma; that is, as b 2 - a c / a + 2 b must always be more than b - c; and, consequently, a b - a c / a + 2 b be more than b - a; that is, a b + a c / a + 2 b be more than b - a; that is, E M must be more than a third proportional: to E S and E A, in order to have a point of inflexion take place in the curve: but in the present case, E S, E A, and E M, being as 13568 : 1, and 13567 : 340, or 0.39; therefore EM is less than the said third proportional; and, consequently, the curve M m m, generated by the centre of the moon, has not a point of inflexion, or is no where convex towards the sun. See Ferguion's Astronomical, p. 129. Sec. Macaulay's Account of Sir Isaac Newton's Phil. Difc. book iv. ch. 5. p. 336. &c. 410. Rowe's Fluxions, p. 127. &c.

MOON, Astronomy of the. 1. To determine the period of the moon's revolution round the earth, or the periodical month; and the time between one opposition and another, or the synodical month.

Since in the middle of a lunar eclipse the moon is opposite to the sun, compute the time between two eclipses, or oppositions, between which there is a great interval of time; and divide this by the number of lunations that have passed in the mean time; the quotient will be the quantity of the synodical month. Compute the sun's mean motion, during the time of the synodical month, and add this to the entire circle described by the moon. Then, as the sun is to 300°, so is the quantity of the synodical month to the periodical.

Thus, Copernicus, in the year 1500, November 6, at twelve at night, observed an eclipse of the moon at Rome; and August 1, 1523, at 5° 25', another at Cracow; hence the quantity of the synodical month is thus determined.

Obs. 2 An. 1523 23° 4° 25'.
Obs. 1 An. 1500 310 2° 20'.
Interval of time An. 22° 292° 2° 25'.
Add the intercalary days 5.

Exact interval An. 23° 297° 2° 25'.

Which, divided by 282 months, elapsed in the mean time, gives the quantity of the synodical month 42521° 9° 59'; that is, 29° 12° 41'.
From two other observations of eclipses, the one at Cro- cow, the other at Babylon, the same author determines more accurately the quantity of the synodical month to be

\[ 42524' 3'' 10''' 9'''. \]

That is, 29\(^d\) 11\(^m\) 43\(^s\) 10\('s\). But this is less than the true synodical month, which is 29\(^d\) 12\(^m\) 44\(^s\) 3\('s'\).

The sun's mean motion in the time \(29\) 6' 24'' 18''

The moon's motion \(\ldots\)

Quantity of the periodical month 27\(^d\) 7' 43\(^s\) 5''

Hence, 1. The quantity of the periodical month being given, by the rule of three we may find the moon's diurnal and horary motion, &c. And thus may tables of the mean motion of the moon be constructed.

2. If the sun's mean diurnal motion is subtracted from the moon's mean diurnal motion, the remainder will give the moon's diurnal motion from the sun; and thus may a table thereof be constructed.

3. Since, in the middle of a total eclipse, the moon is in the node, if the sun's place be found for that time, and to this be added fixed signs, the sun will give the place of that node.

4. From comparing the ancient observations with the modern, it appears, that the nodes have a motion, and that they proceed in antecedentia, i.e. from Taurus to Aries, from Aries to Pisces, &c. If, then, to the moon's mean diurnal motion, be added the diurnal motion of the nodes, the same will be the motion of the moon from the node; and hence, by the rule of three, may be found in what time the moon goes 360° from the dragon's head, or in what time the sun goes, and returns to it; that is, the quantity of the draconic month.

5. If the motion of the apogee be subtracted from the mean motion of the moon, the remainder will be the moon's mean motion from the apogee; and hence, by the rule of three, is determined the quantity of the anomalitic month. See the preceding part of this article.

To find the Moon's Age or Change — The following canon, in which the twelve numbers answer to the twelve months, beginning with January, will serve for this purpose.

The sun, bate 30, to the moon's day add,

Or take from 30, age or change is had.

The reason of adding these numbers to the epact, in the several months, is because the lunar synodical months fall short of the calendar months; so that the epact, which expresses how much the lunar year falls short of the solar, or calendar year, must be considered as continually increasing; and, therefore, to find the new moons, which are the beginnings of the synodical months, an addition must be made to the epact in every month, and more and more as the year advances; which additional numbers are called the mensural epacts. Only nothing is to be added to the epact in January, because the annual epact, together with the day of the month, does then express the true age of the moon: but as January has 31 days, which is near 2 days more than a synodical month, therefore the beginning of the lunar month in February will fall 2 days sooner than it did in January; consequently 2 is the mensural epact of February; and then, as February has but 28, or at most 29 days, which may be accounted 1 day less than a synodical month, the next lunar month will begin 1 day later in March than it did in February; consequently the mensural epact of March decreases instead of increasing, and is but 1. If from thence you reckon the lunar months to consist of 30 days and 29 intercalably, the new moons will fall so much earlier in the following months than the new moon did in January, as is expressed by the mensural epacts in the canon, viz. 2 days in April, 3 in May, &c., until they amount to 11 days at the end of the year, which are then added to the annual epact.

</table>
Explanation of the Tables.—By Tables I. and II. the mean age of the moon, at any given time, may be found to the nearest minute, by adding the epact of the given year and month, and the propounded time reduced to the meridian of Greenwich. If this sum exceeds a mean lunar, or 29 days 12 hours 44 minutes, deduct it therefrom. The mean time of new moon is found by subtracting the sun of the epacts of the given year and month, from 29 days 12 hours 44 minutes; but if greater than that quantity, subtract it from 59 days 12 hours 29 minutes, to which add the longitude, in time, if easter, but subtract it if wester. The mean time of the preceding, or following full moon, is found by subtracting, or adding 14 days 18 hours 22 minutes, and the quarters, by applying 7 days 9 hours 11 minutes. See Exact and Metonic Cycle.

By Table III. the moon's age is found by inspection only, from the year 1800 until 1804, inclusive; and the method of extending it a few years before or after the limits of the table is obvious.

This table is divided into two parts; the first part, of which contains the months and days, and the other the years, with the moon's age. In this list part, N stands for a new moon, and F for full moon. In order, therefore, to find the moon's age on any given day of any given year, within the limits of the table, find the propounded day under the given month, then, on the same horizontal line, and under the given year, is the moon's age required. Thus, March 12th, 1869, it is a new moon, and on the 18th of the same month, in the year 1878, it is full moon.

The epact for any given year within the limits of the table, is found at the bottom of the column immediately under the given year. Thus the epact for the year 1850 is 17. Mackay's Complete Navigator.

To find the Time of the Moon's being in the Meridian, or Setting.—Multiply the age by 4, and divide the product by 5; the quotient gives the hour, and the remainder, multiplied by 12, the minute.

The reason of this rule, is, that as the moon at the change comes to the south with the sun, or at twelve o'clock, and as there are thirty days, nearly, from one new moon to another, and twenty-four hours in a day; therefore the lores one day with another 12ths, or 14 of an hour in the time of her setting, now the moon's age, a number of days from the change, being multiplied by four, the product is so many fifths of an hour as she has lost, which, divided by five, is reduced to hours, and the remainder, if any, multiplied by 12, will be minutes.

Moon. For the Ephemeris of the, see Eclipses.

For the Moon's Parallaxes, see Parallax.

Moon, Nature and Furniture of the. 1. From the various phases of the moon; from her only showing a little part illuminated, when following the sun ready to set; from that part's increasing as she recedes from the sun, till at the distance of 180° the phases have a full face; and again wanes as the re-approaches that luminous, and loses all her light when she meets him; from the lucid parts being constantly turned towards the world, while the moon increases; and towards the ebb when the decreases; it is evident, that only that part shines on which the sun's rays fall. And, from the phenomena of eclipses happening when the moon should shine with a full face; viz. when she is 180° distant from the sun; and the darkened parts appearing the same in all places; it is evident she has no light of her own, but borrows whatever light the has from the sun; for if she did, being globular, we should always see her with a round full orb, like the sun.

2. The moon sometimes disappears in a clear heaven, so as not to be discoverable by the best glasses; little flaws of the fifth and sixtth magnitudes all the time remaining visible. This phenomenon Kepler observed twice, anno 1580 and 1583, and Hevelius in 1620. Ricciolus, and other Jefuits at Bologna, and many people throughout Holland, observed the like April 14, 1642, yet at Venice and Vienna she was all the time conspicuous. December 25, 1703, there was another total obfuration. At Arles the first appeared of a yellowish-brown; at Avignon rudey and transparent, as if the sun had shone through; at Marfelles, one part was reddish, the other very dirty; and, at length, though in a clear sky, the wholly disappeared. Here it is evident that the colours appearing different at the same time, do not belong to the sun; but they are probably occasioned by our atmosphere, which is variously diffus'd, at different times, for refracting of these or those coloured rays.

3. The eye, either naked, or armed with a telescope, sees some parts in the moon's face darker than others, which are called maculae, or spots. Through the telescope, while the moon is either increasing or decreasing, the illuminated parts in the macula appear evenly terminated; but in the bright parts, the boundary of the light appears jagged and uneven, composed of dimifhing arches, convex and concave. (See Plate XVII. Aptron. fig. 13.) There are also observed lucid parts differed among the darker; and illuminated parts are seen beyond the limits of illumination; other intermediate ones remaining fill in darknesses; and near the macule, and even in them, are frequently seen such lucid specks. Besides the macule observed by the ancients, there are other variable ones, invisible to the naked eye, called new maculae, always opposite to the sun; and which are hence found among those parts which are the soonest illumined in the increasing moon, and in the decreasing moon lose their light later than the intermediate ones; running round, and appearing sometimes longer sometimes smaller.

Hence, 1. As all parts are equally illuminated by the sun, inasmuch as they are equally distant from him; if some appear brighter, and others darker; some reflect the sun's rays more copiously than others; and therefore they are of different natures. And, 2. Since the boundary of the illuminated part is very smooth and equable in the macula, their surface must be so too. 3. The parts illuminated by the sun sooner, and deflected later, than others that are nearer, are higher than the rest; i.e. they stand up above the other surface of the moon. 4. The new macule answer perfectly to the shadows of terrestial bodies.

Hevelius writes, that he has several times found, in skies perfectly clear, when even flaws of the sixth and seventh magnitude were conspicuous, that at the same altitude of the moon, and the moon elongation from the earth, and with one and the same excellent telescope, the moon and its macula do not appear equally lucid, clear and perspicuous, at all times; but are much brighter, purer, and more distinct, at one time than another. From the circumstances of the observation, it is evident the reason of this phenomenon is not either in our air, in the tube, in the moon, or in the spectator's eye; but it must be looked for in something existing about the moon.

Caffini frequently observed Saturn, Jupiter, and the fixed stars, when hid by the moon, near her limb, whether the illuminated or dark side, to have their circular figure changed into an oval one; and in other occultations he found no alternation of figure at all. In like manner, the sun and moon rising and setting in a vaporous horizon, do not appear circular, but elliptical.

Hence, as we know, by our experience, that the circular figure of the sun and moon is only changed into an elliptical
tival one by means of the refraction in the vapoury atmosphere; some have concluded, that at the time when the circular figure of the stars is thus changed by the moon, there is a dense matter encompasing the moon, wherein the rays, emitted from the stars, are refracted; and that, at other times, when there is no change of figure, this matter is wanting.

This phenomenon is well illustrated by the following experiment.

To the inner bottom of any vessel, either plain, convex, or concave, with wax fallen a circle of paper: then pouring in water, that the rays, reflected from the circle in the air, may be refracted before they reach the eye; viewing the circle, suddenly, the circular figure will appear changed into an ellipse.

6. The moon, then, is a dense opaque body, furnished with mountains and valleys. That the moon is dense and impervious to the light, has been shown: but some parts sink below, and others rise above the surface; and that considerably, inasmuch as they are visible at so great a distance as that of the earth from the moon; whence it has been concluded that in the moon there are high mountains, and very deep valleys. Ricciolus measured the height of one of the mountains, called St. Catharine, and found it (as he conceived) nine miles high. The method of measuring the height of the lunar mountains is as follows. Suppose E D (fig. 14.) the moon's diameter, E C D the boundary of light and darkness, and A the top of a hill in the dark part beginning to be illuminated: with a telescope and micrometer observe the proportion of A E, or the distance of A from the line where the light commences to the diameter E D; here we have two sides of a rectangle triangle A E, C E; the squares of which added together give the square of the third side. When the semi-diameter B being substracted leaves A B, the height of the mountain.

Ricciolus, v. gr. found the top of the mountain St. Catharine illuminated at the distance of 7/8 th of the moon's diameter from the confines of light. Supposing, therefore, C E 8, and A E 1, the squares of the two will be 65, whose root is 8.062, the length of A C; substracting, therefore, B C = 8, the remainder is A B = 0.062. The moon's semi-diameter, therefore, is to the mountain's height as 8 is to 0.062; i.e. as 8000 to 62. Supposing, therefore, the semidiameter of the moon 1182 English miles, by the rule of three we find the height of the mountain 9 miles.

Galileo takes the distance of the top of a lunar mountain from the line that divides the illuminated part of the side from that which is in the shade to be equal to a 20th part of the moon's diameter; but Hevelius affirms, that it is only the 26th part of the same. If we calculate, in the manner above stated, the height of such a mountain, it will be found, in English measure, according to Galileo, a little 5½ miles; and, according to Hevelius, somewhat more than 5 ½ miles, admitting the moon's diameter to be 2160 miles. The observations of Hevelius have been always held in great esteem; and this is probably the reason why later astronomers have not repeated them.

M. De La Lande, one of the most eminent modern astronomers, concurs in his sentiments. Mr. Ferguson says, that some of the mountains of the moon, by comparing their height with their diameter, are found to be three times higher than the highest hills on our earth; and Keil, in his "Altronomical Lectures," has calculated the height of St. Catharine's hill, according to the observations of Ricciolus, in the manner above stated, and finds it nine miles. Dr. Herschel, the most accurate as well as industrious observer of modern times, has directed his attention to this subject. He observes, with regard to the method pursued by Hevelius, that it will only avail when the moon is in her quadratures; for in all other positions, the projection of the hills must appear much shorter than it really is. Let S L M, or S L m (fig. 15.) be a line drawn from the sun to the mountain, touching the moon at L or l, and the mountain at M or m. Then to an observer at E or e, the lines L M, or l m, will not appear of the same length, though the mountains should be of an equal height; for L M will be projected into o n, and l m into o N. But these are the quantities that are taken by the micrometer, when we observe a mountain to project from the line of illumination. From the observed quantity o n, when the moon is not in her quadrature, to find L M we have the following analogy. The triangles o N L, r M L, are similar; therefore, L o : L O :: L r : L M :: \( \frac{L O \times o n}{L o} = L M \):

but L O is the radius of the moon, and L r, or o n, is the observed distance of the moon's projection, and L o is the sine of the angle \( \frac{\pi}{2} \) L S, which we may take to be the distance of the sun from the moon, without any material error, and which, therefore, we may find at any given time from an ephemeris.

E.G. On June, 1780, at seven o'clock, Dr. Herchel, found the angle under which L M, or L r appeared, to be 40°.625, for a mountain in the south-east quadrant; and the sun's distance from the moon was 125° 5', whose sine is 0.8104; hence, 40°.625 divided by 0.8104, gives 50°.13, the angle under which L M would appear, if seen directly. Now the semi-diameter of the moon was 16° 23', and taking its length to be 1090 miles, we have 16° 23' = 50°.13

:: 1090 : L M = 56.73 miles; hence, M P = 14.7 miles.

The instrument used by Dr. Herchel in his observations was a Newtonian reflector of six feet eight inches focal length, to which a micrometer was adapted constituting of two parallel hairs, one of which was moveable by means of a fine screw. His observations were numerous, and from the result of all, he concludes, that the height of the lunar mountains in general is greatly overrated; and that, with the exception of a few, they do not generally exceed half a mile in their perpendicular elevation. Our author had not an opportunity of particularly observing the three mountains mentioned by Hevelius; nor that Ricciolus found to project a sixteenth part of the moon's diameter. If Kell, he says, had calculated the height of this hill according to the theorem which he has given, he would have found (supposing the observation to have been made, as he says, on the fourth day after new moon) that its perpendicular height could not well be less than between 11 and 12 miles. Phil. Trans. vol. lxx. pt. 2. art. 29.

The heights, &c. of the lunar mountains being measurable, astronomers have taken occasion to give each its name. Ricciolus, whom most others now follow, distinguishes them by the names of celebrated astronomers; and by these names they are still expressed in observations of the lunar eclipses, &c. (See fig. 16.) For an account of the Volcanos in the Moon, see that article. See also Lunar Spots.

Astronomers are now generally of opinion, that the moon has no atmosphere of any visible density surrounding it, as we have: for if the had, we could never see her edge to well defined as it appears: but there would be a fort of mist or hazeme around her, which would make the stars look fainter, when they are seen through it. But observation proves, that the stars which disappear behind the moon retain their full lustr in until they seem to touch her very edge, and then they vanish in a moment. This has been often observed by astronomers, but particularly by Cassini of the star γ in the breast of Virgo, which appears single and round to the bare
Moon.

As to the Influence of the, on the changes of our weather, and the constitution of the human body, we shall observe that the vulgar doctrine concerning it is very ancient, and has gained credit among the learned, without sufficient examination; but it is now generally exploded by philosophers, as equally delusive of all foundation in physical theory, and unsupported by any plausible analogy. The common opinion is, that the lunar influence is exerted at the syzygies and quadratures, and for three days before and after each of those epochs. There are twenty-four days, therefore, in each synodic month, over which the moon at this rate is supposed to preside, and as the whole consists but of 29 days, 12½ hours, only 3½ days are exempt from her pretended dominion. Hence, though the changes of the weather should happen to have no connection whatever with the moon's aspect, and they could be distributed in an equal proportion throughout the whole synodic month; yet any one who shall predict, that a change shall happen on some one of the twenty-four days assigned, rather than in any of the remaining 16, will always have the chances 24 to 3½ in his favour. Men may, therefore, easily deceive themselves, especially if in so unfettered a climate as ours. Moreover, the writers who treat of the figs of the weather, derive their prognostics from circumstances, which neither argue any real influence of the moon as a cause, nor any belief of such an influence, but are merely indications of the state of the air at the time of observation: such are, the shape of the horns, the degree and colour of the light, and the number and quality of the luminous circles which sometimes surround the moon, and the circumstances attending their disappearance. (See the Aristarchus of Aratus, and the Scholia of Theon.) The vulgar soon began to confide those things as causes, which had been proposed to them only as figs: and the notion of the moon's influence on all terrestrial things was confirmed by her manifest effect upon the ocean. See on this subject, Phil. Trans. vol. Ixxv. pt. 2. p. 178, &c.

The famous Dr. Mead was a believer in the influence of the sun and moon on the human body, and published a book to this purpose, intitled "De Imperio Solis ac Lunae in Corpora Humana:" but this opinion has been exploded by philosophers, as equally unreasonable in itself, and contrary to fact. As the most accurate and sensible barometer is not affected by the various positions of the moon, it is not likely that the human body should be affected by them. See Lunatic.

Moon. Har vesli. It is remarkable, that the moon, during the week in which she is full in harvest, rises sooner after sun-setting than she does in any other full-moon week in the year. By doing so, she affords an immediate supply of light after sun-set, which is very beneficial to the farmers for reaping and gathering in the fruits of the earth: and therefore they distinguish this full moon from all the others in the year, by calling it the harvest-moon. Mr. Ferguson has given a full account of the harvest-moon in his Astronomy; the substance of which is as follows, in a problem on the common celestial globe.
Make chalk-marks all round the globe, on the ecliptic, at 12° degrees from each other (beginning at Capricorn) which is equal to the moon's daily mean motion from the sun; then elevate the north pole of the globe to the latitude of any place in Europe; suppose London, whose latitude is 51° degrees north.

This done, turn the ball of the globe round, westward, in its frame; and you will see that different parts of the ecliptic make very different angles with the horizon, as these parts rise in the civil: and therefore, in equal times, very unequal portions of the ecliptic will rise. About Piscis and Aries, even of these chalk-marks will rise in little more than two hours, as measured by the motion of the index on the horary circle: but, about the opposite signs, Virgo and Libra, the index will go over eight hours in the times that seven marks will rise. The intermediate signs will rise more or less partake of these differences as they are more or less remote from those above-mentioned.

Hence it is plain that when the moon is in Piscis and Aries, the difference of her rising will be little more than two hours in seven days; but in Virgo and Libra it will be eight hours in seven days: and this happens every month of the year, because the moon goes through all the signs of the ecliptic in a month, or rather in 27 days, 8 hours.

The moon is always opposite to the sun when she is full, and the sun is never in Virgo and Libra but in our harvest months; and therefore, the moon is never full in Piscis and Aries (which are the signs opposite to Virgo and Libra) but in our harvest months. Consequentially, when the moon is about her full in harvest, she rises with less difference of time, or more immediately after sun-set, than when she is full in any other month of the year. In our winter, the moon is in Piscis and Aries about the time of her first quarter, and rises about noon; but her rising is not then taken notice of, because the sun is above the horizon.

In spring the moon is in Piscis and Aries about the time of her change; and then, as she gives no light, and rises with the sun, her rising cannot be perceived.

But in harvest, the moon is full in Piscis and Aries (these signs being opposite to the sun in our autumnal months) and rises soon after sun-set for several evenings successively; which makes her regular rising very conspicuous at that time of the year, as it so beneficial then to the farmers in affording them an immediate supply of light after the going down of the sun.

This would always be the case if the moon's orbit lay in the plane of the ecliptic. But as the moon moves in an orbit which makes an angle of 5 degrees 18 minutes with the ecliptic, and crosses it only in the two opposite points called the nodes, her rising when in Piscis and Aries, will sometimes not differ above an hour and forty minutes through the whole of seven days; and at other times, in the same two signs, she will differ three hours and a half in the time of her rising in a week, according to the different positions of the nodes with respect to these signs; which positions are constantly changing, because the nodes go backward through the whole ecliptic in 18 years and 22 days.

This revolution of the nodes will cause the harvest moons to go through a whole course of the most and least beneficial states with respect to the farmers every nineteen years. The following table shews in what years the harvest moons are least beneficial as to the times of their rising, and in what years most, from 1807 to 1861. The columns of years under the letter L, are those in which the harvest moons are least of all beneficial, because they fall about the descending node; and those under N are the moon of all beneficial, because they fall about the ascending node. In all the columns from N to S, the harvest moons gradually descend in the lunar orbit, and rise to lesser heights above the horizon. From S to N, they ascend in the like proportion, and rise to greater heights above the horizon. In both the columns under S, the harvest moons are in the lowest part of the moon's orbit, that is, farthest south of the ecliptic; and in the columns under N, the reverse. And in both these cases, their risings, though not at the same time, are nearly the same with regard to the difference of time, as if the moon's orbit were coincident with the ecliptic.

We may observe farther, that in summer with the full moons are low, and their slant is short above the horizon, when the nights are short and we have the least occasion for moon-light: in winter they go high, and slant long above the horizon, when the nights are long, and we want the greatest quantity of moon-light. Moreover as the sun is above the horizon of the north pole from the 20th of March till the 23rd of September, it is plain that the moon, when full, being opposite to the sun, must be below the horizon during that half of the year. But when the sun is in the southern half of the ecliptic, he never rises to the north pole, during which half of the year, every full moon happens in some part of the northern half of the ecliptic, which never sets. Consequentially, as the polar inhabitants never see the full moon in summer, they have her always in the winter, before, at, and after the full, shining for fourteen of our days and nights. And when the sun is at his greatest depression below the horizon, being then in Capricorn, the moon is at her first quarter in Aries, full in Cancer, and at her third quarter in Libra. And as the beginning of Aries is the rising point of the ecliptic, Cancer the highest, and Libra the setting point, the moon rises at her first quarter in Aries; is most elevated above the horizon, and full, in Cancer; and sets at the beginning of Libra in her third quarter, having continued visible for fourteen diurnal rotations of the earth. Thus the poles are supplied one half of the winter time with continual moon-light in the sun's absence; and only lose light of the moon from her third to her first quarter, while she gives but very little light, and could be but of little, and sometimes of no service to them.

Moon, Prime of the. See Prime.
Moon-Eyes, in the Manage. A horse is said to have moon-eyes when the weakness of his eyes increases or decreases according to the course of the moon; so that in the wane of the moon his eyes are muddy and troubled, and at new moon they clear up; but full he is in danger of losing his eye-light quite.

where he practised till he acquired considerable reputation. He was employed by the prince Borgeofe to conduct the alteration made in the gardens of his villa, near the Porta Pinciana, which he conducted with the taste of the modern English school of gardening, and was liberally remunerated by the prince. He died young, and left but few works behind, but for which he was more than duly extolled during his life. He was the pupil of Alex. Runceman.

Moore, Sir Jonas, an eminent English mathematician in the 17th century, was born at Whitloe, in Lancashire, about the year 1620. He applied himself principally to the study of the mathematics, for which, from his childhood, he had discovered a strong partiality. This favourite pursuit he cultivated with great diligence and success, and acquired such a reputation that during one of the expeditions of king Charles I. into the northern parts of England, he was introduced to his majesty as a person fluent and learned in those sciences. Upon conversing with him, the king expressed much approbation of his acquisitions, and gave him a promise of encouragement, which laid the foundation of his future fortune. He was afterwards appointed mathematical tutor to the king's second son James, to instruct him in arithmetic, geography, and the use of the globes. During Cromwell's government, he appears to have followed the profession of a public teacher of the mathematics; for he is styled in the title-pages of some of his publications, a "professor of the mathematics." Mr. Granger says, in his "Biographical History of England," that he was employed by the commissioners for draining and dividing the fens; and in his survey, he observed that the sea made a curve line on the beach, from which he took the hint to keep it effectually out of Norfolk. This added much to his reputation; but no mention is made of the period of his life when he was thus occupied. After the reformation of Charles II., he was excommunicated and deprived of that prince, by whom he was notified and employed by that prince, who behelded on him the honour of knighthood, and at length promoted him to the important office of surveyor-general of the ordnance. He frequently availed himself of his interest at court for the advancement of learning, the encouragement of merit, and the establishment of institutions likely favourable and beneficial to the interests of the public, and of science in general. He patronized the famous Mr. Flamstead, who had but a very scanty income at Cambridge, when he took him under his protection. In connection with Sir Christopher Wren, he urged the king to erect Flamsteed-house at Greenwich for a public observatory in 1675, recommending Mr. Flamstead to be the king's astronomer, to make observations there; and being surveyor-general of the ordnance himself, was the reason why the salary of the astronomer-royal was made payable out of the office of ordnance. Being elected a governor of Chrift's hospital, he was very instrumental in perfuading the king to found a mathematical school there, with the allowance of a handsome salary for a master to instruct a number of boys in the sea-service. The school being established, there was still wanting a methodical work necessary for the instruction of the young people. This Sir Jonas Moore undertook, but death put an end to his labours before the work was completed. We are not informed of the year when that event took place, but it was probably in 1681, or rather before this, as the work referred to was published in that year by his sons-in-law, Mr. Hanway and Mr. Pottinger, who spared neither expense nor labour to have it finished in the best manner, and securing proper assistants for the purpose. Besides the "New System of Mathematics," in 2 vols. 4to., which was the title of his posthumous work, Sir Jonas published "Arithmetic, in two Books, viz. Vulgar Arithmetical and Algebra," which went through several editions; and he translated from the Italian "A General Treatise of Artillery," by Morus.

Moore, John, an English prelate, educated at Clare Hall, Cambridge, where he took his degree of D.D. in 1681. He was consecrated bishop of Norwich in 1691, and translated to Ely in 1707. He died in 1714. His sermons were published by his chaplain, Dr. Samuel Clarke, in one volume, 8vo.; and his library was purchased by king George II., who gave it to the university of Cambridge.

Moore, Philip, a learned clergyman of the church of England, was born in 1706. In his time he was admitted into holy orders, and was appointed chaplain to the venerable Dr. Wilton, bishop of Sodor and Man, whose friend and companion he was for many years. At the funeral of that excellent prelate, he was appointed to preach the sermon, which has been published in Crotwell's edition of the bishop's works. Mr. Moore was chaplain to Douglas, in the Isle of Man, and obtained the rectory of Kirkbride. He devoted much of his time to the instruction of young persons, and in revising the translation of the holy Scriptures into the Manks language. He engaged in this work at the recommendation of "The Society for promoting Christian Knowledge," at whose request he also translated into the same language the book of Common Prayer, bishop Wilton on the Sacrament, and other pius and practical pieces. He died in 1783, in the 78th year of his age. His remains were attended to the grave by a great number of the most respectable inhabitants, and by the whole body of the clergy of the island, all of whom, with the exception of four, had been educated by him.

Moore, Edward, a poet and dramatic writer, was born in 1712 at Abingdon, where his father was settled as a dissenting minister. He was destined for business, and, at a proper age, was placed with a wholesale linen-draper in London; after leaving him, he went as a linen-factor to Ireland, where he remained some years. Upon his return he entered into partnership with an Irish gentleman, but they were not successful in their commercial speculations. He determined to quit trade, and devote himself to the profession of an author; and his first publication was "Fables for the Female Sex," which were printed in 1744. He was assisted in this work by Mr. Henry Brooke, author of Gul- tus Vafa. It was very well received, and obtained for the author the patronage of Mr., afterwards lord, Lyttleton. In 1748 Moore appeared as the defender of his patron's political character, and his panegyric, in a poem, entitled "The Trial of Selim the Persian for high Crimes and Misdemeanours," in which, under the mask of irony, he pays him many elegant compliments. In the same year he brought on the stage a comedy, entitled "The Foundling," which was not very successful, though aided by the acting of Garrick, and the other principal performers of the time. From Garrick he afterwards received substantial benefit: when, in 1754, he produced his comedy of "Gil Blas," it was, by the influence of the manager, forcibly carried through nine nights at Drury lane, notwithstanding a violent opposition. Garrick also exerted himself most vigorously in favour of his friend's tragedy of "The Gamester," brought on the stage in 1755. This is the principal dramatic performance by which Moore is known; it being now, at the distance of nearly 60 years, frequently represented. The story being taken from common life, is thereby rendered more impressive; and the horror inspired by the catastrophe, though painful to the feelings, is salutary in enforcing the moral
moral lesson intended by the writer. In 1758 he began a periodical paper, entitled “The World,” by Adam Fitzadam, which is among the few works of the kind that have obtained success since those of Addison and Steele. For this he was chiefly indebted to the contributions of the wits of the age. The names of the earl of Chesterfield, Horace Walpole, Richard Owen Cambridge, Soame Jenyns, and others, are sufficient to attest the editor's respectable character and connections, and to ensure the high value of many of the papers. While engaged in this publication, he died of an inflammation of the lungs, in the month of February 1757; at the age of 45. “He had published,” says his biographer, “in 1756, a collection of his works by subscription, in a 4to volume, dedicated to the duke of Newcastle, and dedicately complimenting his brother Mr. Pelham; but it was his fate to live on the verge of that indigence, which is generally the lot of those who trust to their pen alone for a subsistence. He was a man greatly beloved in society, for the simplicity of his manners, and the vivacity of his conversation. He left a widow and an only son, whose whole education and settling in the world were generously undertaken by Lord Chesterfield. Mr. Moore, as a poet, is chiefly remembered by his “Fables,” which are sprightly, ingenious, and instructive. His other verses are, for the most part, effusions of the light familiar kind, and fongs of which half, several were set to music, and became popular in their day.

Moore, John, archbishop of Canterbury, was son of a grazier at Gloucester, and educated at the grammar school of that city, after which he was entered at Pembroke college, Oxford. Being taken into the family of the duke of Marlborough, as tutor to one of his sons, he obtained, through that interest, a prebendal stall in the cathedral of Durham; in 1773, the deanery of Canterbury; and in 1776, the bishopric of Bangor; from whence, in 1783, he was raised to the archbishopric of Canterbury. He died in 1804.

Moore, Dr. John, a native of Scotland, born in 1739 at Stirling, the ancient residence of the Scottish kings, was the son of the Rev. Charles Moore, a clergyman of the established church, who was in high estimation among his people for the purity of his manners, and the amiableness of his disposition. He was one of the ministers of Stirling, and contrived, at that period, to live in a respectable manner on the usual stipend of 120l. per annum. On the death of his father, about the year 1755, John, then but five years old, removed with his mother to Glasgow, of which city the chief was a native, and where a small estate bequeathed to her by her father was situated. The lady, with the greatest spirit of mind, was enabled to superintend, with propriety and effect, the education of her son, and his three sisters. Being herself eminent for piety, she fulfilled the same principle into the minds of her offspring. After the necessary preparation in grammar learning, the subject of this article was matriculated at the University of Glasgow, and attended its various classes. As he was intended for the profession of medicine, he was placed under the care of Dr. Gordon, who did not disdain to unite the kindred arts of surgery and pharmacy. After he had obtained a sufficient knowledge of the practice of medicine, he went abroad to exercise the art in the army under the duke of Cumberland, in the Low Countries. On his return to England, he settled some time in London, attending the lectures of his countryman, Dr. Hunter, and obtaining every assistance in the way of his profession that the metropolis could afford. From London he went to Paris for farther improvement. Here he resided about two years, and acted as surgeon to the household of the earl of Albemarle, the British ambassador. On his return, he again attended the lectures of Dr. Hunter, and went through a course under Dr. Smellie, then a very celebrated accoucheur. He now settled at Glasgow, first in connection with Dr. Gordon; and when this gentleman quitted the general practice, Mr. Moore chose for his associate Mr. Hamilton, professor of anatomy. In 1769 he was introduced to the family of the duke of Hamilton, by attending the young duke, James-George, then labouring under a consumptive complaint, of which he died in the fifteenth year of his age. In 1772 he obtained the diploma of doctor of physic from the university of Glasgow, and was soon after engaged by the duchesses of Hamilton and Argyle to accompany her son on the continent. They spent five years together in this tour, and visited France, Italy, Switzerland, and Germany. This journey, added to his former residence in France and Flanders, gave him that intimate acquaintance with foreign manners, which he has so happily displayed in his several publications. On their return in 1778, Dr. Moore brought his family from Glasgow to London; and in the following year he published “A View of Society and Manners in France, Switzerland, and Germany,” in two volumes. In 1781, another, intended as a continuation, entitled “A View of the Society and Manners of Italy.” These works were extremely well received by the public, who seemed to consider them as among the most entertaining books of Travels that had appeared for many years, replete with amusing and characteristic sketches, and remarkably free from national prejudice or selenic censure. They went through several editions, and were quickly translated into various foreign languages. As if unwilling to suffer his medical character to sink into that of an author, he published, in 1786, a volume of “Medical Sketches,” treating in a popular manner on several important topics relative to health and disease. This was well received; but the author was fopposed to have given some offence to a few narrow minded men among his brethren, by the discolure of certain arcana, which they, for the sake of interest, wish to conceal. It proved that he had studied his profession with diligence, accuracy, and success; but it probably had little effect in extending his medical practice. Dr. Moore, as a writer, next appeared in a new character, when in 1789 he published a novel, entitled “Zelucu; various Views of Human Nature.” The tendency of this work, which abounds with many interesting events, is directed towards the education of youth; and it evinces were fully the fatal effects resulting from uncontrolled passion on the part of a darling son, and unconditional compliance on that of a fond mother. In Zelucu, Dr. Moore has displayed a knowledge of mankind, and a force of moral painting, which rendered that work much superior to the ordinary compositions of this class, and at once placed him high among the writers of fictitious narratives. The French revolution was the topic that next employed his pen. Dr. Moore, instead of surveying it at a distance, like the bulk of mankind, contemplated a very critical portion of it on the spot: he was not, indeed, present at the destruction of the Bastille, a structure dedicated for centuries to the crimes of a capricious and unbridled despotism; but he resided in France when the foreign armies, who assumed to give law to an independent state, were driven back by the enthusiasm of a whole people, who, at that period seemed resolved to be free. In 1795 he published “A Journal during a Residence in France, from August to the middle of December 1792, &c.” In this work, which consisted of two volumes, he followed his usual method of anecdote and description, interwoven with remarks; and
MOORE.

and of the many writers on this interesting subject, he has been ranked among the most discriminating and impartial. The same character will deservedly attach to his "View of the Causes and Progess of the French Revolution," which was published in 1795 in two volumes, 8vo. The doctor begins with the reign of Henry IV., and ends with the destruction of the royal family in 1793. Recurring to fiction, Dr. Moore published in 1796, "Edward, a fragm. of Human Nature, taken from Life and Manners, chiefly in England." Edward is a foundling, like Tom Jones, originally brought up in a work-house; but his real name and family being discovered, he is finally united to Caroline. In 1800 he published his "Mordaunt," a novel, in three volumes, being "Sketches of Life, Characters, and Man- 
ess, in various Countries; including the Memoirs of a French Lady of Quality." He is supposed to have had his own son, general Moore, the subject of our next article, in view, when he comes to Mordaunt's arrival in Corsica, from Gibraltar, and is the eye-witness of and actor in the siege of Calvi; and he feizes this opportunity of debilitating the merits and talents of that son, who has done so much honour to his family and country. Dr. Moore spent the last years of his life in retirement at Richmond, where he died in 1823, regretted for his fezcal and domestic virtues.

Moore, Lieutenant-General Sir John, son of the preceding, was born on the 13th day of November 1761, in the city of Glasgow. At the proper age he went to the grammar school, but his inclination was so strong for military studies, that he left school at the end of the first term, and became a pupil in the academy of the celebrated Charles Balfour. Five years afterwards he entered the army, and was made a lieutenant in the 51st regiment, of foot, in the year 1776, then quartered at Minorca. He returned to Scotland in the same year, and from thence he went to join his regiment, and continued to serve with it till he obtained a lieutenancy in the 82d, commanded by that excellent officer, brigadier-general Francis Maclean, with which he went out to North America. The 82d was stationed, for the greater part of the remainder of the American war, in Nova Scotia; so that Mr. Moore had but little oppor- 
tunity, while in the regiment, of seeing real service, except in the expedition to Penobscot, where, for the first time, he was in action, being then a captain-lieutenant. He com- 
manded a piquet, stationed on the river to oppose the landing of the American forces, was very sharply engaged, and nearly cut off with his party, before he regained the fort from which he had been sent, and which had been raised by general Maclean.

At the peace in 1783, captain Moore was reduced with his regiment. He was soon after brought into parliament, for the boroughs of Lanark, &c., by the interest of the duke of Hamilton. In the year 1787, or 1788, he obtained the majority of the 4th battalion of the 6th regiment, then quartered at Chatham; and very soon after, major Moore negotiated an exchange into his old regiment, the 51st, then in Ireland. He now devoted himself to the study and practice of his profession, which was, through life, the object to which all his wishes pointed, and the road in which he determined to march in pursuit of fame and ho-
dered to receive him, he had to solicit the agent of transports to find one; and having purchased bedding, and a few ready made shirts and stockings, failed for the West Indies with the fleet at day-light on the 28th, with no other baggage than a small portmanteau, and what he could purchase the evening before he failed at Portsmouth. Not one regiment of his own brigade was in the fleet, and he had the prospect, when he arrived in the West Indies, of finding himself without a command, as general Perryn would of course take the command of his own brigade.

On his arrival at Barbadoes, on the 13th of April 1796, he had an opportunity of waiting, for the first time, on the commander-in-chief, and relating to him his situation. This was the commencement of his acquaintance with Sir Ralph, and that fatiguing and attentive observer very soon distinguished him. It had been intended to send him to St. Domingo, but on his expressing an earnest desire to be employed in the expedition about to be undertaken by Sir Ralph in person, his request was granted, and in the course of the operations against St. Lucie, which immediately followed, the commander-in-chief employed him in every arduous and difficult service which occurred. It was also during the operations against St. Lucie, that lieutenant-general Sir John Hope, at that time a brigadier-general and adjutant-general to the army, and general Moore became known to each other. A friendship commenced, which gradually increased as they saw more of each other in the arduous and brilliant services on which they were employed in different parts of the world, under their illustrious commander-in-chief, and continued without interruption till the subject of this memoir justified his noble career, when it fell to the lot of the surviving friend to complete the last action of his life—to pay the final sad tribute to his fame; and record his merits in the manly and high-minded style of an accomplished soldier. General Moore certainly had opportunities, during the siege of Morne Fortune at St. Lucie, which lasted from the 26th of April to the same day in May, of eminently distinguishing himself; he did not let these opportunities slip, and his conduct, as Sir Ralph expressed in his public orders, was the admiration of the whole army. Sir Ralph, immediately on the capitulation, bestowed the command and government of the island on general Moore, paying him, at the same time, the highest compliments on his conduct: this public approbation, from so good a judge of military merit, was very honourable to, and highly valued by, the general; he, however, did all he could to induce Sir Ralph to keep him with the army, and employ him in the reduction of the other islands, but without effect. Sir Ralph, in a manner, forced this important command upon him, at the same time giving him the most flattering reasons for willing him to accept of it.

The admiral and general failed from St. Lucie on the 3d of June, leaving brigadier-general Moore in a situation which required, from whitt remained to be done in each a climate, perhaps more military talent, and a greater degree of exertion and personal risks, than ever there had been occasion for during the reduction of the island. The French commanding officer, and the principal post in the island, had surrendered, but numerous bands of armed negroes remained in the woods. The proprietors of the plantations were afraid to remain on them, and were chiefly assembled in the towns. The Moroines was quite open, and there was no accommodation for a garrison.

The works and guns mounted were left as they were when surrendered; all the stores of ammunition and provisions for this post were to be brought from a very considerable distance, the rainy season was just begun, and there was no hospital for the sick. The utmost activity and exertion were requisite to arrange every thing, and put the island in a tolerable state. He had at first between 4 and 500 men, mostly recruits, and they were falling sick very fast; in less than a month, of three regiments stationed in Morne Fortune, only between 6 and 700 men could be furnished fit for duty. He found it necessary, in order to inspire confidence in the owners of estates, and reduce the blacks in the woods, to be continually on the alert; he traversed the island in every direction, visiting and establishing stations for the protection of the peaceable inhabitants, and preventing supplies being sent to the brigands from Guadaloupe. He exposed his person in this obscure but necessary warfare almost incessantly, being frequently engaged in the woods with the insurgents, whom at last he succeeded in completely reducing.

He had two narrow escapes from violent attacks of yellow fever; the last rendered it necessary that he should be relieved from the command of the island, and he returned to England in the month of July or August 1797.

In the month of November 1797, Sir Ralph Abercrombie having been appointed commander of the forces in Ireland, deigned that brigadier-general Moore might be put upon the staff in that country, which was done, and he accompanied Sir Ralph to Dublin on the 2d day of December 1797.

During the time that Sir Ralph commanded in Ireland, which was at a very critical period, immediately preceding the rebellion in 1798, Moore had an important command in the south of Ireland, which was very disaffected at the time, and was also the quarter where the enemy were expected to make a landing. His head-quarters were at Bandon, and the troops under his command amounted to 3000 men, amongst which were 12 companies of light infantry of the Irish militia remarkably fine men; his troops were considered as the advanced corps of the south. Almost immediately after Sir Ralph gave up the command in Ireland, the rebellion broke out. The brigadier was very much employed during this unhappy warfare, sir under major-general Johnstone, at New Ros, where the insurgents suffered much. He was immediately afterwards detached towards Wexford, at that time in the hands of the rebels. He had on this occasion only the 60th yagers, or sharpshooters, 900 light infantry, 50 of Honpech's cavalry, and six pieces of artillery. He was directed to proceed to Cooke's mill, where he was to be joined by the queen's 25th regiments from England, which had landed at Duncannon fort. With the he was to proceed to Taghmon. On the 20th of June, the day after his moving from New Ros, he waited at the place appointed for the two regiments to join till three in the afternoon, when, hearing nothing of them, he began to be apprehensive that as by the general plan it had been settled he should be at Taghmon that day, his not arriving might perhaps frustrate the plan of operation; he therefore determined to move on with the force he had, about 1000 men, great part of whom were Irish militia. He had not marched above a mile before a large body of rebels appeared on the road, marching to attack him. There was no want of courage or good will on the part of the Irish militia, but at that time they were very ill disciplined. The brigadier-general had examined the ground, as well as the short time would allow, in the morning, and as soon as he saw of the position was fixed, his men to advantage on the right and left of the road, while the yagers were sent on to flummish, and the gun advanced to a commanding position at the crossing of two roads. The rebels attacked with great spirit, but, after an obstinate contest, were driven from the field, and pursued with great loss. They amounted to about 6000 men, and were commanded by general Roche, a priet. After the action, the two regiments under lord Dalhousie arrived from Duncannon fort.
It was then too late to proceed to Taghmonle, the brigadier therefore took post for the night on the ground where the action began. Next day, the 21st, he continued his march; on the road he was met by two men, one in red, with a white handkerchief in his hand; they proved to be from Wexford, one of them an officer of militia, who had been taken prisoner some time before, with proposals from the rebels to lay down their arms, on condition of their lives and properties being secured to them. As the brigadier had no authority to treat, he made no answer, but determined, instead of stopping at Taghmonle, to proceed on to Wexford, and take a petition to command the town, without entering it until general Lake and general Johnstone should arrive. On approaching the town, a great crowd of people were seen running out of it, and a house was observed on fire: this led general Moore to suspect that the rebels meant to burn the place and perhaps murder the prisoners in their possession. He therefore advanced rapidly, sent lord D'Aushoue into the town with two hundred men to release the prisoners, and secure tranquillity; here they witnessed the most affecting scenes that can be imagined, fathers and husbands meeting their wives and children whom they thought had been murdered. Many of the gentlemens, whose families were prisoners in the town, had attended him as guides. The rebels had piked and shot 40 of their prisoners the day before, on the bridge at Wexford, and that very evening it was intended to have burned the rest, if the general had not interposed to save them. Thus had the good fortune, by his energy and decision, to perform one of the most pleasing services that could fall to the lot of an officer. Next morning general Johnstone, and afterwards general Lake, arrived with their different columns from Enniscorthy, where the day before they had联合 attacked, beat, and dispersed the rebels on Vinegar hill, with little loss on their side, but great slaughter on that of the rebels. Brigadier-general Moore continued to serve in Ireland under lord Cornwallis, until the latter end of June 1799, when he was ordered to return to England, to be employed on the expedition under sir Ralph Abercrombie. He had been employed under lord Cornwallis from the time of that nobleman's arrival in Ireland during the rebellion on all occasions of importance, and treated in the most confidential manner by him. While general Moore was in Ireland, he succeeded to the rank of major-general, and had a regiment given him. He left Ireland on the 22d of July 1799, and arrived in London on the 28th. Being appointed one of the major-generals to the army assembling under sir Ralph Abercrombie at the camp of Shirley, near Southampton, he joined the troops very soon after his arrival. The expedition failed from Ramsgate and the Downs on the 13th day of August. On the 27th the army landed to the southward of the Holder fort, in the face of the enemy, who were driven from the beach. It was intended that major-general Moore should form the Holder with his brigade the same night: fortunately the garrison, amounting to 2000 men, evacuated it in the evening, and marched to join the rest of the enemy's troops, and he took quiet possession of it. The surrender of the Dutch fleet immediately followed the occupation of the Holder, which enabled admiral Mitchell to enter the Texel. Thus a very important piece of service was performed, though at first every thing had looked most unpromising, the enemy, perfectly apprized of the intended attack, and occupying a very strong post. Sir Ralph shewed, on this occasion, a great deal of enterprise, and success rewarded his spirit and decision.

On the morning of the 10th of September, sir Ralph's position was attacked before daylight by the combined force of French and Dutch, amounting to about 13,500 men. They were repulsed with great loss. Major-general Moore's post was warmly attacked, and he received a musket ball on the finger of his right hand; his spy-glass, which was shattered in his hand, fortunately turned the ball, and prevented it going through his body. The same evening the duke of York arrived at the Holder, and in the course of the two following days the reinforcement of Russian and English disembarked, and made the united force amount to between 30 and 40,000 men. Major-general Moore's brigade continued in the division of the army commanded by sir Ralph Abercrombie. The general attack on the enemy's line, which took place on the 19th, entirely failed, owing to the magnificent of the Russians. Sir Ralph's division accomplished the service allotted to it with complete success and very little opposition; but the failure of the attack on the left occasioned the recall of sir Ralph, and the abandonment of all the advantages which he had obtained. On the 2d of October the enemy were again attacked. The fourth brigade under major-general Moore, with two troops of dragoons and two mounted squadrons, formed the advanced guard of sir Ralph's division. The first brigade of guards under major-general Dorke followed, then the sixth brigade under major-general Hutchinson. The rear was commanded by colonel McDonald. The infantry moved in column along the beach, the artillery on the right, and the cavalry, about 1100, under lord Paget, on the right also. The advance of the column depended on the tide. At fix in the morning it was low enough for them to advance, and they moved forward. Sir Ralph directed major-general Moore to form part of his brigade, so as to oppose the enemy stationed on the sand-hills. About this time, their light troops and hussars began to skirmish with the advanced guard. General Moore had fearfully formed two regiments, namely, the 25th and 79th, in pursuance of sir Ralph's orders, when they were attacked. These two regiments repulsed the enemy with great gallantry, charged them, and drove them for a considerable distance, though not without loss, general Moore himself being shot in the thigh, which, however, did not prevent him from doing his duty. These regiments were reinforced by the roylads and 49th, and some time afterwards by the grenadier battalion of the guards. The enemy on the sand-hills continued to retreat as these regiments advanced, till they reached within a couple of miles of Egmont-on-Zee, where they were met by a strong reserve of the enemy, which advanced on them with great intrepidity. Major-general Moore's brigade in the course of five hours continued movement and action, forming the advance, and at the same time covering the flank on the sand-hills, were much dispersed and infinitely fatigued. He saw himself on the point of being surrounded, and seeing the impossibility of rallying the men under so hot a fire, great numbers continually falling in every direction, he had just determined to let them fall back to a certain distance to the rear, and then to endeavour to rally and bring them back. At this moment he received a musket-ball through his face that knocked him down. He was runned, and could make not effort to rise. Two soldiers of the 92d lifted him up and supported him to the rear. When the 92d came up, those who were before retiring returned to the charge, attacked the enemy with spirit, and drove them off with slaughter, but not without great loss. Of major-general Moore's brigade alone, the killed and wounded amounted to 44 officers, and upwards of 600 non-commissioned officers and privates.

General Moore, being unfit for further exertion, was carried to

ried to the rear, where his wounds were dressed. He was then placed on his horse, and, supported by his groom, he was conveyed back to his quarters, a distance of ten miles. After General Moore was carried off, the column advanced no farther; the rest of the day was passed in skirmishing. Towards dusk, the enemy, who had brought up some cannon on the beach, made a charge with their cavalry, and got possession of two guns, but were instantly charged, by Lord Paget, with a few light dragoons and a good many officers who happened to be with him, repulsed, and the guns retaken.

The column under Sir Ralph was too much jaded for further effort; he had expended himself very much during the whole day, and two horses had been killed under him. General Moore had one horse shot under him in the interval between his wounds. It afterwards appeared, that the referee, on joining General Coote's brigade, fell in with the enemy upon the land-hills, close to the right of the Ruffians, and were engaged, in some degree, the whole day. Had they not inclined to the left from Camperduyn, but continued to move along on the flank of Sir Ralph's column, they would have arrived fresh and in good order at the point of its destination by twelve or one o'clock; but, as it was, the column was so harassed, the regiments, one after another, being brought into action, Moore's brigade, in particular, being rendered quite useless, that they were forced to stop short, not having, at the close of the day, 2000 men who had not been in action, and those, from fatigue, unfit for any further exertion. The enemy were, however, forced to quit the field, and Bergen, Alkemaar, and Egmont-un-Zee, were entered by our troops the following day.

As soon as Major-General Moore could be moved from his quarters, he was taken to the Helder, where he embarked on board the Amethyst frigate, and arrived at the Nore on the 24th, from hence he proceeded to London. Soon after his return to England from the Helder, a second battalion was added to the 52d regiment, and the command of it was bestowed by the king, in the most gracious manner, on Major-General Moore. The major-general had by nature an excellent constitution, which he had strengthened by exercise, and never having addicted himself to intemperance, his wounds closed in the course of five or six weeks. He joined his brigade at Chelmsford on the 24th of December, 1799. In the early part of the year 1800, it had been intended to send a body of troops to the Mediterranean under Sir Charles Stuart; he wrote to General Moore and proposed to him to serve under him, which was accepted with the greatest pleasure. It was at first intended that Sir Charles should take out of England 15,000 men, but it was afterwards found that the regiments allotted for this service, and which had been part of the expedition to Holland, were insufficient, and only amounted to 10,000 effective. About the middle of March, the first division, amounting to 5000 men, embarked under Major-General Pigot. At this time a change took place in the plan of the expedition; Sir Charles had some disagreement with ministers, and resigned his situation. Sir Ralph Abercombie was appointed to the command, and Major-General Moore was named as one of his major-generals, with Hutchinson and Pigno, who failed after the end of April, with the 5000 men. Sir Ralph was appointed Commander-in-Chief in Portugal and the Mediterranean; he embarked on board the Sea-Horse frigate on the 13th of May, and failed the same day, accompanied by Hutchinson and Moore. They arrived at Gibraltar the 6th day of June, failed again the 11th, and arrived at Minorca on the 22d of June. Sir Ralph, on his arrival at Mahon, found letters from Lord Keith informing him of the surrender of Genoa to the Austrian general Melas, who had left a garrison of between 2 and 3000 men in it, and had marched to oppose Bonaparte, who had crossed the Alps with 35,000 men, and was marching into Italy. Lord Keith communicated to Sir Ralph the request of General Melas, that he would lose no time in going to Genoa. The troops were formed in two divisions, the first under Major-General Hutchinson and brigade-general Doyle, and the second under Major-General Moore and brigade-general Oakes. In the course of the 23d of June, the whole were embarked and failed for Genoa. By baffling winds and calms they were kept back, and did not get within sight of Genoa until the 26th, when they met a fleet of war, which informed Sir Ralph that the Austrians had evacuated Genoa, and that Lord Keith, with the fleet, was in Leghorn road. On the arrival of Sir Ralph with the troops off Leghorn on the 18th day of July, he learned the news of the battle of Marengo, with all its consequences. Sir Ralph had not above 5000 men with him, so that he had no reason to regret the delay, as with so small a force he could not have turned the course of events in favour of the Austrians. The troops returned to Minorca, part of them being sent under Major-General Pigot to Malta, to assist the Maltese in the blockade of the French garrison there. It was not long after this that the troops which had been employed under brigade-general Mainland in Quiberon bay arrived at Minorca, under Lord Dalhoulie, consisting of 3800 men. A fresh arrangement was made in the brigading of the army. It consisted of two divisions before, and now was formed into three brigades and a reserve; the latter was given to Major-General Moore. The whole embarked at Mahon in the course of the 20th, 25th, and 28th of August, amounting to about 10,000 men, and arrived at Gibraltar on the 13th of September. On the 19th, the army under Sir James Pulteney arrived from the attempt on Ferrol. The whole force, under Sir Ralph, failed on the 20th from Gibraltar for Tétuan bay; it amounted, after the junction of Sir James Pulteney's army, to 26,000 infantry fit for duty. They anchored in the evening in Tétuan bay, where they were employed watering until the 27th of September. The fleet was under the command of Lord Keith, and the object of this expedition was an attempt upon Cadiz. The fleet was detained in the straits, and in Tétuan bay, until the 2d of October, by westerly winds, when the whole, confining of about 150 sail, passed through the Gut, and anchored in sight of Cadiz on the 4th. It is not necessary to discuss the merits of this undertaking. The intention was to land to the northward of Rota, to march round and endeavour to destroy the arsenal at the Caraccas and the Spanish fleet. Major-General Moore was to land first with the brigade of guards and the reserve, in all about 5000 men. Sir Ralph wished to have a decided opinion from Lord Keith whether or not he might depend upon a constant communication being kept up with the fleet during the operations on shore, and for security for the re-embarkation of the army when the service was over. It was the opinion of the field-officers, that on the wind coming to the S.W., all communication must cease with the shore; and the fleet put to sea. Under such circumstances, it is surprising that even an attempt should have been made. On the morning of the 6th of October, the fleet being under way, the signal was made for the troops to prepare to land. The honourable captain Cochran, of the Ajax, had the direction of the landing, and major-general Moore was on board with him; when the boats were assembled they were found not sufficient to contain
MOORE.

contain more than 3000 men, which was very short of the number Moore was ordered to make the landing with: it was at this time one o'clock, and before they could be landed, and the boats returned to the ship for more, it would be dark. The troops were therefore re-embarked, and preparations were ordered for making the attempt next day. That night it began to rain and blow from the S.W. right on shore, and the next morning the whole fleet, at the expense of some cables and anchors, got to sea. From that day until the 21st of October, this large fleet was beating about from Tetuan bay to Jeremie, according as the wind was; on the 22d the greatest part of them had got to Gibraltar, and it was intended to have gone to the Tagus to water the ships and refresh the troops. On the 24th, orders arrived from England for the armies to separate. Six battalions were ordered to serve under Sir James Pul tney, and were to go to Lisbon, the rest of the army were to continue under Sir Ralph Abercrombie, and to go to Egypt. Major-general Moore failed with the fifth division, consisting of those ships that were most ready, on the 27th of October, and arrived at Minorca on the 5th of November. From thence they failed to Malta, where the whole armament met, and were detained for some time by contrary winds. While preparations were making for the descent on the coast of Egypt, which was at this time intended to be near Damietta, to take possession of that and from thence march directly upon Cairo, Sir Ralph sent major-general Moore to visit the Turkish army near Jaffa, to communicate with the grand vizier, and to form an opinion of their force, and how far any effective co-operation could be expected from it. He landed at Jaffa on the 9th of January, from on board the Camelion, a vessel of war, and immediately proceeded to the vizier's camp. The first news he heard on his landing was the death of brigadier-general Kohler, the chief of the mission with the Turkish army, who was an able officer, full of zeal and intelligence, who had lived a long time with them, and was the only man that could have given him information, to be depended on, of the true state of their magazines and the organization of their armies. He found the vizier a weak-minded old man, without talent or military knowledge, who received him perfectly well: he remained five days in the camp, in the course of which he gained sufficient information of the state of the army and its resources, to satisfy himself that Sir Ralph must trust entirely to the British fleet and army, as the vizier had not, at this time, the means of providing for his army during their crossing the desert. Their force, at this time, consisted of about 15,000 men, composed of an equal number of cavalry and infantry, and 50 pieces of field artillery. The plague was never out of their army, which, from all he could learn or observe, seemed to him little better than a wild ungovernmental mob. They had lost in the last seven months 6000 persons by the plague, and the loss in the camp in one day was estimated at about 200 men. He left Jaffa on the 14th, and joined the army on the 20th. Sir Ralph was not at all disappointed with the report and opinion general Moore gave him; he had always been convinced that he had only the British force to depend upon, but it was necessary to ascertain the character and state of the Turkish army by the report of an officer selected for that purpose. Sir Ralph then determined to land in the bay of Aboukir, and march immediately upon Alexandria. At this time it was the opinion of the naval officers that the army, until they got possession of Alexandria, must depend upon the navy entirely for their supply of water, which was to be effected by boats following the line of the coast between Aboukir bay and Alexandria, for at this time it was not known that the supplies could be forwarded by the lake Madie. Aboukir is 18 miles from Alexandria.

Every thing was ready for failing from Marsamusc on the 18th of February. During the time the expedition remained there it was very usefully employed for making this very formidable attempt on an enemy at that time sup- posed to amount only to about 14,000 French soldiers, besides the Greeks and natives, whom they had armed and disciplined. Whereas, it afterwards appeared, that there were not fewer than 33,000 French troops in Egypt. The army was exercised in practicing landing, and every necessary arrangement made that the genius and experienced skill of Sir Ralph could devise. Horses and mules for the artillery were procured, and about 400 cavalry were mounted. On the 22d of February the expedition, consisting of upwards of 15,000 soldiers, failed in 180 vessels of all descriptions. On the 2d of March they anchored in the bay of Aboukir. The weather was so bad that no attempt could be made to land before the 7th, so that the enemy had plenty of time to make every preparation to oppose them. The chief enemy was Major-M'Kerras, and major Fletcher, who had been sent from Marmora, in time to reconnoitre the coast: they had gone too near in an open boat, were attacked by an armed gerrn from Aboukir, and Major-M'Kerras was killed, and the boat, with major Fletcher, was taken. This was a serious loss, particularly at that time. Major-general Moore was sent, accompanied by colonel Liutendahl, two days before the landing was made, to reconnoitre the place which was pitched upon for the purpose. From a bomb vessel which lay a mile and a half from the beach, they made their observations. On the right was a high sand hill, on the left the lake Madie: the space between, about a mile in length, was the place for the landing. The ground to the left was woody and uneven, and favorable for covering and concealing an enemy close to the shore. They threw no force, except their patroons and piquets extended along the line. The ground to the right of the sand hill was fronded and commanded by the gun of the fort of Aboukir. No works could be seen, but as the fleet had appeared off Alexandria on the 18th of March, and had anchored in the bay on the 2d, it was reasonable to suppose that every precaution was made to oppose the landing. Major-general Moore, on reconnoitring the beach, was convinced that the high sand-hill was either the right or the centre of the enemy's position, he believed it to be their right, and determined to carry it with the right of the reserve, as it commanded the beach on each side of it. On the 7th, the wind having abated, and the surf on the beach considerably gone down, the reserve, the guards, and two regiments of major-general Coote's brigade, received orders in the evening to get into the boats at two o'clock the next morning. They formed the first disembarkation. The rest of the troops were moved in the evening from the large ships without, to those drawing less water and lying farther in shore, for the purpose of supporting the first disembarkation more expeditiously. Captain Cochrane, of the Ajax, had the direction of the landing. Two vessels were anchored in the evening near the shore, one to mark the right of the landing, and the other the intermediate point on the same line for the centre, and the boats, as they received the troops, were to rendezvous along-side these two vessels, where captain Cochrane, and the captains of the navy under his command, were to arrange them according to their respective divisions, and to the different brigades and regiments, as they were intended to form in order of battle. Soon after day-light in the morning of the 8th, the boats were at the rendezvous. The reserve
which formed the right was directed to the centre of the high sand-hill, the rest of the troops directed by them. Major-general Moore, and the honourable colonel Edward Paget, were in the boat with captain Cochrane. At eight o'clock in the morning the signal was made to advance. The French had been looking at them for two hours. They were drawn up to oppose them. They fired on the boats from 15 pieces of cannon, as soon as they were within reach, first with round shot, then with grape, and the infantry began as soon as they came within musket shot. The boats continued to row on readily, the sailors and soldiers cheering as they approached the beach. Many were killed and wounded, and some of the boats were sunk. The fire from the enemy of grape and musquetery was very severe. As soon as the boats touched the ground, the officers and men sprang out on the beach and landed. Major-general Moore, at the head of the grenadiers and light infantry of the 46th, with the 43d and 58th regiments in line, ascended the sand-hill. They did not fire a shot till they gained the summit, when they charged the enemy, drove them, and took four pieces of cannon, with part of their horses. The French retreated to the border of a plain, where general Moore halted, as upon the left a heavy fire of musquetery was kept up. Brigadier-general Oakes, with the left of the reserve, consisting of the 42d Highlanders, the 58th regiment, and the Coriscan rangers, landed to the left of the sand-hill, and were attacked by both infantry and cavalry, which they repulsed and followed into the plain, taking three pieces of artillery. The guards and part of general Conte’s brigade landed to the left of the reserve, they were vigorously opposed, but repulsed the enemy, and followed them into the plain. The want of cavalry and artillery (for it was some time before the guns which were landed could be dragged through the sand) saved the enemy from being destroyed. This was one of the most splendid instances of British intrepidity that perhaps ever happened. The enemy had eight days to assemble and prepare, and the ground was extremely favourable to them. The loss of the enemy was considerable, that of the British amounted to 600 killed and wounded, of which the reserve lost 400.

In the course of the afternoon the rest of the army landed, and the whole moved forward a couple of miles, where they took post for the night.

On the morning of the 9th, major-general Moore and lieutenant-colonel Andruther, the quarter-master-general, went forward with the 92d Highlanders, the Coriscan rangers, and some cavalry, to look for a new position. The country was unequal, sandy, and thickly intersected with palm and date trees. He posted the 92d at a place about two miles in front, where there was a small redoubt, and where the space became more narrow than anywhere else, by the sea and lake Madie running up on each side. He then went forward with the cavalry, until they were met by a strong patrol of the enemy, on which they retired. On reporting to Sir Ralph, he directed major-general Moore to take post with the reserve on the ground where he had placed the 92d; by noon he had taken possession of the post with the reserve, and placed his out-polls. On the 10th there was some skirmishing with the out-polls of the reserve and the enemy’s cavalry. The main body of the army was detained in their post-position, till, by the exertions of the navy, the hores and provisions were landed and forwarded to them. On the 11th, Sir Ralph went to the reserve, the brigade of guards moved forward, and took post half way between them and the rest of the army. The lake Madie was ordered to be examined, with a view to the practicability of conveying the army horses by it, which it was afterwards found could be done. On the 12th, the army moved forward in two columns, each composed of a wing. The reserve, in two columns, formed the advanced guard to each column. The enemy’s cavalry retired skirmishing as the army advanced. The army halted at a tower that they found evacuated, from the top of which a body of infantry was seen advancing. The line was instantly formed, and the army advanced with the utmost regularity and steadiness. The enemy, on seeing this movement, first halted, and afterwards retired to some heights which terminated a plain, where the British army took post for the night, and lay on their arms. Major-general Moore had the direction of the advanced polls; and the 90th and 92d regiments, though not belonging to the reserve, were placed under his orders for the night.

The out-polls of the enemy and the advanced guard of the British were so near each other, that it was impossible that either army could move without bringing on a general action. At fix o’clock in the morning of the 13th the army moved forward in two columns from the left, each composed of a line. The reserve, in one column from the left, marched on the right of the other two, to cover the flank. Sir Ralph’s intention was to attack the enemy’s right, and, if possible, to turn it. The 90th and 92d regiments formed the advanced guard to the two columns of the army, and, having got too far in front of the columns, were attacked by the main body of the enemy, and suffered severely before the columns could come to their support. These two regiments, however, maintained their ground, and defeated a body of cavalry that attempted to charge them. The action now became general along the line; the French, being forced back, retreated, covered by a numerous artillery, halting and firing wherever the ground favoured them. The British army advanced rapidly without artillery, as their guns, being dragged through sand by the seamen, could not keep up with the infantry. The reserve remained in column on the right flank covering the two lines, and though mowed down by the enemy’s cannon in front, and exposed to musquetery from hillars and light infantry from their flank, continued to move forward with pitch steadiness and regularity, that at any time during the action and pursuit, they could have been wheeled to a flank without an interval. The two lines advanced with equal order until they reached a rising ground, where there were the ruins of an ancient building of considerable extent; from this height they saw the enemy retreating in confusion through a plain, under cover of the fortified heights in front of Alexandria. Sir Ralph followed them into the middle of the plain, where a consultation was held, and it was then intended that general Hutchinson, with part of the second line, which had been left engaged, should attack the enemy’s right, while major-general Moore, with the reserve supported by the guards, attacked their left near the sea.

General Hutchinson had a considerable circuit to make to get to the ground where he was to make his attack, and the attack of the reserve was to be regulated by his. When he got to his ground, the position of the French was found to be strongly defended by a numerous artillery, and covered bybesides by the guns on the fortified heights near Alexandria, that the attack was given up, and as the army were in their present position exposed to the enemy’s cannon without being able to re-ulcse, a position on the height in the rear was marked out, to which the army fell back as the evening advanced. This severe action cost the British army 1300 killed and wounded. The enemy had between 5 and 7000 men in the field, their artillery was exceedingly well served, and being abundantly supplied with artillery horses, and having besides so great a superiority of cavalry, that the few belonging to the British could not act, they were
were enabled to make good their retreat under a tremendous cannonade, galloping off with their guns, as the British closed, to wherever the ground favoured them, and then renewing their fire. The French labs could not have been equal to that of the British, from the circumstances above stated.

The position of the British was not a bad one, with the right to the front, and the left to the lake of Madre and the cauld of Alexandria. A redoubt was thrown upon the right in front of the reserve, and two upon the canal on the left, which was the weak side, having an extensive plain in front and rear of it. Heavy cannon were landed and placed in these field-works, which made the position of the army tolerably secure. Water was found by digging wells, so that the harrowing operation of supplying the army with that necessary article was not required: their chief want, at this time, was that of fuel. The situation of the British army at this period was certainly a very critical one. The French army which had fought them on the 13th was a small portion of the troops they had then in Egypt. They were posted opposite to them on very strong ground, from whence they could not be driven without heavy cannon; after which, the siege of Alexandria was to be undertaken by an army very inferior in numbers. It was quite evident that when government ordered Sir Ralph on this expedition, they were ignorant of the force that the French had in Egypt, and had suffered themselves to be deceived by erroneous information, and misled by the intercepted letters. Sir Ralph was well aware of the arduous task he had to perform, and of the improbability of final success; he was, however, determined that no efforts should be wanting on his part to fulfil the service he was sent on, and, at all events, to support the honour and reputation of the British army. He knew that at this time Menou was collecting a force at Demenbour: the army that had as yet opposed him was commanded by general Friou. It was sir Ralph's intention, as soon as the heavy cannon and intrenching tools were got up, to attack the enemy on both their flanks; if he failed, he would retire to their present position, until another was prepared in the rear to favour their retreat, and the re-embarkation of the army. The camp of the British was about four or five miles from Alexandria. In front of the reserve, which formed the right of the army, was a very extensive ancient ruin, which the French called Cuzaf's camp; it was twenty or thirty yards retired from the right flank of the redoubt, and commanded the space between the redoubt and the sea. In the redoubt and the ruin, major-general Moore had posted the 28th and 58th regiments, and had made his arrangements with brigadier-general Oakes, in case of attack, to support this pool, which was the place for the reserve to fight from, indeed, from the nature of the ground, if the enemy carried it, it would have been impossible for the British army to remain in this position. He was the major-general of the day on the 28th. After visiting the pikets, he remained with the left picquet of the reserve until four in the morning of the 21st. The enemy had been perfectly quiet during the night. Nothing had been observed from them but some rockets, which they were accustomed occasionally to throw. Thinking every thing quiet, he had left orders with the field officers to retire to their posts at daylight, and was riding towards the left to give similar orders. Just as he reached the left picquet of the guards, who were to the left of the reserve, he heard a fire of musketry on the left, but every thing continuing quiet on the right, from the style of the firing, and from other observations he had made the evening before, he suspected it was a false alarm; he was, however, riding along towards the left, when a firing commenced from the piquets of the reserve; he instantly turned, laying to his aide-camp, "this is the real attack, let us gallop to the redoubt." He met the pikets falling back, and by the time he reached the redoubt, in which colonel Paget with the 20th were posted, he found it warmly attacked. The day was not yet broken, and the smoke made it darker. The general orders were for the troops to fland to their arms at a hour before day-light, and fortunately they had fallen in before the attack began. The honourable colonel Paget with the 28th manned the redoubt, and he had two companies in reserve, which he formed on the left of it, as the redoubt was open in the rear: the 58th regiment lined the old ruin, and, when the attack commenced, brigadier-general Oakes brought down the left wing of the 42d Highlanders to the left, according to the previous arrangements. Major-general Moore had sent captain Anderson, his aide-camp, for the right wing of the 42d, and with orders for the 23d, and four flank companies of the 40th, to support the ruins. He was speaking to colonel Paget on the platform of the redoubt, when his horse was shot in the face, and colonel Paget received a wound in the neck, which knocked him down. The dark-ness prevented the motion of the enemy from being seen, but their drums were beating the charge, and their voices were heard encouraging one another to advance.

About this time, some perfon said to major-general Moore that the French had turned the left of the reserve. He at first thought they had mistaken the 42d for the enemy, as he saw them moving on the left where he had ordered them; but colonel Paget, who had recovered from the run of the blow he had received, and had been mounted on his horse, rode up to him and said, "I assure you the French have turned us, and are moving towards the ruin." He looked, and saw a column of French completely in the rear. At this instant, the right wing of the 42d came up, ran to them, ordered them to face to the right-about, and, pointing to the French column, ordered them to charge the enemy, whom, he cried out, were completely in their power. He charged them with the 42d, using the bayonet, drove them into the ruin, where they were received by the 58th, and not a man of that column escaped being killed or taken prisoners. The instant this was done, he led them back to the flank of the redoubt, and on the way met another column of the French, that had also penetrated. He attacked them with the 42d and part of the 28th, and drove them back. In this charge he was shot through the leg. The 42d and 28th, pursuing the enemy too far, got into disorder, and were charged suddenly by the cavalry. Major Hony- man, seeing that general Moore had difficulty in walking from his wound, lent him his horse. The French cavalry had got completely among the 42d and 28th; but these gallant regiments, though in disorder, rallied, and brought down to many men and horses with their fire, that the cavalry were driven off. The great object of the French was to carry the redoubt, and turn the right of the army: accordingly their great effort was again the reserve. They made another desperate attack with a line of infantry in front and on both flanks of the redoubt. The 58th regiment in the ruins allowed them to approach within sixty yards, and then gave them their fire so effectually as to knock down great numbers, the rest went off. Upon the left of the redoubt the 42d and 28th repulsed what was in front, but, while following, were again charged, and penetrated by a large body of cavalry, who palled quite through and into the rear of the redoubt. Sir Ralph was surrounded, and must have been taken or killed, but a folder of the 42d shot the hussar who was attacking him. Major-general Moore
Moore had to clasp spur to his horse to get clear, and galloped to the ruins, to bring up some of the troops from thence, which he knew were formed, and in good order. The 28th regiment, who were lining the parapet of the redoubt, seeing the cavalry enter the rear of the redoubt, faced about, without quitting their ground, and killed all the dragoons who had entered it. The 42d, though broken, and persisted by the cavalry, were individually fighting, intermixed with them: major-general Moore ordered the four flank companies of the 42d from the ruins to fire high, and pour in a couple of volleys, though at the risk of hurting the 42d, and part of the 28th.

In an instant the field was covered with men, and horses galloping without their riders. This body of cavalry was destroyed. Every attack the French made was repulsed with great slaughter. In the early part of the action, and in the dark, some confusion was unavoidable, but wherever the French appeared, the British went boldly up to them, even the cavalry breaking in had not in the least dismayed them. As the day broke, the foreign brigade under brigadier-general, afterwards Sir John Stuart, who fought the battle of Maia, came to the second line to the support of the reserve, shared in the action, and behaved with great spirit. Day-light enabled major-general Moore to get the reserve into order, but there was a great want of ammunition. The guns could not be fired for a very considerable time, otherwise the French might have suffered much more severely, while retreating from their different unsuccessful attacks, than they did. The enemy's artillery continued to gall the British fiercely with shot and shells, after the infantry and cavalry had been repulsed. The British could not return a shot. Had the French attacked again, the British had nothing but their bayonets, which they unquestionably would have used, as never was an army more determined to do their duty. But the enemy had suffered too severely, that the men could not be got to make another attempt. They continued in front at a distant musket shot, until the ammunition for the English guns was brought up to enable them to fire, when they very soon retreated. While the attacks were made on the British right, a column attacked the guards on the left of the reserve, but were repulsed with loss. The French general, Menou, had concentrated the greatest part of the force in Egypt for this attack: the prisoners flated his force in the field at about 13,000 men, of whom between three and four thousand were killed or wounded. The British army left about 1300 men, of whom about 550 belonged to the reserve. This battle commenced at half part four in the morning, and terminated about nine. The French made three different attacks, with superior numbers, the advantage of cavalry, and a numerous and well served artillery. The British infantry here gave a decided proof of their superior firmness and hardihood. Sir Ralph, who always exposed his person very much, in this last battle carried the practice perhaps farther than he had ever done before. Major-general Moore met him early in the action, close in the rear of the 42d, without any of the officers of his family; and afterwards, when the French cavalry charged the second time and penetrated the 42d, major-general Moore faw him again and waved to him to retire, but he was instantly surrounded by the huzars; he received a cut from a saber on the breast, which penetrated his clothes and just grazed the flesh. He received a shot in the thigh, but remained in the field until the battle was over, when he was conveyed on board the Foudroyant. Major-general Moore, at the close of the action, had the horse killed under him that major Honeyman had lent him. When the battle was over, the wound in his leg became a flux and painful, that as soon as he could get a horse, he gave the command of the reserve to colonel Spencer, and retired with brigadier-general Oakes, who commanded the reserve under him, and who was wounded in the leg also, to their tents in the rear. Brigadier-general Oakes was wounded nearly at the same time, and in the same part of the leg that major-general Moore was, but they both continued to head the reserve until the battle was over. When the forage had disposed their wounds, finding that they must be some time incapable of action, they returned to the Diadem troop ship. Captain Anderdon, one of Moore's aide-camps, and who had served with him ever since he was a general officer as brigade-major, or aide-camp, was surrounded and in the hands of the huzars at the time that they charged the 42d, and was shot through the shoulder and fell; when he recovered his senses, he found himself lying among dead huzars and their horses.

Sir Ralph Abercrombie died of his wound on board the Foudroyant on the 28th day of March, deeply lamented by the army, and by none more than by major-general Moore, who had served so much with him, had been so distinguished by him, and who, being honoured with his complete confidence, knew how to elevate his upright and honourable character. He was a man of excellent judgment and great courage, which, aided by long military experience, and the greatest zeal in his profession, made him the best officer. He possessed great firmness and decision, the enterprising spirit of youth and bravery to excess. The great disadvantage he laboured under was being extremely short-quicked, which made him flound in need of good executive general officers under him. On death the command devolved on major-general Hutchinson.

The French, after their defeat on the 28th of March, strengthened and contracted their line of defence in front of Alexandria, and after leaving a sufficient force for the defence of the place, detached the greater part of their force to Rhamanie, which was the key of their communication with Cairo. Major-general Hutchinson at first detached colonel Spencer to Rosetta, with about 1000 British and a body of between 4 and 5000 Turks, which had arrived about the time of sir Ralph's death.

The town was evacuated by the enemy on his approach. It is unnecessary here to detail the operations in Egypt that followed the battle of the 28th, as major-general Moore was conveyed on board the Diadem troop ship until the 18th of May, when he was removed to Rosetta for the benefit of a change of air. He suffered very severely; the ball had paffed between the two bones of his leg; he endured a long confinement and much torment, from inflammation and surgical operations. When at length he could move on crutches, and was removed to Rosetta, where he got a house on the banks of the Nile, agreeably situated, he began to recover rapidly. On the 26th of June the wound, though not yet closed, being in a healthy state, he could no longer rest the defile he had to rejoin the army under lord (then major-general) Hutchinson; he embarked in a garron on the Nile, and arrived within a few miles of the camp before Cairo on the 28th; on the 29th he joined the army and took the command of the reserve. The treaty for the surrender of Cairo, and evacuation of Egypt by the garrison, was just brought to a conclusion. The Turkish army under the grand vizier was encamped on the eil side of the Nile; they were in considerable force, and had a short time before defeated a body of 4000 French who had marched against them from Cairo. The British, the Turks under the captain pasha, and the Naimulks, were encamped on the well side of the Nile; the communication with the vizier's army was kept up by a bridge.
bridge of boats; on the 10th of July the French evacuated Cairo. General Hutchin-son and general Craddock, being both indisposed, the former ordered major-general Moore to take the direction of the march of the army to the place of embarkation. Every previous arrangement being made with the French general, the march commenced on the 15th of July, at day light, in the following order. The Turks, the baggage of the British, the first line, the cavalry, the rear guard, the French army, and the Malamusk. In this manner they proceeded to the place of embarkation at Rosetta, encamping every night; the ground for the French army being given to them every evening by the British quarter-master-general, was about two miles from the British, who encamped with their front to the French, and who, agreeably to the capitulation, preferred their arms, and a certain quantity of ammunition.

This extraordinary march lasted till the 31st of July, the greatest order being preferred in both armies. No communication between them was suffered but by special leave. The moment they came to their ground, every evening the piquets were posted. The French army that surrendered at Cairo did not consist of less than 10,000 fighting men, of which about 800 were cavalry, and they had 50 pieces of cannon well horded and equipped. About 2000 of the French army were on board the garrisons that attended the army down the Nile. Major-general Moore continued to serve in the army of Egypt until after the surrender of Alexandria, when he returned to England, the peace having been very soon concluded after that event. He received the honour of knighthood, and the order of the Bath, almost immediately after his return to Egypt.

During the time he was constantly on the home staff, and on the breaking out of the war in 1803, he was stationed at Sandgate, on the coast of Kent, which, during the alarm of an invasion from Boulogne, was an important post. His brigade consisted of the two battalions of his own regiment, the 52d, the 43d, the 93d line regiment, the 4th or king's own, and the 78th Highlanders. The 52d and 43d had begun to be formed on a plan of his own as light corps, which was the beginning of the light division, that has been found so useful on the peninsula of Spain; and their great superiority having now been established by real service in the field, many other regiments have since been formed upon the same system. General Moore's object was to combine the knowledge and practice of the duties of light troops, with the general system for the movements of the army, and to form these regiments so as to be ready to act either as light troops, or in the usual mode, according to circumstances.

In the month of June 1806, lieutenant-general Sir John Moore was sent to Sicily to serve under general Fox, as second in command. He continued in that situation till the month of July 1807, when general Fox, whose health was unequal to active operations, returned to England, and Sir John Moore was appointed commander-in-chief in the Mediterranean. He continued in Sicily till the latter end of September 1807, when he received orders to embark with part of the army and proceed to Gibraltar, leaving the command in Sicily to general Sherbrook. He embarked on the 24th of October on board the Chiffoline frigate. The general officers he was directed to take with him were named, and also the regiments, in all upwards of 7000 men.

It was now intended that he should afford assistance to Portugal, at the time of the first invasion of that kingdom by Junot. Indeed, however, of accepting the proffered aid, the prince regent of Portugal adopted, as he imagined, the only measure by which he could preserve his own honour and safety, and afford a chance to such of his subjects, as preferred liberty and tranquillity in the Brazils to the tyranny of the French, of accompanying him in his emigration. His fleet, which had long been in a state of preparation, failed, under the protection of the English, to the Portuguese settlements in South America, the king embarking on board the slop commanded by captain Graham Moore, brother to Sir John, on whom the command of the expedition devolved.

Sir John returned, according to the instructions previously given him, to England, without landing in Portugal, and he was in the spring of 1808 dispatched to Sweden with 10,000 men, to affix against a combined attack from Russia, France, and Denmark. On the 17th of May this army reached Gottenburgh; and it was soon intimated, that the troops must not land. The folders and horses, consequently, remained toiling on board the crowded transports for several weeks. Sir John Moore prudently suppressed the feelings excited by so inhosipitable a reception, and so opposite to what he had been led to anticipate. He repaired, however, to Stockholm to communicate his orders, and to concert measures for the security of Sweden. He there found that the king of Sweden was bent on conquest, though he had not an army adequate even to defend his own country. He proposed, that the British should remain in their ships, till some Swedish regiments could be collected, and that the combined forces should land and conquer Zealand. Sir John was too experienced an officer not to foresee the absolute impracticability of the project. He represented, in the most respectful manner possible, that the difficulties were such, as to be surmounted by the brave troops. It was not proposed, that the British alone should land in Ruffian Finland, form a fortress, and take a position there. This notion was considered by the British general as more perilous than the former, and he endeavoured to prove that 10,000 British were insufficient to encounter the principal force of the Ruffian empire, which would quickly be brought against them. The objections which he was obliged to make to these and other schemes equally absurd, drew upon him the reprobation of his Swedish majesty, who arrested him in his capital. He, however, with considerable address, withdrew from the thraldom of Sweden without committing his government. On his return, he was honoured with the approbation of the ministers and his sovereign, and there seems no doubt, that with a general poffessed of the good fens and political fennics, the army would have been exposed to inevitable destruction. After having acted in the Mediterranean and also in Sweden as commander-in-chief, Sir John Moore was superseded by Sir Harry Burrard, and was called upon to serve in Portugal, as third in command. Upon such treatment many an officer would have resigned, but Sir John Moore was superior to modern military fentiments; he loved his country, and was ready to serve it in any situation flagell out for him by his sovereign. He failed with his commanding officer in the fleet to Portugal on the 31st of July. They did not arrive at Lisbon with their army till after the battle of Vimeira, and the subsequent martial measures. Little of importance occurred for some weeks; but on the resignation of Sir Harry Burrard, Sir John Moore was, on the 6th of October, appointed to the chief command of an army to be employed in Spain. It had been the design of government, since the month of August, to send an army to the north of Spain; the project was now to be put into execution, and Galicia, or the borders of Leon were fixed upon by the war minister
Two nights after writing this letter, Sir John was awakened from his sleep by an express to inform him that the French army had advanced, and taken possession of the city of Valladolid, which is but twenty leagues from Salamanca. We have before observed that Sir John was positively informed that his entry into Spain would be covered by 60,000 or 70,000 men; and that Burgos was the city intended for the point of union for the different divisions of the British army. But already not only Burgos, but Valladolid, was in possession of the enemy; and he found himself with an advanced corps in an open town, at three marches distance only from the French army, without even a Spanish piquet to cover his front! He had at this time only three brigades of infantry, without a gun in Salamanca. The remainder, it is true, were moving up in succession, but the whole could not arrive in less than ten days.

At this critical time the Spanish main armies, instead of being united either among themselves, or with the British, were divided from each other almost by the whole breadth of the peninsula. The fatal consequences of this want of union were but too soon made apparent; Blake was defeated, and a report reached Sir David Baird that the French were advancing upon his division in two different directions, so as to threaten to surround him. He, consequently, prepared to retreat upon Corunna; but Sir John Moore, having ascertained that the report was unfounded, ordered Sir David to advance, in order, if possible, to form a junction with him.

It was at this moment that Mr. Freere, the British ambassadour at Madrid, first commenced his official communications with Sir John Moore. Either from an excess of zeal and hope which clouded the knowledge which he professed of Spanish affairs, or from an utter ignorance of them, unbecoming and disgraceful in a diplomatic character, situated as he was, where he had access to the best sources of information, he represented the defeat of the armies of Blake and of Ultrasound, and the consequent success of the French army, as of trivial moment, and strongly pressed the British to press forward to the capital. Sir John Moore, however, fortunately had more accurate and earlier means of learning the operations of the Spanish and French armies. On the 28th of November he received information that Cailanos was completely defeated, and now there was no army remaining, against which the whole French force might be directed, except the British; and it was in vain to expect that they, even if they had been united, could have resisted or checked the enemy. Sir John Moore, therefore, determined to fall back on Portugal, to halter the junction of general Hope, who had gone towards Madrid, and he ordered Sir David Baird to regain Corunna as expeditiously as possible. This determination to retreat created dissatisfaction among the army, who could not be judges of the necessity of the movement. Mr. Freere also wrote expressly against it, mentioning the French force as "about eleven thousand only;" though if he were at all qualified for the duties of the high office to which he had been appointed, he might have known that Bonaparte was rapidly advancing with nearly eighty thousand men. Is it a sufficient excuse for Mr. Freere, that he was deceived by the truculent Morla; ought he to have trusted to the information of a single man, when he had the means of getting at real facts from unquestionable sources of authority? The fate of Spain and of the whole British army depended upon the knowledge of the truth; and had the requisitions and advice of Mr. Freere, who, perhaps, followed the counsels of Morla, been literally obeyed, not a man of the British army could have escaped.

When Sir John Moore had determined upon a retreat, he assembled
fended the general officers, and showed them the grounds of his resolution; he told them he had not assembled them, in order that they might be induced to commit themselves by giving any opinion upon the subject; he took the whole responsi-
bility upon himself: all that he required of them was, that
they would immediately prepare for carrying it into effect.
The idea of retreating was still very generally disapproved,
and murmurs against it from officers of rank were heard in
every quarter. "Even the staff officers of sir John Moore's
family lamented it, and, for the first time, doubted the
wisdom of his decision." He, however, had the satisfaction
of learning, very soon after, that general Hope completely
agreed with him.

Had sir John Moore followed the dictates of his own
judgment, and acted on what he knew was the real state
of Spanish affairs, and the strength, position, and probable
movements of the French armies, he would have carried his
determinations of retreat into immediate and complete exe-
cution. But unfortunately for his country, before he could
carry his plans into effect, he received letters from Mr.
Frere, dated the 9th of November, strongly pressing him
to advance to Madrid, and giving a most flattering picture
of the enemy's defeated and demoralized spirit of the people,
and of the ample resources of the country. This communi-
cation was soon followed by a messenger sent expressly by the
prince Castelfranca and Morla, the governors of Madrid,
with a paper signed by them, in the name of the sup-
reme junta, and dated on the second of December. This
paper was an exaggerated flattering representation of the
zeal and resources of the Spaniards, and the statements con-
tained in it were farther recommended to sir John Moore's
attention by another letter from Mr. Frere, dated even the
third of December, from Talavera, in which he preludes the
general, in the strongest terms, to advance to the capital,
although that capital had, unknown to him, been abandon-
to the enemy on the preceding day without his being aware
of it. In an evil moment, the British general, not sus-
pecting the traitorous intentions of Morla, suffered his own
judgment to give way to the representations of the traitors
in Madrid, and Mr. Frere. He hesitated his retreat, and
even ordered sir David Baird to advance; for it could never
enter into the conception of sir John Moore, that the two
chiefs of the junta had confided to betray the capital of their
own country, and to entice the army of their ally into the
power of the enemy. Nor could he suspect, when a con-
fidential agent of Mr. Frere was representing Madrid as
in little danger, that, in fact, it had already submitted at the
very sight of the French army; that the Spanish chiefs were
crouching at the feet of Bonaparte; and that the people at
large were overwhelmed with terror and despair. Nor was
it imaginable, to an ingenuous mind, like that which sir John
Moore possessed, that the British minister should be so grossly
deceived, as to send, for his instructions, intelligence the re-
verse of the truth, and to require of him, in so positive a
manner, to succour a city which had actually surrendered.
Yet this Mr. Frere, on the day after the surrender of Ma-
drid, urges on the general the propriety, not to lay the
necessity of supporting the determination of Spanish people
(in defending Madrid) by all the means which have been
entrusted to you for that purpose. I have no hesitation in
taking upon myself any degree of responsibility that may
attach itself to this advice."

As, however, sir John Moore had now completely effected
his junction with general Hope, and had removed every
obstacle to his junction with sir David Baird, whenever it
might be deemed expedient, he determined to peril his
resolution of advancing, though that resolution had been
formed, under the idea that Madrid not only held out, but
was capable of opposing the French for a considerable
length of time, if not with ultimate and complete success.
Sir John was anxious to meet the wishes of his troops, by
leading them against the enemy, he determined, therefore,
to attack Soult, who was posted at Saldanha, by which he
thought he should draw off the French armies to the north
of Spain, and thus afford an opportunity for the Spanish
armies to rally and re- unite. Soult was probably posted in
that spot, with so small a body of men, for the purpose of
enticing the British army farther into Spain, or at least of
occupying their attention; while Bonaparte, in person,
with his whole disposable force, endeavored to place him-
tself between the British army and the sea. At length the
two armies met; and the superiority of the British cavalry
was eloquently displayed in a most brilliant and successful
skirmish. About 600 of the imperial guards of Bonaparte
were beaten, and driven off the field by half the number of
British, leaving 55 killed and wounded, and 70 pris-
Ioners, among whom was general le Febre, the commander
of the imperial guard. Notwithstanding this and other ad-
 vantages gained over the enemy, a retreat was become indis-
putably necessary: and the only difficulty was to determine
the route that ought to be pursued. The French that were
now dispatched after sir John Moore, upon the lowest calcu-
lation, amounted to 70,000 men, while the troops under the
British commander were not more than 27,000. Sir John
Moore was anxious to have defended the passes of
Galicia, but this he was often prevented from doing, owing
to the immense superiority of the enemy, want of provi-
sions, and the danger of having his positions turned. So rapid
was the march of the main body of the French army under
Bonaparte, and so closely did they pursue sir John Moore,
that the advanced guard of the enemy entered Fordeillas
on the same day that the British began to retreat from
Sahagun, so that the distance between them was scarcely 30
miles.

Sir John Moore, in his retreat, instead of being benefited
or aided by the Spanish troops under Romana, was greatly
impaired by them. He had given strict directions to that
commander to leave the route to Aforga open for the
English; yet when he arrived at that town, he found it
completely occupied by Romana's troops, and it was not
without the utmost difficulty, and the exertion of much skill
and activity, that sir John Moore was able to draw off his
army from it before the arrival of the French. The situa-
tion of the British at this time was most desperate. In the
middle of winter, in a dreary and desolate country; the sol-
diers, chilled and drenched by deluges of rain, went by
long and rapid marches, in bad roads, were almost entirely
destitute of fuel, either to dress their food or dry their
clothes, and when they did halt, found it extremely diffi-
cult, frequently impossible, to procure shelter. Their pro-
visions were scanty, and procured with great labour, and in
an irregular manner; the wagons, in which were their mag-
zines, baggage, and stores, were often deserted in the
night-time by the Spanish drivers, terrified at the approach
of the French: the bullocks and mules by which they
were drawn could not be made to move, except by their
native drivers; it was, therefore, frequently necessary to
destroy the provisions and stores, in order that they might
not fall into the hands of the enemy. In one instance there
were even two carts with dollars to the amount of 25,000l.
which, for want of proper cattle to draw them, fell behind,
and after every effort to save the money, so necessary at that
moment,
possibly, out of the house. Some few were prevailed upon to move on, but neither threats nor the approach of the enemy could induce the greater number to quit the house.

At length the rear guard was compelled to march and leave these defenseless people to their fate. The road was filled with Spanish and British stragglers, armed and unarmed, males, carts, women and children, all mingled in strange confusion.

As the French dragoons galloped through this long line of stragglers, they flashed them with their swords mercilessly to the right and left; and these men were often so insensible from liquor, as neither to make resistance nor get out of the way.

At Lugo Sir John Moore was anxious to engage the enemy; and he was satisfied that the general orders, already cited, had produced such an effect in his army, as to give an earnest of victory. A flight firm, maintained in which the British rushed forward with charged bayonets, and drove the enemy's column down the hill with considerable slaughter.

After this, marshal Soult, having experienced the talents of the general, and the impetuosity of the troops he had to encounter, did not venture to renew the attack; from this, it was concluded, that his intention was to harass the British as much as possible during their march, and to defer his attack till the embarkation. This was on the eleventh of January, and on or before that day the Spanish central junta had pledged themselves, and so also had Mr. Frere, that 44,000 Spanish soldiers should be united to his army, whereas not a single Spanish soldier was to be seen. The British army had been followed and assailed by all the disaffected French army, and was totally abandoned by the Spaniards, who neither united with them, according to their stipulation, nor had a single Spanish corps advanced to attack, or even to threaten the French posts, now weakened by the absence of their army. Thus was Sir John Moore again deceived by a million from the Spanish government, and the British minister, and the devoted troops had nothing on which they could depend but their arms.

The general, thus situated, judging it neither safe to act offensively, nor to delay their retreat any longer, quitted his ground in the night, leaving fires burning to deceive the enemy. The French did not discover their retreat till long after day-light, so that the British army got the start of them considerably. On the eleventh of January, the whole of the British reached Corunna, the port where they hoped to embark, not, however, without the probability of a battle. In this they had to encounter many adverse circumstances; they were exhausted and almost worn out by a rapid march of 250 miles of a dreadful country, in the most inclement season of the year, deprived of every accommodation, and often defective of food and shelter. They had been obliged to sacrifice most of their baggage, and some of their artillery; the greater number of their horsey had been put to death, to prevent them from falling into the hands of the enemy. Notwithstanding these and other difficulties; notwithstanding they were dispirited in not finding the transports at Corunna, the British army rejoiced that before they quitted the shores of Spain, they should have an opportunity to front their enemies. At the sight of them their wearied and exhausted limbs were braced with new vigour, and the native valor of British soldiers supplied the place of refreshment and relief.

The enemy gave no particular indications of attack till about noon of the 16th of January; at this time Sir John Moore was giving directions for the embarkation; but the moment intelligence was brought that the enemy's line were getting under arms, he struck spurs to his horse, and
and flew to the field. The advanced piquets were already
beginning to fire at the enemy's light troops, who were
pouring rapidly down the hill on the right wing of the
British. Early in the action, Sir David Baird, leading on
his division, had his arm shattered with a grape-shot, and
was forced to leave the field. At this instant, the French
artillery ploughed from the heights, and the two holding
lines of infantry mutually advanced, leaving a shower of
balls. They were still separated from each other by stone-
walls and hedges. A sudden and very able movement of
the British gave the utmost satisfaction to Sir John Moore,
who had been watching the manoeuvre, and he cried out,
"That is exactly what I wished to do." He then rode
up to the 90th regiment, commanded by majors Napier and
Charles Banks Stanhope, who had got over an inclosure in
their front, and were charging most valiantly. The
general, delighted with the gallantry of the two majors, who
had been recommended by himself to the military rank they
held, exclaimed, "Well done the 90th! Well done my
majors!" The plaudits of their general and beloved friend
excited them to new efforts, and they drove the enemy out
of the village of Elvina with great slaughter. In the con-
flct, major Napier, advancing too far, was severely wounded
and taken prisoner, and major Stanhope received a ball
through his heart, which instantly put an end to a most
valuable life. So instantaneous must have been the death
of major Stanhope, that a sense of pain had not torn from
his countenance the smile which the bravery of his soldiers
and the applause of his commander had excited.
Sir John Moore proceeded to the 42d, and addressed
them in these words, "Highlanders, remember Egypt." They
rushed on, driving the French before them. He lent
Captain Harding to order up a battalion of guards to the
left flank of the Highlanders, upon which the officer com-
manding the light company, conceiving that, as their ammu-
nition was nearly expended, they were to be relieved by
the guards, began to fall back; but Sir John, discovering
the mistake, said, "My brave 42d, join your comrades,
ammunition is coming, and you have your bayonets." They
instantly obeyed, and moved forward. While the general
was speaking, a cannon ball struck him to the ground. He
raised himself, and sat up with an unaltered countenance,
looking most intently at the Highlanders, who were
warmly engaged; Captain Harding allure him the 42d
were advancing, upon which his countenance immediately
brightened. The general was carried from the field, and
on the way he ordered Captain Harding to report his
wound to General Hope, who assumed the command. Many
of the soldiers knew that their two generals were carried off
the field, yet they continued the fight till they had achieved
a decisive and brilliant victory, over a very superior force.

The fall of General Moore is thus described by Captain
Hardinge: "I had been ordered by the commander-in-chief
to drive the battalion of the guards to advance; which bat-
talion was at one time intended to have disembogged a corps
of the enemy from a large house and garden on the opposite
side of the valley; and I was pointing out to the general the
situation of the battalion, and our horses were touching,
at the moment that a cannon-shot from the enemy's battery
Carried away his left shoulder, and part of the collar-bone,
leaving the arm hanging by the flesh.

"The violence of the stroke threw him off his horse on
his back. Not a mole of his face altered, nor did the sight
betray the least sensation of pain.

"I dismounted, and, taking his hand, he pressed mine
forcibly, calling his eyes very anxiously towards the 42d
regiment, which was hotly engaged; and his countenance
expressed satisfaction when I informed him that the regiment
was advancing. Afflicted by a soldier of the 42d, he was
removed a few yards behind the shelter of a wall.

"Colonel Graham Balgowan and captain Woodford
about this time came up, and, perceiving the state of Sir
John's wound, instantly rode off for a surgeon.

"The blood flowed fast, but the attempt to stop it with
my fist was useless, from the size of the wound.

"Sir John affected to being removed to a blanket to the
rear. In raising him for that purpose, his sword, hanging
on the wounded side, touched his arm, and became entangled
between his legs. I perceived the inconvenience, and was
in the act of unbuckling it from his waist, when he said, in
his usual tone and manner, and in a very distinct voice, It
is as well as it is; I had rather it should go out of the field
with me."

The account of this disaster was brought to Sir David
Baird while the surgeons were dressing his shattered arm.
He ordered them instantly to desist, and run to attend on
Sir John Moore. When they arrived, he said to them,
"You can be of no service to me, go to the soldiers, to
whom you may be useful."

As the soldiers were carrying him slowly along in a blanket,
he made them turn him round frequently to view the field
of battle, and to listen to the firing, and was pleased
when the sound grew fainter. On his arrival at his lodgings
he was in much pain, and could speak but little, but at intervals
he said to Colonel Anderdon, who for one-and-twenty
years had been his friend and companion in arms—"Ander-
don, you know that I always wished to die in this way."
He frequently asked "Are the French beaten?" and at
length, when he was told they were defeated in every point,
he said, "It is a great satisfaction for me to know we have
beaten the French." —"I hope the people of England will
be satisfied; I hope my country will do me justice." Having
mentioned the name of his venerable mother, and the names of
some other friends for whose welfare he seemed anxious
to offer his last prayers, the power of utterance was lost,
and he died in a few minutes without a struggle.

Thus fell, at the age of forty-seven, at the conclusion of a
critical victory, which preferred the remainder of his
army from destruction, lieutenant-general Sir John Moore,
a name that must be long dear to his country, which was
well disposed to do justice to his memory, and gratefully to
acknowledge, in every possible way, the important services
which he had achieved for it.

We have devoted a longer space than usual to comem-
orate the actions of this hero; but in doing so, we have
had an opportunity of putting on record, in a work that
is likely to be durable, the brilliant exploits not only of the
subject of this article, but of the British military, who
v defeat and intrepidity were never more distinguished than
in those actions in which Sir John Moore took a distinguished
part, and in which, as we have seen, he received no fewer
than five wounds; one in the head, from a shell, in Corriscas;
three in Holland, before he could be prevailed on to leave the
field; a musket-shot in Egypt, which, however, did not inter-
rupt his exertions till the battle was won; and a cannon-ball
in Spain, which bereaved his country for ever of his services.

Sir John Moore spent his life in the army, and his popu-
laritv among the officers and soldiers was never exceeded,
which was owing to his mode of and unassuming manners;
firmness, tempered with kindness, towards those under
his command, and to a conduct to all superficially just. He
was indefatigable in the duties of his profession; when en-
gaged in actual warfare, he always rode between three and
four in the morning, lighted his fire and candle by a lamp,
which
which was placed in his room, and employed himself in writing till eight o'clock, when the officers of his family were assembled for breakfast. After breakfast he received the general officers, and all persons with whom he had business; and the necessary orders were issued. He always rode before dinner, either to view the troops, or reconnoitre the country.

On the 25th of January, the earl of Liverpool, in moving the thanks of the house to the officers who had gained the battle of Corunna, referred to the loss which the nation had sustained in the death of sir John Moore, "wholly whole life," he said, "had been devoted to the service of his country; for there was scarcely any action of importance, during the two last wars, in which he had not participated." In the same evening lord Castlereagh exprest his sorrow "at the loss of one of the ablest of our generals, possessing, in an eminent degree, every valuable quality that can dignify the man, and enhance the superiority of the soldier; giving, in the evidence of his past life, the best assurance of what might have been expected in future, had he lived from zeal, intrepidity, and talents." He concluded by moving, "That an address be presented to his majesty, requesting that a monument be erected in the cathedral of St. Paul's, to the memory of the late lieutenant-general sir John Moore, knight of the Bath, who, after an honourable and meritorious life, fell by a cannon-ball, in the action near Corunna, on the 16th of January 1809, after having, by his judicious dispositions, skill, and gallantry, repulsed an enemy of superior force, and secured to the troops under his command a safe and unmelodicated embarkation."

To all which we may subjoin the following very handsome tribute of respect paid to his memory, by his royal highness, the commander-in-chief, in the general orders, issued from the Horse-Guards, February 1, 1809.

"The benefits derived to an army, from the example of a distinguished commander, do not terminate at his death; his virtues live in the recollection of his associates, and his fame remains the strongest incentive to great and glorious actions.

"In this view, the commander-in-chief, amidst the deep and universal regret, which the death of lieutenant-general sir John Moore has occasioned, recalls to the troops the military career of that illustrious officer for their instruction and imitation.

"Sir John Moore, from his youth, embraced the profession with the feelings and sentiments of a soldier: he felt, that a perfect knowledge, and an exact performance of the humble, but important duties of a subaltern officer, are the best foundations for subsequent military fame; and his ardent mind, while it looked forward to those brilliant achievements for which it was formed, applied itself, with energy and exemplary industry, to the duties of that station.

"In the school of regimental duty, he obtained that correct knowledge of his profession, so essential to the proper direction of the gallant spirit of the soldier; and he was enabled to establish a characterical order, and regularity of conduct, because the troops found in their leader a striking example of the discipline, which he enforced on others.

"Having risen to command, he signalized his name in the West Indies, in Holland, and in Egypt. The unremittent attention with which he devoted himself to the duties of every branch of his profession, obtained for him the confidence of sir Ralph Abercromby; and he became the companion in arms of that illustrious officer, who fell at the head of his victorious troops, in an action which maintained our national superiority over the armes of France.

"Thus sir John Moore, at an early period, obtained, with general approbation, that conspicuous station, in which he gloriously terminated his useful and honourable life.

"In a military character, obtained amidst the dangers of climate, the privations incident to service, and the sufferings of repeated wounds, it is difficult to select any one point as a preferable subject for praise; it exhibits, however, one feature so particularly characteristical of the man, and so important to the bent interest of the service, that the commander-in-chief is pleased to mark it with his peculiar approbation.

"The life of sir John Moore was spent among the troops.

"During the season of repose, his time was devoted to the care and instruction of the officer and soldier; in war, he courted service in every quarter of the globe. Regard-

"His country, the object of his latest solicitude, will rear a monument to his lamented memory: and the commander-in-chief feels he is paying the debt tribute to his fame, by thus holding him forth as an example to the army."

Among the works referred to for the facts of which this article is composed, we may mention the volumes of the New Annual Register; An Historical Sketch of the last Years of the Reign of the late King of Sweden; and above all, to Mr. James Moore's valuable and very interlocking Narrative of the Campaign of the British Army in Spain, &c.

MOORE, in Geography, a county of North Carolina, in Fayette district; containing 3767 inhabitants, including 600 slaves. Its chief town is Alfordton.

MOORE Bay, a small bay of the Atlantic ocean, on the west coast of the county of Clare, Ireland. It merely serves for small craft, and is frequented by fishermen; but indifferent as it is, it is the only break in the rocks to which the same can be applied, from the mouth of the Shannon to Dunmore, a coast peculiarly dangerous to navigators. (See MALBAY.) N. lat. 52° 38'. W. long. 9° 35'. Cruttwell. McKenney. Beanpot.

MOORE Town, a town of Jamaica; 22 miles E.N.E. of Kingston.

MOOREAH, a town of Hindoufan, in Robiuland; 20 miles N.E. of Bereilly.

MOOREFIELD, or Moonstown, a post-town of New Jersey; 13 miles E. of Philadelphia.

MOORE, a town of Bengal; 8 miles S. of Doega.

MOOREFIELDS, a post-town of America, and capital of the county of Hardy, in Virginia, situated on the east side of the fourth branch of Patowmac river; containing a court-house, gaol, and between 60 and 70 houses; 25 miles from Romney.

MOORGONG, a town of Hindoufan, in Barar; 13 miles N.W. of Chanda.

MOORGULL, a town of Hindoufan, in the cirr of Cacoci; 21 miles W.N.W. of Collinotta.

MOORHU, a town of Bengal; 30 miles E. of Doega.

MOORJA, a town of Africa, in Lambaris; 150 miles E. of Sogo.

MOORING, at Sna, is the act of confounding and securing a ship in a particular station, by chains or cables, which are either fastened to the adjacent shore, or to anchors in the bottom. A ship, when launched from the fleeks, is furnished with one
one 'head' anchor, and another which is termed a launching-anchor, somewhat heavier than the 'head' anchor, hanging by hoppers to the cat-heads; by one or both of which the ship is first brought up, and afterwards warped to her 'head and stern moorings,' which are as follow. Across the bottom of the harbour or river, two chains, parallel to each other, if the bed of the river will admit of it, are extended at the distance of 200 feet from each other, by means of anchors, having only one fluke, which is sunk, and secured in the ground by piles, on the opposite fides, near low-water mark. To the rings of the anchors these chains are attached by a peculiar fort of link, called a 'shackle.' Each of these chains has, at about one-third of its length, a large iron ring, to which is fastened a chain, called an 'up-and-down span;' which, lying on the ground, connects the parallel chains, and serves to keep them steadily in their places. At about 30 or 40 feet distance from each other, along each chain, chain-pendants, from five to nine in number, are fastened, having, at the end which connects with the ground work, a shackle; and at the other end, a link called a 'Jew's-harp,' through which the bridge or hawser of a ship, when moored, is passed. The centre chain-pendent is fixed to the ring of the chain; and the number of the chains must depend upon the number of tiers required, each tier occupying two chains, because the ships are moored head and stern. But every tier does not always occupy two whole chains; because, unless a passage between the tiers is requisite, the chain to which the head chain-pendent of one tier is affixed, has likewise fastened to it the stern chain-pendent of the next tier. These moorings are used in rivers or harbours of small extent, to which they are adapted; but in other places, not frequented by many ships, or of considerable extent, there is another fort in use, called 'swinging moorings.' These differ from the former only in this; the ground work being the same. To the ring of the chain is fixed one chain-pendent, the end of which is passed through a large buoy; and to that is connected a swivel-ring by a shackle, and thus kept constantly from flashing into the ground. This is used for mooring one or two ships to. Near each end of the chain is fixed one chain-pendent, or more, supported likewise by a buoy, used only for the purpose of warping ships from the middle to any intended place.

To the 'head' and 'stern' moorings, ships are thus fastened: cleanch the end of a bridge to the Jew's-harp of the chain-pendent, and pass it into the hawse-hole; then heave it up, and bit it, like the after-bridles, into the gun-room port, or into the quarters, and take a round turn round the beam of the after-hatch, and crofs it with a throat and round fastening; or, if more convenient, round the jear-bits. To moor to 'swinging moorings,' pass out the ends of the bridge, one on each side, through the hawse-hole next the stern; then pass them through the swivel-ring of the chain-pendent; then return them into the ship through the after hawse-holes, and bit them. In this situation a ship is fitted for sea, by regularly fowing her ballast, and gaffing on board her rigging, foles, &c. See BALLAST.

A great number of moorings of this fort are fixed in the harbours adjacent to the king's dock-yards, as Deptford, Chatham, Portsmouth, Plymouth, &c. Falcour.

When a ship is come to anchor in a situation where she is to remain, she is secured by moorings. It is of essential importance that she should be well secured by mooring; the practice of which must depend upon the variety of situations, the settings of the tides, and other circumstances. When the belt bowser is gone, and about the length of two cables is run out, the small bowser is let go; and, when that has taken the ground, you have in one cable's length upon the belt bowser, and veer away a cable's length of the small bowser; and thus a ship is kept at an equal distance between both, the one lying to the head, and the other to the stern. In roads where there is much tide, and freights are expected, ships moor according to the rate of the current, one anchor riding to the flood, and the belt anchor and cable to the ebb. In roads where there is little or no tide, ships moor according to the rate of the most prevailing wind on the coast. It may so happen, according to circumstances of situation, that the vessel must ride by a greater scope on one cable than the other, but fill the manner of letting go the anchors is the same.

Another method of mooring is by carrying the last anchor out in a boat to the place appointed, and then letting it go. Steadying or mooring with a hedge is rarely done in this manner.

Moorings with two, three, or more anchors abreast is performed by letting go the number of anchors necessary, and veering away. This practice is adopted in cafes of danger, and must be guided by circumstances; e. g. if one ship cannot clear the shore under her lee by falling, on account of a strong wind and high sea, the only resource is to let go all the anchors in the most advantageous manner possible. For this purpose, let the cables that are bent be got clear for mooring; then fur all the square falls as speedily as possible, and furl the ship along the shore under the lay-falls. When the square falls are furled, let go the weather-mooring anchor, and veer away the cable quickly; then let go the next weather-mooring, and so on, till all the anchors are gone nearly in a line along the shore: thus when the ship becomes windward, all the cables may be made to bear an equal strain, and are separated from each other. For other methods of mooring in a tide's way, or in a storm, of backing an anchor, by letting go a small anchor abreast of a large one, to which it is fastened, and of keeping a clear hawse, we refer to the "Elements and Practice of Rigging and Seamanship," vol. ii.

To Moor across, is to lay out one of the anchors on one tide.

To Moor along, is to have an anchor in a river, and a hawser on shore.

To Moor quarter-berth, is to moor quartering between the two first ways.

Moorings for east, west, &c. is when they observe which way, and on what point of the compass the wind or sea is most likely to endanger the ship, and there lay out an anchor.

Moorings a fair berth, at Sea, is mooring in a place free from any annoyance.

Moorings a preserve, is to have an anchor out, and a hawser aboard; then the ship is moored with her head aboard; and two cables are the leaf, and four the belt to moor by. See ACHOR.

Moorings water-berth, is to moor neither along by nor athwart the tide, but quartering between both.

Moorings Point, in Geography, a cape on the S. coast of the island of St. Christopher; two miles S.E. of Baffet-terre.

MOORKYN, a town of Hindooftan, in the circar of Gungleo; 10 miles N.E. of Gangpoure.

MOORLY, a town of Bengal, capital of the circar of Jaffore; 55 miles N.E. of Calcutta. N. lat. 23° 10'. E. long. 90° 21'.

MOORS. See Morocco.

Moors, in the Isle of Man, those who summon the courts for the several headings; such are the lord's bailiffs. Every
Every moor has the like office with our bailiff of the hundred.

MOORSHEADIK, in Geography, a city of Hindoostan, in Bengal, situated on the western arm of the Ganges, which is here very low in the dry season, about 12 miles from it, and about 150 miles above Calcutta. It was the capital of the Bengal provinces, until the establishment of the British power; and even long after, it was the seat of the collector-general of the revenues, being a more central situation than Calcutta. It is very large, but ill built; and in its plan so very irregular, that it is difficult to estimate the quantity of ground upon which it stands. It is a modern city, and does not contain any magnificent buildings, either public or private; nor was it ever fortified, except by an occasional rampart thrown up round it, on the intrusions of the Maharrats in 1742. It is now decaying, especially since the removal of the board of revenue to Calcutta, in 1771. N. lat. 24° 11'. E. long. 88° 26'.

This city was founded by Jaffier Khan, then called Murshed Culi, who removed the seat of government thither from Dacca, and gave his own name to the new metropolis.

MOORSOON, a town of Hindoostan, in Orissa; N. E. of B assertTrue.

MOORUDE, a town of Hindoostan, in Dowlatabad; 10 miles W. of Carmulla.

MOORISH EARTH, in Agriculture, that fort of earth or foil that is prevalent on moors. It is in general a very fine black mould, sometimes found under a pretty thick sward or grass, but more frequently under mols, or straggling plants of heath. It differs from peat in that it does not stick together, nor has the fibrous roots, or bituminous adhesive quality of it; peat, when dry, becomes hard and firm; this falls into powder. It is of a spongy nature, and ready to imbibe moisture, which adds considerably to its weight. There is commonly underneath it, as under most earths of this kind, a bed of clay, or some sub stance impervious to water; so that the particles of bodies decayed on the surface, not being admitted into the foil, remain upon that surface dry, and increase its thickness, according to the continuance of the cause. When this kind of foil is collected in a place where running water, in rainy seasons, brings with it loam or other rich foils from the neighbouring grounds, it then acquires a greater degree of cohesion, hardens when dry, and resembles the cleaning of ponds more than the former.

But the most considerable foil of this kind is the fort called peat. This is usually full of roots of weeds, and even of trunks and branches of trees and other plants. It always contains a bituminous substance, which renders it very inflammable when dry; at which time it also becomes very hard, though it is quite soft when in the bed in which it lies; being easily cut. It is observed by Mr. Maxwell, "that the whole mass and body of this foil is a dunghill made up of rotten timber, grass, weeds, and often mud washed from the higher grounds about it, by the land-floods; than which there are few richer compots."

It is believed that "the qualities of moorish grounds, especially the moily kind, differ very little from one another in any other respect, than with regard to the better or worse quality of the earthy material which makes a part of their composition, and the difference of their depths. They are more or less spongy, in proportion as this rich material fills up the cavities of the component vegetables, which are preserved from putrefaction by the acid in the water. The lofs spongy, and the more rotten the earthy matter is, the finer it is for the vegetation of any thing planted in, or grown on them."

MOORS. Land, such fort of land as is principally constituted of earth or foil of the moory or mossy kind. These lands are of different sorts according as the earthy stratum is of greater or less depth. Mr. Marshall has observed, that "the foil of the Highlands of Scotland, compared with that of the moor lands of Yorkshire, has a decided preference; unless upon the summits of the higher mountains, and where the rock breaks out at the surface, or where this is encumbered with loose boulders or fragments of rock; the hills of the Highlands enjoying some portion of foil or earthy stratum between a thin coat of moor; while on the Yorkshire hills, the moory earth, generally of a greater thickness, lies on a dead sand, or an infertile rubble without any intervening soil." And "from the fort of general knowledge which he must necessarily have of both districts, he is of opinion, that the Highland hills (apart from the summits of the higher mountains) are of three or four-fold the value of the eastern moor lands of Yorkshire; more especially of the central and southern swells: the narrow tract which hangs to the north between Guishborough and Whithby, is of a better quality; very familiar in foil to the lower hills of the Highlands."

A great part of the moory lands of Lancashire is probably equal if not superior to either of the above, as having more depth and a better sub-foil.

It is evident that the improvement of moory lands must be effected in different methods according to their particular natures, situations, and circumstances. The first thing to be done, in order to the improvement of moory lands, is to divide them into proper inclosures: not only to secure their future produce, but also to have a means of procuring rich earth to cover the otherwise infertile Chelmsford soil on the surface, and give root to the plants which may afterwards be cultivated on them. Then, as the natural produce of this earth is of no value, its surface should be pared off, in order to be burnt. If the depth of the moory earth be not very considerable, the surrounding foils, which make the inclosure, will afford a rich strong foil, which should be spread about three or four inches thick all over the surface. When the clods are burnt, their ashes should be mixed with this new foil. If no proper earth can be got from the ditches, sand or gravel may be used with success. Gravel is singularly beneficial to such lands. The Berne society, which long since recommended this method of improvement as founded on repeated experience, very properly states, that the good effects of the sand and gravel will be considerably increased by a moderate mixture of dung, and that, especially if the ground be intended for ploughing, this covering should be at least a hand's breadth in thickness. Dung alone would undoubtedly be extremely efficacious on all such foils, in which it is remarked to be of longer service than any other; but a farmer can seldom spare a sufficient quantity of it to go far enough unmixed, or indeed for mixing. In this case, other ingredients must be recurred to, though the sand, or gravel, will generally do great things without any mixture. Well preferred ashes will be of excellent service, and so will the rubbish of old buildings, or any other similar sub stance, when mixed with sand or gravel, even of the coarser kind, and incorporated with this naturally rich earth, which, were its real value known, and the proper method of managing it understood, might claim a preference to any other soil. Loam is still better than either sand or gravel. This should be brought on before the fires are lighted to burn the surface of the moor, and should remain in heaps till it can be equally mixed with the ashes. Lime, where it can be had, will also contribute to the mecharating of moory grounds, and is
very effectual in removing the heath of those of the moory kind, as is experienced in Lancashire. The moory earth, thus covered, is fitted for various kinds of crops.

A late practical writer has suggested, in respect to the thinner sorts of lands of this description, that "heath, is a sort of plant that for the most part infects those soils that are of a moory nature, and in which there is but a small proportion of vegetable matter, on account of there being few leaves or other vegetable products, except the heath itself, to be converted into mould; and that the recurrences of this plant are not found to afford improvement to the soil on which it grows, in the way that is experienced to take place from the decay of many other more sarcarine, mucilaginous, and juicy plants. Hence it probably is, that the heathy soils are most foul poor and unfriendly to the growth of useful crops, whether of the grain, leguminous, or grass kinds."

In bringing this sort of land into the state of cultivation— as it has been found from repeated trials, that where the heath is turned down without being removed or completely destroyed, it keeps the furrow-slices from coming into intimate contact with each other, so as to confine and retaining a due degree of moisture, the decomposition and decay of the heath may be quickly effected, and the soil of course in too open and loose a state for the growth of almost any crop; it should be cut as close to the surface of the ground so it can be conveniently done; or, what is probably a better practice, removed, by paring off a very thin slice of the surface ground with it, and then either consumed by means of fire, or applied to such other purposes as may be necessary."

And after noticing the use of long heath in thatching, forming rinces for milk vessels, and in making concealed drains, Dr. Headrick, in a paper in the second volume of Communications to the Board of Agriculture, remarks, "that in the dry spring months it is capable, in many cafes, where it grows high and of considerable cleftness, of being burned without the labour and expence of either of the above operations. But in all cafes where fire is employed, as the staple of soils of this kind is seldom deep, care should be taken that the combustion be not carried to too great a height, so as to prove injurious by consuming the small portion of vegetable material that may be present. The operation of cutting the heath, may be most conveniently performed by an implement of the fcythe kind, only made much shorter and of greater strength, so as not to give way or break by the slices of the stems of the plants."

And that "the heath having been removed in some of these ways, lime in its cauliage or most active state is to be applied in large proportions, either over the whole of the surface before the ground is ploughed, or upon the soil when turned up. The former method is, however, to be preferred, as coming more intimately in contact with the plants, where lime is scarce, and cannot be laid on in large quantities; but where it is plentiful, the employing it in both ways might be more beneficial, by its thus tending more readily to the destruction of the roots as well as the stems of the plants. Where it can be procured, lime should, however, always be put on in large proportions on first bringing heathy or moory soils into the state of cultivation, as little savings in this respect, in the first influence, may often prove highly disadvantageous in the end."

It has been observed by an able writer, that experience has proved that the addition of lime to the ashes of the pared surface operates much more beneficially than if spread in any other manner: and that the larger the quantity the greater the effect, and probably the greater the proportional effect; that is, six chaldrons of an acre will do more than twice the good of three chaldrons: the chemical effect both in neutralizing the acids found in all these soils, and also in destroying the roots left of the spontaneous growth, depending, in some measure, on the effect taking place directly."

A writer in the twentieth volume of the Annals of Agriculture, states, "that eight chaldrons an acre, laid on at once, have converted a moor into meadow worth twenty-five shillings an acre; but the same moor, under one chaldron per acre per annum for eight years, has not been worth seven shillings and sixpence an acre. The effect of lime on all soils long in cultivation is problematical, and does not answer the expense in one in ten; but in new moor lands the effect is prodigious and hardly credible: laid on ling mountains without tillage, without paring, or other operation than merely cutting the ling, and spreading the lime, such moors have been changed from one shilling to twenty shillings per acre; but the quantity has been fifteen or twenty chaldrons per acre." It is, however, noticed, that "the application must always be regulated by the circumstances of the case. Where the expense per acre is forty or fifty shillings, the improvement will ultimately come high. And in order that the calcareous matter may be as intimately as possible blended with the particles of the soil, and thereby exert its effects most extensively, it should be applied over the land in the most perfect state of pulverization, and as equally as it is possible to spread it out. Where the lime is applied with sufficient attention to these circumstances, it generally destroys the heath in a short time, probably in some measure by its powers of attracting moisture from the soils, and combining with the acid alimentant juices of the heath plant, and rendering them incapable of affording that kind of support which is requisite for its healthy growth, as well as by the alteration of texture that is produced in the land, and the caustic destructive action that may take place in consequence of its coming into contact with the roots in that state. This is probable, from its being found to be the most effectual, when laid on such lands in the state of quick-time, though something may no doubt depend on the exsurgents with which moisture is attracted by it in such cafes. After the lime has been applied, especially where the surface has been pared off and confumed by fire, the ploughing should only be flight, so as to blend it and the ashes with the soil, but not to place them at a great depth below the surface of the land."

However, where heathy or moory land has a higher degree of surface wetness, and is not so much over-run with the plant as to prevent its being employed as pasture, it may sometimes, it is observed, be brought into cultivation by merely removing the super-abundant moisture by proper drains, burning the heath in the spring months when suitably dry, and afterwards parching it closely with heeph, so as to keep it from feeding; as in this way, in time, it in some cafes becomes wholly removed from the soil. And when this sort of ground has been broken down and pulverized as much as possible, by the operations of ploughing and harrowing, it should always, while not too stiff, be sown with some sort of clofe luxuriant green crop, such as turnips, peas, and tares, that may be fed off by heeph; but where it has a four quality, and is more stiff, clayey, and adhesive, those plants that strike more deeply into the soil, as beans, Swedish turnips, buck-wheat, rye, and oats of the grey kind. In many cafes too, rape, peas, clover, and vetches, will succeed in a very beneficial manner. But as the principal intention in most cafes of breaking up this sort of land, is that of bringing it in a cheap and expedient manner to a suitable condition, after a grain crop or two, for growing grass, the green crops, of whatever description they may be, should be confused by animals upon

Vol. XXIV.
the ground, especially where the soil is such as to admit them without injury; as in this method, a high degree of fertilization and improvement may speedily be obtained, at little or no expense, from the great benefit the animals receive. If it can be conveniently done, two or more of this fort of crops may be confumed on the land, in the same season with full more beneficial conseqesues. Where the soil is too wet, stiff, and poachy, to admit of this practice, the crops may be drawn or cut, and converted to the feeding of cattle in the house. It has been well suggested in the Annals of Agriculture, that proper cropping "is the keystone of tillage," and that if it be not attended to with great care, the whole of the improvement may turn out disadvantageous.

There is also another method of improving these soils by such crops as the above, which is that of turning them down, when in their most succulent states, by the plough. This may be a judicious and useful mode on the drier and more sandy descriptions of these soils, where they may readily undergo putrefaction and decay, but in the more tenacious forts, and where there is a four disposition that would greatly retard the process, it would seem to be much less beneficial than that of feeding them off by some form of live stock. On the whole it is concluded, that in whatever method they may be brought into the state of cultivation, the process of tillage should not be carried further than the destruction of the healthy or other coarse plants, and the removal of the four and unfriendly disposition of such soils for the growth of useful vegetable productions. They should be then restored as soon as possible to the state of grase or pasture, as that is the proper application of them.

In the Perthshire Agricultural Report, it is stated, that some practical improvers on these thin moory soils pare and burn, then spread the ashes with a little lime, four turnips, to be fed off the first year by sheep, the young year plough again for turnips, and feed them off in the same manner, then lay the lands down with barley and grases feeds. This is, the writer says, the practice on the Nairn estate betwixt Perth and Dunkeld. On the opposite side of the Tay, it is the practice of another improver to plough the moor in the winter, letting it lie in this state all the next summer, ploughing it from three to five times in the following summer, as may be necessary; then to lime and sow oats the third spring, laying down with a crop of barley and grases feeds in the fourth year. Some, with the intention of being more expeditious, begin by trenching through the winter, at the expense of four pounds the acre, for a crop the succeeding spring. This is the practice in the district between Perth and Coupar. Some fuppofe that paring and burning should be practised on the thinnell soils of this fort, when the subfoil is gravel or sand, under the idea that all moory lands should be treated in the same way, and that not a particle of earth can be destroyed by the process, which puts the able writer in mind of boys, who while a tick for a certain purpose, until it be fo worn down that it becomes useless for any purpose whatever. And an opinion of other improvers of moor is, "that the land ought to be ploughed, and lie in that furrow for one year; that against the succeeding spring and summer, it ought to be cut up-ploughed and harrowed, till the clods are reduced, lined the next autumn, drawn in ridges, and ploughed for the feed furrow in spring. This method of reclaiming moors is recommended by a gentleman's factor in Strathforn, and is very similar to the practice betwixt Perth and Coupar. Both have this to recommend them, that the quantity of soil is not diminished, where there seems so little to spare." And Mr. Buchanan of Camllochy, in the neighbourhood of Perth, who has improved upwards of five hundred and fifty acres of new ground of this kind, (which is as much perhaps as any other person in Perthshire has done), "lays lime on the surface in the summer or autumn, and leaves it generally for two or three years, spread in this manner, that it may sink into the ground and mix intimately with the soil. If the land has been well limed, the first crop will be tolerably good; the second heavy; and the land is by this time so well pulverized, that it is easily made for barley and grases feeds the following year. In some cases, he interposes a fallow crop of potatoes or turnips, between the second crop of oats and the barley crop. By this management, he has seen on his new ground, the two first crops of oats remarkably good; the second especially, which exceeded barley an acre. His moors cultivated in this manner, where the ground was high, the heath as tall as a person's knee, and the soil not worth one shilling an acre in its former state, have continued to carry grases crops, and let at between nine and ten shillings of yearly rent, for the space of twenty years, without any future drefling, and without any symptoms of the heath attempting to arise. Farmers may grudge to lose the interest of money laid out in lime, for the two or three years before the land be in crop; but this is a fallacy; the interest is not really lost. The soil is meliorated to such a degree by the top-drefling of lime, that the grases raised thereby does more than repay the interest of the lime. Much expense is also saved by ploughing only once for every crop of oats." The writer further remarks, that if there is a certain barrenness of soil, in which the heath delights; and whenever that barrenness is removed it does not thrive; neither does it thrive in the other extreme of the poor soil, and most exposed situations. To every plant there is a particular quality of soil, a certain degree of moisture, of warmth, and exposure which is natural. Different plants, as well as different animals, have peculiar climates, which are accommodated to their constitution; and even in the same country, one species of plant is found in the valleys and another in the hills; nay, in the same field and soil, if its nature and qualities be changed by cultivation, its productions will change of course. Allow your drains to flop in a field which had once been properly drefled; let it become four, spouty ground, it becomes instantly filled with sifes, rushes, and other aquatics." But "drain and cultivate the same field again; these coarse grasses disappear, and others which are peculiar to dry land succeed in their place. Fold sheep, lead rivulets, or lay enriching manure on the most barren ground, which is not overcharged with water, and the richest carpet of close fine grasses will spring up spontaneously. Remove them before it be fully saturated, and it will gradually return to its former fertility. Were all plants fitted by nature to thrive only in the same circumstances, we should have, at least, half of the globe without any plants at all; what might therefore appear, by superficial observation, to be a mangled in nature, or a defect in the bounty of heaven, is, upon a closer inspection, recognized to be the effect of conglutinated wisdom, and of goodness without bounds. From the frozen tops of the highest mountains down to the bottom of the warmest valleys, every degree of heat and cold, of barrenness and fertility, of wetness and dryness of soil, providence has adapted to the nature of particular plants, which come to perfection where another species could not live; and these various plants are the food of different animals, that no creature might be deprived of nourishment peculiar to its kind." In short, "without entering on that polemical point in agriculture, the food of plants, (which has been long a problem, and will probably remain to be solved by future ages,) we may safely
safely remark, that whatever is their food, they are taught by nature to seek after that food which suits their kind. They uniformly reject other food; and when forced, by the unkindness of man, to accept of food unsuitable to their constitution, they soon decay. It is, therefore, probable, that the food of all plants is not the same; but that some of them prefer one kind of food, and some another, and these in various degrees. At any rate, whatever their natural aliment is, or when the earth is brought by industry to have that aliment, there we uniformly see them making their appearance; and yet we cannot rightly tell how.

There have lately been great improvements made on different forts of moory lands in Yorkshire, where there are immense tracts of moors. In the Agricultural Report of the North Riding of Yorkshire, it is stated, "that an improvement was made upon Lockton moor, about six years since, on a quantity of land of about seventy acres, which would not let for more than 1s. per acre, before it was inclosed. Of this, forty-eight acres were pared and burnt, and found with rape, except about an acre fown with rye; the produce about sixty quarters. The rye grew very strongly, and in height not less than six feet, and was fold, while standing, for five guineas the acre. The land was only once ploughed, otherwise the crop of rape would probably have been much better. One hundred and twenty chaldrons (each thirty-two bushels) of lime were ploughed into the field, which, for want of more frequent ploughing, probably was not of the service it otherwise might have been. Part of the land was afterwards fown down with oats and feeds; the former of which afforded but a moderate crop, the latter a very good one, and has since produced two loads, 120 stones each, per acre. The feeds fown were rye-grafs, rib-grafs, white clover, and trefoil; of thefe, the first succeeded remarkably, the others not so well; potatoes threw very well; turnips not equal to them. A farm-house has been built upon it, which now, along with five acres more of the fame kind of land, is let on lease, at 3cl. per annum. The soil confiited, in general, of bency peat, upon red grit-flone, with a mixture of clay upon lime-flone; this land is, in some places, at a considerable depth, in others, sufficiently near the surface for lime to be burnt upon the premises."

But it is stated "that the greatest and most profitable improvement the reporter has met with, is one made by Richard Simpson, at Samtoft, upon Pickering moors, of which he has given the following circumstantial account. The land was allotted to him on the inclosure of the common of Pickering and Newton. The allotment contained 315 acres, and was situated on the northern verge of those lime-flone heights which border the valley in an east and well direction for above thirty miles, from near Helmley to Scarborough. To the north of this tract of limelone, which, in most places, rises with a gentle slope from the plain of the vale, and bears a breadth of two or three miles, lies the wild, and chiefly uncultivated tract, called Black moor, which cannot contain less than 300 square miles, not one-tenth part of which is in a state of cultivation. The soil of the farm may be classed in this way.

**Clafs 1.**—One hundred acres pretty frong loam, of a moderate depth, upon limelone.

**Clafs 2.**—Seventy acres of a deep sandy foil, with more or less of a red-flone earth intermixed. These two clafes were over-run with heath, or ling, in patches, with brakens (fern), and a tough moily herbage intermixed.

**Clafs 3.**—One hundred and forty-five acres of a black moory foil, covered with an uniform coat of heath, with a few brakens, and here and there a few tufts of bent gras intermixed.

It is suggested, however, that although the upper foil of this laft clafs was nearly alike, confisting of half putrid heath, intermixed, like all the upper foil of the dry part of the moors, with black and grey gritty (chiefly siliceous) sand, and had occasionally, when common, been pared for turf for fuel, yet the sub-foil, in different parts, varied materially; and on that difference of sub-foil he founded his hopes of improvement, and he was not deceived in the event. About 100 acres of this laft clafs, although the upper foil was uniformly black, and in some places two, in others, from that to fix inches thick, yet the foil beneath had every appearance of what, had it been on the surface, he should have called a light sandy loam intermixed with a free-stone gravel, and had, undoubtedly, once formed the upper foil, before the ling or heath had encroached upon and disfigured the other grases, which, in all probability, exilid there: this is a procefs which is going on every day, and has undoubtedly taken place on molt of the borders of the moors to a considerable breadth; for ling will thrive on almost any foil, and remarkably well on a light sandy loam; and being a perennial, and he may add, a permanent plant, retaining its items and branches all winter, and its items generally rising above the surface of snows, its feeds are carried thence by the winds to considerable distances, where being lodged, on the melting of the snows, and vegetating, the ling produced gradually destroys the more tender grases growing in its shade; add to this, the foil produced by the gradual decay of the ling becomes continually more fit for its propagation, and more unfit for the produce of almost every other species of vegetables.

And the remaining forty-five or fifty acres had an upper foil, similar to the laft described, and a sub-foil of a hard-eemented grey fand, of a moft unpromising appearance, as impenetrable to water as the clofeft grained flone, and almost as hard; and, what was worse, this stratum was too thick for the plough to penetrate through it. This is the world species of land he has seen upon any part of the moors; for the produce of any kind of corn, even rye (except in patches), going off before it shoots into ear, although remarkably healthy and vigorous until the period immediately preceding its floating, which he supposes must be owing to its then sending forth roots to derive nutriment from a greater depth, and meeting with this sub-foil totally unfit to afford that nutriment, it withers and dies. This happens alike in a wet or dry feason; and yet even this land, where lime may be had at a moderate rate, may be appropriated to some purposes with benefit to the proprietor; for, when pared and burnt, and well limed, both white clover and rye-grafs thrive on it remarkably well.

It is remarked that he has been thus particular, because being well convinced that there are some thousands of acres on the borders of Black moor, and in patches adjoining several of the small cultivated valleys that run through it, of a foil and sub-foil similar to the hundred acres of the third clafs above described; and as this land, where lime can be had at any reaonable price (as from 3d. to 6d. per bushel) will pay very well for cultivation, being molt of it fit for the produce of either rye, turnips, or oats, at the first, and what is not so, being fown with rye, and laid down two or three years with gras feeds, will then produce turnips and oats; and on all of it, white clover and rye-grafs will succeed remarkably well, particularly the former: if the owners of such lands could be induced, by a more minute exa-
MOORY LAND.

mination of the foil, and more particularly of the sub-foil, to bring them into a state of cultivation, it would not only be a benefit to themselves, but of public utility; for in their present state, they are worth a mere nothing, not 6d. an acre.

It is added, that entering on the above farm in the year 1787, it was evident, that the nature of the moaty herbage, intermixed with patches of ling, on even the belt of the limestone and sandy foils, indicated paring thin, and burning, as the belt handfast; so indeed he thought, and so in general acted; but being a young farmer, and having frequently heard it asserted, "that to burn foil was to destroy it," he ploughed out ten acres of the belt herbage, and the most free from ling, on the lime-foil, without paring; he may add, that he had sufficient caufe to repent it, for he has not even had one middling crop from it since; and although laid down with feeds, they have by no means so good an appearance as thefoe in the same year on similar foils, although he has expended as much lime and manure on this as on any part of the farm.

And it happened to him likewise, that paring and burning the black moory foil on a good sub-foil, would answer a doubly good purpose; for by paring tolerably thick and burning, he not only changed the worst and leaf putrid part of the foil into good ashes, rich in alkaline salts, but, by so doing, he brought the sub-foil within the reach of the plough, and could, at pleasure, mix it with the remaining black foil, and expose it to the influence of the air and other causes.

It is further stated that he kept, likewise, another object in view, and that was, to begin with a larger proportion of the best and most productive land, and a smaller of the worst, that, by so doing, it might not only pay for its own cultivation and improvement as he proceeded, but that he might get into a better flock of manure. The first year he paréed and burnt 120 acres, viz: eighty of the classes one and two, and forty of classes three. On most of this, three chaldrons (of thirty-two bushels each) of lime were laid on each acre, but on part of it only two; he was induced to do this, because although our present chemical knowledge of the properties and component principles of lime is very confined, and we are utterly ignorant of its mode of acting as a manure, yet it is known that lime and alkaline ashes mutually aßist each other's action, as manures, in a very eminent degree, and that if lime is intended to be used at all in a succession of crops, it is always best to lay it on with the ashes. On such parts of these eighty acres as were got burnt, &c. previous to the beginning of May (about fourteen acres), he fowed oats, with once ploughing, and had a tolerable crop, viz: near seven quarters per acre. He fowed forty acres with rape, with once ploughing, &c., produce, in 1788, 160 quarters, four quarters per acre: the remaining twenty-six acres he sowed with turnips, ploughing once, and had a very good crop, which was eaten on the land with sheep, and was succeeded with oats, above seven quarters per acre.

And the ten acres he had this year ploughed out without paring and burning, were a similar foil to the above eighty acres, most of it classes one. He sowed this with grey peas; produce not a quarter per acre.

But the forty acres of classes three he paréed thick, burnt, and laid on about three chaldrons of lime per acre. Such part of it as had the best sub-foil he ploughed in May, and harrowed and crossed-ploughed the latter end of June, and sowed with turnips, which bring a tolerable good half crop, were eaten upon the land with sheep, and succeeded, 1788, by a crop of oats of from five to six quarters per acre. Being in want of herbage for sheep, he fowed down this field, about fourteen acres, with feeds, along with the oats, viz: white clover, about five pounds per acre, and the common hay-feeds of the country, about five bushels per acre; they came remarkably well: and the year following, this field was almost an entire sheet of white clover. One thing in this field deserves remark: about an acre of it, of as good a foil as any of the reel, was not limed; the consequence of which was, that although not perceptible in the turnip crop, it was very much so in the oats, and still more in the grass-feeds; very little white clover was to be seen: and now, although the other parts of the field have a tolerably good herbage, with a few thinly-flattered small branches of ling coming amongst it, (owing, he supposes, to its not having been long enough in tillage to destroy all the roots of this hardy plant), yet that part of the field unlimited, is nearly desitute of herbage, and covered with heath.

However, about sixteen acres, the other part of this forty, being of a somewhat inferior sub-foil, and the black moory foil of a greater depth, he sowed with turnips, with once ploughing. These were a very poor crop, the bottoms in general not larger than the common hedges crab: they were eat with sheep in the autumn, and the land sown with rye, which produced about two quarters per acre. Grass-feeds were sown amongst the rye, in the spring of 1788, in the proportion last mentioned; they came remarkably well; and the herbage the two following years was almost entirely composed of white clover. The remaining ten acres were of the cemented sandy sub-foil above described. A little turnip seed was likewise thrown upon it, after once ploughing, which produced a few dwarf tops, but no roots that were eatable. These tops, or leaves, were eat with sheep in the autumn, and the land then sown with rye, and with grass-feeds in the spring following, in the same quantities as the last mentioned. Produce of rye, six to eight bushels per acre, and these of inferior quality. The grass-seeds came remarkably well; and even on this foil the white clover, for the first two years, was in far greater quantity than all the other grasses put together. The herbage of these forty acres, being adjacent to the farm-lead, is yet of tolerable quality: but here and there a spring of young heath. He intends, therefore, to plough it out the next spring, and rely it with grass-feeds, after another succession of crops.

The writer proceeded in this manner in 1788, 1789, 1790, and 1791, in which year he had gone over all his farm, except a few acres situated on hill sides, the declivities of which were too steep for ploughing. He consequently paréed, burnt, and limed, as above, but varied occasionally the crops. What, after the experience he has had, he would recommend as the best course for a black moory foil, is to pare, burn, and lime, plough twice, and sow rye in the autumn of the first year: to follow for turnips for the next crop. If a little manure can be had for the fallow, there is a greater probability of the turnips succeeding; and if a scare is not to be had, the lime and ashes, with the melioration of the air the foil has already received, will, he says, render it much fitter for a crop of turnips than it was when newly opened. On these dry light moory foils, the turnips should be constantly eaten upon the land with sheep, and may be succeeded with oats or rye, according to the better or worse quality of the sub-foil. With this first crop, after turnips, the land ought to be sown with feeds, in which white clover and rye-grasses ought to be in the greater proportion; in grasfs, it should lie three, four, or five years, as pasture-ground.
ground; when on being ploughed out again for another succession of crops, as in the manner below:

and on the worst sub-soil, grey peas or rye, then turnips, to be followed with rye with grass seeds; it will generally be found that the soil will be in a much fitter state for the production of these crops, than in the first succession, always remembering to lim the turnip crop, and, if to be had, lay on a little manure likewise. And as no more than two crops ought to be taken for one fallow on any light upland soil, perhaps the best mode of opening out-lands of the description of clays one and two, is to pare, burn, and lay on three or four chaldrons of lime per acre with the ashes, to plough twice for turnips, to eat them on the land with sheep, and to fallow with oats, &c.; and after one or two successions of crops, the land ought to be laid down with grass-seeds, always remembering, whatever the succession, to lay down the first year after a fallow, when, after a few years left, it may be ploughed out again with advantage.

It is concluded that as the lands of clays one and two, and the better sorts of clays three, are brought to an immediate state of improvement, and the profits arising therefrom are evident from the bare inspection of the crops, it will be only necessary to compare the expense and improvement on the worst species of land in clays three. This he rates to be as below:

So that there will be a loss of 2s. 3d. per acre; but then it is to be considered, that the herbage of the first three years is worth more than 10s. per annum, and that the soil, by the operation of the lime, is in a continual state of improvement; and has every appearance of being worth 5s. per acre to farm. He owns he should not have attempted to cultivate land of the last description, had it not unavoidably fallen within the ring-fence of the farm; and being already enclosed, there was a greater probability of its paying for the improvement.

He states that the great error into which many, in his collection, have fallen, in opening out-land for the first time, is, the ploughing out the tough moss sward without paring and burning; the consequence is, that for the first four or five years there is an almost total failure of crop, and, of course, a want of manure for the next succession. This is done under the mistaken idea that by burning, so much of the soil is almost totally diffipated and lost. Now, although we are in want of experiments to make it evident, that greater proportion of vegetable matter is diffipated in suffering combustion with a slow fire, and in contact with earthy matter, than would be diffipated in the same undergoing putrefaction; yet we know, that as all vegetable soils contain more or less of calcareous earth in its mild state, the subjecting this to the action of fire, must increase its activity as a manure, by bringing it nearer to the state of quick-lime, and that the silicious and argillaceous parts of the soil are not diffipated in burning. Modern chemistry will throw much light on this subject. It has been observed, however, by others, that paring and burning have very different effects, according to surface and soil: it is an expensive operation, and can only be repaid by one or two succeeding good crops. In good soils, no doubt of the propriety; but where ling abounds on a thin soil, with gritty pebbles, they are conversed as much may be done by burning the ling. Ploughing, and letting it lie fix or twelve months, then harrowing, liming, and taking two or three turnip-crops, grass-seeds, and no corn: this should be done by the landowner; no tenant will bear the expense. When land falls into their hands, it is exhausted by crops of grain, and then the land is condemned, as having been good for nothing; whereas, these lands are grateful, when properly laid to grass, and will, by sheep-grazing, arrive, at a future time, to afford profit, and some improvement, under the plough. The firth of these writers is "far from asserting, that a soil will not become thinner by repeated burnings; but he is of opinion, that it will not become so in the degree generally imagined; and he is an advocate for only the first paring and burning of very old fawd, or heath." By others, however, it is said, that "much depends on the situation of the improver of this land: it must be supposed he has a farm of old land, and this new falls by a division of common. In this case, the rent of the new is of no consideration: he can, in September or October, easily spare his ploughs, when he feels little expence in ploughing fifty acres; if it lies even twelve months, where is his loss? It is gaining from the fensons. Crofts-plough and harrow well; the spring following, plough, lime at the rate of two or three chaldrons per acre, not more; turnip, eat with sheep, then break the tough fod; turnip again, without lime: your fod is now acting in part as manure. In the spring, use the same quantity of linc, and fewer grass-seeds. Here is no advantage in having oats; the land is hurt by it. If paring such land was abolished, it would prevent such crops. Ploughing up is flow; but the land is fertilizing, and the fod adds to the soil; and it will be found, in future, grass. He has a proof of this management on a turfly thin soil, within a few inches of land sub-fratta: had this been followed up with oats, he should have got into the land." On this it is remarked, that the above writer "seems to conclude, that if land be pared and burned, corn must be grown thereon. This is not a necessary consequence. If he is going to improve any of these moor lands, the firth considerations are, what does he want to obtain?—Improvement of the land.—By what means can he best obtain that?—By producing the largest quantity of food for sheep.—How is this to be obtained?—By paring and burning, and the use of lime; and by those means, a larger crop of either turnips or rape may be obtained, than by lime without paring and burning; and the better the crop of turnips that is obtained.
MOORY LAND.

tained the first year, the better the second year; and the bet-
ter the crops of turnips are, the better will the grass be in
the future years.

Various other improvements have been made in this part
of the kingdom, on lands of the moory kinds. It has been sug-
ggested by Mr. Marshall, that in the deep
kinds of moory lands, or those of a morassly nature, after
freeing them from superabundant moisture by proper drain-
ing, the proper means of bringing them into a state of cultiva-
tion, so as to let, at their full value, to ordinary tenants,
are the following:

"The first work, in a large undertaking, is to divide the
feite of improvement into fields, suitable to the farm or farms
in which they are intended to be laid, with ditches running
in such directions as will lead off surface-waters, without the
expanse and incumbrance of deep open drains within their
areas; then to adjust the surface of each field in such a manner
as will shoo off rain-water into the intersecting ditches; in or-
der that, should a fall of rain happen during any stage of the
proces of cululture, the work may not, for any length of time,
be impeded." And that "as the surfaces of lands of this na-
ture are mostly rugged, uneven, and of a loose spongy
texture; this generally renders them unfit for the operations
of tillage without some previous affilience of manual labour.
And when the moory earth, or vegetable mould is deep, and
rises to the surface without any covering of fossil substan-
ces, it requires some length of time to bring it to a texture suf-
ciently firm for the ordinary purposes of aration. Hence
the general principle of improving deep moory lands, which
have not been supplied by nature or art with fossil coverings,
evidently appears to be that of converting them to the state of
profitable herbage, before the production of corn-crops be
attempted." In effecting which, "the process will ever be
the seat directed, by the existing state of the feite to be im-
proved. If the inequalities of its surface are large and
abrupt, the first bulines is to adjust it, so far as to admit of
the operations of tillage, whenever they may be required,
and can be properly performed; as well as to convey off
surface-waters in the way already suggested. And this done,
to pare off the minor protuberances (the tufts and haflocks
formed by particular plants in its watery state), and more or
less of its surface in general, so as to cut off the plants and
flate mould which occupy it; and thus to give a degree of
frethness to the whole." But "if, in a dry feation, the sur-
face is found to be firm enough to bear the tread of cattle or
horses, the latter operation may be done with a paring-
plugh; if not, with a paring-plade, or brest-plugh." And
when, "after the surface has been thus cut over, and the
flate of drynesses of the foile can be ascertained by its colour,
any particular parts appear to be insufficiently freed from
moiture, covered drains may generally be made, at a small
exence, with the fibrous tufts which grow on the surface,
(as with hard materials), and which will lie a length of time
in the land, before they decay." And "the remainder of the
roots and mould, pared off, require to be burnt, their
ashes to be spread evenly over the surface, and to be im-
mediately harrowed, or raked into the fresh mould; to prevent
their being displaced by the wind." When, "in this state of the
process, a fossil substance of almost any kind can be
spread over the ashes at a moderate exence, grains-seeds may
be immediately harrowed, or raked into this covering, and
the surface be left to acquire a fward, without further trou-
bles; continuing to keep the young herbage closely patured
when the season will permit, first with sheep, and afterward's
with heavier flock; until the surface be rendered firm, and
the foile be sufficiently bound together, with the fibrous roots
of herbage, to bear a succeffion of corn-crops; if such
should become advisable." It is added, that "an objection to
this summary way of bringing the ground into the state of
herbage, lies in there being no immediate gross return for the
money expended in draining and cultivation. But to at-
tem to raise corn on a raw moras, or a black peat-mofs,
 malaysia, on spongy vegetable mould, would only be increas-
ing the expenditure, without any certainty of return. Let us,
therefore, look for a productive and marketable crop, that
may be raised with more certainty." It is noticed, that "in
the south-wel quarter of Scotland, potatoes have lately
been raised, even in deep spongy peat-mofs, with good ef-
fect. The practice is to plant them in beds, divided by deep
trenches; more or less dung being used in their cultivation.
Without this it is considered to be in vain to expect a crop." But,
"to a certain extent, in a populous country, where dung and labour are plentiful (the whole being done by
manual labour), this practice is very eligible, and does great
credit to any person who trud it out. For after one or per-
haps two crops of potatoes have been taken, a crop of oats is
obtained. But everything is still effected by manual labour.
And, even with this, a very wet spring, or a cold moit
summer, fecceeded by early frosts, may frustrate the planter's
hopes." Consequendy, "what is most defirable, in this
cafe, is a crop which is fown and reaped in the summer
months; and which requires neither labour nor attendance
during the moit fespons of autumn, winter and spring.
And fortunately, such a crop is, he observes, natural, or
has been long incurred to the climate of this island; and is,
moreover, one of the moit profitable crops in English agri-
culture. This crop is rape-feed; which is not only fown,
but reaped in the very height of summer. And a foil, in
which it is known to delight, is that of reclaimed wattery
lands, in a state of herbage." It is added that he "had
not, however, known it to be raised on crude moory ground,
as a first crop after draining, until he tried it a few years
ago, in the south of Scotland; where a considerable extent
of ground of this nature had been drained, levelled, pared
and burnt, and the ashes ploughed under by a young im-
prover, without a proper plan for carrying on the improve-
ment. He directed part of it to be lowed with rape-feed;
though the season of fowing was then getting too late;
namely, the latter end of July, or the beginning of Au-
salt." And that "the result, notwithstanding this and an-
other unfavourable circumstance which it was too late to avoid
(the land having been laid much too flat for a wister crop),
was such as to prove, sufficiently, that rape-feed may be
raised with profit, as a first crop, on drained moory foile.
And it is highly probable, that many extensive tracts of
lands, which now lie entirely waste, and as nuisances in their
neighbourhoods, may through its means be improved, with
immenfe profit to their proprietors. The experiment may
be tried at a small exence. The cost of the labour and
feed required, for a sufficient trial-ground, is inconsiderable.
The proof is not whether rape will thrive as herbage, but
whether it will nature its seed, on the given foil, in
the given situation. Having received a recompence for the
previous expenses, in one or more rape-crops (for there is no danger, in this cafe, of exhausting the foil, of
impoverithing ten feet deep, perhaps, of vegetable mould),
it remains to lay the foundation of more permanent pro-
fits." And, "this may be done, in his opinion, by fowing grains-seeds, either with, or over, the rape-crop,
or after the fields have been drawn, as fespons and cir-
cumstances may require; continuing to flock the ground,
in the manner already recommended, until the surface be suf-
ficiently.
It is called the moor of Orchill, and the following is a calculation of the expense and profit of covering it with trees:

**Expenses and Profit.**

**Plantation, Drs.**

**Balance in favour of planting** | 5,182.343 | 9 0 |

And it is further rated, that "after allowing the value of the weeding to go for back-gone trees, and other contingent expenses, not adverted to, which is surely enough, the profit is beyond conception. And were this plan to be adopted by the proprietors of this or other large moors, larches might be planted in some places, especially along the boundaries of different properties; and wherever the soil or the bleakness of the exposure is thought unfriendly, larches might thrive better than common firs, being the hardiest and the most valuable plants of the two. If there happens to be rivulets, aln would thrive on their banks, and elms, oaks, or beeches on any dry spots of green ground. This variety would remove the dull sameness of the plantation and enliven the prospect. Eight or ten rows of firs, as having of all trees the best shelter, by continuing to any age, feathered to the ground, might be planted next the fence, to defend the whole plantation from sudden gusts or streams of wind. The expense on the plants might be, in a great measure, saved, and the trees rendered more congenial to the climate, by having the seed sowed in the country."

It is added, that "the prime coil of the fir-plant will be 2746l. 3s. which might in a great measure be saved; and of planting 4012l. 10s. of which one-fourth may be saved."
sified. After the first 15 or 20 years, the foresters will pay themselves out of the sale of woodings; and their wages may be sified entirely after the last weeding at 30 years.

And it is suggested, that "everywhere has beheld the astonishing plantations at Cullen-houfe and Monymusk in Aberdeenshire, by the late proprietors of these places, and also by heritors in different parts of the kingdom, who had a taste for improvement and underflood their interest, will see the propriety of turning such moors as this to account. It is not a mere experiment, it is not without precedent, it is no chimera. They have many patterns before their eyes."

And with the view of shewing the expense of this system of improvement on a small scale, it is stated, that "one acre of land at one shilling of yearly rent, by compound interest at five per cent, for the space of 80 years, is worth 48l. 10s. 1½d. The same acre planted with common firs, and weeded down by various thinnings to 11½o, and sold at the end of 80 years for five shillings each, would amount to 20l. And if more valuable timber were planted, it would fetch more. Whenever the land will not let at more than one shilling, or one shilling and sixpence the acre, and is unfriendly to cultivation by the plough, it is by far the best method of turning it to account, to plant it full of trees suited to its nature. Even common firs, in this way, will bring a sum equal to six shillings an acre of yearly rent; and moreover, it is of no small consideration, that the moat barren and bleak moor, by this management, will be rendered perfectly green; and if depurated by sheep, when the trees are cut down, it will remain green, and continue to let at a decent rent." It is farther noticed, that "we were gentlemen of fortune to allot a small sum annually, perhaps from 10l. to 50l., according to their income, for raising plantations on different parts of their estates, the advantage to their heirs and to the public would be incalculable in every point of view. Nor does the writer fea ny solid objection against it. It is in vain to reason with those who will do nothing for politerity, because politerity has done nothing for them; as Swift expresses the argument of the slothfully selfish. The most plausible objection to this reasoning is, "that if all the low moors and other places not of the value of one shilling an acre yearly, and unfavourable to tillage, were planted, the country would be so much overstocked with timber, that it would give no price."

This objection might be got rid of by answering, that so long as the value of an acre in planting was superior to one shilling of yearly rent, even the desire of profit ought to recommend planting; nor ought a generous man to regret, that the public were served in timber at a more moderate price. But this subject claims attention; and the following considerations are submitted to the reader:—if the premises in the objection do not exist, the conclusion, being only hypothetical, must fall to the ground. There is little hope, that all proprietors will plant their moors in one generation, and, therefore, little danger that the country will be overstocked with timber. Their views, their taste, their mode of expenditure, and many of their other habits are so extremely various, that there is no period, in which all or even a considerable number of them will adopt this mode of improvement. And it is added, that "the fir woods on the shores of the Baltic are decreasing so fast, by the continual and growing demand upon them, that they have retired far to the inland parts of these countries; and the navigable land carriage, together with the freight, insurance, and duty, has raised the price 50 per cent. within these few years; and if this goes on, it is difficult to lay to what amount the expense of foreign timber may arife."

If the price become excessive, and that there be no supply of native fir, the improvement of the country, in the article of building, which is so ornamental to it, will become stationary; none being able to afford the expense of lodging themselves comfortably, except the affluent and great. And, "in countries at a distance from water carriage, where there is no pit-coal, and where the moles are altogether or nearly exhausted, the inhabitants must feel the inconvenience of being in want of an article, which is so very necessary to their comfort, unless they have wood to burn. Some counties in England, and many parts of the continent, are in a deplorable condition in this respect. A supply of wood for fuel can never, in these circumstances, be plentiful, without extensive plantations on land, which is unfit for grazs or corn." It is also supposed, that "it is a preamptive proof that this country was warmer, and the temperature of the air more mild, than at present, when our very mountains produced grain. This mildness of the climate was, it is conceived, occasioned by nothing else than the woodinefs of the country at that era.REFIRE, says he, the caufe, and the effect will follow. The more wood there is in a country, in northern latitudes, the more temperate the climate, and the more genial the influence of the air. Add to this, that in point of beauty, there is no comparison between a bleak moor covered with fluted heath, and a waving forest clad with the livery of nature."

It is also flated, that "on the hills of the moor of Orchill, there is a belt of fand, on which broom and furze are growing, particularly on the efl, towards Auchterarder. The foy, in which furze is found, invites the indufly of the husbandman, with an altered prospect of an immediate and abundant return. Where broom grows, the soil is lighter, and has for the most part a gravelly or sandy bottom. The former is a good mould, and fitted for molt crops. The latter is well adapted for turnips and red clover; and after refting a few years, will bear plentiful crops of grain; but having a weaker body than the former, it requires to be tenderly dealt with in cropping. Let not the husbandman be fuprised to fee these plants rise, even at the interval of 50 years or more, after they seemed to have been extirpated; the feet of some plants remain long in the ground, without being deprived of the germ, or vegetative principle. Marle abounds in the country round this moor, and is well calculated to stimulate fuch foils. Nature has indeed provided, in molt situations, some manner that will increase the fertility of the earth. Lime is now carried to that part of the country; and the numberless little rills, which descend from the moor in all directions after rain, would enrich the grals in many places, as may be fecn in every little hollow between the hills. All these act indeed as a stimulus alone, which is moftly the cafe with every species of calcareous earth, of which they are entirely compofed: but when argillaceous earth can be had at hand, it adds to the quantity of soil, strengthens the flamina, binding together the loofe particles of such land as this, and thereby enables it to fiand more frequent tillage." It is further flated by the fame writer, that "from behind Culrofe, al the way to Blairingone, there are feveral tracts of walle and barren moor. The cafl of Dun-}

---

MOORY LAND.

and
land on the verge of the bank east from Aberdalgie to the great road. In the two places last mentioned, trees of hard wood, which are more valuable than firs, would thrive and come to perfection.

And it is properly remarked, that, "in plantations of fir, where the soil is tolerably good, young trees of hard wood, especially oaks and elms, may be put in among the firs, which protect them, and do not much retard their growth by exhausting the soil: but care must be taken to cut down occasionally such of the firs trees as interfere with their tops, by first lopping off their branches, and then laying down the trunk; which practice may be continued until all the firs, thought necessary to be taken away, are felled. In this manner one may have the benefit of almost two plantations on the same ground at once; the young trees being well advanced before the older ones are taken out of their way. This practice is becoming more general every day. In other cases a belt of firs is planted round, to protect other trees in the middle of a plantation, without which precaution the interior trees, in certain situations, would be too much exposed: but this management is left to be depended on, unless the ground be level and the firs somewhat tall before the other trees are planted."

The writer also relates, that, "in the higher parts of the Sheriff moor, near Dunblane, there are near seven thousand acres, calculated only for being planted. The lower parts of this moor are, in some places, cultivated; and the soil being deep, if it were drained, pared, and burnt, might be improved still farther up, on the west side of the moor. The higher parts being planted with trees, and the skirts being reclaimed by tillage and grazes, would be an ornament to a country which is naturally cold and bare." And it is here remarked, that "the vall fir woods already mentioned, which are growing naturally in Rannoch, besides others in Strath- spey and elsewhere in the north of Scotland, are raised much farther above the level of the sea, than any of those places here recommended for plantations of fir. The plantations of Lord Dundonald behind Culrofs, and those on the Knock of Crieff, are thriving on a soil as poor. These instances, and the fine plantation lately cut down at Turcleum, behind Drummond castle, a higher spot than any of them, may open the eyes of men to see what might be done on the Sheriff moor, on that of Orchill, and in similar places, which at present are of very little value."

The writer concludes by suggesting, that, "besides the moor in the Sheriff moor, not here mentioned, there are some other beeching wales, covered with a thin stratum of moss, on a bed of gravel, which produce nothing but heath; one at Comrie, one at Dunira, one at Doune, one near Callander, and in other places. Mr. Drummond of Comrie, who lately purchased Dalgarrofs, has boldly lined off streets and a marketplace through the very heart of the moor, feued out part of the ground, and the new settlers are going on with spirit, to lay on new soil, and otherwise to improve one of the most barren spots in the country; and men will be enabled to live where, a few years ago, fearlessly a sparrow could find subsistence. Such are the effects of industrious under the direction of good fences!"

Further, "the moor in the vicinity of the house of Dunira has been reclaimed some years ago. Mr. Dundas has planted the most barren spots, with a variety of trees suited to the soil; and, wherever there was any depth of earth, the expense of cultivation has been rewarded by extensive and rich fields of grass. The plantations on the flat below will form vine with the waving oak woods on the declivity of the winding hills and in the face of rocks, with which this singular place is surrounded." And also, "in the valleys of the

Seedlaw hills there are several spots of short heath, which are planted; but there are others of a better quality, which ought to be top-dressed with lime or marl, to raise a herd of grazes. This climate in general is too unfavourable for raising much grain; but potatoes and turnips, succeeded by a crop of barley and grasses feeds, might grow in many places, which, at present, are totally neglected."

The different facts of this kind which have been stated, are sufficient tolew the vall advantage that may be derived from this sort of improvement in many parts of moory lands; and others may be seen in the excellent report from which these have been taken, as well as that of Invernessshire. Great improvements of this nature are likewise about to be undertaken by different spirited individuals in Lancafshire. See WASTE LANDS.

MOOY Soil: such a foil as is chiefly constituted of earthy matters of the moor kind. This sort of soil occupies large tracts in some districts, as has been sufficiently seen in the preceding article; which see, as also Soil.

MOORZAN, in Geography, a town of Africa, in the kingdom of Damharra; 75 miles N.E. of Segro.

MOORZELE, a town of France, in the department of the Lys, and chief place of a canton, in the district of Courtray. The place contains 3655, and the canton 13,114 inhabitants, on a territory of 721 kilometres, in 5 communes.

MOOSE-DEER, in Zoology, the Cervus Alces, which see. The first mention we find of this remarkable animal, is in a tract of Mr. Joffelyn's, entitled "New England Rarities." That author says, it is a very fine creature, growing to twelve feet high; the horns are extremely beautiful, with broad palms, some of those full grown being two fathoms from the tip of one horn to the tip of the other. The same author, in another work, entitiled "Two Voyages to New England," calls this creature a monter of superfluity; and says, that when full grown, it is many times larger than an ox. What Nell says of this animal feems copied from Joffelyn. But the best account we have of it, is from Mr. Paul Dudley. This gentleman says, that they are of two kinds: the common light-grey moose-deer, called by the Indians *wapoofs*, and the larger black moose. The grey moose is the same animal which Mr. Clayton, in his account of the Virginian quadrupeds, published in the Philosophical Transactions, calls the elk; and this is the creature described in the Anatomical Discoveries of the Paris Academy, under the name of the flag of Canada. Horns of this creature have been sent from Virginia, and called elk's horns: they are wholly the same with those of our red deer, except in size, weighing about twelve pounds, and measuring from the butt to the tip about six feet long. Phil. Trans. N. 444 p. 386. Also vol. vii. p. 447.

Mr. Dudley says, that the grey moose is like the English deer; and that these creatures herd together thirty or more in a company. The black or large moose has been taken, he says, measuring fourteen spans in height from the withers, which, allowing nine inches to the span, is ten feet and a half.

The flag or male of this kind has a palmed horn, not like that of our common or fallow deer, but the palm is much longer and more like to that of the German elk; but it differs from that in having a branched brow-antler between the butt and the palm, which the German elk hath not.

The large horns found fossil in Ireland, have, from their vast dimensions, been supposed to have originally belonged to the black moose-deer; but they, as likewise molt other of the large horns found in this part of the world, must be referred to the elk kind, but of a species different from the O European,
MOO

European, being provided with brow antlers, which that wants. Some of these horns are near twelve feet between tip and tip, and six feet four inches long; and may probably be ranked among those remains which fossilists disfiguring by the title of diluvian. The largest horns of the American moose ever brought over are only-thirty two inches long, and thirty-four between tip and tip.

Mr. Ray mentions, in his Synopsis of Animals, a pair of extremely large sable horns, which he saw in a museum in Suffolk; but he mentions no brow-antlers in these, and therefore probably they, as well as some others preferred in museums, were the horns of the German elk. See Cervus Alces.

Moose Hillock, in Geography, the highest of the chain of mountains in New Hampshire, the White mountains excepted. It takes its name from its having formerly been a remarkable range for moose, and lies 70 miles W. of the White mountains.

Moose Island, a small island on the coast of Maine in America, at the mouth of Schoodic river, containing about 30 families. At the S. end of this island is an excellent harbour, fit for the construction of dry docks.

Moose, or Mooshead, Lake, an irregularly-shaped pond of water in Lincoln county and State of Maine, which gives rise to the easterly branch of the Kennebec river, which unites with the other, above Norridgewock, about 20 miles S. of the lake. It is said to be three times as large as lake George: on the N. and W. of the lake are very high mountains.

Moose River, a river of America that rises in Muskegon lake, and after pursuading a north-easterly course, and receiving, about 12 miles from its mouth, a southern branch, discharges itself into the southern part of James's bay, North America, by the fame mouth with Abitibi river. Moose fort and factory are situated at the mouth of this river, N. lat. 41° 16'. W. long. 81° 51'; and Brunswick house is on its W. bank, about lat. 50° 30'. Beyond Brunswick house is a fall of 50 feet, above which the river is deep and navigable to a considerable distance; the soil and climate above the fall being very good. Also, a short stream in Grafton county, New Hampshire, running north-easterly from the White mountains into Amenia Cobbin river.

MOOSERAI, a town of Hindoostan, in Bahar; 5 miles N.W. of Bahar.

MOOSHEDA, a small circar of Bengal, bounded on the N. by Dinagepur, on the E. by Jangipur, on the S. by Betinoria, and on the W. by Pootola.

MOOSEE, or Moossedeo, a town of Africa, and capital of Gotto; 116 miles S.W. of Tombuctoo. N. lat. 27° 3'. E. long. 0° 16'.

MOOT, a town of Hindoostan, in the circar of Goohd; 18 miles S.W. of Koch.

MOOR, El, a town of Nubia; 35 miles S. of Chaggae.

MOOT-HILLS, in British Antiquities, denote hills of meeting, on which our British ancestors held their great courts. Many of these still exist not only in the British dominions, but also in the Netherlands. They commonly consist of a central eminence, on which the judge and his attendants, beneath was an elevated platform for the parties, their friends, and "compurgators," who sometimes amounted to two or more, and this platform was surrounded with a trench to secure it from the access of the mere spectators.

MOOR, formed either from the Saxon meton, meaning, or from the French moir, ward, in Law, a difficult case or question, argued by the students of inns of court, by way of exercise.

MOOTACHILLY, in Geography, a town of Hindoostan, in the Carnatic; 28 miles W. of Terriore.

MOOTAGARA, a town of Hindoostan, in Golconda; 45 miles S.E. of Hydrabad.

MOOTAGOOD, a town of Hindoostan, in Golconda; 5 miles W.N.W. of Combemab.

MOOTA-GONGA, a river of Hindoostan, which runs into the Gonga, or Bain Gonga; 40 miles S. of Bundowrah, in Berar.

MOOTAI, a town of Hindoostan, in the cirar of Cuddapah; 54 miles N. of Gadacota.

MOOTAN, a town of Hindoostan, in the cirar of Hind; 10 miles S.W. of Hufinganbad.

MOOTAPADDY, a town of Hindoostan, in Madura; 10 miles E. of Nattam.

MOOTAPELLY, or MEDITYLLI, a town of Hindoostan, in the cirar of Guntoor, on the coast of Coromandel, at the mouth of a river, which runs into the bay of Bengal; 75 miles S.W. of Malupatam. N. lat. 15° 35'. E. long. 80° 16'.

MOOTER, in the Dock-Yards, the person who forms and smooths the tree-nails for use.

MOOTING, in Law, the chief exercise formerly performed by students in the inns of court; being the arguing of cases, which young barristers practised at appointed times, the better to enable them to undertake the defence of their clients' causes.

Such as, from their learning and standing, were called by the benchers to argue moot-cases, were sometimes called utters barristers; the rest who, for want of experience, &c. were not admitted, were by some called inner barristers. The place where the moot-cases were argued, was anciently called a moot-hall.

In the inns of court there was a bailiff or surveyor of the moots, yearly chosen by the bench to appoint the moot-men for the inns of chancery, and to keep account of performance of exercises, both there and in the house.

MOOTING, the making a tree-nail exactly cylindrical to a given size, called the moot.

MOOTINGY, in Geography, a town of Hindoostan, in the cirar of Guntoor; 18 miles E. of Guntoor.

MOOT-MEN, in Law, were those who argued moot-cases.

Out of these moot-men were chosen readers for the inns of chancery: where, in term-time, and in vacations, they argued cases in the presence of attorneys and clerks.

MOP, in some counties in England, is the term for what is called the statute in other places; being the time that young persons who intend themselves for servants, meet at some certain place, in order to be hired into services.

MOPAR, in Geography, a town of Hindoostan, in the Carnatic; 40 miles S.W. of Ongole.

MOPEHA, a low uninhabited island in the Pacific ocean, near Otaheite, and W. of Murray. See Howe's island.

MOPENDA, a province of the kingdom of Anziko.

MOQUEGNA, a town of Peru, in the diocese of Arequipa; 70 miles S. of Arequipa. N. lat. 17° 20'. W. long. 70° 50'.

Gen. Ch. CaL Perianth inferior, of one leaf, turbinate, internally villous, with five roundish, acute, marginal segments.
ment. Cor. Petals five, roundish, inserted between the segments of the calyx. Stam. Filaments numerous (about 40), inserted into the calyx, capillary, longer than the corolla; anthers roundish, incipient. Pijl. Germin roundish, hairy, in the bottom of the calyx; style lateral, from the base of the germin, ascendent, as long as the filaments, hairy in its lower half; stigma obtuse. Peric. and Seeds unknown.

M. guianensis Aubl. t. 208.—A tree, found by Aublet in the forests of Guiana, flowering in May. The trunk rises to the height of 50 feet, with a thick reddish bark. The wood is white, not compa. Leaves alternate, four to seven inches long, and two or three broad, elliptical, pointed, entire, smooth, and shining, with one rib and several transverse veins. Footstalks short and thick. Flowers white, in axillary and terminal clusters, whose stalks are triangular. Aublet saw nothing of the fruit, nor of the advanced germin, but analogy leads us to presume it a single-seeded drupa. No mention is made of any particular uses or qualities of this tree, which the above author calls in French Moguiler; perhaps a translation of the generic name.

MOQUIS, or Moquiabos, in Geography, a savage tribe, who inhabit the centre of the Mother chain of mountains, in the part of America bordering on New Mexico. They were formerly converted by the Franciscans: but they have since killed all the missionaries and abjured the Christian faith.

MOR, a town of Arabia, in Yemen; 11 miles E. of Loheia.—Aflo, a town of Arabia, in the mountains; 15 miles N. of Hagez.—Aflo, an island of Denmark, in the gulf of Lymfiord, sixteen miles long and six wide; containing a town and several villages.

MORA, a town of Portugal, in the province of Alentejo; 22 miles N.W. of Evora.—Aflo, a town of Spain, in New Castle; 16 miles S.E. of Toledo.—Aflo, a town of Spain, in the province of Catalonia, on the Ebro; 18 miles N. of Tortola.—Aflo, a town of Sweden, in the province of Dalecarlia; 55 miles N.W. of Falcon.

MORABAD, a town of Hindostan, in Agimere; 50 miles S. of Koopnagar.

MORABEL, a town of the island of Ceylon; 28 miles N. of Trincomal.

MORABIN, JAMES, in Biography, a man of letters, and secretary to the lieutenant-general of the police in Paris, was a native of La Flèche, and died in 1762. He published "A Translation of Cicero's Treatise on Laws," and of the dialogue on orators generally attributed to Tacitus: "Histoire de l'Exil de Ciceron," which has been translated into English: "Histoire de Ciceron," 2 vols. 1745. This work appeared nearly at the same time with that of our own countryman Dr. Middleton on the same subject, and shared with it in reputation: "Nomenclator Ciceronianus," and "A Translation of Boethius de Consolatione." MORACA, in Geography, a river of Albania, which runs into the lake of Scutura; 10 miles N. of Antivar.

MORAD DUGH, a mountain of Asiatic Turkey, in the province of Natalia; 30 miles S.W. of Kuitaja.

MORAD SIUL, one of the branches of the Euphrates, that rises 20 miles E. of Dadjin, and joins the other branch 45 miles S. of Arzangia.

MORADGUNGE, a town of Hindostan, in Oude; 13 miles S. of Azimgur.—Aflo, a town of Hindostan, in Allahabad; 30 miles N.N.W. of Allahabad.

MORIÉA, in Botany, a name given by Miller, from whose Dictionary, ed. 8, Linnaeus adopted it in the sixth edition of his Genera Plantarum, in honour of Robert More, eq. of Shrewbury, said, by the author first mentioned, to have been "well skilled in the science of botany, and also in other parts of natural history." This is all we ever heard of his claims to the above distinction. Thum. the first printer of Morea was designed to commemorate Dr. Moræus, the father-in-law of Linnaeus, who wrote on the Aequum Napoleon, for whose sake perhaps Linnaeus the more readily admitted this name. For the same reason we may willingly retain it, in case the pretensions of Miller's friend should be deemed equivocal.—Linn. Gen. 27. Schreb. 26. Willd. Sp. Pl. v. i. 240. Mart. Mill. Diff. v. i. 24. Ker (Gawler) in Sims and Kon. Ann. of Bot. v. i. 238. Att. Hort. Kew. ed. v. i. 110. Juff. 58. Lamarck Uppi. t. 31. Genett. t. 13. Thumb. Diff. 6. (Vicefemale). De la Roche Diff. 14. Redout. Lill. i. 1. 42.)—Cladis and order, Triandria Monogynia, or rather Monadelphia Triandra. Nat. Ord. Enfres, Linn. Iridis, Juff.

Gen. Cal. Spatha of two valves, involute, permanent. Cor. regular, of six petals, spreading, the three alternate ones considerably smaller, sometimes ascending. Stam. Filaments three, awl-shaped, more or less united, above the base of the petals into a tube, erect; anthers vertical, erect, oblong, clawed at the base. Pijl. Germin inferior, oblong, more or less cylindrical; style cylindrical, short; stigmas three, spreading each with a petal-like, oblong, somewhat dilated, cloven appendage, presifed against each filament. Peric. Capsule oblong, angular, of three cells and three valves. Seeds numerous, orbicular, depressed.

Eff. Ch. Corolla regular, of six petals, superior; the three alternate ones much smaller. Stigmas erect, with a petal-like appendage. Stamens united. Capsule with many seeds.

We have already, under the article Iris, adverted to the difficulty of distinguishing that genus from Morea. They agree in their petal-like stigmas, except that in Morea this, as well as the filaments, are more erect. Morea appears to us distinct in having six separate petals, without a tube, and the stamens united above the base of those petals, into more or less of a tube. The Viciafexia of some authors is separated from them by Morea, because the filaments are united more completely; but there are so many gradations in the degree of union, that we cannot think of the distinction just. Several plants have been referred to Morea by Mr. Ker, and by the late Mr. Dryander in Hort. Kew, which, though we dissent unwillingly from such authorities, we cannot but remove to Syringchium, because of their nearly equal, and all alike spreading, petals, and narrow stigmas; their filaments also being perfectly monadelphous. There are Morea virgata; Jacq. 12. Rare. t. 228. M. elegans; Jacq. Hort. Schoenbr. v. i. 12. M. petalata; Curt. Mag. 1695. M.edita; Jacq. 12. Rare. t. 226. Wildenow has fifteen species of Morea; Thunberg, in his Differtation on the genus, published in 1787, has twenty-one; but several of each do not correspond with the above characters. Mr. Ker enumerates twenty-six in the Annals of Botany, and there are eighteen in the new edition of Hort. Kew. Linnaeus mentions but two in his Sp. Pl. but there are twelve in the 14th edition of Syll. Veg. chiefly derived from the Supplementum, being mostly borrowed from Thunberg.

Examples of Morea are M. tridentata. Sword-leaved Morea. Linn. Mant. 28. Act. n. 18. Curt. Mag. t. 693. Redout. Lith. 45.—Leaves equitant, sword-shaped, perennial. All the petals spreading, nearly of equal length; the alternate ones much narrower.
narrower. Native of the Cape of Good Hope. Miller cultivated it in 1758, and figured it in his *Leaves*, t. 239, f. 1. This is the *Irises compresa* of Thunberg, Linn. Suppl. and Willd. Sp. Pl. v. 1. 230, as Mr. Ker justly observes, and as we find by a specimen from Thunberg. The habit is more like an *Iris* than molt of the present genus. *Root* tubrous, perennial, tufted. *Stem* twelve or eighteen inches high, ascendent, compressed, smooth, often bent, butightly leafy. *Leaves* numerous, chiefly radical, as tall as the stem, sword-shaped, dark green. *Flower-flasks* clothed with several clefylindrical sheaths. *Corolla* white, two inches broad, the three petals marked at the base with a yellow oblong spot. Filaments generally quite dif

M. pascuana. Peacock Moreza. Ait. n. 3. Curt. Mag. t. 1247. (Iris pascuana; Linn. Suppl. 98. Willd. Sp. Pl. v. 1. 238. Jacq. Hort. Schoenbr. t. 10. Andr. Repof. t. 364.)—Smaller petals with an awl-shaped incurved point; larger nearly orbicular; all dotted at the base. Stem mostly simple, hairy as well as the leaves.—Native of the Cape. Introduced by Grimwood and Co. into England about the year 1790. *Alt.*—The leaves are long, very narrow, flattened and hairy, as indeed is the whole herb. *Flower* of a deep rich orange, the petals all dotted towards the base: the larger ones marked with a green and purple eye-like spot, of great beauty. The *filaments* are united almost all the way up, so that this species is by Descandole referred to *Vitexvica*.

M. tripetala. Three-petal-like Moreza. Ait. n. 4. Curt. Mag. t. 202. (Iris tripetala; Linn. Suppl. 97. Jacq. Ic. Rar. t. 221.)—Three alternate petals minute, linear, sometimes wanting. Procured from the Cape in 1802, by E. Woodford, eq.—A delicate, slender, smooth species, much resembling an *Iris* of the bulbous tribe, in the position of its style, and long linear claws of the larger petals, but distinguished from that genus by monadelphous *flamines*, and the entire want of a tube to the corolla. From the rest of its own genus it differs in having very small, linear, feebly recurved inner, or alternate petals, which are often altogether wanting. The colour is pale blue, purplish, or pink, with a yellowish dark-edged eye on the three large petals.

M. edulis. Eleufent-rooted Moreza. Ait. n. 8. Curt. Mag. 613, 1238. (M. vegeta; Jacq. Ic. Rar. t. 224, but not of Linn. and M. fugax; Jacq. Hort. Vind. v. 3. t. 20. Iris edulis; Linn. Suppl. 98. I. longifolia. Schwefl. Ic. t. 20. Andr. Repof. t. 47.)—Lower leaf extremely long. Petals all widely spreading; the alternate ones oblong, about half the size of the others. Filaments distinct.—Very common and abundant in various places at the Cape of Good Hope. Th ump. Diff. 31. The bulbs are eaten, chiefly by the Hottentots. The one or two radical leaves are twice or thrice the height of the stem, which bears two or three very pretty flowers, usually purplish, with a yellow eye on each larger petal, but sometimes the whole flower is pale yellow, with a few darker speck.

Some species, with a long tube to the corolla, appear to us improperly referred to this genus, as belonging, on that account, to *Iris*. Such as *M. longiflora*, Ker. in Curt. Mag. t. 712. Ait. n. 91. a dwarf species with golden flowers; and *M. Syfrinichum*, Ker in Ann. of Bot. v. 1. 241. Ait. n. 15. (Iris Syfrinichum; Linn. Sp. Pl. 59. Sm. Pl. Graec. Sibth. v. 1. 30. t. 42. Redout. Lilliac. t. 29. Syfrinichum purpureum et minus; Ger. em. 103.)—This last is a native of various parts of the south of Europe. Its *bulbs* are said to be valuable. The *filaments* seem united to the *style* rather than to the *corolla*, in Mr. Bauer's drawing in Pl. Graec.; but Ventenat describes them as connected with the *corolla*, and separate from each other, which is as they should be in an *Iris*. We have never seen a fresh specime.

MORGA, in *Gardening*, affords plants of the bulbous-sterous-rooted herbaceous flowering perennial kinds, of which the species cultivated are the iris-petalled morza (*M. iris-petala*); and the iris-like sword-shaped morza (*M. iridio-
dides.*)

Method of Culture.—These plants are all capable of being increased either by seeds, offsets, or parting the roots, which should be performed in August, in all the methods; the seeds being sown in small pots, and plunged into a bed of old tanners' bark under a common frame. It is chiefly sown for the sake of raising new varieties. It should be noticed likewise that the plants require the shelter of a frame in winter, being apt to draw up weak when placed in the dry flore. Where they can enjoy the free air in winter, when the weather is mild, and be secured from frost and hard rain, they flower and ripen their seeds better than with more tender management. In summer they should be fully exposed to the open air till the approach of autumn, when they should be removed into the shelter of the frame.

All of these afford variety among other perched plants in the greenhouse, and other collections.

MORAGATCHA, in *Geography*, a town of Bengal; 18 miles S. of Calcutta. N. lat. 22° 27'. E. long. 88° 18'.

MORA, is the name given at Otaheite, in the South-Sea, to their burying grounds, which are also places of worship and sacrifice. This is a pile of stone raised pyramidically upon an oblong base or square, two hundred and sixty-feet long, and eighty-seven feet wide. On each side is a flight of steps; those at the sides being broader than those at the ending, so that it terminated not in a square of the fame figure with the base, but in a ridge, like the roof of a house. There were eleven of these steps to one of these morais, each of which was four feet high, so that the height of the pile was forty-four feet; each step was formed of one course of white coral stone, which was neatly squared and polished; the rest of the masts, for there was no hollow within, confined of round pebbles, which, from the regularity of their figure, seemed to have been wrought. The foundation was of rock-itoones, which were also squared. In the middle of the top flood an image of a bird, carved in wood, and near it lay the broken one of a fish, carved in stone. The whole of this pyramid made part of one side of a spacious area or square, 360 feet by 354, which was walled in with stone, and paved with flat stones in its whole extent. About a hundred yards to the wall of this building was another paved area or court, in which were several small stages raised on wooden pillars, about seven feet high, which are called by the Indians *cattuss*, or *cattuss*, and seem to be a kind of altar, as upon these are placed provisions of all kinds, as offerings to their gods. Some of them were seen whole logs, and on others the skulls of above fifty, besides the skulls of many dogs, and of human sacrificial, which are taken up after they have been several months under ground. The principal object of ambition among the natives is to have a magnificent morai. The male deities, for they have them of both sexes, are worshipped by the men; and the female by the women; and each have morais to which the other sex is not admitted, though they have also morais common to both. Hawkesworth's Voyages, vol. ii. p. 166—239. Cook's Third Voy-

MO-RAISAH, in *Geography*, a sea-port of Africa, in the kingdom of Tunis, with a small harbour, in the bay of
of Tunis, anciently called “Maxula,” 24 miles E.S.E. of Tunis.

MORALS, any thing relating to the manners or conduct of life.

Besides the theological virtues, as faith, hope, charity, &c., there are also moral virtues; as justice, temperance, &c.

Moral Action, or Act, is such as render the agent good, or evil; and, consequently, rewarded, or punishable, because he does them. See Action.

Moral Cause. See Cause.

Moral Certainty, or Assurance, is used to signify a very strong probability; in contradistinction to a mathematical demonstration. See Certitude.

Moral Education is that branch of education which respects the moral or active principles of the mind, considered in distinction from the intellectual powers. By moral education we understand that series of means by which the affections and dispositions are cultivated, regulated, or restrained; and by which the moral sense or conscience is directed, enlightened, and invigorated.

Intellectual and moral education in various ways coincide with each other. There is, indeed, no doubt, that a very high degree of intellectual, is consistent with a low degree of moral culture; and, on the other hand, great excellence of character is often found, where there has been no opportunity for the higher exercises of the understanding. Nevertheless, the noblest heights of moral excellence can only be attained, where the intellectual principles receive a suitable cultivation. The mind is requisite, not merely to treasure up the stores of literature and science, but to prefer, for future use, and to recollect, the dictates of moral wisdom, and the results of moral experience. The habit of observation is essentially necessary to trace out the effects of our conduct on the happiness of others. Without the habit of attention, the lessons of the moralist, in whatever form delivered, will have only a momentary influence on the heart. Without the power of calling off the mind from the external impressions, the higher and more refined motives would have little effect in regulating the conduct. If the imagination be neglected, so as to become incapable of carrying the mind out of the range of the objects of memory or actual sensation, benevolence will lose some of its most powerful stimuli, and the efficacy of religious functions will be materially impaired. Without a proper cultivation of the judgment and the reasoning powers, the dictates of moral sense will often fail in correctness; the consequences of actions will be incorrectly appreciated; the reasonings of the moral instructor will not be understood; and the mode of carrying into effect the purposes of wisdom and benevolence, will be frequently mistaken. To neglect the cultivation of the intellectual powers, from the idea that they are unnecessary to worth of character, would then be acting upon very erroneous principles. If the moral sense is fairly analysed, it will appear that it is in part founded upon the exercise of these powers; and that, in a great variety of instances, it implies their operation. As long as we give the judgment the supremacy among them, and cultivate the rest with a view to it, we need not fear that we should injure the moral culture of the mind.

We are fully aware, (and it is a consideration which must delight every heart in which there is a spark of philanthropy,) that by the wise conduction of our nature, happiness is made to depend much more on a proper regulation of the affections and dispositions, than upon the cultivation and refinement of the intellectual powers; and that the former may attain a high state of purity and worth, without eminence in the latter: but we conceive also, that it cannot be denied, that to make right affections extensively efficacious in promoting the good of mankind, considerable cultivation of the understanding is absolutely necessary; and with the same degree of heart, he will be the happier man, as well as the more useful member of society, whose mind has acquired the highest degree of correctness and comprehension. A well regulated understanding is a most important aid in tracing out the principles of morality, their mutual connections and dependencies, their extent and their consequences. He whose mind has been well trained and disciplined, will be best able to understand the evidence of important truths which do not lie within the reach of sense; he will be better capable of forming, and the way they are to be employed for the improvement of himself and others.—The pleasures of imagination, says the great Hartley, “are the next move above the sensible ones, and have, in their proper place and degree, a great efficacy in improving and perfecting our natures. They are to men, in the early part of their adult age, what playthings are to children; they teach them a love for regularity, exactness, truth, simplicity; they lead them to the knowledge of many important truths relating to themselves, the external world, and its author; they habituate to invent, and reason by analogy and induction; and when the social, moral, and religious affections begin to be generated in us, we may make a much greater progress towards the perfection of our natures, by having a due flock, and no more than a due flock, of knowledge, in natural and artificial things, of a relish for natural and artificial beauty.”

—Besides, the stores of science and literature in various ways contribute to promote the ends of benevolence, and they are often eminently subserve, even to the interests of religion. Among the objects of philosophical research, this is peculiarly the case with the various branches of natural history and philosophy, and all that respects the practical laws of the human mind; and we should be induced to follow up this idea a little at large, if we had not already said as much perhaps as is requisite for our present object, near the close of the article Intellectual Education.

The moral culture of the mind is, in like manner, of great importance, even with a view to its intellectual culture; and this in several ways. It is almost impossible for a person to be at all conversant in education, without perceiving how much the progress of the mind in the acquisition of knowledge, and still more in the development and improvement of its various faculties, depends upon the dispositions. The affections, when wisely directed and regulated, afford powerful motives to the due employment of those means by which the culture of the understanding is to be effected; and the ill-direction of the affections not only operates to the loss of those valuable excitations, but throws positive impediments in the way of improvement. Pride, perverseness, and obstinacy, the eager or indolent desire of self-gratification, all directly tend to impede the mental progress. Vanity, in youth, we are not disposed to regard with too fustisious an eye; for it is then only the excess of qualities which are of eminent value; but pride commonly presents an effectual bar to improvement, so far as depends upon individual efforts. Perverseness and obstinacy, as long as they continue to have power, materially interfere with the cultivation of the judgment, and thwart the endeavours of those who would guide the mind in the paths of knowledge. And that desire of self-gratification, which, even at an early period, makes the difficulties of intellectual acquirements burdensome and disappointing, has often destroyed the vigour of body and mind, and blasted the fairest hopes of eminence. (See also Intellectual Education, columns. 7, 13, 15, &c.) Again, truth is most easily discerned, especially in the extensive and mult...
MORAL EDUCATION.

most important departments of moral science, where the understanding is not clouded with those prejudices which habitual candor would dispel; where a rational, not depressing, humility enables it to perceive its own deficiencies, and lead it to seek for farther light; where the love of truth is a ruling feature, and will not allow it to listen to the suggestions of indolence, but urges it to press forward whenever important truth is to be obtained, and keeps it from those departures from the straight forward road, which an unrestrained attachment to its own theories is constantly producing.—Thus, again, the means employed for the moral culture of the mind, will necessarily bring into exercise the intellectual powers. Among a large proportion of the community, there are the chief sources of intellectual culture; and, indeed, with the exception of those derived from the usual employments of life, we may justly say they are their only sources; and wherever they are judiciously employed, they cultivate the judgment and the reasoning powers; they increase the comprehension of the mind, exercise its attention and abstraction, and certainly go hand in hand with the best objects of literary and scientific pursuits, in their effects upon the understanding in general. We shall never be found among those who depreciate the importance of literature, or of physical science; but we have no doubt that the effects upon the intellect, of the well-directed pursuit of religious knowledge, (to let out of view the higher departments of mental and moral science,) are not inferior to those of literary and scientific pursuits, in cultivating those mental habits and powers, which are of the greatest importance in the conduct of life, in promoting the happiness of the individual, and his benefit to others. The laborious clades of the Scotch afford a striking illustration of this truth. During a large portion of the time in which they have manifested the acuteness and penetration of thought, the solidity of judgment, and the habits of reflection for which they have been justly so much noted, these qualities have been chiefly brought into exercise by their religious culture. And we have no hesitation in saying, more generally, that the pursuit of religious and moral science, has been an eminent means of promoting the intellectual improvement of our species. The powers of the mind have had a most important exercise while engaged in it; and the activity, depth, and, frequently, accuracy of research which it has produced, have often, either directly or indirectly, been efficacious in extending the limits of human knowledge on other subjects. And we believe it to be a fact, which is abundantly well authorized by experience, that the well-directed pursuit of moral and religious truth, has the most happy effect in increasing the vigour and comprehension of the mind; and that numerous influences have occurred, in which such pursuits, under the guidance of good sense, and stimulated by right dispositions, have most materially cultivated accuracy of judgment and extension of views, and have produced a degree of sublimity of soul, which is altogether out of the reach of those who reit with secondary objects merely, however important these may be in themselves and in their connections. Once more, the moral culture of the mind aids the intellectual, by leading the mind, in its choice of objects of pursuit, to those which, while they are most beneficial to mankind, have, at the same time, the direct tendency to bring into exercise the powers most important to the right conduct of life. Some of the foregoing remarks more immediately relate to that stage of the mental progress, in which the work of self-education begins; but we believe they may lead the parental instructor to some useful conclusions; and we wish to add, that those whose names rank the very highest in the departments of physical and mental science, Bacon, Boyle, Newton, Locke, and Hartley, were men whose minds were under strict moral regulation; and those who trace out its effects on their labours and pursuits, will probably agree with us in opinion, that they owed much of their comprehension of mind, discernment, and penetration, to their moral culture. “Some people have a notion,” says Mils Edgeworth, “that the understanding and the heart are not to be educated at the same time; but the very reverse of this is perhaps true: neither can be brought to any perfection, unless both are cultivated together.” Pract. Ed. ch. x.

Our readers will have perceived, that in moral, we include religious education. We are not aware how either those who acknowledge the divine authority of the gospel, and their consequent obligation to make its principles and precepts its rule of life, or those who have studied in the schools of religious philosophy, and discovered that religious principle and religious affections constitute an essential part of moral excellence, can hesitate in considering the cultivation of them as a part of their duty. We feel ourselves fully borne out by the founded views of mental philosophy, as well as by the laws of Christianity, when we affirm, that those principles of action which respect the Supreme Being, are, in themselves considered, of the highest obligation,—that they afford the most beneficial regulation to all the inferior principles of our nature,—that they give stability and refinement to those affections and dispositions which are themselves component parts of human duty,—and that, in proportion as they acquire their due extent and influence as primary motives, the moral character is improved and exalted. Regarding the cultivation, therefore, of the religious principle, as a most important branch of education, we should feel it a dereliction of duty, if, on this occasion, we did not lay before our readers our views as to the mode by which it is to be effected. In doing this, we are aware of the delicacy of our ground; and while we endeavour to bring forward those general principles of religion, in which we should supposse all agree who acknowledge with us the divine origin of Christianity, we shall scrupulously aim to fler clear of all those controverted points of doctrine which at present so much aggravate the public mind. We solicit from those of our readers who may have been too much accustomed to separate religion from morality, to give our remarks a candid perusal; and perhaps for the cultivation of those dispositions which respect the social and private duties, we may be able to afford them some hints: but as our system of morality is Christian morality, we apprehend that they will perceive indications of our radical principle in almost every part of what we have to offer. We earnestly wish to lead parents, and others who are concerned in the early stages of education, to take as much pains to give the mind right biasses, and to cultivate the rudiments of right affection, respecting religious duty, as to give habits favourable to the pursuit of literature and science, and to the exercise of the social and private virtues.

We shall be led to enter more at large into the justification of our views as we proceed; but we may take this opportunity of reverting a little to some remarks which we made in the 9th and 10th columns of Intellectual Education. In reference to the incomparable elementary works of Mils Edgeworth, we spoke of “their striking and much-to-be-lamented deficiency in every thing like religious principle;” and, with the same general view, we expressed our opinion, that her work on education is “essentially deficient.” With respect to the latter, we do not mean to say that the authors of Practical Education had not a full right to chose for themselves what objects of education they would attend to; and, as we have already intimated, we are fully aware of the extreme difficulty of writing on the subject of religious education.
MORAL EDUCATION.

education, so as to be satisfactory to all parties; but when they declined it altogether, it would surely have been desirable to state, that it was from no want of conviction of the supreme importance of religion, and the necessity and duty of early religious culture, but from the apparent impossibility of adapting their observations to the generality of those who might advantageously employ their remarks on moral culture. Prefixed to the second edition of Practical Education, we do indeed find some remarks in reference to Mr. Pictet's Strictures on their silence respecting religion. "Children usually learn the religion of their parents; they attend public worship, and both at home and at school they read the Bible and various religious books, which are of course put into their hands. Can any thing material be added to what has already been published on this subject? Could any particular system meet with general approbation?" But surely this refers solely to religious instruction. Reflecting the bulk means and degrees of communicating religious knowledge, it is perhaps impossible to lay down any plan that will be generally acceptable or practicable: but the communication of religious knowledge is not the most essential part of religious education. The authors of Practical Education, in too intimate an acquaintance with the nature of the affections in general, to authorize the supposition that they can imagine religious affections can spring up in the mind without cultivation; or that religious principles can be formed, without the use of means analogous to those by which the disposition to obedience, the love of truth, and the social affections, are produced and cultivated in the heart. Where found views of the nature of the mind prevail, the only point is, whether religious affections and principles constitute a part of our duty; if they do, there can be no question but that, to give them their due influence and stability among our principles of action, the cultivation of them must be begun early, before the mind is pre-occupied, before it is riveted on the objects of fashion, or the subordinate pursuits of the imagination and self-interest. And we should have rejoiced at a work which displays so much soundness and strength of moral principle, and which affords such excellent instructions respecting the regulation of the temper, the formation of the habits of obedience and veracity, and the cultivation of the social affections, had also contained some directions that might have affiliated parents, anxious to discharge their duty to their children to their full extent, in ascertaining how they were to produce, exercise, and regulate those other affections, which, when become habitual, and made the actuating motive of the conduct, contribute in so eminent a degree to the present and future happiness of the individual, and to his progress in every department of moral excellence. It would have been well if the authors had, for the benefit of others, registered the results of their own experience, relative to the manner of cultivating those religious principles, which, under all the varieties of Christian faith, cannot be regarded as otherwise than essential to the discharge of Christian duty. It might have dissuaded some, who rate low the importance, or rather the necessity, of religious principle; and it might have furnished the bigot with the opportunity of finding out deficiencies in the authors' creed, because they had not taught the peculiarities of his own; but no judicious person of the first class would have been prevented from deriving from their more general observations, that information on education which their work is so eminently calculated to communicate; and as to the latter class, we believe they must be allowed to go on in their own way, for it is seldom practicable to enlighten the judgment, where religious bigotry gains an absolute sway. In these remarks we are not without a view to our own justification, and that of other writers, who at present or in future may pursue the same track, if indeed justification is required for contributing a little towards the furtherance of the most important objects of education.

But it would be injustice to the authors of Practical Education, not to add, that at the close of the advertisement to their second edition, they state that they "continue to preserve the silence upon this subject which they before thought prudent; but they disavow, in explicit terms, the design of laying down a system of education, founded upon morality, exclusive of religion." And to the fame purpose is a letter which we have recently received from Mr. Edgeworth, in which he enters somewhat more explicitly into the subject. After expressing himself in very favourable terms respecting our preceding article on education, and the manner in which Practical Education has been discussed in it, he adds, "I must, however, regret that an error pervades the whole, which has been adopted by most of our critics, and which we most earnestly deprecate,—the imputation of disregarding religion in education. In the French translation of Practical Education, this subject is discussed in the preface, and I beg from your justice, that some occasion may be taken of entering our protest against this charge. In a book written by Mifs Edgeworth and me, called Professional Education, we hope that under the chapter 'clerical education,' we have evinced a proper sense of the clerical character, and an enlarged view of religious function. We wrote this chapter for the clergy of the establishment, to which we belong; but our views in Practical Education were not confined to any sect or nation. Our private tenets are of little consequence to the public; but we are convinced that religious obligation is indispensably necessary in the education of all descriptions of people, in every part of the world."—"We dread fanaticism and intolerance; while we wish to hold religion in a higher point of view than as a subject of exclusive possession, or of outward exhibition. To introduce the awful ideas of God's superintendence, upon puerile occasions, we decline. At the same time we have not presumed to blame others for acting upon a different persuasion—I have the honour to be a member of the board of education in Ireland. My opinions on the subject of national education appear in our reports. By them I hope I shall obtain the justice due to me on this subject; and that it will appear that I consider religion, in the large sense of that word, to be the only certain bond of society." Mr. L. does not give us express permission to use his letter in the manner we have done; but it appears the surest way to avoid further error; and we confidently hope for his excuse, if we have gone beyond his intentions. Reflecting the part of professional education to which Mr. Edgeworth refers, if our plan was less limited, we should offer some remarks; and we shall only add here, that the plans which the author would adopt, to infuse a devotional taste and religious principle into the mind of a boy designed for the clerical profession, must, so far as they are judicious and effectual, be alike important for children in general, whatever be their destinations in life. If there be any pursuits which are inconsistent with religion, children cannot, of course, be religiously educated for them; but in so far they must be inconsistent with duty. And if the opportunities for the cultivation of religious principle are greater in the clerical profession than in any other, and its moral dangers fewer, then there is the greater necessity that those who are designed for the more active pursuits and employments of life, should be early imbued with those principles which may be their safeguard, and which will never be fo
MORAL EDUCATION.

well cultivated by the individual himself, as when there has been a judicious foundation laid for them in early culture.

We must not omit also to mention, that we have been honoured with a letter equally flattering to us, from Miss Edge-水肿; one leading object of which is to rectify an error into which we appear to have fallen, in speaking of her in connection with Practical Education, "as if it were entirely her work." We had not forgotten what is stated in the pre-

face, that the chapters which more immediately refer to liter-
ary and scientific instruction were written by Mr. E.; that the sketch of the introduction to chemistry was written by Mr. Lovell; and that the chapter on obedience was written from the late Mrs. E.'s notes; but in INTELLECTUAL Education our concern was merely with the general principles of intellectual culture, and not with the application of them to the manner of teaching any particular object of intellectual pursuit. Now those parts of Practical Education to which we had occasion to refer, were written by her; and without de-
preciating the value of the other parts of the work, we have been much accustomed to consider these as the subordinate departments, and the leading features of the work as her's, that we may perhaps express ourselves on this point with some degree of inaccuracy, which, however, we hope we have now sufficiently rectified. With that modesty and love of truth which her writings imply, Miss E. is still more anxious to reduce our appreciation of her own merit in the departments which Mr. E., in his preface, speaks of "as written by her." "This," she says, "is literally true; but he should have added, that the materials were received from what I saw and heard in the daily education of his family. The children mentioned in 'Practical Education,' my half brothers and sisters, were educated by my father, and by their own excellent mother, who devoted her whole time and thoughts to the subject. I was grown up at the time they were infants, and thus I had, during the whole course of their education, daily opportunities and leisure to observe its progress; and from seeing and hearing so much on education, I was better enabled, perhaps, to write upon this subject than upon any other." We can only say that if her advantages have been great, she has made an excellent improvement of them. In common with her writings in general, those on education clearly shew, that she pithfully, in an eminent degree, the talent of bringing forwards the ample flow of accurate knowledge with which enlightened and comprehensive observation and experience have supplied her, in that time and manner which will give them their greatest practical utility.

There are several works on education, which, to parents who are anxious to fulfill their duties to their children, may supply, in a great measure, the deficiencies to which we have referred in Practical Education. Mrs. H. More's works, directly bearing on education, furnish some exceedingly im-
portant observations; mixed indeed with much which we cannot adopt or approve, but in themselves of flattering value. Miss Hamilton's first volume we have formerly spoken of as of eminent service in the cultivation of the affections. Her remarks are often deficient in coherence and precision; and in various parts they want that minuteness which is necessary to give them full force in their application; but we regard her work as the best calculated we know, to aid the religious mother in training up her children in the ways of wisdom. We should be unpardonable if we did not also refer our readers to Dr. Puseley's Observations on Religious Education, contained in his Miscellanea, Observations relating to Education, and also published separately. However variously that eminent character may be estimated by different parties in religion and philosophy, they who have studied those parts of his works which directly bear upon religious philosophy, and the application of it to the conduct of life, cannot fail to assign him a high rank in the scale of utility; and in the work to which we have referred, he has shown, with a strength and perspicuity of reasoning, which one would conceive no well regulated mind could refut, that early attention to the religious education of their children, is incumbent on all who wish that they should, in the progress of life, fulfill the duties of Christian morality. We may have farther occasion to refer to, or select from, that work. The following observations from the second section, tending to show that religion is the first rational object of education, to completely and well express our own opinions of that point, that we make no apology for here introducing them to the notice of our readers.

"The general object of education is evidently to qualify men to appear to advantage in future life, which can only be done by communicating to them such knowledge, and leading them, to form such habits, as will be most useful to them here-
after; and in this the object of their future being, to which their education can be supposed to bear any relation, is to be considered.

"If I knew that my child would die when he had at-
tained to the age of five or six years, and that his existence would then terminate, I should certainly make no provision respecting him for any thing beyond that term, but endeav-
our to make him as happy as I could during the short pe-

riod in which he could enjoy any thing. I would, for the fame reason, provide for him only such gratifications as his infant nature was capable of.

"Again, if I knew that he would attain to the age of manhood, but that then his existence would not be prolonged any farther, I should endeavour, as well as I could, to qul-
ify him for acting such a part as would be useful to himself

and others in that period, but should never think of extend-

ing my plan so far as to enable him to pass a comfortable old age, a term of life to which I knew he never would arrive.

"For the same plain reason, a man who believes that the whole period of his own existence, and that of his offspring, is confined to the present life, would act very absurdly if he

should train up his children with a view to a future life, ex-
cept so far as he should think that such a farther, though a

chimerical object, might be subordiant to his proper conduct in the present life.

"These are obvious considerations, which ought to have their weight with all rational beings; and according to them, the mere man of the world must allow, that a Christian, who, as such, believes that himself and his offspring are destined to exiit in a future life, and that the principles and habits that we form here have a decisive influence on our happiness here-
after, would act irrationally, if he did not use his utmost

endeavours to give his children such principles and habits, as would deserve to them an interest in a future world.

"Moreover, since a Christian regards this life, principally, as it is subordiant to another, which is of infinitely more value, he must consider the duties of religion as the first thing to be attended to by him, and must be taught to disregard all authority that would enjoin upon him a conduct which would be detrimental to his greatest and ultimate interest; because he will gain more by his obedience in his regard to a higher authority, than he can lose by opposing an inferior power.

"The first thing, therefore, that a Christian will naturally inculcate upon his child, as soon as he is capable of receiving such impressions, is the knowledge of his Maker, and a steady principle
principle of obedience to him; the idea of his living under the constant inspection and government of an invisible being, who will raise him from the dead to an immortal life, and who will reward and punish him hereafter according to his character and actions here.

"On these plain principles I hesitate not to assert, as a Christian, that religion is the first rational object of education. Whatever be the fate of my children in this transitory world, about which I hope I am as solicitous as I ought to be, I would, if possible, secure a happy meeting with them in a future and everlasting life. I can well enough hear their reproaches for not enabling them to attain to worldly honours and dignities; but to have been in any measure accusatory, by my neglect, to their final perdition, would be the occasion of such reproach and blame, as would be absolutely inexplicable."

In the remainder of this article, we shall pursue the following plan. We shall first enter pretty much at large into the sources and culture of the filial affections; secondly, we shall state some important principles respecting the affections in general, introducing, by way of inference and illustration, some of those observations which, agreeing to a more extensive plan than we find our limits will permit, we had proposed to make the subject of separate divisions: thirdly, we shall make some remarks respecting the specific culture of the moral principle, or conscience; and fourthly, we shall conclude with some observations more directly respecting religious education in the earlier periods of it.

I. Filial Affections.—These may, in various ways, be considered as forming the general basis of the whole moral structure; and we have no doubt that upon the manner in which they are formed and cultivated, the happiness of the individual, and the excellence of his character, very greatly depend. We of course include, under the term filial affections, those which respect not merely the actual parent, but persons who may, from the loss of that relation, or other causes, stand, more or less, in the place of the parent during the early periods of education. Correct views, as to the origin of these and other affections, will be found of inestimable importance in the cultivation of them; and we shall here give a brief analysis of the filial affections, with a view both to afford the proper cultivation of them, and to throw some light on the means of cultivating other classes of affections.

A child receives almost all his earliest pleasures from his parents, or in connection with them. These all leave behind them feelings which the ever active principle of association unites and blends together, and connects with the apperception, and idea, and name of the parents; and thus renders it pleasant to a child to feel them, and to hear and think of them. By degrees he learns to distinguish them, as the cause of many things which give him pleasure; he perceives them endeavouring to do what will make him feel happy: he is the object of a thousand tender endearments and kind offices; and every thing of this description, which at all affects his mind, leaves some impression behind it, which unites and blends with the feelings before produced, by other similar circumstances. Thus gradually rises up in the mind, that part of the filial affection which we term love.

If children have little intercourse with their parents, or that be little productive of pleasing feelings, their love will be weak; in other cases it often early proves very powerful. It cannot advance far, without exciting in the mind of a child the disposition to do what he finds will please his parents. He is early incited to this by the promise of some gratification, by the expectation of some endearment, &c.; and such is the wife structure of our mental frame, that what is often done with a view to some good, gradually becomes itself pleasant, and is done without any direct view to that good. Thus a child forms a desire to please his parents, which constitutes another part of filial affection.

Again, in a wife education it will often be found necessary to check the gratifications of a child, to use the language and tone of disapprobation, and sometimes even to inflict pain. Every circumstance of this kind leaves behind it an impression, which uniting and blending with others of the same kind, produces the feeling of fear. If this, owing to any cause, is excessive, it gives to the filial affection a character which makes it rather the source of pain than of pleasure, and sometimes even overcomes the love. On the other hand, where it is moderate, (arising only from that degree of private or pain which is necessary for the future welfare of the child,) so far from lessening the happiness of the filial affection, it increases it, blending with the love so as to lose its own painful influence, and, at the same time, giving firmness and even vigour to filial love, by heightening the disposition to obedience, and thereby increasing the pleasing concomitances of obedience, by heightening the fear to offend, and consequently preventing the ill concomitances of disobedience. Thus by pleasures derived from the care and tenderness of parents, and by the privations and pains which their care and tenderness may involve, a vast number and variety of impressions are produced, which, all uniting and blending together, constitute the filial affection, confining principally in fear and love, the desire to please, and the fear to offend.

As the child advances in knowledge, and as the conscience acquires its power, the sense of obligation, the perception of the virtues of his parents, the feelings which he is led to entertain towards God, and a great variety of other sources, contribute impressions of duty, of gratitude, of respect, &c. towards the general affection, uniting and blending with it, and increasing its strength and vigour; so that it often becomes a leading affection through the whole of life.

We have taken only one cafe, but the reader may easily pursue the same plan in other cases. Perhaps it may be truly said, that in no two instances is the filial affection in every respect the same: it is formed from impressions so numerous, so various, and often so peculiar; and depends so much upon peculiarities in the dispositions and conduct of the parents, and in the dispositions of the child.

What may with propriety be termed the natural affection of children towards their parents, (arising without the exercise of reflection at all, merely by the operation of the affectionate principle,) is, we apprehend, almost always the strongest towards the mother; at least if she has also been the nurse: and as the pleasurable feelings of infancy do greatly contribute their share towards the formation of more complex pleasures, and as they cannot be replaced but by a long series of exertions, a mother who wishes to polish the highest degree of her children's affection, and the greatest influence in the regulation of their conduct and dispositions, must also be their nurse. We have often heard of what are called the instinctive feelings of filial affection. The term instinct, when applied to the human mind, we regard as a mere appeal to ignorance; but we have no doubt that the early associated feelings towards a parent, particularly towards a mother, may exist long after the direct remembrance of her has altogether ceased, and that the fear of her, after long absence, may produce strong emotions in the mental frame, though the memory furnishes no distinct traces of her visible appearance, her tones, &c.; and though no communication is made respecting her relationship to the individual.

We are not disposed to treat all stories of parental or filial sympathies as fabulous: the nature of the human mind is
indubitably such, that the trains of association may be set in motion, without the direct exercise of the understanding, and often without the individual perceiving why the object so affects him.

But to return: parents will naturally feel diesem that their children should possess towards them a lively and durable affection; and that their own moral influence on their minds may be such as to enable them to be of the greatest assistance to them in the journey of life. These two things the wise parent will never separate; we should perhaps say, that so far from being in any way incompatible they necessarily accompany each other. The true point to be aimed at is, to temper the conduct towards the child, that while he possesses all those enjoyments which are consistent with his present health and comfort, it shall not be at the expense of the future. Whenever the gratification of a child’s wishes will necessarily lead on to cravings of greater indulgences, clearly inconsistent with health or comfort, it is called and not to stop at the first point. Indulgence is the most early for the present, but its results are permanently injurious. It is not too much to say that the over indulgent parent will have lost of the affection of his children, than he who steadfastly pursues the plan which he deems most for their happiness. We have already remarked, that displeasing associations, (where not accompanied with a sense of injustice, as they never will be, if a child is properly educated, and a parent has attained a tolerable degree of self-government,) so far from weakening love, do in reality strengthen and invigorate it. Contant indulgence may give a greater degree of softness to affection; but it will never produce what is steady and pure. Affection so produced will necessarily be selfish, till the sense of duty, derived from other sources, comes in to lend its aid; and the strong sense of duty is too seldom to be produced, where the system of habitual indulgence is carried to a great extent. And besides, let indulgence be carried to the greatest possible extent, it cannot always give way to those wishes and defires which it fosters; and the pain arising from refusal is by far the greatest and most likely to weaken affection, where it necessarily has the appearance of caprice, by its occurring in cases where indulgence has often been experienced. It is a difficult medium to observe between unnecessary approaches towards authority on the one hand, and weak indulgence on the other; and it requires no small degree of mental regulation, on the part of the parent, to preserve it; but where the aim of the judicious parent is steadfastly directed to the future, while at the same time he endeavors to make the period of childhood the period of natural, simple pleasure, there is no great danger of his going far wrong. He will often be called upon to give up his own gratification (for to an affectionate parent, it must ever be gratifying to promote even the present pleasures of his children); but if his affection desere the name, if in fact it be not a mere fondness mere childish than perhaps he would like to own, though they cannot look beyond the present moment he will; and whenever he perceives that the gratification of their wishes, whether in the way of obtaining direct pleasure, or avoiding something which is painful, would be attended with injurious consequences upon their health or comfort upon their posterity or not it of obedience, there he ought to be firm but mild in his regulations. Indeed, if there be one thing more than another which constitutes the secret of education, in all periods of it, but most particularly in the earliest period, it is mild consistent firmness on the part of the parent; and where this quality is possessed habitually, or at least employed in intercourse with our children, and guarded in its operation by sound views as to the moral structure of the mind, the best effects may be expected on their temper, happiness, and worth of character.

But it may be said all this is only general argument; and while the truth of it is allowed, its application is not easily to be seen. We admit it; but we cannot go as far as general principles; and we are most devious to lay down such, if practicable, as may aid the conscientious and judicious parent in the most important part of his work. We should term it false indulgence where a parent, from fondness or weaknesses of mind, either permitted or gave a gratification, or gave up a privation or punishment, where the former had been expressly refused or forbidden, and the other expressly determined; where, at the solicitation of his child, he gave him gratification of the palate, &c. which he thought likely to be injurious to him, either by their immediate effects, or by directly leading on to other things which would certainly be injurious; where, in order to avoid the pain of disappointing his child, he allowed him departures from these regulations which he believed to be important to his mental or moral progress; where, in short, the gratification is to his own fondness, rather than arising from an enlightened affection for his offspring. Excessive indulgence is often viewed in a very venial light, in the earliest periods of education, in the education of infancy; but those who carefully watch the progress of the mind, will agree with us in opinion, that indulgence then either prepares the way for habitual continued indulgence in childhood, to the weakening and prevention of the most valuable moral qualities; or treaures up for it, pains and privations and disappointments, which, unless very judiciously managed, must break the activity of the mind, or four the temper; and that it even lessens the comforts of infancy; for its gratifications cannot always be acceded to, and the more its injurious defires are gratified, the more numerous they necessarily become, so as to be continually adding to its painful disappointments. And this is particularly the case during those diseases which affect infancy, (the final cause of which it is perhaps difficult fully to perceive, but which certainly tend to heighten the affection and tenderness of care of parents, and to increase false affection in older children, by shewing how much their parents endured for them.) The child whose defires while in health have been made the constant object, will necessarily have tenfold calls for gratification, when, even in the best regulated temper, frettfulness is to be expected; and then the parent experiences the punishment of false tenderness. Every privation, every little painful feeling, is heightened in its effects, because the gratification of the defires does not prevent or remove them; while children whose real wants have been made the guide of gratification, will have fewer wants and defires, and have the better chance of having those anierred, and their minds diverted from the present feelings.

The true rule we are perplexed is, to encourage and promote the simple natural pleasures of childhood; to prevent or supply as far as possible its simple natural wants; but not to futter its caprices, to gratify its inclinations, where this must be done at the expense of important habits of obedience, of order, &c. or to give way to its desires, or perseverations, or intrigues, where a different course of conduct would otherwise have been thought most expedient. If the plan of steady constant firmness be begun sufficiently early, there is no fear of its effects; where it proceed from an enlightened affection, it will be united with all that will be necessary to produce a lively filial affection in return; and what is even more important, this will have nothing mixed with it that is calculated to check its influence, and to make it unsteady.
Moral Education.

We are fully aware of the great difficulty which in many cafes excites on the part of the parent to maintain that persevering mild firmness, which we hold to be the most essential quality for nurses in moral education; but where the endeavours to obtain it, or to preserve it, are prompted by warm affectionate enlightened tenderness, they will seldom fail to operate sufficiently to produce the most important effects. And parents who are under the influence of enlightened and vigorous affection to their children, never need be afraid of their want of affection to themselves. Where they take a share, or at least manifest an interest, in their children’s sports, where they obviously contribute, as a parent can, in a thousand little but interesting ways, to the pleasures and comfort of their children, while tenderness is allowed to express itself on all suitable occasions, but does not degenerate into capricious unbecoming fondness, there is no reason for apprehension lest they should not be loved by their children. The education which parents must give themselves in order to educate their children properly, is not the least among the moral benefits of domestic life.

Though parents will be often led to express the tenderness which they feel for their children, they will be careful not to expect too much of the appearance, or even reality of it, from them in return. Some children are constitutionally more susceptible than others, and have more the habit of expressive feelings; and it is certainly very pleasing to the parent, to perceive their little sensibilities manifesting themselves in the direction of filial regard, by those ardent expressions which are affecting in proportion to their simplicity and reality: but we are not to imagine, that because others do not use those expressions, that therefore their affection is weak; nor should we draw this inference, even if we have reason to believe, that not only the expression, but the reality, of lively feeling is wanting. The liveliness of feeling is one thing, and the readiness of affection another; and we ought to rest satisfied, if we perceive genuine indications of affection, operating in those ways which best accord with the age and mental progress of the child. We have known a little girl, about two years and a half old, fit for hours in the room with her mother when ill, carefully avoiding all noise in her little amusements: we are certain that the affection of this child (now about three years older) is equally tender as it was, and much more a durable, steady principle; but we wish doubt if it could reasonably be expected from her, now her imagination is more lively, and she has been more accustomed to active play with other children, to remain thus quiet while she knows that they are playing in other parts of the house. Nor should we expect, even at the same period of maturity, the same indications of affection in all circumstances. The tired child at night may be unable to play, or even to feel, that love which was obvious when the arose brisk as the lark; or the little mind may be occupied with what, for the time, may engross the whole attention, and the whole interests of the mind.

The little attentions of affection should never be made burdensome to children; they cease to have their influence in invigorating it, when this is the case. The ingenuous expression, ‘Mamma, I will lay with you, if you will it; but, if you please, I would rather go and play with sister,’ should never meet with the slightest indication of disapprobation, or of disappointment. Children are not to be expected to calculate as we can do; or act from the dictates of habitual principle. The present pleaure is the most imperative one. If the parent’s convenience or comfort require the self-denial, let it be exercised; and let it, if possible, be made pleasant, though without direct reward. But if not, it is better that the self-denial should usually be on the part of the parent, and nothing will eventually be lost by it.

Expressions of affection should not be the subject of praise, any more than the want of them should of censure or punishment. If commonly bought, or extorted, they will too often, as far as affection is concerned, be mere expressions. We however wish to except the earliest marks of love, where perhaps the love is rather the result of the expression, and its reward, than the expression the natural dictates of the affection. We do not like to see them, even then, however, made so much as is commonly the case the object of bribery or reproach. Nor will a wife parent expect or encourage from a boy the same degree of affectionate expression, (either in manner or words,) as is not unusual among girls. The physical sensibility of a boy is, or ought to be, less lively. If constitutionally it is not so, the object should rather be to lessen it than to cultivate it. The comparative expressions of affection should never be made the subject of praise or censure: the indications of obedience may. A child can understand whether he is more or less obedient than another, but it is not easy for him to comprehend, that he loves his parents less, because he shows fewer outward marks of affection, except, indeed, so far as they are at the same time proofs of obedience.

Marks of parental tenderness should be so regulated, as to leave no impression of caprice or partiality on the minds of children. If the little efforts of a child to please, or to simple expressions of love, are sometimes received with warmth of satisfaction, and at another time, in the same circumstances, as far as the child is concerned, with coldness or displeasure, it will produce constraint, and operate much against the progress of filial love and parental influence. If, without any offensive difference in the conduct of different children, one is treated with kindness and attention, and another with at least apparent coldness or dislike, the most injurious effects must be expected, both on the filial and fraternal affection; and the rudiments of envy and jealousy will be certainly and effectually sown. The wise parent will sometimes be obliged to make a difference in the treatment of his children, founded upon the difference of conduct; and perhaps it is often difficult for him to avoid feeling more affection for one than for another, founded upon some accidental or correct affectation: but the children of one family should perceive no difference in their parents’ treatment of them, except when that difference arises from greater or less degrees of obedience or general propriety of conduct.

But after all, the grand point is less to secure affection, than to secure influence; and as to the former, the parent acting with a view to the future, rather than to the present gratification, and at the same time not sacrificing the enjoyment of the present, from unfounded suppositions as to the power and purity of motives, but aiming to make the period of infancy and childhood as pleasant as it can be, consistently with the benefit of the future, (by furnishing useful and interesting occupation, guiding and aiding the little sports of childhood, &c.) will be very day increasing the number or the strength of those fibres, which will strike a deep root into the heart, and make the plant of filial affection luxuriant, yet hardy and productive. With respect to the latter, we are of opinion, that it cannot be secured too early; and that the more it exists as a habit, the greater probability there is, that filial affection, while it acquires vigour, will at the same time receive few of those interruptions, which may be necessary to make the felicity of indulgence healthy and strong, but which are not requisite when affection is not produced by capricious fondness, or even by excessive indulgence.
MORAL EDUCATION.

effective but steady tenderness, but by enlightened attention to the present pleasure and lawful welfare of a child. We do not mean to discourage parents who have neglected the cultivation of the habit of submission in infancy; if from circumstances which are often unavoidable, self-willedness has then been allowed to gain too much power, still if the process of moral culture are not too long neglected, and are steadily pursued, though they will be more difficult, they will seldom fail to be successful. Bodily or mental pain will often be found necessary in such cases; but if judiciously administered, and submission mildly, but steadily exacted, the little wayward mind will be brought into habits of obedience, which will only require to be persevered in.

How much this is for the enjoyment of childhood, and how much too for the comfort of parents, those only who have had experience in education can fully appreciate. We have before our eyes an instance in point. An infant about a year old, during the long continued illness of its mother, had been excessively indulged by her nurses; her cries had been encouraged, by making them, rather than her real wants or comforts, the guide of gratification; she had been allowed to exercise her little tyranny and caprice over her elder sister, to the great diminution of her comfort; and, altogether, had been brought too much into that flirt, in which the bid fair to be a spoiled child. The generally engaging manners of the child prevented her faults from being much observed by others; but those who felt most interested in her happiness, few with pain the rudiments of extreme selfishness and imperious wilfulness. Their efforts of course were directed to the correction of them; and two or three years have brought her little mind under much greater control, without losing any thing of her vivacity or attractive interest; and we can say from minute observation, that in no instance has the punishment or restraint, which has been perfectly steady, but mildly and sparingly employed, been productive of any effect which did not add something to her affection for her parents. Her selfishness is most strikingly diminished, and her obedience (as far as intention is concerned) is certainly decided. The older child of whom we spoke had the advantage of greater early restraint; which, in addition to a greater accuracy of observation and judgment, without having any effect upon her happiness, except that of making it more steady, has given her at the age of five or six years, a degree of mental and moral regulation, which we have seldom witnessed in so young a child, united to great sweetness of disposition and activity of mind, and altogether rendering her as happy, we conceive, as a child can be; in various ways increasing her pleasures, and freeing her from the most bitter feelings of disappointment.

We trust we shall meet with our readers' excuse in these details. We are not defirous of inventing theories; we do not expect to communicate much information on the subject, to those enlightened and judicious parents who have already given it its full attention; but we may corroborate their experience; and our wish is to enable ourselves to indulge the hope, that our labours will be found of practical use to those who have yet to learn something on the subject. To them we also recommend the study of Mrs. Edgeworth's chapter on obedience. Mr. E.'s preface informs us, that it was written from the notes of the late Mrs. Edgeworth, and it shows a judicious acquaintance with some of the most important practical laws of the mind, and must furnish to every parent valuable hints in different periods of education.

As Practical Education is probably accessible to all our readers, we shall here give ourselves with recommending the whole chapter to their careful perusal, and merely making a few remarks on a position which we think erroneous.

"When children begin to reason," says the author of this chapter, "they do not act merely from habit; they will not be obedient at this age, unless their understanding is convinced that it is for their advantage to do so." From this position we altogether dissent. We admit that they should not then act merely from habit; that it is in parents to make the reasons of obedience obvious, to gain their understandings on their side; but we feel authorized to say from experience, that affectation and habit united, will, long after a child begins to reason, continue to be the most powerful motives to obedience. Affectionate and well-trained children learn confidence in their parents, and to stay from the want of anything to destroy confidence, than from the actual perception of the beneficial ends of parental injunctions. Not that this should be neglected, not that the reasons of our injunctions should never be pointed out, where they can be made intelligible to the minds of our children, and the advantage of attending to them made obvious; but they should be accustomed to act upon that confidence; it should be founded on the habitual truth and kindliness of their parents, and upon a perception, early acquired, that they submit to much that is painful, and to many privations to do their children good, upon a conviction which will do much more than reasoning, that their parents know best what is advantageous for them, and are very defirous to make them happy. Let the understandings of children be enlightened on these points, as they can bear it; but if selfishness and imperious wilfulness, and in the improvement of their minds, and not merely their bodies, and upon the perception of the value of weak indulgence, and of weak submission, where the submission should have been given by the other side, there will be confidence without any calculations of advantage; and we do not hesitate to say, that such an obedience of confidence and affection is, at present, worth much more as a moral quality, and will have greater influence through life, in the regulation of the heart.

Perhaps we differ from Mrs. Edgeworth, more in appearance than in reality; but we are inclined to consider this as one part of a fable in which prudential considerations seem to us to have too much sway, and regard to duty as such, too little. We speak from experience when we say, that when the understanding is sufficiently ripe to reason, it also is to feel the motives arising from a sense of duty; and we place our chief dependence upon our continuing to supply the principle of obedience, with all the strength which habitual submission, affectionate confidence, and a sense of duty would contribute to it. At the same time we are fully aware, that with a view to that confidence, the reasons of our injunctions should very often, indeed generally, be unfolded as much as is practicable. But where the disposition to submit has been habitually and thoroughly produced, where there is affection and moral principle to work upon, we have a much stronger hold upon the mind, than by making the why, and why not, the source of obedience to our injunctions or prohibitions. It is often difficult to calculate what exactly is understood of our reproofings; and frequently where the understanding is sufficiently advanced to understand them, the feelings, in some way or other, often either prevent the inferences from being seen, or at least weaken their efficacy on the cunctard. Where the habitual disposition to obedience has been long and early cultivated, there the reasons of a parent's conduct, within the reach of the child's understanding, will be much easily perceived, and every
Every influence in which they are unfolded will then contribute to increase the habit, as much, perhaps, as the habitual impulsion of parental wisdom and kindness, but not more than this.

We shall now proceed to state the principles which appear to us to be the most important in procuring obedience. We should begin early, indeed it can fearfully be too early, to accustom our children to habitual attention to those regulations respecting diet, rest, etc. which we deem best adapted to promote their health and comfort. The cries which indicate real want should always be attended to, or, if possible, anticipated; but the cry of humour, or the little tones of impatience, should never gain their end. In such cases, the proper way appears to be, to change the current of thought by diverting the attention from the object of painful feeling. Obedience should be as much as possible be associated with pleasing feelings. These may sometimes be left to be supplied by the natural consequences of obedience; but often, in the early stages of the habit, they may be fictitious; and in all stages, parental approbation, and its effects, should be associated with obedience, and the contrary with disobedience. Where the object of parental directions is not left to a child's choice, the expression of them should not be such as to excite the feeling of desire to choose; injunctions should always be decisive though mild. We have no wish that children should be mere machines, to move only as they are moved; they should often be left to the promptings of their own inclinations, where these do not interfere with the plans of the parent for their improvement and happiness; and it is only thus that their understandings can acquire strength, or their minds, in general, obtain activity or life. But whenever there is such interference, then prompt obedience should be secured; it should never be imagined that disobedience will be permitted or connived at. The directions of the parents should be explicit, decisive, and unalterable; if obedience is to be conditional, and made dependent upon circumstances, those circumstances should be clearly understood. It appears best, however, to express obedience but little; if the habit be early begun, it will not often be requisite to do so; it will be enough to let the simple word of a parent be known; but where it is come to the point of direct obedience or disobedience, it must be carried through. It must never be within the child's experience, that he has gained a victory over his parents. The parent should, however, be cautious of bringing matters too often to this crisis. And it should always be in things which are practicable, and where obedience can be compelled if necessary. This point is well illustrated by Mrs. Edgeworth. Neither will the judicious parent exercise the habit of obedience beyond its probable strength, in opposition to violent motives to the contrary; in such cases, if obedience from any cause is requisite, opportunity should be given to lessen the power of those motives. An instance has just occurred to our notice. A. (now four years old, the child of whom we before spoke) was sitting on the arm of her little chair. Her father thought it dangerous, and desired her to leave it, which she immediately did. To make her understand the danger, he told her to sit upon it again, and he would show her how easily she might have fallen. The child had had a fall a short time before, which he did not know; and the apprehension of falling again, though he told her she should not be hurt, overcame confidence and obedience, and the refractory, but without any ill humour. Her father desired her elder sister (five years and a half old), on whose confidence and obedience he could depend, to mount; and the experiment was tried without hurt or danger. The younger child at once followed her sister's example. Where the present temptations to disobedience are great, and the habit of obedience weak, there it is wisest to remove or prevent the temptation; and certainly the habit should not be too much exposed to trials; but if they are proportioned to its strength, and agreeable consequences in parental approbation and its effects be associated with the exercise of it, they tend much to give it life and energy. We think we have seen considerable advantage arising from some very early fmctitious trials of obedience, respecting abstinence for a short time from little gratifications of the palate. Where these do not produce an ill effect they certainly produce a good one.

Notwithstanding what we have already said, we cannot forbear quoting, from Practical Education, a very important principle, to which we perceive we have in no way referred. "Praise, and look of approbation, which naturally express our feeling when children do right, encourage the flightless efforts to obey; but we must carefully avoid shewing any triumph over yielding stubbornness. When children are made ashamed of submission, they will become intrepid, probably unconquerable rebels."

One other circumstance of great consequence we must not omit to mention, that parents should not interfere with each other's injunctions; the authority and influence of each should be readily employed to support the authority and influence of the other. Whatever discussions and disagreements as to plans and principles take place, it should not be in the hearing, at least in the understanding, of children. They should see both their parents as much as possible actuated by one mind. Where both go hand in hand in the work of early education, great hopes may be entertained, that their future influence will be what is so earnestly to be desired, for promoting the happiness and moral worth of their children; where there is a want of unanimity in views and feelings, considerable difficulties will arise, and great prudence must be employed. For such cases we find it difficult to offer any specific directions. If one of the parties poises judgment and good temper, (especially if that one be the mother,) the unhappy effects of difference may in a great measure be avoided; but of course the benefits of unanimity cannot be expected.

We have not said any thing in relation to the external appearances of respect which children should preserve towards their parents. Though we value filial, not flavih) obedience above every thing in the conduct of the child towards his parent, yet we are decidedly of opinion, that those modes of expression should be taught and required, which are consistent with the leading characteristics of the filial relation. Affection should never degenerate into that rude familiarity, which by degrees will destroy the internal feeling of respect. Habits of civility should early be required, not only on their own account, but also from their intimate connection with the exercise of some of the most valuable qualities of childhood and youth. We do not mean that filial respect is to be secured by enforcing the external indications of it; but it is agreeable to the laws of the mind and to common experience, that these external indications will assist in generating or strengthening the feeling, when its foundation is laid on the parent's poising the qualities requisite for its permanency.—To what extent this principle should be carried, we do not feel able to decide; it must essentially differ in different cases. Our forefathers probably carried it far beyond the limits of reason; we appear to have gone to the opposite extreme; but as the feelings of respect are alluredly necessary, in order to give confidence and durability to the higher ingredients of the filial affection, we should be careful left, through the wish to secure the love of our children, we lose the advantage of their respect.
MORAL EDUCATION.

They should be taught to honour their parents, as well as obey them. We have no wish to curb the playful fancies of childhood; we have no wish to see parents exclude themselves from sharing in and brightening their enjoyments; from occasionally being their playfellows as well as their instructors; but in the midst of all, they should remember their relation; they should check the marks of disrespectful rudeness; and aim themselves to keep the adjustment of the balance between affection and respect, which cannot otherwise be expected from their children. We are, perhaps, in the present day, rather too much afraid of forms. They often, indeed, serve instead of the fulsibance; but in many cases, they tend to give support to the fulsibance, and even, by the re-action of affection, to produce it. We conceive that it is very desirable to begin, in children, those little attentions to their parents' comforts and conveniences, which, as they advance towards youth and manhood, contribute so much to strengthen the affections. These should, however, be encouraged, rather than exacted; and the parent should carefully avoid expecting them too much, and making them the criterion of affection, &c. especiously, as we have already stated, with respect to boys. But if they are begun sufficiently early, they will not be burdensome; while they cherish grateful feelings towards the parent, they will also infall in cultivating that habitual attention to the little wants and conveniences of others, which forms the most valuable ingredient in politeness, and which contributes so much to the pleasures of domestic life.

Gratitude is a more delicate plant than civility and respect; and must be left very much to itself. By occasionally leading the minds of children to observe, for themselves, the degree of exertion and self-denial which their parents undergo, in order to promote their happiness and improvement,—by thawing them how many advantages they possess, owing to the kindness of their parents, which other children do not or cannot have,—by our own simple expressions of gratitude for favours shown us, and by bringing them to the employment of similar expressions for the kindness of their friends towards themselves,—in short, by indirect rather than direct culture, that most valuable quality, a genuine filial duty, may be produced. If, by experience and observation, children are led, in advance of their perception, to be sensible of the favours which they receive, but we expect little from those expressions of thankfulness, which, from being regularly exacted, without regard to the state of the feelings, must become a mere form. Where the soil is properly prepared by the culture of obedience and filial regard, gratitude will grow without much trouble; it more requires the aid of the understanding, than those: it, and it requires, too, a higher state of excitement of feeling. The little mind must be alive and engaged on the subject, in order to feel gratitude; and the direct expressions of this, or any other feeling, should not be encouraged where the feeling itself does not at the time exist.

In the periods of infancy, habitual, but not painful, submissiveness, is what we are to aim at. In childhood obedience must continue to be habitual, but its foundation should be enlarged by confidence, love, and fear; and as the understanding expands, to these should be added, the influence arising from the actual perception of the beneficial efforts of obedience, which it is well for children to be led to trace out for themselves, rather than to have them brought too forcibly and distinctly into view. In the more advanced period of childhood, implicit submission should be left and left expected. We do not mean that obedience should not be required, wherever obedience is enjoined; but that the conduct of the child should be more left to be guided by his own choice. Where the habit of obedience has been early begun, and long continued,—where it has been cultivated as a quality of the utmost importance in the moral structure, and not from the parents' love of power,—and where it has been exercised with mild firmness, the expression of parental will will usually be found sufficient to lead the child to that plan of acting which the parent judges best; but as our object in education should be to fit our children to act well their parts in life, we must gradually loosen their dependence upon our guidance, without weakening their disposition to follow it, whenever we think expedient to give it. Our children should more and more become our friends; and the tone and manner of authority should give way to the mild influence of fatherly affection and duty. They should be led to perceive how much our happiness depends upon their right conduct; how much it is their duty, from every motive, to endeavour to promote our happiness; but we should take care to avoid communicating to them the impression, that we think more of our own than of theirs. We are not aware of any way in which this can be effectually avoided, but by really studying their welfare as the first object, and regulating our plans by an enlightened view of it. Where they can be led to perceive the end of our solicitude, and how much it does contribute to their happiness, our influence must necessarily be increased; and though we should never loosen the feelings of obedience, though the understanding has acquired full vigour, and some experience has been made of the firmness of principle and the soundness of judgment, we should in reality exercise the habit, and not by any means throw off its restraints, yet it should be our steady aim to keep them from being felt, and to secure obedience left through the medium of parental authority than of parental influence.

We are not without a deep sense of the difficulty of all this. We are aware that it requires great self-control on the part of the parent, and in many influences a new kind of education; and the difficulties of executing these defirable objects are increased almost indefinitely, by not beginning early enough. Even if we have been happy or wise enough to do this, yet unless parental authority has been steadily guided by the actual perception of the object of it, it will be a difficult task to fade imperceptibly from the direct exercise of it into the milder but not less efficacious form of paternal influence. And for that influence we must look most to the maternal parent. If her endeavours have been successively directed, in the earliest periods of education, to obtain a confident, steady authority over the minds of her children,—if, as they advance in life, it has been supported by the more obvious and direct authority of the father, by respect for her understanding, by grateful affection for that winning tenderness which, in its, appears much in a father, even where it is powerfully felt,—if it have not been weakened by fable indulgence on the one hand, or on the other by the disposition to rebel, not infrequently produced by its excessive exercise,—a mother's influence will be felt through life, and will prove a most powerful aid in promoting the moral culture and happiness of the child. Direct parental authority is, we think, more likely, from various causes, to be properly modified in the female sex; but we are also satisfied that where a father, by full regulation of his own views and feelings, leads his children to love as well as respect him, and as they advance towards ripen years to regard him as their friend and wise adviser,—where he leaves them to themselves as is requisite to give them experience in life, and introduces the direct authority of the paternal relation, only where it is really necessary for their welfare,—he, too, will have a moral influence on their minds, which will make his intrusions
fritations of powerful efficacy through life, and probably prevent his children from taking any important step without, at least, honestly receiving the advantage of his advice. Still, from the necessary avocations of the male sex, and the usual engrossment of their time and thoughts in employments which, at least, are not domestic, the education of infancy and childhood, and much of the most important moral culture of the more advanced periods, will be derived, if obtained at all, from the female sex; and on this account, as well as with a view to their own happiness, we earnestly with to feel: the cultivation of their judgment made much more an object than at present it appears to be, and to perceive that their education has in view to qualify them for the most important and interesting domestic relations, rather than to shine in the sphere of fashion and accomplishments.

Our observations directly respecting the fetal affections, have extended beyond what we at first contemplated; and we shall have occasion to revert to them. But they lie at the foundation of moral education; and the analysis and means of cultivating one class of the affections, throw great light on the origin and culture of others. We shall now proceed to some more general considerations respecting the

11. Practical Laws of the Affections in general, so far as they particularly respect the procresses of education. All the affections are formed in the same way as our other compound ideas, (to use this term in its most extensive sense,) viz. by the agency of the affective power, in combining together, in various ways, the relics of sensations, or the previously formed combinations of them. (See Intellectual Education, col. 23.) It is thus that the whole system of mental pleasures and pains is constructed; even of those which ultimately become the most refined, and the most remote from every appearance of mere sensation. The sensible pleasures and pains leave behind them, corresponding to the ideas of light or sound, derived from their respective sensations. These feelings become associated with other feelings derived from the same or similar external objects; and when the union has been exercised sufficiently long, they have become blended together, so as to form a complex though apparently simple feeling, which itself may become united with other complex feelings, and so on. The greater the number and diversity of the component feelings, the more remote will the complex feeling be, from resemblance to the original sensible pleasure or pain. These complex feelings are continually receiving fresh materials, from the union and combination of the simple feelings derived immediately from sensation, of the various complex feelings associated with those sensations, and of those which in different ways are called up by the links of association more immediately connected with the powers of memory, imagination, and reflection. Altogether, in many instances, the vividness of the mental pleasures and pains may be as great as those of sensation; and indeed we know, as a matter of fact, that the influence of the former on the mind, is often much greater than that of very vivid pleasures and pains of the latter class.

As much as this, one would conceive, must be admitted by all who have attentively considered the laws of association, and the actual procresses of their own minds in the formation, or variation, of the feelings associated with any object, and the gradual formation and refinement of the feelings of children. Whatever may be thought respecting the duration of all the mental powers into sensation, retention, and association, (see Intellectual Education, col. 23) there seems to be scarcely room to doubt, that all the internal objects of those powers, all the notions and feelings of the mind, do arise from the relics of sensation, variously combined and modified by the agency of the affective power. The sensible pleasures and pains of childhood, therefore, though in their immediate effects evanescent, are of great consequence as the rudiments of mental feelings; and with a view even to the moral culture of the mind, it is of great importance, during the early part of life, to keep the inlets of sensation in a fit state for receiving its pleasures and pains, and not to check the one, or impose the other, except where an enlightened regard to the future welfare requires it. The health of the body should be attended to, not merely as a means of present and future enjoyment, but as increasing the fund of materials for the purest mental pleasures. Childhood should be regarded as the time for the acquisition of materials, not only for the intellects but for the affections. Its pleasures should be restrained only by those limits which the laws of sensation and association impose; which require that they should be moderate, and connected only with such objects as will not lead to future pains. Its unavoidable pains should, as far as possible, be removed; and no avoidable ones should be imposed, except what the laws of association require; that is, those which are necessary for removing or preventing of greater evil, either by remedying bodily disorders, and destroying false associations, or by combining sensible pains with such objects as would lead to future pains, more important either as to vividness or duration.

Considering the natural, simple pleasures of childhood, therefore, as the rudiments of those which are to accompany the individual through the whole of his existence, as what will form a part of the most refined and important feelings, we ought not to view them with indifference or disdain. Our object should be to promote them; and as long as they remain within the limits of nature, we need not be afraid lest they should produce any injurious effects on the mind. It should be our aim, as the mind becomes capable of relishing more refined pleasures, to call it off gradually from making the pleasures of mere sensation a primary consideration; but we need not be too suspicious of these, especially during the earliest periods of education. The pleasures of taste, for instance, contribute an essential share towards the formation of some of the most valuable and refined feelings; and while we take care to prevent their being made the food of self-indulgence, and to keep the mind from resting upon them as of themselves essential to the happiness of life, we may make them of great service in the cultivation of the bell affections. The sensual affections certainly have their origin in these pleasures, and they furnish some of the most powerful ingredients in the early formation of the other social affections. Hartley is of opinion, that a great part of what he terms the intellectual pleasures, (or, as we should prefer calling them, mental pleasures,) are ultimately deducible from those of taste; and that the principal cause of the greatness and constant recurrence of these pleasures, from our infancy to the extremity of old age, is to introduce and keep up pleasurable flaters, of feeling, and to connect them with foreign objects. The social pleasures, he continues, "come in a particular manner to be derived from this source; since it has been customary in all ages and nations, and is in a manner necessary, that we should enjoy the pleasures of taste in conjunction with our relatives, friends, and neighbours. In like manner," he adds, "nauseous tautes, and painful impressions upon the alimentary duct, give rise and strength to mental pains. The most common of these painful impressions is that from excess, and consequent indigestion. This excites and supports those uneasy flaters, which attend upon melancholy, fear, and sorrow." Hence, while we keep our children carefully aloof from the habit of gluttony, both on account of the future tendency
tendency to it, and the present pains and injurious effects of it, it appears abundantly clear, that we ought not, from a refinement unfounded in the laws of the human mind, to refuse to make the pleasures of taste, during the early stages of the moral progress, subservient to the culture of valuable affections. There is no reason why, in those stages, its simple enjoyments should not be associated, (in the way of consequences or rewards,) with right conduct. They will contribute something towards the general rock of pleasure resulting from the discharge of duty, long after the mind would feel uneasy at receiving them as the effects of it, and absolutely spurn them if considered as rewards for it. It is by no means necessary, even in those early stages, that those pleasures should be made of themselves important, or be regarded in that light; by the children they may be associated with the symbols of parental approbation or parental affections, and deriving interest (we may say their chief interest) from that circumstance, they also contribute to make such approbation and affection more pleasurable, and therefore more the object of desire.

We have before our eyes, infancies in which this proceeds frequently goes forward, without presenting the slightest reason to apprehend, that the pleasures of taste will acquire a fictitious importance, or that the habit will be formed of undue relish for them. They evidently contribute a large share towards the promotion of filial and fraternal affection; and these, in their turn, in various ways restrain the excitement of these pleasures beyond their due limit, and make them interesting, rather by the associated circumstances, than by the sensations themselves. The effect of that restraint, without making any direct object of it, we have had a satisfactory opportunity of witnessing. The child of whom we have already spoken as unhappily managed by her nurse, now a little more than four years of age, a year or two ago was accustomed eagerly to devour these niceties which were given her, apparently to have the part which she knew her elder sister would give her from her own share. At present, she has not only ceased to expect this unreasonable attention to her venial, but undesirable gluttony, but is almost always ready and willing to give up part of her own share to her sisters or parents; and seems to take little pleasure in eating, unless one or other of those around her is sharing with her.

Children are much more likely to acquire habits of gluttony, or excessive but factitious indulgence of the pleasures of the palate, from what they see around them among grown-up persons, than from the simple gratifications of it which suit their age, and unapplied to the taste. And we are not afraid of employing them among the incentives to the commencement of habits, and among the rudiments of affections, which are of the highest importance to the moral worth and happiness of the individual. It may to some appear a paradox, but we have no doubt, that even the affections which respect the Supreme Being, derive some of their ingredients from this source, through the medium of the filial affections; and we are perfectly satisfied, that if this and other sources of sensible pleasures and pains could be dried up in infancy, without destroying the sensations which merely contribute to form perceptions, the man might, to a certain extent, be an intellectual being, but would be without internal feelings or affections of any kind: he might be supported in his by the care of others; but he would be without any motive to action, except what operates through pure intellect: he would be without desires or aversions, hopes or fears.

Though for our purpose very great precision of nomenclature does not seem necessary, and we have gone on a good way without explaining our terms, yet it may not be useless to employ a paragraph in endeavouring to give some idea of the classification of our mental feelings to that respected class of our female readers, (for such we hope to have,) who have not yet entered much into the study of mental philosophy. We have no wish to see the female sex spend their time on metaphysical speculations; but the aid which an acquaintance with the practical laws of our frame, (with the grand principles of association,) affords in the work of education, particularly of early education, is almost incalculable. Supposing that by association a very complex pleasurable feeling, formed also by association, has been so connected with any object, as to be excited by the sensation or idea of that object, by degrees the object is considered as the source of that feeling; and the pleasurable feeling, blended with the idea of the object's being the indirect or immediate cause of it, is called love: the opposite feeling, produced by corresponding but opposite associations, is called hatred. We do not here speak of the particular modifications or restrictions of these feelings, which are endless, but of the general feelings excited in our minds by objects causing, or being supposed to cause, pleasurable or painful feelings. When either of them (the love, for instance) is habitually connected with any object, it is called an affection for that object; and all its various modifications, however and in whatever degree produced, (if they are more than the ebullitions of the moment, being permanent feelings, ready to be excited by the appropriate object in appropriate circumstances,) are also termed affections. If from any strength in the exciting cause, or peculiar sensibility of the frame, or peculiarly active associations connected with objects of a specific call, that cause produces a vivid excitement of feeling, which (though it may last, perhaps, for some time, if not excessive in degree) gradually loses its vividness, and altogether ceases, or settles down into a more permanent, but less lively feeling,—that vivid, vigorous feeling is denominated a passionate. The mind may have such a predilection to a certain set of passions, that these may be easily excited, and by every such excitement increase the disposition to future excitement, and at the same time add to the strength and vividness of the more permanent corresponding affections: but the passion cannot, from the nature of the mind, last very long in a state of great excitement, unless there be a continued repetition of the exciting cause; and if such is frequently the cafe, the mind must by degrees become diseased, and be constantly on the verge of injury, in some or other of its forms. From this account it appears, that the passions and affections principally differ from each other in their degree and duration. There is a third class of feelings, which may more properly be called emotions, than either passions or affections. These are flates of pleasure or of pain, following the excitement of some affection, and generally accompanied or blended with trains of conceptions and thoughts, but which have not that vividness and strength which is essential to a passion, and are left generally than other passions or affections, for a longer period. Love and hatred (which terms we here employ in their most extensive senses, as not necessarily including either good-will or ill-will, in any of its different degrees) may exist in the state of passions, as well as of affections; and their milder states of excitement are properly termed emotions. In certain circumstances, they excite to obtain the object of love, or to avoid the object of hatred, and they are then called desire and averien; with which qualifications, also, they may exist in the state of affections, emotions, or passions: but, in general, the two last terms are most appropriate. Hope and fear arise from the probability or uncertainty of obtaining the good desired, or avoiding
avoiding the evil shunned. These can scarcely ever be termed affections; they are rather the passions or emotions springing from the affections of love and hatred. In like manner, joy and grief (which are strongly excited states of feeling, arising from the possession or loss of some good, or the avoidance or endurance of some evil) are seldom sufficiently steady and permanent to receive the appellation of affections, but are properly termed passions, and their milder states of excitement may be well denominated emotions. A tendency to the exercise of a class of affections, or to the excitement of a class of emotions and passions, is called a disposition. The temper seems to comprehend the dispositions in general, whether they relate to facial or personal affections; provided they are habitual, and affect the external conduct, (words and actions,) in our intercourse with those around us. All the affections, emotions, and passions, in every state of excitement, and under every modification, are comprehended under the general term feeling; but since the affections (whether existing in the tranquil state of simple complacency or displacency, or operating to produce desire or aversion, &c,) are the sources from which all the emotions and passions spring, we speak of the culture of the affections as in reality comprehending the regulation of the whole system of feeling.

We will now state, in a connected form, the leading principles respecting the affections, &c. which appear to be of the chief importance in regulating the plans of moral education; and then proceed to offer some remarks and illustrations founded upon them, which may aid the judicious parent in employing them.

1. The affections, according to the statements we have already made, are derived immediately from sensible pleasures or pains received in connection with any object, or from compound feelings already formed by association, or from both together. They depend, therefore, for their formation, upon the general activity of the associative power, upon the proper supply of materials from sensible or mental pleasures and pains in connection with the object, upon the physical sensibility of the frame, and upon the facility and vividness of the powers of recollection and conception. The same series of external impressions, (if such a cafe were possible,) continued through the whole processes of education, would not, in individuals of different physical temperaments, or different degrees of vigour in the mental powers, produce the same system of affections; nevertheless, in their leading features, the same external impressions will commonly generate similar affections.

2. The affections which have been formed towards any object are capable, in favourable circumstances, of being transferred to another poffeffion (or suppos'd to poffef;) the characteristic qualities, owing to which they were originally formed; and in proportion to the degree in which these are (suppos'd to be) poffeffed, and to the variations which exist in their combinations and connected qualities and relations, will be the modifications which this transference will produce on the original affection. And it is an extremely important circumstance respecting the transference of affections, (by which, however, we would not understand, to mean, not the removal of them from the original object, but the association of them with one which did not before poffefs them,) that it may take place through the medium of the intellect alone, as well as by external impressions; by the exercise of the memory, the understanding, or the imagination, as well as by actual fenfation. If correspondence or similarity of relation or qualities is perceived in two objects of the mind, the feelings associated with the one will, in proportion to the degree of that correspondence or similarity, become associated with the other.

3. The vigour (including vividness and steadiness united) of any affection will depend upon the vividness and number of the component parts, upon the susceptibilities of the physical and mental constitution, upon the aid it receives from the influence of sympathy and intentional culture, upon its similarity to the prevailing dispositions of the mind, and upon the frequency and continuance of its exercise, as a whole, in some or other of its component affections. But,

4. Though the vigour of an affection depends, in a great measure, on the frequency of the exercise of the feelings composing it, yet mere feelings, unaccompanied with the active employment of them as motives, rapidly lose their vividness and strength, unless supplied with repeated accessions of the component sensations and simpler feelings.

The best way to cultivate any worthy affection is to bring it into exercise as a motive to action, while, at the same time, we supply it with fresh materials derived from affection, sympathy, foreign excitement (if necessary), and, above all, its own appropriate pleasures, arising directly from its exercise, and from the perception of its influence on personal or social happiness.

5. Affections (whether of love or hatred, of desire or aversion) may be eradicated, if they have not been too long exercised, and too much associated with the general dispositions of the mind. They may indeed acquire such power, that they can be rooted out by no human discipline or efforts; but such can seldom be the case, during the usual periods of education, and especially the early periods. To destroy any wrong disposition will be difficult, in proportion to the degree in which it has gained habitual power, and in which it is supported and cherished by other related dispositions; but it may commonly be effected by perseverance in the judicious and steady culture of opposing dispositions, in the careful avoidance of the causes of its excitement, and in the regular restraint of its exercise by negative discouragements, or by positive inconvenience and bodily pain, according to the nature of the disposition, and to the general qualities of the temper.

The refinement of mental pleasures or pains consists in their remoteness from senfation; the diftance of affections, in their having no farther end than their own immediate object.

6. The refinement of our feelings is a very gradual process. It depends upon the variety of the sources of senfation, upon the strength of the retentive power, upon the activity of the associative power, and upon the supply of suitable materials for the formation and growth of the different classes of mental pleasures and pains. When complex feelings of different classes are formed, they contribute, in a variety of ways, through the operation of the associative power, to modify one another, and to produce still more complex feelings; and the greater the variety in the sources and character of the component parts, the greater will be the remoteness of the compound from all resemblance to senfation. Even sensible pleasures and pains, derived through different inlets of senfation from the same or similar objects, will, by the operation of association on the simple feelings which they leave behind them, form complex feelings scarcely indicating senfation as their immediate source: and the same might be observed respecting those complex notions, which, under the name of abstract or general ideas, so much puzzle philosophers, who have not been accustomed to the Hartian processes of investigation. "Some degree of spirituality," says Hartley, (meaning that state of mind in which..."
MORAL EDUCATION.

in which its pleasures and pains are not sensible,) is the ne-
cessary conquence of passing through life. The sensible
pleasures and pains must be transferred more and more every
day, upon things that afford neither sensible pleasure nor
sensible pain in themselves, and so beget the intellectual
pleasures and pains." Nevertheless it cannot be doubted,
that those means of intellectual and moral culture, which are
supplied by the pursuits of literary, scientific, and religious
knowledge, do greatly accelerate the progress of the mind
towards spirituality; and this is still more effected, by the
gradual cultivation of the motives of benevolence and piety,
and a sense of duty. Whatever pursuit or pleasure calls off
the attention of the mind from mere sensation, or the plea-
sures most nearly allied to it, contributes to its progressive
refinement. Still that refinement must be gradual. If we
attempt too soon to lead the mind away from sensation, we
shall only impede the progress; we shall flap the sources of
mental pleasures and pains, and thereby weaken them and
their influence as actuating motives; and thus we shall either
leffen the vigour of the intellectual structure, so far as to
prevent all energy of character, or, what is perhaps more
probable, and more to be dreaded, we shall make the
mind the slave of sensible pleasures and pains, when it ought
to be advanced beyond their primary influence. Childhood
is the period for sensation; we do not mean exclusively, but
principally: and he who, during it, attempts to check its
pleasures, farther than is necessary to prevent present or fu-
ture pains, will, as far as his culture is effectual, either turn
youth and manhood into childhood, or altogether nip the
blossom of vigorous, steady affection. If, however, this
perverion of nature is accompanied by the cultivation of a
strong and actuating sense of duty, ill effects may be greatly
refrained; but we doubt not, they must always be felt,
either in the diminution of moral vigour altogether, or in the
want of a proper balance and due proportion among the
affections.

7. The last of the general principles which we proposed
to state, respects the disinterestednels of the affections: and
here we must enlarge at some length. Two opposite opinions
have long been entertained, and are still often advanced on
this subject. Some have maintained, that the human mind,
in all its feelings and promptings to action, is influenced by
selfish motives; that, in fact, there is no action or feeling
which can be called disinterested. Others have, with more
success, maintained, that the mind can be, and often is, dis-
interested; that a person frequently performs an action,
tending to the good of others in a greater or less degree,
without the remotest reference to himself; with no other
motive than a desire to produce the benevolent effect pro-
posed. The degrading system of the former is seldom
adopted except by speculative men, who have been led by
circumstances, happily not universal, to see merely the dark
side of human nature, and to form a more gloomy picture of
its selfishness than truth would allow: or by others, who
have expected too much, owing to the beautiful speculations
of theory; and having been disappointed, by comparing
them with their own feelings in many instances, or with the
too general conduct of mankind, have thence gone into the
unsounded opinion, that all the actions of all men are selfish.
But many of those, who are undoubtedly right in the pleas-
ing belief that the affections and motives of men are often
characterized by disinterestedness, have greatly erred re-
specting the nature of it. From attending to its state in
their own minds, or the minds of others, where it is habitual
and extensive, and forgetting the states which have led them
to this noble ennuence, they have considered disinterestedness
as an innate principle of the mind, and represented it as the
first step towards worth of character, whereas it is in reality
the last. They have, therefore, clipped the commencement
of virtue in colours which belong only to its completion;
and hence two practical ill conquences have followed:
some persons have neglected the culture of disinterestedness,
both in their own minds and in those of others, from sup-
pposing it to be a necessary quality of all virtuous affections;
and others have been driven to defend, on comparing the
representations of theory with the sature fate of their own
minds, supposing that they could never attain to what they
see spoken of as alone deserving the appellation of real worth
of character. The more correct views undoubtedly are,
that disinterestedness is the last stage of an affection; that it
may be hallowed or retarded by attention or neglect, as to
the culture of that affection; and that disinterestedness, as
the general character of the mind, is the highest point of
excellence, and what should be our object; but it can only
be acquired by a long course of moral (including reli-
jous) culture.

Of the progress of an affection, from the state in which
the object of it is desired as a means to some suppos'd good,
and to that in which it becomes the sole end, the most sim ple
instinct, and what is frequently adduced for the purpose, is
the love of money; and this serves exceedingly well in con-
nection with the general principles of mental philosophy,
and might not be useless in reference to our immediate object:
but this will probably be better answered, by taking, for
the purpose of illustration, an outline view of the formation
of disinterested benevolence.

Every human being receives his first pleasureable impres-
sions in society. His appetites are gratified by the affinities
of those around him; and probably there is no agreeable feel-
ing which is not in some way or other associated with those
who attend him in the period of infancy and early child-
hood. Hence arises sociability, or the pleasure derived from
the mere company of others; and as the child increases in
years, the associated pleasure increases almost continually.
In the innocent and generally happy period of childhood,
he receives all his enjoyments in the company of others;
most of his sports and amusements require a playfellow; and
if, by any untoward circumstances, he is prevented from join-
ing his companions, he feels an uneasiness which it is scarcely
in his own power to remove, but which vanishes soon as he can
rejoin them. But his happiness derived from others greatly
depends upon their happiness. He is happiest when those
around him are happy; partly from the contagion of feel-
ing, and partly because his means of happiness considerably
depend upon the convenience of others. If his companions
are ill, his sources of pleasure are diminished; if his parents
are unable to take their customary care of him, he loses
it in various ways; he loses the cares of affection, or the
little knellbells of parental tenderness. Hence the comfort
and happiness of others necessarily become the object of
desire; and even in young children it not unfrequently hap-
pens, that this desire becomes sufficiently disinterested to
lead them to forego small pleasures, or undergo little inconve-
niences and privations, with no other view than to increas e
the comfort of their parents, or to prevent what would di-
minish it. Benevolence is that affection which leads us to
promote the welfare of others to the hell of our power;
and general benevolence is founded on particular benevolence,
for instance, upon benevolence towards parents or other con-
nections. We have seen its rudiments, and it may be well
to pursue it a little farther. The endeavour to promote the
comfort or welfare of others is, in the early part of life,
MORAL EDUCATION.

almost invariably followed by an increase of pleasurable feelings. Parents approve these endeavours, and they tell their children that their heavenly Father approves of those who try to do others good. Children and young persons are continually feeling and observing the good effects of benevolence, as manifested in their own conduct, or in that of those around them; and hence, in well-disposed children, the pleasurable feelings associated with benevolent actions are very strong; they are very glad to see others made happy, and very glad to be able to make others happy; and the pleasure derived from the approbation of others, and the sympathy of their own minds, the increase of good-will in the person benefited, and the expression of it, the accordance with all the religious feelings which are pos-

sessed, and various other circumstances left general, add, together, such a flock of pleasurable feelings to the doing of good to others, that, by degrees, in some or other of its branches, it becomes an object of desire altogether independently of any consideration beyond itself. A person who has completely gone through this process, desires to benefit others without any reference to his own personal benefit in this world, or even in the next: he employs the different opportunities which present themselves to him of doing good to others, without thinking of any thing more than the immediate object. If it call for great exertion on his part, great efforts of self-denial, he brings to his aid the desire of following the dictates of duty, of obeying the commands of God; and where his benevolence, his love of duty, and his love of God, are in a great degree purified from self (and in proportion to such purification), he will forego great pleasures, and endure great pains, without a thought beyond the production of the good which he has in view, and the obedience to the claims of God and duty. Great heights of excellence are seldom attained without a large portion of the discipline of trial and affliction; and imply the suitable improvement of it; but a less and not dependable height is often obtained. Benevolence may, with propriety, be termed disinterested, when it is a considerable number of its promptings, it has no end besides the good which it proposes; and in this degree it exists (we doubt not) in great numbers; and by those who have advanced thus far, that improvement may without much difficulty be made, by cultivating a general love of duty, and a regard to the will of God, which would refute, beyond the possibility of all rational controversy, the opinion that the human mind is radically evil and universally selfish.

There are few points in moral investigations more inter-

esting, or of greater practical value, than the tendency to love and to desire to promote objects which have no im-

mediate connection with our own good, without any reference to our own good. That the human mind is capable of grofs selfishness, which defines all present discipline to correct, is a fact which cannot be denied, and which should excite our vigilance and concern in the work of self-culture as well as in the business of education. But it is no less a fact, that it is also capable of disinterestedness which shall run through the whole of the conduct, and prompt uniformly and flex-

dibly to the promotion of others' welfare. The earliest plea-

sures are personal; we wish not to call them selfish, because that term seems to be generally appropriated to those feelings which not only have a direct explicit reference to our own real or imaginary good, but also prompt to the pursuit of this, to the neglect or injury of others. In this sense the mind cannot, with any propriety, be said to be originally selfish; but its earliest pleasures are personal; and its earliest desires are consequently personal. Its interest in the plea-

sures of others, arises originally from their connection with

the personal pleasures; and, consequently, the love of others, and the desire of benefiting them, are originally interested; that is, they arise from the dependence of its own personal pleasures on their pleasures. There is nothing criminal in this; it is according to the laws of our mental frame: the mind is criminal only where it rebels here, for it cannot with-

out being wrongfully impeded. If the progress goes on as it ought, the desire will be gradually transferred completely from the original end, personal pleasures, to the good of others, the original means; and then this becomes the end, and the desire is disinterested. We may, therefore, with the confidence of truth, indulge a delightful view of the tendencies and capacity of our nature; and hold up as the object of our steady endeavors aimed at moral improvement, and as the point for which we should prepare, his efforts, and towards which we should direct them, that state of mind, in which to perceive a practicable means of promoting the good of others, and to employ it, will be invariably con-

nected, without any intervening bond of union, without any other motive co-operating but what is as pure as its own benevolence. And the same remarks might be made respecting the love of duty in general.

We may now proceed, as we proposed, to offer some remarks and illustrations founded upon the foregoing principles, which may affect the practical employment of them in the work of education.

1. We are not to expect that any affections will rise up in the mind, unless those external impressions are made, from which the component feelings are formed. A child cannot form an affection for a parent with whom he has no inter-

course of any kind, unless the idea of the absent parent be associated with interesting feelings through the direct efforts of sensations and capacity of our nature; and hold up as the object of our steady endeavors aimed at moral improvement, and as the point for which we should prepare, his efforts, and towards which we should direct them, that state of mind, in which to perceive a practicable means of promoting the good of others, and to employ it, will be invariably con-

nected, without any intervening bond of union, without any other motive co-operating but what is as pure as its own benevolence. And the same remarks might be made respecting the love of duty in general.

We may now proceed, as we proposed, to offer some remarks and illustrations founded upon the foregoing principles, which may affect the practical employment of them in the work of education.

1. We are not to expect that any affections will rise up in the mind, unless those external impressions are made, from which the component feelings are formed. A child cannot form an affection for a parent with whom he has no inter-

course of any kind, unless the idea of the absent parent be associated with interesting feelings through the direct efforts of sensations and capacity of our nature; and hold up as the object of our steady endeavors aimed at moral improvement, and as the point for which we should prepare, his efforts, and towards which we should direct them, that state of mind, in which to perceive a practicable means of promoting the good of others, and to employ it, will be invariably con-

nected, without any intervening bond of union, without any other motive co-operating but what is as pure as its own benevolence. And the same remarks might be made respecting the love of duty in general.
of words, of sympathy, &c. And this process takes place more readily in childhood and youth, because the perception of differences is by no means so early acquired, at least to generally exercised, as the perception of similarity; and because, farther, while the imagination is not sufficiently limited by experience, and by the general culture of the judgment, the impressions exciting pleasurable associations, are readily considered as an index to an extensive combination of good qualities, and the affections are at once communicated, when after impressions will tend to check, to limit, and perhaps altogether to remove them.

2. Closely connected with the foregoing remarks, we may observe, that the general affection of love to any object, and the consequent tendencies of the mind, will not be produced in opposition to an excessive degree of painful feelings, through whatever medium derived, if from any links of connection they become associated with the object, especially if it is regarded as the source of them. We have already had occasion to state, that where painful impressions do not exceed some limit, and do not, from connected ideas, excite these feelings which are allied to hatred (resentment, ill-will, a sense of injustice, &c.), to far from softening love they tend to give it greater vigour and purity; but where their effects are of that decription, or they are in themselves too frequent, or too powerful, in proportion to the pleasurable associations, they must in that proportion check, and perhaps eventually destroy, the affection. If a parent finds privation or punishment necessary for the grand ends of education, and takes care, as far as possible, to let it be perceived that they are employed for these ends only, the dispositions of children must have been ill-regulated, if the employment of them in any degree lessens love. We have seen several instances where affection has assumed its most tender and engaging form, after the parental infliction of punishment; and what is, perhaps, still more deserving notice, even after the punishment inflicted by a tutor, who, we have observed, has, at the hour of reflection, received the most cordial shake of the hand from the boy who, during the day, had been the subject of corporal punishment. Of the modes and regulation of punishments we shall soon have occasion to offer a few remarks; the fact is sufficient to illustrate our present object. But suppose that from any cause the parental relation not only is not associated with pleasurable feelings (in which case, agreeably to the observations in the last paragraph, it will be an object of indifference), but is even associated with the painful one, arising, justly or otherwise, from an excess (in degree or frequency) of painful impressions, from a sense of injustice, from frequent gallling restraints upon the will, &c. it is clear that a parent may become the object of ill-will, and even of hatred. It is a dreadful fate if things have proceeded so far; but they do sometimes go on from the ille to another, far beyond the first idea; and seldom then meet with any limit, excepting those derived from a sense of duty. This is sometimes found to excite in the child (especially where aided by the affection of the other parent) a disposition to patient submission, and perhaps to composition and forbear, rather than to irritation and displeasure. But when a parent forgets his own duties, or from indifference in disposition has not the power to perform them, he ought not to wonder if the tendencies to filial duty (especially those founded on the basis of respect and affection) are not tainted in the mind of his child. From various affections a parent will, almost necessarily, feel some love for his offspring, without any interchange with them; and even in juxtaposition to many painful impressions in connection with them: but in the child there are no such predisposing associations; and whatever affection is formed in early life, is to be formed by actual impressions in connection with the parent, by the means we have already stated.

These views, while they should lead the parent who is justly solicitous to obtain a high degree of the affections of his children, and at any rate to prevent their indifference or ill-will, to avoid all caprice, undue authority, and excessive rigour and severity in his treatment of them, while they should lead him to regulate passions and the infliction of pain, by the ends for which alone they ought to be employed, and to make himself the companion and friend of his children, the associate of their little pleasures, and of felt importance to their comforts and enjoyments,—should also induce him readily to avoid indulging that excessive fondness for self-gratification and self-willfulness, which, if allowed to become habitual to any considerable degree, will assuredly injure the character for life; which must be restrained, if restrained at all, by subsequent pains and privations far exceeding what would in the first instance have kept wantonness and self-love within their proper limits; and which will, therefore, in all probability, lead to impressions of the most painful nature in connection with the parent, if he endeavour to retrieve the consequences of past indulgence by the only means which will be left him (the pain of which will be heightened by comparison with the pain); and which will often produce a similar effect, even if he do not make the attempt, because the more the will is indulged without restraint, the more indulgence it requires, and it is impossible for the parent (however willing he may be to give up every thing for the comfort of a darling child, whom, perhaps, excessive fondness alone has injured) to carry indulgence to the degree which will be requisite for the gratification of ill-regulated desires.

These views also furnish some obvious hints respecting the culture of the fraternal affections. Children necessarily have many pleasures in common, which can be enjoyed without any mutual interference; and these directly tend to make the compositions of childhood the objects of complacency and love. But where several children are together, especially where their ages are nearly the same, there are numerous occasions in which they must give up little gratifications in compliance with each other's wishes, numerous cases in which their little pleasures must interfere with each other. If these occurred without a repetition of the associated pleasures, especially when countenanced by a general felicities of character, they must soon destroy fraternal affection. When they are not too impreissive, or too frequent, they contribute to the formation of the habits of self-denial, in a degree which is fearfully effectible in infancy education, because there are, in such cases, comparatively few occasions in which the habits can be brought naturally into exercise; but beyond the limits to which no killing injury is done to mutual affection, it should be the care of parents on no account to permit such trials to extend. They should avoid all unnecessary causes of contention; they should employ the nicest equity in settling the little contending claims; and they should occasionally connect, with absolute quarrelling, the painful feelings arising from separation, and the suspension of their mutual pleasures. In such cases, however, the separation must be made at least irksome and disgraceful; so that the unpleasant feelings attending it may be greater, or at least more impreissive, than those which caused their separation. We need fearlessly revert to the principle already referred to under the culture of the first affections, that parents should most carefully avoid exciting envy and jealousy among their children by their own expressions of partiality,
MORAL EDUCATION.

Nothing more decidedly tends to check the growth of mutual affection among children than this; and till affection has acquired habitual vigour, and is supported by good fence, and a fence of duty, it can seldom stand against such impressions.

3. In order to cultivate any affection, while itself is in its early flages, and in the early flages of the moral progress in general, we shall often find it advantageous to associate with it, or in connection with it, supplies of such pleasurable feelings from foreign sources of sensation and imagination, as will blend themselves with the appropriate pleasures of the affection, and by increasing them afflil to increase its vigour, and the tendency to exercise it. In the later periods of the moral progress, if there is a tolerable degree of sensibility, and a healthy state of the system generally, the mental feelings will usually be found sufficiently vigorous to supply the place of direct sensation; though, even then, where sensations (as is commonly the case if the mind has gone through its usual culture) are connected with mental feelings, so as to become the index of them, they are powerful means of transferring those feelings to objects not immediately belonging to them. But in the earliest periods: the eye, the ear, and the taste, may be made to contribute materials for the most valuable and most highly refined affections; and may be employed in connection with a greater or less degree of the pleasures of imagination, as circumstances permit or direct. Agreeably to these ideas, the parent who is defirous of cultivating the affections which respect the Supreme Being, will find advantage in marking occasionally at least, associating with the ideas of him, the pleasures derived by the young mind from the beauties of nature, the music of the birds, and any other innocent source of sensible gratification; and this will of course be doubly effective, if the affection can be accompanied with a direct reference to him as the cause of those pleasures, provided the mind is capable of perceiving the connection, both by its progress in cultivation, and by attention at the time. We are, for similar reasons, among those who are defirous that the pleasurable feelings derived from simple solemn harmony (whether vocal or instrumental), should be associated with the thoughts and emotions excited by the hymn of gratitude, love, and confidence. Among the young and uncultivated, the effect is clearly and decidedly beneficial: and to those of more refined affections, it will serve to introduce and keep up pleasurable states of the mind, and often, by the influence of our associated nature, to excite those devotional feelings with which they have been long connected. Care must of course be taken, that the music employed with devotional expressiveness, be not of such a nature as to call off the attention of the mind from the import of the words employed; and still more that the use of it do not degenerate into the more gratifications of musical taste: but we doubt not, that, under suitable regulations, the direct and natural effect of music, in cafes to which we refer, is to afflil in generating or cultivating the devotional affections, and to aid their exercise. Though affections will seldom be vigorous which have had no painful impressions mixed with them, and never unless they are made actuating motives of conduct, yet it must be our aim to supply them with a sufficient flood of pleasurable impressions in order to keep up their life and power. The exercise of useful habits should commonly be associated with pleasure: they should be called into exercise when the mind is alive to enjoyment: and it is a simple, but most important principle, that whatever disposition or habitual tendency is suitably exercised when a child is cheerful and active, and receiving pleasurable impressions from external objects, it will receive some addition to its pleasures and strength, from the foreign associations communicated by the feelings and impressions of the time. Whenever, therefore, a habit, which we think important, is at its commencement irksome, if not painful, foreign pleasures (sometimes even those of mere sensation) may be advantageously made use of to halen the tendency of the mind to exercise it, or at least submit to it with comfort. If it be thought necessary, for instance, to induce in a great measure the amusements, employments, and sports of children, on the Lord’s day, with a view to the future rather than the present, in addition to rational sources of moral and religious interest of various kinds, which may be referred for that day, we see no objection to employ little extraordinary indulgences of sensation and sociability to afflil in rendering it pleasant. Pleasants, if possible, should always be made; for religion and religious duties should never be viewed with gloom; and the little simple gratifications of the taste, &c., which we would recommend to be given on that day, however little direct alliance they may have with its employments, will contribute to make them pleasant by association, and will do no harm among the young, when habit, and the perception of their importance, and their accordance with the increasing biasies of the mind, require so much aid to make them interesting. That which is pleasant as a means of pleasure, will gradually become pleasant of itself.

4. Though in the earliest flages of an affection, it should not be too much or too frequently called into exercise, in opposition to the feelings of some others, more directly painful, yet to give it vigour as an actuating motive, it must be exercised in proportion to its strength and purity, in ways which call for self-denial and active exertion. A few observations respecting the cultivation of charity towards the poor may afford some illuftrations of this remark among others. If the first acts of charity be made painful, by requiring privations beyond the power of the habit of self-restraint to render them pleasant, it is not to be expected, that, while the impression of that circumstance continues, the desire of doing good will be lively or even pleasurable. Supposing that the parent obviously sympathises with the distresses of the poor, and in various ways is endeavouring to relieve or prevent them, by exertions and benevolent plans, as well as, if the opportunity and means allow, by pecunary aid, it is probable that from mere sympathy, the tendency to active compation will be produced in the mind. We have known a child before she could speak, take an obvious pleasure in dropping the little gift of charity into the poor old man’s hat. The early exertions of a heart should be cultivated, by exciting pity and a desire to relieve the wants which is experienced, through the means of the observation and imagination, and by studying what effect the efforts will have to relieve it, and by associating pleasant feelings (either directly, or, which is much better, indirectly) with the endavour to do good, making it accompanied with, if not actually productive of, a pleasurable state of mind. Carrying the gift of charity to the poor applicant should be made a gratification, and only allowed where there is a claim upon such gratification from right conduct, or, at least, should be refused, where, from any cause, parental disapprobation has been excited. Children who have habitually been taught to consider the comforts of others as a source of gratification to themselves, will early take pleasure in making little sacrifices to relieve the distresses of the poor. We have known a child, three years and a half old, prefer a baby-house of cut paper to a rocking-horse, which had been the object of her wish, "because it cost nothing, and mamma would have the more money to give to the poor." By degrees, when the pleasure
fure of charity is become pretty lively, and the habit of
acting upon it is tolerably confirmed, it will be desirable to
lead to more decided endeavours to relieve the poor, e.g.,
the little semi-elastic may be allowed a small gratuity for
her work, when done properly, and the may be led, without any
thing like constraint, to give her earnings to the poor;
the pleasure of doing which we have seen very strongly
indicated in a child of between five and six years old. Chil-
dren whose wants have been limited and properly supplied,
and whose desires have been tolerably well regulated, will
fondly feel the value of money to themselves, and to give
away a more gift, will little call for the exercise of self-
denial; but at any rate it will be found advantageous to
allow them to make necessary articles of dress, and to give
the produce of their industry to the poor. We believe that
the thanks of the poor never gave any one more unaffected
delight, than they have done to the child before referred to,
when, without the excitement of praise, or even the reward
of sympathy, (expressed in words at least,) from those
whom the bell loves, she has given away the little superflu-
ities in acts of benevolence, and permitted only where the behaviour has
not been unsatisfactory; and after a benevolent action, the
pleasurable state of the mind should be encouraged both
by the conseqences naturally following right conduct, and,
in extraordinary cases, by communicating little simple grati-
fications, which, even without an explicit connection, will
serve to associate pleasure with this branch of duty. With
respect to boys, it will be less easy to call their charitable
feelings into exercise in this manner; but the parent who
demons to cultivate them in the only effectual way, by
active pleasurable exertion, and by little privations propor-
tioned to the degree of their vigour, and such as can be
easily overbalanced, if necessary, by pleasurable feelings
drawn from different sources, will fondly be unable to find
suitable means and opportunities of doing so. When they
are arrived at the age at which allowances of pocket-money
are given them, if their minds have been rightly directed
by example, by occasional exercise, by instructions, &c., they
will often be easily led to employ some of their little superflu-
ities in acts of benevolence; and if these are judiciously
brought about, and directed to objects, the importance of
which is obvious, and if they be associated with pleasurable
feelings (in suitable proportions to the moral progress of the
individual, and to the power of self-denial), derived from
little rational gratifications from the satisfaction of parents,
and (if in a cafe somewhat peculiar, and requiring con-
siderable stimulus) from the approbation of conscience, and
the more direct religious considerations, all will contribute
permanently to the liveliness and vigour of the principle of
benevolence. To shew what we mean by pleasurable affec-
tions from external circumstances, we may take the cafe
where a parent, or tutor, after his boys have been contrib-
uting pretty largely from their limited allowances, to pro-
mote the interests of an important institution for the benefit
of the poor, associates with the act of benevolence the
pleasure they derive from a long wished for walk on a fine
bracing morning, by treading to them, "I hope, my boys,
you will enjoy your walk; you have been doing what
will be beneficial to others; and the pleasure of doing good,
and the pleasure of your exertions, will increase each
other."

The education of the poor presents the young with a
nobile field for the culture of benevolence; and the preva-
ience of charity-schools in general, and especially of Sunday-
schools in particular, affords to mott young persons an op-
portunity of engaging in it. If they are actively employed
in the communication of useful knowledge, and particularly
of religious knowledge, under the guidance and with the
assistance of the greater experience of their friends, it will
render their own knowledge more correct and practical, and will lead them to think more themselves on subjects of religious
duty, and will make the welfare of others an object of solici-
tude and exertion. The young should be early accustomed
to consider the education of the poor as an object of delight,
of wisdom, and of duty; and should be encouraged to con-
tribute their efforts towards it, with a view to their own mo-
ral improvement, as well as to the benefit of their services in
the cause of benevolence.

5. We must endeavour to adapt our means of moral cul-
ture to the general charactar of the mind, whether aris-
ing from physical temperament, or from the actual progress
made in the acquistion and cultivation of the different moral
dispositions and habits. In doing this, though we shall
often find it advantageous to avail ourselves of the power over
the mind which those dispositions and habits present, even when
considered with the worth they bought not to be pernicious, in
(especialy in the more advanced periods of education) it
ought peculiarly to endeavour to supply their defects,
to curb their exccrcences, and to strengthen their right ten-
dencies. And when we think it expedient to employ, in the
way of motive, those dispositions and habits which eventually
must be modified or greatly restrained, we must be careful
that we do not give them too much power in the mind, to
the permanent injury of the moral character, and of the in-
dividual's happiness. We are strongly impressed with the
importance of this last remark, in connection with the sen-
e of ridicule, which so often furnishes to the thoughtless and
difflated, the means of confounding moral dispositions,
of weakening the influence of parental authority, of rendering
the peculiarities of religious profession irksome, if not abso-
lutely painful, and by degrees destroying the impreffion and
perhaps the belief of the grand principles of religion, which
had been early instilled, and long cultivated (and even judi-
ciously cultivated), and employed as the motives of action.
That the mind will be exposed to such influence in inter-
esting cases, we should induce us to avoid, in the early
periods of education, communicating principles of morals and religion, the grounds of which do not appear to
ourselves fully satisfactory, and forming unnecessary con-
nections of those we do communicate, with peculiarities in
manner, drefs, &c.; it should induce us, as the progress of
the mind will permit, to shew the reasonableness and founda-
tion of those principles, and while we point out their im-
portance and mutual relations, to confine the fundamental
principles of belief and practice, within as narrow limits as
possible, and to make our conclusions from them appear as
inferences, the incorrectness of which will not affect the
truth of those fundamental principles; in short, to cultivate
the understanding while we are cultivating the affections,
to habituate to discrimination and to found reasoning,
and to give habitual influence to higher motives of action;
but at the same time it powerfully urges us to avoid giving un-
due strength to the senfe of ridicule, by employing it too
frequently and unnecessarily as a motive; by making it too
much felt, and consequently too much feared; by connect-
ing it with fierce expressions of displeasure, &c.; to ad-
activate that firmness of mind, which, if it do not directly
leffen the dread of it, will do, indirectly, by leflening its
influence as a motive—to accustom the mind to appreciate
the jufhene of the expreffions of ridicule—and to make any
influence of firmneff in opposition to them, for the sake
of adherence to any principle of liberal obedience, truth, up-
rightness, &c. a ground of peculiar approbation, and on
the
the contrary, any influence of submission to it, in opposition to such principles, the subject of pity, of disapprobation, and, if the case requires it, even of contempt. The influence of ridicule operates through the sense of honour and shame, and it may sometimes therefore be expedient, though the less the better, to curb it through the same channel.

We are fully aware, that there are cafes, (particularly where serious displeasure or actual punishment is out of the question,) in which the influence of ridicule may be beneficially employed; that sometimes, where the education of the affections has not been properly or successfully conducted, it must be employed, because no other motives will answer the purpose so effectually and beneficially; and that there are individuals in whom it is even desirable to awaken a feeling of ridicule. And it may sometimes happen, that to prevent exposure to ill-natured ridicule, where its influence would be excessive and injurious, it should be employed with a sparing hand and a clear separation from all malevolent motives; e.g. in connection with little awkwardness of gesture and modes of expression. But where the sufcceptibility of its influence is the most lively, where the general sufcceptibility of the mind is great, and the sense of honour and shame at least very powerful, if not excessive, there it should be our endeavour to lessen its influence, and to turn the current of those feelings into a beneficial channel, by directing them as much as possible from those little qualities which are not essential to true worth, intellectual or moral, towards the higher excellencies, and by refining those motives themselves through the purifying influence of religious principles.

The power of ridicule obviously depends very greatly upon the degree in which the feelings of honour and shame exist in the mind. If our limits could permit, we should be glad of entering fully into the consideration of the formation of those feelings, and the proper regulation of them in education; but we must content ourselves with recommending a few general observations; and to those who wish to enter further into the subject, we strongly recommend the perusal of the 95th proposition in the first volume of Hartley's Observations on Man, and propositions 62, 63, 64, in his Rule of Life, which will probably lead them to most of the conclusions upon which we should wish to enlarge. In Mrs Edgeworth's chapter on Vanity, Pride, and Ambition, they will also find many important remarks, which, in various periods of education, and in various circumstances, cannot fail to be highly serviceable in moral and even intellectual culture. And we may take this opportunity also of recommending to our readers, the truly excellent observations which they will find in Practical Education, in the chapters on Temper, Truth, Rewards and Punishments, Sympathy and Sensibility, Female Accomplishments, Prudence and Economy. These chapters contain a fund of the most valuable instruction and aid, in giving that regulation of the conduct and dispositions, to which we are directed by enlightened prudence, and a sense of duty founded upon it. If the moral system which is displayed in her portion of Practical Education, and in her other writings, had decidedly presented, with its present excellencies, those higher and more ennobling principles of action, to which the foundten views of human nature, as well as the morality of the gospel directs, our wants would then have been completely filled up. We do not wish that the should chiefly herself among the "sectary-metaphysicians," (See Præd. Ed. ch. xxv.); her own independence of mind, and accurate judgment, must have kept her in the eclectic feet of philosophers; but we do most earnestly wish, that while she made the principle of affection in one of its leading operations the basis of her system of education, she had also followed out another of its grand laws, in its connections and consequences. Hartley has unhappily encumbered his doctrine of affection with the theory of vibrations; and he treats upon difficult grounds, with respect to the generalization of the intellectual powers of the mind; but in all that respects the affections, and the mental pleasures and pains in general, their growth and culture, their regulation and refinement, we do not hesitate to express our opinion that his observations are to be regarded as the Principia of moral philosophy.—If the principles of his Rule of Life, (directed, we would admit, of whatever is clearly supported by his philosophical principles,) had furnished the foundation of that morality which is so admirably taught in the Parent's Assistant, Moral and Popular Tales, &c. without introducing these views to adorn and dignify those who cannot feel their force, they might have been made powerfully to contribute (almost without being perceived by any but such as had also imbibed them,) to the cultivation of them in better soil, and to prepare for such cultivation beyond present calculation.

But to proceed. By pride we understand, an unjust feeling of superiority over others, or of elevation in the scale by which the individual estimates honour; by vanity, an excessive desire of the praise or good opinion of others. The former indicates an unfounded opinion as to the title to honour; the latter is generally accompanied with some opinion of that kind, but does not necessarily imply more than an eager desire of honour.

It is difficult to form a comparative estimate of the injurious effects of pride and vanity. When the soil is good, both may produce good fruit; perhaps, however, pride prevents the most effectual obstacles to improvement, and vanity tends most to render that improvement ineffectual. In the earlier periods of life, the good opinion of others is, in most cases, the highest stimulus which the mind can receive; and well directed, it has its full effect in prompting to the attainment of moral and mental excellence. The circle at first is narrow: the few friends on whom we depend for the various comforts and enjoysments of life, are those whose good opinion forms our first object. If these are correct in their appreciation of worth, their good opinion is the source of future excellence; it prompts to the formation of the most valuable habits; and lays the foundation for that desire of honour, which afterwards raises the mind to him whose approbation is happiest. If they make their approbation depend upon right conduct, and do not lavish their praise or their censure, but give it only where, justly estimated, praise or censure is due, the result is valuable; if they teach to value the praise of the wise and good only, vanity will, in time, be brought within proper limits; but they do not do all, if they do not teach, that the pleasures which they at present receive from the approbation of their friends, is afterwards to be chiefly fought for, in that of their best friend; that his approbation is to be made the criterion of excellence; and that by this they must appreciate the worth of all other sources of honour. If indiscriminate vanity be not thus checked, the mind which seeks the good opinion of others, will fall into the opinions and practices of others; and unfounded principles of conduct must be expected, for that on which they are founded is as variable as the mind. The stimulus of praise becomes necessary to happiness; and the mind is incapable of exertion where that praise is not to be obtained; is incapable of acting in opposition to the opinion of those whose censure it deems among the worst of evils, whose praise it regards as an important good. The excessive desire of the
MORAL EDUCATION.

...the good opinion even of the wife and good, is injurious to the mind. It energizes its powers of action, it renders it fickle and inconstant: it prevents from efforts leading to high utility, where those efforts may be misinterpreted; it checks the attention which should be paid to superior honour; and it prevents that ardent desire for the highest approbation, which should be made, as far as possible, the primary object of pursuit.

The workings of vanity ought not, however, to be viewed with too sanguine an eye in the early stages of intellectual and moral culture. Self-diffidence is almost necessary for that culture; and vanity is frequently the offspring of self-diffidence. But great care should be taken to prevent the love of praise from becoming a necessary stimulus to exertion. The stimulus should be levied by degrees; and, if done gradually, the habit which it was intended to generate will be formed, and the exercise of it continued, without this stimulus. Praise is probably employed in education more than is desirable, because more than is necessary; perhaps the simple expressions of sympathy, in successful exertions, would commonly answer every purpose. The employment of these means must, however, be varied by circumstances; but it should always be kept in view, that praise should be little employed in the cultivation of moral worth; that, to that, approbation should be given indirectly: and when believed upon intellectual acquirements, it should be distinctly seen that these are not held in the same rank with the performance of duty. The young should frequently be led, if self-diffidence do not make this a bar to exertion, to contemplate those who have made greater attainments than themselves, and seldom refer to those who are below them. In this, however, such cafes should be added as will prevent, or rather avoid, the excitement of envy; and where emulation gives birth to envy, this should be carefully avoided. But, above all, they should be taught to discriminate in their desire of approbation, and be led by degrees to seek for that approbation which alone is certain, and which alone is independently valuable. The eager desire of the praise of men debases the motives, weakens the mental powers, and produces corroding inquietude: the ardent pursuit of the divined approbation will shipwreck motives to action continually increasing in purity, will strengthen the mind for valuable exertion, and prepare it for permanent happiness.

6. In order to prevent the rise, or check the growth of any disposition, which we conceive to be injurious to the individual, we must avoid the original expressions tending to give birth to it, and to lead to the recurrence of its excitement; and we must aim to produce suitable allocations of a painful nature with its exercise. The more our plans are directed for the prevention of wrong dispositions and habits the better; and the same must be said where they can be properly restrained, by simply avoiding their excitement. Still, however, cafes must occur, in which the correction of them must be brought about through the medium of bodily and mental pain; and the great point is, so to proportion the degree of punishment, and to regulate the manner of it, that it shall not exceed the necessity of the circumstances, and that it bring into exercice no other wrong feelings.

Dissipation, privations, restraints upon liberty, and corporal pain, all of which probably may, in different circumstances, be employed with advantage, have all their peculiar convenience and ill consequences. The fear of blame is a most powerful motive to action, and renders not only the desire of praise, but it is of great consequence that this feeling should exist in the mind with a tolerable degree of vigour; since it is a very important auxiliary of the moral principle, and will sometimes serve to supply its deficiencies: but if it be too much employed, it loses its sedulity, or becomes perverted, or else it acquires an excessive degree of power, and makes the conduct and happiness of life so much dependent upon the opinion of others, as to render these exceedingly unfavourable. The fear of shame constitutes an essential ingredient, in what is commonly termed a regard to character; and among the lower classes of society it should be encouraged, we had almost said, without limit, because there are so many causes continually operating upon them, particularly in the present periods of difficulty and distress, to reduce it within narrow limits, or to destroy it altogether; and the want of it is, in all cases, greatly to be regretted. Like most other valuable principles, however, it is liable to great abuse, and to an injurious direction: and it is greatly to be feared, that in the usual fylphs of public education it is thus abused; since, from the prevalent modes of punishment, it is left excited by what ought certainly to be the chief source of it. the having merited punishment, and being in consequence exposed to it, than by the want of fortitude in bearing it. When disgrace is employed, it should be associated only with conduct which is really disgraceful; and it should be proportioned to the degree of impropriety or bafeness observed; and we should be peculiarly careful that we do not disdain the fear of it, by exciting it too frequently, or on occasions in which it is merely fictitious. If a parent is continually making trifles the subject of disgrace, the sense of shame must either become excessively inordinate in its influence, or children will lofe it altogether; both which effects are earnestly to be deprecated.

Respecting little privations of personal gratification, there is always some danger, lest those gratifications should acquire an undue degree of importance, by being made the means of punishment; and we conceive they should not be employed for this purpose in cafes decidedly immoral. But in connection with a want of industry, we see no adequate objection to the occasional diminution of the pleasures of the palate. The health, of course, must be taken care of; but it is a clear maxim of retributive justice, "if any one will not work, neither let him eat." This is often actually carried into effect, by a natural connection in real life; and we are satisfied that it may be advantageously employed, by an artificial connection, in education. When, from any cause, a considerable degree of parental displeasure is manifested, it will sometimes be found desirable, if the painful feelings directly arising from it do not seem sufficiently lively to suspend those little simple pleasures of the palate which extend beyond the absolute wants of nature; indeed, as long as a child is under a parent's displeasure, there should be as few gratifications as possible to look to for relief; and if the uneasiness which it produces is not itself sufficient to make the usual pleasures of childhood infipid, it is desirable to increase that uneasiness by fictitious associations. A parent's displeasure should always be felt to be a serious evil.

Solitude, confinement, and other kinds of restraint, may all, in appropriate circumstances, be employed with effect; but there are some dispositions upon which they operate very injuriously. Some children, when under such punishment, not having the usual external impressions to change the current of thought, seem to employ their leisure in the exercise of bad dispositions. Where this is the case, no benefit can accrue from them, and much injury made. Then, not only in some instances, they afford too much opportunity for the play of the imagination. But the expectation of the loss of play, as a recompence for the want of diligence
MORAL EDUCATION.

gence at business, is often a pretty powerful, and it is a natural stimulus; and not unfrequently there are instances in which it is beneficial to employ solitude (provided it be not too long continued), as a means of leading to reflection on improprieties of conduct.

Reflecting corporal pain, we have no hesitation in saying that experience has compelled us to give up our theories against it. We are now satisfied that there are dispositions which are much less injured by this kind of punishment, than by any other which would be effectual. And we are further convinced, that in the earliest periods of childhood, before the time when the mind can be properly influenced by moral motives, corporal pain, sparingly but firmly administered, will often be of much more service, and do much less harm, than any other species of punishment. If this be employed at that early period, to overcome the rudiments of obstinate disobedience (which is the only case in which we have occasion to perceive its expediency), it will have a great deal of the management of a different description in the later periods of education. Perhaps, if parents were able to undertake the sole management of the education of infancy, it might justly be attributed to themselves, if such punishment were ever necessary; but, as circumstances usually are, a great part of the work of education conflicts in endeavouring to destroy dispositions and associations which the ignorance or carelessness of others have produced. We are not disposed to think that falsehood, falsehood, injustice, 

&c, should in childhood be made the ground of corporal punishment; there will, in general, be better punished by their natural consequences, which may even then be brought into view. But where habits of this decidedly immoral nature have been suffered to gain great strength, and have been carried on to the period of early youth, where the sense of shame has scarcely any power, and the natural inconveniences of those habits may be comparatively easily avoided; there (and also in cases of carelessness perverse disobedience) the rudiments of moral discipline and feeling may, we think, be advantageously begun by severe corporal punishment. We have known such cases; and experience has led to our conclusion. When such means are resorted to, it would be cruelty to employ them slightly. They should be resorted to such a way as to afford the individual no support from sympathy, and yet be impressive to others. And their whole accompaniments should give them a real importance in the estimation of all concerned.

But whatever the punishments employed, it will be of great advantage that the following principles be distinctly kept in view. 1. Punishment should, as much as possible, be appropriate to the offence, in kind and still more in degree. If it can be made to reembrace the natural consequences of ill conduct, it will have double influence in real life. If it have its due proportion, it will be less likely to excite the sense of injustice, and will contribute to the correction of the conscience. 2. Punishment should be certain when appointed. There may be circumstances in which it would be injustice to punish; and if these clearly authorize the remission of the punishment, it may be attended with more benefit to remit than to inflict. But such cases can be but rare, where the declaration of consequences does not arise from the daily tribulations of passion. 3. The disposition should be carefully studied, and those means employed which best suit it; which are most likely to check wrong habits and dispositions, without implanting others in their stead. 4. Punishment should always be guided by the only justifiable ground of it, the moral benefit of the individual, and of those within the influence of his example and of his punishment; and, as much as possible (especially in the most painful exercises of punishment), it should be obvious that it springs from the desire to do good. It may sometimes lose a little of its immediate efficacy; it may excite less terror than if the result of passion; but while the infliction of pain (we particularly refer to corporal punishment) is accompanied with earnestness, it should clearly appear that it is the result of the same benevolent determination with which the feeling surgeon amputates a limb to save the life of his patient.

Punishment, if it operate beneficially, does so in two ways; by producing actual painful affections in connection with the dispositions or habits, thus diminishing the tendency to exert them; and by exciting the fears with respect to the future. The former is the best possible effect; and the latter, to a certain extent, cannot but be beneficial. The principle of fear, where not excessive, and where properly regulated, is of the utmost consequence, in connection both with the general conduct of life and with personal safety. But where it is excessive, it degenerates into cowardice on the one hand, and superlition in its various forms on the other. From the former springs a host of moral evils: where fortitude does not constitute, in some tolerable degree, a part of the character, enabling the mind to support not merely bodily but mental pain, and to remain firm in the course of duty, without being too powerfully affected by the apprehensions of imagination, or by actual suffering, there can be no stability of character; it must be weak and wavering, the sport of fools, and, what is worse, the sport of the wicked and designing. From the latter originate all the degrading views of the Supreme Being, and of religion in general, which contribute to fill the mind with a thousand imaginary terrors which often destroy the influence of real religious principle in the individual himself, and render religion insupportable in the eyes of others. In childhood, excessive timidity of character (whether arising from constitutional tendencies or early associations), should be carefully guarded against; it is the parent of meaner and falsehood; and in every period of education we ought to be extremely cautious, to curb our punishments should operate to the weakening of the mind, instead of the supplying it with vigorous motives to avoid what is wrong. Fear should be associated with the idea of doing wrong, rather than with the consequences of it, and fill more rather than with painful feelings not springing from ill conduct. The fortitude arising from constitution and the early care of parents is valuable, that of principle is invaluable. On the regulation of the principle of fear, we refer our readers, with great satisfaction, to the third letter in Miss Hamilton's first volume. The whole work does credit to the author's understanding and to her heart.

7. Since the affections and dispositions may indisputably be excited, not only by impressions of actual sensation, but through the operation of the memory and the imagination, it is of the utmost consequence to the purity of the mind, and to the due restrained upon the sensual desires, that care be taken, from early years, to preserve the mind from all impressions calculated to give a premature rise, and excessive strength to those desires. In connection with this point, we beg leave, for the present, to refer our readers to some extremely important considerations (the matter of which will, to the judicious mind, compensate for some little peculiarities in the manner), contained at the close of prop. 53, in Hartley's Rule of Life.

8. As the progres to diiferent states must always be gradual, and in many cases must be slow, we are not to expect too much, in this respect, from our children, nor too much disapprove the indications of attention to personal pleasures,
pleasures, provided it appear to be only in the natural pro-
gress of the mind. We may make our children hypocrites;
but we cannot all at once make them disinterested. We
may lead them to conceal their motives, or even to profess what
do not actually; but we cannot thus communicate that
purity and refinement which, by the truly established laws
of the mind, are the result only of long continued proc esses,
only advancing without our aid, but not unfrequently to
be greatly afflicted, partly by fostering and exercising right
dispositions, and not less by checking counteracting af-
sociations. It should never be forgotten that steady habitual
disinterestedness is the last stage of an affection.

Some may, however, suppose that children are usually
more disinterested than persons who have had experience
in life; and it may contribute materially to our leading objects,
if we add a few remarks on that point.

Children often appear disinterested when they really are
not so, because we do not sufficiently take into account the
quick changes of their feelings; sometimes letting a light
value upon what a few hours or even minutes before they
were extremely pleased with; and at other times the reverse.
Hence they are readily induced to give away what they
have been delighted with; and to make what we erroneously think sacrifices, without an effort. But again,
we are apt to think them disinterested, when they give up
what they really like, only, or principally, because they
thus have a greater share of the pleasure resulting from their
obedience to their friends, praise or other rewards. Now,
the approbation of their friends is, to well-disposed children,
of such great value, that praise affords them some of their
highest gratifications. And, therefore, when, for the sake
of that approbation, they give up play-things, or any other
objects of pleasure, &c. so far from being disinterested, they
are eminently self-interested: but their self-interestedness is of
a much more refined and superior description than that
which would prevent the little sacrifice; one which, with
due care, will prove a most powerful engine in the moral
and religious culture of the mind, by increasing the influence
of the parent and instructor. Again, children are usually
influenced more by present than by future objects, however
far superior these may be in their value and durability.
Few children early attain such command over themselves,
as voluntarily to give up a present source of pleasure for a
future one: and where it is done, it is rather in compliance
with the wishes and injunctions of their friends, than from
any comprehensive conception of the future good. It is
an excellent thing to obtain the sacrifice by means of any
worthy feeling: all we wish to observe is, that children do
not feel the real value of future pleasures, and therefore
easily yield to that which is most powerful at the time.
Hence, therefore, they appear disinterested, because they
cannot properly calculate the value of the good which they
relinquish, and do in reality prefer the greatest present plea-
urse; or rather they are actuated by the greatest present plea-
urse.

We do, however, cheerfully admit, that some children
very often are, in some lesser, disinterested: for instance,
will obey their parents, will tell the truth, will endeavour
to increase the comforts of others, without any reference
direct or indirect, to any personal gratification: and we also
admit that there are some children too frequently, as they
grow up, become more selfish; and that sometimes the constitutional selfishness, through which (among other causes) they have in some instances become disinterested, proves the cause, under improper regulation, of their
becoming selfish, and that to a degree which those of less
prompte never masoifeld. But those marks of disinterestedness
are by no means difficult to be accounted for. The habit
of obedience, for instance, is the constant object of a
parent's care and exertions; and in a well educated child
there are no strongly opposing dispositions to be checked
before obedience can be secured. Little pains are quickly
forgotten, though their effects remain; future pleasures are
thought of but little, and the value of their sacrifice not
fally estimated; the constant connection is formed between
pleasurable feelings and obedience, and unpleasant feelings
and disobedience; above all, obedience, prompt and cheer-
ful obedience, is early and easily cultivated, so as to pro-
duce a regular habitual tendency to it; and as soon as a
child acts solely from the impulse of an habitual disposition,
he is so far disinterested. But this disinterestedness is not
to be relied on as a settled principle; steady habitual disin-
terestedness of any worthy affection can scarcely be pro-
duced till the affection has been exposed to the influence of
opposing impressions, and till the mind has gone through
much moral discipline.

9. In order to produce disinterestedness as a habitual
prevailing quality of the mind, while we make the exercise
of the disposition sufficiently pleasant, by various means, we
must carefully avoid leading the mind to set up the plea-
ures themselves. In the later periods of education, we must
associate pleasure with actions, left as positive rewards, than
as the results of valuable qualities. We must frequently
excite to the exercise of them, without hope of immediate
satisfaction, and even in opposition to expected inconve-
niences, and at the expense of present privations. And we
must gradually raise the mind to the higher motives: subdi-
tuting by degrees for those which are personal, such which
are refined and disinterested, and which carry the mind out
of itself. The cultivation of the religious affections, and of
an habitual fenfe of religious duty, has a more special ef-
eect in elevating the mind towards the heights of disinter-
tedness. The hopes and fears of religion have themselves a
purifying influence; and there is no motive which can have
a more direct and powerful tendency, (in proportion to its
own strength and constancy,) in giving firmness and purity
to the moral principle, than the habitual regard to the will
of an omnipresent being, and an habitual desire of his appro-

10. Much may be done by the proper regulation and
communication of external impressions, (operating directly
by sensation, and will more through the medium of the
associated feelings,) towards the formation, growth, strength,
and purity of some dispositions, and towards the prevention,
restraint, or eradication of others; yet, throughout, we
must be extremely careful so to direct and moderate our efforts,
that we do not proceed beyond the natural progress of
the mind, that we do not, through fear of their exceller,
by too violent a restraint upon principles of real, though
inordinate and temporary value; and that we do not, from
a sense of their great importance, too rapidly hinder the
growth of others. In short, having from philosophy and
experience obtained just views of the nature of the moral
principles of the mind, their origin, progress, and termination,
we must carefully follow nature. The contentious
parent is sometimes as much in danger of attempting too
much, as others are of doing too little. We recollect fe-
eling, some years back, (in one of our most popular periodi-
cal publications,) an animated paper, designed to restrain the
excessive anxiety of parents, which was attributed by some
to the pen of a writer eminently qualified to aid the reli-
gious parent in the works of education, and respecting whom
our only subject of regret is, that he has not done more.
—the author of Hymns in Prose. Parental solicitude should
always
always be put under the guidance of patience, good sense, and experience, and, if possible, of mental philosophy.

III. The Moral Sense, or Conscience. — The conscience is that internal principle, which, without reasoning, without direct reflection on the consequences of actions, or even on their obligation, at once approves certain dispositions or actions, or courses of actions, as right, and as what we ought to cultivate and practice, and at once disapproves of certain dispositions and actions, or courses of actions, as wrong, and as what we ought to check and avoid. The human mind is so formed, that such a principle will spring up in it, if the individual is placed in circumstances common to almost every human being. Thus, universal experience proves; and it is a question of no great importance, though by no means difficult to be decided, whether, if a human being could grow up to maturity, without having from infancy any intercourse with his fellow men, and without any supernatural impressions, he would manifest any such principle. What is of the greatest importance, is, that its dictates are not universally the same, and that it is an improvable principle; that to give it early correctness and vigour, requires great care on the part of those who are concerned in the early periods of education; and that to give it its due flexibility, accuracy, and influence, requires the use of suitable means in every period of life.

If the dictates of the conscience were at all times the same, or if it were not an improvable principle, the rules of revelation and all moral culture would be useless. We cannot doubt that the contrary is the case. In the heathen morality, as Hartley observes, taken generally, some of the higher virtues which Christianity points out to our attention and observance, were omitted, and some were even the object of contempt: many erroneous views were prevalent; some were even recommended; ambition, of the most selfish kind, was esteemed virtuous; and many kinds and degrees of humility were treated with reproof and contempt. And, as to the devout affections, they were defined as love, and their fear was supererogation. "The heathen philosophers," says Paley, "though they have advanced fine fayings and sublime precepts in some points of morality, have greatly failed in others;" and he brings forward a series of instances, in justification of his remarks, from among the most eminent and excellent of the ancient philosophers, which are sufficient to show the inestimable value of the morality of the gospel, as well as to prove the point in question. (See Moore's interesting and valuable Life of Paley, p. 740.) "There is scarcely a vice," he elsewhere observes, "in which in some age or country of the world has not been countenanced by public opinion." And what diversity do we perceive at present? Even among those whose minds are cultivated, but not brought under the restraining guidance of religion, we hear murder, under the name of duelling, vindicated, and even applauded; and we find the Christian's forbearance and forgiveness reproached as meanesses and cowardice. How common is it, even where persons are really on the whole influenced by religious principle, to depart, without hesitation, from the strict dictates of Christian integrity or truth, where the end, as they think, is a good one, and such as to justify the means; and in some instances even to approve of direct falsehood and prevarication, where their feelings of benevolence prompt them to endeavour to prevent some suppedo inconvenience on the part of others, or to obtain some suppedo good for them. Those who have had much experience, and have paid much attention to what passes within them, though they may feel the decisions of their consciences to be generally correct, can scarcely fail to call to mind instances, in which they have acted under the conviction that their conduct was right, when further reflection and examination have led them to believe the contrary; and those who are not able to trace infinences in which their consciences actually approved of what they afterwards thought wrong, will be able to perceive a progress in the correctness and extent, the readiness and vigour, of the decision of their conscience.

Those who have had much concern in the early education of children, can feel no difficulty in tracing (generally at least) the progress of the moral principle; and correct views as to the laws and operations of the human mind, leave us little room to doubt, that its pleasures and pains are formed, like all other mental pleasures and pains, by the ever active principle of association, connecting, combining, and blending together a vast variety of feelings, more or less complex, so as to form from them a set of feelings, most powerfully influencing the conduct, and contributing most essentially to the happiness or wretchedness of the individual.

The feelings are derived from, and confit of, all the other pleasures and pains of our nature, so far as they are consistent with one another, with the frame of our nature, and with the course of the world. (See Hartley, vol. i. prop. 99.) They are continually presenting themselves, urging to think some branches of conduct, and to pursue others, rewarding us for our obedience with some of our purest and best satisfactions, and punishing us for our neglect and disobedience, with emotions of great and right (and others similar to them) pleasing feelings, derived directly from sensation, or from the approbation of friends, &c.; and with the words wailed, wrong, &c., painful feelings, in like manner derived directly from sensation, or from the feelings of shame. If children have the happiness to have parents, whose ideas respecting duty are generally correct, these feelings will be properly directed; and they will then be increased, strengthened, and rendered more and more lively, by the continual addition of many others, derived from various sources. If not, there will be a proportionable deficiency, or erroneousness, in the dictates of the conscience, which will be to be corrected, if corrected at all, by experience, or by increased knowledge, afforded by the Scriptures, or some other rule of life, engaging duty, and the consequences of performing or neglecting it. But supposing the generally favourable, and not uncommon case, (where an individual has had the advantage of an early correct direction of his moral feelings,)—here all the pleasures arising from the exercise of the filial affections, all the pains arising, as natural consequences, or as direct punishment, from disobedience, or neglect of parental injunctions, contribute their share to strengthen and enliven their feelings. As soon as some knowledge of God and of a future life has been obtained, the affections which are formed towards God, the hope of future happiness, and the dread of future misery, begin to add to the vigour and extent of the feelings of conscience; and they continually, and through life, contribute these impressions, which powerfully tend to give life, activity, and energy, to its pleasures and pains, while at the same time they correct and confirm its dictates. Separate from this source, though not independent of it, the beneficial tendency of right conduct and disposition, and the injurious tendency of the contrary, with respect to the happiness both of the individual and of others,
MORAL EDUCATION.

in the way of interest, or reputation, or social comfort, whether the result of experience, or observation, or pointed out in a less imperative, yet often effectual way, by the instructions of parents, &c. add to the strength and livelihood of the emotions of approbation and disapprobation.

Though the feelings of the moral sense have a general agreement in their force and direction in different individuals who have enjoyed the usual advantages for the cultivation of the conscience, yet even in them the component parts must be very considerable, both in kind and degree; and without attempting, therefore, to enter into a minute account of the formation of those very complicated feelings, composed, as they are, of a vast variety of other feelings, themselves greatly complicated, it may be sufficient to observe, that every pleasing or painful impression, received in connection with right or wrong conduct, contributes towards the formation or growth of the pleasures and pains of conscience; every instance in which approbation, reward, or any other good conseqences, are actually experienced, or are observed to be experienced by others, in consequence of right conduct; every instance in which the mind is led to perceive the beneficial tendency of right conduct, its suitableness to the cause of providence and to the frame of man; every instance in which our own right conduct does good, or gives pleasing satisfaction to others, especially to those whom we love; every instance in which the heart is impresed with the conviction, that he who is greater than the heart, knows and approves of sincere and dutiful obedience to his commands; every thoughtful reflection on the infinitely blissful consequences of a course of steady obedience to duty; and every instance in which the present supports of obedience are experienced, or perceived in others,—contributes its share towards the formation and strength of those feelings of love and approbation of what is considered as our duty, which make the contemplation of right actions and dispositions a source of delightful emotion, and which reward the performance of the one and the exercise and culture of the other, by that approving testimony which has often been an abundant recompence for the greatest pains and privations to which duty may direct. And, on the other hand, every instance in which displeasure, shame, punishment, or any other ill consequences, are actually experienced, or are observed to be experienced by others, in consequence of wrong conduct, or in which the mind is led to perceive its injurious tendency, its unsuitableness to the cause of providence, and to the frame of man; every instance in which our own wrong conduct does injury, or gives painful regret to others, especially to those whom we love; every instance in which the thoughtful conviction is excited, that he who knoweth every secret of the heart, is displeased with disobedience, and that the consequence of every act of disobedience, of every indulgence of wrong disposition, of every neglect of duty, and the affections enjoined by it, will, in his all righteous ordinances, be followed by its proportionate diminution of happiness, or increase of misery, probably in this life, but certainly in the other; —every instance in which the present pains of conscience are experienced, or observed in others, in consequence of neglect of its dictates, or disobedience to them—contributes its share towards the formation and strength of those lively feelings of disapprobation or even abhorrence, with which we contemplate what, in others, is considered as inconsistent with, or contrary to, duty, and of reward, in consequence of wrong actions and dispositions in ourselves, which punish the performance of the one, and the neglect of the other, with pains which often exceed in vividness the torture to which the human being is exposed in this world, which, though sometimes overcome by the battle and pleasures of the world, seldom fail to revive in the period of worldly dutiefs, or in the time of sickness and the apprehension of death, and which will in all probability constitute a great part of the punishment of futurity.

The account which we have given of the nature of the moral principle, affords to those who are concerned in early education, a strong motive to do what they can to give accuracy and extent to their views of duty; to heighten the pleasures and pains of the conscience, so as to bear a due proportion to the degree in which wrong actions are injurious or right ones important; and to lead them, by all the means in their power, by instruction, by praise and censure, by reward, by discipline, and by example, to a constant submision to its decisions. It shews the great importance of beginning early, while the heart is not occupied by the pleasures and cares of the world; and that it is free from all prejudice against duty; while its sensibilities are tender; and while impressions in favour of duty may be permanent. Where the moral principle is cultivated early in life, there is something to be effected by the exertions and instructions of others; by the warnings afforded by the course of providence; and by the views of duty and its consequences, afforded by the gospel. Where it has been neglected, no efforts can completely supply the deficiency. The judgment may be enlightened, but the conscience will never then acquire its full strength, its vividenes, and its power.

These views, reflecting the origin and growth of the feelings of the moral sense, appear sufficient to lead the reflecting parent to all the principles of fundamental importance in the culture of it; and we shall only subjoin a few inferences and additional hints, which may aid a little in the application of them.

1. We must, throughout, proportion our instructions, as well as our intentional impressions, whether pleasurable or painful, to the strength and refinement of the conscience.

The principles we communicate, and the pleasures and pains which we employ, should be suited to the general progresg of the mind in intellectual culture and refinement of feeling, and to the slate of the moral principle in particular. Motives, which at some periods of the moral progress would be most advantageously employed, would be preponderous in others, either absolutely ineffectual, or absolutely injurious.

2. The feelings of honour and shame must be employed with great care, and connected principally, and in due proportion, with right and wrong conduct and dispositions. In employing the former, however, especially in the later periods of education, it should seldom be by the direct expressioin of praise in connection with particular actions, but by approbation given to similar actions in others, and the like indirect means. Nearly allied to this observation we may remark,

3. That care should be taken to regulate our modes of expression in conversation, that feelings of approbation or disapprobation should be associated in the minds of our children, in something like a suitable proportion to the value of different qualities or actions.—If children hear us express as much approbation, and in the same terms, of the skill of a gentleman coach-driver, of the abilities of a philosophical lecturer, and of an individual who has just performed an elevated act of disinterested virtue, is it possible that they should not feel great confusion of ideas; if each is termed a noble fellow, and with the same emphasis and animation, how can the youthful understanding calculate with sufficient accuracy, to appreciate the import of the expression, in the same way that we should do? We have taken a somewhat peculiar case, but it may serve a little to shew the necessity of attention to the power of words. If the
The influence of association was left out of view. that power must be deemed magical. It is one grand means, (indeed the grand means,) not only in the communication of knowledge, but in the regulation of the desires and affections, and the transfer of them to appropriate objects.

4. We cannot, however, prevent the formation of incorrect affections; and it is of singular importance, that we accustom our children to the utmost openness of disposition, so that we may employ useful means of correction. The parent, who has acquired the frank confidence of his children, has a means, of incalculable importance, of knowing the erroneous judgments and feelings which they form respecting moral principles, and of gradually correcting them. If sufficient care is taken in the early formation of the moral principles, and, as the mental progres permits, in shewing their foundation, erroneous ones will seldom gain much hold on the mind, unless supported by the affections; and we may sometimes be satisfied to leave them to be corrected by the gradual illumination of the mind and actual experience: but, in general, as error leads on to error, especially if it accord with wrong moral biases, it is better to avoid the causes of error, and as much as we can, (without attempting too much, and thereby eventually defeating our object,) we should destroy the false affections, which may lead to baneful consequences. —If an example be required, of the way in which we would endeavour to effect such separation, we may give one, which may be serviceable in the later periods of education. Suppose the ideas of merit have been attached to that frivolous kind of courage, which leads a man to engage in a contest, in which the life of one individual at least, and perhaps the happiness of several, may be sacrificed at the thrme of offended honour; —our aim must be to associate the dreadful consequences of his conduct with the conduct itself; to bring into view the injury to society from the violation of its laws, and the loss of a perhaps useful member; the injury to the connections of the individual, from the cruel breach made in their peace and means of happiness; and the injury to the individual himself, by hastening his period of probation with this additional guilt upon his head; even the injury done to the avenger of wounded honour; by cultivating the feelings of resentment, by loofening the restraints of passion, may be added to the mals of evils resulting from the exercise of private revenge. These things frequently brought into view in sufficient detail, as opportunities direct, and events furnish impressive illustration, must gradually weaken, and eventually destroy, the association already formed; must associate demerit, instead of merit, with the conduct of the duellist, and attach the idea of merit strongly to him, who nobly refits the opinion of the world with respect to honour, and declines obedience to the laws, which it imposes, when in opposition to those of confidence and of God.

5. We may here hint at the great importance of care in the felection and employment of books; and in the proper regulation of foreign interference in education, during especially its early periods. We do not object to the occasional employment of works of fiction, calculated to bring into view the application of moral principles; but those principles should be correct. When this is the case, such works often do much to supply the want of experience, and to impress strongly on the mind the effects of right and wrong conduct. Not that the moral should be forcibly brought into view; children will, in such cases, usually pass over it, to go on with the story; but, if worth anything, the narrative will of itself communicate the moral. The great point is, that the effects displayed should be natural; so that the expectations, as to the present consequences of right conduct, may not be raised to a romantic height, or the influence of the narrative destroyed by its obvious improbability. The idea should be forcibly impressed, that the directions of duty must be the primary consideration; its present consequences should be only secondary motives.

—Children should have as little to learn respecting moral as physical truths: and parents should therefore read, with a parent’s eyes, the books which they put into their children’s hands. We do not wish, that every thing should be omitted which is not correct and found in principle; but opportunities should be sought and employed, to lead to discrimination and correction.

6. It is of great importance for the confirmation and correction of moral principles, that the young should be early led to exercise their understandings on them, and to give their opinion, and the grounds of it, on questions of moral conduct, faited to their progres and circumstances. If a proper degree of mental humility have been preferred, so as to leave the heart open to conviction. such an employment cannot fail to be eminently useful, in the corroboration, extension, and correction of the dictätes of the conscience.

—They should also be led to compare thes dictates with fixed rules of duty of general application, and to determine their correctness, on the contrary, by the comparison. The moral sense is greatly benefited by early habits of self-inpection.

7. The passing occurrences of life will often afford us a valuable aid in the impreffion of moral principles on the mind. In some instances, the effects of right or wrong conduct can be clearly thrown to the young, by actual obervation; in others, without naming the individual, the nature and consequences of his departure from duty, may be forcibly brought into view. —Thee (and simlar means) must, however, be employed, only when the understanding is alive to perceive the connection, and when the feelings are not pre-occupied or languid. —Next to them in their effects, and in some instances far beyond them, is the animated detail of the biographer. The class of practical biography (in which of course we include the biographical facts contained in the scriptures) is of eminent value in moral (as well as mental) education; and the earlier the mind receives a bias to such reading the better. It is one ill effect of the present profusion of “little novels,” that they, (like the novels of more advanced periods,) where too freely perused, destroy the zeal for sober realitues, however well told. We do not class all tales under the head just mentioned. Some we have already referred to with general decided approbation (though in some instances not quite satisfactory respecting the consequences of right conduct); and we will mention another of great interest and value, Saltzman’s “Elements of Morality;” a work which admirably fulfills the promise of its title. The plate should never have been omitted; though their effect would not be lessened, if they were reduced a little nearer to modern costume.

8. Biography, when most minute, and therefore most valuable, brings into view the caufes and effects of actions in their connections; and this is one great advantage of it. It has another, where it is also faithful, that it prepares the mind to expect, (what not even the cultivation of habitual candour should prevent being brought into view, in real life, on improsession opportunities,) that, in the good, mixed with excellencies, will be found qualities which ought not to be approved and imitated; and among the bad, qualities which tend to render their conduct attractive. The mind, we are again led to observe, should be habituated to discerning the caufes of its approbation and disap-
MORAL EDUCATION.

disapprobation. A sound discriminating judgment is of the utmost service as the basis of moral culture.

9. The habit should be very early begun, of attending to the dictates of the conscience. Children may be early led to think of them, and be guided by them. We have noticed decided indications of great correctives and strength of moral principle in a child of five years old. It was an important direction, which, we are told, a dying mother gave her son, early to learn to say CRY NO. — Our rule through life should be to enlighten and obey the conscience; and the rule cannot be acted upon too soon.

10. Though the moral sensibility of the mind should not be allowed to degenerate into frivolous scrupulousness, it should be kept lively, and made extensive in its application. In connection with this principle, we may farther observe, that the mind should not be too much accustomed to actual or fictitious scenes of criminality. Buchanan relates, that the scenes of brutal sensuality and barbarous cruelty, with which the worship of Juggernaut is attended, seem to produce little painful feeling in the minds of the English officers, who reside near the temple of the East Indian Moloch. "They said, they were so accustomed to them, that they thought little of them; they had almost forgotten their first impressions." The vivid feelings of the conscience will, in all probability, be heightened by intercourse with the world; but they should not be worn out before the moral principle, from habitual exercise, has gained power enough to do without them.

11. The fact referred to in the last paragraph is only one instance of the operation of a most important principle, a principle of the most extensive application; that feelings become less vivid by repetition, while habitual motives become more powerful by exercise. Be the habit what it may, the effect of custom is to increase its power. We find it to be the case in those little peculiarities of glee, of tone, of look, which give the external characteristics to the individual; and still more so, in our mental and moral processes of every kind. Its influence extends to our trains of thought respecting the past and present, to the operations of imagination respecting the future, and to our internal motives and habitual tendencies. Appetite, thought, emotion, passion, desire, affection, and action, are all subject to the same law. With respect to feelings, repetition gradually leisens their vividness. This is the case with the feelings of compassion, for instance, excited by the frequent contemplation of fictitious, or even of real distress. The sensibilities which are designed to excite to benevolent exertion, and which, if thus employed, while they become less ardent, will produce more and more confirmed habits of active benevolence, if they are allowed to spend themselves in mere feeling, lofe not only their vividness, but their vigour. They may continue to delude their possessor with the idea that they have really the feelings of compassion, because, from long habit, the tear flants at the tale of woe; but if compared with their former state, they would appear lifeless; and they must be pronounced worthless, because they are unproductive of any efforts or privations for the good of others. It is true, there are, in many instances, means of increasing the causes of feeling, where the same causes would lose their efficacy, at least their impressiveness. The pleasures derived from the discharge of duty, for instance, are all self-consistent, and they spring from such numerous and copious sources, that they increase by employment in activity and vigour, as well as purity; but we think it cannot be denied, that even these lessen in vividness, in the middle and later periods of life. Such indisputably is the general law of our frame. Familiarity with any feeling or impression renders it less vivid; and the principle leads to an important rule in education, that where it respects important moral views and motives, (which ought to have influence in the mind, but which will be opposed by various external circumstances and internal dispositions,) the one should not be excited, nor the other produced, except when the underflanding and affections can be made to receive them, so that they may contribute something towards the formation of the character. Connected with these remarks we must add, as what may be of use, especially in the later periods of education,

12. That the feelings should never be excessively excited. [We are aware that such statements are indefinite; but our object is to lead judicious parents to think on what we regard important principles of the human mind, and to attempt the application of them.] Repeated and strong excitement of feeling is usually followed by inability to derive pleasure even from those external objects, which, if the mind were in its natural state, would readily yield to it; by inability to relish the common comforts of life, or to engage with satisfaction in its common duties; and, indeed, for a time at least, by inability to enjoy again those emotions, which, while they lasted, seemed to raise the mind to the highest pitch of delight. Excessive excitement of feeling, be the object what it may, is always attended with similar effects; and those ought to be most carefully guarded against it, who are most prone to it, whose feelings are lively and imagination strong. It is very apt to make the thoughts and desires centre in personal happiness. There is a virtuous, a religious sensibility; and where this is properly regulated, it conducts to high excellence of character; but there is also a selfish sensibility, acutely alive to every feeling and want which respects itself; there is a morbid, a sickly sensibility, which confines itself in feeling, which seldom produces any valuable exertion, which shrinks from self-denial and privations, which makes even benevolence itself a burden; and this is often originally produced or greatly cultivated by excessive excitement of feeling. Where the sensibility is directed in a religious channel, there is often great necessity for caution. Where the feelings are not employed as the actuating motives to that regulation of the dispositions and the conduct, in which religion really consists, however much they may be made to light up the flames of envious emotions, of imaginary piety, they will by degrees lose all their real worth, acquire a merely selfish character, and at last sink into a state in which the whole power of religion will be lost. Wherever the parent perceives such tendencies of the mind, as may conduct to these deplorable effects, they should be peculiarly careful to lead their children from the indulgence of feelings which have no direct reference to duty and the welfare of others, and from the excessive indulgence of any; to lead them, as much as possible, to employ these feelings in some useful channel, and to attend to the common concerns and duties of life; and to confine them, (not of course by compulsion,) in a great measure, to those pursuits, whose direct tendency it is to strengthen and cultivate the powers of the understanding, to the partial or entire exclusion of those which enliven and excite the sensibility and the imagination. And the same means may be of service, where the period of parental education is at an end.

13. Though we cannot enlarge upon the observation, yet we must add, that the cultivation of genuine openness and strict veracity is of the utmost consequence, for their own sake, and in connection with the moral progress in general, and especially with the habit of integrity in all its branches. The habit of truth should be the object of solicitous care,
MORAL EDUCATION.

both because it deserves it, and because it requires it. Under the head of Memory, in Intellectual Education, we have already made some remarks on the grand mental cauæ of falsehood. Fear, in all its directions, (whether of sensible pains or privations, of parental displeasure, of disgrace, &c.) is the most powerful moral cauæ, and firmness of mind, and habitual confidence, must be cultivated with a view to prevent it. If no deception (we go beyond the direct employment of actual falsehood) be ever employed in our intercourse with our children; if truth, in all its branches, be constantly the subject of our approbation, and departures from it, (however marked with ingenuity, wit, or even good intentions,) of our disapprobation; if our reproofs and punishments be not too severe; if the consequences of ill conduct be as far as possible alleviated, where followed by a frank avowal of it; if confidence be given with caution that it be not misplaced, (and thus falsehood encouraged by success,) yet that caution do not degenerate into suspicion; if wilful departures from truth be uniformly associated, in a reasonable degree, with their natural effects in a want of confidence; if more direct and powerful punishment be employed where this means is inadequate,—as it sometimes will be, since, without deception, we cannot give the idea that we disbelieve the lying child as much or as long as the lying man;) if moral and religious principle be employed, as occasion may require and direct, to aid the representations of prudence; the effect of all will be decided and permanently beneficial; the love of truth, and the habit of veracity, will grow and flourished; falsehood will become the object of shame and abhorrence, and will be habitually and carefully shunned, as an evil of incalculable magnitude. Miss Edgeworth's Chapter on Truth, we have already referred to. Those who follow us with satisfaction in our next division will, in some instances, go farther than the does: but it is an excellent chapter; and some of her tales in The Parent's Assistant will afford a real assistance to parents, in the cultivation of this invaluable quality, and of integrity in general.

14. Some other hints, respecting the means and manner of cultivating the moral sense, may be derived from the remarks in the next general division; and we shall only add here, preparatory to it, that the cultivation of the religious principle is of the utmost consequence, to give vigour, stability, purity, and correctness to the conscience.

IV. Early religious Education.—Religious truths are those which immediately respect the character of God, and his dealings with mankind. Religious affections are those which gradually rise up in the mind from impressions, or reflections, respecting the character and dealings of God; for instance, gratitude for his goodness, awe of his power, reverence for his greatness and knowledge, fear of his displeasure, desire of his approbation, obedience to his will, confidence in his wisdom and mercy. When religious truths are accompanied with the corresponding religious affections, and thereby influence the conduct, they are called religious principles; and the affections themselves, when they influence the conduct, are also called religious principles. A man cannot be said to have religious principles, merely because he believes there is a God, and has right ideas as to his character and dealings. Religious truth may be posessed, without its influencing the heart and life; and when that is the case, a man cannot truly be said to be a religious man, nor his principles religious. Whatever those opinions and desires are, which influence the dispositions and the conduct, those are our principles; and if they are inconsistent with religion, or at least have nothing to do with religion, we are not religious, and cannot be said to live religiously. It appears desirable to mention these things, plain as they certainly are, because many, it is to be feared, imagine that they are giving their children religious principles, when they are only teaching them religious truths. If these influence the conduct, it must be by their exciting hopes and fears, desire and love; if awe and reverence, love and gratitude, the desire to please, and fear to offend, be not produced in the youthful heart, it is of comparatively little consequence that we teach them to repeat, or even to understand the most important truths respecting God. Religious knowledge may exist without religious affections; and it is perhaps because this distinction is not sufficiently observed, that so many unhappy supposes that religious principle is easily acquired, and even that it will come of itself. Where the understanding is tolerably well cultivated, a considerable degree of religious knowledge may be gained by any one without much trouble. We have only to read our bibles, and we will learn from them the most important truths. We have only to frequent the house of religious worship and instruction, or read such books as are accessible to almost every one, and we shall be able to gain pretty clear and accurate views as to the import, and extent, and connection of those truths. All this is very useful, and it is an excellent foundation for right affections; and it serves to strengthen and enliven them, where they have been formed: but all will do without the affections themselves. Perhaps it may be truly said, that a young person, of a good understanding, and a ready retentive memory, may gain, by a day's instruction, an acquaintance with all the grand leading truths of religion. But can any one truly affirm, that thus the love and fear of God may be acquired, as habitual affections of the mind; that thus they may be made actuating principles of the conduct? Daily experience must convince us, that it is only by careful and long continued cultivation of those affections, that we can give them sufficient power to enable them to regulate our conduct and disposition; and this even where they have happily been early and successfully implanted by wise and religious parents and friends: and experience must convince us how difficult this cultivation becomes, where it has been early and long neglected; and this in proportion to the degree in which it has been neglected, in proportion to the degree in which our prevailing habits and dispositions are consistent or inconsistent with religious principle.

With respect to the communication of religious knowledge, the business of parents is, in the early stages of education, comparatively plain and easy: indeed the chief danger is attempting to do too much. The progress of the understanding is necessarily slow; and as much injury may be done by endeavouring to hasten it too much, as by suffering it to go on without direct cultivation. We must, therefore, aim to proportion the communication of truth to the faculties of those who are to receive it. The most important truths respecting the attributes and dealings of God are the most simple; and though even these cannot be fully comprehended by a child, yet they can be so far understood, as to lay the foundation of religious affections and of religious conduct. It may not be desirable, in the earliest periods of instruction, to communicate all those truths together, or to dwell long at a time upon them: opportunities too should be chosen, when the little mind is alive and active, but at the same time disposed for thought; but they should be frequently chosen. When once some notions respecting God have been introduced into the mind, they should not be allowed to escape, nor to lie unemployed, but should often be repeated, and connected with various other thoughts.
MORAL EDUCATION.

thoughts which naturally lead to them, and particularly with those which are pleasing, and likely of themselves to be repeated. For instance, children should be taught, when any observation of their own leads them to it, that it is God who keeps us alive; that it is God who takes care of us, that he made the different objects which attract their attention, that it is he who makes the leaves and the grapes grow, and the fields look beautiful, &c. Need we apologize for this minuteness? If it should prove useful to any of those respectable mothers who are endeavouring to give their children early religious knowledge, or to any of those who may hereafter fill that important relation, we are satisfied.

Perhaps before any ideas respecting the Supreme Being are introduced into the mind of a child, circumstances may have led the parent to speak to him of the good Jesus. Most persons who have access to, and opportunities of seeing the children pictures of the gospel history; and though these may not suit the taste or understanding of those whose minds are cultivated, yet if they are tolerably correct, they have a very important effect in giving distinct and vivid conceptions respecting our Saviour, and thereby produce an interest in several circumstances related in the gospels, which may be made intelligible to a mind scarcely capable of receiving the idea of God. But when a child has been taught the leading truths respecting God, then the chief truths respecting Jesus should be connected with them: for instance, that he was sent by God to tell us that we shall live again, and to teach us what God would have us do, how we may please God, and what will displease him. If we do not think it necessary to go beyond the plain declarations of our Saviour himself, in relation to his nature, little or no difficulty can attend our instructions respecting him: they may be made intelligible and interesting to those who are too young to form any very distinct idea respecting the Supreme Being, and at the same time tend to aid the recurrence of the thoughts of God, when they have been formed.

Children at first, probably always, conceive of God as having a human form; but though this can scarcely be prevented, and may not be injurious in the earliest periods of their religious culture, yet we ought to avoid fixing the idea in their minds by any visible representations of the Supreme Being. We have seen such representations; and however unexceptionable in themselves, (which all are not, for some are calculated to destroy devotion,) we are satisfied that they ought to be left in the way of children. The use of them may aid the conceptions in the first instance, but they will afterwards have a directly contrary effect, and they must impede the refinement of our ideas. Our aim should be, to proportion our instructions respecting God to the understandings of our children; and we should therefore at first confine ourselves to the most simple and impressive truths; but it should always be our endeavour, though we cannot communicate the whole truth, to give them nothing but the truth. Children will form imperfect and incorrect ideas, which will be gradually improved and corrected afterwards; but, if possible, an express declaration on the part of the parent should never be such as must be, or ought to be, rejected, as the understanding becomes more matured.

When and how shall we begin to teach our children respecting God? Las, we doubt not, been the solicitous enquiry of many religious parents. "To feel the full force of the idea of God," says Mrs. Barbauld, in the preface of her admirable, and indeed invaluable, hymns, "a child should never remember the time when he had no such idea;" and in this sentiment we cordially agree. As soon as the understanding of a child appears sufficiently unfolded to form some notion of the infection and agency of an unseen being, the first opportunity which presents itself should be chosen, and a few impressive thoughts introduced, which afterwards, in all probability, will often excite the enquiries of the child, and lead on to the gradual communication of all that is necessary. At what period the understanding may be expected to be thus unfolded, cannot, we imagine, be exactly specified; but it will probably be found to be before the age of three or four years. Nor can any definite advice be given respecting the mode of first introducing these thoughts; but if a parent be sufficiently defirous of finding opportunities, they will not be long wanting, particularly in reference to the younger children.

There can be little doubt that the best mode of early religious instruction, is by conversation; and that in almost every period of it, this should, as much as possible, be encouraged, provided that care be constantly taken, to make it consistent with the reverence with which we should always think and speak of God. But it will seldom be long after a child has learned something of God before he is able to read respecting him. His attention should then be led to some of the most impressive and interesting passages of the Bible, with which parents should also make themselves familiar; and perhaps not long after it may be desirable to lead him to learn some of the most striking expressions respecting the attributes of God; such for instance as are contained in the 103d, 139th, and 145th Psalms. In this state of religious instruction, some of Mrs. Barbauld's hymns may be advantageously read, and perhaps committed to memory; as also some of Dr. Watts's, either in the state in which they were left by the author, or as altered by later editors (according to the views of the parent; and for the same purposes, we cannot but mention a very superior little publication, entitled Hymns for Infant Minds. Many of these hymns are in every respect unexceptionable, containing simple, affecting, and often elegant statements, of the fundamental principles of piety, and of Christian truth and duty in general; and the rull may, in private use, be either altered, or omitted, at the discretion of the parent. They proceed, we believe, from the same source as 'My mother,' the delight of affectionate children, and (except the last verse) truly excellent in itself, and in its effects on their minds. About the same period, (which will probably be about four or five years of age,) the plan of catechizing may be advantageously begun. A first catechism should be very short, and as simple as possible. The grand advantage of this mode of religious instruction is, to lead to conversation, and to the gradual explanation of the more usual terms respecting religious truth and duty, which will essentially contribute to prepare the way for further instruction. "It is objected to catechizing," (says Dr. Priestley, in the preface of his catechism for children,) that, in this method of instruction, we teach children the use of words, before we can possibly give them adequate ideas of their meaning; and therefore, that we only lead them to entertain a confused and wrong notion of things. But this is, in fact, the case with almost every word a child learns; and there is no remedy for it. Children learn all words mechanically, by imitation; and from the same principle, will even repeat them in connection with other words, long before they have any tolerable idea of their meaning, as may be found by questioning them about the words they use. But by using them themselves, and hearing other persons use them, in a great variety of connections, they learn their true sense by degrees. This, however, is always a work of time. Besides, an imperfect knowledge of things is often better than no knowledge at all. In this
MORAL EDUCATION.

this case, if a child do but entertain a very imperfect idea of God, of his duty, and of a future state, he will get such ideas as will be of some use to him at present, but of much more use as he grows up; and they will be of much more use then, for having been improved early.

We are decided advocates for the early employment of the memory in the acquisition of religious knowledge; and in laying up a store of devotional compositions and expressions.

The full force of what is thus acquired cannot be understood at the time; but such expressions serve as a bond of affection for the ideas derived from future impressions, and make these more practical; and at the same time prepare a fund of the most valuable and interesting occupation for the mind, when, from weaknesses or depression, the higher intellectual faculties cannot be exerted. On this point, however, we have already offered some remarks in the section on Memory in Intellectual Education; and we shall only observe, that from our own experience we feel confident that such occupations need not, in any way, impede the pleasures of childhood.

Children who are properly trained," says Mr. Edgeworth, (Prof. Ed. p. 91.) "employ their thoughts or serious subjects, without being urged to it." We have known the voluntary (and indeed un marshalled) repetition of Dr. Watts's little hymn, beginning 'Great God to thee my voice I raise,' (in a tone of fervent sweetness, simplicity, and quiet enjoyment, which we shall never forget,) cheer a wakeful hour of the night, when the little creature (then between five or six years old) could not have any impression to destroy the feeling of solitude, and foresaw to a tranquil compofure, which made her fay, when spoken to by her parents from an adjoining room, that she was very happy. Such circumstances should never be made the subject of commendation to a child; but we need not fay, that they reward the parents' efforts and solicitude, as the early promise of moral worth.

Children cannot be too familiar with the historical parts of the bible; and with these other parts which will abifull in cultivating their ideas with respect to God and duty. To give them a few general notions of the scripture history, they may learn some short historical catechism (e.g. Dr. Watts's, either in its original or altered state); and when they are old enough to understand a regular abridgment of the bible, a simple and correct one, (such a one, we should fay, as Mr. Turner's,) will be found of great service in connecting together the separate narratives which they read or hear.

It will also be of great importance, that parents should do what they can to enable children to understand what they read; and here they will find the knowledge which they have themselves acquired, from various sources, in the earlier part of their lives, of singular advantage to them. If unhappily they have too much neglected the acquisition of such knowledge, still if they are in earnest in the work, they will avail themselves of any opportunities in which they may have of gaining the requisite information; and perhaps it is not one of the least advantages attendant upon this branch of religious education, that it makes a parent's own knowledge more complete and practical.

In the early periods of religious instruction, the object must be to communicate knowledge gradually; in the later periods, to cultivate such a taste as will lead young persons to seek for themselves the sources of knowledge. If the cultivation of the religious affections go hand in hand with the communication of religious knowledge, some interest will be felt in all religious knowledge which is intelligible; and the field is so wide and interesting, and valuable and instructive books are now so much in the power of every one, that if a young person have acquired that taste, and it is sufficiently con nected on the part of the parents, particularly by early habit, the leisure of the Lord's day at least will seldom fail to be given to the pursuit of religious knowledge.

It is of great importance in early religious instruction, that we should not attempt to explain to children what is beyond the actual state of their understandings; but accustom them to wait patiently until their minds are more advanced. If parents sufficiently profess the confidence of their children, they will be readily satisfied when they are told, with respect to any difficulty, that they cannot understand that now, but that those who are older, and know more, do understand it, and they will too. Where we can make them fully understand the reasons of our own conduct, or the reasons of what they know of the dealings of God, this should be done; and their inquiries should be encouraged; but even with respect to our own plans and intentions, they must often exercise confidence and submission; and it is wise early to produce the fame with respect to the dealings and commands of God. They can, in some cases, be made to perceive that they now understand what they did not at some past period; and still more easily, that they can themselves understand what their younger brothers and sisters cannot. As they advance in observation and understanding, and make inquiries with respect to the providence of God, it will sometimes be necessary to go further, and impress upon their minds the idea that there are some things which we ourselves, and even the wisest of mankind, cannot fully understand, but that in heaven we shall know more, and shall understand what we now cannot. To keep up a disposition to re search and inquiry, is highly important; but it is also important to regulate the understanding and imagination of the young, that they may be prepared for difficulties; prepared to expect that in the works and ways of God they shall meet with what they cannot understand; to feel confidence in the great truths of religion, though accompanied with difficulties; and to obey even where they do not see the reasons of the commands of God.

Though religious belief must, in the early periods of life, be chiefly founded upon authority, yet we ought, as circumstances permit, to render it rational, by shewing the grounds of it. The convictions arising from early education, founded solely on parental influence, are, indeed, often as effectual in regulating the conduct, and so far as valuable as those which are the result of individual examination; but it will too often happen, in this age of inquiry, that where this is the only foundation, those convictions will easily be shaken, especially where they oppose wrong dispositions. Important truths, of the full foundation of which we are ourselves firmly con vince, on patient examination of their evidence, should be early instilled into the mind, even when the grounds of them cannot be shewn; they will indeed to a certain extent be prejudices, but so are all the convictions of children, excepting those which they derive from the evidence of their senses. It is a part of the wise ordinations of providence, that before the understanding can properly exert itself, a lively belief may be formed in truths of importance for the conduct of life; and by producing that belief, we not only do what is necessary for the right direction of childhood and youth, but we in reality give the best preparation for what is emphatically called a rational faith. And this will be easily formed, if we have been careful to communicate truth only. The proofs of the being and attributes of God may be made intelligible even to children. They may early be taught some of the grounds of our belief in the divine authority of Jesus Christ; and at a subsequent period, of our belief in the genuineness of the Scripture. As they advance in life, books may be put into their hands, which will most materially assist in forming a rational conviction; and in this connection we cannot but strongly
We cannot flatter parents by saying, that the religious instruction of the young can be conducted without steady efforts on their parts; but their duty is plain, and their reward will be great. Notwithstanding the circumstances and the fashions of the times, one day does in a great measure remain our own; and we earnestly wish that parents would have the firmness to make its employments and pursuits such, that that day, at least, may bring with it the expectation and desire of religious instruction. This is taking the most favourable case; but a mother, and it is from maternal influence and exertion that we must expect most in the early periods of education; a mother, if not immersed in the occupations and pleasures of life, will often find opportunities of giving religious instruction, and of strengthening the desire to attain it.

In a former part of our article, we spoke of the filial affections as the best foundation for the religious affections. Where love and gratitude, and submissiveness, have been formed towards the earthly parent, they will easily be transferred to our heavenly Father. Where these, from any cause, are wanting, they can only be gradually supplied, as the understanding and conscience open, by the same impressions with respect to God, by which they are produced with respect to the parent. The religious affections will often be found to bear a great resemblance, in their peculiarities, to those of the filial affections; and this is particularly the case with respect to the disposition to obedience. We have no hesitation in pronouncing submissiveness to parents to be, very generally, almost an indispensable requisite to the early formation of that disposition to obey God, which is the object of all religious culture, and without which the most lively affections are worthless. If a child love his parents, if he even fear them, it does not necessarily follow, and the contrary too often happens, that he has the habitual disposition to obey them; and if love and fear exist towards his parents, without that disposition, they will not in all probability early produce it towards God; and if they do not early do it, they too seldom will at any future period.

Where filial love has been produced in the mind of a child, love towards God will go hand in hand with an acquaintance with his goodnens in its various forms. Before the understanding of a child is sufficiently unfolded, to form some notion of the inspection and agency of an unseen being, (which appears to be the proper period for the commencement of religious instruction,) there will be feelings in his mind, connected with the expressions good, kind, doing good, taking care of, &c. Suppose a mother, when first communicating some knowledge of God, speaks to her child of the good God who is very kind and good to us, is always doing us good, and taking care of us, &c., it is obvious, that the feelings already connected with those words, will become connected with the word God, and with whatever notion the child may form of God; and thus the beginning is made of love to God. We tell our children that God loves us, and is our heavenly Father; and the love which they have towards us, begins to unite itself with the idea of God. Where we have ourselves right feelings towards God, they will often influence our tones and manner of speaking; and these, by the influence of our associated nature, call up and exercise similar feelings in their minds, and thus unite them more firmly with the idea of God.

If we are sufficiently in earnest in cultivating the religious affections of our children, we shall find various opportunities of giving them proofs of the goodness of God, suited to the state of their understandings, in the works of nature around us, in the formation of our frame, in the events of life, &c., and while seeking for these proofs, for the cultivation of their affections, we shall cultivate our own. We shall lead them to think of God as the giver of every good thing. And we shall often speak of him as having sent our Lord Jesus Christ to teach us how to be good and happy. We shall tell them that he loves those who try to please him, by being and doing good. We shall shew how much good it does to us, to do what God has commanded us; and we shall often speak to them of that world, where God will for ever make the good happy, happy beyond anything we can now think of. As opportunity offers, and the understanding will bear it, we should explain, as far as we are able, those things which at first sight appear inconsistent with the goodness of God; and especially, we should lead them to feel complete confidence in the divine goodnens, though they cannot perceive that all things are for good. Filial confidence should be early and carefully cultivated towards the parent, and then it will be easily transferred towards God.

Though we should frequently introduce thoughts of the divine goodnens, we must be careful to take opportunities for this purpose, when the minds of our children are favourably disposed to the reception of them, when the attention will be excited by them, and thus some impression produced. And, considering how short the time must be, during which the attention of a child can be given to thoughts of an unseen being, we should rather aim at frequency of impressions, than at the long continuance of any one.

We have only spoken of the cultivation of the religious affections, by conversation respecting the divine goodnens; but it is obvious that this is only one means. The delightful representations of God, which are given in the Scriptures, and all that children read in other books respecting his goodnens and mercy and paternal care, and all that they hear from the same purpose in the public services of religion, will, if sufficiently attended to, contribute their share towards the early love of God, by calling into exercise the affection which is already formed, and by leaving new impressions which will contribute to its liveliness and vigour. And there are two other most important means, the one is leading them to express their feelings in prayer to God; and the other, to guiding their conduct and dispositions by precept, discipline, and example, that they may think of God with pleasure, because their own hearts tell them that he views them with approbation.

It will not be necessary for us to be equally minute in shewing the formation of the fear of God. Nearly the same means of culture must be adopted; but our success will be more sure. Pain affects the mind more powerfully than pleasure; and fear, which springs from pain, is, therefore, more active and easily formed than love, which springs from pleasure. It is, perhaps, impossible, that the fear of God should not spring up in the mind, where tolerably correct ideas respecting him have been communicated. Every thing which is attentively heard or read, reflecting the greatnens, majesty, power, and justice of God, tends to produce the awe and fear of him; and this is heightened by the declarations of the Scriptures respecting the dreadful consequences of disobedience to the will of God. While we endeavour early
early to cultivate reverence and awe of the Supreme Being in the minds of our children, we must, however, be careful not to heighten it into terror. A due proportion of the fear of God, is, in general, necessary, to render the love of God a steady actuating principle of the conduct; and when properly blended with it, and moderated by frequent recurrence, (as all feelings are, unless otherwise enlivened,) it in reality increases it; but often has the exclusive cultivation of fear been the fertile source of superstition, and of degrading ideas respecting the God of love; and still more frequently has it contributed to destroy the influence of religion, by making the thoughts of God painful to the minds of the young, and thereby destroying all disposition to cherish them. We remember hearing a person of great piety, benevolence, and amiableness of disposition, express the idea, that in all her endeavours to cultivate the love of God, she continually felt the ill effects of the terrific views of the Supreme Being, which had been early impressed upon her mind, almost to the exclusion of those representations which would have excited love. She was fully convinced of the goodness of God; but fear seemed to overpower her convictions, at least to prevent their exciting their due proportion of love; and the lovely and paternal attributes of the Supreme Being were seldom a source of delight and consolation to her mind. On a heart left pure, and a judgment left enlightened, either superstition or practical atheism would probably have exercised absolute sway.

We have more than once stated, that the religious affections may exist, even with a considerable degree of vividness, without having much power in regulating the heart and life, without becoming religious principles, i.e. habitually actuating motives. Our object throughout, in our endeavours to bring up our children religiously, must be to give the affections which we cultivate in their minds towards God, as much power as possible as actuating motives; to give them as much influence as possible over the other dispositions and the conduct. We are not to leave this till the affections, by frequent impressions, acquire great firmness and vividness; but to aim to give them their proportional influence in every stage of their progress. A child who is capable of understanding somethings of the inspection and agency of the unseen God, who has at all learnt to define his love, and to fear his displeasure, is capable of being influenced by religious motives. This we know from experience. That the religious affections may subsist, without properly influencing the conduct, may be understood from what happens in the case where submission has not been cultivated in a child through the false indulgence of a parent. Such a child is frequently found to be very affectionate, and often manifests a warmth and strength of love which forcibly delight the parent's heart, and yet excite regard to a parent's feelings and dispositions, only where its own little selfish gratification prompts to such regard. In like manner, lively compassion to the distressed may exist, and often does exist, even in young persons, without exciting one active endeavour to relieve. And their religious affections may exist, and even with considerable liveliness, (especially the feelings of love and gratitude,) without acquiring any influence over the heart and life.

Our aim then must be to give them this influence; and in proportion as they acquire it, will the affections themselves acquire activity and vigour. It cannot be doubted that religious obedience is the best means of cultivating, supporting, and confirming the religious affections; that habitual regard to the will of God, where ideas respecting him are tolerably correct, will always cherish the love of God where it exists, and will gradually produce it where before it did not exist. He who is brought up in the fear of God (we do not mean literal terror but reverential awe), and under its influence has acquired a habitual regard to his will, will not be long deluded of those feelings with respect to him, which the thoughtful contemplation of the Scripture declarations is so well calculated to excite.

The foundation of such regard to the will of God, is to be laid in the mind of a child by forming the habit of filial submission to his parents: and where this, to any great degree, is wanting, the difficulties of obedience to the will of God will too generally prevent the formation of that actuating regard to it which is the sum and substance of religious principle. Parents should, therefore, as much as possible, acquire influence over the minds of their children, if from no other motive, with a view to make them religious. We cannot too strongly impress it upon our minds, that habitual filial submission to earthly parents is the best foundation for habitual filial submission to our heavenly parent.

Another point is, that we early accustom our children to consider it as an object of the first importance, that they should do what God commands, and avoid what he forbids; unsparing to them, as circumstances enable us, the consequences of obedience and disobedience in this life; but particularly impressing upon their minds the more certain and obvious confessions in another life. Whether we should most excite their hopes or their fears, must perhaps be left to be determined by their peculiar dispositions and habits; but, without a doubt, both should be employed as occasion directs; and they should, from a very early period, be led to consider it as certain that we shall all live again, and be happy or miserable according to our conduct and disposition in this life. I do not mean that these motives should be brought forwards too often, for thus they may lose their force; but on all occasions where the mind seems capable of feeling their force, and of being influenced by them, then should they be employed.

Where these hopes and fears exist with tolerable strength (or even where children have learnt the rudiments of religious knowledge, and have been accustomed to define the love, and to fear the displeasure of their parents), the idea of God, as the constant witness of all their words and actions, will often produce the desire of his love and approbation, and the fear of his displeasure. This powerfully aids the influence of the religious affections; and the impression that God loves the good, and is displeased with the wicked, should be early produced and frequently exercised. When influences of truth, obedience, kindness, disinterestedness, and the like, in our children, have obtained our own approbation, with our tender endearments should often be connected the idea, that the great and good God, our heavenly Father, who always sees us, is also pleased with them and loves them. When the contrary faults have excited our displeasure, with our reproof or correction, we should occasionally introduce the impression of the divine displeasure; carefully, however, connecting with it the idea, that as they may regain our approbation, so they may also regain the approbation of God.

Further, we should early accustom our children to consider what our duty is. For this purpose, we must make them early and well acquainted with the practical parts of the New Testament; often bring them to their recollection in connection with what is right or wrong in their conduct, and teach them to consider the precepts of Jesus and his apostles as our rule of life, which we must obey if we would please God, and avoid the punishment of disobedience. We should certainly endeavour, where we can, to throw them these reasons of the divine commands; and this more and more as their understanding gains strength; but let it be obvious to
MORAL EDUCATION.

them, that we do ourselves consider it as quite sufficient, if God has commanded us to do, or to avoid any thing. Let us, by every means in our power, inculcate the necessity of obedience to the will of God, and form and strengthen the dispositions to submition; and let us habitually cultivate the impreasion in their minds, that the example of Jesus, and the precepts of the gospel, give us certain information as to the will of God, and that it is our duty steadily to guide our dispositions and conduct by them. It will add the influence of the example of Jesus, if we cultivate as much as possible that love to him, and gratitude for his exertions and sufferings to do us good, which will readily spring up in the young mind from the thoughtful perusal of the gospel history; and it will greatly aid the power of religious principle, if we often lead them to consider what he did, or what he would have done in like circumstances with us. For a similar reason, we shall do well to make them acquainted with other illustrious examples of Christian worth, particularly among the young; and all have one book at their command in which they will find a store of such examples as have, in innumerable instances, been highly beneficial.

Another point of great importance is, that we early accustom children to reflect on their actions and dispositions, and compare them with the Scripture rules of duty. A want of this tendency to reflect on the past, is one cause of that deficiency which we often observe in the power of the conscience, even where its dictates are correct. It should be exercised as soon as our children are capable of recollection and reflection; and it will lay the foundation of a most important habit, if we accustom them, as soon as their minds have made sufficient progress, every evening to think over the conduct of the day. Such an employment, early pursued under the observation of the parent, encouraged, and indeed at first exercised, by parental aid and influence, will have the most valuable effect. It will produce an habitual disposition to self-inspection; it will make duty more thought of, and obedience to duty more an object; and it will, if steadily cultivated, become itself a habit which will retain its influence through life, and effectually prevent that thoughtlessness as to our conduct and the effects of it, which is among the foremost ranks of the causes of disobedience and neglect of Christian duty.

Once more, as soon as our children are capable of it, we should teach them to pray to God. By praying, we mean expelling to God as ever possible with us, the dispositions and habits in which we have of his being and perfections, the feelings which those sentiments excite (whether of gratitude, reverence, love, fear, or repentance,) and our supplications for future good. At first it may be necessary to supply our children with words; if so, they should be simple but expressive, and the whole should be very short. We may by degrees lead them to express their thoughts and feelings in their own words, and the more this is done the better; but whatever means we employ, they should be used regularly, and at least daily; and by our own manner and expressions, we should always make this exercise of the devout affections fervent, reverential, and impressive. When right ideas and feelings towards God have been duly impressed, prayer early made habitual, exercised regularly, fervently, and thoughtfully, is perhaps of all the most powerful means (and a most powerful stimulant of all other means) of cultivating the devout affections, of making them actuating principles, of producing a steady, habitual, reverential regard to the will of him who always sees us, knows every purpose of our hearts, and will finally be our judge. And (at the risk of being thought to have altogether left sight of the nature of our work) we feel impelled to add that family worship should go hand in hand with private prayer. Independently of its great importance to ourselves, there is no doubt that it eminently contributes to impress deeply a sense of religion on the minds of children and domestics, and to aid the influence of its functions.

The cultivation of religious affections and principles, must be expected to be a work of time; and it should be our endeavour to proceed in it steadily rather than quickly. The growth of affections and habits cannot be forced; and we may, by too great haste and too little attention to the natural progress of the mind, prevent, rather than promote, the influence of religion in the heart. It must be our aim to choose opportunities for this purpose, when the mind is in a fit state for the reception of religious impressions; to seek for them often, to make our instructions interesting. The point must not be given up because we do not succeed all at once; if some means fail we must try others, employing the influence of religious fear or love, as we find the dispositions of our children require it, but endeavouring, by every means in our power, to give their young minds a permanent bias in favour of religious principle. We must make religion as interesting as we can to them, but never lessen their reverence for it, nor their ideas of the necessity of obeying the divine will.

We must not consider religion as confined to the affections, dispositions, and habits, which directly respect God, but bearing in mind that every right disposition and habit constitutes a part of it, and contributes to increase its influence, that every wrong disposition and habit is forbidden by it, and contributes to increase its influence,—we must do everything in our power to cultivate and cherish the one, and to check and repress the other. Nothing destroys religious principles sooner, than the indulgence of sinful dispositions and sinful habits; and he who would have his child religious, must carefully guard against whatever would lead to them. In the words of the great Hartley, "affectionate parents" should "labour from the earliest dawns of understanding and defire, to check the growing obstinacy of the will; curb all failies of passion; impress the deepest, most amiable, reverential; and awful impressions of God, a future state, and all sacred things; restrain anger, jealousy, selfishness; encourage love, compassion, generosity, forgive-ness, gratitude; excite, and even compel to, such industry as the tender age will properly admit of." These words may be said to contain the form and substance of religious and moral education; and those who have leisure and ability to study the principles of that eminent philosopher, as contained in his Observations on Man (and especially as respects our present object, in the Rule of Life, contained in the second volume) will find them of inestimable use in the regulation of their own dispositions, and the fulfilment of their duties, particularly in that most important duty, the religious education of the young.

As mothers have, in the early periods of education, peculiar influence, and opportunity of cultivating the religious affections and principles, we carefully wish to see them making this peculiarly an object, cultivating their own affections and knowledge with a view to it, biding their plans of life and their social intercourse as much as possible to it, and regarding nothing short of absolute necessity a sufficient excuse for partial attention to it. And, with the same view, it should be the steady endeavour of all parents to cultivate the underlayings and enlarge the minds of their daughters, to teach them the wise employment of their time, to teach them more noble accomplishments than those of now and talk to implant in their minds,
MORAL EDUCATION.

and steadily to cherish religious affections and principles. While they pay due attention to other branches of knowledge, let them not neglect the knowledge of God and duty: while they acquire those accomplishments that will grace the social circle, and add attractions to goodminds, let them learn to set a higher value on, and more sedulously cultivate, the inward adornings of the mind. They should be educated as those who may be engaged in the most important of all duties; they should be so educated, that, should they be called to fulfil those duties, they may train up souls for immortal happiness.

We wish to add, that early attention to the religious education of our children, needs not in any way lessen the activity or enjoyments suited to their age. We know this from experience, and can speak with confidence. The little girl, to whom we referred in a former part of this division, is as playfully active, and as regularly happy with her dolls, her bricks, her rude drawings, and her out-door amusements, as any child we ever saw. If it were not so, we should fear, lest the religious culture she has received should have been premature and injurious; but we see, in various ways, that it directly, and still more indirectly, promotes her little enjoyments, as well as her mental improvement. We think it proper, however, to observe, that from different circumstances in her situation and early habits, and also, perhaps, from her natural temperament, (which originally manifested too much of what may be termed physical sensibility, and which her parents endeavoured to leisun, or at least to regulate;) this child has peculiar tendencies and opportunities for the religious cultivation of her mind; and in a younger child, though by no means without religious impositions and biases, we have perceived, at corresponding ages, a very material difference in the capacity for receiving ideas, and for forming the rudiments of the affections, respecting the Supreme Being. This we say, lest our remarks should excite any degree of despondency in the mind of any mother, solicitous for the religious welfare of her children; and, in this case, we indulge the expectation, which we may also indulge in any similar case, that by a steady perseverance in the use of suitable means, the end will eventually be answered in the communication of correct ideas and right affections of a religious nature, though the latter will of course be subject to those modifications, which arise from diversities in the original tendencies and acquired dispositions and habits in general.

If our limits would permit, we should be happy to conclude this article by extracting from Dr. Priestley's Observations on Education, the whole of the 17th section, in which the importance of early religious instruction is argued, with the strength of demonstration, from a particular consideration of the principles of human nature. We trust few of our readers will omit to avail themselves of his Observations; but we cannot forbear quoting one or two passages, and giving a brief abstract of the whole.

After observing, generally, that the impression which ideas make upon the mind, does not depend upon the definitions of them, but upon the sensations and a great variety of ideas which have been associated with them; and, in particular, that in the mind of a person who has been accustomed to hear and think of God from his infancy, who has been much conversant with the Scriptures, and has lived in a general habit of devotion, the idea of God must have acquired a thousand associations, forming one complex feeling, which cannot be fully explained to another, and still less communicated to one who has had no such advantages for religious impressions; this religious philosopher illustrates his observation, by the diversity of feelings, associated, in different cases, with the term father, where, nevertheless, the general definition of it must be invariable. He then proceeds:

"In like manner, besides those ideas annexed to such words as God, religion, future life, &c. which can be communicated to others by their definitions, there are what are sometimes called secondary ideas, or feelings, which are aggregate sensations, conflicting of numberless other sensations and ideas, which have been associated with them, and which it is absolutely impossible for one person to communicate to another; because the same education, the same course of instruction, the same early discipline, the same or similar circumstances in life, and the same reflections upon those circumstances, must have concurred in the formation of them. They are, however, those infinitely complex and indefinable feelings that often give those ideas their greatest force, and their influence upon the mind and conduct: because dispositions to love, fear, and obey God have a thousand times followed those complex feelings, and pious and worthy resolutions have been connected with them. On this account, persons whose education has been much neglected, but who begin to hear of religion, and apply themselves to it late in life, can never acquire the devotional feelings of those who have had a religious education; nor can it be expected that they will be uniformly influenced by them. They may use the same language, but their feelings will, notwithstanding, be very different."

Dr. P. then shews, that this is nothing more than what takes place in other similar cases; and next advances some impressive statements, respecting the powerful influence of general states of mind, of habits, and of the affections, in connection with which, we feel impelled to refer our readers to his discourses on habitual devotion, the duty of not living to ourselves, and the danger of bad habits, in which, in a most simple and striking manner, he has made some of the leading principles of mental philosophy eminently subservient to the interests of religion. He urges the importance of early religious education, from the mental influence it affords of reclaiming those who, on the entrance upon the world, may have thrown off the restraints of duty, and from the great loss of favourable opportunities for such purposes, caused by the contrary tendencies. He shews that through unnatural associations of ideas of honour, spirit, &c. with religious and pious habits and practices, and of the opposite ideas with some virtuous and religious duties, every thing belonging to strict morals and religion is by many regarded with aversion and contempt; that, for want of early religious impressions, this turn of thinking may be so confirmed, that nothing in the usual course of human life shall be able to change it; and that the very things which are the means and incitements to religion and devotion, in those who have been well-disposed minds, have the very opposite effect on others. This he illustrates and confirms by additional considerations; and concludes,

"The plain inference from all this is, that if we allow that religious impressions should ever have a serious hold upon the mind, they must be made in early life. Care, however, must be taken, lest, by making religious exercises too rigorous, an early aversion be excited, and so the very ends we have in view be defeated."

This inference, we are fully convinced, is alike founded upon the soundest views of human nature, and by extensive and enlightened experience; and upon it, our preceding statements rest for their justification.

In our last article on the subject (Physical Education), we shall have an opportunity of suggesting some hints on a point of great moral importance; and we shall also defer...
Moral Evidence, Evil, Fables, Good. See the several sublimatives.

Moral Impossibility, is what we otherwise call a very great, and almost insuperable difficulty; in opposition to a phisical, or natural impossibility. See IMPOSSIBLE.

Moral Liberty, Necessity, and Perfection. See the sublimatives.

Moral Philosophy, a science whose object is to direct and form men's manners; to explain the nature and reaon of actions; and to teach and instruct us how to acquire that felicity which is agreeable to human nature. See Moral Philosophy.

Moral philosophy is the same with what we otherwise call ethics, sometimes morality. See also Obligation and Virtue.

Moral Quantity. SeeQUANTITY.

Moral Sense, the faculty whereby we discern or perceive what is good, virtuous, beautiful, &c. in actions, manners, characters, &c.

An ingenious author has endeavoured to prove, that it is a peculiar sense whereby we get the ideas of these things; and denominate it a moral sense. See SENSE.

Moral Theology is that which treats of cares of conscience; called also causality, or causatical divinity.

Moral Universality. See UNIVERSALITY.

Moral of a Fable is the instruction drawn from it. Thus when Phaeton at the end of a fable adds, Hoc ills dictum qui, &c. this makes what we call the moral: the Greeks called it περιπολος, when at the end of the fable; and προτασσεμα, when at the beginning. Among the Latins it was called affabulatio. See FABLE.

MORALEA, a town of Spain, in the province of Leon; 6 miles S.E. of Zamora.

MORALES, CRISTOFERO, in Biography, an eminent Spanish composer of music, in the service of the pontifical chapel at Rome, and who flourished from the year 1540 to 1564. He preceded Palestrina, who was not twelve years old when Morales first appeared as a composer. Several of his productions were published at Venice among those of Cofiando Felia, Adrian Willaert, and Archadelt, with whom he was contemporary, besides the following works, to which no other name was prefixed than his own.

Two books of masses, the first for five voices, the second was dedicated to pope Paul III. for four, 1544, Venice. Magnificat 8 tonarm, 4 voc. Ven. 1562. Lamentations Hieremis, 4, 7, & 6 vocum, Ven. 1564. Adami (Osservazioni, p. 165.) tells us that his famous motet, “Lamentabatur Jacob,” which was prefixed in the archives of the pontifical chapel, at the beginning of the present century, and annually sung on the first Sunday in Lent, is a wonderful composition. “Il quale in vero e una maraviglia dell’arte.” 1b.

Several of his motets were published at Venice 1543, among the “Motette trium Vocab ab pluribus Authoribus compositae,” and are prefixed in the British museum, the style of which, though learned for the time, is somewhat dry, and the harmony, by his frequent use of unaccompanied 4ths and 9ths, uncouth and impish; yet, till supplanting the more pleasing works of Palestrina, his compositions were in very high favour at Rome, in the papal chapel, where he was a singer during the pontificate of Paul III.

MORALES, AMBROSIO DE, a Spanish historian and antiquarian, was born at Cordova in the year 1515. His father, Antonio, was a physician of such high reputation, that the marquis de Pielego presented him the house in which Seneca was said to have lived, saying, that the dwelling of the illustrious Cordoban ought to be inhabited by none but by a Cordoban, who was himself equally wise; and cardinal Cifneros appointed him to the first chair of philosophy at Alcala. Fernando Perez de Oliva was his maternal grandfather, and Ambrosio says, that he availed himself of his learned geographical work, “Imacense del Mundo,” as of a thing which was his own by inheritance. His youthful studies were directed by persons of the highest reputation; he became a good Grecian at an early age, and while but a mere child, he translated the fable of Cebes. Notwithstanding his aspirations after literary fame, religious enthusiasm mingled with, and at one time totally suppletted them. He wrote at the beginning and end of all his books the name of Jesus, with an alpha and omega, and composed the following couplet in honour of the name;

“Dulce mihi nihil esse precor, si nomen Jesu Dulce abit cum fit hoc sine dulce nihil,”

which he transcribed into all his books, frequently using as a motto “Tiempo fué, que tiempo no fué?;” Time was when time was not. Sometimes he would use as an emblem, four ravens flying down with bread and meat in their bills, in reference to Elijah, with the motto “Adjicentur.”

At the age of nineteen he renounced the world, and entered into a convent under the name of “Ambrosio de Santa Paulo.” The world he had already conquered, but in the ardour of youth he had other passions to contend with, and which were not so easily subdued. Determining to secure himself from the sin to which he felt himself most prone, he followed the example of Origen, in the complete and most dangerous way. He recovered from the effects of the wound; his fanaticism sobered down into a quiet and settled bigotry, but it ceased to be a ruling passion. In consequence of this circumstance he was either expelled the order, or quitting it of his own accord. He set off for Rome and narrowly escaped drowning; the danger that he thus incurred he considered as a manifest sign that he was not to proceed on the voyage, and instead of going to Rome for a dispensation to be permitted to remove, he went to court, where his friends had interest enough to procure it for him, and ever afterwards he lived as a secular priest. Soon after this his father died, and he was appointed to a professorship at Alcala. The object of his most ardent wishes was to excel as a Callalian writer, to investigate the antiquities and write the history of Spain. He began to collect materials for this work in 1544, but it was not for twenty years that he set himself seriously to the subject of arrangement in order to publication, and even then he was deterred from advancing under the notion that Florian Ocampo, the famous chronicler, who had published the fabulous history, had also proceeded down to the Gothic period, and written the antiquities also. At length he was undeceived, and found that Ocampo had made no progress beyond what he had published, and on the death of that author he was made chronicler himself. His first appearance as an author was as the defender of Zurita against his enemies. After this he published several other pieces; and having brought down his history to the destruction of the Gothic

S. of Tamalameque.

MORALITIES, in English Antiquity. See MYSTERY.

MORALITY denotes a conformity, in things and actions,
to those unalterable obligations which result from the
nature of our existence, and the neceffary relations of life:
whether to God as our creator, or to mankind as our fellow-
creatures.

For other definitions of morality or virtue, given by some
celebrated writers, as well as different hypotheses relating to
its foundation, see Moral Virtue.

MORALITY is also used for the science or doctrine of mo-
rals, or the art of living well and happily; deduced from
reason, and the nature, relation, and finenes of things.
In this fentie it amounts to the fame with what we omither

calls Ethics, Moral Philosophy, or the doctrine of Offices.

Notwithstanding the great obfcurity and uncertainties in the
moral science, Mr. Locke is of opinion, that the doctrine of
manners is equally capable of being brought to demon-
tration with the doctrine of quantity and number; that is,
with the purest parts of mathematics.

According to this author, the idea of a Supreme Being,
infinite in power, goodness, and wisdom, whose workmanship
we are, and on whom we depend; and the idea of ourselves,
as underftanding, rational creatures; would, if duly con-
dered, afford fuch foundations of our duty, and rules of
action, as might place morality among the fciences capable of
demonstration; in which we need not doubt but that,
from principles as incofincible as thofe of the mathematics,
by nectary consequences, the meafure of right and
wrong might be made out to any one, who will apply him-
self, with the fame indifference and attention, to the one,
as he doth to the other of thofe fciences: for the relations of
other modes may certainly be perceived, as well as thofe
of number and extension. E. g, that "where there is no
property, there can be no injustice," is a proposition as
certain as any in Euclid; for the idea of property being a
right to any thing, and the idea of injustice being the inva-

fion or violation of that right, it is evident, that thofe ideas
being thus established, and thofe names annexed to them,
we can as certainly know this proposition to be true,
as that a triangle has three angles equal to two right ones.
Again, "no government allows absolute liberty:" the idea
of government being the eftablifhment of society, upon
certain rules or laws, which require conformity to them;
and the idea of absolute liberty being for any one to do
whatever he pleases, I am as capable of being certain of the
truth of this proposition, as of any in mathematics.

What has given the advantage to the ideas of quantity,
and made them thought more capable of certainty and de-
monstration than the ideas of good and evil, right and wrong,

1. That the former can be represented by fentible marks,
which have a nearer correspondence with them than any words
or founds. Diagrams drawn on paper are copies of the ideas,
and are not liable to the uncertainty that words carry in their
figuration; but we have no fentible marks that referme
our moral ideas, and nothing but words to express them by;
which, though, when written, they retain the fame, yet the
ideas they fland for may change in the fame man, and it is
very seldom that they are not different in different perfons.

2. Moral ideas are commonly more complex than figures;
whence these two inconveniences follow: 1. That their names
are of more uncertain figuration; the precife collection of
fimple ideas they fland for not being fo easily agreed on; and
fo the flgn that is used for them in communication always,
and in thinking often, does not readily carry with it the fame
idea.

3. The mind cannot easily retain those precife combina-
tions fo exactly and perfectly, as is neceffary in the exami-
nation of the habitudes and correspondences, agreements or
disagreements, of feveral of them one with another, espe-
cially where it is to be judged of by long deductions, and the
intervention of feveral other complex ideas, to chew the
agreement or disagreement of two remote ones.

One part of these disadvantages in moral ideas, which has
made them be thought not capable of demonstration, may in
a good measure be remedied by definitions, setting down that
collection of fimple ideas which every term shall fland for, and
then using the term readily and conftantly for that precife
collection.

The mathematician considers the truth and properties be-
longing to a reftangle or circle, only as they have ideas in
his own mind, which possibly he never found actually exist-
med mathematically, that is, precisely, true; yet his knowledge
is not only certain, but real; because real things are no
further, nor intended to be, meant by any fuch propositions,
than as things really agree to thofe archetypes in the mind.
It is true of the idea of a triangle, that its three angles are
equal to two right ones; it is true also of a triangle, whereby
it exists: what is true of thofe figures that have
barely an ideal eftinance in the mind, will hold true of them
also, when they come to have a real eftinance in matter.
Hence it follows, that moral knowledge is as capable of
real certainty as mathematics: for certainty being nothing
but the perception of fuch agreement, by the intervention
of other ideas; our moral ideas, as well as mathematical,
being archetypes themselves, and so adequate or complete
ideas, all the agreement or disagreement we shall find in
them will produce real knowledge, as well as in mathe-
matical figures. That which is requisite to make our know-
ledge certain, is the clearness of our ideas; and that which
is required to make it real, is that they answer their ar-
chetypcs.

But it will here be faid, that if moral knowledge be placed
in the contemplation of our own moral ideas, and those are of our own making, what strange notions will there be of justice and temperance! what confusion of virtues and vices, if every man may make what ideas of them he pleases? It is answered, no confusion or disorder at all in the things themselves, nor the reasonings about them, no more than there would be a change in the properties of figures, and their relations one to another, if a man should make a triangle with four corners, or a trapezium with four right angles; that is, in plain English, change the names of the figures, and call that by one name which is called ordinarily by another. The change of name will indeed at first disturb him who knows not what idea it stands for; but as soon as the figure is drawn, the consequences and demonstration are plain and clear.

Just the same is it in moral knowledge: let a man have the idea of taking from others, without their consent, what they are justly possessed of, and call this *jusus*; if he pleases; be that the name there, without the idea put to it, will be mistaken, by joining another idea or his own to that name; but it is the idea of that name, or take it, such as it is in the speaker's mind, and the fame things will agree to it, as if you called it *injustice*. One thing we are to take notice of, that where God, or any other law-maker, has defined any moral names, there they have made the essence of that species to which that name belongs; and there it is not safe to apply or use them otherwise; but in other cases it is bare impudence of speech to apply them contrary to the common usage of the country in which they are used.

MORAMEO, in Geography, a river of Africa, which runs into the Atlantic. 8. lat. 17° 55'.

MORAND, SAUVEUR FRANÇOIS, in Biography, a Parisian surgeon of great eminence, was born in that metropolis in 1657, where his father also practised the profession, and held the office of surgeon-major to the Invalids. Sauveur received his literary education at the college Mazarin, and was instructed in his profession by his father at the hospital of the Invalids. He rose to the malchirship of the company of St. Côme, (which was afterwards erected into the Royal Academy of Surgery,) and was appointed demonstrator of surgical operations to that body in 1725. In 1728 he appeared as an author on the subject of lithotomy, and published his "Traité de la Taille au haut appareil, &c.," the high operation being then universally practiced by the surgeons of Paris. But, in the following year he was commissioned by the Academy of Sciences to visit London, with a view of witnessing the lateral operation, as performed by Chevillello with so much success; and on his return to Paris, he introduced that mode of cutting for the stone, at the hospital of La Charité, of which he was made surgeon. The success and consequent reputation which attended his new mode of practice, brought a crowd of pupils to his hospital, and multiplied his professional honours. He became director and secretary of his company, and held the latter office with great distinction for many years after it was made a Royal Academy. He was admitted a member of many foreign societies, especially the Royal Society of London, and the academies of Stockholm, Peterburgh, Florence, Bologna, and Rouen; and was nominated pensioner and professor of anatomy to the Royal Academy of Sciences at home. He was likewise appointed to several professional posts connected with the army; and in 1751, was honoured with knighthood, of the order of St. Michael. He was everywhere respected and admired as a gentleman, and as a man of cultivated understanding and taste. He died in 1773, at the age of seventy-six.

MORAND, JEAN-FRANÇOIS-CLEMENT, a Parisian physician of distinction, was the son of the eminent surgeon, who is the subject of the preceding article. He was born at Paris in April 1726, and received the degree of doctor in medicine in 1730, and was soon afterwards appointed professor of anatomy in the same schools. He obtained a high reputation in his profession, and received many honours, having been elected into the Royal Academy of Sciences of Paris, the Royal Society of London, and many other learned bodies; and he was likewise appointed physician in ordinary to Stanislaus, king of Poland, and duke of Lorraine. He died in 1784. The following is a catalogue of his writings. "Histoire du Maladie ligulière, et de l'examen d'une femme devenue en peu de temps contraire par un ramollissement general des os," Paris 1752. "Nouvelle description des grottes d'Arcy," Lyons 1752. "Lettre a M. le Roi au sujet de l'Histoire de la femme Suppôt," Par. 1752. Suppôt was the woman affected with the softening of the bones, described in the foregoing memoir. "Éclaircissement abrégé fur la Maladie d'une vieille de St. Geoffray," and "Receuil pour servir d'éclaircissement, &c.," relating to the same subject, Paris 1754. "Lettre fur l'Instrument de Roonhuyzen," 1755. "Lettre fur la qualité des Eaux de Luxemburg en Franchise Comité," published in the Journal de Verdun, March 1756. "Memoire fur les Eaux à hémale de Bains in Lorraine, &c.," in the Journal de Medecine, tom. vi. 1757. "Du Charbon de terre et de les Mines," fol. 1769. This forms the fourtieth number of the arts described by the Academy of Sciences of London, and was then little known in France, and Morand took a journey to Liege, for the purpose of examining the mines; and in 1770 published his "Memoire fur la nature, les effets, propriété, et avantages du charbon de terre, apprêter pour être employé commodément, économiquement, et fars inconvenient au chauffage, et à tous les usages domestiques." He also wrote an "Eloge" of his father, and a "Memoire fur la qualité dangereuse de l'ameuqie des Apothecaires de Lyons." Eloy Dict. Histo. Gen. Biog.

MORAND, PETER DE, a poet and dramatic writer, was born at Arles in 1701, and at a very early age he displayed talents for poetry, which gained him considerable reputation. Being disappointed in his marriage he devoted himself to a life of dilipation, and to the literary profession. He wrote two tragedies, of which one was very successful, but the other failed. One of his most popular pieces was a comic,
This black spongy earth they cut into oblong squares, with iron spades made for that purpose, eight or nine inches long, and four or five broad; as the men cut them up, they are carried and spread on a dry ground, to be dried in the wind and sun. Some of these become harder, some softer, according to the nature of the mould or earth: the more black and solid they are, the better fire they make; and those are the least esteemed which are grey, light, and most spongy.

When they have cut off one surface of four or five inches deep, they proceed downwards to another, and so to a third and a fourth, till they come to the hard strata; unless they be flopped with water, which they also ordinarily remove by making a channel, if they can; but where they cannot, there the water stagnates. In such indefinite pits, or pent-dikes, as they call them, where water hinders the cutting of spongy earth to the bottom, the pits will be filled up again, in some years, with a new spongy earth; which, in process of time, comes to the confidence of pent-moors, as at first, and a furious healthy turf grows over the top of it. When the dykes are dug down to the hard channel, the moors do not renew, as in the other case; though it has been observed, that if they be cut down to the channel, provided the healthy turf cut off from the top be laid on the channel, in course of time the moor grows again. These moors are always level; though they are frequently found on hills, and near the tops of them too; yet, as that curious nobleman observes, the moors have always a deficient to them, and generally from them; incomprehensible as it was, for there were no objection to them, that those that improve it, and that it was as good for use as any old wood is; only, through having inhabited a deal of moisture, it takes some time to dry, in order to fit it for burning.

There are many places where wood will not grow, where the moors are well flocked with this under-ground timber; but yet it appears there must have been woods formerly there; else how came they in the moors? To prove this, that noble lord gives us the history and origin of a few moors, in great measure from his own experience. In the parish of Lochburn, in the year 1651, he saw near the top of a very high hill, a plain about a mile over, then covered with a firm standing wood, but which was so very old, that not only the trees had no leaves or bark on, but the outside, for the space of an inch inwards, was dead white timber, though within they were firm. Coming by the place fifteen years after, he could not discover the least appearance of a tree; but, instead thereof, there was a plain green ground covered with a moor, the trees being all fallen, and having been so thick over one another, that the green had over-run the whole timber, by means of water and sponginess from the hill above it, and stagnating on the plain. He adds, that none could pass over it; the turf not being firm enough to support them. In thirty years more he found this whole piece of ground turned into a common peat-moor, and the country people digging turf and peat there. This accounts for the generation of moors, and whence it is that many of them are furnished with timber.

It appears from the whole, that all the trees which we find in this sélitt slate, originally grew in the very places where we now find them, and have only been thrown down and buried there, not brought from elsewhere. It may appear indeed an objection to this opinion, that most of these foliée trees are of the fir kind; and that Ceasar says, expressly, that no fir grew in Britain in his time; but this
easily answered by observing, that these trees, though of the fir kind, yet are not the species usually called the fir, but pitch-tree; and Caesar has no where said that pitch-trees did not grow in England. Norway and Sweden yet abound with these trees, and there are at this time whole forests of them in many parts of Scotland, and a large number of them wild upon a hill at Wanerton in Staffordshire, to this day.

In Hatfield-marsh, where such vast numbers of the foffile trees are now found, there has evidently once been a whole forest of them growing. The laft of these was found alive, and growing in that place within a hundred years last past, and cut down for some common use. See Beg-Wood.

The Roman historians tell us, that when their armies pursued the wild Britons, these people always sheltered themselves in the mire woods, and low watery forests. Caesar expressly says this, and observes, that Caffibelan and his Britons, after their defeat, passed the Thames, and fled into such low morales and woods, that there was no pursuing them; and we find that the Silures fixed themselves in the same manner when attacked by Ostorius and Agricola. The same thing is recorded of Venutius, king of the Brigitantes, who fled to secure himself in the boggy forests in the midland part of this kingdom; and Herodian expressly says, that, in the time of the Romans pursuing their conquests in these islands, it was the custom of the Britons to secure themselves in the thick forests which grew in their boggy and wet places, and when opportunity offered, to issue out thence and fall upon the Romans. The consequence of all this was, the destroying all these forests, the Romans finding themselves so plagued with parties of the natives issuing out upon them at times from these forests, that they gave orders for the cutting down and destroying all the forests in Britain which grew on boggy and wet grounds. These orders were punctually executed; and to this it is owing, that at this day we can hardly be brought to believe that such forests ever grew with us as are now found buried.

The Roman histories all join in telling us, that when Suetonius Paulinus conquered Anglesea, he ordered all the woods to be cut down there, in the manner of the Roman generals in England; and Gallen tells us, that the Romans, after their conquest in Britain, kept their soldiers constantly employed in cutting down forests, draining of marshes, and paving of bogs. Not only the Roman soldiers were employed in this manner, but all the native Britons made captives in the wars, were obliged to affit in it: and Dion Cassius tells us, that the emperor Severus left no less than fifty thousand men in a few years time, in cutting down the woods and draining the bogs of this island. It is not to be wondered at, that such numbers executed the immense destruction which we find in these buried forests. One of the greatest subterranean treasures of wood is that near Hatfieid; and it is easy to prove that these people, to whom this havoc is thus attributed, were upon the spot where these trees now lie buried. The common road of the Romans out of the south into the north, was formerly from Lindum (Lincoln) to Segeboschum (Little-Burrow upon Trent), and from hence to Danum (Doncaster), where they kept a standing garrison of Criptonian horse. A little off on the call, and north-east of their road, between the two last named towns, lie the borders of the greatest forest, which I learned with wild Britons, who were continually making their fellies out, and their retreats into it again, intercepting their provisions, taking and destroying their carriages, killing their alies and pillagers, and disturbing their garrisons. This at length so exasperated the Romans, that they were determined to destroy it; and to do this safely and ef-

fectually, they marched against it with a great army, and encamped on a great moor not far from Fimmingly: this is evident from their fortifications, yet remaining.

There is a small town in the neighbourhood called Otterfield, and as the termination field seems to have been given only in remembrance of battles fought near the town where names ended with it, it is not improbable that a battle was fought here, between all the Britons who inhabited this forest, and the Roman troops under Ostorius. The Romans flew many of the Britons, and drove the red back into this forest, which at that time overspread all this low country. On this the conquerors, taking advantage of a strong south-west wind, set fire to the pitch-trees, of which this forest was principally composed; and when the greater part of the trees were thus destroyed, the Roman soldiers and captive Britons cut down the remainder, except a few large ones, which they left standing, as remembrances of the destruction of the red. These single trees, however, could not stand long against the winds; and these falling into the rivers which ran through the country, interrupted their currents, and the water, then overspreading the level country, made one great lake, and gave origin to the moories, or moory bogs, which were afterwards formed there, by the workings of the waters, the precipitation of earthy matter from them, and the putrefaction of rotten boughs and branches of trees, and the salt increa-se of water mois, and other such plants which grow in prodigious abundance in all these sorts of places. Thus were these burnt and felled trees buried under a new-formed lpongy and watery earth; and afterwards found on the draining and digging through this earth again.

Hence it is not strange, that Roman weapons and Roman coins are found among these buried trees; and hence it is that among the buried trees some are found burnt, some chopped and hewn; and hence it is that the bodies of the trees all lie by their proper roots, and with their tops lying north-east, that is, in the direction in which a south-west wind would have blown them down. Hence also it is, that some of the trees are found with their roots lying flat, these being not cut or burned down, but blown up by the roots afterwards when left fingle; and it is not wonderful that such trees as these should have continued to grow even after their fall, and shoot up branches from their fides, which might easily grow into high trees. Phil. Trans. N. 275.

By this system it is also easily explained why the moor-foil in the country is in some places two or three yards thicker than in others, or higher than it was formerly, since the growing up of peat-earth or bog-ground is well known, and the foil added by overflowing of waters is not a little. As the Romans were the destroyers of this great and noble forest, so they probably were also of the several other ancient forests; the ruins of which furnish us with the bog-wood of Staffordshire, Lancashire, Yorkshire, and other counties. But as the Romans were not much in Wales, in the Isle of Man, or in Ireland, it is not to be supposed that forests cut down by these people gave origin to the foffile wood found there; but though they did not cut down these forests, others did; and the origin of the bog-wood is the fame with them as with us.

Holmgrefed informs us, that Edward I., not being able to get at the Welsh, because of their hiding themselves in boggy woods, gave orders at length that they should be destroyed by fire and by the axe; and doubtless the roots and bodies of trees found in Pembrokeshire under ground, are the remains of the execution of this order. The foffile wood in the bogs of the Isles of Man and Anglesea, is doubtless of the fame origin; though we have not any accounts extant of the time or occasion of the forests there being destroyed; but
but as to the fossil trees of the bogs of Ireland, we are expressly told, that Henry II., when he conquered that country, ordered all the woods to be cut down that grew in the low parts of it, to secure his conquests by cutting away the places of resort of rebels.

We have an account in the Philosophical Transactions of a moving moat, near Church-town, in Lancashire, which greatly alarmed the neighborhood as miraculous. The moat was observed to rise to a surprising height, and soon after sunk as much below the level, and moved slowly towards the south.

MORASTEN, in Geography, a town of Sweden, in the province of Upland; 5 miles S.E. of Upsal.

MORAT, or Murtin, a baillage of Switzerland, belonging to Bern and Frutig; into which the reformation was introduced in 1540, by a majority of voices, in presence of deputies from Bern and Friburgh.—Also, the capital of this baillage, which stands pleasantly upon the edge of a small lake, about six miles long and two broad, in the midst of a well cultivated country. The lakes of Morat and Neuchatel are parallel to each other, and separated only by a ridge of hills: the former is the most elevated, for it discharges itself by means of the river Broye, into the lake of Neuchatel. According to M. de Luc, it is fifteen French feet above the level of that of Neuchatel. Both these lakes, as well as that of Bienna, formerly extended much farther than their present limits; and, from the position of the country, appear to have been once united. Morat is celebrated for the obstinate siege sustained against Charles the Bold, duke of Burgundy, which was followed by the battle of Morat, fought on the 22d of June, 1476. In this famous engagement the duke was routed, and his whole army almost destroyed by the confederate troops of Switzerland. Not far from the town, and adjoining to the high road, was erected a monument, which was a square building, filled with the bones of the Burgundian soldiers, who were slain at the siege and in the battle. In March 1798 the French troops demolished this edifice. Morat is 12 miles W. of Berne. Coxe’s Travels, vol. ii.

MORATA, OLYMPIA FULVIA, in Biography, an Italian lady, was born at Ferrara in 1526. Her father was a learned professor, and gave her an excellent education. She became tutees to the princes of Ferrara, and declined publicly in Latin and Greek. Olympia married Grunthel, professor of medicine at Heidelberg, where she died in 1555.

Her works, consisting of orations, letters, dialogues, and translations, were printed at Baffo in 1562, 8vo.

MORITA, in Geography, a small island in the bay of Honduras, near the E. coast of Rusatan. N. lat. 16° 25’. W. long. 86° 58’.

MORATALAZ, a town of Spain, in New Castile; 22 miles E. of Ciudad Real.

MORATALLA, a town of Spain, in Murcia; 24 miles S.S.W. of Chinchilla.

MORATUR, or Maramatur, in Law, signifies as much as, he demurs; that is, the party here goes not forward, but retires or abides by the judgment of the court, who take time to deliberate, argue, and advise thereon.

When the counsellors of the party are of opinion that the court or plea of the adverse party is insufficient in law; then he demurs, or abides in law; and refers the same to the judgment of the court. See DEMURRER.

MORAU, in Geography, a river of Austria, which gives name to Moravia, rises in the Sudetic mountains; and passing by Olmutz, joins the Danube not far to the W. of Pressburg.

MORAVA, a town of Servia, on a river of the same name, which was the ancient Margus, and runs about 120 miles into the Danube. Morava is six miles N.W. of Sapskin.

MORAVAVISAR, a town of European Turkey, in Servia; 40 miles N.N.W. of Niffa.

MORAVIA. Marquise of, a country bounded on the N. by Bohemia and Silesia, on the E. by Silesia and Hungary, on the S. by Austria, and on the W. by Bohemia; containing about 1,400 square miles. On the frontiers of Hungary, Bohemia, and Silesia, it is partly cultivated by mountains, and partly by woods. One-half of it is mountainous and woody; and in the more cultivated circles and tracts are many moraines, bogs, and lakes. In the former part the temperature is cold, and requiring even a flame in summer; and yet it is more favorable than the other even level districts. The country produces more corn than its inhabitants consume, hemp and flax, and good fodder, and also fruit-trees and vegetables, besides vines that yield white and red wines. It has good pasturage for all sorts of cattle, and plenty of game. Here are also wolves, bears, and leopards; quarries of marble, and other minerals, such as those of alun, iron, sulphur, faltorp, and vitriol; and springs impregnated with those minerals. The number of market-towns and villages in Moravia has been estimated at 2,550. The language of the country is a dialect of the Slavonic, but the German is very common. The states of the country consist of the clergy, lords, knights and burgesses. Christianity was introduced here about the middle of the 9th century; the prevalent profession is that of the Roman church, subject to the jurisdiction of the bishop of Olmutz. The articles of commerce consist of manufactures of cloth, iron, glafs, pepper, gunpowder, &c. which, on the whole, are considerable. Till the 9th century, the kings of this country, anciently inhabited by the Quadi, and afterwards by the Slavica, were powerful and independent; but in the time of Charlemagne they became his vassals. In 1086 Moravia was declared a marquisate, and united with Bohemia. The whole marquisate is divided into six circles, each of which has its captain, whose authority extends to the quartering, marching, and maintenance of the soldiers. The capital is Olmutz.

MORAVIAN, or BOHEMIA BRETHREN, in Ecclesiastical History, were Protestants of Bohemia, who, in the 15th century, threw off the despotick yoke of Rome, animated by the zealous exhortations and heroic example of John Huss. These Moravian brethren were distinguished by several religious institutions of a singular nature, and well adapted to guard their community against the reigning vices and corruptions of the times. In 1532, they united themselves to the Lutheran churches in Saxony; but after the death of Luther, and their expulsion from their country in 1547, many of them, who retired into Poland, embraced the religious sentiments and discipline of the reformed, and by degrees they all entered into the communion of the Swiss church. This union was, at first, formed on the express condition, that the two churches should continue to be governed by their respective laws and institutions, and should have separate places of public worship; but, in the following century, all remains of distinction were removed in the synodes held at Altrog in 1620 and 1627, and the two congregations were formed into one, under the title of the Church of the United Brethren.” From this honourable origin the modern Moravians are ambitious to derive their descent. See HERRNUTHERS and Unitas Fratrum.

MORAWEN, in Geography, a town of Bohemia, in the circle of Chrudim; 6 miles N.E. of Chrudim.
MORAYSHIRE, or the county of Elgin, one of the northern counties of Scotland, is bounded on the N. by that branch of the German ocean called the Moray-Firth; on the E. and S.E. by Banffshire; on the S.W. by Inverness-shire; and on the W. by that county, and by Nairn. The figure of this shire is extremely irregular, being in several places intersected by districts of the counties which form its boundaries. It extends in length from N. to S. about 32 miles; and in average breadth, from E. to W., about 80. In ancient times the limits of this county were much more extensive than at present, comprehending all that tract of country which lies between the river Spey on the E. parts, the Farar or Beauly on the N.W., and the northern confines of Argyleshire on the W. When this larger county was subdivided, and its name confined to the present extent, it was uncertain, but that event must probably took place at a period later than the tenth century, when the "district" or "province" of Morayshire is frequently mentioned by writers in their reference to a subsequent era.

This county is naturally divided into two portions; that known as the Lowlands, and the other Brae-Moray. The former of these, lying along the sea-shore, and comprehending an extent of 200 square miles, is a fine champagne country, though diversified by many gently rising grounds; which being either covered with trees, or in a state of high cultivation, form a landscape, in general much superior in beauty, fertility, and riches to any northward of the Grampian hills. The latter, comprising about 600 square miles, and confining the upper or southern division, is, on the contrary, a mountainous country, intersected by several fertile valleys along the banks of the different streams, which take their rise in, or flow through it. This district, particularly its uppermost portion, is chiefly occupied by extensive forests of different kinds of trees, but the fir and the oak are most prevalent.

The soil and climate of Morayshire, as in most counties of similar extent, surface, and position, are variable. The Lowlands in general participate in the fair weather which is found to prevail over the whole eastern coast of Scotland. Indeed in that respect this district is peculiarly favoured by its situation, as lying between the mountains of Sutherland on the one side, and those of Banff and Aberdeen on the other. For the clouds borne aloft on the winds pass from the one range to the other, with great rapidity over the subjacent plain, which affords no object sufficiently high to attract or impede their course. The proximity of the sea prevents the snow from remaining on the ground for any lengthened period of time; and is, likewise, the cause of its seldom falling in very considerable quantity. In short, these circumstances combine to render the climate here more mild and favourable, than probably occurs in any district of Europe under the same latitude. The hilly part of the county has a climate of a much ruder description. Winter commences here earlier than in the Lowlands, and lingers a month or five weeks later.

In the maritime district the great proportion of the soil is a rich deep clay, which, if under proper management, would equal in fertility the similar soil of the Carre-of-Gowrie. The surface of the remainder of this level consists principally of a deep black loam, or of a light and sandy soil. That in the valleys of the hilly parts is formed chiefly by the washings of the streams; and where cultivation has taken place, on the sides of the hills, the soil is of a moorish quality, and more or less blended with mofs. The sandy soil is greatly intermixed with gravel and large pebbles.

On the subject of agriculture, it may be observed, that its condition in this county varies with the changes of soil and climate, which its different portions exhibit. Wheat is raised only in the lower district; but oats, barley, peas, and beans, potatoes, turnips, and artificial grasses, are prevalent over the whole cultivated extent of the shire. No fixed rotation of crops seems to be adopted, though in all the larger farms a certain portion of land is annually fallowed; some laid down with turnips, and some with grass. In Strathspey, one-half of the lands is usually under oats; and on the remaining half is grown a considerable portion of grass, with small quantities of beans, peas, turnips, and potatoes. Lime, either manufactured in the county, or imported from the Frith of Forth, or from England, is much employed as a manure. The most extensive farms here contain from a hundred to a hundred and fifty acres of arable land; but farms in general divide them into thirty or forty acres under tillage. In Strathspey they are of much greater extent for the moor part than in the low country, owing to the circumstance of their having been formerly wadsetted, or pledged for debts by the family of Grant; or though the wadsets are redeemed, yet the farms mostly continue in the hands of the descendants of their ancient poissure. Farm-houses, in the Lowlands, where the farms are of tolerable extent, make, in general, a respectable appearance; but the dwellings of the poorer tenants are extremely mean. The farm-servants are usually maintained in the family; the ordinary breakfast being porridge made of oatmeal, which is ate warm with milk or small beer; for dinner a kind of dammy, called towens, is made from the bran of oatmeal, and ate chiefly with milk; and for supper, greens or cabbage, either cut small, or mashed, and afterwards boiled with an addition of oatmeal and salt; and at each meal there is an addition of bread made from a mixture of oats, bean and peas-meal. On Sundays and other holidays the dinner is broth, made of poultry, green or wheat porridge; and flummery, a thick kind of oatmeal and milk, is generally eaten after dinner.

The chief plantations in the lower portion of the county are the property of the earl of Fife and the heirs of the late earl of Finlare. These consist of various sorts of forest trees. In Strathspey there are very extensive plantations of Scotch fir on the estates of Grant of Rothiemurchus, the Duke of Gordon, and Sir James Grant. The forest of Gle-moor, which has been mostly cut down within these last twenty-six years, afforded many trees fit to be used as masts for vessels of a considerable size, and some even fitable for the royal navy.

The principal rivers of this county are the Findhorn, the Spey, and the Lossie. The Findhorn rises in Inverness-shire, and after a course of nearly fifty miles, in a north-easterly direction, falls into the Moray Frith at the harbour of Findhorn; the Spey likewise rises in that county, and flows into the sea at Tainmouth, forming, for a considerable extent, the boundary between Morayshire and Banffshire. The Lossie takes its rise in the hills between Dollar and Strathpey, in the upper district, and discharges its waters into the Frith at Lossiemouth. Several rivers of inferior size unite with each of these larger ones during their current through this county. Of the lakes here, Loch Spynie is the only deserving of notice. It is about three miles long and one broad, and appears to have been an arm or branch of the sea, though now shut up by a considerable extent of valuable land. This lake abounds with pike and perch, and is much frequented by fowls.

Moray-
Morayshire does not contain any metallic veins, at least none have yet been discovered. Fire-clay, grey-plate, and limestone, however, are found in great abundance. In the district of Rathemurchat is a great mountain of the latter, which is calcined with wood, and chiefly employed as a manure. A rock of fine agate appears on the side of a hill near the church of Rothes. It is very hard, heavy, of a smooth uniform texture, and of considerable breadth; the red being remarkably clear and finely flaked through the stone. Mr. Williams, the mineralogist, says, this is the largest and most beautiful agate rock he ever saw, and is to line and hard as to be captain of the highest labour in polishing.

The only mineral plants in the parish are those in the parish of Duthil, which have been long esteemed for their medicinal properties in urinary complaints, and are supposed to resemble the Seltzer waters in containing fixed air.

Numerous interesting remains of antiquity are found in different parts of Morayshire. Elgin is distinguished by the ruins of an ancient cathedral, originally built by bishop Murray, whose episcopal seat was translated hither from Spynie in the year 1224. Having been burnt to the ground, however, in 1392, by Alexander Stewart of Bardenock, it was re-founded by bishop Bannock. (See ELGIN.) The remains of Priardine abbey stand on the north side of the river Liffa, six miles to the south-west of Elgin. This monastery was founded, by king Alexander II., in the year 1200, and dedicated to St. Andrew. The religious were monks of Vallet-Cantium, a reform of the Cistercians following the rules of St Bennet, and were brought hither by Wiliam Malvoliit, bishop of St Andrews, from the diocese of Lomures, in France. From the appearance of the ruins, this institution seems to have been one of considerable extent and riches. On the south bank of Loch Spynie are the ruins of the ancient palace of the bishops of Moray, which is said to have been one of the most magnificent episcopal seats in Scotland. Lochinvar castle, in the parish of Edinkillie, has evidently been a place of great strength. Catharine de Beaumont, widow of David de Hatling, earl of Atholl, was blockaded here during the captivity of king David Bruce, by sir Alexander Moray the regent. Edward III., however, faved her from falling into his hands, by compelling him to raise the siege the year following, when he marched his army so far north as Inverness, with the view of enforcing the submission of the whole kingdom. The present remains of this castle cover a space of ground not less than 100 yards square. Near this fortress are the vestiges of another, called Doune-hill, which appears to be of more ancient date than the former; and was probably one of the strongholds to which the inhabitants retired with their cattle upon the invasions of the Danes, Norwegians, or Danes. It is situated on a conical mount, defended on the one side by the deep rocky channel of the rapid river of Davie, and on the other by an immense fosse or ditch, with a strong rampart on the outside, mostly composed of stones, some of which are apparently vitrified. About a mile higher up the river stands the castle of Dumphmail, long the property of the family of Dunbar; and in the parish of Dyke is that of Darnaway, the venerable mansion of the earls of Moray, of the Randolphs, the Dunbars, the Douglares, and the Stuarts, all names of much note in the page of history. The grand hall in this castle, built by Thomas Randolph, regent of Scotland during the minority of king David Bruce, is by much the oldest and most remarkable part of the buildings; and measures 89 feet in length by 35 in breadth. In the parish of Duffus may be discovered traces of some ancient military works, which are attributed to the Danes. The spot on which they are situated is called the Burgh; and is supposed to be the real site of the fortresses mentioned by Buchanan, as having been surrendered to the Danes upon the defeat of Malcolm II. At the western extremity of the parish is an obelisk or stone cross, conjectured to be the same which was erected to commemorate the rout and dispersal of the forces of Canons by the same monarch in the pursuit of the Danes, after the victory of Panbride, in Angus. The village of Duffus is further remarkable for a figure, in the centre of which stands the church, surrounded by four streets regularly paved, the workmanship of Oliver Cromwell's soldiers. Many other curious monuments of antiquity are still visible in different parts of this county, among which Swindo's stone, or pillar, on the road from Nairn to Forres, particularly demands attention. This stone is universally allowed to exceed in ornamental workmanship all the other obelisks in Scotland; and is even generally supposed to be the finest monument of the kind now existing in Europe. Its height above ground is not less than 23 feet, and it is said to fink twelve beneath it. Its breadth is about four feet. The portion above the surface of the ground is divided, on the E. side, into seven compartments, containing a variety of baso-reliefs, representing military figures. On the other side is displayed a fumigious cross, and under it appear two personages in the attitudes of reconciliation. It is remarkable that no distinct tradition concerning this obelisk has reached the present period; hence its origin and intention are doubtful, but it is usually supposed to have been erected in memory of the peace concluded between Malcolm and Canute, upon the final retreat of the Danes from Scotland.

Morayshire, according to the parliamentary returns of 1801, contained 6126 houses, and 26,795 inhabitants, viz. 11,793 males, and 14,992 females. Of this number, 8151 are employed in agriculture, and 4410 in the different departments of trade and manufacture. Pennant's Tours in Scotland. Chalmers' Caledonia. Beauties of Scotland, vol. iv. Antiquities and Scenery of the North of Scotland, by the Rev. Charles Cardiner. 4vo.}

MORBEGNO, a town of Switzerland, the hamfoft in the Valteline, lies on the left side of the Adda, at the foot of the southernmost chain of mountains. It has more shops and carries on more trade than all the others united. It is the residence of a bailiff, who bears the title of Podella; 11 miles S.E. of Chiavenna. See VALTELINE.

MORBEN, a mountain of Scotland, in the county of Perth; 12 miles W.S.W. of Crieff.

MORBEYA, a river of Morocco, which runs into the Atlantic, near Azamor.

MORBID, from Morbus, diseaue, is applied, in medical language, to every thing connected with disease; thus we say morbid secretion, morbid poison, morbid structure, and even morbid anatomy; meaning by the last the anatomical investigation of those changes in the organs of the body, which disease has left behind it, when fatal.

MORID Pajen. This term was first invented by Mr. Hunter to make a necessary distinction between those secretions by which animals in a state of health are able to injure others; and those which no animal possesses but in a morbid or diseased state. When the viper injects its venom, however deleterious it may be, he is himself in health, and the higher that health, the stronger will his venom prove. But the small pox is always a diseased action in the perfom who communicates, as well as in the perfom who is affected by it. This distinction, important as it must appear, as soon as propounded to the understanding, was overlooked long after Mr. Hunter had pointed it out, and is scarcely yet vernacularized even among medical men.
MORBID POISON.

The earlier writers on the subject of poisons, seem to have taken Celsus as their model, who was acquainted with no morbid poisons but the hydrophobia. It is not to be wondered at that accurate writers should have placed in succession morbus rabies canis, morbus serpentum, litus apsidum, arach, orpiment, &c. and afterwards venena vel in ivil vel in poisons effumpta. But it is less excusable that Mead, in a Treatise on Poisons, should have made no other distinction between poisons, than from the kingdom of nature from which they are derived, or from their property of injuring by being applied to the stomach, or externally by a wound.

Mr. Hunter's distinction might have been of less importance, had not the former incorrectness considerably influenced the practice of those who were misled by their own terms. Thus, when it was found that mercury was a remedy against the venereal poison, it was soon considered as an antidote; and as the principal medical industry of the ancients had been directed to the discovery of antidotes, it was presently conceived that mercury might be applied in all cases of poisons.

But the great advantage which medicine has derived from Mr. Hunter's distinctions is, that it has led to an accurate discrimination between the laws of different animal poisons, and to a more correct mode of ascertaining the characters of each of the various morbid poisons. In these views we shall now proceed with the article before us.

Mr. Hunter called those poisons which form a part of the animal when in health "the natural poisons." Dr. Adams prefers the term "original poisons," inasmuch as both those and the "morbid" are progeny of nature, but the first only are secretions of the animal in his original or unaltered condition. This then marks the first distinction. The second, and not less important, is, that an animal affected by an original animal poison has no power of communicating a similar disease to another; whereas one affected by a morbid poison acquires all the properties of injuring in a similar way, and communicates the same property to such as are poisoned by him. An animal bitten by a serpent has no power of communicating a similar morbid influence by his own bite; but many animals bitten by a rabid dog have the power of communicating a similar effect to other animals of their own, and even of different species and orders.

The original and morbid poisons affect locally or constitutionally, and sometimes in both ways. But there is one important distinction, namely, that an animal may remain susceptible of the effect of the original poisons if he surives the disease excited by them; whereas, as far as morbid poisons have been traced, no constitutional effect can be a local and time excited by the same poison in the same subject. If that provision had not been made against those poisons which affect by effluvia, such as the small-pox, the constant apprehension of disease from sources from which we could never protect ourselves, would have rendered life so precarious as to be scarcely worth acceptence.

Mr. Hunter divided the morbid poisons into the simple and compound. The simple are those which affect locally or constitutionally, but not both ways; those which affect locally and constitutionally he called compound. There is some difficulty in marking this distinction, because there are few, if any, which may not be called compound, and there are some which are occasionally simple and at other times compound. Thus, the venereal disease, which Mr. Hunter uses as an illustration of a compound, is more commonly a simple poison, affecting only the parts to which it is applied. The cow-pox, in the same manner, is generally only a simple poison, but sometimes affects distant parts of the body; and the small-pox, which for the most part affects the whole, is sometimes confined to the inoculated part. On this account Dr. Adams has preferred the division into such as produce their effect by contact or effluvia, or both. The venereal poison is never found to produce its effect but by application in a substantial form. The cow-pox is of the same description. The measles, on the contrary, are with difficulty, if at all, communicated but by effluvia, and the small-pox may be communicated by either one or the other. We have thought it right to mention these distinctions, though to us neither of them appears of sufficient importance for any practical purposes.

Mr. Hunter was of opinion that the morbid poisons are for the most part of recent date. It is certain, that excepting hydrophobia, they are not to be traced in the writings of the ancient physicians. He imputed them to some accidental intercourse between animals of the same or different species; and conceived that when such a cause has induced only a local disease on a part not likely to be applied to another animal, the effect has probably ceased with the animal which has been first injured. But if the disease could be communicated by effluvia, it would spread as long as that effluvium was inhaled by animals susceptible of its impression; hence the almost universality of small-pox. Or if its local effects were produced on parts of animals often brought into contact and not exposed to fight, the communication of such a disease would be as general as such intercourse was promiscuous. Hence the rapid spread of typhus among such as are unacquainted by the laws of charity.

The only work which Mr. Hunter has left us on morbid poisons, is his celebrated Treatise on the Venerable Disease. In this work, by his happy talent of discrimination, by his unwearying industry, which was only equalled by his accuracy, he at length ascertained the true character of a disease, till his time was supposed to be confused by no laws, and hence termed a proteiform complaint. By the use of this convenient term many other obnoxious local diseases were so confounded by former writers, that at last it was suspecred an individual or even a family once infected could never with any certainty be considered as pure. All this erroneous mode of reasoning, if it could be called reasoning, Mr. Hunter effectually overturned, by ascertaining the true character of typhus, (see Lues Venerum,) the manner in which it is cured, the chances of its occurrence afterwards in distant parts of the body, the means of curing it in each, and the causes which for a time might interfere with, or render ineffectual the only certain remedy. Besides the ignorance of his predecessors on most of these points, another fruitful source of error to themselves, and of consequent misery to their patients, was the imitating other morbid poisons for the venereal, merely because they appeared in parts most liable to the latter. Of these he gave several instances in the nipples from sucking, the gums from the transplantation of teeth, and in those organs which are the usual seat of the disease. Cases of each he describes with great accuracy under the term "diseases resembling the lues venerei," and concludes this invaluable present to posterity with the following paragraph: "I cannot conjecture," says he, "without intimating that undescribed diseases resembling the venereal are very numerous; and that what I have said is rather to be considered as hints for others to prosecute the inquiry further, than as a complete account of the subject."
MORBID POISON.

merous objections, which we may suppose, appeared to doctrines at that time so new and so contrary to generally received opinions.

In the beginning of 1795, appeared the first edition of Dr. Adams's Treatise on Morbid Poisons, the title of which showed that it was principally directed to the inquiry which Mr. Hunter had left for others to prosecute. After vindicating his matter from the attacks of every author who had opposed or misrepresented him, Dr. Adams attempts a methodical arrangement of all those appearances which had, till Mr. Hunter's time, been confounded with syphilis. In doing this, he very happily avails himself of an enumeration of all the ulcers, described by Celsus, on the parts usually exposed to the venereal poison. He shows that the above-mentioned author, who is admitted to have flourished more than a thousand years before this formidable disease was known, describes, with much accuracy, in his chapter De observarum partium visitis, nine forms of ulceration, all of which differ from the proper character of the venereal, as traced by Mr. Hunter, and even by Altricus, Boerhavus, and every other respectable writer; and that many of these ulcerations are mentioned by modern authors as forms of the venereal disease, which they found themselves unable to cure, and which they acknowledge were often exasperated by mercury. A reference to these writers serves him at once as an illustration of Celsus, and as a proof that diseases, described by that author, ought not to be confounded with one which is admitted by almost every writer to have arisen from long since his days.

Having disposed of this grand question, Dr. Adams makes the first attempt at something like a classification of morbid poisons from the local actions excited by them. Thee we shall offer in his own words.

"If this distinction," says he, "of morbid poisons may be admitted, it will resolve itself into the following division:

1. Slough, with consequent fungus and scab, as in yaws.
2. With suppuration and scab, as in small-pox.
3. Preceded by ulcers and followed by immediate skinning, as in several anomalous morbid poisons.
4. With ulceration, and each in succession, as in the sloughing phagedena.
5. Ulceration kept up by the secreting pus, as in fivvens and some anomalous phagedena.
6. Slough, with a thickened edge and base, as in the venereal ulcer."

Such was the state of our progress towards an accurate discrimination of diseases so important, not only to medicine, but to the common intercourse of society, when Dr. Adams published his first edition. In this also was contained the first printed account of cow-pox, which was introduced in illustration of Mr. Hunter's suggestion, that the morbid poisons might originate by the intercourse of different species of animals. A few years afterwards, Dr. Jenner published his valuable discovery, and from that time the term morbid poison has been more generally adopted and understood.

In the year 1804, Mr. Abernethy published his "Classification of Tumours," with a number of cases, supposed to be venereal, though evidently arising from other causes. The haity manner in which his work was compiled, prevented (as the author acknowledges) his marking, with sufficient accuracy, those discriminations by which the true might be distinguished from what he terms the pseudo-syphilis. His facts are, however, invaluable, and these he seems, by a kind of courtesy, to confine to the arrangement of Dr. Adams, or to any one who might find leisure and diligence to pursue the subject methodically.

Three years afterwards appeared Dr. Adams's second edition of Morbid Poisons, improved by all that had been offered by other writers since his first, and most of all by the facts he had collected in the island of Madeira, in different parts of Great Britain, and even by experiments made on his own person. He was now able to give a clinical description of yaws and sevens, to trace the progress of the acrasia syphilis in himself, and to mark the distinction between the disease it induces and the true itch. This was settled the long disputed point concerning the supposed cause of the itch, which some had imputed to an infect the excision of which was denied by others. The confused notions also arising from the term elephantiasis, and the various diseases confounded under that general name, were accurately developed. (See the article Elephantiasis.) But what adds much to the value of Dr. Adams's researches, is their immediate application to practical use, for though our knowledge may not yet be sufficiently mature to offer a name for every morbid poison as it may occur in practice, yet by the arrangement he has made we shall rarely be mistaken in the application of a remedy. To afford us in this respect, he has drawn our attention to the natural and artificial modes of cure in those morbid poisons, whose characters are now well ascertained, and has thus taught us to account for our occasional successes, and too frequent failure in attempting to cure them by mercury, merely from its constant efficacy in syphilis. Some, he describes, whose progress is slow and like the yaws, may be at any time supplied by mercury, but the consequence of this suffocation is only the reappearance of the disease in an aggravated form; others may, like syphilis, be more rapid, and require to be instantly arrested by mercury; and many others may cease spontaneously, or yield to caustics, or other topical applications. From these considerations, more particularly the calamitous effects of giving mercury early in yaws, and many other morbid poisons, he concludes with advising, that that mineral should never be exhibited in the early stages of morbid poisons with which we are not well acquainted, unless the ulcerative process should be so rapid as to render it absolutely necessary to make every attempt at arresting its ravages.

We shall not offer any opinion on doctrines in many respects so new, and which certainly mark profound application, whether they may fland the test of future experience or not. But it is equally our duty and gratification to rate one important refult which seems to have arisen from these inquiries, and which we hope will be confirmed. None of our readers need be reminded that the Europeans have been accused of carrying a disease to the South Sea Islands, which is said to have exterminated whole districts. It seems that, by pursuing the accounts of different writers, Dr. Adams had some years past not merely questioned the ravages from this disease in Otaheite, but even doubted whether it had ever appeared there at all. (See Dr. Adams's Edition of Mr. Hunter's Treatise on the Venereal Disease.) About ten years ago, Mr. Wilson, surgeon of the Porpoise troop of war, arrived at Otaheite, strongly impressed with an apprehension of the prevalence of syphilis, and of the consequence to the health of his crew, who were destined to a much longer voyage. With this impression he examined all his men daily, and was very diligent in learning which of the natives were affected. In his inquiries he was greatly assisted by the missionaries, who spoke with much directness on the prevalence of this dreadful malady in the island. After examining
examining every subject, however, Mr. Wilton became satisfied that the disease, which the Europeans were accused of importing did not then exist, and probably never had been known in Otaheite.

We have dwelt thus particularly on this half topic, first to remove the reproach from the English and French, who have mutually accused each other, and next to show, by this single instance, how much the knowledge of disease has been improved by the accurate discrimination of morbid poisons.

Mornin, in Painting, is particularly applied to fat flesh very strongly expressed.

MORBIDERY, in Geography, a town of Hindostan, in Canara: 13 miles N. of Mangalore.

MORBIGN, one of the nine departments of the N.W. region of France, so-called from the river or canal, which communicates with the sea from Vannes. This department was formerly Lower Bretagne, a maritime territory between Vilaie and Finisterre, in N. lat. 48°. It is bounded on the N. by the department of the North Coasts, on the E. by the department of the Ile and Vilaine, on the S.E. by the department of the Lower Loire, on the S.W. by the sea, and on the W. by the department of Finisterre. It contains 70674 square miles, or 328 square leagues, and 425,425 inhabitants. It is divided into four districts or arrondiments, 37 cantons, and 321 communes. Its four districts are Poitou, including 91,783 inhabitants; Poirem, 88,504; L'Orant, 122,798; and Vannes, 123,857. According to Halleinfrate, it is divided into nine districts and 70 cantons, and contains 281,565 inhabitants. Its capital is Vannes. Its contributions in the year 11 of the French era, amounted to 12,477,245 francs, and its expenses to 2,577,171 francs. 66 cents. The soil, though unequal, is fruitful, yielding grain, rye, flax, fruits, and excellent pastures. It has mines of lead and coal. Belle-île, belonging to this department, contains 5366 inhabitants, and is abundantly fertile. Honac and Hude are islets of little importance, inhabited by fishermen.

MORBILLI, in Medicine, an appellation given to the measles by the Italian physicians, signifying, as it were, a little plague; for il morbo (the disease) was, in their language, applied to the plague.

MORBUS, a term purely Latin, signifying disease; which see.

Morbis Arctatus. See Jaundice.

Morbis Cholera. See Cholera.

Morbis Comitialis. See Epilepsy.

Morbis Coecus. See Hip-Joint, Diseased of.

Morbis Gallicus. See Lues Venerea.

Morbis Hungaricus. See Hungaricus morbus.

Morbis Prodrumatis. See Prodrumous.

Morbis Pediulitis. See Pityriasis.

Morbis Region. See Jaundice.

Morbis Viridans. See Chlorosis.

Morchell?, in Botany, a name of Peroon's, of whose derivation we can determine nothing. It seems made out of the English Morel, which Dr. Johnson by mistake refers to Salamin, misled, as it should seem, by the French name of the Nightshade, Morelle. Pers. Syn. Fung. 618. Class and order, Cryptogamia Fungi. Nat. Ord. Fungi.

This genus is very properly separated from Peroon from the Phallus of Linnaeus and other writers, from which it differs no less in nature, than in the above-mentioned characters. Instead of being of a short-lived watery texture, odourly scented, and poisonous, it is of a leathery and permanent substance, eatable and of a delicious flavour; in every respect much nearer to Helvella than to any other genus.

Eight species are defined in the author above quoted. Of these the most important is

M. efculentus. Edible Morel. (Phallus efculentus: Linn. Sp. Pl. 1648. Huds. 629. Pl. Dan. 1. 53. Helvella efculentus: Sowerby, t. 57.)—Cap contracted at the base. Stalk nearly solid. Found in dry woods, and hedge bottom, especially retired and rather curious spots. It is said to spring up abundantly where trees have been burnt down, which was formerly practised in Germany, by those who collected this fungus for profit, till the method was forbidden by law. The eatable Morel has a thick stalk, of a pale buff or dirty white, an inch or two high. The lead or cæp is cellular, like a honey-crop, or like the second stomech of an ox turned inside out; (see Mammalia) its colour an uniform brown, more or less pale, or greyish, in different individuals. This fungus is readily dried, and may be preserved for months, or even years. Its use is to give flavour to sauces and soups, rather than as a dainty by itself.

The central figures, in Sowerby's plate, are considered by Peroon as a distinct species, and called

M. p. tub. Open Morel.—Cap open and foreceding at the base; its cells rhomboid. Stalk hollow. Found with the former.

The late M. Ventenat has thrown much light on the different species of Morrhella, under the name of Phallus, in the first volume of the Mémoires de l'Institut. M. MORCONE, in Geography, a town of Naples, in the county of Molife: 69 miles S.N.E. of Marseille.

MORCAE, a town of Austrian Poland, in Galicia; 12 miles S. of Halicz.

MORDANTS, in Dying, are substances employed to increase the permanence and beauty of the various colouring matter. In the more general sense, a mordant is considered as an intermediate sub stance to increase the affinity of the colouring matter for the substance to be dyed. Other substances are also called mordants, which have merely the effect of increasing the intensity and brightness of the colour, or, as the dyers term it, to bring it out. Of the first kind we have decided examples in alum and oxide of iron. In order to demonstrate the effect of affinity in the operations where alum is used, we may give a short description of the process of printing a piece of calico. Since the earth or base of the alum is found to be the essential ingredient, it has been found that when the acetate of alum is employed, the stuff takes the earth from that acid with greater facility than it does from the sulphate of alum; when alum is used. For this purpose the alum is mixed in certain proportion with the acetate of lead. By this means the acetate of alum is obtained in solution, while the sulphate of lead can be separated on account of its insolubility. The acetate of alum is then made of sufficient confidence for printing, and is applied to the stuff. After this, the whole of the piece is dipped into a madder bath. Those parts where the alum has been applied assume a deep and lively colour, while the ground is very faint, and of a dirty hue. If the stuff be now repeatedly boiled with braise, and exposed to the air and light, the ground becomes white, while the printed parts remain permanent. In this process it is clearly shown that the stuff in itself has not a sufficient attraction of the colouring matter to receive a permanent dye, without the presence of the alum, which, by its common affinity to both, renders the colour intense and permanent.

This theory is supported by many collateral facts. If a solution of alum, or of the acetate of alum, be added to almost any
any coloured infusion, a precipitate will be found consisting of the earth combined with colouring matter. If the precipitate of alum be mixed with an addition of an alkali, the coloured precipitate is much more abundant. It is on this principle that lakes used in painting are formed.

The attraction of the alumine is not left apparent for the stuff to be coloured. Berthollet found that by boiling wool with alum, the earth combined with the animal matter which was re-dissolved by sulphuric acid. And M. Curanda has lately ascertained that when alum is boiled with cotton, some of the alum combines with it; since the original quantity could not be obtained by evaporating the water in which the stuff had been boiled.

The action of oxyd of iron as a mordant is not left conspicuous in printing calico, as in the use of alum the acetate of iron is found more proper than the sulphate; not merely because the oxyd is separated with greater facility, but on account of doing less injury to the texture of the stuff. Those parts printed with the acetate of iron, without any other procés, affume a dark orange, which colour is in fact the same with the common iron mould. If, however, the stuff to be printed be dipped in a bath of madder, it will affume a dark brown, or amber, to which affumption of colour, sometimes approaching to black. This difference is modified by the strength of the bath and the thickness of the iron tint.

Tartar (super-tartar of potash) is much used in dyeing as a mordant, although the nature of it is not well understood. Berthollet found that when wool was boiled with alum alone it acquired a very harsh feel, while that boiled in a mixed solution of alum and tartar was more soft to the touch. The former did not take so bright a colour from the madder bath as the latter. This is a remarkable circumstance, since these two salts have no action on each other. The above chemist, however, is of opinion that the intermediate affinity of the stuff may cause some decomposition. He further thinks, that the tartar has the effect of preventing the too great action of the alum upon the wool, which is much greater than its action upon cotton and silk, in the alluming of which no tartar is used.

The muriat of tin is a mordant of considerable importance in dyeing scarlet. The oxyd of tin has a strong attraction for colouring matter, particularly that of cochineal. This oxyd, like alumine, affumes a deep red, and in common with the stuff and the colouring matter, effecting only the pure part of the latter. (See Tin, Muriat of.) Other substances are employed in dyeing which come under this head, such as muriats of soda and ammonia, acetate of lead, sulphate of zinc, &c. In dyeing the turkey-red, the animal substance with which the stuff is impregnated is supposéd to act as a mordant, by having a greater attraction for the madder than the cotton to be dyed. See Dyeing and Printing.

MORDAUNT, CHARLES, in Biography, earl of Peterborough and Monmouth, distinguisht in the history of our country, the eldest son of John viscount Avalon, and Elizabeth Carey, was born in 1662, and brought up to the sea service. In 1680 he distinguisht himself by his courage at Tangiers, then besieged by the Moors. Having succeeded his father in his title and seat in the house of peers, he spoke against the repeal of the Test act, which James II. endeavoured to promote, and, disapproving the measures pursued by that prince, he obtained leave to go to Holland, under the pretexts of taking command of a Dutch squadron in the West Indies. At the Hague he was one of the first of the English nobility that engaged in the designs of the prince of Orange, who paid great deference to his advice, and whom he accompanied in his expedition to England. On the accession of that monarch, he was rewarded with several high and important state offices. In 1692 he served a campaign in Flanders under king William, by whom he had been raised to the dignity of earl of Monmouth, and in 1697 he succeeded to the earldom of Peterborough, on the death of his uncle Henry, the second earl of that title. In 1705 this noble lord was constituted, by queen Anne, commander-in-chief of the forces sent into Spain, in support of the arch-duke Charles, competitor for the crown, and also joint-admiral of the fleet with sir Cloudesley Shovel. He displayed great bravery and skill as commander of the British forces in Spain, where he took Barcelona, and brought several provinces to acknowledge Charles III. as their king. A junction was afterwards made between the different corps in Charles' interest, and lord Peterborough expected to have had the chief command. Being disappointed in this, he quit the army in disgust, and embarking on board an English ship, failed for Genoa. The loss of the battle of Almanza, and the other disasters in Spain which followed the earl's dereliction, exposed him to censure, and the queen refused to admit him into her presence till he should have justified himself from some charges transmitted by king Charles. The confederation of his conduct, civil and military, was, in consequence, taken up by both houses of parliament, when he cleared himself so effectually, that the enquiry was dropped, and the house of lords voted that he had performed many eminent services during his command in Spain. In 1710, 1711, he was employed in negociations at Turin, and at some other Italian courts. He was created knight of the Garter in 1713, and in a very short time afterwards was sent again into Italy, as ambassador-extraordinary to the king of the Sicilies, whence he did not return till after the queen's death. During the reigns of George I. and George II. he bore the commision of general of all the marine forces in Great Britain, but was not again engaged in active services. He died at Lisbon, in 1755, at the age of 73. The private character of this nobleman has been thus described: 'Born with an exalted imagination, a romantic cast of mind, and a restless activity, he fluid distinguisht from ordinary mortals in every thing which he did.' He said of himself, 'that he had seen more kings and more politicians than any other man in Europe,' and to this part of his character Swift alludes in a poem on the earl, which concludes with these lines:

"A skeleton in outward figure,
His meagre corpse, tho' full of vigour,
Would halt behind him were it bigger.

"So wonderful his expedition
When you have not the least suspicion
He's with you like an apparition.

"Shines in all climates like a star,
In fenes bold, and fierce in war;
A land commander, and a tar.

"Heroic actions early bred in
Ne'er to be match'd in modern reading
But by his name sake, Charles of Sweden."

Lord Peterborough was a wit, and very ready at repartee: being once surrounded by a mob, who took him for the duke of Marlborough, then very unpopular; he said, 'I will convince you I am not the duke: in the first place, I have but five guineas in my pocket; and secondly, here they are, much at your service;' he threw his purse among them, and got off with loud acclamations.

MORDEHI, an East Indian name for a disease, to which the people of that country are subject. It consists in a violent...
lent disorder of the stomach. The great heats, copious
sweats, and supervening cold of that country, all
naturally tend to weaken the stomach. Now if the
inhabitants eat or drink immoderately at night, the
conceit of their aliment may be but very unduly
performed. Hence, besides this diathesis of the
stomach, they are subject to others of the bowels;
and diarrhoea are very common among them,
and with difficulty cured.

**Mordeilla**, in *Natural History*, a genus of insects
of the order Coleoptera, of which the generic character is,
antennae moniliform, or pectinate; head deflected
and bent under the neck; shells curved downwards towards
the tip: at the base of the abdomen, and before the thighs, is a broad
lamina. Of this genus there are thirty-four species enumer-
ated by Gmelin, and divided into two sections.
The insects in section A have their antennae moniliform;
fore-feet clavate, hind-feet filiform.

Species.

* Aculeata. This is the most common of the British
species, measuring from a quarter to half an inch in length:
it is entirely black, and of a smooth surface; the abdomen
is compriessd, and terminates in a spine or sharp point;
stretching beyond the wing-sheaths; the legs are rather long,
and the insect, when disturbed, has the power of leaping or
springing to a small distance. It is usually found on plants,
in gardens, and other places. It is observed to vary occa-
ionally in colour, having the wing-sheaths sometimes marked
by two transverse, cinereous, villous bars.

Fasciata. Tail ending in a point; body black; shells
with two cinereous bands. It is found on flowers in the
southern parts of Europe.

8. Punctata. Tail ending in a point; shells black, with
four yellow dots, the first lunate. It inhabits South America.
The head is brown; thorax yellowish, villous, with
four brown dots before, and waved streaks behind; shells
grey; spine at the end of the abdomen black.

Testacea. This is black; shells are telfaceous, and
edged with black. It inhabits Africa, on the Daccaus.

Centralis. Tail ending in a spine; the body is black,
and the abdomen fulvous. It inhabits Germany.

* Abdominalis. The tail in this like-wise ends in a spine;
the body is black; the thorax and abdomen fulvous. It is
found in many parts of Europe. The head, breast, shells,
abdominal spine and legs black; thorax and abdomen ful-
vous, pilifer, immaculate.

* Humeralis. Black; shells yellowish at the base. It
is found in this country, and other parts of Europe, on
flowers.

Lateralis. Black; mouth, sides of the thorax and legs
telfaceous. It is found in Holface on flowers.

Frontalis. Black; front and legs yellowish. Inhabits
Europe.

Atra. Black, immaculate; tail not spiny; found in
Denmark.

Thoracica. Black; head and thorax yellow. This is
found in divers parts of Europe.

Rufícolis. Black; mouth, thorax and legs yellow. It
is found in France, and resembies the last named species.

* Flava. Yellow; shells tinct with black; is found on
umbellate flowers in several parts of Europe.

Uniciespídate. Yellow; abdominal lamina blue; tho-
rax tinctispídate behind; shells with three black dots. It
is found in Siberia.

Munina. This is said to be pubcrent, undulate and
macresc; the thorax has three black dots.

6. Punctata. Glossy black; shells with three white dots.
It is found in Germany.

* Oxycanthæ. Telfaceous; head black; thorax
brown. It inhabits England, and is found on the flowers
of the "Cratus oxycanthæ."

* Melanopus. Black; shells, thorax, and head telf-
aceous. This is also an English insect.

* Bicolor. A native of our own country; black shells
feetaceous tipp with black, a black band in the middle.

Perlata. Glossy black, sub-villous; hinder margin
of the thorax, and four spots on the thorax, purpled. It is
found among the Alps.

Raspites. An inhabitant of France; brown, legs fer-
ruginous.

* Clavicornis. This species is entirely pimpce; the
antennae are clavate; it is found in England, on the flowers
of the "Rheum rhabarbarum," and has been thought not
to belong to this genus.

B. The insects of this section have the antennae pectinate;
the feelers uniform.

Species.

Subdipera. Shells very short, ovate, vaulted, palelith.
It inhabits Provence. It is describcb as having the antennae
yellow; thorax gibbous, black; wings exerted, longer
than the body, whitish with a brown spot in the middle; legs
dufky; pale rufous at the tip; abdomen of the male black,
of the female pale, with a black tail.

Ferruginea. Rufous; breast, tail and legs black. It
inhabits the East Indies. The antennæ are black, the wings
brown.

Nasuta. Body entirely black, immaculate; it inhabits
Japan, and has been described by Thunberg.

Pecinita. Rufous; shells black; found in America.

Antenna are black; head rufous; eyes black; thorax nar-
rrower before, pointed behind; shells black at the base, with
a cinereous blotch in the middle; wings black; legs rufous,
the joints black.

Paradoxa. Black; sides of the thorax and shells telfa-
ceous. It inhabits the umbellate plants of Europe.

Flabella. Telfaceous; mouth, breast, and back of the
abdomen black. It inhabits Italy. The antennæ are
black; the first joint ferruginous; head telfaceous; mouth
black; abdomen very obvue, telfaceous black on the
back.

Punctata. Thorax telfaceous, dotted with black;
shells black-edged. Inhabits Cayenne. The antennæ are
black; dots on the thorax 4, 1, 2; margin and future of the
shells telfaceous, with a black dot at the tip; the legs are
black; thanks telfaceous at the base.

6. Maculata. Black; thorax ferruginous; shells telfa-
ceous, with three black spots. It is found in America.

2. Maculata. Ferruginous; breast black; shell telfa-
ceous with a black spot. Inhabits Hungary.

Dimidiata. Black; the shells on the upper half are
yellow. The body is of a glossy black, except the upper
half of the shells; the abdomen is very obtuse and almoat
truncate.

Limhata. This is ferruginous; the crown, disc of the
thorax, and shells are black.

Popillnea. Black; shells are telfaceous with three
black bands, the first annular; it is found in Germany on
the poplar-tree, whence it derives its name. The head is
dufky; the antennæ are ferruginous tipp with black.

Mordellæ, in Geography, a town of France, in the
department of the Ille and Vilaine, and chief place of a can-
ton, in the district of Rennes. The place contains 2292, and

the canton 6664 inhabitants, on a territory of 100 kilometres, in seven communes. 

MORDENTE, Ital. literally means biting. 

MORDEN, or MORDOX, a name given to a difeafe very frequent among the inhabitants of Goa, which consists in a nauea, and continued vomiting, and usually feizes the patient suddeuly and unexpectedly, and often proves fatal. 

MORDOVA, in Geography, a town of Russia, in the government of Tambov; 32 miles S.E. of Tambov. 

MORDOVES, a nation of the Russian empire, called by the Russians Mordva, and dwelling on the Oka and Volga, in the governments of Kazan, Nishe-Negorod, Ufa, Simbirsk, and Penla. Although they are not fo numerous as the Tcheremis and Tcheuvaques, they form a very considerable nation, which has been found to increase on every successive enumeration, and divide themselves into two main items, Mokfchan and Erfan, by which they are peculiarly named; though the general appellation of Mordva is not unusual even among themselves. This nation, in the opinion of several Russian antiquarians, is the name which Nelter mentions under the names of Meres or Meriones, on occasion of the national confederacy entered into by the five Slavonian and Finnifh tribes on the lake Ilman for the founding of the Russian flate, and who, at that time, inhabited the districts of Roodof, Halibfch, Rolftona, and Yaroflaf. Tooke’s Russian vol. iv. 

MORE, ANTONIO, in Biography, born at Utrecht in 1519, was a very successful painter of portraits in a style far advanced above his Flemifh or German contemporaries, yet still formal and imperfect, compared with that of Titian and Vandyke. The cardinal Granvelles introduced him at the court of the emperor Charles V. who sent him to Portugal; where he painted the king, John III., his queen, and the Infanta Mary, flir wife of Philip II., and was most amply rewarded. He afterwards came to England to paint the portrait of queen Mary, then engaged to the fame Philip, and for that picture received 100l. a gold chain, and was made painter to their majesties, with a pension of 100l. per quarter. He remained in England during Mary’s reign, and was very much employed, so that most of the noble families in the country are adorned with some of his pictures. On the death of that queen, More returned with Philip to Spain, highly favoured by the king, whose familiarity with him placed his life in danger; for More ventured to return a flap on the queen, which Philip in a playful manner gave him, by rubbing some carmine on his majesty’s hand. This behaviour was accepted by the monarch as a jeft, but it was hinted to More that the holy tribunal might regard it as sacrilege, and he fled, to save himself, into Flanders, where he was employed by the duke of Alva. Philip invited him back to Spain, but he excused himself, and did not return. Though portraiture was the source of More’s general occupation, yet he had very considerable talents for history. A very fine work of his representing the Ascension of our Saviour is in the gallery of the Louvre at Paris. The style of the composition, which confids of Jefus Chrifl ascending, crowned by two angels, and accompanied by the figures of S. Peter and S. Paul, is of the severe and grand fyle employed by Fra. Bartolomeo; the colouring is exceedingly fine, and correspondent to the style of design; he has been laftfulful in the expression of the principal figure; if that had been moreJeft and grand, this picture would alone place More among the very flirft chefs of artists. He died in 1575, at the age of 76. 

MORE, SIR THOMAS, an illuftrious flatefman, the only son of Sir John More, a judge of the king’s bench, was born in London in 1485. Having received an excellent education, he was placed in the family of cardinal Morton, archbishop of Canterbury, and chancellor. He there fo much distinguished himself by the quickness and brilliancy of his talents, and by the amiablefles of his temper, that the cardinal was accustomed to fay, “This child, though only waiting at table, will prove an extraordinary man.” Hence we learn how customary it was, at that period, for children of gentlemen to submit even to menial conditions, when received into the houses of the great. However degrading this may appear to us, it has been juftly observed, that perhaps it was not more fo than the custom of faggings in our public schools, to which boys in the fame rank of life are obliged, even now, to submit. The youth did not remain long in this situation; he had put forth the promise of fine abilities and a powerful mind, and was in a short time removed to Canterbury college, now Chriflchurch, Oxford, where he pursu’d his studies with diligence and fuccefs, and when he had completed his academical course, he was entered at the New Inn, to be initiated in the legal profeflion, with the view of practicing at the chancery-bar. After this, he seems to have changed his plans, and to have removed to Lincoln’s Inn, where he remained till he was called to the bar. He was naturally very facetious and cheerful, nevertheless he began, before he arrived at the years of manhood, to ponder on those personal authorities which are considered as essential to the devout character in the church of Rome, to which church he was, through the whole of life, zealously attached. In his twenty-second year he was elected a member of the parliament called by Henry VII. for the purpose of demanding an act for the marriage of his eldefb daughter to the king of Scotland. The commons in general thought the demand exorbitant, but no one had courage to oppose it, till Mr. More fet the example, and by his powerful eloquence the motion for complying with the king’s wishes was rejected. This service, so honourable to his integrity, was unquestionably attended with considerable hazard. Henry was engaged at the opposition made to his demand, and not finding in a mere lad a profitable object of his royal vengeance, who had probably nothing to lose, he contrived a quarrel against his father, and threw him into the Tower as a clofe prisoner, where he was kept, till he opened the dungeon gate by submitting to an arbitrary and heavy fine. The young man, probably, felt a hundred times more for the confequences inflicted on a parent for the维护 of his own integrity, than he would from any personal sufferings, and, unwilling to involve his father or friends again in the king’s displeasure, retired from public notice, and passed several years in privacy, and in the studies of the French language, of history, and of those arts and sciences which were deemed the liberal arts. It is supposed that during this period he filled the office of law-fader at Furnival’s Inn, which he held three years, and after this we find him living in the neighbourhood of the Charter house, in the practice of all the devotional exercices and authorities of the rigid order which then inhabited it, but without taking the vow. He had, it is known, a great inclination to enter into the functions of the ecclesiastical flate, but either from the perfuasions of his father, or from an unwillingness to be bound by the strict rules of the church, he abandoned the defign. By the recommendation of his friend dean Colet, he married the eldefb daughter of Mr. Colt, of New-hall in Essex. It has been faid that, in viifiting this gentleman, he was struck with the charms of the fecond daughter, but that unwilling to entangle the eldefb, he paid his addresses to her. After his marriage, he applied himfelf diligently to his profecion as a lawyer, in London, and very soon found himfelf in poffeflion of an annual income of more than 400l. which at that time was
was considered no mean sum to be derived from a profession. His great reputation caused him to be employed by the English merchants as their agent in some important matters of dispute between them and the merchants of the Steelyard, on which occasion he went to Flanders. In 1516 he accompanied, to that country, the commissioners sent to renew the alliance between Henry VIII. and Charles, then archduke of Austria, and his conduct on this occasion rendered the king very defires of engaging him in his particular service. Although his time must have been fully occupied, yet in the midst of all his engagements he found leisure to write, in the Latin language, his "Utopia," which he dedicated to a gentleman of Antwerp. This production made him known to the learned abroad, and he engaged in a corrcspondence with several eminent men of letters, among whom was the great Erasmus. With this illustrious scholar he had contracted an intimate friendship in 1510, when he visited England, which appears always to have subsisted between them.

Mr. More was not only a man of the strictest integrity, but possessed a mind incapable of being swayed by the principles of avarice and ambition, and he steadily refused a pension from the king, which was prefixed upon him by cardinal Wolsey, on the ground that such an obligation from the court would shackel him in the performance of his duty as a law-officer of the city, should any matter of dispute occur between them. At length the great credit which he acquired in pleading before the bar-chamber for the release of a ship of the pope's, which had been claimed as a forfeit to the crown, determined the king toinfult on his accepting the place of master of reqeuas. In a short time after this, he received the honour of knighthood, was admitted a member of the privy-council, and received into a familiarity with his majesty, which seemed to entitle him to all the honours and emoluments of a chief favourite. Henry conferred with him on all the topics of literature and philosophy with which he was wont to be generally acquainted, without the labour of study, and in this way, notwithstanding the aversion of the ancient fage, there does seem to be a royal road to science. The king likewise amused himself with the wit and humour of More's relaxed conversation, and often required his attendance at his private suppers with the queen, for the purpose of "making them merry." Sir Thomas was no doubt very much flattered by this extraordinary mark of distinction, but he found that it encroached too much upon his leisure and domestick comforts, and he became grave in the presence of his sovereign, that he might have liberty to be merry at home. In 1520, the king conferred upon him the office of treasurer of the exchequer, and he removed to a spacious house at Chelsea. In 1522, when the king had summoned a parliament for the purpose of raising supplies for the war with France, he procured the nomination of his favourite, sir Thomas More, to be speeker of the house. On this occasion, his speech to the king, on being preferred to him for approbation, was unworthy his great mind, but he redeemed his character when the cardinal came down to the house, with all his late dignity to overawe that assembly into a compliance with his master's wishes for a subsidy, by refusing to lend the king any answer by his minister, and by granting him only the half of what he demanded. If, however, in this railliance, he gave any personal offence to the court, it was of no long duration, for in 1526 he was appointed to the chancellorship of the duchy of Lancaster, and in the following year was joined with Wolsey and others in an embassage to the French king. Shortly after this, Henry came to see him at Chelsea, and walked with him more than an hour in his garden with all the marks of partial friendship. After he was gone, Mr. Roper, fon-in-law to sir Thomas, struck with the high honour, congratulated him upon such a distinguishing mark of the royal favour. The prudent statesman looked beyond the surface, and was well aware of his master's capricious and tyrannical temper; while therefore he acknowledged that for the present moment, he probably poffessed as much of the king's regard as any subject in the kingdom, he added, "Son, I may tell thee that I have no cause to be proud on that account, for if my head would win him a battle in France, it would not fail to go off."

The opinion of sir Thomas with regard to the intended divorce of the queen, was unfavourable to the wishes of the king; nevertheless, upon the disgrace of Wolsey, Henry raised him to the high office of chancellor of England; this was in the year 1530, and he was the first layman that ever occupied that station. He proved himself, in every respect, worthy of the elevated rank assigned by him to his viceroy, and the office was never filled by any person who surpassed him in diligence, honour, and integrity. The suitors were probably few in number, but for the dispatch of their causes he sat every afternoon in his own hall, and when he resigned the seals there was not one cause remaining for decision. Bribes were much the fashion of the day, but he rejected them all, and that without any show of austerity, but in a good-humoured way, that seemed peculiar to himself. An instance is mentioned very much to his credit; the wife of a man, who had a suit in chancery, having brought him a gold cup as a present, he ordered it to be filled with wine, and drinking her health, delivered it to her again as a new-year's gift. At another time a lady presented him with a pair of gloves, and forty pounds, in angels, in them; "Mr. Gref, said he, "since it would be unmanly to refuse your gift, I accept the gloves, but utterly refuse the lining." In proof of his great impartiality, one of his sons-in-law, Mr. Hean, having a cause depending, was advised by the chancellor to submit to arbitration, which he refused, prefuming, probably, upon the favour of his great relation, but he had the mortification afterwards to find a decree given directly against him. He was zealous in his endeavours to discourage vexatious and litigious suits, though he was not altogether disinclined to the prosecution of such. He had, as we have seen, a warm and ardent attachment to the then established system of religion, and could not bear the contempt that the reformers threw upon it, which he conceived to be subversive of all regular government and subordination. He was, probably, consulted by Henry when he composed his work against Luther, and to that reformer's contemptuous answer he wrote a reply, in which, having the argument against him, he heaped together all the terms of virulent abuse that the Latin language could afford. He afterwards wrote against the historian Tindal; and could not even speak of the reformers, or heretics, as he called them, without hatred and fury; In a letter to Erasmus, he declares, without hesitation, that so great was his dislike to them, that unless they repented he would torment them by all the means in his power. It is even said, and seemingly on unquestionable authority, that he caused Mr. Bainham, a gentleman of the Temple, accused of favouring the new opinions, to be whipped at his own house, in his presence, and afterwards faw him put to the torture in the Tower. By these levities this unfortunate gentleman was induced to recant, but, as it happened in other cases, he afterwards repented of his timidity, avowed his opinions, and was actually burnt in Smithfield: this was probably after More was out of office, as Erasmus affirms that no one was ever put to death while he was chancellor. His intolerance in matters of faith is a subject of great regret; but his prejudices were those of an honest heart, though
though unquestionably in this respect of a narrow mind. The bishops, feeling their obligations to him for assignment in the support of their cause, made up a purge among themselves, and presented it to him, but he refused it, and would not permit any of his family to accept it.

His integrity and ferupulous regard to conscience were soon to be put to the severest test, and the manner in which he went through his trial has conferred great honour on his memory. Nothing could induce him ever to concur in the king's favourite project of a divorce, and being sensible that Henry would, notwithstanding any advice to the contrary, in the end carry the point, he resigned the fees after holding them two years and a half. He now resolved to quit all political concerns, and devote himself to literature and religion. Although the king had expressed himself very graciously to Sir Thomas on his resignation, yet the chancellor's reluctance to his will deeply offended him, and notwithstanding any outward marks of civility, the tyrant probably meditated schemes, worthy of his own dark and guilty mind, to free himself from the reproaches of so worthy and upright a fervent. In his reign, we have more than once hinted, ruin was never far distant from the man who dared to thwart his pleasure.

The first circumstance that gave the king a handle against Sir Thomas More, was the imprisonment of Elizabeth Barton, the holy maid, or nun of Kent. When she opened her commission to admonish the king of his crimes against the church, she was arrested, and made him privy to her pretended revelations. Her affected simplicity and holiness seem to have made considerable impression upon him; she wrote him a letter, and on this circumstance being made known, the king directed him to be prosecuted as an accomplice with her, and they were named together in one bill of attainder. While this was filed over him, a committee was appointed to hear his justification of himself; this plan was not, however, intended to free the accused, but with the view of entrapping him to assent to the king's divorce, which Henry thought he would gladly do, to escape the danger that threatened him. He nobly withstood the temptation, and completely cleared himself from every imputation of crime, that the king, though most unwillingly, permitted his name to be taken out of the bill. He was next involved in the guilt of refusing to acknowledge the king's claim to ecclesiastical supremacy, and the renunciation of all obedience to the pope. Sir Thomas was cited again and again to appear and take the new oaths, he as frequently refused, and being at length found liable to his purpose, was committed to the Tower, and indicted for high treason, on the statute made for the occasion. While he remained in prison, his wife was allowed to visit him, and, in vain, used her worldly arguments to persuade him to comply with the king's pleasure.

Having remained in prison about fifteen months, it was resolved to bring him to trial at the king's bench. The indictment was drawn, and being read to him, he, without any hesitation, pleaded not guilty; he justified himself in a masterly manner, that the attorney-general could not venture upon a reply. The solicitor-general, Rich, to obtain the favour of the court, swore that he had heard the venerable prisoner maintain that the parliament could not make the king supreme head of the church, and upon the evidence of this wretch, which was not only not supported by any other persons, but contradicted by Sir Thomas More, and by several noble lords who were present at the time, the words charged were said to be spoken, and who all declared they heard no such words; the jury suffered themselves to be managed as to return in a few minutes a verdict of "guilty of high treason."

Sir Thomas More was author of many pieces besides his Utopia, a catalogue of which may be seen in the first volume of

"In that disgraceful age of servitude," says the writer of the article in the General Biography, "juries indeed seemed to have no other rule than the king's pleasure, and a criminal in the eyes of the court was almost sure of being condemned by his country." Sir Thomas More was unmoved at the sentence, which, though quite conscious of his innocence, he probably expected; and he was ordered back to the Tower. On his road, his favourite daughter, Mrs. Roper, who had been anxiously waiting the event, burst through the throng, fell on her knees before her father, and closely embracing him, could only utter the words, "My father, Oh my father!" He tenderly returned her embrace, exhorted her to patience, and resignation to the divine will, and parted from her. Scarcely had they separated, when in a new paroxysm of grief, she again burst through the crowd, and clung round his neck in piteous anguish. His firmness was now overcome; tears flowed plentifully down his cheeks, till with a final kiss she left him. On the fatal day, July 5, 1655, he stripped himself of his gown, and walked cheerfully to the place of execution: observing that the scaffold was but flenderly built, he turned to the lieutenant of the Tower and said, "I pray you, Mr. Lieutenant, see me safe up, and for my coming down let me shift for myself." He requested the executioner to offer up their prayers for him, and to bear witnesses that he died in and for the holy Catholic church, and had been a faithful servant of God and the king. He then addressed himself to his Maker, and calmly submitted to the blow of the executioner, having first requested him to stay his hand till he had removed his beard, which, said he, "has committed no treason." A single stroke severed his head from his body. Such was the end of Sir Thomas More, at the age of 55.

Sir Thomas More was esteemed one of the greatest prodigies of wit and learning that England ever produced before his time. He was meek, humble, and charitable, and a defier of the things of this world. His talents and learning were great and profound. He probably had not his equal in the knowledge of divinity, the laws of his country, the Latin and Greek languages, poetry, and the mathematics. His society or correspondents, in each of these, were regarded as the lights of the world. He could enumerate among his friends Erasmus, Colet, Tontalb bishop of Durham, Blothob of Rochester, Lynace, Lily, and many others, of whom several have celebrated his memory in their respective works. Erasmus, speaking of him in the period of his prosperity, says, "More has built near London, upon the Thames, a commodious house, neither mean nor the object of envy. There he converses affably with his family, his wife, his son and daughter-in-law, his three grand-daughters, and their husbands, with eleven grand-children. There is no man living to affectionate to his children, and he loves his old wife as well as if she were a young maid. Such is the excellence of his temper, that with whatever happens, which could not be prevented, he is as well pleasing as if it could not have been better. His house may be referred to Plato's academy, or rather may be called a school or university of the Christian religion, for there is no one in it who does not read or study the liberal sciences; piety and virtue are the care of all; neither quarrels nor intemperate words are heard; more

his household discipline is not maintained by harsh and lofty language, but by kindnes and courtesy; every one performs his duty with alacrity, nor is sober mirth wanting."

Sir Thomas More was author of many pieces besides his Utopia, a catalogue of which may be seen in the first vo-
lume of the "Athenae Oxonienses:" they were chiefly contro-
versial, and have been long since forgotten. His English
works were published collectively, by order of queen Mary,
in 1557, and of his Latin works editions were given
Baili, in 1567, and at Louvain in the preceding year. His
Utopia was translated by bishop Burnet, and has been fre-
quently reprinted in an English version. The edition referred
to in this article is by Thomas Williamson, eqq. in 1751, to
which are added a short account of the author's life and
trials, and a prayer composed by Sir Thomas More while a
prisoner in the Tower.

Of his children, his favourite was Margaret, the wife of
William Roper, eqq. whom he educated in classical lite-
rature with great care, and who is celebrated by Erasmus on
account of her solid learning, the amiableness of her dispo-
sition, and the purity of her virtues. Her reverence and
affection for her father were unbounded. After his head
had been expelled during fourteen days upon London bridge,
she found means to procure it, and preserving it very care-
fully in a leaden box, gave directions that it should be placed
in her arms when she was buried, which was accordingly done.

MORE, ALEXANDER, a celebrated preacher among the
French Protestants, the son of a Scotch divine, the principal
of a Protestant college in Languedoc, was born in 1616. He
soon distinguished himself among his contemporaries by
his acquirements in literature, and when he was scarcely
twenty years of age, he obtained by his merit alone the
professorship of Greek at Geneva, in opposition to a num-
er of other candidates, whose years, it might have been
expected, would have given them the ascendancy. Having
fulfilled the duties of this office for about three years, he
succeeded the learned Spanheim, who had removed to Ley-
den, as professor of divinity, and as minister in the church
of Geneva. As a preacher, Mr. More possessed very popular
talents, which, united with great learning, gave him a super-
iority over many of his brethren, which excited their jealousy
against him. His own temper was far from conciliating, it
was laity, vindictive, and fatirical; hence he became in-
volved in numerous quarrels. He held at different periods
the professorships of divinity at Hardewyc, at Middelburg,
and the professorship of history at Amsterdam. While in
the last named situation, he obtained leave of absence for a
few months for a journey to France. He extended his route
to Italy, and was noticed with respect by the grand duke
of Tucceany, who made him several handsome presents.
During his stay in this country he wrote a fine poem on the
defeat of the Turkish fleet by the Venetians, for which the
republic of Venice presented him with a chain of gold. In the
spring of 1650, he returned to his professorship in Holland,
and retained it till 1659, when he went to Paris, and became
minister of a church in that city. Some attempts were
made to get him diffused, but they were ineffectual. In the
paupit, he attracted great and extraordinary crowds of
auditors, and was regarded by the auditory as incomparable
preacher. It was a matter of considerable dispute whether
his excellence lay in anything solid, or only in show; whether
it deserved to be called a flash of lightning, or a steady light.
Those who were for decrying his talents, admitted that he
must be heard with pleasure, and that he had the power of
exciting the passions in a very extraordinary degree. In the
mufl of the climate with which he was acquainted, his repu-
tation was attacked, and he was accused of deeds uncon-
scionable to the character of a Christian minister, by persons
who were themselves respectable, and against whom no
charges could be made. The particulars of these charges,
and of the proceedings instituted against him, are given by
Bayle, who says, farcally perhaps, that "his death
which was very edifying, and the marks of piety which he
discovered in his last sickens, blotted out the remembrance
of what might have been irregular in his behaviour." He
died in 1670, at the age of fifty-four. He was author of
many works, written in the Latin language; one on grace
and free-will, and one on the holy scriptures; some Latin
orations, and Latin poems, more learned than elegant;
nevertheless some of them were much read and applauded;
and a piece entitled "Alexandri Mori Fides Publica," &c.
which was intended as a defence against Milton's attack
for fingendo into the world "Regii Sanguinis Clamor ad
Caetum."

MORE, HENRY, an eminent divine of the church of
England, and a Platonie philosopher, was born at Gran-
tham, in Lincolnshire, in the year 1614. He was a lad of
fine promise, and was sent at the proper age to Eton school,
where, in the course of three years, he made extraordinary
progrès in the Greek and Latin languages. From Eton he
was sent to Cambridge, and was entered of Chiril's col-
lege in the year 1631: (and now,) says he, "a mighty
and almost immoderate thirst after knowledge possessed me;
I immersed myself over head and ears in the study of phi-
losophy; promising a most wonderful happiness to myself
in it." In this temper of mind he applied himself to the
diligent perusal of the works of Aristotle, Cardan, Julius,
Scaliger, and other eminent philosophers, and in a short time
made himself master of their doctrines; and took his de-
gree of B.A. in 1635. He appears to have met with but
little satisfaction in their respective systems, and abandoned
the scholasties, determining to search for better guides to
the object which he was seeking after. He accordingly
began to study the Platonic philosophy; from this he was
confirmed in the conviction, that something greater and
more divine than the knowledge of human things, con-
stitutes the supreme felicity of man; and that it is attain-
able only by that purity of mind, and divine illumination,
which will raise him to an union with God. In the year
1639, Mr. More took his degree of M.A., and in the fol-
lowing year he published a work, entitled "Psychozoia,
or the first Part of the Song of the Soul, containing a Chris-
tian-Platonic Display of Life," which he reprinted in
1647, with other parts of the long, and some smaller pieces,
in an octavo volume, under the title of "Philosophical
Poesies," which he dedicated to his father. Having been
elected a fellow of his college, he became tutor to many
young persons of rank, and among others to Sir John Finch;
and out of the college he was tutor to the sister of Sir John,
lady Conway, whose genius and temper were nearly allied
to his own, and with whom he entered into an intimate
friendship. At the demise of this lady, who equipped the
trusts of the Quakers, he drew up some of his treatises,
perticularly the "Conjectura Cabalistica," and the "Phi-
losophia Teutonica Censura;" in return for which he left
him a legacy of 500L. Previously to the publication of this
last piece, he had taken his degree of doctor in divinity, and
from this period he appears to have devoted himself very
much to the retirement of a college life. In 1642, he re-
signed the rectory of Ingoldsby, which had been purchased
for him by his father. He might have been elected to the
mastership of his own college, in 1654, in preference to Dr.
Cudworth, but he preferred the enjoyment of undisturbed
study, and contemplation, to any honours and emoluments
which the world had to offer. In his college he lived gen-
erally unobtrusive, though he constantly refused to publishe
the "Greewaut. He saw, and occasionally wept over, the
misfortunes of his country, but he was for the most part, like
Archimedes,
Archimedes, as bully occupied in his chamber, as to be inattentive to things without. He corresponded with Des Cartes, and embraced many of his theories, though his discomfiture pointed out the fallacy of some of his arguments, and the weaknesses of some of his reasoning. Offers of high church preferment were proffered upon him, but he refused them all: he was almost wholly occupied in composing and publishing books, intended to establish the principles and maxims of virtue and religion. Of these, one of the most popular was entitled "The Mystery of Godliness." The high character which he had attained by his works, though hostilely theological, occasioned his being selected to be one of the Royal Society, with the view of giving reputation to it before its establishment by the royal charter. He was accordingly proposed as a candidate by Dr. Wilkins and Dr. Cudworth, and in due time elected. Dr. More died in 1687, in the seventy-third year of his age. He was highly esteemed and well spoken of by persons of all parties: he was distinguished by the most ardent piety, and an irresistible spirit. He is described by Bishop Burnet, as an open-hearted and sincere Christian philospher, who studied to establish men in the greatest principles of religion, in opposition to the gloomy tenets of Atheism. Hobbes said, "If his own philosophy were not true, he knew of none that he should so much like as that of Dr. More's." His "Enchiridion Ethicum" is highly applauded by lord Shaftesbury and Mr. Addison, as an admirable system of ethics; and his "Divine Dialogues," on the attributes and providence of God, have been much read and admired. Biog. Brit. Enfield's Hist. of Phil.

Mores, in Geography, a township in Northumberland county, Pennsylvania.

Mores's Head, in the Manor. See Mores's Head and Roan.

Morea, in Geography, a country of European Turkey, in the form of a peninsula, joined to the rest of Greece by the isthmus of Corinth; anciently called "Pelopennesus." The kingdoms of which it once consisted were Sicily, Argos, and Mycenae, Corinth, Achaia propria, Arcadia, and Laconia. It derives its present name, as it is said, from "Morus," a mulberry-tree, either from its resemblance in shape to the leaf of this tree, or from the number of mulberries which the country produces. It has several rivers, lakes, and mountains, and also many fertile and delightful plains. By the treaty of Carlowitz, the Turks ceded the whole Morea to the Venetians, but in the year 1717, again dispossessed them of it. It is divided into four districts.

Moredagong, a town of Hindoostan, in the circuit of Ellichpour; 24 miles S.W. of Akowla.

Moreau, La Demoiselle Fanchon, in Biography, a famous singer in the ferius opera at Paris, had great success after La Rochois had retired from the stage in 1697. Her first performance was in the prologue of Luili's opera of Phaeton in 1683. She quitted the theatre in 1708, to marry M. de Villiers, an officer of the king's household.

Her sister, Louise Moreau, sung in the year 1689, in the prologue to Proserpine, and was much applauded. Laborde.

Moreau, René, an eminent physician of the seventeenth century, was born at Montreuil, in the province of Anjou, in 1587, and was admitted to the degree of doctor in the faculty of medicine at Paris in 1618. He was distinguished as a man of general erudition, as well as his professional talents, and was in great favour with the court. He was appointed professor of medicine and surgery at the Royal College, and filled his post with great reputation; and during the years 1636 and 1631, held the office of dean of the faculty of medicine. He died in October, 1656, at the age of sixty-nine. His principal writings were as follows: "De Milione Sanguinis in Pleuritis, cum vita Petro Briffeti," Paris, 1622. "Schola Salernitana, hoc est, de valeutudine humana," 1625. This book passed through many editions. "Vita et Leones Jacobus Sylvius," Geneva, 1635, prefixed to an edition of the works of that author. "Epitola exequenae ad C. V. Baldum de affecto loco in Pluritis," Paris, 1641. "Epitola de Laryngotomia," Paris, 1646, published with the "Exercitationes of Angina of Thomas Bartholin. "Tabula methodi universalis curandorum Morborum," 1647. He also translated from the Spaniard, Colonero's work, "Du Chocolate, Discours curieux, divisés en quatre parties." Eloy Díez. Hist. Med.

Moreau, Jacob Nicholas, counsellor of the court of aids, historiographer of France, librarian to the queen and senor royal, was born at St. Florentine in 1717. He wrote several works, the chief of which are, 1. "Memoires pour servir à l'Histoire des Cacouacaus," 12mo. 2. "Memoires pour servir à l'Histoire de notre Temps," 2 vols. 12mo. 3. "Observateur Hollandais; quatre Principes de Morale, de Politique et de droit Publique, ou Dicours fur l'Histoire de France," 21 vols. 8vo. He was guillotined in 1794. Nouv. Dic. Hist.

Morecambe Bay, in Geography, a bay in the Irish sea, on the coast of Lancashire, at the mouths of the rivers Leven and Duddon. N. lat. 54° 4'. W. long. 3° 52'.

Moree, a town of France, in the department of the Loire and Cher, and chief place of a canton, in the district of Vendôme. The place contains 912, and the canton 7711 inhabitants, on a territory of 237 1/2 kilometres, in 10 communes.—Allo, a river of Bengal, which runs into the bay. N. lat. 21° 50'. E. long. 91° 3'.

Moreira, a town of Portugal, in the province of Beira; 32 miles S.E. of Lamego.

Morel, in Biography, a name well known among the eminent French printers. Frederick, the elder, a native of Champagne, was king's printer at Paris, and interpreter to his majesty for the Greek and Latin languages; he composed several works, and died at Paris in 1553, at about the age of 62, leaving a son, known as Frederick Morel the younger, the most celebrated of the family, who succeeded his father, in 1581, as king's printer in the Hebrew, Greek, Latin, and French tongues. He was well versed in these languages, translated from the Greek, and published, from the manuscripts in the king's library, a number of authors, particularly the fathers, with annotations of his own. He facilitated every thing to study, and being informed that his wife was in the act of expiring, he refused to quit his pen till he had finished what he was about, and by that time news was brought him that she was dead; to which he coolly replied, "I am sorry for it—she was a good woman." He died in 1638, at the age of 78. He had a brother Cloud, who was nominated king's printer in 1622. He gave valuable editions of several Greek fathers, and other authors, to which he prefixed learned prefaces of his own composition. He died in 1626, while he was engaged in an edition of St. Athanasius and Libanus, which was completed by his son Cloud, who succeeded to the business. Charles, another son of Frederick, exercised the same office with credit, which he resigned, in 1639, to his brother Giles. The latter printed an edition of Avicenne, Greek
Greek and Latin, in four volumes folio, and the great Bibliotheca Patrum, in 17 volumes. Morel.

Morel, William, a native of Normandy, professor of the royal court, in 1555, as director of the royal press, and gave good editions of several Greek authors. He wrote a "Commentary on Cicero de Finibus?" "A Table of the Seita of Philosophers?" and "A Dictionary in Greek, Latin, and French." He died in 1564.

Morel, Andrew, a famous antiquary, was a native of Berne, in Switzerland. He excelled in the science of medals, and was author of a work of great value, which did not live to complete, entitled "Specimen universi rei nummariae antiquae," 2 vols. 8vo. He was offered the place of keeper of the royal cabinet of medals at Paris, on condition of renouncing the Protestant religion, which he refused. He was confined some time in the Battle, and on gaining his liberty he went to D'Armstadt, in Germany, where he died in 1703. In 1734 was published, in 2 vols. folio, "Thesaurus Morelanius, familiaris Romanorum Numismata omnia, et disposita ab Andrea Morello, cum Commentariis Havercampi." Moreiri.

Moreland, in Geography, the name of two townships of Pennsylvania; one in Philadelphia county, the other in that of Montgomery.

Morelet, the Abbé, in Biography, a man of letters, contemporary and companion with all the first men of genius and talents in France during the latter part of the last century. He was in England, and a guest at the earl of Shelbourne's (marquis of Lansdown) during the American war, and intimate with Garrick, whom he had known in France. He had much taste and passion for all the fine arts, but chiefly for music, which he had studied, and upon which he seemed much to have meditated.

In 1759, he published a small pamphlet "On Musical Expression and Imitation," which is full of ingenious ideas, and well written.

M. Laborde, in 1780, speaks of the abbé's pamphlet in the following manner.

"This little work on musical expression is as well written as well thought.

"According to him, 'Music is a succesion or a combination of measured sounds; a succesion in simple melody, a combination in harmony,' and it seems as if it could not be better defined.

"He fulfills that music executed by the same organ as the language is spoken, and aiming at the same sense, becomes itself a language. We shall subscribe to this opinion, if we will allow that this language is extremely confined, and can only give us the comprehended mafs of sentiments, as grief, joy, hatred, &c.; but never the details, as disdain, contempt, surprise, &c.

"The abbé gives many examples of imitative poetry, which, in his opinion, and in that of our greatest poets, is the first, or rather the only poetry. We confefs, to our shame, that we prefer the poetry in which we find ideas, to that which only furnishes images, as we prefer that music which conveys to our ears sweet harmony, sometimes by new means, out of the common road, to the pretended dramatic harmony which seems only to imitate the cries and convulsions of a delirium, &c. Wherever there is no melody, we find no music, and when that melody is not sufficiently by harmony, we find nothing better. [The reader must be apprized that M. Laborde is a sworn foe to Italian and German music, and a true believer in Lulli and Rameau.]

"We cannot make a stronger objection to the abbé Morelet's doctrine than he has made himself.

"It may, indeed, be said, that this pretended imitation is absolutely arbitrary, and the work of an imagination which creates agreeable fictions for itself, which feeds illusions and refinements where there are none. What refemblance can there be between the rising of the sun, the freshness of the morning, and all the means which music has of imitation?"

"This work, continues M. Laborde, is a matter-piece in style and found reasoning. Moreover, we mean not here to contradict the opinion of the author, nor that of those who think like himself. Each is at liberty to believe what he imagines he feels. Of all opinions we only condemn those which are supported insufficiently and against conviction; yet we sometimes meet with such in the commerce of society."

"We speak of this little work of the abbé Morelet, as it is the only one with which we are acquainted that concerns music; but who does not know his other writings?"

"Our readers will permit us to quote the following admirable fimple from the abbé's pamphlet before we leave it: "A beautiful and pathetic air is the collection of a multitude of accents escaped from foulds of sensibility, as to the features of Venus have each exulted separately, but never together. The sculptor and the musician unite these different features, and give us pleasures which truth and nature never gave."

"The abbé's speculations of more than forty years ago, seem to suit modern music much better than any compositions sufficing at the time his pamphlet was written, which has drawn from us an article nearly as long as the ingenious abbé's little tract itself.

"Morel, N., a painter of flowers and fruits, born at Antwerp about 1664, and a disciple of Verenadal. When he had obtained by his abilities a considerable reputation, he went to reside at Bruffles, where the court refided, and there soon became known to, and employed by, those of the highest rank.

"The compositions of his pictures are in very good style, and are executed with freedom, and a rich tone of colouring, suitable to the subjects he usually represented. He lived to an advanced age, extremely respected and esteemed.

"Morell, Thomas, a learned English divine and lexicographer, was born in 1701, and died in 1784. He published valuable editions of Ainsworth's Latin Dictionary, and Herderic's Greek Lexicon; and was the author of Annotations on Locke's Essay on the Human Understanding; he also assisted Hogarth in writing his Analysis of Beauty, and selected the passages of Scripture for Handel's Oratorios. Anecd. of Bowyer.

1. M. rubra. Loureir. Cochininch. Native of fields and thickets in Cochinchina, and cultivated in China, where it becomes much larger. We know nothing of this plant, but from
from Loureiro, who says that it is a tree about eight feet in height, with a tortuous brown stem, and spreading branches. Leaves on stalks, oblong, a little pointed, mostly entire, occasionally interruptedly serrated, smooth, scattered. Flowers in lateral, short cattkins. Drupa red, acid, about eight lines in diameter, pulpy on the outside after the manner of a mulberry, with a furrowed nut like a peach. Its flavour and colour are like the acid red cherry, being grateful to the taste and wholesome for the stomach. This fruit is eaten by the Chinese in its crude state, but the Europeans make it into tarts or cakes. In Cochinchina, when half ripe, it compotes a sauce for fish, and when ripe, a wine is extracted from it, which is by no means to be deplored either for its taste, smell, or colour.

MORIELL, in Geography, a town of Spain, in Valencia, with a castle. 26 miles W.S.W. of Tortosa.

MORIELLI, Giovanni, in Biography, a comic opera-finger with a powerful base voice, and a considerable share of the true humour of a buffo caricato, arrived here from Vienna in 1787, with the Storace. The first time we heard him perform, we made the following record in our musical memorandum-book; which, though fourteen years have elapsed since he first trod our stage, he is still alive and vigorous, at least in voice, so that our opinion of his abilities remains the same as when the following entry was made.

"Morelli has a base voice of nearly the same force and compass as Tafeta, but infinitely more flexible and agreeable. He is likewise a good actor, and superior in all respects to every buffo caricato we have had since Morigi's first appearance in the Buona Fighuola, 1766; yet, as a principal finger to supply the place of a tenor, it must be owned that he is inadequate to the expectations of those who remember the sweet voice and excellent humour of Lovatini.

MOREL, Louis, an ingenious nobleman, was the son of Sir Thomas Parker, in the county of Essex, and a great favourite with Henry VIII, who raised him to the peerage. He secured that monarch's favour by conciliating his divorce from Catherine, and his marriage with Anne Boleyn. He died in 1547. Lord Morely wrote several Latin poems. Walpole's Royal and Noble Authors.

MOREMALLA, in Geography, a town of Bengal; 30 miles S.E. of Moorshedabad.

MORENA, a bay on the coast of Chili, with a convenient harbour for careening ships, though narrow, and not safe with a N.W. wind. S. lat. 23° 45'.

MORENGO, a town of Italy, in the department of the Serio; 10 miles S.S.E. of Bergamo.

MORERI, Louis, in Biography, celebrated as the first author of the great historical dictionary which goes under his name, was born, in 1645, at Bargemont, a small town in Provence. He was educated with a view to literary pursuits, and studied rhetoric and philosophy at the Jefuits' college at Aix. He appeared as an author at the age of eighteen, and published a collection of poetry: after this he obtained employment as a translator and compiler. He took holy orders, preached on controversial topics at Lyons during five years, and was created a doctor of theology. About this time he formed the plan of a new historical dictionary, for which his principal qualification was a good knowledge of the modern languages. His "Dictionnaire Historique" was first published at Lyons in 1674, in one volume folio. It was dedicated to M. de Longueville, mean, bishop of Apt, in Provence, with whom he passed a year in quality of chaplain. He accompanied that prelate to Paris in 1675, and was introduced to the affections of clergy, and to the principal men of letters. His great object seemed to be to revive, correct, and augment his dictionary, and to this he applied himself so assiduously, that he injured his constitution, and died at the early age of thirty-seven. He had, previously to his death, prepared a second edition of his work, which appeared in 1681, in two volumes folio. This work professedly treats of history, chronology, geography, biography, mythology, &c. and has passed through many editions. One of the most important improvements which it received was from the celebrated John le Clerc, who published an edition of it in 1691, in four volumes folio. It has always been in high estimation, and in general been relied on for matters of fact; though the foundation of Bayle's Dictionary was professedly the correction of errors that he had laid crept into the dictionary of Moreri. New editions and supplements were published from time to time, till at length, in 1759, the twentieth edition appeared at Paris in ten thick volumes folio. It is to this edition that the present work is indebted for much information in various biographical articles. Under the article Moreri, in the edition just referred to, we have an historical account of the progress of the Historical Dictionary from the commencement, and the writer concludes by saying, "The great number of editions that have been published of Moreri's Dictionary, demonstrates the great utility of this important work. Other nations have envied France the execution of so vast a project, and many persons have given, in their own language, elaborate works on the same plan. Thus we have seen a Moreri in English; another in Germany, printed at Bafle; another printed in the Spanish language at Paris. And at this present time (1759) there are four Jefuits, of whom two live at Turin, and two at Florence, preparing a translation into the Italian, to be printed at Nice, in 12 vols. folio." Moreri.

MORES, Edward Rowe, an English antiquary, was born in 1736, at Tunstall, in Kent, and educated at Merchant Taylors' school, from whence he removed to Queen's College, Oxford, where he published an ancient fragment, entitled "Nomina et Insignia Gentilitia Nubilium Equitumque sub Edwards princeps Regis Militantium." 40. In 1752, he was chosen a fellow of the Society of Antiquaries; and he projected the Equitable Society for the Infruance of lives and survivorship by annuities. He was the author of "The History and Antiquities of Tunstall in Kent," and "A Dissertation on Founders and Founderies." He died in 1778. Pref. to Hill. of Tunstall.

Mores, in Geography, a town of the island of Sardinia; 23 miles E. Alghieri.

MORESK, or Morisco, a kind of painting, carving, &c. done after the manner of the Moors: consisting of several grotesque pieces and compartments promiscuously intermingled, not containing any perfect figure of a man or other animal, but a wild resemblance of birds, beasts, trees, &c.

These are also called arabesques, and are particularly used in embroideries, damask-work, &c.

Morefque dances, vulgarly called morrice-dances, are those altogether in imitation of the Moors; as farbands, chacons, &c. and are usually performed with caitans, tambours, &c.

There are few country places in this kingdom where the morrice-dance is not known. It was probably introduced into this country about, or a little before the reign of X. Henry
Henry VIII., and is a dance of young men in their shirts, with bells at their feet, and ribbands of various colours tied round their ears, and flung across their shoulders.

MORET, in Geography, a town of France, in the department of the Seine and Marne, and chief place of a canton, in the district of Fontainebleau; 9 miles N.E. of Nemours. The place contains 1650, and the canton 8253 inhabitants, on a territory of 142 kilometres, in 14 communes.

MORETEL, a town of France, in the department of the Ille-et-Vilaine, and chief place of a canton, in the district of La Tour du Pin; 7 miles N. of it. The place contains 849, and the canton 13,939 inhabitants, on a territory of 250 kilometres, in 20 communes.

MORETON-HAMPSTEAD, a market-town and parish in the hundred of Teignbridge, Devonshire, England, is situated 11 miles from Exeter, and 185 from London, on a gentle eminence, bounded on every side but the west by lofty hills. The face of the country in the vicinity is strewn with scattered fragments of rocks; some of which are so large, and so singularly pelted on each other, as to give the idea of buildings thrown down by an earthquake. The town is governed by a portreeve and other officers, who are elected annually at the court-leet of the lord of the manor. The inhabitants, as enumerated under the act of the year 1800, amounted to 1768: the number of houses being 459. Many of the lower classes of people are employed in the manufacture of woollen yarn and ferges. The principal public edifices are the parish church, three meeting-houses for dissenters, and a respectable charity-school. Three fairs are held here annually, and a weekly market on Saturdays. Beauties of England and Wales, vol. iv.

MORETON-Hen-Marsh, or Moreton-in-the-Marsh, a well-built village in the upper division of the hundred of Westminister, in the county of Gloucester, England, is situated on the Roman fons-way, four miles from Stow, 27 from Gloucester, and 83 from London: being about two miles west from the place where an ornamented pillar, inscribed "This is the Four-Shire Stone," marks the point of meeting of the counties of Gloucester, Oxford, Warwick, and a detached part of Worcestershire. Moreton was anciently the property of the abbey of Westminister, and continued part of its possessions till the revolution, when it was granted to the dean and chapter of Westminister, whose property it still remains. The abbots endeavoured, by various means, to increase its importance; and procured the charter of a market, and the privileges of exempting the burgesses, as they were then called, from tolls in the several counties above-mentioned. But the place never attained any considerable consequence; and the market has been long disused; an ancient building, supported by pillars, in the middle of the village, is said to have been the market-house. Two annual fairs are still held here. According to the population survey in the year 1801, the number of houses in this parish were 171; that of the inhabitants 829; the poorer classes of the latter are chiefly employed in spinning linen-yarn. Its situation on the fons, and the discovery of some coins in the vicinity, indicate that Moreton was once a small Roman station. Beauties of England and Wales, vol. v. Rudge's History of Gloucestershire, vol. i.

Moreton's Bay, a bay on the E. coast of New Holland, between Cape Moreton and Point Lookout.

Moreton, Cape, a cape on the coast of New Holland. S. lat. 26° 56'. E. long. 106° 28'.

MORETTA, a town of France, in the department of the Stura, seated on a small river, which runs into the Po; 16 miles S. of Turin.

MORETUM, among the Romans, a kind of fallad, composed of the eight following ingredients, viz. garlic, parsley, rue, coriander, onions, cheese, oil and vinegar.

MOREUIL, in Geography, a town of France, in the department of the Somme, and chief place of a canton, in the district of Montdidier; 9 miles N.W. of it. The place contains 1499, and the canton 11,719 inhabitants, on a territory of 1924 kilometres, in 25 communes.

MOREY, a town of France, in the department of the Jura, and chief place of a canton, in the district of St. Claude; 10 miles N.N.E. of it. The place contains 1218, and the canton 10,834 inhabitants, on a territory of 2224 kilometres, in 11 communes.

MOREZZO, St., or St. Maurice, a town, or rather village of Switzerland, belonging to the Grisons, in Upper Engadina, is agreeably situated upon the side of a hill, overlooking a small lake, which lies in the bottom of the mountains, and is bounded by rising banks, studded with wood and pasture. This village is remarkable for a copious spring of mineral water, much esteemed for its efficacy in the cure of several disorders: it issues from the ground at the distance of half a mile on the other side of the river Inn, and is strongly impregnated with vitriol: 25 miles N.N.E. of Chiavenna.

MORFIL, or Marfil, a name given by the traders to raw Ivory; which see.

MORGAN, in Geography, a river of Persia, which runs into the Sihom, on the borders of Bucharah.

MORGAGNI, Gian Battista, in Biography, an eminent physician, distinguished particularly by his anatomical researches, was born at Forli, in Romagna, in February, 1682. He lost his father in his infancy, but under the judicious direction of his mother, his education was very successfully conducted; and he displayed a proficiency in classical and philosophical acquirements beyond his years. Thus well prepared with preliminary knowledge, he commenced his medical studies at Bologna with great ardour, and from attracted the attention and esteem of his able mentors, Valvala and Albertini; the former of whom availed himself of his assistance in the researches into the organ of hearing, which he was at that time prosecuting, and in drawing up his memoirs upon that subject. Morgagni also performed the duties of the professorial chair during the absence of Valvala on a journey to Parma, and illustrated the lectures, which he delivered on this occasion, by numerous anatomical preparations. These illustrations, and the easy and perspicuous eloquence in which he addressed his auditors, added to his kind and engaging manners, obtained for him a general esteem, as well as the friendship of the most distinguished philosophers of the place. His zeal in the pursuit of knowledge led him, however, to visit other schools of medicine. He went first to Venice, where he cultivated several branches of physics, with the assistance of Poleni, Zanichelli, and other scientific men; and afterwards he visited Padua, where he attended the schools, under the direction of distinguished professors, with his accustomed industry. After having completed this comprehensive course of study, he returned to settle at his native place. He soon perceived, however, that this was too limited a circle for the exercise of his talents, and readily followed the advice of Guglielmini, who prevailed him to return to Padua. Here he did not remain long without occupation; for the death of Guglielmini, in 1710, occasioning a vacant chair, by the succession of Vallisneri to that of the latter, Morgagni was nominated
Morgan, William, an eminent Welsh prelate, was educated at St. John’s college, Cambridge, after which he obtained the vicarage of Welfpool, and in 1505 was made bishop of Laidaff, from whence he was, in 1601, translated to the bishopric of St. Asaph. He died three years after this elevation. He is particularly known as having had a principal concern in the translation of the Bible into Welsh, which was first printed in 1588.

Morgan, in Geography, a district of North Carolina, bounded W. by the State of Tennessee, and S. by the State of South Carolina. It is divided into the counties of Burke, Wilkes, Rutherford, Lincoln, and Buncombe; and contains 49,184 inhabitants, including 4643 slaves.

Morganian Marriage. See Marriage.

A New Holland genus of herbaceous plants, next akin to herpestis, fee that article, but differing in having an equally divided calyx, and a more unequal corolla. The stem is erect, quadrangular. Lower linear. Flower-flats axillary, single, flowered, each with a pair of bracts at the top. Flowers blue.

1. M. glabra.—Smooth. Leaves linear, slightly toothed. Stalks when in flower nearly as long as the calyx.

2. M. pubescens.—Downy. Leaves somewhat lanceolate, toothed. Stalks when in flower shorter than the calyx.

Both species were gathered by Mr. Brown in the tropical part of New Holland. He conceives them to be specifically distinct, though very nearly related to each other.

Morgan, in Geography, a settlement in Kentucky; 38 miles E. of Lexington.

Morgantown, a poft-town and capital of the Morgan district, situated in Burke county, near Catabaw river, and containing about 30 houses, a court-house and gaol; 45 miles from Wilkes. N. lat. 35° 47'.—Also, a poft-town of Virginia, and shire-town for the counties of Harrison, Monogahela, Ohio, and Randolph, situated on the E. side of Monogahela river, and containing a court-house, a stone gaol, and about 60 houses; 30 miles from Brownsville. This town may be considered as the head of navigation on the Monogahela.

Morganza, a town of Washington county, Pennsylvania, almost surrounded by the E. and W. branches of X 2 Charter's
MORGARTEN, mountains of Switzerland, in the canton of Schweitz, in which is a pass, famous for a victory gained by 1300 Swiss posted upon the mountains over Leopold duke of Austria, who in 1315 marched against the confederate cantons, at the head of 20,000 troops. The Swiss, it is said, lost but fourteen men in this memorable engagement, which has been compared to the battle of Marathon, that ascertained the liberties of Greece, as this affirmed the independence of the Swiss; 10 miles S.E. of Zug.

MORGAY, in Ichthyology, an English name for the seafish, called also the rough banded-fish, one of the galeus kind; the catalogus minor of Salvian, and mythus Bellatrix terius of Belionius. See Squalus Catalogus.

MORGENSENBERGHORN, in Geography, a mountain of Switzerland, considered as one of the principal Alps, in the canton of Bern; its height is 7456 feet.

MORGENFELD, a town of Prussia, in the province of Brandenland; nine miles N. of Rattenburg.

MORGES, a town of Switzerland, in the Pays de Vaud, the capital of a bailiwick, on the N. side of the Lake of Geneva, with a port and quay. It is situated at the extremity of a beautiful bay, and its environs are extremely pleasant; the banks of the lake forming an amphitheatre, that gently rises to the Jura, and Mont Blanc presenting itself through an immense opening in the opposite chain of rocks, which seems to have been formed by nature for exhibiting a sublime perspective of that beautiful mountain. Near the town is a lime-tree twenty-four feet four inches in circumference, with branches of magnificent extent; and it has also a companion about three feet less in girth.

MORILL, among the Mabometans, a feot, who lay much fires upon belief, and Rand opposed to the alwided.

MORGO, in Geography, an island in the gulf of Venice, near the coast of Friuli. N. lat. 45° 44'. E. long. 13° 16'.

MORGONG, a town of Bengal; 25 miles W. of Moorshedabad.

MORGUES, Matthew de, in Biography, preacher to Lewis XIII., and almoner to Mary de Medicis, was born at Langres in 1582. He wrote several pieces against cardinal Richelieu, on which account he was obliged to quit the kingdom, but after the death of that minister he returned to Paris, where he died in 1670. He was an author of "Sermons" and many other works. Moreri.

MORGUI, in Geography, a town of Hindooftan, in Mysore; 16 miles N. of Rettinghery.

MORIANGE, a town of France, and principal place of a diocese, in the department of the Meuse; 21 miles E.S.E. of Metz. N. lat. 48° 55'. E. long. 4° 43'.

MORHOF, Daniel George, in Biography, a learned miscellaneous writer, was born in 1639 at Wilmarn, in the duchy of Mecklenburg. Having laid a good foundation in classical learning, he was sent to study at Stettin and Ruplock, and in consequence of a copy of Latin verses which he composed while he was at the latter university, was made professor of poetry there in 1666. In 1669 he was appointed to the chair of poetry and eloquence at the university of Kiel, and in 1671 he was made professor of history, to which was added the office of public librarian. He was incessant in his pursuit of knowledge, and laboured so hard in the duties attached to his different offices, that he fell into a languishing state, and died in his fifty-third year. The writings of Morhof are numerous, consisting of poems, orations, and dissertations, on a great variety of topics, but that which is best known, and reckoned the most valuable of all his pieces, is a general account of books and authors, entitled "Polyhistor de Notitia Auctorum et rerum commentarum." This was printed in 1688. It has passed through many editions with considerable augmentations, of which the best is that by John Albert Fabricius, in three volumes 4to. 1732.

MORHUA, in Ichthyology, a name used by some authors for the common cod-fish. See Gadus Morhua.

MORI, in Geography, a town of Hindooftan, in Oude; 16 miles N.E. of Fyzabad.

MORIA Kts, a town of Hungary; 18 miles S.S.E. of Debreczin.

MORIAH, Mount, in Scripture Geography, a mountain near Jerusalem, on which the famous temple of Solomon was built (2 Chron iii. 1.), situated S.E. of Calvary, having Millo on the west, and so called from the filling up of that deep valley, in order to raise it to a level with the rest. It has been commonly thought that on this mount: Abraham was commanded to offer up his son Isaac; though this notion is liable to some objections. The Samaritans, by reading its name in Genesis (xvii. 6—xiv. 2) Moriah, instead of Moriah, have taken occasion to affirm, that it was mount Gerizim, near Shechem and Moreh, on which God directed the patriarch to make this sacrifice.

MORIAM, in our Old Writers, a head-piece called a pot, flat. 4 & 5 P. & M. c. 2.

The word comes from the French mon, or Italian mon, i.e. caffis. See Monion.

MORIANI, in Geography, a town of Corsica (Golo), in the department of Balta, the canton of which contains 7792 inhabitants.

MORICHES, a place with a post-office in Suffolk county, New York; 213 miles from Washington.

MORIENBEY, a tolerably deep bay on the E. coast of the island of Cape Breton, near Miray bay, from which it is separated only by Cape Brule.

MORIGI, Andrea, in Biography, an excellent comic singer with a bafe voice, who arrived in England with Lovatini in 1756. His voice, humour, and action, in performing the part of Tagliaferro in the Buona Figliuola, were so perfect and so amusing, that they established his favour with the public in whatever part he afterwards appeared. He quitted England but a few years ere he returned again in 1783; and remained here till he was totally worn out in the service of that public which suffered him, unobserved, to approach

"Misery's darkest cavern—
Where hopeless anguish pour'd her groan,
And lonely want return'd to die."

MORILLEAH, in Geography, a fort of Hindooftan, in Bahar; 15 miles E. of Birtah.

MORILLES, a kind of mushroom, about the bigness of a walnut, pierced with holes like a honeycomb, and said to be good for creating an appetite. They are also accounted
accounted restorative, and frequently used in sauces and
guuts.

MORILLON, in Ornithology, the name of a species of
duck, bearing the same with the capo raffo, a small red-
headed wild duck. See DUCK.

MORIMAL, in Geography, a town of Hindoostan, in
the cinctur of Cuddap a; 25 miles N.E. of Gandicotta.

MORINGAMBO, a feast on the W. coast of Ma-
dagascar. S. lat. 14° 30'.

MORIN, John Baptist, in Biography, a celebrated
physician, mathematician, and astrologer, was born at Ville-
Franche, in Beaujolois, in February, 1583. He made an
early proficiency in his studies at Aix, in Provence, and
even taught philosophy in that city before he was twenty
years of age. He afterwards went to Avignon for the
purpose of studying medicine, and took the degree of
doctor in that faculty in 1613. He then went to Paris,
where he obtained the patronage of the bishop of Bou-
logne, and was sent by him to examine the nature of
metals in the mines of Hungary. From the observations
which he made in those deep caverns, he imagined he had
discovered three regions into which the interior of the earth
was divided; and published a work, entitled "Nova Mundi
sublunaris Anatomia," which, in those credulous times, ob-
tained the conviction of many readers. Upon his return to
Paris, he found a Scotch astrologer, of the name of Davison,
sharing the patronage of the bishop; and he not only studied,
but became a zealot in that art, and subsequently obtained
much reputation in the practice of it. For at that period,
the courts of the greatest princes, and some of the most distin-
guished characters in science, were filled by the delusions
of judicial astrology. His first success in this science was prac-
ticed on his patron: for having consulted the stars, in order
to calculate the events of the year 1617, he informed the
bishop of Bouligne, that he was threatened with the loss of
liberty or of life. At this intelligence, the prelate, though in-
fatuated with the pretended science, only laughed; but, as
soon as the credit of the astronolger, the bishop engaged
soon afterwards in some late intrigues, and having em-
barked with the unsuccessful party, he was treated as a rebel,
and actually imprisoned in that year. Morin also obtained
access to the two celebrated cardinals Richielien and Mazarin,
who were weak enough to give their confidence to his pre-
tended skill, and actually consulted him about their affairs.
The latter even granted him a pension of two thousand livres,
which was regularly paid; and obtained for him the appointment
of professor of mathematics in the Royal College of
Paris. The count de Savigny, secretary of state, also de-
pended upon his astrological computations, and especially
consulted him respecting the proper time of paying his visits
to the cardinal Richelieu. When queen Chriftina, of Sweden,
was at Paris, the sent for Morin, and expressed her high ad-
miration of his talents, informing him that he deserved him
the greatest astrologer in the world. Bayle has detailed a
great number of examples of his predictions, and of his pro-
cedings in evading the construction of them, when not suc-
cessful; to which the curious reader may refer. He at-
tempered to confute the system of Copernicus; but was
treated with much pointed ridicule, in addition to solid
argument, by Gaffendi, Bernier, and other scientific men,
who laughed at his follies, and exposed the falsehood of his
pretended art. Nevertheless Morin was polifhed of scienti-
fic attainments by no means contemptible; in so much that M.
des Cartes, on whole theory of light he had published some
animadversions, entered into a correspondence with him,

MOR

considering his objections as deserving of serious considera-
tion. Morin died at Paris in November, 1656, at the age
of seventy-three.

He wrote a great number of works, in addition to the
anatomy of the earth already mentioned: namely, "Altrono-
nicarium Domorum Cabala detecta," 1623; "Trigono-
metriz canonice libr i ii." 1633. A book entitled, "Quod
Deus fit," which was afterwards published, in 1655, in a
larger form, with the title of "De vera Cognitio Dei ex
folo Nature Lumine." "Famnzi problematis de Tellarici
Motu vel Quoio hastem optata Solution," 1631; and some
other pieces against the system of Copernicus. "Ad Auf-
trales et Boreales Archlogos pro Aftrologia refutans Epis-
toles," 1628; and a curious treatise, entitled "Refutatio
compendiosa erronett et detextandi Libri de Praedamatis,"
1656. His favourite work, the result of thirty years of
labour, intended to illustrate the pretended science of judicial
astrology, was published after his death, in 1661, at the
Hague, with the title of "Aftrologia Gallica." The
bublyon of Poland, at the recommendation of one of her se-
cretaries, defrayed the expense of this publication, on which
he expended two thousand crowns. See Bayle, Dict. Hist.

MORIN, Louis, a physician and botanist of much singu-
laritv of character, was born at Mans, in July, 1635.
His father having a numerous family, and only the slender
income afforded by a place in the salt-office, was enabled to
give this, his eldest son, the mere rudiments of scholastic
education. During this early period of his life, he acquired
a partiality for botanical pursuits; and when he left school,
he set off for Paris on foot, herborizing by the way, for
the purpose of studying philosophy in the metropolis. His at-
tachment to botany naturally led him to the choice of
medicine as a profession; and, during his application to this
science, perhaps from the necessity of rigid economy, in
which his circumstances placed him, he led the life of an
anchorite, retreating his diet to bread and water, with the
occasional indulgence of a little fruit. This mode of life
greatly diminished the number of his wants, and was pro-
bably the origin of that extraordinary difinterrednefs and
benevolence, by which he afterwards greatly distinguished.
He obtained the degree of doctor of the holy foother.

His botanical knowledge procured him the esteem of Meffieurs
Fagon, Longuet, and Galois, and he was frequently con-
fulted by them, during their labours in the formation of
the catalogue of the plants in the royal garden, which was
published under the name of M. Vallot, the first physician,
in 1666. He had been several years in practice, before he
obtained any public mark of esteem, when at length he
was appointed empellant at the Hotel Dieu; but a consider-
able time elapsed, before his humble merit, unsupported by
intrigue or solicitations, was recompened by the place of
penionary-physician to that hospital. Yet he derived no
advantage from the pension, which he always returned into
the money box, taking care that that act was seen by no
one. Although his constitution was delicate, and his frame
slender, yet he continued to restrict himself to the following
regular life of activity and ablcmisorinefs. At all rea-
sons he rose at two in the morning, and spent three hours
in his devotions. Before fum in summer, and somewhat
later in winter, he visited the poor patients in the H6tel
Dieu, and usually heard mass at Notre Dame. He dined at
eleven; and after dinner indulged his botanical tastes at home,
or, in fine weather, at the royal garden. He then put
himself in his closet, if he had no poor patients to visit, and
continued the day in study, or received visits at home,
which,
which, however, he did not encourage. He always retired to rest at seven.

MORIN. Morin was appointed associate-botanist to the revived Academy of Sciences, through the recommendation of M. Dodart, whom he succeeded as penfionary-botanist, in 1707. During the absence of Tournefort, on his voyage to the Levant, in 1700, the poet of demonstrator of plants in the royal garden was confided to him, at the request of that great botanist; who also honoured him by giving his name to a new plant, *Marina Orientalis,* which he brought from the East. A few years before his death, his strength began to fail, and incapacitated him from continuing his active duties; and he then found it necessary to add a little wine to his diet: but he sunk under a gentle and gradual decay in 1715, in the 80th year of his age. He left behind him no other property, except a library, valued at nearly 20,000 crowns, a herbals, and a collection of medals. He published two papers in the Memoirs of the Academy; one, containing an erroneous physiological hypothesis respecting the passage of the drink to the bladder; and the other, a "Memoire sur les Eaux de Forges." Among his papers were a very minute index to Hipppocrates, Greek and Latin; and a meteorological journal of more than 40 years. Eloy Dict. Hist. de la Med. Gen. Biog.

MORIN, JOHNA French learned ecclesiastical and oriental scholar, was born at Blois in the year 1591. Having been instructed in classical learning and the belles lettres at Rochelle, he was sent to Holland, and entered as a student at the university of Leyden. Here he went through the usual courses of philosophy, mathematics, and the law, and afterwards applied himself to the study of divinity and the oriental languages, in which he greatly excelled. He had been educated in the principles of the Protestant religion, but on his return to Paris he became a convert to popery, through the arguments or perfusion of cardinal Perron. For some time he resided in the cardinal's house, afterwards he became a member of the congregation of the Oratory, and in this retreat he applied himself with the greatest affinity to the study of literature, and from time to time presented the world with the various fruits of his labours. In 1626 he published, "Exercitationes de Patriarcharum et Primatum Origine, et Antiqua Cenfurium in Cleris praxi," which he dedicated to pope Urban VII. He was next employed in a new edition of the "Septuagint," after the Vatican edition, published at Rome by order of pope Sixtus V. in 1587. This edition was published, in 1628, under the title of "Biblia Sacra LXX. Interpret. Graec et Latine: cum Novo Testamento Gr. Lat. &c." in these volumes folio, which is now very rare. In 1631 he published "Exercitaciones in utrinque Pentateuchum Samaritanorum," the principal object of which is to prove the superior integrity of the Samaritan to that of the Hebrew text. This was followed by his edition of the Samaritan Pentateuch, with a Latin version in the Polyglot of Le Jay. In the year 1635, M. Morin published the first part of another work in support of the superior integrity of the Samaritan to the Hebrew text. The second part of this work did not make its appearance till after the death of the author. The reputation of this writer spread to high with the clergy of France, that the prelates in their assemblies were frequently determined by his advice, on subjects of the greatest difficulty and importance. His fame extended to Rome, and he was invited by Urban VIII. into that city, with a view of affording his assistance in promoting an union between the Latin and Greek, as well as the other oriental churches. He arrived at Rome in the year 1639, and met with a very friendly reception from cardinal Barberini, who introduced him to the learned men of the city, and particularly to Lucas Hollenius, and Leo Allatius, the former, keeper of the Vatican, and the latter, of the Barberini library. In the said repository of learning he met with ample flogs for the gratification of his literary curiosity, but he had not been occupied more than nine months in the buffine for which he came: before cardinal Richelieu directed the superiors to recall him to France. He returned in 1640, and from this period spent his time in laborious study, and in the publication of many learned works. He died in 1659, at the age of sixty-eight, highly respected for the qualities of his heart, as well as for his great literary acquisitions. In 1652 father Simon caufed to be printed at London, "Antiquitates Ecclesiæ Orientalis," consisting of letters to and from Morin; to which is prefixed a life of Morin, suppos'd to be written by father Simon; in this work is inserted a lift of his "Opuscula," to the number of eighteen articles. To Simon's life of our author the reader is referred for more particulars relating to Morin.

MORIN, JOHN, a French priest and philosopher, was born at Meung, near Orleans, in the year 1705. Of his early life we have no account, but in 1732 he obtained the professorship of philosophy at Chartres, and discharged its duties with uncommon zeal and affiduity for eighteen years. In 1750, as a sort of recompence for his services, he was, by the bishop, nominated to a canonry in his cathedral. He had some years previously to this published a treatise, "On Universal Mechanism," and also "A Treatise on Electricity:" this was laid before the public in 1748, when the late named science was in the lato of its infancy, and the work of Morin led him into a controversy with the celebrated abbé Nollet, who wrote reftrictions upon it. Morin replied to them, and with his answer he closed his labours as an author. His name and reputation float high as a philofoher in the academies of sciences at Paris and Ronen, of both which institutions he was a correfpondent. He purfued his experiments till his death in 1764, when he was about the age of 59.

MORIN, PETER, a man of letters, biblical scholar and critic, was born at Paris in the year 1531. His father had employment in the parliament, and as he intended his son for the fame purpofes, he directed his attention, at a very early age, to the study of the civil law. At the same time he was carefully instructed in classical leaming. When his judgment began to ripen, he became deeply enamoured with the study of the belles lettres, and afterwards applied himself diligently to the sacred scriptures, the fathers, and ecclesiastical antiquities. He went to Italy, at that period the grand resort of men of leaming, where he was employed by Paul Manutius, the learned printer at Venice. From this city he removed to Vicenza, in 1555, where he taught the Greek language and cosmography; and from that place he went to Ferrara, where he was introduced to the cardinal, brother of Hercules, dub of Ferrara, with whom he lived some time. In 1559, he was devious of paying a visit to Rome, when his father recalled him to France, where he wished him to enter at once into domestic life, and into the businefs of parliament, but he was too much attached to literary pursuits, to gratify the wishes of his relation; returned to Italy, and arrived at Rome in 1565. He examined the remains of ancient art and grandeur, and visited every place of celebrity. At Verona some notes upon St. Chrysostom's "Commentary on the Epistles of St. Paul" were communicated to him, which induced him to attend carefully to that work of the Greek father, and
Morin, in Geography, a town of Hispaniola; 10 miles E. of Cape Francois.

Morina, in Botany, received its name from the celebrated Tournefort, who, during his residence at Erzeron in Armenia, met with this new plant in one of his daily botanicizing excursions, in the valley of the four mills near that town. "In one of these mills," says he, "we proceeded to name one of the finest genera of plants in the Levant; to which therefore we gave the name of a person highly estimable for his science and virtue, M. Morin, of the Royal Academy of Sciences, Doctor of Medicine of the faculty of Paris, who has since had the singular good fortune of raising this plant from seed in his garden, it having succeeded nowhere else. The flower seems proud to bear the name of M. Morin, who has always been passionately devoted to botany. Vaillant, however, would not adopt this name. Tourn. Voy. v. 2. 119. Cor. 45. t. 485. Linnaeus, Gen. Pl. 18. Schreb. 24. Wildk. Sp. Pl. v. 1. 172. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 1. 66. Sm. Prod. Fl. Græc. Sibth. v. 1. 18. Jull. 194. Lamarck Illnitr. t. 5. (Dotothea; Vaill. Mem. de la Acad. des Sc. for 1722.)—Clas and order, Diandria Monogynia. Nat. Ord. Aggregate. Linn. Diptasee. Jaff.

Gen. Ch. Cal. double. Perianth of the fruit inferior, of one leaf, cylindrical, tubular, permanent, its orifice bordered with upright, awl-shaped, spiny teeth, of which the two opposite ones are longest. Perianth of the flower superior, of one leaf, tubular, the size of the former, in two rather deep, obtuse, emarginate, upright, permanent segments. Cor. of one petal, two-lobed; tube very long, thread-shaped at the base, gradually dilated upwards, a little incurved; limb flat, obtuse; its upper lip rather the smallest, cloven half way down; lower three-lobed; all the segments rounded, uniform, the middle one rather the most prominent. Stam. Filaments two, bristle-shaped, parallel, curved, rather shorter than the limb; anthers erect, heart-shaped, dilated. Pijl. German globifer, between the two perianths; style thread-shaped, parallel to the filaments, but rather longer; stigma capitate, inflated. Perfia none. Seed solitary, roundish, crowned by the calyx of the flower.

Eff. Ch. Corolla unequal. Calyx of the fruit of one leaf, unequally toothed; that of the flower two-lobed. Seed one, crowned with the calyx of the flower.

1. M. perfica. Perifian Morina. Linn. Sp. Pl. 59. Sm. Fl. Græc. Sibth. v. 1. 20. t. 28. (M. orientalis; Mill. Dict. ed. 8. M. orientaliis, carline folio; Tourn. Cor. 48. Voy. v. 2. 120. t. 120.)—Native of Armenia, according to Tournefort; Linnaeus says, of Perfia near Isphahan, but we cannot find his authority. Mr. Hawkins informs us he gathered this fine plant on the mountains of Parnassus and Cylensi, in elevated fields, where the soil is rather rich, flowering in August. Dr. Sibthorp has left no mention of the place where he met with it. From plants raised formerly at Paris, the Morina was once in our gardens; but was killed both in England and France, by the hard winter of 1740, except that M. Du Hamel, according to Miller, saw it in his garden. The late Mr. Davall had it alive at Orbe in Switzerland, and, if we mistake not, M. Olivier brought some seeds from Perfia, which vegetated at Paris.—The root is perennial, tap-shaped. Stem erect, straight, three feet high, perfectly blemish, leafy, obscurely quadrangular, furrowed, downy; spongy and hollow within. Leaves oblong, narrow,

acute,
MOR

acute, generally smooth, pinnatifid; the lobes numerous, palmate, with strongly spreading fringes: radical ones erect, tapering at the base: those on the stem shorter, four in a whorl: the floral ones sellole, still shorter and broader. Whorls very numerous, axillary, many-flowered. Flowers erect, about two inches long, reaching from one joint to the next, extremely elegant, white, changing to pink before they decay; the tube hairy. Tournefort compares their scent to the honey-fuckle. They form a singular combination with the thistle-like herbage.

MORINA, in Gardening, affords plants of the hardy herbaceous flowery perennial kind, of which the species cultivated is, the Perian or Oriental morina (M. pericha).

Method of Culture.—This is increased by seeds or offsets from the roots. The seeds should be sown in the autumn in the places where the plants are to grow, as, from having a strong tap-root, they do not bear shifting well. The ground in the bed or border near them should not be afterwards much disturbed, the plants being only kept clean. They may lie in two or three years after being raised.

In the latter mode the offsets should be floated from the roots while young, and be planted out where they are to stand, in the latter end of the summer, being afterwards treated as those raised from seeds.

The plants decay to the ground in the autumn, new leaves being sent up in the spring; but the roots continue several years when not stridden, or injured by severe frosts. These plants are highly ornamental in the principal beds and borders of pleasure-grounds and gardens.

Gen Ch. Cal. Common receptacle roundish, collecting the flowers, which are sterile, into a globular head. Perianth scarcely observable, five-toothed, superior. Cor. of one petal, funnel-shaped; tube cylindrical; limb in five lanceolate, acute, flat, widely spreading segments. Stam. Filaments five, very short, inserted into the upper part of the tube; anthers linear, erect, nearly as long as the tube. Pied. German inferior; style simple; stigma clavate, rather thick. Peric. Berry nearly ovate, angular in consequence of preflure from those around it, abruptly, of one cell. Seeds two, convex on the outer side, flat on the inner.

Obl. It must be confessed that Juffieu has been much happier than Linnæus, in his determination of the natural order of this genus.

1. M. umbellata. Umbellate Morina. Linn. Sp. Pl. 250; excluding the synonym of Rumphius. (M. n. 81; Linn. Zeyl. 34.)—Erect. Leaves lanceolate-ovate. Flowers are umbellate.—Native of the East Indies. Linnæus describes it as a tree, with leaves recalling those of Cephalanthus, opposite, ovate inclining to lanceolate, falcate, entire. Umbellไฟellate, each consisting of several equal flanks, bearing solitary heads of aggregate flowers, and terminating the oblique branches.—We have never seen an authentic specimen, nor do we find any figure. Professor David Van Royen has favoured us with a specimen of what he took for this plant, in which the remains of six unbellate flower-flasks terminate the branch, but all remains of fructification are gone. The leaves are obovate, pointed, entire, paler beneath, with a little glanular pubescence at the origin of each vein; as in both the other species; otherwise they are smooth on both sides, and not unlike Cephalantbus. Stipulas infralocularis, tubular, clove. It is very probably what Linnæus intended. Can this be Plukenet’s t. 361. f. 3? or Lamarck’s t. 153. f. 3?

2. M. citrifolia. Broad-leaved Morina. Linn. Sp. Pl. 250. Att. n. t. (M. n. 82; Linn. Zeyl. 34. Cada Plava; Rheedae Hort. Malab. v. 1. 97. t. 52. Baccarum latifolia; Rumph. Amb. book 5. 158. t. 19.)—Stem arborescent. Flowers solitary, lateral, smooth. Leaves smooth, elliptic-oblong.—Native of the East Indies. The Linnæan specimen, certainly the plant of Rheedae, has very smooth laurel-like leaves, elliptic-oblong, four or five inches in length, acute at each end, rather oblique, with one rib and many transverse veins; which half are glandular, with a foot of pubescence, where they separate from the mid-rib. Flower-flasks opposite to one of the leaves, taking the place of a leaf which is wanting, smooth, about twice the length of the foot-flasks. Head oblong. Corolla externally smooth. Rheedæ says this is a tree, growing in sandy, rocky places. The aggregate fruit is ovate, two or three inches long, fidect and bitter.

We have from Dr. Roxburgh, under the same name, what seems a different species; the leaves being smaller, more ovate and pointed, all of them opposite, the flower-flasks axillary, and the limb of the corolla externally hairy. Indian botanists, who may have opportunities of comparing more perfect specimens, must decide whether this be more than a variety. M. Poiret, in Lamarck Dict. v. 4. 315; makes mention of another variety, or probable species, conformed under citrifolia, which may possibly be what we shall next describe.

Gen Ch. Cal. Common receptacle roundish, collecting the flowers, which are sterile, into a globular head. Perianth scarcely observable, five-toothed, superior. Cor. of one petal, funnel-shaped; tube cylindrical; limb in five lanceolate, acute, flat, widely spreading segments. Stam. Filaments five, very short, entered into the upper part of the tube; anthers linear, erect, nearly as long as the tube. Pied. German inferior; style simple; stigma clavate, rather thick. Peric. Berry nearly ovate, angular in consequence of preflure from those around it, abruptly, of one cell. Seeds two, convex on the outer side, flat on the inner.

Obl. It must be confessed that Juffieu has been much happier than Linnæus, in his determination of the natural order of this genus.

4. M. Roioc. Procumbent Morina. Linn. Sp. Pl. 250. Att. n. t. 11. (Roic; Plum. Gen. 11. t. 26.)—Stem procumbent. Leaves ovato-lanceolate, smooth; with axillary downy glands to the veins. Flower-flasks very short, lateral or terminal. Tube of the corolla cylindrical, roughish.—Native of the island of Maurits. Commonly cultivated by Thouin to the younger Linnæus. The stem is woody, with twined, and perhaps trailing, branches, downy when young. Leaves three inches long and one broad, lanceolate, somewhat obovate, tapering much at each end, paler beneath, roughish on both sides with minute points; the ribs and veins hairy. Flower-flasks lateral, opposite to a solitary leaf, hairy, an inch long, solitary except at the end of the branch, where there are two, one of them being terminal, the other opposite to the uppermost leaf. Head globose, small, of but few flowers. Corolla above an inch long, slightly rough at the tips, and edges of the segments only.

5. M. fruticosus. Procumbent Morina. Linn. Sp. Pl. 250. Att. n. t. 11. (Roic; Plum. Gen. 11. t. 26.)—Stem procumbent. Leaves ovato-lanceolate, smooth; with axillary downy glands to the veins. Flower-flasks very short, lateral or terminal. Tube of the corolla cylindrical, roughish.—Native of the island of Maurits. Commonly cultivated by Thouin to the younger Linnæus. The stem is woody, with twined, and perhaps trailing, branches, downy when young. Leaves three inches long and one broad, lanceolate, somewhat obovate, tapering much at each end, paler beneath, roughish on both sides with minute points; the ribs and veins hairy. Flower-flasks lateral, opposite to a solitary leaf, hairy, an inch long, solitary except at the end of the branch, where there are two, one of them being terminal, the other opposite to the uppermost leaf. Head globose, small, of but few flowers. Corolla above an inch long, slightly rough at the tips, and edges of the segments only.
MOR

smoothish stalks, sometimes opposite to a leaf, but more generally terminal. The root is reported to yield a yellow or purple colour, becoming black with iron, which probably may be of use in dyeing. Jacquin says it may be procured in any quantities.

6. M. retusa. Blunt Morinda. Larnack Dict. v. 4. 316. Arboreous. Leaves oval, abrupt. Heads sessile, terminal. Native also of Madagascar. "Very distinct from the former. Branches hard, knotty, forked. Leaves much more crowded than in any of the foregoing; oval; obtuse and abrupt at their summit; contracted at the base." The Flowers are described as perfectly terminal, in a round sessile head, and yet in the specific character they are called lateral.

We adopt this, as well as the last, entirely from Pouret.

MORINELLA, TURNSTONE, or SEA-DOTTEREL, in Orniology. See Tringa morinella.

MORINELLUS, DOTTEREL. See Charadrius morinellus.

MORINGA, in Botany. See Hyperanthera.

MORINGEN, in Geography, a town of Germany, in the principality of Furthlenberg; 66 miles N.W. of Constance. —Alfo, a town of Westphalia, and principality of Calenberg, seated on the Mohr, which runs into the Leine, and containing two churches; 10 miles N.N.W. of Gottingen. N. lat. 51° 38'. E. long. 9° 55'. —Alfo, a town of Bavaria, four miles S. of Friedberg.

MORINI, in Ancient Geography, the name of a people who inhabited the sea-coast in the northern part of France, from Montreuil-sur-Mer to Calais; and hence Virgil calls them "extremi hominum." However, they seem to have advanced into the interior of the country, for Ptolemy assigns them to the capital of Ternania, and they also poiffeled on the sea, towards the coast, Geffonneum. Their name was derived from the word "Mor," signifying in Celtic the sea, and thus designates a maritime people. Some authors have ascribed to the Morini the diocese of Tournay; but M. d'Anville was of opinion that this belonged to the Nervi. The country of the Morini was in a great measure covered with forests, lakes, and fiftes, encompanied by marshes; and hence they were enabled to maintain their liberty. Caesar at length subdued them and subjugated them to the Aretabii. Pliny fays that their country warmed with geese, and that these furnished a principal article of merchandize. He adds that their linen cloth was also a commodity in which they had considerable traffic.

MORINIÈRE, ADRIAN CLAUDE LE FORT DE LA, in Biography, a French writer, was born at Paris in 1656, and died in 1708. He was author of many works, of which the principal are. 1. "Choix des Poesies Morales." 2. "Bibliotheque Poetique." 3. "Paffe-temps Poetiques, Histoires, et Critiques."

MORION, in ancient Armoury, a kind of open helmet without visor or beaver, somewhat resembling a hat; it was commonly worn by the harquebussers and musqueteers. See MORIAM and Pot.

MORION, in Botany, a name given by the ancients to a kind of nightshade. The ancient Greeks, Theophrastus and others, called all the nightshades in general by the name phrynie. Some of these they said were poisonous, and others inoffensive. The poisonous were of two kinds, some bringing on sleepy disorders, and others making the patient mad.

The efficent kind was the pomum amoris, or love-apple, eaten at this time by the Portuguese and many other nations, and by some in England. Some after-writers use the word morion as a distinctive name for those kinds of nightshades which caused sleepy disorders; and after these some used it as the peculiar name of one species, and others as the name of the male mandrake of Dioscorides, whose fruit, according to that author, was commonly eaten by the shepherds; but when taken too largely, threw them into sleepy disorders. From this word morion has come, in all probability, the Latin name morilla, given at first to the pomum amoris, of love-apple; and afterwards, according to Æmilinius Nacer, to all the nightshades; for he expressly says, that those plants which the Greeks called frigetina, the Latins called morilla; and that the old Greeks called all the nightshades frigetis.

MORION, in the Natural History of the Ancients, a name given to one of the semi-pellucid gems, more commonly called prassolit. It is a stone appearing externally only of a fine deep black; but when held up against a candle, or against the sun-nape, giving a very beautiful red, in different degrees, from that of the hyacinth to that of the amethyst or carbuncle.

MORIS, in Geography, a town of New Mexico, in the province of Mayo; 100 miles N.E. of Santa Cruz.

Mort's, or Morris's Bay, a bay on the S.W. coast of Antigua; four miles W. of Falmouth harbour.

MORISA, a town of Japan, in the island of Niphon; 167 miles S.W. of Mexico. N. lat. 34° 6'. E. long. 151° 30'.

MORISCOES, an appellation given by the Spaniards to the Moors of Granada, in order to distinguish them from the Moors of Barbary. The expulsion of these people from Spain forms an important event in the history of that country, and also in the history of perfecution; and it therefore becomes necessary to give a detail of the leading circumstances that attended it. It is well known that when the city of Granada was taken by king Ferdinand of Aragon and queen Isabel of Castile, in the year 1492, the Moorish government in Spain, which had lasted above 700 years, terminated; and yet the Moors did not immediately leave the country. The body of the people, not only of the kingdom of Granada, but also of Valencia, though conquered by the Christians in 1236, and of Murcia, conquered by them in 1265, belonged to that race; and beside these, others were dispersed in great number over Castile, Espanada, Aragon, Catalonia, &c. All these Moors maintained their separation from the Spaniards, by an obstinate adherence, not only to the language, habit, and customs of their ancestors, but to their religion likewise, which was the Mahometan; few or none of them, in a long lenes of years, having been converted to the Christian faith, by all the efforts of the Spanish friars for this purpose. The Spanish princes, apprised of the danger that was likely to result from the connection that was likely to subsist between the Moors of Barbary and those of their own country, so nearly situated with respect to one another, made every attempt in their
MORISCOES.

their power to dissolve their natural attachment, cemented by similarity of religious profession; and with this view they employed the ecclesiastics in vigorous measures for converting them to Christianity. The friars, failing in their casual endeavours, for accomplishing the object recommended to them, represented the Moors as an obstinate and hardened set of people, who were not to be overcome by arguments, nor by any other methods, unaccompanied with violence. Accordingly they advised the princes either to banish the Moors, or to make them all slaves, if they refused to become Christians; or, at least, to take all their children from them, and baptize them, so that the next generation might become Christians. The council of Toledo, however, expressly prohibited the compulsion of infidels to be baptized; and Thomas Aquinas, and most of their other divines, declared it to be unlawful to baptize the children of infidels without the consent of their parents; and, therefore, the methods proposed by the friars were not adopted: more especially, as the Moors, when they professed the dominion of the country, had never forced any of their Christian subjects to change their religion, and king Ferdinand, upon the surrender of Granada, had engaged himself by oath, if the Moriscoes wished to remain in Spain, not to molest them on account of their religion. The Jews, however, not having been protected by any such engagement, were ordered by a royal edict, within three months after the capture of Granada, if they would not be baptized, to depart with their families in the course of four months, on pain of death; upon which many of them removed, and those who remained, after the expiration of the stipulated term, were stripped by the king of all their property, and sold to his subjects for slaves. It is said that above 800,000 men, women, and children, were driven out of Spain at this time.

As to the Moors, it was found that, in the year 1499, few of those who inhabited Granada had been converted to Christianity; and therefore Ximenes, archbishop of Toledo, was charged to pursue some course for converting the Moors to the Christian faith. The archbishop, determined to succeed in every measure which he undertook, began by mild treatment to engage in his interest the chief men among the Moors, some of whom became converts; but others were found invincible by bribes and promises. The prelate changed his plan, and had recourse to severer methods of conversion, ordering the irreligious to be loaded with chains, thrown into dungeons, and treated as the most notorious malefactors. Imitated by this cruel treatment, the Moors took up arms; but their insurrection being suppressed, 50,000 of them, inhabitants of the city of Granada, purchased their lives by confessing to be baptized, and the archbishop so far triumphed in his successes, as on his departure to have left one professing Mahometan in the city. The Moors of the country were alarmed, and fortified themselves among the mountains, resolving to die Mahometans with their swords in their hands, rather than submit to be baptized by compulsion, as their countrymen had been in the city; but though many of them, with their women and children, were put to the sword, others collected together in a formidable body, which called forth the interposition of the king in person, who being joined by a powerful host, very rapidly reduced all the Moorish towns that were in arms; obliging all the inhabitants to purchase their lives by confessing to be baptized. The Moors that were left in arms among the fortresses of the mountains petitioned the king to allow them to transport themselves to Barbary, offering to pay ten dollars per head for every one that embarked: the king's want of money prevented those who could pay their ransom to depart, and those who were under a necessity of remaining were forced to be baptized. In a few months, above 200,000 men, women, and children were converted by the king and the archbishop of Toledo from the Mahometan to the Christian profession, though it is said that scarcely one in that large number was truly converted to the Christian faith.

The Inquisition, regarding these forced baptisms as good and valid, exercised its usual cruelties on those Moors who were convicted of having afterwards returned to Mahometanism. Not fewer than 100,000, living and dead, present and absent, had been condemned for apostacy by the inquisition of Seville in the space of forty years; of which number 4000 were burned, and 35,000 were reconciled, the rest having made their escape into Barbary. During the remaining part of the reign of Ferdinand and Isabel, and the whole reign of Charles V., we hear little more of the Granada Moriscoes, than that they universally continued to be Mahometans, and manifested an extraordinary aversion to Christianity, which avarition was increased by the fiery zeal of the inquisition. Thus the friars went on preaching and the inquisitions went on burning the Moriscoes, until the year 1568; when Philip II., by advice of his council and ecclesiastics, published certain laws, which were framed with a view of extinguishing in the Moriscoes the memory of their being descended of the Moors; the remembrance of which was thought to contribute not a little to their obstinacy in the religion of that nation. The rigorous execution of these laws induced the Moriscoes to seek relief from the grand signor and the Moors in Barbary; who sent 800 Turks, with a great quantity of arms and ammunition, into the kingdom of Granada, who were joined by the Moors from all parts, taking up arms and recommencing the profession of the Christian religion. Against these the king ordered his troops to march; but in the course of eighteen months, he was able neither to conquer them nor to starve them among the mountains. At length, however, they were totally subdued, and compelled to leave the kingdom of Granada. From this time they were dispersed over the kingdom of Castile, and some other inland provinces, in which they and their posterity continued until the time of their general expulsion, in the year 1610. Notwithstanding all the diligence and cruelties which were used to reconcile these Moriscoes to Christianity, they and their posterity still continued as much Mahometans in their hearts as ever they had been.

This was also the case with regard to the Moriscoes of the kingdoms of Valencia and Aragon, who continued professed Mahometans for 300 years, after they were conquered by the Christians; and who, having been all baptized by extreme force, remained Mahometans in their hearts till they were all expelled Spain. The Spanish historians are not agreed as to the number of the Moriscoes that were driven from Spain in the year 1610. Some say they were a million, others that they were 900,000; but the greater number of writers concur in ascertaining, that they were 800,000 men, women, and children, besides those that were slain or detained. These Moriscoes were indolent and peaceable inhabitants of Spain, and constituted the strength of the kingdom by their application to agriculture, manufactures, and trade. The expulsion of them was such a fatal blow to Spain, that the has not to this day, 1 or, indeed, is ever likely to recover it. Soon after this disastrous event, Spain began to feel its bad effects, as we may infer from a memorial delivered in 1618, to Philip II., by a Junta that had been assembled by the king, to consider what remedy might be applied to the ruined state of his kingdom. The duke of Lerma, the chief author of the depressing expulsions, was turned from court and deprived of all his offices; his chief confidential and counsellor, Don Rodrigo Calderon, was committed.
committed to prison, and after imprisonment for 24 years, put publicly to death in the great place of Madrid; and the archbishop of Toledo, who had been also a zealous promoter of the expulsions, died, a few days after his brother the duke was dismembered from court, merely of grief and discontent. And king Philip, who died soon after, is said by a famous Spanish historian, to have had his conscience upon his dead brother's overwhelmed with horrors, which has been attributed to his concern in these expulsions, by means of which, in violation of all the laws of religion and humanity, he had plunged more than 100,000 families in distress and misery; a reflection that must have agenizing to a perfon summoned by death to answer for his conduct before the divine tribunal, where, as an excellent writer expresses himself in immediate reference to this subject, "they are to have judgment without mercy, who have showed no mercy to their fellow creatures." In the instance above mentioned, we perceive the injurious effects of perfecution, with respect to the internal prosperity of a country. A similar instance occurs in the revocation of the edict of Nantes. Geddes's Tracts, vol. 1.

MORISON, Robert, in Biography, a botanist of the 17th century, whose name is familiar to all, from the popularity of his principal work as a book of reference, was born at Aberdeen in 1630. Being designd for the church, he devoted himself to the study of mathematics in that university; but was diverted from that pursuit by a taste for physic, and especially botany. Thee studies in their turn gave way, for a time at least, to his loyalty, and he actually became a soldier in the service of king Charles. After receiving a dangerous wound in the head, in a battle near his native town, which for a while disabled him, he retired, like many of his countrymen after the ruin of the royal cause, to Paris. Here he became tutor to a young man of some fortune, while he sedulously cultivated the studies necessary for his profession, and took the degree of doctor of physic at Angers, in 1648. Botany however was his most favourite pursuit; for it appears that as soon as a prospect opened of his deriving a living from that source, he "threw physic to the dogs." M. Robin, who had then the care of the royal garden at Paris, conceived so favourable an opinion of Morison, that he recommended him to the patronage of Gallon, duke of Orleans, and he was entrusted with the care of that prince's garden at Blois, accompanied by a handsome salary. He held this charge from the year 1650 to 1668, when the duke died. During that period he devoted himself to the study of theoretical as well as practical botany. He began to plan a system, on the subject of which his royal patron is reported to have delighted to confer with him. He was also dispatched on several botanical expeditions, to various parts of France, for the purpose of enriching the garden. A catalogue of this garden was printed in 1653, by Abel Brunyer, physician to the duke; of which Morison afterwards published at London, in 1669, a new and enlarged edition, accompanied by a regular and professed criticism of the works of Calpar and John Bauhin. For this last performance he has perhaps incurred more blame than he justly deserves. Harper terms it "an invicious work," though he says the remarks are for the most part true. Morison gives to these great men all the rank and honour which their eminent learning and industry deserve; and while he proceeds, without ceremony, to a plain and simple indication of their mistakes or imperfections, he expresses a wish of having his own errors, of which he does not doubt the existence, likewise pointed out. The Hortus Flora is disposed in alphabetical order, and accompanied by a double dedication, to king Charles II., and James duke of York, to whom its author had become known in France. When king Charles returned the forfeit of his fathers, Morison, who the same year was deprived, by the death of the duke of Orleans, of his chief attachment to France, gladly obeyed the summons of his royal master, to settle in England. The minister Fouquet is said to have offered, in vain, the most liberal temptations to retain him. On arriving in London, he received the titles of King's Physician, and Royal Professor of Botany, with a salary of 200l. a year, and a house, as superintendent of the royal gardens. He was also elected a Fellow of the College of Physicians.

Whether the gardens of Charles II. were very botanical, or whether they flourished much under the care of the subject of this article, does not appear. He was himself transplanted to a more promising scientific nation, nine years afterwards, when he became Professor of Botany at Oxford, and was again dubbed Doctor of Physic, his foreign degree giving him no rank in that university. He gave a couple of lectures there in the autumn of 1670; as well as in several succeeding years, as long as he lived. He had for some time been meditating, and collecting materials for, a great universal work on botany. Of this he published an excellent specimen in 1672, being a methodical arrangement of umbelliferous plants, in folio, accompanied with plates. He takes the leading characters of these plants from the seeds, though some of them, under the same denomination a tribe of different genera, whose indiscrimination in one measure, though very slightly, agrees with the true umbilicata, but which are otherwise totally different, such as Valiantia, Thalidium, Spiraea. This is certainly as great an error as ever the Baulins committed.

In 1674, Morison edited at Oxford a thin quarto, from the manuscripts of Boccone, describing a number of new plants from Sicily, Malta, France, and Italy; a work illustrated with 52 plates, 45 of which were re-engraved, after some, less accurately finished, under Boccone's inspection. The figures, though diminished, are in general very expressive, and many of the plants are no where repre- sented.

Morison's great work, entitled Plantarum Historia Universalis, Oxoniensis, appeared in 1690, in one volume folio, comprising five sections of herbaceous plants, with numerous plates, in each of which 12 plants are commonly delineated. This was called the second part of the work; the first, containing sections of trees and herbs, having been postponed, as the most easily to be finished at any time; but it never appeared, nor is there any certainty of its ever having been written.

A second volume, called the third part, was published in 1699, long after the author's death, by Jacob Bohart. This comprehends 10 sections more, and concludes the system, as far as regards herbaceous plants. Of these 10 sections, four only were finished by Morison; the rest having been the performance of the editor. The plates of grashes, which make a part of the eighth section, are remarkably good, and are universally cited by succeeding writers. The other figures throughout these volumes, though in general use, are for the most part not original, nor are they entitled to the praise of accuracy as copies. The drawing of many of them is defective; their outline unlike the originals; parts are improperly added, or carelessly misrepresented; and the whole betray signs of haste and frequent intation; defects indeed not altogether avoidable, in so great an undertaking; The editor of this latter volume claims for the author great honour as the inventor of a system. It cannot be denied, however that the outlines of Morison's system are evidently to be traced in the work of Calsilanus, published in 1583, and
and Use of Two Arithmetic Instruments: together with a short Treatise, explaining the ordinary Operations of Arithmetic, &c.Prefixed to his most excellent Majesties, Charles II., by S. Morland, in 1662.¹ This work, which is exceedingly rare, and which has been in the hands of the writer of this article, is illustrated with twelve plates, in which the different parts of the machine are exhibited; and whence it appears that the four fundamental rules in arithmetic are very readily worked, and, to the author's own words, "without charging the memory, disturbing the mind, or exposing the operations to any uncertainty."

That these machines were at the time brought into practice there seems no doubt, as by an advertisement prefixed to Mr. Morland's work, it appears that they were manufactured for sale by Humphry Adanson, who lived with Jonas Moore, esq. in the Tower of London.

In this place, having omitted it under the article Arithmetic, we may just notice that early Stanhope, about thirty years since, invented two machines for the like purposes as those of Mr. Morland were intended, and it is said his lordship, when proposing a plan to parliament for the reduction of the National debt, verified the truth of all his calculations by means of those instruments, of which the following is a brief description. The smallest machine, which is intended for the first two rules of addition and subtraction, is not larger than an octavo volume, and by means of dial-plates, and small indices moveable with a steel pin, the operations are performed with undeviating accuracy. The second, and by far the most curious instrument, is about half the size of a common table writing-dek. By this, problems in multiplication and division, of almost any extent, are solved without the possibility of a mistake, by the simple revolution of a watch and a multiplier and multiplicand, in one instance, and the divisor and dividend in the other, are first properly arranged; then, by turning the wheel, the product or quotient is found. What always appears singular and surprizing to spectators, is, that in working sums in division, if the operator be inattentive to his business, and thereby attempts to turn the handle a single revolution more than he ought, he is instantly admonished of his mistake by the sudden springing up of a small ivory ball.

MORLEY, Thomas, a disciple of Bird, bachelor of music, and one of the gentlemen of queen Elizabeth's chapel, who, though a good practical musician, acquired more celebrity by his treatise, entitled, "A plain and easy Introduction to Practical Musicke," than by his performance or compositions, though eminent for both.

If due allowance be made for the quaintness of the dialogue and lye of the times, and the work be considered as the first regular treatise on music that was printed in our language, the author will merit great praise for the learning and instruction it contains. At the same time, however, it is curious, and in some things which contain his great pains to explain; as well as by the introduction of new methods of notation, new harmonies, and new modulations, since his time, which, to render intelligible, require a more recent elementary treatise. Yet though this work is redundant in some particulars, and deficient in others, it is full curious, and fully allowed to have been excellently adapted to the wants of the age in which it was written. However, its late republication in the original form, totidem verbis, whatever honour it may reflect on the memory of the author, somewhat disgraces later times, which have not followed this treatise, by producing a better and more complete book of general instructions in English, after the lapse of so many years, and the perpetual cultivation and practice of the art, in our country, both by native musicians and foreigners.

"Analyse of Morley's Introduction."—The gamut and time-table employ the eight or nine first pages of this work. After which, modes, figures, points of perfection, and alteration, augmentation, and diminution, all now obsolete, occupy many pages. The old and exploded proportions given under the names of figuration, tripola in the minim, quadrupla, septuplata, induction, and equa, would now be studied a pure parts, as no good ear can bear, or found judgment make use of them.

The second part likewise is wasted in frivolous dialogue a, now useless matter. The definitions of concords and discords, indeed, and their use in discant, or plain counterpoint, are the subjects of conversation; but the knowledge it conveys is so inadequate to present purposes, and the student is led to it by such an indirect road, that it is to be feared he will be so bewildered in the pursuit, as to acquire but little clear gain for his trouble. Indeed the prohibitions are such as will lead a student of the present time into doubt and error. Page 75, he utterly condemns, as against the principles of music, the use of two fifths, though one be false. Indeed the use of the tritonus and fesse fifth is constantly avoided by old harmonists; which is excluding the use of one of the most abundant sources of beauty and passion in modern music. Whoever first combined the sharp 3d and 7th to the 5th of the key, and invented this chord 6

 INTO THE SECOND, 6 TO THE SHARP LEVENTH, AND 4 TO THE 5

fourth of a key, conferred as refreshing a benefit on the craving lovers of music, as Moses did on the thirsty Israelites, in producing water with his wand from the rock on mount Horeb. These combinations, though unknown to old masters, are utterly indispensable in the present regle de l'Octave.

To say the truth, master Morley is not very nice or accurate in these examples of counterpoint which are given as his own, and left as models of perfection. Page 76, in the last examples, there are two faults, which would not be pardoned by modern ears or judgment: in the first of the two, bar 5; the fourth between C and G, is inipid and unmeaning; and in the second of the examples, bar 5, the modulation from the chord of D major to C, is used sans fin, and, in two parts, without a warrantable or good effect. Fig. Few of the examples are elegant, or worthy of imitation now; and it appears as if the attentive examination of all good modern compositions, in score, would be of infinitely more service to a student, than the perusal of all the books on the subject of music that were written during the sixteenth and seventeenth centuries. Corelli, Handel, and Geminiani for fugues; Haydn, Mozart, Bocherin, Phyle, John Christian Bach, Abel, Giordani, Beethoven, &c. for symphonies, quartets, trios, duets, and other music for voices; Tartini and Giordani for solos; Domenico Scarlatti, Alberiz, Emanuel Bach, Schobert, Eichner, Haydn, Mozart, Kotzebuch and Beethoven, Clementi, Diabelli, Steibelt, Burney, Cramer, &c. for harpsichord and pianoforte pieces; Vinc. Pergolese, Halle, Jomelli, Perez, Galuppi, Piccini, Sacchini, Pasdelou, Sarti, and Naftoli, for vocal compositions; and above all, Handel and Sebastian Bach for organ and choral music, almost all to be found in our own country, and all models of perfection in correctness of composition, knowledge of instruments, rhythm, modulation, new effects, pathos, fire, invention, and grace.

It has ever been our with condescendingly to do justice to the learning
learning and contrivance of old masters, and to recommend the study and performance of their works to our readers, as curious and historical specimens of the best music of their own times; without as the sole flute and models of perfection to young professors for all times, who wish to please, improve, and are expected to keep pace with modern improvements. To such we would first recommend the study of the best modern authors; and then, as matters of curiosity and amusement, to enquire into the productions and genius of former times, in order to extend their knowledge and views, and prevent embarrassment or surprise, whenever they happen to be called upon to perform or speak of such works.

The third part of Morley's Treatise contains more curious specimens of useful knowledge in old counterpoint, than the rest of the book. He is much obliged, however, to Tigrini, whose Compendium was published in 1588, and others, for many of his examples, whose names ought not to have been concealed. Tigrini has indeed been pillaged with such haste, that a typographical error has not been corrected; a few of these cadences have even been disingenuously disguised, and their places transposed.

Upon the whole, though the book is curious, and full of information concerning the music of the sixteenth century, it must be owned, that the language in which it is written, is at once uncouth and affected; and that neither the melody, nor harmony it recommends and teaches, is of this world, at least of this age; no certain scale is given of major or minor keys; nor is the modulation he uses that of the present times. Indeed no keys are determined except E major, and D and A minor; and though so much is written concerning the moods, or measure, yet nothing is said of accent, or the preparation, use, and resolution of discords in general.

Having spoken fully of Morley as a theorist, we shall proceed to consider his merit as a practical musician. And in comparing his compositions with those of his predecessors, they do not appear so original as we at first imagined them. During the time of writing his Introduction, he must of course have consulted the productions of many authors; and he has not done it unprofitably, as a composer, any more than a theorist. It has been said, that "we often remember what we read, without recollecting that we ever read it; but it frequently happens, that what we take for invention, is only reminiscence," which is a charitable apology for seeming plagiarist. The melodies, however, of Morley, are somewhat more flowing and polished than those of the old authors, on whose property his memory, perhaps imperceptibly, had fastened; but, besides these, it is plain that he sometimes condescended to use the same materials as his contemporaries, and to interweave the favourite passages of his times into his works, of which the following is a chronological list:

- Canzonets, or little short songs, of three voices
- Madrigals, to four voices
- Ballads, or Fa la, to five voices
- Madrigals, to five voices
- Canzonets, or little short Airs, to five and six voices

Of the following publications he was little more than the editor.

- Madrigals, to five voices, collected out of the best Italian authors
- The Triumphs of Oriana, to five and six voices composed by divers several authors. Newly published by Thomas Morley, Batchelor of Musicke, and Gentleman of his Majesties honourable chapel.

These madrigals, in number twenty-four, of which the bulk of the 12th and 24th was composed by Morley, were written, set, and published, in honour of queen Elizabeth, who is figured under the name of Oriana. The composers of the rest were Michael Effe, Daniel Moreno, John, Mundy bachelor of music, Ellis Gibbons, John Bynet, John Hilton B. M., George Morcan B M., Richard Carlson, John Holme, Richard Nicholass, Thomas Tomkins, Michael Cavendish, William Cobbold, John Farmer, John Wilby, Thomas Hunt B. M., Thomas Welkes, John Milton, father of the great poet, George Kirbye, Robert Jones, John Leffey, and Edward Jofin B. M.

As it gave the ton to the rest of Europe, but particularly to England, in all the fine arts, during the reign of queen Elizabeth, it seems as if the idea of employing all the best composers in the kingdom to set the songs in the Triumphs of Oriana to music, in honour of our virgin queen, had been suggested to Morley, and his patron, the earl of Nottingham, by Padre Giovenale, afterwards bishop of Saluzzo, who employed thirty-feen of the most renowned Italian composers to set canzonetti and madrigals in honour of the Virgin Mary, published under the following title:

— Tempio Armonico della beatissima Virgine nostra signora, fabbricato per opera del Reverendo Padre Giovenale, A. P. della Congregazione dell' Oratorio. Prima Parte, a tre voci Stampa in Roma da Nicolo Matti, 1599 in 4to.

Confort Leffons, made by divers exquisites authors, for six different instruments to play together, viz. the treble lute, pander, citterne, base viol, flute, and treble viol. Dedicated to the Lord Mayor, 2d edit.

Mafter Morley, supposing, perhaps, that the harmony which was to be heard through the clattering of knives, forks, spoons, and plates, with the galing of glasses, and clamorous conversation of a city-feast, need not be so accurate or refined, was very nice in setting parts to these tunes, which are so far from correct, that almost any one of the city waits would, in musical cant, have vaunted as good an accomplishment far le champ, or rather far le chant, which teems the original and true reading of that phrase. We remember very early in our musical life, to have heard one of the Tower waits at Shrewbury playhouse, vamp a lute, upon all occasions, he being utterly unable to read any one that was written; and as our ears were not very much offended by the difsonance, we supposed that by habit, he contrived, at leaft, to begin and end in the right key, and was quick in putting accidental modulation. See what has been said of Extemporaneous Devices, in Dr. Burney's Hist. of Music, vol. ii. p. 142. See also DISCANT.

A plain and easy Introduction to Practick Musick.

It does not appear that any of Morley's church music was printed during his life. Dr. Tudway, however, has inserted several valuable choral compositions, by him, in the collection made for Lord Harley, 1715; amongst which are his "Funeral or Dirge Anthems, as performed at Westminster Abbey at Royal and Noble Funerals," and printed by Dr. Bayce, in the first volume of his Cathedral Services, and an Evening Verse Service, in five parts, in D minor, which has never been printed. In queen Elizabeth's music-book there are likewise five different sets of lessons, or pieces for the virginal, composed by Morley.

As fo many of his pieces have been printed in score for the new edition of his Introduction, under the eye of the late
late Dr. Samuel Howard, by Randal, we shall say no more about them.

The Burial service, composed by Morley, which is supposed to be the first that was composed after the Reformation, still continues to be used in Westminster Abbey on great and solemn occasions.

We heard this service admirably performed in 1760, by the three united choirs of Westminster, St. Paul's, and the chapel-royal, at the funeral of his late majesty George II. in Westminster Abbey, where it had a most solemn effect. Nothing seems better suited to so awful an occasion than this music, in a minor key, and chiefly in simple counterpoint, but with a grave, and now uncommon, harmony and modulation, which added to the grandeur of the effect. The few short points of fugue and imitation introduced in this composition are such as were not common when the service was produced, nor have any of them been debased since by vulgar use. As this composition is so admirably printed by Dr. Boyce, and may be easily consulted, we shall detain the musical reader with a few remarks on it, referring to that copy, as we are unable to admit it to our plates. And we shall begin by observing, that the four first bars are remarkably solemn, and that the major third to G, after being faintly in G minor, the preceding parts of the phrase, is unexpectedly grand and pleasing. The point at "And though after my skin, worms destroy this body," is admirably conducted. And, though in simple counterpoint only, the harmony and modulation to "This Lord gave, and the Lord hath taken away," convey something particularly majestic and grateful to our ears. The points at "He cometh up, and is cut down," and "Of whom may we seek for succour," diversify and give relief to the plain counterpoint in an ingenious manner; but the passage "Shut not thy merciful ears to our prayers," is extremely beautiful in the three essentials of good music: melody, harmony, and accent. Every part is chantante, or signs, without any seeming subserviency to the rest: and the words, which seldom happens in music of the sixteenth century, are well expressed, if we except the length given to the particle to in the treble and counter-tenor parts, which might easily be corrected by shortening the two first sounds to the more important word "ears," and allowing only a crotchet to the following proposition. And in this manner the words of many of our old and venerable compositions for the church might be adapted, in order to obviate the objections that are justly made to the want of attention in their authors to accent and syllabic quantity: and this seems to be infinitely more defirable than the superfluousness of these admirable specimens of choral harmony, in favour of more invidious modern productions, which can boast of no other perfection than that, which, according to Pope, is in the power of every dull grammarian and critic, who "Commas and points can be set exactly right." But thus alone will not constitute good music, without genius, invention, melody, harmony, modulation, and variety of measures and effects. We shall only mention one point more in this venerable service, where the greatest musical art is united with the happiest verbal expression, at "Suffer us not at our last hour," and where the fullness is made in each part with great reverence and solemnity. Indeed we see but one passage which we could with other-wise than the author has left it; and that is at "I heard a voice from heaven," where the word "from," being in the same harmony as the subltiantive "heaven," is invidus and unmeaning. The natural combination for that leading and unsustained part of the bar, seems to be C, with a 6th. We cannot conclude, without requiring such of our readers as understand and feel good composition, to attend to the solemn, unusual, and pleasing effect produced in many places of this service by mere common chords: particularly at those words, "He sleeth as it were a shadow:" and by the flat 6th given to G, when the ear is accustomed to expect a 9th: as at those words, "Blessed are the dead which die in the Lord."

MORLEY, George, a learned prelate of the church of England, was born at London in the year 1597. His parents died while he was very young, and left him almost a destitute. He met, however, with friends, by whose interest he was elected one of the king's scholars in Westminster school, at the age of fourteen, and in 1615 he was admitted a student of Chrift-church college, in the university of Oxford. He took his degree of B.A. and M.A. in 1618 and 1621. In 1628, he accepted an invitation to become domestic chaplain to Robert, earl of Carnarvon, in which situation he continued till the year 1640. Afterwards he was made chaplain to Charles I., who preffented him with the canony of Chrift-church, in 1641. In the following year he took his degree of D.D.: he was a zealous adherent to the cause of the king, and gave one year's income towards the expenses of the civil war. He possessed great influence among the leaders of both parties, and so highly was his integrity estimated, that he was told he should remain unmodelled in the emoluments of his preference, and not be required to subscribe any thing against his conscience, provided he would affure the ruling powers that he would not actually oppose them. He chose rather to participate in the fortunes of his suffering brethren, and was thrown into prison. Upon his liberation, finding himself deprived of all his possessions, and what was dearer to him, of liberty of conscience, he resolved to retire to the aiylum of king Charles II. in Holland. He accordingly quitted England in 1649, repaired to the Hague, and was graciously received by his prince, who kept him confidentially about his person. While Dr. Morley continued abroad, he formed an acquaintance and intimacy with several foreigners, who held distinguished stations in the ranks of literature, particularly with the famous Bochart, Salmius, Daniel Heinisch, and others. When measures were secretly preparing for the restoration of Charles II., chancellor Hyde sent Dr. Morley over about two months before it took place, with letters from the king, and himself, to the leading men in the nation, and as a proper person to afford in paving the way for that event. The chief purpose of his mission was to contradict the opinion, that the exiled prince had become a convert to popery. Upon the restoration of Charles, Dr. Morley was instantaneously returned to his canonry, and in a few weeks after he was promoted to the deaconry of Chrift-church, which was followed by his nomination to the bishopric of Worcester. He was consecrated in October 1660, and in the following year he was one of the principal managers at the famous Savoy conference. In 1662, he was translated to the see of Winchelsea, in which he remained till his death, in 1684, when he was in the eighty-sixth year of his age. "He was," says bishop Burnet, "in many respects a very eminent man, pious and charitable, of a very exemplary life, considerably learned, but extremely passionate and obstinate." He had been a liberal benefactor to the university of Oxford, in which he received his education; for he gave a hundred a-year to Chrift-church college, and he founded in Penbrooke college three scholarships for the isle of Jersey, and two for Guernsey, of ten pounds per annum each. Bishop Morling, or Mortling, in our Old Writers, the wood which is taken from the skin of dead sheep, whether killed, or dying of the rot. See SHIRLING.
MORLUNDA, in Geography, a town of Sweden, in the province of Smaland; 41 miles N. of Kalmar.

MORMANDO, a town of Naples, in Calabria Cita; 16 miles N.W. of Caffano.

MORMANT, a town of France, in the department of the Seine and Marne, and chief place of a canton, in the district of Milan; 10 miles N.E. of Milan. The place contains 995; and the canton 10,938 inhabitants, on a territory of 527½ kilomètres, in 29 communes.

MORMON, in Zoology. See Sima Malmon.

MORMORA, L., in Geography, a town of France, in the department of the Stura, on the Maira; 14 miles S.W. of Saluzzo.

MORMYRUS, in Ichthyology, a genus of fishes of the order Branchioloegous, according to the Linnaean system, having gills without bony rays; but Dr. Shaw and some other naturalists have put it in the order Abdominabili. The generic character is, head smooth; teeth numerous, notched; aperture of the gills linear, without a cover; gill-membrane with one ray; body feally. Three species are described by Gmelin, which are as follow:

Species.

Cyprinoïdes. Tail bifid, appendaged; its habits resemble, in some measure, those of the genus Cyprinus, whence it derives its name. It has an obtuse snout; the upper jaw is longer than the lower, and it has twenty-seven rays in the dorsal fin. It is a native of the river Nile.

Anomalodes. This species has a sharp snout, equal jaws, twenty-six rays in the dorsal fin, and a bifid acute tail. The dorsal fin is placed opposite to the anal, and is somewhat shorter than that fin. This also is an inhabitant of the Nile.

Kanxume. Tail bifid, obtuse; dorsal fin with sixty-three rays. It has a whitish and very much compressed body, and is found in the Nile. The aperture of the gills is perpendicular; the snout is conic, deflected; the lower lip is the longer; belly straight, but rufing from the vent; lateral line straight, in the middle of the body; tail and dorsal fin linear.

This genus has of late years been examined with much attention by M. Geoffroy, who has increased the species from three to nine. He observes, that the body is compressed, and that the structure of the tail is unusual, being of a considerable length, and of a sub-cylindrical and inflated appearance, on account of its containing the glands from which the oily matter along the lateral line is secreted: he also observes that the stomach is strongly muscular; that the ovariuni is single, and that the swimming-bladder is almost the length of the abdomen. The new species are the following:

Oxyrhyynchus. This species has a straight snout; the lower jaw is longer than the upper; and the dorsal fin runs the whole length of the back. Found in the Nile.

Salamia. In this the lower jaw is longer than the upper, and the dorsal fin is shorter than the anal, but opposite to it. It was observed by Geoffroy in the defert near Salaya, in Africa, where it had been thrown by an inundation, and left in a dry flat.

Bebe. This has an obtuse snout, and the dorsal fin is six times shorter than the anal, but is placed directly opposite to it, as in the Salamia. It is a native of the Nile, and observed in plenty near the region of Bebe.

Hers. A native of the Nile, having an obtuse snout; the upper jaw longer than the lower, and dorsal fin running the whole length of the back.

Baze. This likewise has an obtuse snout; the upper jaw is much longer than the lower, and the dorsal fin is of equal length with the anal.

Haselquist. This species has twenty rays in the dorsal fin, twelve in the anal, and a forked tail. It derives its specific name from the naturalist who first observed it in the Nile.

Mormyrus, a species of sparis. See Sparus Mor- myrus.

MORMONT, in Geography, a town of France, in the department of the Rhone, and chief place of a canton, in the district of Lyons; 10 miles S.S.W. of Lyons. The place contains 2750, and the canton 17790 inhabitants, on a territory of 120 kilomètres, in 12 communes.

MORONAY, Philip, lord of Plessis Marly, in Biography, an illusior: French Protestant, who flourished in the sixteenth and seventeenth centuries, was born at Buhl, near Bihuy, in the French Vexin, in the year 1549. His father, James, was a descendant of an ancient and noble family, and as he was zealously attached to the Roman religion, he intended to educate his son Philip, the subject of this article, to the ecclesiastical profession. He was the rather induced to this step from the circumstance of his having a brother already high in the church, who promised to resign hereafter his benefices in favour of his nephew. These prospects were disappointed by the death of the dignitary, while Philip was only in the eighth year of his age. In the mean time his mother had become a convert to the Protestant religion, and had taken care to infil its principles into the mind of her son. His father died in 1560, after which his widow made an open and undisguised profession of her religious principles, and had the Protestant worship conducted at her mansion of Buhl. Philip studied at several of the universities at Paris and elsewhere, and made a rapid progress in the several departments of literature to which he bent his mind. Before he had completed his eighteenth year, his uncle, the archbishop of Reims, came to Paris, and hewing examined the young man, as to the proficiency he had made in his studies, was surprised at the depth and extent of his erudition. He was aware also of his seduction from the religion in which he had been brought up, and endeavored by every means in his power to reclaim him, promising to resign his bishopric in his favour at some future period, and to find him promotion in the church immediately. Thence he declined, and in 1567, upon the commencement of the troubles in France, M. du Plessis found himself under the necessity of quitting the metropolis, and returning to Buhl. He resolved to take up arms, and to serve under his maternal uncle, but in proceeding to the army his horse fell under him, and both bones of his leg were broken. During a long confinement, the result of this accident, he composed a poem on the civil war, and some sonnets in praise of Cogni. On the peace signed in 1568, he began a tour in foreign countries, as well for the improvement of his mind, as with the view of the more perfect recovery of his crippled limb. He went to Geneva, which he was obliged to quit in a very short time, owing to the plague breaking out in the city. From Geneva he passed to Heidelberg, where he began the study of the civil law, and the German language. In the course of six months he made himself so far acquainted with the language, as to be able to read all kinds of books in it. Having quitted Heidelberg he travelled to the principal cities in Italy, and we find him proceeding to Frankfort, Padua, and Venice. At the last named city he became acquainted with Perrot de Mezieres, who excited in him a desire of travelling into the East; but owing to the war which then existed between the Turks and Venetians for the island of Cyprus, he was obliged
Mornay.

obliged to relinquish the design. In 1571, he went to Rome, where he was exposed to some danger on account of his religion. In the following year we find him in England, where he met with a most gracious reception from queen Elizabeth, whose courtiers seemed to vie with each other in the attention which they showed him. On his return to France he paid a visit to Coligny, and while staying with him, he drew up a memorial of the observations that he had made in Flanders; and a piece intended to demonstrate the justice and advantages of declaring war against Spain; both of which were presented to the king by the admiral, who urged his majesty to improve the opportunity that offered itself by sending M. de Plessis to the prince of Orange, for the purpose of conciliating the efforts of France and the United Provinces, but the king refused to attend to the advice thus offered: he had no wish to come to a misunderstanding with the Spaniards, and he was meditating, at the very moment, the destruction of the Protestants of his own country. De Plessis forewarned the minister before he arrived, but he could not persuade Coligny to doubt the king's sincerity. The former, from the apprehension which he entertained, took the precaution of removing his mother, while he determined to remain in Paris to brave the storm, and to avert his suffering brethren. At length the fatal eve of St. Bartholomew arrived; and he was awakened in the dead of the night by the savage butchers who were executing the orders of a still more savage monarch. Coligny fell a sacrifice among the multitudes whose lives were taken away on that tremendous night. But De Plessis, when he found that all resistance would be in vain, escaped to England, the happy asylum of the persecuted in many periods of her history. Here he met with a cordial reception from princes of all ranks, and particularly from Mr. Secretary Wallingham. When it was known at Paris that he was safe in England, the ambassadour of the elector of Saxony, and other German princes at the court of Charles IX., wrote to his friends to supply him with every thing of which he might stand in need. To confide himself under the auspices of his afflicted countrymen, he betook himself to his studies; and to drive away, if possible, the wretched thoughts respecting his friends, less fortunate than himself, he wrote "Remonstrances," in which he exhorted the queen of England to undertake the protection of the suffering church. In 1574, he returned to France, and upon his arrival he attended a council of the Protestant chiefs, in which it was proposed that the party should immediately take arms to provide for the security of their own rights by promoting the views of the duke of Alençon. This project, though opposed by Du Plessis, was carried by a majority, and he, foreseeing the ill consequences, retired to Sedan.

While at this place he married, and wrote, at the request of his lady, "A Treatise on Life and Death," which was afterwards published at Geneva, and translated into several different languages. Previously to his marriage he had engaged in an unsuccessful conflict with part of the king's troops; was wounded and taken prisoner; but after the confinement of a few days, and by assuming a false name, he was allowed to return himself on easy terms. In 1576, he again took arms, and now his adherents were so powerful, that the king's party deemed it expedient to propose a negotiation, which was accepted. After this Du Plessis entered into the service of the king of Navarre, afterwards Henry IV. of France, and was admitted into his most intimate councils, and by this step he was enabled to render essential service to the Protestant cause. In 1577, he was sent by his master on an embassy to the queen of England, to explain to her the justice of their cause, and solicit pecuniary assistance, which he obtained to the amount of eighty thousand crowns. During his continuance in England he was enabled to perform very acceptable services, as well for the United Provinces as for the Low Countries. He devoted his leisure moments to the diligent perusal of the Greek and Latin fathers, and composed his treatise "Concerning the Church," which was published in 1577. In the following year the prince of Orange was called by the States-general to Antwerp, and Du Plessis having taken leave of Elizabeth, went to that city to assist at the deliberations. Here his pen was employed in endeavours to check the intemperate zeal of some reformers, who disgraced their cause, and excited prejudices against it, which occasioned a rupture between the provinces by their outrages against the ecclesiastics, the churches, and other religious houses. The talents and zeal of M. Du Plessis were held in such dread by his opponents, that a base attempt was made to take him off by poison, but the strength of his constitution was superior to its effects. Scarcely had he recovered from this attack, when he was called again into the active service of the king of Navarre. But in the midst of his political exertions he composed, and in 1580 published at Antwerp, a work entitled "On the Truth of the Christian Religion," in which he shewed himself a very able combatant of atheistic and other erroneous principles; and in the following year, to render his labours more generally useful, he translated it into the Latin language. In 1582, he left Antwerp for Paris, and from this time till 1593, when the king (Henry IV.) renounced the Protestant religion, Du Plessis was consulted by him on a variety of occasions, and called upon to write his edicts, manifestos, and other late papers. In 1582, his sovereign was desirous of nominating him his chancellor, but this he declined: in a few years afterwards he was appointed governor of Saumur, and upon the accession of Henry IV. he was made counsellor of state. In 1593, when the king intimated his intentions of conforming to the Catholic church, Du Plessis did all in his power to dissuade him from that measure; and when he found it impossible to save him from the disgrace which he believed must attach to his name by such a dereliction of principle, he withdrew from the court, and occupied himself in his studies, in the duties attaching to his government, and in exertions for the Protestant cause. He took an active part in all the negotiations between the king and his subjects of the reformed communion, till the celebrated edict of Nantes was obtained in 1598. He also distinguished himself by his writings in defence of religion. In 1598, he published his book on the "Eucharist," which occasioned a conference between him and Du Perron; the result of this was, that Du Plessis obtained the appellation of the Protestant pope. In 1607, he published his treatise entitled "The Mystery of Iniquity, or the History of Papacy." About the same time he published "An Exhortation to the Jews concerning the Messiah," in which his knowledge of the Hebrew literature is advantageously displayed. He was author of other works, and from his papers have been published, "Memoirs, &c. containing of Discourses, Instructions, Letters, Dispatches, &c." in four volumes, quarto. In 1621, he remonstrated freely with Lewis XIII., against his determination to make war upon the Protestants, but his zeal on this occasion was the means of depriving him of his government of Saumur, upon which he retired to Poitou, where he died in 1623, at the age of seventy-four, sincerely regretted by the Protestants, whose champion he had been, and esteemed by the Catholics on account of his talents and integrity, and for the private virtues which adorned his character. Morev. Mornay.
MOR

MORNAY, in Geography, a town of France, in the department of the Ain, and chief place of a canton, in the district of Nantua. The place contains 425, and the canton 6,503 inhabitants, on a territory of 147½ kilomètres, in 15 communes.

MORNE AU DIABLE, a cape on the W. coast of Hifpaniola. N. lat. 19° 12'. W. long. 72° 47'.

MORNE de Gros, a town on the island of Hispauola, on the N. coast; 25 miles S.E. of Porte Pairs.

MORNE Rouge, a town on the N. coast of Hifpaniola; 7 miles S.S.W. of Cape François.

MORNING, the beginning of the day; or the time of the Sun-rising.

The astronomers reckon morning, manfc, from the time of midnight, to that of mid-day. Thus an eclipse is said to begin at eleven o'clock in the morning, &c.

Mornings-hine, in Geography, a town of Bavaria, in the principality of Aichhätt; 6 miles W. of Aichhätt.

MORO, a river of Hindostan, which runs into the Chamb, about ten miles N.E. of Suijpour, in the cazar of Rantapour—Affo, a mountain of Piedmont; 14 miles W. of Domo d'Ocella.

Morb Gaffe, a fortresses on the Headland, on the E. side of the channel of the Hannah, in the N.W. part of the island of Cuba; it is the first of two strong calles for the defence of the channel. This fort is a kind of triangle, fortified with baftions, on which are mounted about 60 pieces of cannon, of 24-pounds. From the caile runs a wall or line mounted with 12 long brass cannon, of 36-pounds, called, by way of eminence, "the Twelve Apollûres:" and at the point between the caile and the sea is a tower, where a person is stationed for giving signals of approaching vessels. See HAVANA.

MOROCARPUS, in Botany, so called by Ruppius, from the resemblance of its fruit to a mulberry. See BILUM.

MOROCCO, or MAROCCO, Empire of, comprehends the two kingdoms of Morocco and Fez, which were formerly part of the ancient Mauritania, (which fea,) and are situated on the south western borders of Barbary, hence sometimes called Weil Barbary; it is bounded on the N. by the tribes of the Almoravids in the Mediterranean; on the E. by the kingdom of Tlemcen or Tremscen, and the defart of Angad, from which it is separated by the river Mullavia and its southern branches, and also Vedi d'Elgerid, Bled-derred, or Bledulgerid; on the S. by the Defart, or Sahara, and on the W. by the Atlantic ocean. It extends from the 28th to the 36th degree of N. lat. and from about 2o to 11° 30' of W. long.; its greatest length from the N.E. to the S.W. being about 500 miles, and its greatest breadth about 260, and about half as much where it is narrowest. The territories of Morocco are formed by the union of several small kingdoms, anciently limited to a single province, and perpetually at variance among themselves, till at length they were subdued and united under one sovereign by the sharifs. The southern part of the empire contains the kingdoms of Sus or Sus, Tarudant, Morocco, Tafilt, and Sughmkea; and the northern, thoute of Fez, Miquinez, and Tremeen; the latter, which was formerly subject to Morocco, having been conquered by the Turks of Algiers, is now a part of the territories of that regency. See each respectively.

The kingdom of Morocco comprehends at present the provinces of Morocco, Efcura, Rannau, Denguella, Abda, Sherma, Hea, Sus, Dra, and Gefula; that of Fez contains those of Tememina, Shavoya, Tedla, Beni-Haffen, Fez, Rif, Garret, Shaus, and Algemb or El-Garb. These provinces have been called by other names, so that the geography of the country has been confused; and besides, the limits of these provinces have frequently varied, according to the different tribes that have occupied them, and this variation of extent has occasioned a variation of name. Besides the provinces which compose the empire of Morocco, the sharifs claim sovereignty of the Vled de Nun and the defart or Sahara, but their authority over these is very precarious, being dependent on the will of their subjects and temporary circumstances. The people who inhabit these deserts, far removed from the centre of despotic authority, live in tribes or small republics, and choose their own chiefs. They nevertheless retain for the emperor of Morocco that respect and veneration which his power, and the idea they have of his supremacy, as head of the church, inspire; but they pay or refuse tribute according to their own pleasure. This part of the coast has been called Vled de Nun, from Cape Nun discovered by the Portuguese in the beginning of the 15th century, and to which they gave this name, because those who first doubled it never returned.

The whole empire of Morocco is surrounded to the E., N., and W., by a chain of valleys and mountains, which are distinguished according to the number and names of the tribes by which they are inhabited. From Laracha to near Saffi, the western part of it forms a fort of plain, which, in many places, is fifteen or twenty leagues in breadth, from east to west. The maritime provinces of this empire are Garret, Rif, Garret, Beni-Haffen, Tememina, Denguella, Abda, a part of the former, Hea, Sherma, and Sus. The northern provinces, E. of that of Sus and N. of Vled de Nun, are those of Dra and Gefula, near mount Atlas, the province of Morocco, of considerable extent, bounded to the N. by the province of Efcura or Aflora, and by mount Atlas to the E., Efcura and Rannau, Tedla, along the eastern side of mount Atlas, and having to the W. the province of Shavoya, and the province of Fez, with its numerous dependencies. (See each of these respectively.) The eastern boundary of all the western provinces of Morocco is mount Atlas. To the east of this mountain is the kingdom of Tafilt, which fea.

The cities and towns in the empire are neither large, numerous, nor populous. The desarts, jealous of their authority, and fearful of being deprived of the power they abuse, confine cities and strong places as more favourable to rebellions and the liberty of the subject, than camps; and therefore their towns are weakly fortified, and in a small degree capable of defence on the land side. The empire of Morocco is separated on the N. from the kingdom of Algiers, (which see,) by the river Mullavia, which falls into the Mediterranean. The emperor professes no place on this northern coast known by the name of Rif; thence he once had having been taken by the Spaniards, who still possess them, four are Alubenna, Mellila, and Velles de Pegnon or Gomera. Other cities and towns are Temoz, Cemal,
The chief rivers in the empire of Morocco are the Mulla-
via, Molucha or Mullooyah, the Taga, Talmuda or Ta-
muda, which, as well as the former, springs from mount
Atlas, and discharges itself into the Mediterranean, the El
Kofe, or Lucuus, deriving its name from its arched windings,
El Kofe signifying, in Arabic, an arch, the Bait, rising
in the Atlas, and partly losing itself in the swamps and lakes
of the province of El Garb, and partly falling into the
river Sebou, Seboo or Cebo, Ba-Regreg, rising in the
Atlas, and after traversing the plains of Beni-Hallen,
discharging itself into the ocean between the towns of Sallec
and Rabat, the Morbeya, Ommirabib or Ammirabes, which
rises in the Atlas, and after separating the province of Fez
from that of Tedia, and dividing the part of the empire W.
of Atlas into two parts, enters the ocean at the port of
Azamor, the Tenifit, a deep large river, which rises in the
Atlas and discharges itself into the ocean about 16 miles
S. of Safi, Tadif, which runs into the ocean a few miles S.
of Tegrewelt, or Cape Olfem, the majestic river Sus or Sufa,
which runs into the ocean, Draha, rising in the Atlas and
disappearing in the absorbing sands of Sahara, the Meffia,
called Wed-Meffa, which flows from the Atlas, drained off
by the farmers during its passage for irrigating their land,
&c., at low water separated from the ocean by a bar of
sand, and finally the Akaifa, navigable to Nun or Noon,
called Wed-Noon, or Wed-Akaita. Many other streams
fall into these principal rivers. The mountains of Morocco
are thoese of the greater Atlas, surrounding the empire on
the S. in form of a crescent, and separating Barbary from Bled-
dalgerid. This then passes about 30 miles E. of the city of
Morocco, is immensely high, the most elevated part being
estimated at 11,980 English feet, and through this mountain
covered with snow. It is visible at sea several leagues off
the coast. The mountains that form these chains are in many
places very fertile, and produce excellent fruits. In the
branches E. of Morocco are mines of copper, and those
which pass through the province of Sus yield besides
copper, iron, lead, silver, sulphur, and saltpetre: here are
also mines of gold mixed with antimony and lead-ore.

Some of these mountains consist of lime-flour, or clay, or
of a mixture of both: the granite on which these masses
rest must be at a considerabe depth, since no vestiges of it
are anywhere visible, not even among the fragments and
loose stones with which the fields abound. The calcareous
mountains are generally covered with fields of various kinds,
and other marine productions, so that no doubt can be
entertained with regard to their origin. The argilaceous
mountains exhibit either horizontal or vertical strata, and
are not seldom dissected by veins of foliated calcareous spar.
The considerable thickness of the stratum of mould by which
all these mountains are covered, is a sufficient proof of the
very remote antiquity of the vegetations they exhibit. The
soil consists either of pure sand, often passing into
quick-sand, or of pure clay, sometimes so abundantly mixed
with iron ochre, that the productions of the earth are con-
ciderably influenced by it. A great part of the province
Abda, near Safi, is on this account called bed hamar
(the red land): all its natural productions, such as wax,
rum, wool, &c. being distinguished by a reddish tint pe-
clusar to them. The wool is so much affected by it, that
neither washing nor bleaching can produce a change; whilst
the natives of the province of Abda are known from other
Moors by their hawks, which are constantly of a reddish
colour.

The inhabitants of the upper region of Atlas live four
months in the year in excavations of the mountains, viz.
from November to February inclusive. The little Atlas
extends along the Barbary coast from the frufts of Gibraltar
to the district of Bona in the kingdom of Algiers. See ATL.

The climate of Morocco is temperate and fustidious, and
not so hot as its situation would lead u to suppose. It is
defended by the Atlas from the east winds, that would scor-
ch the earth; watered by the streams descending from this lofty
and extensive chain, which not only diffuse verdure over the
face of the country, but temper the summer heat; and re-
fracted from the west by the regular breezes that are wafted
from the sea. In this climate the rains are regular in winter,
though the atmosphere is not laden with clouds. In Ja-
uary the country is covered with verdure, and enamelled
with flowers. Barley is cut in March, and the wheat harvest
is in June. All fruits are early in this climate; the vintage
terminates in the beginning of September, and grapes are
occasionally ripe at the end of May. The winters are not
severe, so that ice is unknown, except on the summits of the
mountains, and snow and hoary frost are uncommon
phenomena, and fire is seldom necessary. The thermomet-
er seldom fums to more than 5° above the freezing point.
The soil is exceedingly fertile, and cultivation requires little
labour. Notwithstanding the fulness of the climate and the
productivefulness of the soil, the swarms of locusts that infest
this country commit the most dreadful ravages.

The wealth of Morocco very much consists in the fert-
ility of its soil; its corn, fruits, flocks, fiax, sail, gulls,
and wax, would not only supply the wants of the inhabi-
tants, but yield an immense surplus for trade and barter
with other nations, if its government were stable and secure,
and if subjects were allowed to enjoy the fruits of their
labour and their property in safety. The increase of corn in
Morocco is often as sixty to one, and the proportion of
thirty is held to be an indifferent harvest. The exportation
of corn, however, is forbidden by an intolerable religion
and restricting laws, which do not permit the super-abundance
to be sold to infidels. The property of land is also prec-
curious. Every thing in this despotic empire is subject to
the caprice of the sovereign, and the laws of the moment.

Hence it is that in this country the present system of
husbandry is exactly similar to what it was several hundred
years ago; the whole of its agriculture, in particular, being
confined to the cultivation of the most indifpenable granges,
such as wheat, barley, Turkey-millet, or aldora (Hel cus
ferghum), mays, and chick-peas (Cicer arietinum). Molt
of these are sown in the months of November and Decem-
ber, and reaped in May or June. Their implements of
agriculture are in exact correspondence with their ignorance
of every thing relative to the cultivation of the soil: all
that is done before sowing consists in harrowing up the
earth with a mort wretchedly constructed plough: but with
all this mismanagement the crop does not exceed twenty, may
even thirty times the quantity of seed committed to the
earth. In general they make use of no manure, except
which is left on the fields by their flocks and herds.

But those who inhabit places near forests and woods,
avail themselves of another method to render the soil pro-
ductive. A month or two before the rains commence, the
farmer sets fire to the underwood, and by this confagation
is char
clears as much land as he intends to cultivate. The soil immediately after this treatment, if carefully ploughed, acquires considerable fertility, but is liable soon to become barren, unless annually fertilized by proper manure. This system of burning down the woods for the sake of obtaining arable land, though not generally permitted in lands differently regulated from this, is allowable in a country, the population of which bears so small a proportion to the fertility of the soil, and in which the most beautiful fields are suffered to remain unproductive for want of hands to cultivate them. In this manner the nomadic Arab proceeds in his confinements till the whole neighbourhood around him is exhausted; he then packs up his tents and travels in search of another fertile place, where to fix his abode, till hunger again obliges him to continue his migration. Thus it is computed, that at one and the same time, no more than a third part of the whole country is in a state of cultivation.

Extensive forests are not to be met with in Morocco; the woods consist chiefly of middle-sized trees, such as oaks, and often merely of thorns, particularly of some species of rhamnus, rock roses (Cistus), phyllyrea, a few species of arbutus, broom (Spartium), furze (Genista), philiechis (Pilaaza), heaths (Erica), &c. The banks of the rivers are decorated with rockrose (Nerium oleander), the rough mullein (Smitha alpe), and the Rubus fruticosus. In the rocky parts of the old walls, are found among other plants, the prickly caper-bush (Capparis spinosa), and dwarf palm (Chamaerops humilis). The more considerable woods, or forests, in the northern parts of the country, consist of cork-trees (Quercus suber), evergreen oaks (Quercus ilex), and on the mountains of the interior a species of spruce fir is found, the wood of which has the pleasant scent of cedar, and is used for the purpose of building, &c. The woods of the southern parts are composed of the Argan oil-tree (Eleodendron argan), Egyptian mimosa (Mimosa milotica), a new species of arbor vitae (Thuia articulata, Vahl), purple juniper (Juniperus phoenicea). In the neighbourhood of Taghelt, Sus, and in the southernmost parts, the date trees (Phenicis dactyliferas), form continued forests, and produce plenty of fruit; but in the northern parts they are cultivated only as curiosities, and are almost cotemporary barren.

The inclosures of the gardens are quick hedges, made of Indian figs (Carbus opuntia), and the great aloe (Agave americana); which two vegetables are particularly well calculated for this purpose in the climate of the country, as they are not affected by the winter season, and where the faving of the soil is no object to the agriculturist. The produce of the gardens consists chiefly in grapes, oranges, lemons, figs, almonds, pomegranates, walnuts, chestnuts, peaches, apricots, mulberries, and the carob tree or St. John's bread (Ceratonia siliglua), being of rare occurrence. Of the smaller plants the most esteemed are water and other melons, calabashes, cucumbers, love apples (Solanum lycopersicum), beans, lentils, red and white leeks, radishes, arachokes, &c. Alhenna (Lawsonia inermis) is particularly cultivated in the southern provinces on account of its leaves being made use of for dyeing and for other purposes. Tobacco is cultivated chiefly at Mequinez and Fez, from whence the leaves are exported to other places of the kingdom, where they are manufactured as well into tobacco for smoking as into snuff. Hemp is cultivated in the gardens; the herb is dried, cut into small pieces, and used as tobacco, or externally as a powder, called Higulbs. Its operation on the body is that of opium, spirituous liquors, or other intoxicating substances; inured, it is made use of by the Moors as a substitute for wine, which their religion forbids them to drink. Apples, pears, and cherries are here and there met with, but they are mostly very indifferent, and therefore not held in esteem. The Moors, who are naturally indolent, neglect the culture of their fruits. The almost spontaneous fruits of the country are oranges, lemons, grapes, and figs. Water-melons are seen everywhere, and apricots, apples, and pears are occasionally found, as we have already mentioned. The olive is cultivated along the coast, particularly to the south. Gum, almonds, dates, cheftnuts, wax, and tallow, are the productions of various provinces in this empire.

As to the ancient commerce of this country, we can find no certain or satisfactory report. It is probable, however, that the Carthaginians, who were an enlightened and industrious people, and who governed parts of Africa and established settlements on its coast, must have contributed caravans to exchange their products for the gold and other productions of interior Africa. The progress which navigation made, in the fourteenth and fifteenth centuries, must have considerably affected the commerce of Africa, and have infensibly attracted it from the centre towards the sea-coast, on the west, which approaches the equator, and where the French, Portuguese, Dutch, and English, each emulative of the other, have successively formed establishments. The great rivers of Africa, which empty themselves in those seas, united its utmost boundaries, and the ports of Europe, the received gold-duff, ivory, ambergris, Guinea pepper, and other productions, of inland Africa; the exclusive enjoyment of which had till that time, been confined to the bordering nations, and even to them became objects of luxury. After the destruction of Carthage and Rome, the Moors, having had no intercourse of a commercial nature with Europe till towards the fourteenth century, must have confined their trade to the more central nations of Africa, with which they respectively interchanged their products. There they probably vended their merchandise of woollen-stuffs, sheep-skins, cloth, corn, salt, and dried fruits. In exchange for these they obtained gold-duff, ivory, Guinea pepper, and flaves. Such was, probably, the first source of the wealth of the empire of Morocco. The Moors on the confines of Africa might still possess nearly the same resources, if they had the same facility of communication. That of Morocco, whose situation is more central, has, perhaps, profited the least by them during the three last centuries, either on account of the frequent revolutions which their empire has undergone, or because their despotic government has to entirely shackled trade and industry. In the sequel of this article it will appear what is the present commercial intercourse between the empire of Morocco and the nations of Europe.

The inhabitants of the empire of Morocco, known by the name of Moors, are a mixture of Arabian and African nations, formed into tribes; with the origin of which our acquaintance is very imperfect. It seems probable that most of the "Cafts," which occupy the provinces of Morocco, have been repelled from the eastern to the western Africa during the different revolutions that have agitated this part of the world; that they have followed the standards of their chiefs whose names they have preferred; and that by these ways, as well as the countries which they inhabit, are distinguished. At present these tribes are called "Cables," or "Callies," from the Arabic word Eobell; and they are so numerous that it is impossible to have a knowledge of them all. The different tribes that people this empire may be distributed into two principal classes; viz., the Brebos and Brebberos, probably the aborigines, and the Moors, most of whom are the descendants of those who were driven out of Spain. (See Morocco.) Both these tribes adopted the Mahometan religion on the first
first invasion of the Arabs. For an account of the Brebes, see that article.

There is another class of persons, denominated Shellalis, who inhabit the Atlas mountains, and their various branches south of Morocco; they live generally in towns, and, like the Brebes, are mostly occupied in husbandry, though differing from them in their language, dress, and manners: they live almost entirely on (Aflona) barley-meal made into gruel, and barley washed or granulated, which they mix with cold water when travelling; this is called "Zimeta." Many of these people are reported to be descended from the Portuguese, who formerly pooffled all the ports on the coast, but who, after the discovery of America, gradually withdrew thither. East of Morocco, near Dimnet, on the Atlas mountains, there is still remaining a church, having inscriptions in Latin over the entrance, supposed to have been built by them, which, being superstitiously reported to be haunted, has escaped destruction. Their language is called Annalik.

As for the Moors, the greatest number of them are extended over the country, and the red inhabit the cities. The former live in tents, and every year form fresh encampments in order to give rein to the land, and to obtain fresh pasturage; but they are not allowed to remove without having first informed their governor. Like the ancient Arabs, they are wholly addicted to a rural life. Their encampments are called "Douhars," and composed of numerous tents, which form a crescent, and their flocks and herds returning from pasture occupy the centre. Each douhar has a chief, who is invested with authority for superintending and governing a number of these encampments; and many of the latter subdivisions are again re-united under the government of a "bashaw," some of whom have 10,000 douhars under their command. Their tents, of a conical form, and about 8 or 10 feet high in the centre, and from 20 to 25 in length, are made of twine, composed of goats' hair, camels' wool, and the leaves of the wild palm, so that they keep out water; but being black, their appearance at a distance is not agreeable. In camp the Moors live in the utmost simplicity, and present a faithful picture of the earth's inhabitants in the fifteenth ages. In the milk and wool of their flocks, they find every thing necessary for their food and clothing. It is their custom to have several wives, who are employed in all domestic affairs. Beneath their ill-fitted tents they milk their cows and make butter; they fort and sift their wheat and barley, gather vegetables, grind flour with a mill composed of two round stones, 18 inches in diameter; in the upper one of which is fixed a handle by which it is made to turn upon an axle. They daily make bread, which they bake between two earthen plates, and very often on the ground heated by fire. Their common food is "Coofeefood," which beer. When the officers of the camps receive strangers, they kill a sheep, which they immediately roast and serve up in a wooden platter. The women are also employed in preparing their wool, spinning, and weaving in booms hung lengthways in their tents. Thus they make their "hacks" or "haykes," which, without dreading, netting, or dyeing, are immediately applied to use. Thus the constant drees of the country Moors, without either shirts or drawers, linen being deemed a luxury fit only for the court and city. The fancy of which the country women are most drollish consists of large ear-rings, in the shape of a crescent, or silver rings, with bracelets and rings for the small of the leg. They also wear necklaces of small coloured glass-beads, or cow-grains strung on a filkien thread. They also paint the face, neck, bosom, and almost their whole body with the forms of flowers and ornaments; making impressions with models in which are the points of needles, that slightly raise the skin, under which a blue colour is infected, or gunpowder pulverized, which is never effaced. The women of some Moorish tribes hear on the forehead, or on the chin, a cro fus, denoting probably that they are the descendants of those who were formerly subjected to the Christians of Africa, and who, to avoid paying taxes like the Moors, thus impressed crofses upon their skins, that they might pass for Christians. The country Moors regard their wives more as slaves than as companions, and compel them to submit to every drudgery, except that of tilling the ground. The skin of the country women is tanned, as they walk unveiled; and in some places they paint their cheeks, and everywhere trim their hair, their feet, and their finger ends, with an herb called "Henna," (see Alcann) which produces a deep saffron colour. In their douhars, which are scattered through the country, and commonly fixed near some rivulet or well, there is a tent for the reception of travellers, where they find poultry, milk, and eggs, and furage for their horses. Over the tents of travellers there is a guard, left only of the Moors, who are naturally thievish, should attempt to commit a robbery. The douhar is responsible for all thefts committed in its vicinity, during the day, or in sight of its encampment. To facilitate barter there is a public market held every day, except Friday, in various quarters of each province. Here the neighbouring Moors assemble to buy or sell cattle, corn, vegetables, dried fruits, carpets, hatchets, and all the productions of their country. On the outside of the market they have usually shows, buffoons, fingers, dancers, and merry-angels. On one side is the place of the barbers or surgeons, to whom they bring their sick to be cured of strains, dislocations, or other accidents. The Moors of the countries differ but little from those who live under tents; but they affect a superiority, of which they are vain. They are of the same general origin; unless we suppose, that the former are intermixed with the descendants of those Moors of Spain, who, after their expulsion, preferred a city to a rural life. Their houses have in general few conveniences: they have no windows, and they are seldom more than 16 feet high. They have all terraces on the roof, which are formed of earth and mortar; their furniture chiefly consists of mats, carpets, some chairs, a chaff, a table, and a bed, which is concealed by curtains. The inhabitants of cities have only one wife; but they have female negroes, whom they may take as concubines. In their drees they are distinguished from the country Moos by wearing a shirt and linen drawers, and an upper garment of cotton in summer, and of cloth in winter, which they call a "Cafian." Obliged as they are to conceal their riches, the Moors wear no jewels; very few of them have so much as a ring, a watch, or a silver snuff-box. The Moorish women of the cities seldom leave the house, and they are always veiled. They are not, however, in general very reserved: those of the south are the handsomest, and they are so reserved, or so guarded, that their relations do not enter their houses, nor their tents. Nevertheless there are tribes, who are not inferior, but are an object of curiosity to a traveller. The females of the cities are more addicted to finery than those of the country. The Moors present their wives with jewels of gold, silver or pearl, but very few wear precious stones. They have rings both of silver and gold, also ear-rings, in form of crescents, bracelets of silver and gold, and silver rings at the lower parts of their legs. Although the use of white paint is unknown among the Moorish women, and that of red feldem recurred to, it is not uncommon for them...
them to dye their eyebrows and eyelashes, and to trace on
their feet, the palms of their hands, and the tips of their
fingers, regular figures with henna.

Among the Moors and Jews, who people the empire of
Morocco, there is an intermediate class of perfons, called
renegades, who have renounced Christianity to embrace
Mahometism. Many of these were originally Jews: the
Moors do not hold them in the least respect, and the Jews are
still less honoured. These apostates only intermarry among
each other. The Jews are very populous in the empire of
Morocco. Profligates in Spain and Portugal, they have
found an asylum in this empire. They poiffe neither lands nor
gardens, nor can they enjoy their fruits in tranquillity.
They must wear only black, and are obliged, when they pass
near mosques, or through streets in which there are sanctuaries,
to walk barefoot. Notwithstanding their oppression, and the contempt with which they are
 treated, they have many advantages over the Moors: better
understanding the nature of trade, they act as agents and
brokers, and profit by their own skill and cunning, and the
ignorance of the Moors. Some are mechanics, such as
goldsmiths, tailors, gunsmiths, millers, and masons; they
are also employed by the emperor in receiving the customs,
coming the money, and in intercourse with European mer-
chants, and in all negotiations with the various European
governments. The wives of the Jews in Morocco are in
general well-formed, handsome, with good Complexions, and
very fine eyes, addicted to drees, and somewhat inclined to
gallantry. As the Jews throughout the empire live separa-
rate from the Moors, they enjoy their religious rites with
considerable liberty. See Algiers and Barbary.

The Moors, as we have already said, are pastoral people,
and their wealth consists in their flocks and herds. The
wool of their sheep is partly employed in their own clothing
and carpets, and partly sold to foreign nations. The
wool is of various sorts; some kinds being very coarse
and others very fine, and particularly that of Teda. In
the empire of Morocco there are few black sheep. Oxeas
of a small breed are plentiful; for home consumption the
Moors fatten their beef and preserve it from year to year;
their raw hides are sent in prodigious quantities to Mar-
elles. The camel is an animal of great value and ufe to the
Moors; as it is used for the purposes of agriculture, as
well as for travelling; and its fleh also serves for food. The
horses of Morocco are in general good, and they are taught
to endure fatigue, heat, cold, hunger, and thirst. They
are formed for fleetness and activity, but the breed is
decreased, except in Abdas, and about Morocco. Mules are
much used, and the breed is encouraged. Poultry is abun-
dant in Morocco; pigeons are excellent; partridges are
plentiful; woodcocks are scarce; but snipes are numerous
in the seafon; the strich is hunted both for sport and for
profit, as its feathers are a confiderable article of trafic
harmful good; but rabbits are confined to the northern
part of the empire from Laracha to Tetuan. Fallow deers,
roe-deers, the antelope, foxes, and other animals of Europe,
are not very abundant in Morocco; lions and tigers are not
uncommon in some parts of the empire: of all the species
of ferocious animals found in this empire, the wild boar is
the most common: the fow has several fitters in the
year, and her young, which are numerous, serve as food for
the lion. The tame varieties of fowl, that are found in the
Mediterranean, are taken on the shore of West Barbary.

The religion of the Moors is Mahometism, which
they very rigidly observe. They follow the fect of Abdallah
Melek, or Meir, who was one of the four commentators
on the Koran. Saints and their sanctuaries are very nume-
rous among the Moors; and they are devoutly invoked by
the men for the cure of their diseases, for the fertility of
their lands, and for success in their undertakings; and by
the women for the blessing of children. Some of them pre-
tend to have charms against wizards, forcers, the poison
of serpents, and other venomous insects. They even eat
scorpions. The number of saints contributes very much
to the increase of superstition among the Moors, of which
their despotic governors are not at a loss to avail themselves.
The Moors of the country never fall, after harveil, to per-
form a visit of pilgrimage to the faint, whom they highly
venerate, carrying their fift fruits as an expression of ho-
mage and gratitude. Their priets, their judges, all the
learned in the law, every well informed perfon, together
with their sharifs or nobles, are held by the Moors to be
holy; and they extend their veneration even to Christian
priests. Madmen, idiots, and dotards are supposed by
the people to be pollefled by a divine spirit. The sanctu-
aries of the saints are very numerous, and there are four
which large poffessions are annexed. The propenlity of the
Moors to superstition, enthusiasm, and fanaticism
spires them with a veneration for each of their number as
have made the pilgrimage to Mecca. Even a camel, that
has been at Mecca, is well fed, maintained without work,
and allowed to graze freely wherever he shall stray.

The two Mahometan festivals, called Bairam and Corban,
are each of them kept by the Moors for eight days; and
they also obferve the anniversary of Mahomet in the fame
manner; and they celebrate the festival of the new year
for ten days after its commencement.

No government can be imagined more absolute than that
of Morocco. The subject throughout the empire has no-
thing which he can call his own, not even his opinions or
his exiflence; his maller deprives him of his property or
of his life whenever he pleafes. The services that are per-
formed to the sovereign are gratuitous, and merely honor-
ary; and the favours, which he may think proper to bellow
at his own plenure, are the only revenue of thofe who per-
form them. Wherever the monarch happens to be, he grants public
audiences four times a week for the distribution of justice;
and this the Moors call holding the "Melhooar." While
he performs these functions, he fits on horseback, with an
umbrella held over his head by one of his grooms; and
this, in Morocco, is the fole diftinctive mark of royalty.
Although all may have access to thofe public audiences, no
one is admitted without a prefent proportioned to his wealth
or ftation, or the importance of the matters depending,
and the circumstances under which he is obliged to treat.
The governors of provinces give money, flates, foraffes, and
camels; private perfons pretent haicks, carpets, cloths, or
other effects; a poor man will offer an old camel, two
sheep, a goat, nay even three hens, or a dozen of eggs.
The governors or bailiffs exclusively regulate the police
of their districts; and they take care to increase the revenue
by their authority, or by availing themselves of the alter-
cations which the spirit of iniquitude raises among the
Moors. When the bailiffs have acquired wealth, the em-
peror ftrips them of it, and this kind of retributive justice
coduces to the benefit of his treafury. Money, in this
government, confitutes the crime, or obtains the pardon of
the accused.

In the empire of Morocco there is no code of laws; but
the practice of juftrprudence is reduced to the application
of certain principles deduced from the Koran, and its
com-
pleadings, he, afflicted by some other men of the law, gives sentence according to the majority of opinions. If the parties are dissatisfied, they may appeal to the emperor; but this is a case which seldom happens. The Moors, when they quarrel, insult and abuse each other, but seldom strike.

As to the state of knowledge among the Moors, much cannot be said in commendation of it. Deriving their language and religion from the Arabs, they seem not in any degree to have participated of their knowledge. The Moors of this empire, though the Moors of Spain blended with those of Morocco may be found among their progenitors, have preferred no traces of the genius of their ancestors. The Moors have no conception of the speculative sciences; those among them who can read, and their number is very small, seldom read anything but their books of religion. Education consists merely in learning to read and write; and as the revenues of the learned are derived from those talents, the priests and talibas among them are the sole depositaries of this scanty knowledge. The Moors, like the Arabs, adopt the practice of rhyming and singing the history of any extraordinary event. The Moors of Spain paid particular attention to the study of physic and astronomy, and they have left valuable monuments of their skill and attainments, but the modern Moors are much degenerated: they have no inclination to the study of science, and they are shamefully ignorant both of diseases and their remedies. Their most common physicians are their talibas, their fakirs, and their fants, in whom they repose a superstitious confidence. Astronomy is almost unknown to the Moors; although they lead a kind of wandering life, under the canopy of the heavens, always open to their view, they have little acquaintance with celestial bodies; and they are totally unable to calculate eclipses, which they always interpret to portend evil. However, magic, the companion of astrology, has here its followers, and it is particularly studied by the talibas in the southern parts, who successfully use it in imposing upon Moorish credulity with strange dreams, and ambiguous forebodings and predictions. The language of the empire of Morocco is Arabic; but it exists among them in a very corrupted state.

In the character and manners of the Moors we discern the deleterious effects of despotism on the one hand, and slavery on the other. Despotism so debases the soul, that it is insupportable neither of fortune nor of elevation: the slaves only learn the will of their masters, and have not even an idea of liberty. With less sensibility than other men, they are faithful neither to their relations, nor friends, nor country; their vices are the opposite of all good faith; they love not one another, and foreigners they love still less. Easily supplied, and inhabiting a naturally fertile country, the Moors are little addicted to labour; and hence it is that they have little vigour, and little of that characteristic energy which gives birth to noble ideas, and to great crimes or great virtues. This flourish of the faculties keeps them in eternal fluidity, and is the very prop of despotism; for it seems to be a well-founded remark, that governments are more or less arbitrary, in proportion as the people are more or less informed. The Moors are cast in body as well as in mind; though they are tolerably well-formed, have regular features, good teeth, and fine eyes, yet their countenances are deficient of expression or mind. Their whole aspect bears the stamp of slavery and oppression. Avaricious by nature, these people are addicted to accumulate and to conceal wealth. This propensity of the Moors renders them plant, cunning, and disagreeable; and generally inclined, especially among the lower orders, to theft and rapine.

Although truth and candour would not warrant our saying that there are no individuals, whose actions are just or generous; yet it behaves those who deal with them to be wary, for they will never discover something of the Moor. Let any one read the account of Mungo Park's travels, and their indignation will be excited by the treatment which he experienced from the Moors.

The Moors, like other Mahometans, live, in the computation of their time, the lunar months and year; but in some of their astronomical calculations, and for the purpose of regulating the hour of prayer according to the feasons, they have recourse to the solar year, adhering to the old file. They count the days of the week by hrih, second, third, &c. from Sunday to Saturday, which mode of reckoning they esteem to have received from the Hebrews.

The Moors marry young, the age of puberty of the females being 15. They are permitted to have four wives, and as many concubines as they can maintain. In some parts the husband receives no portion with his wife, but pays for her; but it is most common for the parents to give a portion with the bride. If the be repudiated, the husband restores it two-fold: if the husband die, the wife recovers her portion, and the eighth part of his eftates. The children of the wives have all equal claim to the effects of the parents; those of the cunctines can only claim half as much. As women are not admitted into the society of men, young périons do not marry here from love, but for convenience; and the relations form the contract, and settle the terms of it. The purity of the bride at the time of marriage is much regarded, and proofs of it are required and publicly exhibited. Among the Moors it is customary to marry their male and female negroes, and after a certain period to restore them to freedom; but after they recover their liberty, they live by labour.

At the close of harvest, it is the custom of the Moors to lay up their corn in matamores, that is, in pits where it is long preferred. (See Matamore.) They also deposit their riches, as well as their corn, in the ground. They have some other customs, which we shall summarily recite; such as their repugnance to the killing of flocks, which they deem sinful: they hold it contrary to the spirit of religion, and betraying irreverence, to bury the dead in mosques, thus profaning the temple of the Most High by the putrefaction of dead bodies. The deceased is not kept in the house, unless he expires after fun-fet, but his body is transported to the mosque. The Moors sing at their burial service, an ushage which they have probably adopted from the Christians of Spain, as the Mahometans do not sing. On Friday women repair to the felpulchres of the dead, to weep and pray at the resting-places of those whose memory they hold dear. The Moors have a custom of making bon-fires at the feast of St. John, but can give no reason for it; however, the origin of this custom is of very ancient date. The people of this country have a particular aversion to bells, originating probably from their aversion to Callillians.

The military establishment of the empire of Morocco is the result of a succession of accidental circumstances. Some few years ago 50,000 negroes were kept in pay by Morocco; but with views of economy, the emperor disarmed and disbanded them; and now the total amount does not exceed more than between 15 and 18,000 men, who are kept in constant pay; and even some of those are sent into distant provinces, to protect the tax-gatherers. Nevertheless, most of the Moors are soldiers: as each of them keeps a house, a fabric, and a musket, and they are ready to march at the first warrant of the monarch. Although the population of this empire bears but a small proportion to its extent, the emperor
emperor might with great ease raise from 2 to 330,000 men, if such a force were found to be necessary. The emperor has few infantry in his service, the chief force of his army consisting of cavalry. The Moors are good horsemen, and capable of being good soldiers, though not actually formed for this purpose. Armies among the Moors are usually drawn up in a crescent, the strength of which is in the centre, and here the artillery is placed; and their whole art of attack consists in acting with the detachments of the two extremities, so as to suround the enemy, put him between two fires, and at the same time expose him to be cannonaded by the artillery. The emperor has of late procured more than 60 mortars of various dimensions, and above 200 pieces of artillery; and he has exercised some percons in the art of gunnery. The musquets are forged in the empire of Morocco of iron procured from Bificay; they are about 6½ feet long, and are so much loaded with iron as to fatigue the soldier. Their fabres are also manufactured in Morocco of Bificay iron. Gunpowder is likewise made in this empire.

It is probable that, after the expulsion of the Moors from Spain (see MOROCCO), and those revolutions which internally disturbed the empire of Morocco, all naval exertions were long renounced. The coasts of Barbary, washed by the Mediterranean and the Western ocean, only gave harbors to some pirates; and the progress of their art was, it is prefixed, would not be very great, when the Portuguese had conquered Ceuta, Azilla, and Tangiers. Navigation began to be encouraged under the reign of Muley Ishmael. When these towns had been abandoned, and commerce became more generally promoted throughout Europe, Salle became a port of some consequence, and the Salle rovers were formidable to the merchants of Europe. When Sidi Mahomet, a late emperor, had made peace with the principal nations of Europe, he collected all his vessels into a squadron, that he might maintain his marine force, and add to its respectability. Although the naval strength of the emperor of Morocco is not very considerable, the situation of his flates will always afford him an advantage: he poaches Tangiers and Tetuan at the different mouths of the firth, through which vessels from all parts of the globe, failing for the Mediterranean, must pass; and his row-galleys, in so narrow a passage, are always capable of calculating their distance and ascertaining a safe retreat.

The revenues of the emperor of Morocco cannot be easily estimated, as they entirely depend on his will. In the present exhausted state of the empire, the various taxes united are scarcely sufficient for its own support: and the treasury of the emperor, which was formerly very considerable, was reduced in 1782 to about two millions of ducats, or about five hundred thousand pounds sterling. Such is the state of an empire which nature has enriched with its gifts, and which, after having been laid desolate by the conflicting factions of man, is at present scarcely sufficient to supply his wants.

Various and contradictory statements have been made by travellers of the population of this country. A late writer has collected from the best sources of information to which he could have access a variety of particulars, from which we deduce the following general results. The total population of the principal towns, which he enumerates, is stated at 895,603: that of the provinces and flates, also specified, is given at 10,341,000; and the total is as follows: the tribes of the Brebers of North Atlas altogether amount to 3,000,000; the district of Taflet contains 670,000; the provinces of the Morocco empire, west of Atlas, include 10,341,000; and the inland cities, towns, and ports contain 895,600; fo that the total population of the whole empire, including Tafilet, amounts to 14,886,000 persons.

If we except some trifling barter, the safety of the sea has been the principal cause why the nations of Europe have made treaties with the emperor of Morocco. England is the first power which concluded treaties of friendship and commerce with the emperors of this country. Poising Tangiers, ceded to her by Portugal in 1662, an interdict was fulfilled between England and Morocco; but it was often interrupted by the caprices of Muley Ishmael. At the commencement of the last century a treaty of peace was renewed under George I. After the death of Muley Ishmael this treaty was confirmed, and renewed in 1728 by Muley Achnet Daby, and a little time after by Muley Abdallah. The English have long maintained a trade on the coast of this empire, where they sell coarse cloths, serges, linens, peters, lead, mercer's commodities, and the iron which their ships bring from Bificay. In return they receive sometimes oils, gums, waxes, elephants' teeth, and have often sent, in French bottoms, to Marfilles oils, rawn hides, and wool. Before the American war, that separated America from England, they also exported a number of mules to North America; but the diminution of that part of their dominions has greatly diminished their trade with Morocco, which was not very considerable.

In 1752 an ambassador was sent by Muley Abdallah into Holland, and the republic then made its peace with that emperor; but subsequent revolutions gave little security to that treaty. Holland was the first power that renewed treaties of peace with Sidi Mahomet; but this emperor afterwards, viz. toward the end of 1774, declared war against the Dutch. However, Holland renewed the peace in 1778. Holland afterwards carried on some trade with the coast of Morocco, and conquest has almost rendered her imports necessary, for there are quantities of Silefan linens, called platillas, many of the coarse linens of the Baltic, and others, some few spices, drugs, tea, timber, iron of Bificay, and quantities of the cutlery and mercury wares of Germany. Holland has been used to receive from the coast of Morocco, in return, sometimes oils, wax, gums, and elephants' teeth; but as these returns, which suit the Dutch merchants, are insufficient to balance the quantity of merchandise they send thither, they have almost continually profited by the facility with which they can run for the French ports, to send oils to Marfilles, wools, and raw hides, which there find a more ready sale than in the north. The court of Denmark began to negotiate with Sidi Mahomet in 1755. But interruptions occurred, and the Danes could obtain the continuation of peace merely by paying annually the sum of 25,000 piastres. Denmark has not itself any trade with that coast. The Swedes concluded peace with the emperor of Morocco in 1763, on condition of paying a certain tribute; but in 1771 Guilliaume III. objected to this tribute; and it was at length agreed, that the king of Sweden should send an ambassadour and a present once in two years to the emperor of Morocco. The Swedes have no commercial intercourse with this empire. The republic of Venice made peace with the emperor of Morocco in 1765, on condition of paying an annual tribute of upwards of four hundred thousand pounds, but after some temporary discord, peace was established in 1781. That republic has no commercial intercourse with Morocco, and therefore, like the courts of Denmark and Sweden, pays this tribute solely for the safety of navigation. The court of Spain, as well as that of France, made peace with the emperor of Morocco in 1767, but a rupture occurred between Spain and the emperor, and the court of Madrid, deeming to con-
treaty, was ratified with remaining in a kind of
truce. Sidi Mahomet renewed peace with Spain in 1785.
Between Portugal and Morocco there is no continued trade;
and the intercourse of the two courts is simply confined to
testimonies of friendship: the republic of Genoa only enjoys
a kind of truce with the empire of Morocco, wholly un-
supported by any treaty. In 1777 the emperor of Morocco,
being at peace with the principal commercial nations, granted,
by public letters, entire liberty to all ships to trade with;
and enter, his ports, professing himself desirous of maintaining
peace with the whole world. But this declaration produced
little effect, and was soon counteracted by his conduct.
The United States of North America, after securing their
independence, wishing to profit, during the year 1786, by the
pacific dispositions which the emperor of Morocco announced
to all commercial nations, concluded a treaty of peace with
this monarch. The French have been accustomed to vend,
on the coast of Morocco, much of the linen of Britain,
and of other places, some raw silks from the farthingales of
Fez, unspun cotton, Baggard common papers, mercery
goods, fine silks, cloths, fugar, and coffee, and as much fulpher as the emperor requires: and they have re-
ceived, in exchange, wool, oils, raw hides, gums, and ele-
phants' teeth.

The duties, coins, weights, and measures in Morocco are
almost as variable as the opinion of the emperor. The duties
both of exportation and importation have been very various,
and are entirely arbitrary. The coins, which are current
over the coast of Morocco, are those of the emperor, and
those of Spain. The coins of the emperor are those of
silver, filver, and copper, which have no fixed value. The
gold ducat, which is very scarce, and which has little circula-
tion, is worth 15 ounces, corresponding to eight and four-
ence English. The silver money is the current ducat, the
ounce, and the blanquil. The current ducat is worth 10
ounces, the ounce four blanquils, and the blanquil 24 livs.
The livs is the only current copper coin. The value of the
blanquil is nearly seven farthings English; so that the ounce
is worth five shillings and fourpence. The Spanish pianfle is current in trade, but though in general its
value is fixed, it may vary according to the convenience
of the emperor, and his interest in rendering pianfles scarce
or common. The weights by which they buy and sell in Mor-
occo are equivalent to the weights of Paris, or to the poids
de mare or pound of 16 ounces; the subdivisions of which
are in both places the same. Merchandize is generally sold
by the quintal of 100 pounds; but some commodities are
sold by the great quintal, or 150 pounds. Corn is measured
along the coast of Morocco in different ways. In the
southern provinces, known by the name of the kingdom
of Morocco, wheat is sold by the garara and the mood.
The garara contains 40 mood, and the mood weighs from 18
to 20 pounds; so that the garara must be nearly 800 weight.
In the kingdom of Fez, from Salé to the north, corn is sold
by the fatha, the fahah, and the mood. Four mood make
one fatha, and 60 mood one fatha; and hence the weight of
the fatha must be 12 quintals. The corn measures, however,
are liable to variance, according to the will of the emperor.
The measures by which cloth is sold, and woollen are sold
is called equivale, which is the rub of the ancients. The
equivale contains 19 inches four lines; and as the French ell is 44
inches, 25 equivales are nearly equal to an ell.

Morocco. History of. This country, having continued
about four centuries under the Roman yoke, from the
invasion of Julius Cæsar to the declension of the empire, fell
immediately under the Goths, who crost over from Spain,
and made an easy conquest of its provinces. This new
government lasted till about the year 600, when the Saracens,
a nation no lefs furious than the Vandals, tyrannized over
them in their turn; till they were driven out by the Arabsians,
who, besides their natural ferocity, were actuated by a fiery
zeal to propagate Mahometism, every where by force of
arms, and overrun this whole country, obllging the inhab-
Itants to submit to their religion as well as government.
For some time the administration of the country was ex-
ercised by the lieutenants of the caliphs; but their seat of
government being dilant, having been successively removed
from Medina to Damascus, from Damascus to Cufa, and
from Cufa to Bagdad, infenilbly enfeebled their authority.
The Arab generals in Africa, availing themselves of these
circumstances, in favour of their ambitious projects, excited
commotions towards the end of the eighth century, and
aspired themselves to sovereignty. The descendants of Ma-
omet, called to the throne by the veneration in which they
were held by the wiligar, railed new factions; and the first
among the Edilites, who took their name from
Edris, son of Abdallah, descendant of Ab, husband to the
daughter of Mahomet. From Herbelot we learn, that their
dynasty was exterminated by the Fatimites, who pretended
that they were the descendants of Abi and Fatima, the
daughter of Mahomet: this latter dynasty, the founder of
which took the name of Mohadi, director of the faithful,
had some successe in Egypt; but its duration in Maurita-
iunia, which was exposed to numerous revolutions, was only
momentary. This part of Africa was afterwards governed
by four principal dynasties, the Morabethoon, the Moahedins,
the Benimeren, and the Sharifs of two different branches.

Edris, having escaped the massacre of all the kinfmen of
Ali at Medina, fled in 768 into Mauritania, in order to
avoid the perfecuting fword. Here he conducted himself
with fo much prudence, that he gained the affection of the
people, so that they were deffrous of living under his
government and embracing his religion. His exemplary
conduct and diligent instruction scattered the seeds of Mohammed-
ism in this country, where the greatest part of this religion
was established from the first monarchy established in Africa after Mahomet. This Edris much interceded himself in favour of the Arab Moors in
Spain. From Marron we learn, that the house of Edris,
and the house of Mequinne, reigned in Mauritania in 914,
and that reinforcements were sent over from this country
into Spain in 920 and 925. During the progresses of the
1oth century, disturbances occurred; and El-Mohadi, said
to be a descendent of Ali and Fatima, dehaued against
the house of Edris on the ground of heresy; and having made
himself master of several cities, deposed the sons of Edris
from their governments, before the succours which they had
petitioned from the king of Cordova arrived. El-Mohadi
declared himself caliph, and took the title of Hafs, or Atlas
to extend his dominion. In process of time this usurper was
affiliated, and with him terminated the dynasty of the
Fatimites. This was succeeded by that of Morabethoon,
so surnamed from the strict observance of religion by the
tribe of which he was chief. The armies of this chief were
constantly victorious, and after various battles, he remained
sovereign of Mauritania. In 1086 he was succeeded by his
son Joseph, whose subjects proclaimed him king. He is
said to have finished the city of Marakefch, or Morocco,
which
which had been begun by his father, and there established his seat of empire. This prince vanquished the king of Fez, and seized on his kingdom, which was thus, for the first time, united to that of Morocco. The reputation acquired by Joseph Ben-Tefflin was so great, that in 1097 the Mahometan kings of Spain fought his alliance, and proclaimed the supreme sovereignty, thus hoping to establish and extend their empire. Accordingly he passed over into Andalusia, and joining his forces to those of the Mahometans in Spain, conquered the city of Seville and its environs. Upon his return to Africa, he proclaimed the "Gazia," or war of religion. Attended by a large force, he again passed over into Spain, and in 1102 he was master of all Andalusia, Granada, and Murcia. Joseph died at Morocco in 1110, and was succeeded by his son Ali, who built the grand mosque at Morocco, continued to succour the Mahometans of Spain, commanded respect by his military exploits between the years 1112 and 1115, and had for his successor his son Brah, with whom terminated the dynesty of the Morabites or of Morabothoon. The first king of the race of the Moahditis, called by the Spaniards Almoahdites, was Abdulmomen, or, as Herbelot calls him, Mahomet Abdulmomen Ben-Tommet, who was chosen king of Morocco in 1148. This king slanged the son of Brah, who had been acknowledged king, and who was the last of the house of Tefflin, the founders of the city, as well as the empire of Morocco. Although Abdulmomen destroyed Morocco on his accession to the throne, he afterwards rebuilt it; but at the same time ensued a savage order, that all the Morabothoon, who were found throughout his empire, should be put to death. The eastern provinces of Africa, however, shook off the yoke of the kings of Morocco, and elected for themselves independent chiefs; but Abdulmomen remained master of all Mauritania, and preferred the two kingdoms of Fez and Morocco, which had been united under Joseph Tefflin. He was also able in 1149, and again in 1151, to succour the Mahometans of Spain. This prince died in 1155, and was succeeded by his son Joseph, who persecuted the measures in Spain, which his father had projected. In 1154, he was killed in Spain by a fall from his horse, and after several divisions among the Moors, his son Abu-Jacub, who, named Almanfor, the invincible, was proclaimed emperor. The conduct, courage, and activity of Jacob soon established his supremacy over the African coasts as far as Tunisia, and also preferred that which had been acquired over the Arab Moors of Spain. Almanfor, having reduced his sujets to subordination, published the "Gazia," or war against infidels, similar to the crusades of the Christsians, and marched into Spain with a large army. After a series of successful exploits till the year 1197, he returned into Africa to quell some commotions that had occurred during his absence. Almanfor, having violated his promise, by putting to death a Marabaut, whom he had promised to pardon, on account of services rendered to him during his siege and capture of Morocco, is said to have disappeared and wandered through the world, or most probably performed the pilgrimage to Mecca, as a private person, in expiation of his crime. During his absence, his son, Mahomet Ben-Naffer, called also Nafer-Al-Melck Ben-Manfoor, was proclaimed king, and took possession of his father's throne in 1210. This prince went over to Spain, in order to extend his conquests, but in July 1212, the Moors, in an engagement with Alphonso, suffered a total rout; so that Mahomet Ben-Naffer returned to Africa in disgrace, and soon after died, leaving his empire to Said Barrax, one of his grandsons. After the death of Said, who was assassinated by a traitor, the principal perfons of the Moahditis elected his uncle, Abdul Cader, in his room; but this prince, not able to secure the confidence of the people, was obliged to surrender his power to Abdallah, one of the race of the Benenrins, who was the first of that dynasty, that possessed himself of the foreign authority. Abdallah was succeeded by his son, whose death made way for the accession of his uncle Ben-Joseph; who wholly deprived the Moahditis of their power. The kingdom of Morocco, by this change of its monarchs, lost the sovereignty of Spain, but Ben-Joseph, occupied with foreign conquests or government, established more firmly his authority in Mauritania. In 1275, however, he passed over into Spain, and having committed various ravages in the kingdom of Andalusia, returned into Africa. After the death of Ben-Joseph, he was succeeded by his son Abu-Said, who, like his father, made several expeditions into Spain, all of which were unsuccessful. His reign was tranquil until the year 1303, when his son occupied the throne, which was vacated by his death; and he was succeeded in 1318 by Joseph-Beac-Jacob. After the death of this monarch, Abu-Hassen, his son, took possession of the throne, and by various military operations in Spain, involved himself in expenses, which, joined to his fueed, produced murmurs among his subjets, of which one of his sons, named Abdulmomen, avenged himself, drew upon several tribes to his support. Abu-Hassen, another of his sons, instigated a rebellion against him, and ultimately succeeding, took possession of the kingdom in 1354; and remained in quiet possession of it till his death in 1409, when he was succeeded by his son, Abu-Said, a prince addicted to pleasure and debauchery; and in consequence of which, several internal commotions made way for the succession of his son Abdallah, in the year 1423. Abdallah reigned with justice for several years, but at length he was slain by an inhabitant of Fez, who was a sharif, and who was proclaimed sovereign instead of Abdallah, with whom terminated the family of the Benenrins. This sharif was overpowered by Muley-Shaik, who was the first of the kings of the race called Merini, the descendants of a branch of the Benenrins. The family of the Merini were unable to maintain their authority, and the kingdoms of Fez and Morocco continued in a state of anarchy till the beginning of the 16th century. At this time, a Moor of the province of Dara, whose name was Mahomet-Ben-Eb-Abi, calling himself a sharif and descendant of the prophet, availed himself of the opportunity that presented itself for accomplishing his projects of ambition. With this view he feut his three sons, in 1508, in pilgrimage to Mecca, who, on their return, were highly honoured by the Moors. Having thus established their reputation, their father professed his scheme of ambition. At length Achmet, the eldest of his three sons, aided by the principal men of Morocco, was proclaimed king. In process of time, the power and the ambition of the sharifs advanced together; and two of the brothers divided their conquests; the eldest, Muley Achmet, retained Morocco; and Muley Mohamet took up his residence at Tarudant, by which they might mutually succour each other against the Portuguefe and their allies, who were masters of the greatest part of the western coast, from the cape of Aguer to the province of Deguela inclusive. After a variety of successfive contentions between these two brothers, Muley Mohamet, having feized on the kingdom of Fez, sent Muley Achmet into the desert, with a part of his family, that he might have nothing to fear from his ambition. The former, however, was assassinated in 1556, and the latter was murdered in prison: and thus both these sharifs, who had pernicioufly made religion and good faith a pretext to defpopt their masters and benefactors of fowereugty.
MOROCCO.

reignty, fell themselves, as did also most of their potteries, by the hands of murderers, and thus received the just remembrance of their crimes. Muley Abdullah, the son of Muley Mohamet, was, in 1577, joyfully received at Morocco, whether he repaired as soon as he heard of the death of his father; and having assembled the chiefs of the army and the principal men of the city, he was proclaimed king of Fez, Morocco, and other towns and provinces, under the dominion of the shariif. Upon the death of Abdullah in 1574, he was succeeded by his eldest son Muley Mohamet, for named the negre; and when he prematurely died, Muley Achmet, uncle of Muley Mohamet, was proclaimed king of Fez; and he obliged his brothers to swear fidelity to his son Muley Shek, and to infuse to him the succession. Muley Achmet was loved and respected by his subjects; he was the last descendant of the shariifs, and died in 1603, much regretted. After his death, Muley Sidan, the youngest of his sons, was proclaimed his successor; and notwithstanding the various complaints of his brothers, he remained sovereign of the empire. At length, in 1630, he died at Morocco, leaving princes, as his successors, who were little qualified to govern. Muley Abdelmelleck, eldest son of Muley Sidan, succeeded his father, and was the first king of Morocco, who, beholding several small kingdoms united under his government, assumed the title of emperor. His conduct excited public discontent, and in 1635 he was assassinated. Upon his death, his brother Muley El-Valid ascended the throne; and his reign was distinguished by condescension and affability, so that he gained the cordial esteem of his subjects. His death took place in 1647, and Muley Achmet Shek, the last of the sons of Muley Sidan, was elected emperor. The indolence and effeminacy in which this monarch lived, and the oppressions of the governors of provinces and cities, excited murmurs among the people, and at length universal discontent. The mountaineers, having besieged and taken Morocco, put Muley Achmet to death, and proclaimed one of their chiefs, named Crom-El-Hadgy, who reigned some years, but without the love of his people. This prince inhumane massacred all the descendants of the shariifs, who might disturb his reign; and by his cruelty, revenge the blood and the rights of the house of Merini, whose monarchs these same shariifs had destroyed, after having stripped them of wealth and sovereignty. Crom-El-Hadgy, after having reigned about seven years, closed his life tragically, and was succeeded by his son Muley Shek, who was deposed by a new revolution, which placed the present reigning family on the throne. The Moors of Tafilet, who, on account of a dearth in the province, made a pilgrimage to Mecca, brought back a shariif, named Muley Ali, a descendant of Mahomet, born at the town of Yambo, near Medina, who was treated with great respect, and was at length advanced to the throne. This dynasty acquired the name of Fells, derived from Tafilet, of which Muley Sharif was sovereign. He is said to have had 84 sons, and a greater number of daughters. However that be, the first and the two last, viz. Muley Mohamet, Muley Abdallah, and Muley Ahmad-Senein, resisted an usurpation. The first died in 1664, and was succeeded by Muley Arshid, who terminated his life in 1672, and left behind him a character marked by a succession of cruelties, which the ferocity of his nature rendered habitual, and led him to practise for his amusement. His successor, Muley Ithmael, poissified the same qualities, and filled greater vices than his brother. Wholly regardless of the lives of men, the emperor made it his pastime to affront them with his own hand. The days set apart for prayer were generally dedicated by him to the malefactors, and he seems to have estimated the value of his devotion by the number of his murders. After a reign of 54 years, continually agitated by iniquitude, superstition, and revolt, and fulfilling his sceptre by the most tragical acts, Muley Ithmael died in 1727, at the age of 51 years. His successor was his son Muley Achmet Daihy, who was proclaimed emperor by the grandees and the negroes, and who became brutal by inoffence and intemperance, so that he was despised and hated by his subjects. He died of an incurable dropy in 1729, and was succeeded by Muley Abdullah, who was no less capricious and cruel than his father Muley Ithmael. He was six times deposed, and as often regained the throne. Death contrained him to vacate the throne in 1757, after having divided the empire with his son Sidi Mahomet, who having accustomed the people to respect his authority, succeeded to the throne without opposition. This prince manifested a laudable desire of making peace with the powers of Europe; and accordingly, after confirming that already made between Morocco, England, and Holland, he began his reign with concluding treaties with Denmark and Sweden, and in the following year with Venice, France, Spain, and Portugal. In 1762 the emperor and the grand duke of Tuscany made peace, and the other powers of Italy enjoyed a kind of truce with the empire of Morocco. For the encouragement of commerce, he built the town of Mogodor, where nature had formed a port accessible at all seasons. He ordered the fortresses of Laracha and Rabat to be repaired, embellished each of these cities with some edifices and public markets, and made additions to his own palace at Morocco. He multiplied mercantile establishments on the coast of Morocco; and merchants settled at Santa Cruz, Mogodor, Safi, Rabat, Laracha, and Tetuan. Defiers of effacing the remembrance of all the caprices of his father, he wholly employed himself in the redoration of order, of re-establishing rules for government, and uniformity in the decisions of justice; and with a view of carrying all his laudable plans into full effect, he raised his relation, Muley Dris, to the rank of his most powerful in the empire; but after the death of this prince in 1772, Sidi Mahomet indulged his own propensities more freely, to the dishonour of his government, as well as to the detriment of his country. Sidi Mahomet, who, after a reign of 33 years, died in 1792, was succeeded by one of his sons, Muley Yezid. The present emperor is Muley Solyman, Cheimar's Morocco. Jackon's Account of the Empire of Morocco, &c. 1805. Lempiere's Tour, &c. 1791. Mod. Un. Hist. vol. xiv.

Morocco, the metropolis of the empire of Morocco, was formerly the capital of the kingdom of the same name, bounded by the river Omarbaym, or Morbeya: distant 20 leagues from the sea, E.S.E. of Safi, and not far from the capital Atlas; and built on the site where the ancients placed the "Bocanum Hemerum." Abu Tefifin, first king of the Moors, of the race of the Morabecon, or Marabots, first fixed his residence at the city of Agnial, on the western declivity of Mount Atlas, at a little distance from Morocco. But wishing to establish a capital in a country in a more eligible situation, he chose the spot where Morocco now stands, which is called by the Arabs Marrakech, and by the Spaniards Marrakesh. This city was begun by that prince in the year 1042, and continued by his son and successor, Joseph Ben Abu Tefifin, who kept his court here. In the time of his grandson, Ali Ben Yusuf, it is said to have contained a million of inhabitants, but in later times, it has been much depopulated, and by reason of the devastations of succeeding conquerors, retains little of its ancient magnificence except its general form; and its decay is very perceptibly indicated by the accumulated ruins of
of houses and gardens within the town, which were once the seats of habitations. Its walls are extremely thick, and formed of a cement, composed of lime and sand, which is put in cakes, and beaten with rammers. This mortar, which is called by the Moors and the Spaniards "capia," hardens in time, and turns to stone, especially when the composition is well made, and when it contains a sufficient quantity of lime. The extent of the walls, which, with few exceptions are entire, leads one to conceive of a city that might contain 300,000 souls; though it now appears little better than a desert. The quarters, which have been rebuilt, are at a considerable distance from one another; and the houses are low, dirty, and extremely inconvenient. Chenier doubts whether it contains 30,000 inhabitants, even when the court is there. Other writers reduce the number to 20,000.

Mr. Jackson, professing to derive his statement from authentic information, extracted from the imperial regifter, tells the amount of inhabitants in the city of Morocco to the prodigious number of 270,000. He says, that the breaches in the walls were repaired previously to the siege and capture of the city by Muley Yazid, in 1793; and that some of the houses are built with much elegance and taste, but as they are placed behind high walls, they are not visible from the streets.

Morocco is situated in a pleasanl plain, planted with palm-trees, and mount Atlas to the east, which has a fine and romantic effect; and this plain is rendered capable of the highest cultivation by the numerous streams that traverse it. It was formerly divided into a large number of enclosed gardens, and beautiful plantations of olive-trees, which have, in part, escaped the barbarous devastations of contending factions. It is said that this plain was beautified and enriched by waters inflowing from more than 600 springs in mount Atlas, and that it was abandoned with country-houses and pleasuregrounds; but these were ruined by the revolutions which preceded and distinguished the reign of Muley Ishmael; and it was, with difficulty, that, in 1768, the course of 1200 streams, which wind through this fertile country, was renewed. The city is supplied with water partly from these springs, and partly from the river Tendit, which flows near the city, but principally from a subterraneous brick aqueduct, that goes round the town, 20 feet below the surface, and from which, at about every 100 yards, pipes of brick-work branch off, and convey the water into the different houses.

Morocco possesses several large mosques, without much pretention to magnificence. Within the walls are large enclosed spaces, containing gardens of orange-trees, and pavilions, covered with coloured tiles, and exhibiting a striking contrast to the wretched buildings that surround them; in these pavilions the princes lodge. The body of one of the mosques is supported by many marble pillars, and under it is a cistern, capable of holding a large quantity of water, which is collected in the rainy season, and used by the Mahometans in their numerous ablutions. The town is square, and resembles that of Salé and Seville; it consists of seven itories, and is ascended by a gradually winding terrace, composed of lime and small stones, so firmly cemented as to be almost as hard as iron. On the summit is a turret, in form of a square lantern, which commands a moss extensive prospect, and from which Cape Cantin, distant about 120 miles, is distinctly visible. Another tower is rendered famous by the three golden balls on its top, which together weigh ten quintals, or 1205 lbs. The inhabitants have been made for taking them down, and that those who were concerned in the business were soon after killed. Among the public edifices in this city, we may mention the Elcaifaria, or Kassaria, which is an oblong building, surrounded with small shops, filled with silks, cloths, linens, and other valuable articles for sale. This is a place of resort for conversation, as well as for trade, somewhat resembling our Exchanges in Europe. At the extremity of the city, and near the palace, is the quarter of the Jews, enclosed by walls nearly two miles round, where the Jews reside under the protection of an aicle, to prevent them from insult. Not less than 3000 Jewish families formerly resided here; of which there now remain 200, (Mr. Jackson says 2000,) subject to tyranny, and debased by poverty; oppression having obliged the rest to seek refuge among the mountains. At the extremity of the city, and fronting mount Atlas, is the emperor's palace, which is a very extensive and solid building. The principal gates are Gothic arches of hewn stone, embellished with ornaments in the Arabian taste. Within the walls are various courts and gardens, elegantly laid out. In each of these is a pavilion, to which the emperor retires to take his rest, or amuse himself with his courtiers. These pavilions are square pyramidal edifices, about 40 feet in length, and somewhat less in height, covered with varnished tiles of various colours; and the interior is a kind of spacious hall, admitting light and air. The inside of the halls is painted and gilt in the Arabesque fashion, and ornamented with carvings, containing palaces of the Koran, or other Arabic sentences. The furniture is very simple. The pavilion, containing apartments for the emperor and his women, is in one of these gardens. This building is very spacious, but furnished without any splendid ornaments. The emperor, Sidi Mahomet, who was particularly attached to this city, has caused to be built by Europeans, regular pavilions, on a piece of ground which he has added to his palace. These are finished in an excellent taste, and give an air of grandeur and magnificence to this part of the palace. Between these pavilions and the old palace is a large vacant space, inclosed with walls, called "Medina," where the emperor gives public audience four times in a week. Mount Atlas, E. of the city, defends its environs from the E. wind, which in summer would be scorching, while the fowls on its summit serve to moderate the heat of the climate. The nights are constantly cool, and the principal heat is felt from morn in the morning to three or four in the afternoon. In winter, the snow which falls on the mountains produces a febrile cold; nevertheless, the climate is very healthy. The houses, however, are inconvenient habitations for foreigners, as they are full of bugs; and in summer, scorpions, serpents, and gnats are very troublesome. The city of Morocco, besides its trade with the various districts of the interior country, receives the most considerable supplies of European merchandise from the port of Mogador, which is distant about four days' journey, according to the rate of caravan traveling; a caravan journey being 24 miles. Some of the more valuable articles, however, are transported from Fez to the Mohammed market, such as muslins, cambrics, spicces, teas, pearls, coral, &c., and the elegant Fez manufactures of silk and gold. There is held at Morocco a considerable market every Thursday; at which all articles of foreign as well as home manufacture are bought and sold; and also horses, horned cattle, slaves, &c. Samples of all kinds of merchandise are carried up and down the market and streets of the city by the Deloas, or itinerant auctioneers, who proclaim the price offered, and when no one offers more, the bidder is apprised of his purchase, the money is paid, and the transaction terminates. The shops of Morocco are supplied with merchandise of various kinds by the merchants of Mogador, who receive, in return for European goods, the various articles of the produce of Barbary.
for the European markets. A considerable difference, however, has lately taken place in the mode of transacting business at Morocco: for the present emperor's father respected European merchants, and their book-debts were seldom disputed, and commerce was much encouraged; but Muley Solmon's political principles differ widely from those of his father, that the most trifling transactiion should now be confirmed by law, in order to enable the European to be on equal terms with the Moor, and to entitle him to recover any property or credit given: these measures have their various impediments in the way of commerce, which have very much restricted and diminished it. N. lat. 35° 57'. W. long. 7°.

Morocco, or Marruequin, the skin of a goat, or some other animal resembling it, dressed in lambs or gals, and coloured of any colour at pleasure; much used in book-binding, &c.

The name is ordinarily derived from the kingdom of Morocco, whence it is sopposed the manner of preparing these skins was first borrowed.

We have Morocco skins brought from the Levant, Barbary, Spain, Flanders, and France; red, black, yellow, blue, &c. The various manners of preparing morocco, both black and in colour, are so curious, and so little known among us, that the public will not be displeased to find them here.

Morocco, Manner of preparing black. The skins having been dried in the hair, are steeped in clear water three days and nights; then they are stretched on a wooden horse or leg, like that used by tanners; then beaten with a large knife for the purpose, and steeped afresh in water, changed daily till they be well come again. In this flate they are thrown into a large vat in the ground, full of water, wherein quick-lime has been slaked, where they lie fifteen days: whence, however, they are taken, and again returned every night and morning; they are thrown into a fresh vat of limew and water, and shifted night and morning, as before, for fifteen days longer; then rinsed in clear water: and the hair is then taken off, on the leg, with the knife; the skins are then returned into a third vat and shifted, as before, for about eighteen days; then steeped twelve hours in a river; then taken out, rinsed, put in pails, where they are pounded with wooden pelettes, changing the water twice: then laid on the horse, and the flesh taken off, returned into pails of new water, taken out, and the hair-side scraped; then returned into fresh pails; taken out, and thrown into a pail of a particular form, having holes at bottom; here they are beaten the space of an hour, and fresh water poured on from time to time; stretched on the leg, and keraped on either side; returned into pails of fresh water; taken out, stretched and fewed up all around, in manner of bags, leaving out the hind legs, which serve to make an aperture for the conveyance of a mixture mentioned hereafter.

The skins, thus fewed, are put into lukewarm water, where dogs' excrement has been dissolved. Here they are flithered with long poles half an hour, left at rest a dozen, taken out, rinsed in fresh water, and filled by a tunnel with a preparation of water and femach, mixed and heated over the fire till ready to boil; and as they are filled, the hind legs are fewed up to stop the passage. In this state they are let down into the vessel of water and femach, and kept flithering four hours successively; they are then taken out, and heaped on one another; after a little time, their hides are changed; and thus they continue an hour and a half, till drained. This done, they are loofened, and flithered a second time with the same preparation, fewed up again, and kept flithered two hours, piled up, and drained as before. This is again repeated a third time, with this difference, that they are now only flither a quarter of an hour; after which, they are left till the morning, when they are taken out, drained on a rack, unfewed, the femach taken out, folded in two from head to tail, the hair-side outwards, laid over each other on the leg, to perfect their draining, flithered out, and dried; then trampled under foot by two and two, flithered on a wooden table, what flesh and femach remains scraped off, and the hair-side rubbed over with oil, and that again with water.

Having thus received their oil and water, they are wrung in the hands, then flithered and pressed tight on the table with an iron instrument like that of the carriers, the flesh-side uppermost; then turned, and the hair-side rubbed strongly over with a handful of rushes, to squeeze out as much of the oil remaining within as possible. The first course of black is now laid on the hair-side, by means of a lock of hair twisted and flithered in a kind of black dye, prepared of four beer, in which pieces of old rusty iron have been thrown. When half dry, by hanging in the air, they are flithered on a table and rubbed over every way with a paumelle, or wooden-toothed instrument, to raise the grain, over which is passed a light couche of oil, then flithered by rubbing them with rushes prepared for that purpose. Thus flithered, they have a second couche of black; they are then dried, laid on the table, rubbed over with a paumelle of cork, to raise the grain again; and, after a light couche of water, flithered over anew; and, to raise the grain a third time, a paumelle of wood is used.

After the hair-side has thus received all its preparations, the flesh-side is pared with a sharp knife for the purpose, and the hair-side rubbed strongly over with a woolen cap, having first given it a fultre with barberries, citron, or orange. The whole is finnished by raising the grain lightly, for the last time, with the paumelle of cork, which leaves them in a condition for sale and use.

Morocco, Manner of preparing red. The skins are flithered twenty-four hours in a river, taken out, flithered on the leg, beaten with the knife, returned into the water, for twenty-four hours; re-beaten on the leg, re-flithered; thrown into a vat, and for three weeks taken out, and turned every morning, to dispose them to peel. Being taken out for the last time, they are flithered with the knife; and when the hair is quite off, thrown into pails of fresh water, where they are rinsed; then the flesh-side scrape, thrown into pails, and thus alternately from the leg to the pails, till they leave the water quite clean; then they are put in lukewarm water, with the femach as before; and, after twelve hours, they are rinsed in clear water, and scraped on the leg on both sides, pounded in pails, and the water changed three times; then wrung and flithered on the leg, and passed after each other into water, with alum dissolved in it. Thus shurned, they are left to drain till the morning, then wrung out, pulled on the leg, and folded from head to tail, the flesh inwards.

In this state they receive their first dye, by passing them one after another into a red liquor, prepared with laces, and some other ingredients, kept secret among the marroquiniers. This they repeat again and again, till the skins have got their first colour. They are then rinsed in clear water, flithered on the leg, and left to drain twelve hours; then thrown into water, into which white galls pulverised have been passed through a sieve, and flithered incessantly for a whole day with long poles, taken out, hung on a bar across the water all night, pulled against red, and red against white; and in the morning the water is flithered up, and the skins are returned.
Moron, a river of South America, which rifes about 20 miles S.E. of Riobamba and runs into the Maragaon, 40 miles E. of St. Francisco de Borja.

MORONE, Jony, in Biography, a cardinal and state-man, born at Milan in 1509, was son of Jerome Morone, grand chancellor of Milan, an eminent political character. He was educated partly at Modena, after which, it is supposed, he studied at the university of Padua. At the age of twenty he was nominated by Clement VII. to the bishopric of Modena, but he did not enter upon the charge till the year 1533; even before this so much confidence was placed in his early talents and discretion, that he was sent by the pope into France to induce the king to consent to a peace. In 1536 pope Paul III. appointed him nuncio in ordinary to Ferdinand king of the Romans; he was present at the diet held at Hagenau and Spire, and it was owing to him that the approaching general council was held at Trent. In 1542 he was made a cardinal, and fixed upon as president of the council, though then only thirty-three years of age. In 1544 he was appointed to the legation of Bologna, of which he was deprived in 1548 from the suspicions of the French, who thought him too much devoted to the interests of the emperor. He was, perhaps, for a similar reason, that on the assembling of the council of Trent he was excluded from the presidency to which he had been elected. In 1553 he was sent by Julius III. as legate to the diet of Augsburg, where he vigilantly and warmly defended the interests of the holy see. About this time he exchanged the bishopric of Modena for that of Novara. The cardinal, though zealous attached to the church of Rome, was an enemy to perdition, and on that account fell under the suspicion of the bigot cardinal Caraffa, afterwards pope Paul IV., who caused Morone to be arrested and confined in the castle of St. Angelo. In 1558 he was brought to trial upon the charge of teaching and having taught many opinions connected with the reformed faith. He made his innocence appear, that the pope offered to liberate him from prison, which he refused, unless he would grant him, at the same time, a solemn declaration that he believed him innocent. The pope he refused, and died without coming to a determination, and Morone was admitted to the conclave which elected Pius IV. The examination of his cause was then resumed, and he obtained a complete absolution not only from crime, but even from all suspicion in matters of faith. As a recompence for so serious an injury, he was appointed to succeed cardinal Gonzaga as president of the council of Trent, and by his address he brought his business to a conclusion: in 1563. After this he obtained many fees appropriated to the cardinals, as those of Palestrina, Pesciati, Porto, and Oftia. During the troubles of Genoa in 1577, he was sent thither as legate by Gregory XIII., and contributed very much to the re-establishment of tranquillity. He died at Rome in 1580, leaving behind him a very high character for integrity and activity in the various services which he undertook. Some Latin and Italian letters, an oration before the council of Trent, and another before the emperor Ferdinand; fynodial constitutions for Modena, and a code of laws for the government of Genoa, are proofs that his public occupation did not entirely prevent him from exercising his pen to useful purposes.

MOROSINI, Andrew, in Biography, a senator of Venice, was defended from James Morolin, of a very illustrious family, and was born in 1558. He received an excellent education, and ruled through the different degrees of nobility to the rank of "fiano grande," and to a place in the council of ten. He was three times one of the reformers of the university of Padua, had obtained much wifdom by experience in public affairs, and was accomplished in every branch of polite literature. In 1598 he succeeded to the office of historian of the republic. He was employed this task till his death, which happened in 1618, and he had not then put the work into print. This history was written in Latin, and is a continuation of that of Pietro Bembo. It comprehends the period between 1531 and 1615. It was first published in 1623, and reprinted in 1719 at Venice, in the collection of Venetian historians. It has been ranked among the best performances of that age. He also published, in Latin, a volume of "Opuscula and Epitikes," and a narrative in Italian of "Expeditions to the Holy Land, and the Acquisition of Constantiopole by the Venetian Republic."

MOROSINI, Paul, brother to the preceding, and likewise a Venetian senator, was appointed to the same post of public historian, after Nicholas Constantini. He gave an entire history of the republic from its origin to the year 1487, in the Italian language. It was published in 1637. It is said to be valuable for several notices omitted by other writers who preceded him.

MOROTAI, in Geography, one of the Sandwich islands, 24 leagues W.N.W. from Mowee. The S.W. coast is very low, but the land rises backward to a considerable height, and appeared to be entirely without wood. Its produce consists
MOR

MORROCCO, a town of Hindoostan; 24 miles E. of Tellicherry.

MORPETH, a market and borough town in the western division of a ward of the same name, and county of Northumberland, England, is seated on the northern and southern banks of the Wonbeck river, in the course of the great road from London to Edinburgh. It is a place of remote antiquity, and a borough by prescription, under the government of two bailiffs and seven burgesses. Two members have been sent from this town to parliament since the year 1553, who are elected by the bailiffs and free burgesses, and returned by the former. The number of voters is estimated at about 200, the greater part of whom are under the influence of the earl of Carlisle, and William Ord, esq. who poises the chief part of the burgage tenures. The constitution of this borough is rather singular: among the burgesses there are a few persons of independent principles, but their number is too small to produce any material effect at elections.

Camden informs us that this town was "burned down by its inhabitants in 1215, out of hatred to king John," but the Chronicle of Melrose alludes to a more probable cause for the event, by ascertaining that the barons destroyed it, as they did many other towns, with the view of diversifying that monarch, when on his march to punish their revolt. It was again visited with similar destruction in 1689, at which time the damage was estimated at 35,000l.

The present appearance of Morpeth is that of a small, neat town, situated between the woody banks of the Wonbeck. Here are a county gaol for Northumberland, and an ugly town-house, built at the expense of the earl of Carlisle in 1714, from a design by Vanbrugh. The market day is on Wednesday, when there is usually a considerable show of fat cattle and sheep for the consumption of Newcastle, shields, and Sunderland. The parish church stands about a quarter of a mile from the town, on Kirk-hill; and there is, besides, a chapel at the bridge end. Adjacent to this last, in an old chantry, is a free school, which was founded by king Edward VI. Here was formerly also a hospital for the sick, and at about the same distance as the church, west of the town, appears the whole of a small door-way, which显然ly led into the New Minster abbey, founded in 1139 by Ranulphus de Merlay, who placed in it monks of the Cistercian order. The abbots of this monastery were frequently summoned to parliament during the reign of Edward I.

Of Morpeth castle, which was seated on a considerable eminence close to the town, few vestiges remain, except a portion of the gateway tower, and some fragments of the outer walls. This fortress owed its erection to William lord Greylock in the year 1358, and is laid to have been of some extent and consequence as a baronial mansion. In the time of Leland, who says "Morpeth castle standeth by Morpeth town," it was the property of lord Dacre, as husband of Elizabeth baroness Greyleck; and continued in his family till the reign of queen Elizabeth, when a daughter of Thomas lord Dacre conveyed it to lord William Howard of Naworth, ancestor to the present earl of Carlisle, who landed property nearly encircles the whole town. The north end of Morpeth, called Bollers-green, formerly belonged to New Minster abbey. It was purchased by Thomas Wharton in 1672, and is now the property of Mrs. H. Burdon, his immediate descendant.

According to the parliamentary returns of 1801, this town contains 427 houses, and its inhabitants are estimated at 2951 in number, viz. 1342 males, and 1609 females, of whom 689 are engaged in some branch of trade or manufacture, and 116 in agriculture.

About two miles and a half south-west from Morpeth stands the village of Mitford, which was formerly a market town. The barony here was originally the property of a family which gave its name to the village, and after changing masters several times, and in different ways, has, by an unusual accident of fortune, returned to a collateral branch of its ancient owners, the Mitfords of Molefelden. The castle of this barony stood on a lofty, natural eminence on the south bank of the Wonbeck. When it was originally built, it was, uncertain, but it is mentioned in history as having been destroyed by king John and his Rutos (a band of Flemish troops), when they laid waste this part of the country in 1215. It was rapidly however rebuilt, for in the following year, we find it beleaguered by Alexander, king of the Scots. Leland says, "it was beten downe by the kyng, for one sir Gilbert Middletown robbey'd and cardinall coming out of Scot- land, and the king fled to his castle at Mitford." The ruins of this fabric, now remaining, are the keep-tower and the exterior walls, which have a deep ditch on the south and east sides, cut out of the solid rock. Near the castle stands the present manor-house, the seat of Bertram Mitford, esq., and also the parish church. On a hill, immediately above the village, is St. Leonard's hospital, founded by sir William Bertram in the reign of Henry I., and now converted into a family residence called "The Spital," the residence of Bullock, esq. Above three miles east of Morpeth, on the banks of the Wonbeck, are some remains of Bothal castle, built by sir Robert Bertram in the time of Edward III. According to a survey of it, taken in 1576, the circumference of the walls was 490 feet. These were flanked, on the north, by two polygonal towers, fifty-three feet high, and on the south-west angle by a square turret, whole height measured sixty feet. In the church, which adjoins the castle, may be seen a curious tomb of one of the barons and his lady. It is made of alabaster, and exhibits the recumbent figures of the deceased, with a variety of emblematical figures and armorial devices. A mile from Morpeth is Hartford, the seat of William Burdon, esq. author of "Materials for Thinking," &c. The house, a plain substantial building of yellow stone, consists of a centre and two wings; and was completed in the year 1803, on the site of an old mansion. Near its principal front is the channel of the river Blyth, which meanders through a romantic and picturesque valley. The open country abounds with coal pits, and the soil is mostly a strong clay. The general aspect is dreary and unpleasing.

To the north of Morpeth are several other feats and ruins not unworthy of notice. Cockle-park tower, called in Speed's map Cockey tower, is a curious remnant of antiquity, in the fashion of the old border mansions. Weddrington castle was formerly a most distinguished edifice, though the work of different ages; but was pulled down about 30 years ago, with the exception of an octagonal embattled tower, to which a square modern building has been since added. Felton hall, north-west of Weddrington, is distinguished as the place where the barons of Northumberland assembled in the reign of king John, and did homage to Alexander, king of Scotland. A few miles down the river Coquet, on which this manor stands, is Guyz-ance, once remarkable for a munition built by Richard Tyron; and at Brinkburn was a priory founded by Roger Bertram, baron of Mitford, in the reign of Henry I.

MORPH'S AMUS, μορφαμος, among the Ancients, a kind of dance, in which, by a great many figures, they imitated the transformations of Proteus.

MORPHIUS, in Hippo. one of the dreams which were reckoned the children of Sleep, but which derives its name from μοχφ, form, or shape, because this dream, or symbolically Morphinus, excelled the others, viz. Phobetor and Phantasia, in assuming the guise, man, air, and tone of voice of those whom he was to represent.

MORPHEW, Morpha, in Medicine, a term which has been used, especially by the translators of the writings of the Arabian, and their followers, to denote the lighter species of scaly leprosy, which was denominated αληθη by the Greeks, and alfobak by the Arabs; and which is included by Celius under the head of Πηληγος. See Ληγος of the Greeks, and Leuc, where the characteristics of these diseases are detailed at length.

MORPHO, in Geography, a town of the island of Cyprus, the residence of an aga and a cadi; 33 miles W. of Paphos.

MORRA, a town of Naples, in Abruzzo Ultra; 32 miles N.E. of Aquila.—Also, a town of Hindostan, in Bahar; 8 miles N. of Arrah.

MORRA, Lat., in France, in the department of the Tanaro; 3 miles E. of Cherasco.

MORRHA, in Natural History, a name given by some to the substance more properly called murra or myrrha, of which the cups called myrrhina and myrrhina were made.

MORRHINA VASA, in the Writings of the Ancients.

See Murrina.

MORRICE, Dance. See Morek.

MORRIS, Lewis, in Biography, a Welsh antiquary and poet, was born in the isle of Anglesey in 1702, and died in 1765 at Pensryn, in Cardiganshire. He surveyed the coast of Wales in 1737, by order of the admiralty-board, and his work was published in 1743. Some of his poetical pieces in the Welsh language have been printed, and he left above 80 volumes of manuscripts of antiquity, now deposited in the Welsh charity-school, Gray's-inn lane, London. Owen's Camb. Biog.

MORRIS, Richard, brother of the above, was also a poet and critic in his native language. He was clerk in the navy pay-office, and superintended the printing of two valuable editions of the Welsh Bible. He died in 1779. William Morris, another brother, was a great collector of Welsh manuscripts, and died comptroller of the customs at Holyhead in 1764. Owen's Camb. Biog.

MORRIS, in Geography, a county of America, on the northern line of New Jersey, west of Bergen county. It is about 25 miles long, and 20 broad, is divided into five townships, and contains about 166,809 acres of improved, and 38,429 acres of unimproved land. The eastern part of the county is level, and affords fine meadows, and good soil for Indian corn. The western part is more mountainous, but produces crops of wheat. Here are seven rich iron mines, and two springs famous for curing rheumatic and chronic disorders. Black lead, &c. has been found in the mountains. The number of inhabitants in the county is 17,750, of whom 775 are slaves.

MORRIS BAY, a bay on the west coast of the island of Antigua.

MORRIS Pile, or Moorish Pike, in ancient Artillery, a kind of pike that was much in fashion about the reigns of Henry VIII. and queen Elizabeth. These pikes were used both by land and sea; and though their characteristic peculiarities are not precisely ascertained, many of the morros, used in the exercise of them, resembled their practice with the common pike.

MORRIS TOWN, in Geography, a town of America, and capital of Morris county in New Jersey, containing a Presbyterian and Baptist church, a court-house, an academy, and about 50 compact houses; about 100 miles N.E. of Philadelphia.

MORRISVILLE, a town, or rather village, of Pennsylvania, in Berks county, on the west bank of Delaware river; 6 miles from Brifton.

MORRO di Bonifacio, a cape on the coast of Chili. S. lat. 39° 25'.

MORRO Chico, a cape on the coast of Honduras. N. lat. 15° 35'.

MORRO Cobr, a cape on the coast of Africa, in the Indian sea. N. lat. 8° 5'.

MORRO de Carajachica, a headland on the coast of Peru. S. lat. 19° 35'.

MORRO de los Diabolas, a headland on the coast of Peru. S. lat. 18°.

MORRO Hermoso, a cape on the west coast of California. N. lat. 32° 52'. E. long. 245° 7'.

MORRO Mora, a cape on the coast of Chili. S. lat. 23° 10'.

MORRO-Morro, a town of the government of Buenos Ayres, in the diocese of La Plata; 40 miles N.E. of Cochi.

MORRO de Puebres, a cape on the west coast of Mexico. N. lat. 7° 35'.

MORRO de S. Jorge, a cape on the west coast of America. S. lat. 24'.

MORRO Quebrado, a headland on the coast of Peru. S. lat. 14° 20'.

MORRO de S. Joseph, a headland on the coast of Peru. S. lat. 24'.

MORRON, a town of the island of Cuba; 40 miles N.W. of Villa del Principe.

MORRONE, a town of Naples, in Lavora; 8 miles E. of Canpa.

MORROPE, a town of Peru, near the coast of the Atlantic, in the bishopric of Truxillo, and jurisdiction of Santa Cruz; lying on the road between Quito and Lima, and containing about 160 villages, all Indians; 195 miles N.W. of Truxillo.

MORROQUILLO, a bay of the Spanish main, on the coast of South America. N. lat. 9° 20'. W. long. 75° 40'.

MORS, an island of Denmark, in Lymfords gulf, about 18 miles from north to south, with various breadth from 1 mile to 11 miles. It has several towns and villages. The chief place is Nikkoeping. N. lat. 56° 50'. E. long. 8° 47'.

Mors.
MORS. See MEURS.
MORSCHANSK, a town of Russia, in the government of Tambov, on the Tza; 36 miles N. of Tambov. N. lat. 53° 40'. E. long. 41° 34'.
MORSE, in Zoology, the name of a monstrous sea animal, called by some the morimus and walrus, and by others, very improperly, the hippocampus and equus marinus.

The moramus, or rofulmus, of Linnaeus, is an ill-shaped amphibious animal, of the size of a large ox, covered with a skin like that of the seal, and somewhat resembling an ox in the head; for which reason some have called it the sea-cow, or vacca marina; whereas it has been erroneously confounded by some with the manitai.

It has two large prominent red crooked tusks in the upper jaw, which are as line as ivory, and are used by artificers for the same purposes; and four grinders on both sides above and below, but no cutting teeth. The teeth have been sometimes found of the weight of twenty pounds each. It brings forth usually but one young at a time, never more than two. It is a very strong and vigorous animal, and difficulty taken; when it is caught, it is usually at land, seldom at sea.

Vorflius, who met with a young one of this creature, has very accurately described it: whence we have the best description extant of the nature of the animal. This young one was of the size of a large dog, and in shape much resembled the phoca or sea-calf. Its head was round; its eyes large, and like those of camels; its murrills depressed and wide, and opening and drawing together, as the creature pleased; it had apertures on the sides of the head for ears; its mouth opened round, and not very large; and on the upper lip it had a sort of whiskers, composed of thick cartilaginous bristles; the lower jaw was of a trigonal form; the tongue short and thick, and the mouth well furnished with broad and flattened teeth; its fore-feet, as well as the hinder ones, were very broad; and the hinder extremity of its body very much resembled that of the phoca or sea-calf; when it walked, the fore-feet were directed forwards, the others turned backward; the toes were five on each foot, and these were joined by a membrane, which was remarkably thick; the hinder feet had claws, the fore-ones had not; and the creature had no tail, and crept rather than walked on the hinder parts; its skin was thick and tough, and covered with a few short grey hairs; it made a noise like the grunting of a hog.

These animals inhabit the coast of Spitzbergen, Nova Zembla, Hudson's bay, and the gulf of St. Lawrence, and the Key fea, as far as Cape Tichukfli; they are gregarious; in some places appear in herds of hundreds; are shy animals, and avoid places that are much haunted by mankind. The method of killing them on the Magdalene tiles is said to be as follows: the hunters watch their landing, and as soon as they find a sufficient number for what they call a cut, go on shore, each armed with a spear, sharp on one side like a knife, with which they cut their throats; taking care not to stand in the way of those which attempt to get again to sea, which they do with great agility, by tumbling headlong; for they would crush any body to death by their weight. They are killed for the sake of their oil, one walrus producing about half a ton. The knowledge of this chase is of great antiquity: Othmar, the Norwegia, about the year 890, made a report of it to king Alfred, having, as he says, made a voyage beyond Norway, for the convenience of fishing for horse-whales, which have in their teeth bones of great value, of which he brought some at his return to the king. Pennant.

MORSE, in Geography. See MORGES; MORSELLI, or MORSELL, are denominations given to those forms of medicine intended to be sucked in the mouth, as a lozenge: the word signifying a little mouthful.
MORSIGLIA, in Geography, a town of the island of Corfica; 61 miles N.N.W. of Balia.
MORSKOM, a town of Sweden, in the province of Nore; 16 miles N. of Borgo. N. lat. 60° 59'. E. long. 25° 40'.
MORSONA, a town of Naples, in the county of Molise; 14 miles N.E. of Molise.
MORSUS DIABOLI, in Anatomy, a whimisical name applied to the broad aperture of the Fallopian tube.
MORSUS DIABOLI, Devil's Bit, in Botany, a plant of the feabious kind, which seems to have a fringe around the bottom of its root; otherwise called Facixia. See Scabiosa.
It has its denomination from its roots, which appear as if bitten off at the bottom; which superstitious people attributed to the devil, as done out of envy, lest we should have too much of a fatal root. It was formerly looked on as a good astringhem:; but is now much out of use.

MORSUS Canis Rabidi, in Medicine. See HYDROPHOBIA.
MORSUS Rane, in Botany, Frog-bit. See HYDROCHARIS.
MORSUS Viperis. See VIPER.
MORT D'ANCESTRE, in Law. See ASSIZE OF MORT D'ANZOS.
MORT, among the fishermen of some parts of England, a name given to the salmon while in its third year's growth.
MORT, La, in Geography, a lake of Upper Canada, where the traders have a post to purchase furs of the Indians; 40 miles N.N.W. from Sturgeon lake.
MORTA, a lake of Italy, in the Trevesian; 5 miles N. of Ceneda.
MORTA, in Medicine, an appellation given by Linnaeus, and some others, to a supposed petitional and mortal digital, which has been more commonly denominated Pemmigius, in consequence of the appearance of large vehicles, or bullae, upon the skin, during the fever. It is probable, however, that the history of this vesicular fever is very incorrectly drawn, if it has not originated altogether in mistake. See PEMPHIGUS. See also Linnei Genera Morborum, ch. i. gen. 1.
MORTAGNE, in Geography, a town of France, and principal place of a district, in the department of the Orne; 18 miles N.N.E. of Alençon. The place contains 5720, and the canton 13,008 inhabitants, on a territory of 155 kilometres, in 16 communes. N. lat. 48° 31' E. long. 0° 27'.—Alfo, a town of France, in the department of the Vendee, and chief place of a canton, in the district of Montaigu; 33 miles N.N.E. of Luçon. The place contains 633, and the canton 9220 inhabitants, on a territory of 187½ kilometres, in 12 communes.—Alfo, a town of France, in the department of the Lower Charentes; 12 miles S.S.W. of Saintes.
MORTAIN, a town of France, and principal place of a district, in the department of the Channel; 16 miles E. of Avranche. The place contains 2650, and the canton 10,705 inhabitants, on a territory of 157½ kilometres, in 10 communes.
MORTALITY, a term frequently used to signify a contagious diarrhea, which destroys great numbers of either men or beasts.
MORTALITY, Bills of, are accounts or registers specifying
the numbers born, married, and buried in any parish, town, or district. In general they contain only these numbers; and, even when thus limited, are of great use, by shewing the degrees of healthiness and prolificness, and the progress of population in the places where they are kept. It is, therefore, much to be wished, that such accounts had been always correctly kept in every kingdom, and regularly published at the end of every year. We should then have had under our inspection the comparative strength of every kingdom, as far as it depends on the number of inhabitants, and its increase or decrease at different periods.

But such accounts are rendered more useful, when they include the ages of the dead, and the distempers of which they have died. In this case they convey some of the most important instruction, by furnishing us with the means of ascertaining the law which governs the state of human life, the values of annuities dependent on the continuance of any lives, or any survivorships between them, and the favourable or unfavourable means of different situations to the duration of human life. There are but few registers of this kind; nor has this subject, though so interesting to mankind, ever engaged much attention till lately. The first bills containing the ages of the dead were those for the town of Breslaw in Silesia. It is well known what use has been made of these by Dr. Halley, and after him by De Moivre. A table of the probabilities of the duration of human life at every age, deduced from them by Dr. Halley, has been published in the Philosophical Transactions (see the Abridgment, vol. iii. p. 669,) and has been inserted under the article 'Life-Annuites' in this work; and this is the first table of this sort that has been ever published. Since the publication of this table, similar bills have been established in a few towns of this kingdom; and particularly in London (in the year 1728), and at Northampton in 1735.

Two improvements of these registers have been proposed; the first is, that the sexes of all that die in every period of life should be specified in them, under the denominations of boys, married men, widowers, and bachelors; and of girls, married women, widows, and virgins. The second is, that they should specify the numbers of both sexes dying of every distemper, in every month, and at every age. (See the end of the second essay in Dr. Price's Treatise on Reversionary Payments, vol. ii. 7th edit.) Registries of mortality thus improved, when compared with the records of the feasons, and with the circumstances that discriminate different situations, might contribute greatly to the increase of medical knowledge; and they would afford the necessary data for determining the difference between the duration of human life among males and females; for such a difference there certainly is, much in favour of females, as will appear from the following facts, in addition to those which have been already recited under the article Marriage, which the reader is directed to consult.

At Northampton, though more males are born than females, and nearly the same number die; yet the number of living females appeared, by an account taken in 1746, to be greater than the number of males, in the proportion of 2301 to 1770, or 30 to 31.

In the parish of Holy Cross, Salisbury, in the year 1765, the number of females born of 60 was 13, and of males 2. In the year 1770, these numbers were 11 and 6 respectively; and for 20 years, from 1765 to 1785, eleven out of 966 had died above 90 in this parish, and they were all females.

At Berlin it appeared, from an accurate account which was taken of the inhabitants in 1747, that the number of female citizens exceeded the number of male citizens in the proportion of 429 to 301. And yet out of this smaller number of males, more had died for 20 years preceding 1751, in the proportion of 10 to 17.

At Edinburgh, in 1743, the number of females was to the number of males, as 4 to 3. (See Maitland's History of Edinburgh, p. 220.) But the females that died annually from 1749 to 1758, were to the males in no higher proportion than 3 to 2. See Marriage.

In thirty-nine parishes of the district of Vaud, in Switzerland, the number of males that died during ten years before 1766, was 8170; of females 8167, of whom the number that died under one year of age were 1817 males, and 1503 females; and under ten years of age 3299 males, and 2279 females. In the beginning of life, therefore, and before any emigrations can take place, the rate of mortality among males appears to be greater than among females. And this is rendered yet more certain by the following accounts. At Vevey, in the district of Vaud, just mentioned, there died in the course of twenty years, ended at 1764, in the first month after birth, of males 1753 to 89 females; and in the first year 225 to 162. To the same effect it appears from a table given by Suppinich, in his Gottliche Ordnung, vol. ii. p. 317, that in Berlin 203 males died in the first month, and but 168 females; and in the first year 489 males and but 325 females. And it also appears from a table of Struyck's, that in Holland 396 males died in the first year to 306 females.

The authorities for the facts here mentioned, and much more on this subject, may be found in the second volume of Dr. Price's Treatise on Reversionary Payments, seventh edition.

We shall here only add the following table, taken from a memoir of Mr. Wargentin's, published in the collection of the Memoirs of the Royal Academy of Sciences at Stockholm, printed at Paris in 1772.

In all Sweden for nine years, ended in 1763, the proportion of females to males that died out of a given number living, was

Registries of mortality on the improved plan before mentioned, were established in 1772 at Cheller, and also in 1773.
Mortality.

at Warrington in Lancashire; and they are so comprehensive and correct, that there is reason to expect they will afford much instruction on the subject of human mortality, and the values of lives.

But the country most distinguished in this respect is Sweden; for in that kingdom exact accounts have been taken of the births, marriages, and burials, and of the numbers of both sexes that died at all ages in every town and district; and also, at the end of every period of five years, of the numbers living at every age; and at Stockholm a society was established, whose business it was to superintend and regulate the enumerations, and to collect from the different parts of the kingdom the registries, in order to digest them into tables of observation. These regulations were begun in Sweden in 1755; and tables containing the result of them from 1755 to 1763, have been published in Mr Wargentin's memoir just referred to, and the most material parts of them may be found in an essay by Dr. Price on the "Difference between the Duration of Human Life in Town and in Country Parishes," printed in the sixty-fifth volume of the Philosophical Transactions, part ii.

In the second essay in Dr. Price's "Treatise on Reversionary Payments and Life-annuities," vol. ii. p. 73, the following account is given of the principles on which tables of observation are formed from registries of mortality; and of the proper method of forming them, so as to render them just representations of the number of inhabitants, and the probabilities of the duration of human life in a town or country.

"In every place which just supports itself in the number of its inhabitants, without any recruits from other places, or where, for a course of years, there has been no increase or decrease, the number of persons dying every year at any particular age, and above it, must be equal to the number of the living at that age. The number, for example, dying every year, at all ages, from the beginning to the utmost extremity of life, must, in such a situation, be just equal to the whole number born every year. And for the same reason, the number dying every year at one year of age and upwards; at two years of age and upwards; at three and upwards, and so on, must be equal to the numbers that attain to those ages every year; or, which is the same, to the numbers of the living at those ages. It is obvious, that unless this happens, the number of inhabitants cannot remain the same. If the former number is greater than the latter, the inhabitants must decrease; if less, they must increase. From this observation it follows, that in a town or country, where there is no increase or decrease, bills of mortality which give the ages at which all die, will shew the exact number of inhabitants; and also the exact law, according to which human life lasts in that town or country.

In order to find the number of inhabitants; the mean numbers dying annually, at every particular age and upwards, must be taken as given by the bill, and placed under one another in the order of the second column of the following tables. These numbers will, it has appeared, be the numbers of the living at 1, 2, 3, &c. years of age; and, consequently, the sum, diminished by half the number born annually, will be the whole number of inhabitants.

In such a series of numbers, the excess of each number above that which immediately follows it, will be the number dying every year, out of the particular number alive at the beginning of the year; and these excesses let down regularly as in the third column of the table to which we have referred, will shew the different rates at which human life wastes through all its different periods, and the different probabilities of life at all particular ages.

It must be remembered, that what has been now said goes on the supposition, that the place whose bills of mortality are given, supports itself, by procreation only, in the number of its inhabitants. In towns this very seldom happens, on account of the luxury and debauchery which generally prevail in them. They are, therefore, commonly kept up by a constant accession of strangers, or settlers, who remove to them from country parishes and villages. In these circumstances, in order to find the true number of inhabitants and probabilities of life, from bills of mortality containing an account of the ages at which all die, it is necessary, that the proportion of the annual births to the annual settlers should be known, and also the period of life at which the latter remove. Both these particulars may be discovered in the following method.

If for a course of years there has been no sensible increase or decrease in a place, the number of annual settlers will be equal to the excess of the annual births above the annual deaths. If there is an increase, it will be greater than this excess. If there is a decrease, it will be less.

The period of life at which these settlers remove, will appear in the bills by an increase in the number of deaths at that period and beyond it. Thus in the London bills, the number of deaths, between 20 and 30, is generally above double; and between 30 and 40, near triple the number of deaths between 10 and 20; and the true account of this is, that from the age of 18 or 20, to 35 or 40, there is an afflux of people every year to London from the country, which occasions a great increase in the number of inhabitants at these ages; and, consequently, raises the deaths for all ages above 20, considerably above their due proportion, when compared with the number of deaths before 20. This is observable in all the bills of mortality for towns with which we are acquainted, not excepting even the Bredfast bills. Dr. Halley takes notice, that these bills give the number of deaths between 10 and 20 too small. He considered as an irregularity in them, owing to chance; and, therefore, in forming his table of observations, he took the liberty so far to correct it, as to render the proportion of those who die to the living in this division of life, nearly the same with the proportion which he says, he had been informed die annually of the young lads in Christ-church hospital. But the truth is, that this irregularity in the bills was derived from the cause we have just assigned. During the five years for which the Bredfast bills are given by Dr. Halley, the births did, indeed, a little exceed the burials; but it appears, that this was the effect of some peculiar causes that happened to operate just at that time; for, during a complete century, from 1653 to 1754, the annual medium of births was 1689 (see Dr. Short's Comparative History, p. 63), and of burials 1576. This town, therefore, must have been all along kept up by a number of yearly recruits from other places, equal to about a seventh part of the yearly births.

What has been now observed concerning the period at which people remove from the country to settle in towns, would appear sufficiently probable, were there no such evidence for it as we have mentioned; for it might be well reckoned, that these people in general must be single persons, in the beginning of mature life, who not having yet obtained settlements in the places where they were born, migrate to towns in quest of employment. Having premised these observations, we shall endeavour to explain distinctly, the effect which these accretions to towns must have on tables of
of observation, formed from their bills of mortality; and
the following general rule may be given on this subject.
If a place has, for a course of years, been maintained in a
state nearly stationary, as to number of inhabitants, by
recruits coming in every year, to prevent the decrease that
would arise from the excess of the burials above the births;
a table formed on the principle, "that the number dying
annually, after every particular age, is equal to the number
living at that age," will give the number of inhabitants,
and the probabilities of life, too great for all ages preceding
that at which the recruits cease, and after this it will give
them right. If the accretions are so great as to cause an
increase in the place, such a table will give the number of
inhabitants, and the probabilities of life, too little, after
the age at which the accretions cease; and too great, if there
is a decrease. Before that age it will in both cases give
them too great; but most considerably so in the former case,
when there is an increase.

If a place increases, not in consequence of accretions from
other places, but of a constant excess of the births above
the deaths; a table, constructed on the principle that has
been mentioned, will give the probabilities of life too low
through the whole extent of life; because, in such circum-
fiances, the number of deaths in the first fifteen years of
life must be too great, in comparison of the number of deaths,
in the latter fifteen; and more, or less so, as the increase is more
or less rapid. The contrary, in all respects, takes place where
there is a decrease; arising from the excess of the deaths
above the births.

For example. Let us suppose, that 2,44 of those born
in a town, attain annually to 20 years of age; and that 250
more, all likewise twenty years of age, come into it annually
from other places; in consequence of which, it has, for a
course of years, been just maintained in the number of its
inhabitants, without any sensible increase or decrease. In
these circumstances, the number of the living in the town of
the age of 20, will be always 244 natives and 250 settlers,
or 494 in all; and, since these are supposed all to die in
the town, and no more recruits are supposed to come in, 494
will be likewise the number dying annually at 20 and up-
wards. In the same manner it will appear, on these suppo-
sitions, that the number of the living, at every age, subse-
quently to 20, will be equal to the number dying annually at
that age and above it; and consequently, that the number
of inhabitants and decrements of life, for every such age,
will be given exactly by the table. But for all ages before
20, they will be given much too great. For let 250 of all
born in the town, reach 10 in this case, 280 will be the
true number of the living in the town at the age of 10; and
the recruits not coming in till 20 the number given by the
bills, as dying between 10 and 20, will be the true number
dying annually of the living in this division of life. Let
this number be 276; and it will follow, that the table ought
to make the numbers of the living at the ages between 10 and
20, a series of decreasing means between 180 and (280 di-
iminished by 276) or 244. But in forming the table on the
principle just mentioned, 250 (the number above 20 dying
annually in the town who were not born in it) will be added
to each number in this series; and, therefore, the table will
give the numbers of the living, and the probabilities of life
in this division of life, almost twice as great as they really
are. This observation, it is manifested, may be applied to all
the ages under 20.

It is necessary to add, that such a table will give the
number of inhabitants, and the probabilities of life equally
wrong before 20, whether the recruits all come in at 25;
agreeably to the supposition just made, or only begin then
to come in. In this last case, the table will give the num-
ber of inhabitants, and probabilities of life, too great through-
out the whole extent of life, if the recruits come in at all
ages above 20. But if they cease at any particular age, it
will give them right only from that age; and before, it will
come along on the side of excess; but less considerably be-
tween 20 and that age, than before 20. For example: if,
of the 250 supposed to come in at 20, only 150 then come
in, and the rest at 30; the number of the living will be
given too high, at every age between 20 and 30; but, as
just shown, they will be given 250 too high at every age
before 20. In general, therefore, the number of the living
at any particular age must be given by the supposed table,
as many too great as there are annual letters after that age;
and, if these supplies come in at all ages indiscriminately,
during any certain interval of life, the number of inhabitants
and the probabilities of life will be continually growing less
and less wrong, the nearer any age is to the end of that in-
terval. These observations prove, that tables of observa-
tion formed in the common way, from bills of mortality for
places where there is an excess of the burials above the
births, must be erroneous, for a great part of the duration
of life, in proportion to the degree of that excess. They
show likewise at what parts of life the errors in such tables
are most considerable, and how they may be in a great meas-
ure corrected.

All this shall be exemplified in the particular case of
London.

The number of deaths between the ages of 10 and 20, is
always too small in the London bills, that it seems certain
few recruit's come to London under 20; or, at least, not
so many as before this age are sent out for education to
colleges and universities. After 20, great numbers come in
till 30; and some, perhaps, till 40 or 50. But at every
age after 50, it is probable, that more retire from London
than come to it. The London tables of observa-
tion, therefore, being formed on the principle already mentioned,
cannot give the probabilities of life right till 40. Between
30 and 40 they must be a little too high; but more so between
20 and 30; and most of all before 20. It follows also,
that these tables must give the number of inhabitants
in London much too great.

The first of the following tables is formed in the manner
here explained, from the London bills for ten years, from
1750 to 1760; and adapted to a 1000 born as a radix. The
sum of the numbers in the second column, diminished by
half the number born, is 25757. According to this table,
then, for every 1000 deaths in London, there are 25757
many inhabitants; or, in other words, the expectation of a
child just born is 25757; and the inhabitants are to the annual
burials, as 25757 to 1. But it has appeared that the numbers
in the second column, being given on the supposition, that
all those who die in London were born there, must be too
great; and we have from hence a demonstration, that the
probabilities of life are given in the common tables, of
London observations, too high, for, at least, the first 30
years of life; and also that the number of inhabitants in
London must be left too high, multiplied by the annual
burials. The common tables, therefore, of London obser-
vations undoubtedly need correction, as Mr. Simpson sug-
gested, and in some measure performed; though too im-
perfectly, and without going upon any fixed principles, or
shewing particularly, how tables of observation ought to be
formed, and how far in different circumstances, and at dif-
ferent ages, they are to be depended on. The way of doing
MORTALITY.

This, and, in general, the right method of forming genuine tables of observation for towns, may be learnt from the following rule.

"From the sum of all that die annually, after any given age, subtract the number of annual settlers after that age; and the remainder will be the number of the living at the given age."

This rule can want no explication or proof, after what has been already said.

If, therefore, the number of annual settlers in a town at every age could be ascertained, a perfect table of observations might be formed for that town, from bills of mortality, containing an account of the ages at which all die in it. But no more can be learnt in this instance, from any bills than the whole number of annual settlers, and the general division of life in which they enter. This, however, may be sufficient to enable us to form tables that shall be tolerably exact. For instance: supposing the annual deaths in a town which has not increased or decreased, to have been for many years in the proportion of 4 to 3, to the annual births. It will hence follow, that ⅓ of the perfon who die in such a town are settlers, or emigrants from other places, and not natives; and the sudden increase in the deaths after 20, will also shew that this was an unforeseen event that they enter after this age. In forming, therefore, a table for such a town, a quarter of all that die at all ages through- out the whole extent of life, must be deducted from the sum of all that die after every given age before 20; and the remainder will be the true number living at that given age. And if, at 20, and every age above it, this deduction is omitted, or the number of the living at every such age is taken the same with the sum of all that die after it, the result will be (supposing most of the settlers to enter in before 30, and all before 40) a table exact till 20; too high between 20 and 30; but nearly right for some years before 40; and after 40 exact again. Such a table, it is evident, will be the same with the table last delineated at all ages above 20, and different from it only under 20. It is evident also that, on account of its giving the probabilities of life too great for some years after 20, the number of inhabitants deducted from it may be depended on as somewhat greater than the truth; and more or less in proportion as the annual recruiting is greater or less than the number left. But let us now consider what must be the result of these remarks will be, when applied particularly to the London bills.

In must be here observed, that, at least, one quarter of all that die in London are emigrants from the country, and not natives. The medium of annual burials for ten years, from 1759 to 1769, was 22,050; of births, 15,710. The excess is 7,240, or near a third of the burials. The same excess, during ten years, before 1750, was 10,500, or near half the burials. London was then degenerating. For the last 12 or 15 years it has been increasing. This excess, therefore, agreeably to the foregoing observations, was then greater than the number of annual recruits, and it is now less. It is, however, here supposed, that the number of annual recruits is now no more than a quarter of the annual burials, in order to allow for more emigration in the births than in the burials; and also, in order to be more sure of obtaining results that shall not exceed the truth.

Of every thousand then who die in London, only 750 are natives, and 250 are recruits, who come to it after 18 or 20 years of age; and, consequently, in order to obtain from the bills a more correct table than the first of the following tables, 250 must be subtracted from every one of the numbers in the second column till 20; and the numbers in the third column must be kept the same, the bills always giving their right. After 20, the table is to be continued unaltered; and the result will be, a table which will give the numbers of the living at all ages in London much nearer the truth, but still form what may be termed the second of the following tables. The sum of all the numbers in the second column of this table, diminished by 500, is 20,750. For every 1000 deaths, therefore, in London, there are, according to this table, 20,750 living persons in it; or for every single death, 20½ inhabitants. It was before shewn, that the number of inhabitants in London could not be so great as 2½ times the deaths. It now appears (since the numbers in the second column of this table are too high) that the number of inhabitants in London cannot be so great as even 2½ times the deaths. And this is a conclusion which every one, who will bestow due attention on what has been said, will find himself forced to receive. It will not be amiss, however, to confirm it by the following fact, the knowledge of which is derived from the particular inquiry of Mr. Harris, the late ingenious master of the Royal Mathematical School in Chirith-church Hospital. The average of lads in this school has, for thirty years past, been 8½. They are admitted at 10 years, become 12½ lads, and live about eleven years; and at 21 years and sixteen, will die. They are, therefore, in general, lads between the ages of eight and sixteen. They have better accommodations than it can be supposed children commonly have; and about three hundred of them have the particular advantage of being educated in the country. In such circumstances it may be well reckoned, that the proportion of children dying annually, must be less than the general proportion of children dying annually at the same ages in London. The fact is, that for the last thirty years, 11½ have died annually, or one in 70. According to Table II. of all who complete their eighth year in London, and who are living at that age, and at every intermediate age till 16, one in 74 die annually. It follows, therefore, that according to this table, supposing the lads in Chishurch-school all admitted exactly at eight years of age, and none discharged before they have completed 16 years of age, or before they have reduced eight years (suppositions much too favourable) only a 74th part ought to die annually. This table, therefore, gives the decrements of life in London at those ages too little, and the numbers of the living too great, and this is true of all ages above 20; it must be, therefore, in conformity to what was before shewn, that more people settle in London after 20, than the quarters supposed above; and that from 20 to 35 or 40 the numbers of the living are given too great in proportion to the decrements of life. In this table the numbers in the second column are doubled at 20, agreeably to what really happens in London; and the sum of the numbers in this column diminished by half the whole number of deaths, gives the expectation of life, not of a child just born, as in other tables, but of all the inhabitants of London at the time they enter it, whether that be at birth, or at 20 years of age. The expectations, therefore, and the values of London lives under 20, cannot be calculated from this table. But it may be very easily fitted for this purpose, by finding the number of births which, according to the given decrements of life, will leave 494 alive at 20; and then adapting the intermediate numbers in such a manner to this radix, as to preserve all along between the number of the living at the same proportion to the numbers of the dead. This is done in the third of the following tables; and this table may be recommended as better adapted to the present state of London than any other table. The
The values of lives, however, deduced from it, are in general nearly the same with those deduced by Mr. Simpson from the London bills, as they stand forty years ago; the main difference is, that after 52, and in old age, this table gives them somewhat lower than Mr. Simpson's table.

For the method of applying those observations in determining the number of inhabitants in London, &c., see Expectation of Life.

Under the article Expectation, an account has been given of the difference between the rate of human mortality in great towns and in country parishes and villages. The fourth and fifth of the following tables, compared with the two last, will give a more distinct and full view of this difference:

</table>

All the bills, from which this and the following tables are formed, give the numbers dying under 1 as well as under 2 years; and, in the numbers dying under 1, are included, in the country parish in Brandenburgh, and at Berlin, all the still-born. All the bills also give the numbers dying in every period of five years.

**Table V.**

Shewing the Probabilities of Life in a country Parish in Brandenburgh, formed from the Bills for 50 Years, from 1710 to 1759, as given by Mr. Sufmilch, in his Gottliche Ordnung.

All the bills, from which this and the following tables are formed, give the numbers dying under 1 as well as under 2 years; and, in the numbers dying under 1, are included, in the country parish in Brandenburgh, and at Berlin, all the still-born. All the bills also give the numbers dying in every period of five years.
MORTALITY.

Table VI.
Shewing the Probabilities of Life at Vienna, formed from the Bills for eight Years, as given by Mr. Sufmilch, in his Gottliche Ordnung, p. 32. Tables.

**Mortality.**

Table VIII shews the Probabilities of Life in the Kingdom of Sweden among Males and Females, according to the Medium of Seven different Enumerations in 1757, 1760, 1763, 1766, 1769, 1772, and 1775.
MORTAR.

Mortar, or Morter, in Architecture, a composition of lime, sand, &c. mixed up with water: serving as a cement to bind the stones, &c. of a building.

The ancients had a kind of mortar so very hard and binding, that, after so long a duration as to this time, it is next to impossible to separate the parts of some of their buildings; though there are some who ascribe that excessive strength to time, and the influence of certain properties in the air, which is, indeed, found to harden some bodies very surprisingly.

The lime used in the ancient mortar, is laid to have been burnt from the hardest stones, or often from fragments of marble.

De Lorme observes, that the best mortar is that made of pozzolana for sand; adding, that this penetrates black flints, and turns them white. See Pozzolana, and Puteolana Pulvis.

Mr. Worledge observes, that fine sand makes weak mortar, and that the larger the sand the stronger the mortar. He therefore advises, that the sand be washed before it is mixed; and adds, that dirty water weakens the mortar considerably.

Vitruvius observes, that the finest sands dry sooner than those taken out of rivers. Whence he adds, the latter is fit for the inlaid, the former for the outlaid of a building. He subjoins, that the finest sand, lying long in the air, becomes earthy. Palladio takes notice, that all sands white ones are the worst; and the reason is owing to their want of aperity.

The proportion of lime and sand in our common mortar is extremely variable. Vitruvius prefers three parts of pit-sand, and two of river-sand, to one of lime; but the quantity of sand here seems to be too great.

The proportion most commonly used in the mixing of lime and sand is, to a bushel of lime a bushel and a half of sand, i. e. two parts of lime and three of sand; though the common mortar, in and about London, has more sand in it than according to this proportion. The improvement of mortar is certainly an object of great importance; and different schemes have been suggested for giving it that degree of durability for which the mortar used by the ancients is justly celebrated.

Mr. Dowsie, in the second volume of the Memoirs of Agriculture, p. 20, &c. gives the following method of making mortar imperceptible to moisture, acquiring great hardnese, and exceedingly durable, similar to that used by the ancients, which was discovered by a gentleman of Neufchatel: take of unflaked lime and of fine sand, in the proportion of one part of the lime to three parts of the sand, as much as a labourer can well manage at once; and then adding water gradually, mix the whole well together with a trowel, till it be reduced to the consistence of mortar. Apply it immediately, while it is hot, to the purpose, either of mortar, as a cement to brick or stone, or of plaster to the surface of any building. It will then ferment for some days in drier places, and afterwards gradually concretes, or set, and become hard; but in a moist place it will continue soft for three weeks or more; though it will at length, attain a firm consistence, even if water have such access to it so as to keep the surface wet the whole time. After this, it will acquire a stone-like hardnes, and resist all moisture. The perfection of this mortar depends on the ingredients being thoroughly blended together; and the mixture being applied immediately after to the place where it is wanted. The lime for this mortar must be made of lime-flue, shells, or marle; and the stronger it is, the better the mortar will be; besides, the lime should be carefully kept from the access of air or wet; otherwise, by attracting moisture, it will loose proportionally that power of acting on the sand, by which the incorporation is produced. It is proper also to exclude the sun and wind from the mortar, for some days after it is applied; that the drying too fast may not prevent the due continuance of the fermentation, which is necessary for the action of the lime on the sand. When a very great hardnese and firmnes are required in this mortar, the using of skimmed milk instead of water, either wholly or in part, will produce the desired effect, and render the mortar extremely tenacious and durable.

M. Loriot's mortar, the method of making which was announced by order of his majesty at Paris in 1774, is made in the following manner: take one part of brick-duft finely sifted, two parts of fine river-sand skreened, and as much old flaked lime as may be sufficient to form mortar with water, in the usual method, but to wet as to serve for the sticking of as much powdered quick-lime as amounts to one-fourth of the whole quantity of brick-duft and sand. When the materials are well mixed, employ a small quantity of quick-lime in the leaf, may be added, after the application of it imperfect or impossible. Another method of making this composition is to make a mixture of the dry materials; i. e. of the sand, brick-duft, and powdered quick-lime, in the prescribed proportion; which mixture may be put in sacks, each containing a quantity sufficient for one or two troughs of mortar. The above-mentioned old flaked lime and water being prepared apart, the mixture is to be made in the manner of plaster, at the instant when it is wanted, and is to be well chafed with the trowel. With respect to this method, Dr. Higgins observes, that M. Loriot corrects the bad quality of the old and effete lime, which constitutes the basis of his mortar, and which has regained a part of the fixed air that had been expelled from it, by the addition of fresh and non-effervescent lime, halfly added to it, at the time of using the composition, which must undoubtedly improve the imperfect mass. And he adds, that when an ignorant artist makes mortar with whiting instead of lime, he can mend it considerably by adding lime to it; but his mortar will still be defective, in comparison with the best and most durable, and composed of old flaked lime or whiting; this on repeated trials he has found to be the true flate of the case. Dr. Higgins has made a variety of experiments, in consequence of the modern discoveries relating to fixed air, for the purpose of improving the mortar used in our buildings. According to this author, the perfection of lime, prepared for the purpose of making mortar, consists chiefly in its being totally deprived of its fixed air. On examining several specimens of the lime commonly used in building, he found that it is seldom or never sufficiently burned; for they all effervesced, and yielded more or less fixed air, on the addition of an acid, and flaked slowly, in comparison with well burned lime. Dr. Higgins also relates some experiments, which shew how very quickly lime imbibes fixed air from the atmosphere; on its exposure to which it by degrees looses those characters which chiefly distinguish it from mere lime-flue or powdered chalk: bysoon attracting from thence that very principle, to the absence of which it owes its useful quality as a cement, and which had before been expelled from it in the burning. Hence he concludes, that, as lime owes its excellence to the expulsion of fixed air from it in the burning, it should be used as soon as possible after it is made, and guarded from exposure to the air, as much as possible, before it is used. It is no wonder, therefore, he says, that the London mortar is bad, if the imperfection of it depended solely on the badness of the lime; since the

C C 2
MORTAR.

lime employed in it is not only bad when it comes fresh from the kiln, because it is insufficiently burned, and the air has access to it, but becomes worse before it is used, by the distance and mode of its conveyance, and when flaked, is as widely different from good lime, as it is from powdered chalk. For a similar reason, every other cause, which tends to restore to the lime the fixed air, of which it had been deprived in the burning, must deprive it. It must receive this kind of injury, for instance, from the water, so largely used, at first in flaking the lime, and afterwards in making it into mortar; if that water contains fixed air, from which few waters are perfectly free, and which will greedily be attracted by the lime. The injury arising from this cause is prevented by the sublimation of lime-water, so far as may be practicable or convenient.

From other experiments, made with the view of ascertaining the relative proportions of lime, sand and water, in the making of mortar, it appeared that those specimens were the best which contained one part of lime in seven of the sand; for those which contained less lime, and were too short whilst fresh, were more easily cut and broke, and were practically more to water; and those which contained more lime, although they were closer in grain, did not harden so soon or to so great a degree, even when they escaped cracking by lying in the shade to dry slowly. It appeared farther, that mortar, which is to be used where it must dry quickly, ought to be made as stiff as the purpose will admit, or, with the smallest practicable quantity of water, and that mortar will not crack, although the lime be used in excessive quantity, provided it be made stiffer, or to a thicker consistence than mortar usually is.

Dr. Higgins has also shewn, that though the setting of mortar, as it is called by the workmen, chiefly depends on the evaporation of it, yet its induration, and its acquiring a fowy hardnefs, is not caused by its drying, as has been supposed, but is principally owing to its abstraction of fixed air from the atmosphere, and is promoted in proportion as it acquires this principle; the accession of which is indispensably necessary to the induration of calcareous cement. In order to the greatest induration of mortar, therefore, it must be suffered to dry gently and slow; the evaporation must be effected by temperate air, and not accelerated by the heat of the sun or fire; it must not be wetted soon after it sets; and afterwards it ought to be protected from wet as much as possible, until it is completely indurated; the entry of acridulous gas must be prevented as much as possible, until the mortar is finally placed and quickset: and then it must be as freely exposed to the open air as the work will admit, in order to supply acridulous gas, and enable it sooner to fulfill the trials to which mortar is exposed in cementations buildings, and incrustations.

Dr. Higgins has also enquired into the nature of the best sand or gravel for mortar, and into the effects produced by bone-ashes, pitch powder, charcoal, sulphur, &c. and he deduces great advantages from the addition of bone-ashes, in various proportions, according to the nature of the work for which the composition is intended.

This author describes a water-cement or tucco, of his own invention, for incrustations internal and external, exceeding, as he says, Portland stone in hardnefs, for which he obtained his majesty's letters patent in 1779. As for the materials of which this is made; drift sand, or quarry sand, or, as it is commonly called, pit sand, containing chiefly of hard quartzite flat-faced grains, with sharp angles, the mortar free from clay, fels, and calcareous, gypseous, or other grains. Fix, disposed of water, containing the smallest quantity of pyrites, or heavy metallic matter, in

Prepara by washing, and admitting the least diminution in bulk by washing, is to be preferred to any other. The sand is to be sifted in streaming clear water, through a sieve which shall give passage to all such grains as do not exceed one sixteenth of an inch in diameter; and the stream of water and sifting are to be so regulated, that all the sand, which is much finer than the Lynn sand, together with clay and other matter, specifically lighter than sand, may be washed away with the stream; whilst the purer and coarser sand, which passes through the sieve, subdues in a convenient receptacle; and whilst the coarse rubbish and shingle remain on the sieve to be rejected. The fulminating sand is then washed in clean streaming water, through a finer sieve, so as to be further cleansed and sorted into two parcels, a coarser, which will remain in the sieve which is to give passage to such grains of sand only as are less than one thirtieth of an inch in diameter, and which is to be saved apart under the name of coarse sand; and a finer, which will pass through the sieve and subdue in the water, and which is to be saved apart under the name of fine sand. These are to be dried separately, either in the sun, or on a clean iron plate set on a convenient surface, in the manner of a sand heat. Let the lime be chosen, which is bone-lime, which heats the most in flaking, and flakes the quickest when duly watered; which is the freest made and most closely kept; which diffolves in distilled vinegar with the least effervescence, and leaves the smallest residue insoluble, and in this residue the smallest quantity of clay, gypsum, or martial matter. Let this lime be put in a bals-wired fine sieve, to the quantity of fourteen pounds. Let the sand be shaken by plunging it in a basket, filled with soft water, and raising it out quickly and suffering it to heat and fume, and by repeating this plunging and raising alternately, and agitating the lime, until it be made to pass through the sieve into the water: reject the part of the lime that does not easily pass through the sieve; and use fresh portions of lime, till as many ounces of lime have passed through the sieve as there are quarts of water in the bucket. Let the water, thus impregnated, stand in the bucket, clean covered, until it becomes clear; and, through wooden cock placed at different heights in the bucket, draw off the clear liquor, as fast and as low as the lime fubdues, for use. This clear liquor is called the cementing liquor. Let fifty pounds of the forefauled choine lime be flaked, by gradually sprinkling on it, and especially on the unflaked pieces, the cementing liquor, in a close clean place. Let the flaked part be immediately sifted through the fine bals-wired sieve. Let the lime which passes be used instantly, or kept in air-tight vessels, and let the part of the lime which does not pass through the sieve be rejected; the other part is called purified lime. Let bone-ash be prepared in the usual manner by grinding the whitest burnt bones; but let it be sifted to be much finer than the bonengrained commonly sold for making cupels. Having thus prepared the materials, take fifty-six pounds of the coarse sand, and forty-two pounds of the fine sand; mix them on a large plank of hard wood placed horizontally; then spread the sand so that it may stand to the height of six inches, with a flat surface on the plank; wet it with the cementing liquor; to the wetted sand add fourteen pounds of the purified lime, in several successive portions, mixing and beating them up together; then add fourteen pounds of the bone-ash in succedaneous portions, mixing and beating all together. This Dr. Higgins calls the water-cement coarse-grained, which is to be applied in building, painting, plattening, flooring, &c. differing to white, it excellently fills all cafes, and in fluxing to lay it on by filling the trowel upwards upon it; to wet the materials used with it, in the ground on which it is laid, with the cementing liquor, at
the time of laying it on; and to use the cementing liquor for moistening the cement and facilitating the floating of it. If a cement of a finer texture be required, take ninety-eight pounds of the fine sand, wet it with the cementing liquor, and mix it with the purified lime and the bone-ash as above, with this difference, that fifteen pounds of lime are to be used instead of fourteen pounds, if the greater part of the sand be as fine as Lyon sand. This is called water-cement fine-grained; and is used in giving the kind coating or finish to any work, intended to imitate the finer grained stones or stucco. For a cheaper and coarser cement, take coarse sand or thong five fix pounds of the foregoing coarse sand twenty-eight pounds, and of the finer sand fourteen pounds: and after mixing and wetting these with the cementing liquor, add fourteen pounds, or somewhat less, of the purified lime; and then as much of the bone-ash, mixing them together. When the cement is required to be white, white sand, white lime, and the whitest bone-ash are to be chosen. Grey sand, and grey bone-ash, formed of half-burnt bones, are to be chosen to make the cement grey; and any other colour is obtained, either by chafing coloured sand, or by the admixture of the necessary quantity of coloured tale in powder, or of coloured vitreous or metallic powders, or other durable colouring ingredients, commonly used in paint. The water-cement above described is applicable to forming artificial stone; by making alternate layers of the cement and of flint, hard stone, or brick, in moulds of the figure of the intended stone, and by exposing the maffles so formed to the open air to harden. When it is required for water fences, two-thirds of the bone-ashes are to be omitted, and in its first an equal measure of powdered terras is to be used. When the cement is required of the finest grain, or in a fluid form, so that it may be applied with a brush, flint powder, or the powder of any quartoz or hard earthy fulness, may be used in the place of sand, so the powder shall not be more than five times the weight of the lime, nor less than four times its weight. For initial work, the admixture of hair with the cement is useful. Higgins’s Exp. & Obs. on Carcaceous Cements, &c. 1778e, palfim. See STUCCO.

Mortar. Mixing and Blending of. M. Felthien observes, that the ancient masons were far more scrupulous in this proceed, that the Greeks kept ten men constantly employed, for a long space of time, to each basin; this rendered the mortar of such prodigious hard-ness, that Vitruvius tells us the pieces of plaster falling off from old walls felled to make tables. The same Felthien adds, it is a maxim among old masons to their labourers, that they should dilute with the sweat of their brow, i.e. labour it a long time, instead of drowning it, with water to have done the sooner.

Mortar-Mill, in Rural Economy, a machine contrived by Mr. Supple, for the purpose of saving labour in the making up of mortar, as well as doing the business more effectually and at a trifling expence. It may also be useful in working clay, &c.

And the mode of doing it is thus described by the inventor: “A pit is dug in the ground, which is bricked at the bottom and sides, into which the operator puts the lime. He has a small pond in a small pond of water, which is conveyed at pleasure into the pit, and in a few days the lime is sufficiently faked; he then puts the lime and sand, or gravel, into the mill, which not only mixes both together, but incorporates them in a very effectual manner; and, as the lime is sufficiently moist when taken out of the pit, no more water is required for the mortar. If for present use, the quantity he makes at a time is six bushels, as he finds when more is put in, it is apt to strain the cogs, if not made very strong. If the mortar is made with sand alone, the space between the cogs need not be made so wide as three inches. He has a second shaft, with clover cogs, in order to give the mortar another working; the space between these cogs is but two inches; but it does not answer well till after the first shaft has been used, nor is it necessary, unless for very nice work.” He adds, that he “made 200 barrels of lime into mortar last summer, and has now the like quantity of lime in the pit for the same purpose. He made six barrels of mortar in a day with ease; a boy of seven years old drives the horse, and the most indifferent one is good enough for the purpose, the draught being so easy.” This machine may be wrought by any other power, as water, wind, or steam.

The nature, plan, and construction of the machine are seen at fig. 4, in Plate XXIV. Miscellany, in which A is the plan of the boarded door, raised eight inches from the ground, four feet two inches in diameter, and surrounded by a fourteen-inch wall, whose outside height is two feet. B, a sliding door, two feet wide. C, plan of the shaft, with its cogs, or teeth; its length eleven feet eight inches, breadth eight inches, depth five inches. D, plan of the pot, or axis, on which the shaft turns round; diameter seven inches, height twenty inches. E, plan and upright of one of the cogs, as it stands in the mill. The plan is a rhombus, the longest diagonal is three inches, the short side but two, in order to make the angles of the cogs more acute, by which means they will pass through the mortar with the greater ease.

F, elevation and section of the mill in perspective.

The inventor states, that the space between the cogs is but three inches, except the first to the left of the pot, which is but half an inch distant from it, in order to give the cogs to the left a different direction from those on the right; and its use will, by inspection, readily appear. There must be a space of two inches between the end of the cogs and the wall, in order to give the gravel a free passage, which would otherwise strain the cogs, and stop the course of the mill.”

Besides the common mortar used in laying of stones, bricks, &c., there are several other kinds: as

Mortar. White, used in plattiering the walls and ceilings; made of ox or cow’s hair mixed with lime and water, without any sand. The common method of making this mortar is one bushel of hair to six bushels of lime.

Mortar used in making Water-Courses, Jiffy, &c. is very hard and durable, being made of lime and hogs-grease, sometimes mixed with the juice of figs, and sometimes with liquid pitch; and, after application, is washed over with linseed-oil. See BETON.

For this purpose, mortar made of terras, pozzolana, tile-dust, or cinders, is mixed and prepared in the same manner as common mortar; only that these ingredients are mixed with lime, instead of sand, in a due proportion, which is about half and half. The lime should be made of shells or marble; and in works which are sometimes dry and sometimes wet, instead of terras, which is very dear, tile-dust or cinder-dust may be used.

Mortar for Furnaces, &c. See LUTE.

Mortar for Sun-Dials on walls may be made of lime and sand, tempered with linseed-oil; or, for want of that, with linseed milk. This will grow to the hardners of a flow.

For buildings, one part of washed soap-ashes, mixed with another of lime and sand, make a very durable mortar. See CEMENT.

The salt petre workers in France using the mortar of old buildings for extracting that salt, M. Petit has thought it worthy a peculiar attention, and has made several trials, by way of analysis of mortar, to determine whether it really
and essentially contains nitre in it, or whether it be only serviceable in that mixture of salts from which nitre is produced.

The common managers of the saltpetre works are of opinion, that mortar contains in it all the saltpetre they procure from it; and that the wood-ashes, and other substances they use with it, only serve to absorb the fat or oily parts, and to let the saltpetre at liberty to foam. Thus they pretend to affirm upon experience; but they do not consider, that though they can procure saltpetre from the rubbish or mortar without the addition of wood-ashes, yet it is not pure mortar that they make their experiments upon, but such as is taken from their own heaps, upon which they always throw all the residuum of their former works, and all that liquor which will shoot no more crystals, but which they call the mother-water of saltpetre.

This gentleman, therefore, very properly judged, that to make a regular trial of the mortar or rubbish alone, he must not take it from their stores, used in the saltpetre works, but pick it himself from the ruins of old buildings.

The mark the saltpetre workers have to know good mortar for their purpose is, that it takes acid and salt when applied to the tongue; but to this it may be also added, that it ought to be of a greyish colour, and such as, when powdered and sprinkled upon burning charcoal, yields some sparks of fire; and the more sparks it gives, the better it is for the purpose; and another character of the goodness is, that these well impregnated mortars have a certain uncertainty or finitnes to the touch, which other kinds have not.

The finest of all kinds of mortar for saltpetre work is such as is had from the ruins of old buildings in a low situation, and out of the way of much sunshine; where there has been no great quantity of fire kept, and especially such as has served for the cements of the walls of flaves, or the like.

M. Petit chose from such a wall twelve pounds of old mortar: this he had beaten to powder, and poured upon it eight pints of water; the whole was then set over the fire, and lirred from time to time for three or four hours, that the water might be well tinctured from the mortar; after this the water was filtered through paper, and was then found to be tinctured to a pale, yellow, transparent bitter, and somewhat acid to the taste.

The impregnation may be made without heat, by only stirring the mortar about for nine or ten days in cold water, and a quantity of the salt taken up will be according to the goodness of the mortar and the quantity of water employed.

The common specific gravity of this liquor to water is as 32 to 31, or thereabouts. M. Petit having procured the tincture of fifty pounds of mortar, by several impregnations, in 72 French pints of water, evaporated it so far till it appeared highly charged with saline particles, tainting very acid and bitter, and being of a brownish-red colour; and its specific gravity was in this state to water as 4 to 3, there being more in quantity than about four pints. This was still limpid and of a dusky colour, and was afterwards evaporated over a gentle fire, to the consequence of an extract, which, as it cooled, became much thicker and firmer, resembling butter. This being left open to the air, soon relected into a liquor of the consequence of a syrup: its specific gravity was now to water as 45 to 3; but in leaving it open to the air, it continually attracted fresh humidity, and became less specifically heavy. Experiments made with this extract succeeded in the following manner:

1. It turned the common blue paper to a fine deep red.

The impregnations in water unimpaired do this also in different degrees, according to their strength.

2. Mixed in equal quantities with spirit of nitre and with spirit of sea-salt, it made no effervescence or alteration in either.

3. A leaf of gold being put into the mixture of this impregnation with spirit of nitre, was immediately dissolved; and in an hour or two afterwards, the liquor was much clearer than before.

A leaf of gold being put into the mixture of this impregnation and spirit of sea-salt, was in the same manner dissolved in a few minutes. It is generally supposed, indeed, that the spirit of salt alone will diffuse gold; but there seems to be an error in this, founded on the inaccuracy of the preparation of such spirit of salt; for Messrs. Geoffroy and Boulud have at different times produced before the French Academy spirit of salt carefully prepared by themselves, which would not at all diffuse gold, not even with the assistance of heat: even such spirit of salt would, however, be made to diffuse gold, by mixing this impregnation with it; so that it has the power of dissolving gold in a great degree.

4. A leaf of silver being dissolved in spirit of nitre, and this impregnation of mortar added to the solution, the whole became turbid, and a precipitation happened, part of the matter being thrown to the bottom, and part remaining suspended in form of a white cloud, which kept its place without falling.

5. The impregnation being mixed in equal quantities with oil of vitriol formed a coagulum, and made a great effervescence, with copious red vapours, and a strong smell of aqua fortis; and these vapours appeared at any time, on stirring the mixture, for several days together. If a larger quantity of oil of vitriol be added to this coagulum, it all becomes fluid, but ferments violently; and finally, there will be a white matter precipitated to the bottom of the clear liquor; and if a leaf of gold be brought near this mixture, it will be diffused even by the vapour which exalts from it. Spirit of nitre has no effect upon this mixture, either in its state of coagulum, or when reduced by more oil of vitriol into a clear liquor; but the volatile spirit of urine ferments violently, without the leaf heat with it.

6. Oil of tartar per deliquium being added to the impregnation, the liquors would not readily mix, but remained separate, the impregnation sinking to the bottom; but on stirring them thoroughly together, they finally were made to unite into a white substance like butter, with a strong urinous smell. If a small quantity of corrosive sublimate be added to this mixture, the urinous smell ceases; and if oil of vitriol be added, there is a violent fermentation occasioned; and, in fine, a large quantity of precipitate.

7. This impregnation of mortar being mixed with an equal quantity of a solution of corrosive sublimate, there is nothing remarkable produced, though the mixture be ever so much shaken; but if a little oil of tartar per deliquium be added to this, the mixture becomes turbid, and, on stirring all together for some time, it becomes white and thick like butter. If to this, more corrosive sublimate be added in solution, it becomes orange-coloured; and, on more stirring, this becomes again white; and finally gives a white precipitate at the bottom of a transparent liquor.

8. If, instead of oil of tartar, an equal quantity of lime-water be added, this in the same manner gives an urinous smell, and the whole difference is, that the mixture will not become thick with this, as it will with oil of tartar.

9. The impregnation of mortar produced the same coagulum in mixing with spirit of urine, that it did with oil of tartar per deliquium; but it made no coagulation with spirit of sulphuric acid with lime: the occasion of this difference is, that the spirit of urine contains a great deal of volatile salt, and the other but little. It is a common error to suppose...
pose that the spirit of sal ammoniac, which is most pungent, contains the greatest quantity of salt; but this is not the case, for the spirit made with lime is much more pungent than that with salt of tartar, though the last is well known to contain a much larger proportion of saline particles.

10. If a piece of paper or linen be wetted in this impregnation, and afterwards dried, it takes fire very violently, and sparks with the same violence as if it was impregnated with salt petre.

From these experiments it is abundantly proved, that the impregnation of mortar contains a large quantity of a saline and nitrous ammoniacal salt; for a dissolition of sal ammoniac and spirit of nitre, mixed together, are found to produce all the changes in the different bodies before named, that the impregnation does. On the whole, though it has been supposed by Mr. Tournefort, and others, that mortar contained salt petre, sea-salt, and a fixed alkali; yet there does not appear any proof of its containing any of these salts: no fixed alkali can ever be separated from the impregnation of it; and though the linen or paper, wetted in the impregnation of it, sparkled when on fire, yet it is not nitre, but merely a residue of sal ammoniac, which occasioneth that phenomenon. The same effect is produced, if mortar be wetted with a mixture of spirit of urine and spirit of nitre. And the several experiments before recited prove, that there is in mortar a spirit of nitre and a spirit of sea-salt, which, with the volatile urinous salts, form a nitrous or a saline ammoniac. Mem. Acad. Scienc. Par. 1734.

Mortar, in Chemistry, &c. is an instrument very useful for the division of bodies, partly by percussion, and partly by grinding. They have the form of an inverted bell, and are made of all fizes and materials, as marble, copper, glafs, iron, girt-iron, and agate. The matter intended to be pounded is to be put into them, and there struck and bruised by a long instrument called a pelle. This, when large and heavy, ought to be suspended by a cord, or chain, fixed to a moveable pole, placed horizontally above the mortar, which considerately relieves the operator, because its elasticity afflits the raising of the pelle.

Mortar, in the Military Art, a short piece of ordnance, thick and wide. proper for throwing bombs, carcafses, shells, fizings, andвизings. The purpose of mortar is thought to be older than that of cannon: for they were employed in the wars of Italy, to throw balls of red-hot iron and stones, long before the invention of shells. It is gene-

erallv believed that the Germans were the first inventors. See BOMBE.

The method of throwing red-hot balls out of mortars was first put in practice at the siege of Stralsund in 1675, by the elector of Brandenburg; though some say, in 1653, at the siege of Dremen. For a further account of mortars, see CANNON.

Mortar, Cockorn, a small kind of mortar, invented by the famous engineer baron Cocborn, to throw small shells or grenades. These mortars are commonly fixed, to the num-

ber of a dozen, to a block of oak, at the elevation of 45°. See CANNON.

Mortars, Fire-lock, or Bombards, are small mortars, fixed at the end of a fire-lock: they are loaded as all common fire-locks are; and the grenade, placed in the mortar at the end of the barrel, is discharged by a flint lock; and to prevent the recoil from hurting the bombardier, the bombard is on a kind of halberd made for that purpose. They were first invented by major-general Siebch, a German, about the year 1740.

Mortars, Hand, were frequently used before the invention of coehorns. See CANNON.

Mortars, Land. See CANNON.
MOR

quenty one piece being well proved, i.e. the range of the grenado, bomb, carcafe, &c. being found to any degree of elevation, the whole work of the mortar-piece would become very easy and exact.

But since mortars are not thus familiar, it is required, that the range of the piece, at some known degree of elevation, be accurately found by measuring; and from hence all the other ranges may be determined.

Thus, to find the range of the piece at any other elevation required; say, as the fine of double the angle under which the experiment was made, it to the fine of double the angle proposed, is the range known to the range required.

Suppose, for instance, it be found, that the range of a piece, elevated to 30°, is 2000 yards; to find the range of the same piece, when elevated to 45°.

First, take the line of 60°, the double of 30°, and make it the first term of the rule of three; the second term must be the fine of 90°, the double of 45°; and the third the given range 2000; the fourth term will be 2342, the range of the piece at 45°. If the elevation be greater than 45°, instead of doubling it, take the fine of double its complement to 90°.

As supposed the elevation of a piece be 50°, take the line of 80°, the double of 40°. Again, if a determined distance to which a shot is to be cast, is given, and the angle of elevation to produce that effect be required; the range known must be the first term in the rule of three, which suppose 2000 yards; the range proposed, which we suppose 1600 yards, the second term; and the fine of 60°, double of the elevation for the range of 2000 yards, the third term. The fourth term will be found the fine of 43° 52', whose half, 21° 56', is the angle of the elevation the piece must have to produce the desired effect. And if 21° 56' be taken from 90°, you will have 68° 4'' for the other elevation of the piece, with which the same effect will likewise be produced.

Note, to avoid the trouble of finding fines of double the angles of proposed elevations, Galileo and Torricelli give us the following table, in which the fines of the angles sought are had by inspection.

</table>

The use of the table is obvious. Suppose, for instance, it be known by experiment, that a mortar elevated 15°, charged with three pounds of powder, will throw a bomb to the distance of 350 fathoms: and it be required, with the same charge, to throw a bomb 100 fathoms farther; seek in the table the number answering to 15 degrees, and you will find it 5000. Then as 350 is to 450, so is 5000 to a fourth number, which is 6428. Find this number, or the nearest to it, in the table, and against it you will find 20°, or 70°; the proper angles of elevation. See Range.

For the weight, dimensions, &c. of the bombs, &c. to be cast out of mortars, and the lines of their projection, see BOMB and PROJECTILE.

MORTARA, in Geography, a town of Italy, in the region of the Lombards, being defeated by Charlemagne; seven miles N. of Lucello. MORTAROLOM, a word applied by different writers to different things; from their resemblance to a mortar in shape. The chemists express by this name a small mould made for fashioning their copels; and anatomists call the sockets of the teeth, the mortaria of the jaws.

MORTE, in Geography, a lake of the county of Tyrol; 10 miles E. of Trent.

MORTE Point, a cape of England, on the W. coast of Devonshire, at the entrance of the Bristol channel. N. lat. 51° 16'. W. long. 4° 8'.

MORTEA, a town of France, in the department of the Doubs, and chief place of a canton, in the district of Pontarlier; 12 miles S.E. of it. The place contains 1384, and the canton 6601 inhabitants, on a territory of 2000 square leagues, in seven communes.

MORTELLARI, MICHEL, in Biography, a Neapolitan composer, and excellent singing-master, came from Italy to England with the earl and countess of Spencer in 1750, and immediately had offers of numerous pupils in the first families in the kingdom. He had composed several operas before he left Italy: as "Le Affliture Amorofe," in 1775; "Erio," in 1776; "Don Salterio Citeto," "Il Barere di Lago Nero," "1778; "Alejandro nell' Ind."

His flight through very agreeable and in good taste, never reached the grand or sublime; but his single airs and cantatas abounded in grace and elegance of a particular kind: there is so much facility in them, and they seem to be natural, that it is difficult to imagine the melodies to be new; however, he is guilty of no common plagiarism; for upon examination, we can only find, that he has robbed nature in sentimental expression.

He composed in England the opera of "Armida," jointly with Grefich, in 1786, for Rubini and the Maria. Indeed all the music of this drama, except Maria's songs, were furnished by Mortelli, who had been a disciple of Piccin; but though of the Neapolitan school, his compositions are less bold, nervous, and spirited, than elegant, graceful, and pleasing; but being by birth Palermite, his strains may perhaps be more properly called Sicilian than Neapolitan.

When he quitted England, where, by great labour and economy, he had accumulated a considerable sum of money, which he lent to a Venetian nobleman, who, dying before the writings were properly executed, we fear the money, which he had hitherto advanced, was never refunded by the executors of his noble friend.

After this melancholy event he went into Russia, whence we have not heard of his return.

MORTER, or MORTARA, perhaps the Cenetenum of Pliny, in Geography, an island of the Adriatic, near the coast of Dalmatia, three miles beyond the rock Steffano, 13 miles.
miles in circuit, delightfully situated, susceptible of cultivation, but thinly inhabited. It has a good harbour, and a town in an agreeable valley. Its marble is full of marine sublations; the soil is various; and the strain by which it is separated from the continent is narrow and dangerous. Its inhabitants are addicted to smuggling and piracy. Not far from Morter, on the continent, is "Vodizza," a village noted for its cherries, from which a delicious liquor, called Maraskin, is extracted. N. lat. 43° 57'. E. long. 17° 44'.

MORBERE, in English Antiquity, a mortarium, a light or taper set in churches, to burn over the graves or ashes of the dead.

MORERO, in Geography, a small island of the Mediterranean, near the coast of Sardinia. N. lat. 41° 8'. E. long. 9° 45'.

MORTAGE, in Lact, an obligation, whereby lands or tenements of a debtor are pawned or bond over to the creditor for money, or other effects, borrowed; peremptorily to be the creditor's for ever, if the money be not repaid at the day agreed on.

In this sense, mortgage, in the common law, amounts to much the same with hypotheca, in the civil law.

The creditor holding such land on such agreement, is in the mean time called recent in mortgage. He, who lays the pawn or gage, is called the mortgager; and he that takes it, the mortgagee. If a mortgage includes excessive injury, it is prohibited by the statute 37 Hen. VIII.

The French sometimes use the word mortgage in the same sense in their language, where it stands in contradistinction to a simple contract, which does not carry with it the mean profits, and which they call eij gage, life-pledge.

Granville defines mortgage, mortuum nadum, to be that "enius frutuis vel reiultus interim perspect in nullo se acquietat. Thus, it is called mortgage, i.e., dead gage, of mort, death, and gage, pledge; because whatever profit it yields, yet it redeems not itself by yielding such profit, except the whole sum borrowed be likewise paid at the day; the mortgagee being by covenant to receive the profits till default of payment. Others hold it called mortgage, because, if the money be not paid at the day, the land, mortis, dies, to the debtor, and is forfeited to the creditor.

Thus, if a man borrows of another a specific sum (e.g. 200l.) and grants him an atale in fee, on condition that if be, the mortgager, shall repay the mortgagee the said sum of 200l. on a certain day, mentioned in the deed, that then the mortgager may re-enter on the estate so granted in pledge; or, as is now the more usual way, that the mortgager shall convey the estate to the mortgagee; in this case, the land, which is so put in pledge, is by law, in case of non-payment at the time limited, for ever dead and gone from the mortgager; and the mortgagor's estate in the lands is then no longer conditional, but absolute. But as it was formerly a doubt (Litt. § 257. Cro. Car. 191.), whether by taking such estate in fee, it did not become liable to the wife's dower, and other incumbrances of the mortgage, (though that doubt has been long ago overruled by our courts of equity, Hard. 466.) it, therefore, became usual to grant only a long term of years, by way of mortgage; with condition to be void on repayment of the mortgage-money; which course has been since pretty generally continued, principally because, on the death of the mortgagee, such term becomes vested in his personal representatives, who alone are intitled in equity to receive the money lent, of whatever nature the mortgage may happen to be. As soon as the estate is created, the mortgagee may immediately enter on the lands; but is liable to be dispossessed, upon performance of the condition by payment of the mortgage-money at the day limited. And, therefore, the usual way is to agree, that the mortgagar shall hold the land till the day assigned for payment; when, in case of failure, whereby the estate becomes absolute, the mortgagee may enter upon it and take possession, without any possibility, at law, of being afterwards evicted by the mortgager, to whom the land is now for ever dead. But here again the courts of equity interpose; and, though a mortgage be thus forfeited, and the estate absolutely vested in the mortgagee, at the common law, yet they will consider the real value of the tenements compared with the sum borrowed. And, if the estate be of greater value than the sum lent thereon, they will allow the mortgagee at any reasonable time to recall or redeem his estate; paying to the mortgagee his principal, interest, and expenses: for, otherwise, in strictness of law, an estate worth 100l. might be forfeited for non-payment of 100l. or a less sum. This reasonable advantage, allowed to mortgagees, is called the equity of redemption. And this enables a mortgagee to call on the mortgager, who has possession of his estate, to deliver it back and account for the rents and profits received, on payment of his whole debt and interest; thereby turning the mortgare into a kind of visum nadium. But, on the other hand, the mortgager may either compel the sale of the estate, in order to get the whole of his money immediately, or else call upon the mortgager to redeem his estate presently, or in default thereof to be for ever foreclosed from redeeming the same, i.e., to lose his equity of redemption without possibility of recall. And also in some cases of fraudulent mortgagers, specified in 4 & 5 W. & M. cap. 16, the fraudulent mortgager forfeits all equity of redemption whatsoever. It is not, however, usual for mortgagers to take possession of the mortgaged estate, unless where the security is precarious or small; or where the mortgager negligently ever the payment of interest. When the mortgagee is frequently obliged to bring an ejection, and take the land into his own hands, it is in the nature of a pledge, or the genus of the Roman law; whereas, while it remains in the hands of the mortgaged, it more resembles their hypotheca, which was, where the possession of the thing pledged remained with the debtor. But, by 7 Geo. II. cap. 20, after payment or tender by the mortgager of principal, interest, and costs, the mortgare can obtain no ejection; but may be compelled to re-align his securities. Blacklt. Com. bk ii. cap. 10.

The civil lawyers distingiuish 26 different kinds ofisci mortgates.

MORTIER, a badge or ensign of dignity, borne by the chancellors and great prelates of the parliaments of Paris. That borne by the chancellor was a piece of cloth of gold, lined and turned up with ermin; that of the first presidens was a piece of velvet edged with a gold lace; that of the other prelates was only a piece of gold lace.

They formerly bore it on their head, but afterwards in their hands; except in grand ceremonies, as at the entry of a king. Hence the denomination, presidens à mortier. See CAP.

MORTIER BANK, in Geography, a fishing bank near the coast of Newfoundland. N. lat. 47° 5'. W. long. 54° 48'.

MORTIFICATION, in Surgery, the death of a part of the body. This subject has been so fully treated in another volume of the present work, that it only seems necessary here to make a reference to the article GAN.

D d
MORTIFICATION, in Religion, any severe penance observed on any religious account. How ancient and how universal the practice of it has been, and for what reasons observed, see Fast.

MORTIMER, John Hamilton, in Biography, was born at Earl-Bourne in Sussex, and very early in life exhibited a decided taste and talent for painting. He was therefore placed by his parents with Hudson, but did not stay long with him, nor with Pine, to whom he afterwards went to acquire the rudiments of art. He felt that he had talents, and probably chose to take his own course in the direction of them. He accordingly went to draw from the antique in the gallery which the duke of Richmond munificently opened to artists in Pracy Gardens, and afterwards was a member of the academy in St. Martin's-lane. By his studies in these schools he acquired a considerable degree of knowledge of the human figure, but never enjoyed a feeling of the grand style.

Mortimer, endowed with the faculty of invention, did not allow it to lie unproductive in his mind, but composed a great variety of designs; which unfortunately he executed with too much facility, and was too easily satisfied with his labours, to carry them very far in the road to perfection. At the age of 22 he bore away the prize given by the Society for the Encouragement of Arts, &c. and gained great and merited applause for his performance, which, considering his youth, was at that time an uncommon one. The subject was St. Paul preaching to the Britons, and it is now the altarpiece of the church at High-Wycombe. His favourite subjects were of the grotesque or horrible kind; incantations, monsters, or representations of banditti and soldiers in violent actions. The attempts at real character which he made (and of which he has left us etchings) from some of Shakespeare's most celebrated heroes, are weak and untrue, they leave us nothing to regret in his not having indulged himself in more of the like kind, except for the freedom with which they are executed. They were very highly extolled in his time, but the improvement in art and taste which the country has since experienced has given us more accurate ideas of art, and more just discrimination between ch racter and caricature.

He sometimes was stimulat'd to paint portraits, but was by no means successful. He had no eye to colour, and had too much vivacity of imagination, or rather, perhaps, too little readiness of mind in the pursuit to dwell sufficiently long on matter so interesting as portraiture, when compared with the zeal and enthusiasm excited by historical painting.

He polished great personal activity, and was fond of athletic exercises, but unfortunately devoted too much time to habits of excess in pleasurable indulgences, which brought on premature decline and death in the 59th year of his age, in 1779.

The character which Mortimer left behind him, excepting the weakness of allowing the heat of youthful passions to overcome and mislead him for a time, was highly estimable. He was generous and friendly, lively, engaging, and intellectual. Having once become aware of the folly of vicious indulgence, he determined to adopt a more correct course of life, but unfortunately his good resolutions were excited too late, and the heavy hand of death fell on him before he or his friends were benefitted by them; as far at least as relates to the art he professed.

MORTINSBERG, in Geography, a town of Austria; 40 miles S.S.W. of Zweit.

MORTIS, Causa Donatio. See Donation.

MORTISE, or Mortice, in Carpentry and Joinery, an excavation received within the surface of a piece of timber, to receive the projection on the end of another piece, in order to fix the two pieces together at a given angle. The sides of the mortise are generally four planes at right angles to each other, and to the surface whence the excavation is made. See Carpentory and Joinery.

The word is originally French, mortoise, which signifies the fame; and which Borel farther derives from mordre, to bite.

MORTLAKE, in Geography, a village and parish in the western division of the hundred of Brixton, in the county of Surrey, England, is situated on the southern bank of the river Thames, at a distance of some miles S.W. from London. The manor here at the time of the conquest, and from that period till the reign of Henry VIII. was the property of the archbishop of Canterbury, who occasionally resided at the manor-house. Archbishop Anselm celebrated the feast of Whit on this manor in the year 1099; and archbishops Peckham and Reynolds died there; the former A.D. 1325, and the latter in 1327. After the alienation of the manor, by archbishop Cranmer, the king gave it to his newly erected dean and chapter of Worcester; at which time the manor-house was destroyed, and the manorial residence removed to Wimbledon.

This village is remarkable in the history of English manufactory, as the seat of the first manufactory of fine tapestry established in the British dominions. The buildings of this manufactory, which owes its origin to the patriotic exertions of Sir Francis Cranke, formerly occupied the site of Queen's-head court. They are now wholly demolished, but the house, built for the residence of Mr. Francis Cleynne, the chief designer employed in the work, still continues standing on the opposite side of the road. A manufactory of coffin, began about twenty years ago by Mr. William Saunders, is now carried on by Mr. Vaghtall and Coy. In this village a small manufactory of white flax-ware, and the property of Mr. Joseph Kifhar. The alms-houses here were first founded and endowed in 1628 by John Juxon, esq. and his family, but the endowments were subsequently much augmented by Mrs. Elizabeth Henage. The persons maintained in these houses are poor widows, each of whom receives 2s. 6d. per week; and clothes at stated periods.

A charity-school, which owes its foundation to a bequest by lady Capel, is now in a very flourishing condition; the funds having been so much increased of late by various donations, as to enable the trustees to clothe and educate in it 12 boys and 12 girls.

Mortlake church appears, from a record still extant, to have been originally erected about the year 1348, but no portion of that building now remains, except the outward door of the belfry. The other parts were rebuilt in 1543; and the fourth aisle again, even so late as the year 1725. This church is constructed of flint and flint chequered, and has a square embattled tower of similar workmanship at the west end. The interior is adorned with a very handsome front, which exhibits some rich tracery work; and bears among other decorations the arms of Archbishop Bonare. He also added the nave of the church in the time of Henry VI. Here are likewise, as well as in the church-yard, a number of neat monuments, some of them in honour of distinguished public characters. Among these is one for Dr. Dee, who was remarkable in the reign of Queen Elizabeth for his skill in the occult sciences; and of whom, as well as of his son, some account will be found in a preceding volume. (See Dee.) Another monumental memorial commemorates John Partridge, a celebrated physician and astrologer, who lived in the seventeenth century; a third for Sir John Barnard,
Barnard, alderman of London, within the same period, together with the late Sir Brook Watton, are chiefly worthy of mention. The living here was at one time a rectory in the peculiar jurisdiction of the archbishop of Canterbury, but it is now a perpetual curacy, with a revered salary of 40l. per annum, paid out of the great tithes by the lefsee under the dean and chapter of Worcester, who have the nomination of the curate. Mr. Parkes, curate here during the protectorship of Cromwell, was one of the minions appointed toasso the committee for displacing ignorant and insufficient minions and school masters. An ancient house here is said to have been for some time the residence of that ulterior.

The parish of Mortlake contains about 1400 acres, of which nearly 650 are inclosed in Richmond park. Upwards of 100 acres are waste lands. Of the remainder, 250 acres constitute garden ground, including 31 acres cropped with asparagus, and 10 with lavender. The cultivation of the former of these plants has much decreased here within the last 20 years. At the extremity of the parish, towards Richmond, is a farm consisting of about 80 acres, which has been long in the occupation of his majesty, and is said to be one of the best cultivated spots in England. The soil here consists mostly of land and gravel, but on some spots near the side of the river there is a considerable mixture of clay. On a small hill within the park stands an elegant edifice called the Stone lodge, which was begun by George I. after a design by the earl of Pembroke, but left in an unfinished state till completed by the princes Amelia, when she became range of the park. This lodge was given, in 1803, to lord victor Sidney, in whose possession it still continues. In this parish is the pleasant hamlet of East Sheen, which commands some very beautiful views, from its position on an eminence close to the Thames. Some highly poetical passages in Maurice’s Poem of “Richmond,” are allusive to the scenery, history, &c. of Mortlake, Sheen, and the vicinity.

Mortlake, according to the parliamentary returns of 1801, contains 341 houses, and 1748 inhabitants. The Environs of London, by the Rev. Daniel Lysons, 4 vols. 4to. 1811. Manning and Ray’s History and Antiquities of Surrey, folio.

MORTLICH, or Mortlach, a village of Scotland, in the county of Banff, on a small river which runs into the Spey; once the see of a bishop, founded by Malcolm II. in the year 1010 in commemoration of a great victory obtained by him over the Danes; the see, after continuing 127 years, was removed to Aberdeen by king David I.; 12 miles S.S.W. of Fochabers.

MORTMAIN, in Law, the alienation of lands and tenements to any guild, corporation, or fraternity, sole or aggregate, ecclesiastical or temporal, and their successors; as bishops, parsons, vicars, &c. which may not be done without the king’s licence, and that of the lord of the manor; or that of the king alone, if it be immediately holden of him. (Stat. 7 & 8 W. III. cap. 37.) And by Stat. 9 Geo. II. cap. 36. no manors, lands, or money to be laid out in lands, are to be given for charitable uses, unless by deed executed twelve months before the death of the donor.

The word literally denotes dead-band; being a compound of mort, dead, and main, band. Accordingly Huttonian defines mortmain to be the possession of those who are, as it were, immortal, because they never cease to have heirs; so that the estate never reverts to its first lord: main, band, being used for possession; and mort, dead, by antiphrasis, for immortal. Others affign the reason of the name thus: that the services and other profits due for such lands, should not, without such licence, come into a dead-hand (nauman); i.e. into a hand as it were dead, that is, so dedicated to God, or pious uses, as to be different from other lands, tenements, or hereditaments, and never to revert to the donor, or any temporal or common use.

Purchases in mortmain were usually made by ecclesiastical bodies, the members of which (being professed) were reckoned dead persons in law; and, therefore, the land held on them might, with great propriety, be said to be held in mort a mortuorum. See AMOR TITION.

In order to understand the rise and progress of the statute of mortmain, it is necessary to observe, that by the common law, any man might dispose of his lands to any other private man, at his own discretion, especially when the feudal restraints of alienation were worn away. Yea in consideration of thence, it was always, and is still, necessary (F. N. B. 121.) for corporations to have a licence in mortmain from the crown, to enable them to purchase lands; and such licences of mortmain seem to have been necessary among the Saxons, above sixty years before the Norman conquest. But, besides this general licence from the king, as lord paramount of the kingdom, it was also requisite, whenever there was a meane, or intermediate lord between the king and the alienor, to obtain his licence also, upon the fame feodal principles, for the alienation of the specific land. And if no such licence was obtained, the king, or other lord, might respectively enter on the lands so alienated in mortmain as a forfeiture.

However, such were the influence and ingenuity of the clergy, that, notwithstanding this fundamental principle, the largess, and most considerable donations of religious houses happened within less than two centuries after the conquest; and they formed contrivances for evading the necessity of obtaining licences. In process of time it was observed, that the feodal services, ordained for the defence of the kingdom, were every day visibly withdrawn; that the circulation of landed property from man to man began to flagitate; and that the lords were curtailed of the fruits of their fiegories, their echeates, wardships, reliefs, and the like; and, therefore, in order to prevent this, it was ordained by the council of king Henry III. their great charters, A. D. 1217, cap. 43. M. Oxon. and afterwards by that printed in our common statute books, that all such attempts should be void, and the land forfeited to the lord of the fee. (Mag. Char. 9 Hen. III. cap. 36.) This was afterwards succeeded by the statute de reigno, 7 Edw. I. which provided that no person, religious or other whatsoever, should buy or sell, or receive under pretence of gift, or term of years, or any other title whatsoever, nor should by any act or ingenuity appropriate to himself, any lands or tenements in mortmain; upon pain that the immediate lord of the fee, or, on his default for one year, the lords paramount, and, in default of all of them, the king might enter thereon as a forfeiture.

Farther, the statute of Wiltmiller the second, 13 Edw. I. cap. 52, enacted, that in cases now known under the name of common recoveries, a jury should try the true right of the demanants or plaintiffs to the land; and if a religious house or corporation be found to have it, they should still recover seisin; otherwise it should be forfeited to the immediate lord of the fee, or else to the next lord, and finally to the king, upon the immediate or other lord’s default. And to prevent any future evasion, when the statute of quia emptores, 18 Edw. I. abolished all fainfudations, and gave liberty for all men to alienate their lands to be held of the next immediate lord, a proviso was inserted, cap. 3. that this should not extend to authorize any kind of alienation in mortmain.
MOR

mortmain. And when afterwards the method of obtaining the king's licence, by writ of ad quod damnum, was marked out by 27 Edw. I. fl. 2, it was farther provided by 34 Edw. I. fl. 3, that no such licence should be effectual, without the consent of the menef, or intermediate lords. It was afterwards enacted by 15 Ric. II. cap. 5, that lands which had been purchased to uses, another method of hafion, to which ecclesiastical diversity recurred,) should be amortised by licence from the crown, or else be sold to private persons; and that, for the future, uses should be subjed to the statutes of mortmain, and forfeitable like the lands themselves; and large tracts of land adjoining to churches, and consecrated by the name of church-yards, were declared to be within the compas of the statutes of mortmain. And civil or lay corporations, as well as ecclesiastic, are also declared to be within the mischief, and the remedy provided by those charitable laws. Moreover it was declared, by 23 Hen. VIII. cap. 10, that all grants of lands to superfluous uses, such as obits, chantries, &c., if granted for any longer term than twenty years, should be void. However, during all this time, it was in the power of the crown, by granting a licence of mortmain, to remit the forfeiture, so far as related to its own rights; and to enable any spiritual or other corporation to purchase and hold any lands or tenements in perpetuity: which prerogative is declared and confirmed by 18 Edw. III. fl. 3, cap. 3. And it was farther provided, by 7 & 8 Wm. I. cap. 37, that the crown, for the future, at its own discretion, may grant licences to alien or take in mortmain, of whatsoever tenements may be holden.

The statutes of mortmain were suspended for twenty years by 1 & 2 P. & M. cap. 8, and during that time, any lands or tenements were allowed to be granted to any spiritual corporation, without any licence whatsoever. And, for the augmentation of poor livings, it was enacted by 17 Car. II. cap. 3, that appropriated may annex the great tithes to the vicarages, and that all benefices under 100l. per annum may be augmented by the purchase of lands, without licence of mortmain in either case; and the like provision hath been since made in favour of the governors of Queen Anne's bounty, 2 & 3 Anne, cap. 11. It hath also been held, that, notwithstanding the statute 23 Hen. VIII., a man may give lands for the maintenance of a school, an hospital, or any other charitable uses. But as it was apprehended from recent experience, that perils on their death-beds might make large and improvident dispositions, even for those good purposes, and defeat the political ends of the statutes of mortmain; it is therefore enacted, by 9 Geo. II. cap. 36, that no lands or tenements, or money to be laid out thereon, shall be given for, or charged with any charitable uses whatsoever, unless by deed indented, executed in the presence of two witnesses, twelve calendar months before the death of the donor, and enrolled in the court of chancery within six months after its execution, (except flocks in the public funds, which may be transferred within six months previous to the donor's death,) and unless such gift be made to take place immediately, and be without power of revocation; and that all other gifts shall be void. The two universities, their colleges, and the scholars upon the foundation of the colleges at Eton, Winchester, and Westminster, are excepted out of this act. It hath been determined, that if a man devise his land to trustees, "to be turned into money, and that money laid out in a charity," it is not good within the said cited act; for it is an interfamilial use of land. So a devise of a "mortgage," or of a "term for years," to a charity, is not good; for the words of the statute are, that the lands shall not be "conveyed or settled, for any estate or interest whatsoever, or any ways charged or incumbered, in trust or for the benefit of any charitable use." So also, "money given to be laid out in lands," is expressly within the act; but money given generally is not; and if money is given to be laid out in "land or other- wise," to a charitable use, it hath been determined that such devise it good, by reason of the words "or otherwise." By 43 Geo. III. c. 168, persons may give, by deed enrolled in such manner, and within such time as is directed in England by 27 Hen. VIII., or bequeath by will or testament, duly executed at least three calendar months before their death, to any person or persons, or body politic or corporate, and their heirs and successors, land, not exceeding five acres, or chattels, not exceeding in value 300l. for or towards the erecting, repairing, purchasing, or providing any church or chancel, where the liturgy and rites of the said church are or shall be used or observed, or any mansion-house for the residence of any minister of the said united church, officiating, or to officiate in any such church or chapel. C. &c., Blackst. Com. book ii. chap. 18. See Mr. Higomore's Hist. of Mortmain.

MORTO, or Mortu Island, called also St. Claro, in Geography, an island in the Atlantic, near the coast of Peru, about 3 miles in length, and 3 leagues N.N.E. from the river Tumbaz.

MORTON, RICHARD, in Biography, an eminent physician, was born in the county of Suffolk; and, after taking the degree of bachelor of arts in the university of Oxford, was for some time chaplain in the family of Foley, in Worcestershire. Having, however, adopted the principles of the non-conformists, he was under the necessity, from the intolerance of the times, in the reign of Charles II., to abandon the profession of theology, and adopted that of medicine. He accordingly was admitted to the degree of doctor in this faculty in 1672, having in that year accompanied the prince of Orange to Oxford, as physician to his person. He afterwards settled in London, became a fellow of the College of Physicians, and obtained a large share of city practice. He died at his house in Surrey, in 1698. The works of Dr. Morton have claimed a considerable share of reputation, and bear testimony to some acuteness of observation and activity of practice. They abounded, however, with the errors of the humoral pathology, which was prevalent in that age; and fancied a method of treatment in acute diseases, which his more able contemporary, Sydenham, discredited, and which subsequent experience has generally disapproved. His first publication was entitled "Phthiologia, seu Exercitationes de Phthilis," 8vo. 1689, and was translated into English in 1694. It contains an attempt to arrange the varieties of consumption; but the difficulties, both in the classification and the indications of cure, are complicated and obscure. His "Pyretologia, seu Exercitationes de Morbis universalibus acutis," comprising of two volumes, octavo, was published at an interval of three years: the first volume in 1691, and the second in 1694. It was in this work that his humoral doctrines of fermentation and the agitations of the animal spirits were particularly dwelt upon; and the practice to which they led him was an unusual extenuation of the cordial and stimulating treatment of all fevers, and a more general introduction of the Peruvian bark, by which he probably contributed to prolong the reign of that prejudicial fyllem of practice, in spite of the authority of Sydenham in favour of the cool treatment. His works have been printed collectively at Amsterdam, Geneva, Leyden, Venice, and Lyons. Ely Dict. Hist. de la Med.

Morton, John, an English prelate and statesman, was a native
a native of Dorchester, and became so eminent for his skill in jurisprudence, as to become one of the privy-councillors to Henry VI. and Edward IV. He attained to the highest rank in the church, being first bishop of Ely, from whence he was translated to Canterbury. In the reign of Henry VII. he was appointed chancellor of England; and so great was the friendship of his sovereign for Morton, that he obtained for him a cardinalship. He died in the year 1500.

Morton, James, Earl of, regent of Scotland, was born at Dalkeith in 1530, and educated under the famous Buchanan at Paris. He returned to Scotland in 1554, and greatly promoted the reformation; but being accused of a concern in the murder of lord Daruhy, he fled to England. He was afterwards made chancellor of Scotland, and, in 1574, succeeded the earl of Mar as regent; which office he resigned in 1579. He was condemned for high treason in 1581, and, what is remarkable, was beheaded by a machine, the model of which he had seen in England. It was called the Maiden, and resembled the guillotine, since for r and s was infamously used in France. Morton was the first and last who suffered by it in Scotland. Robertson's Hist. of Scotland.

Morton, Thomas, an eminent bishop of the church of England, was born at York in the year 1564. Having obtained the rudiments of a good education at his native place, and at Halifax, he was sent, in 1582, to St. John's college, in the university of Cambridge. In the usual course he took his degrees of B.A. and M.A.; and in 1592 he offered himself as a candidate for a fellowship of his college, and proved successful against several competitors, solely on the ground of his superior merit. About the same time he was chosen logical lecturer to the university. While the plague raged at York, he preached and administered spiritual comfort to the wretched people. He himself carried with him medicines, and provisions, in large quantities, for their relief; not suffering a servant to attend him, choosing alone to run the risk of such a dangerous intercourse. In 1603 he attended lord Eure, ambassador to the emperor of Germany, as chaplain; and upon his return, he became domestic chaplain to the earl of Rutland; and in 1606, proceeded doctor of divinity at Cambridge. About this time he was appointed chaplain in ordinary to James I., and was presented by his majesty with the deanery of Gloucester, which he soon exchanged for the deanery of Winchelsea. In 1616 he was raised to the episcopal bench, by being nominated to the bishopric of Chester, whom he was translated to Lichfield and Coventry in 1618, and in 1632 to the rich see of Durham, in which he conducted himself with great moderation and equity. till he was involved in the ruin of the church of England during the civil wars. His personal sufferings at this time were very great; he was attacked by the mob, on account of his being a bishop; his property was confiscated, and he himself thrown into prison. He died, at the great age of 95, in the year 1659. He was author of several books in practical divinity. But he is chiefly known, as having by the advice, or rather the command, of Charles I. drawn up the declaration, known under the title of "The Book of Sport," the object of which was the authorizing the practice of certain recreations on Sundays, after the hours of divine service. One of the most remarkable circumstances that occurred during the bishop's continuance in the see of Lichfield, was his detecting the boy of Bilton, in Staffordshire, who pretended to be possessed with a devil, and by this means was made the instrument of the forgeries of the Jesuits and priests, in propagating their superstitions, of which an account is given in many of our histories, and in the Biographia Britannica. See also Ne'ves Hist. of the Puntans.

Morton Bay, in Geography, a bay on the north-west coast of the island of Nevis, near the Narrows, or channel between that island and St. Christopher's; 2 miles N. of Charlestown.

Mortorp, a town of Sweden, in the province of Smalnd; 10 miles W.S.W. of Calmar.

Mortree, a town of France, in the department of the Orne, and chief place of a canton, in the district of Argentin; 7 miles S.S.E. of Argentin. The place contains 775, the canton 743 inhabitants, on a territory of 185 square kilometres, in 15 communes.

Mortuary is a gift left by a man at his death to his parish church, for a remembrance of personal tithes and offerings, not duly paid in his lifetime.

Mortuary is also the fee paid to an incumbent, for carrying a corpse out of his parish to be buried in another.

A mortuary is not properly and originally due to an incumbent from any but those of his own parish; but, by custom, in some places of the kingdom, it is paid to the parsons of other parishes, as the corpse passes through them.

Mortuaries seem originally to have been, like lay heriots, only a voluntary bequest to the church, and the mortuary was anciently brought to the church with the corpse, when it came to be buried, and called a corse present: but so early as the time of Hen. III., it was rivetted into an established custom; infomuch that the bequests of heriots and mortuaries were held to be necessary ingredients in every testament of chattels; infomuch that the lord must have the belt goods left him as a heriot, and the church the second part as a mortuary. But this custom was different in different parishes.

Mortuaries are taken away, under certain conditions and limitations, in Wales, Berwick, and Chelten, by 21 Hen VIII. cap. 6. sect. 6. 12 Anne, Stat. 2. cap. 28 Geo. II. cap. 6.

It is enacted by 21 Hen. VIII. cap. 6. that all mortuaries or corse presents to parsons of any parish shall be taken in the following manner, unless where by custom left or none at all is due: viz. for every person who does not leave goods to the value of ten marks, nothing; for every person who leaves goods to the value of ten marks, and under 50l., 34. 4d.; if above 50l. and under 45l., 6s. 8d.; if above 45l., of what value ever they be, 10s., and no more. And no mortuary shall, throughout the kingdom, be paid for the death of any feme-covert; nor for any child; nor for any one of full age that is not a house-keeper; nor for any way-faring man; but such way-faring man's mortuary shall be paid in the parish to which he belongs. And upon this statute stands the law of mortuaries to this day.

Mortugara, in Geography, a town of Brasil, in the government of Para; 20 miles S.W. of Para.

Mortum Capiet. See Capiet.

Morty, in Geography, an island in the North Pacific ocean, about 60 miles in length from north to south, and from 10 to 25 in breadth; separated from the north-east part of the island of Gilolo by a channel about 25 miles wide, called the "Strait of Morty:" belonging to the sultan of Ternate. N. lat. 2° 54'. E. long. 128° 23'.

Morvet, a town of Gunarat; 40 miles N.E. of Nooagur.

Morven, a district of Scotland, in the county of Argyle, extending in length about 20 miles along the coast.
of Mull, and 10 at its greatest breadth. This is the country of Fingal and his heroes.

MORUGO, a small river of Surinam, which runs into the sea, north of Effequobo.

MORVIDRO, or Murvidro, a town of Spain, in the province of Valencia, supposed to be erected on the ruins of the ancient Saguntum, founded about 200 years before the Trojan war by a colony of Grecians, and destroyed by Hannibal, is a long and narrow town, a league from the sea, at the foot of a mountain of black marble veined with white. The name of Murvidro is said to be derived from "Muris veteres," or "Muros viejos," from its supposed site. This town is surrounded by lofty walls, and flanked by small round towers. Its enclosure has several gates, defended by square towers. The streets are narrow, crooked, and deep, and the houses exhibit a bad appearance. The inns are extensive, more agreeable and airy than the town, and perfectly level. The inhabitants amount to about 5,000. It has one parish church, three chapels of fare, two convents of monks, a convent of nuns, and a corregidor. Its commerce partly consists in brandy, which is exported to the north of Europe and to America; but its more certain resource is the production of the neighbouring lands in oil, wine, wheat, barley, hemp, and carobs. It abounds with vestiges of antiquity, which remind the paffing observer of its original inhabitants, of its victors the Carthaginians, and of its poffefors the Romans. Several Celiiberian and Roman inscriptions are seen; but of the numerous statues that ornamented the temples and other public edifices of Saguntum, one only remains, of white marble without a head, and a fragment of another. The traces of the walls of its circus are still discernible; but its mosaic pavement is destroyed. A greater portion of the theatre remains than of any other Roman monument; 13 miles N.N.E. of Valencia. N. lat. 39° 30'. W. long. 4° 22'.—A river of the same name runs into the sea, a little below the town.

MORVILLE, a small island in the English channel, near the coast of France. N. lat. 48° 52'. W. long. 3° 18'.

MORUM, in Surgery, an excrescence on the surface of the skin, is called from its supposed resemblance to a mulberry.

MORUMGANI, in Geography, a sea-port on the W. coast of Madagascar. S. lat. 15°.

MORUNDA, in Ancient Geography, a town of Afa, in Media, placed by Ptolemy between Larrafa and Tigrana.—Afa, a town of Afa, in Atropatene, situated on the northern part of the lake Spauta.—Alfa, a town of India, on this side of the Ganges, inhabited by the people called by Ptolemy An.

MORUNG, in Geography, a country of Afa, dependent on Thabet, either as tributary or feudatory, situated on the banks of the Cofa, N. of Bengal, and S.W. of Bootan.

MORUNGA. See Mohrunogen.

MORUP, a town of Sweden, in the province of Halland; 25 miles N.N.W. of Helinnaad.

MORUS, in Botany, the Mulberry, one of those ancient and universal names, whose etymology can only be guessed. The tree is called μωρος, the fruit μωρος, by the Greeks; μουρος, by the Latin Murus for the former, and Murum for the latter, have evidently originated. Lexicographers have supposed these words to have originated, either from μωρος, dark, alluding to the colour of the fruits, which every body knows became so in consequence of the adventures of Pyramus and Thalie; or, by antiphrasis, from μωρος, foolish, the Mulberry being esteemed the unwise

Gen. Ch. Male, Cal. Perianth in four deep, ovate, concave segments. Cor. none. Stam. Filaments four, awl-shaped, spreading, longer than the calyx, one of them accompanying each of its segments; anthers simple.

Female, on the same or a distinct plant, Cal. Perianth of four roundish, obtuse, permanent leaves, the two opposite ones lying over the others. Cor. none. Pist. Germ. superior, heart-shaped; stamens two, awl-shaped, long, reflexed, rough, filaments simple. Petals none, except the enlarged, juicy, coloured leaves of the calyx, assuming the appearance of a berry. Seed solitarry, ovate, compeffed, acute.

Obs. The second species of Linnæus, M. nigra, is sometimes perfectly diosceous; very frequently it is partially so, the flammes being in greater perfection in most of the flowers of one tree, the piths in those of another.

Female, Calyx of four leaves. Corolla none. Styles two. Seed solitary, invested with the pulpy calyx.

1. M. alba. White Mulberry-tree. Linn. Sp. Pl. 1398. Ger. em. 1507. Loureir. Cochinch. 555.—Leaves obliquely ovate, somewhat heart-shaped, nearly smooth.—Native of China. Cultivated in that country, as well as in the warmer parts of Europe, for the sake of its leaves as the food of silk worms. (See Silk.) The tree is rather of humble growth, copiously and irregularly branched. Leaves alternate, on longish, slender, smooth stalks, obliquely ovate, in longish, heart-shaped, acute, two inches long, rather bluntly ferrated, sometimes quite smooth on both sides, but more frequently roughish with minute points, without hairs or bristles, furnished with three principal ribs, and many veins hairy at their origin, bright green, deciduous. Stipulas lanceolate, varying in breadth, tawny, membranous, deciduous. Flowers green, in short, roundish, smooth, stalked spikes or heads, which are alternate, several near each other, about the base of the young branches. Fruit of a nearly white, sweetish, infipid, esteemed unwholesome. Wildseed now it varies occasionally to a reddish, red, or black colour.—The leaves on young shoots, from a tree that has been much cut, sometimes become deeply ferrated or lobed.

2. M. lactis. Tartarum Mulberry. Linn. Sp. Pl. 1399. Willd. n. 2. Pall. Rofs. v. 1. p. 2. 9. t. 52.—Leaves elliptic-ovate, obtuse; slightly heart-shaped and equal at the base; equally ferrated, smooth. Native of inundated meadows on the banks of the Wolga and the Don. Pallus. Gerber's specimen in the Linnæan herbarium was gathered at A soph, where Pallus says it is a garden plant. Wildseed with great propriety places this next after the M. alba, to which it is most nearly related, differing in its more elliptical, obtuse, and evenly ferrated leaves, which are quite smooth. Gerber says the fruit is black. Pallus speaks of it as reddish, or pale, of no good flavour, though it is eaten raw, as well as dried, or made into a sweetmeat. A wine is also prepared from it, and a very well-flavoured spirit. This species is reported to be most esteemed for silk worms in China.

MORUS.

1538. Woody. Med. Bot. 352. t. 129. (Morus; Camer. Ept. 179. Ger. em 1507.)—Leaves broad-heart-shaped, unequally serrated, somewhat lobed, rough.—Native of Persia, and, as it is said, of the sea-coast of Italy. Cultivated throughout Europe for the sake of its fruit. Silk worms also will eat the leaves, though those of the first or second species are preferred by persons who rear these valuable insects for profit. This is a larger tree than either of the former, and readily distinguished by its broader, rougher, more coarsely and unequally serrated leaves; longer spikes of flowers; and larger, dark purple, highly agreeable and wholesome fruit. The bark of the root, which has a fignular licea fringe when dry, is acrid, bitter, and catarrhic, though containing some mucilage. It is recommended as a vermifuge, in doses of half a drachm in powder.

4. M. rubra. Red American Mulberry-tree. Linn. Sp. Pl. 1399. Michaux Boreal-Amer. v. 2. 179. (Morifolia virginiana arb., loti arboris infar ramafa, folis amplifilis; Pluk. Phyt. t. 246. f. 4.)—Leaves ovate, taper-pointed, finely serrated; heart-shaped at the base; downy beneath; sometimes deeply lobed. Spikes long and cylindrical. Native of North America, from Canada to Florida. Cultivated here, according to Parkinson's Paradisi 596, early in the 17th century. He says it grows quickly with us to a large tree, and that the fruit is long, red, and pleasantly tasted. The taper-pointed leaves, downy beneath, distinguiished this species, as well as its long, slender, somewhat interrupted spikes. M. canadensis, Lamarck Dict. v. 4. 380, seems but a variety of this.

5. M. indica. Indian Mulberry-tree. Linn. Sp. Pl. 1399. Rumph. Ambob. v. 7. 8. t. 5. (Tinda Parua; Rheede Hort. Mal. v. 1. 87. t. 48. no. 49.)—Leaves ovate, taper-pointed, coarsely serrated, roughish, naked; slightly heart-shaped at the base; often lobed.—Native of the East Indies, and of the isle of Bourbon. Willdenow says it is often met with in gardens, and called a variety of M. alba. From that species however, it may always be distinguished by its rougher and long-pointed leaves; and from the rubra (whose leaves are nearly as much pointed), by their want of all downiness on both sides, as well as by the shorter and thicker spikes. The fruit is reddish. Both the figures above cited are bad. That of Rumphius is rather the better. He says the fruit is delicately flavoured, black when ripe; and that the Chinese feed their silk worms with the leaves. Lour. mentions the fame of the inhabitants of Cochinchina, who transplant the tree every year, that the foliage may be tender.

6. M. latifolia. Broad-leaved Bourbon Mulberry-tree. Lamarck Dict. v. 4. 381. Willd. n. 6—Leaves broad-heart-shaped, pointed, undivided, coarsely serrated; rough above, seiny beneath.—Native of the isle of Bourbon. Poiret in Lamarck describes the leaves as three inches broad, three and a half or four long; their under side remarkably reticulated, and marked with as many little pores, or depressions, as there are rough points on the upper surface.

7. M. auriflora. Southern Mulberry-tree. Lamarck Dict. v. 4. 380. Willd. n. 7.—Leaves oval, long-pointed, naked, roughish, serrated, on long footstalks. Fruit short, with long permanent styles."—Cultivated in the isle of Bourbon. It is not easy to conceive a clear idea of the characteristic marks of this species, by the information in the above work, but we suppose that it may be a variety of M. indica, some specimens of which in our posseon, from the island here mentioned, answer to the description in several respects.

8. M. mauritiana. Laurel-leaved Mulberry-tree. Jacq. Coll. v. 3. 206. v. 4. 224. t. 22. f. 1. Tc. Rar. t. 617. Lamarck Dict. v. 4. 381. (M. amalpii; ibid. 380.)—Leaves elliptic-oblong, entire, rough on both sides.—Native of Madagascar and the Mauritius. A large and strong tree. The branches are rough with small irregular tubercles. Leaves numerous, scattered, three or four inches in length, and one or one and a half in breadth, elliptic-oblong, more or less obtuse, perfectly entire, rough with minute points on both sides, reticulated with innumerable veins. Footstalks thick, not an inch long, rough with small tubercles. Spikes short, cylindrical, axillary, solitary, drooping, on short, thick, rough stalks. Fruit green, sweet with some acidity, one and a half or two inches long. The French call this tree La Rappe, or the rapo tree, of Madagascar. We have a specimen from Lamarck, which proves his plant the same with that of Jacquin. It is a most distinct species, and ought to have been named laurifolia or citrifolia. The leaves seem calculated to serve as a fine Sil, or rap, like some of the fig kind. See Ficus.

9. M. tintoria. Dyer's Mulberry-tree, or Fuitick-wood. Linn. Syll. Nat. ed. 10. v. 2. 1266. Mant. 495. Mill. Dict. ed. 8. n. 5. (M. lacteetens, foliis oblongis acutis, paginis exterioribus producentibus, lino citrino; Browne Jam. 339. M. fructu viridi, lino fulpuroco tintorico; Sloane Jam. v. 2. 3. t. 158. f. 1. Tatai-ba; Pis. Brasil. 163. Marez. Brail. 119.)—Leaves oblong, pointed, finely serrated, rough; heart-shaped and unequal at the base. Spines none.—Native of Jamaica and other West Indian islands, but particularly abundant about Campeachy on the main land, from whence the wood is exported, in great quantities, as an article of trade, and is well known, by the name of Fuitick, as a yellow dye. Sloane describes the tree as having a large and straight trunk, sixty feet or more in height, with long and large roots. w. ofe bark is very yellow. Bark of the trunk light brown, with yellow clefs. Wood very firm and solid, of a very fine yellow. Branches spreading. Leaves alternate, or shortish stalks, rough, dark green, pointed, larger towards the footstalk; Browne describes them as unequal at the base, and Pifo, like Marcgrave, says they are finely serrated. This last character does not appear in their figures, nor in Sloane's. The latter describes the spikes as whitish and short, abundant at the ends of the branches, and the fruit as large as a nutmeg, round, formed like other mulberries, but greenish both within and without, with brown seeds. When ripe it is pellacant, though luciduous sweet. Miller borrowed much from Sloane's account. He raised several plants from seed in the isle of Cheslea, but they appear not to have survived long, being very tender, though of quick growth. It is to be regretted that there is no good figure, nor scientific description, of this valuable tree. We have not even seen a specimen.

10. M. Xanthoxylon. Spinosus Mulberry-tree, or Ballard Fuitick. Linn. Syll. Nat. ed. 10. v. 2. 1266. Mant. 495. Jacq. Amer. 247. Mill. Dict. ed. 8. n. 8. (M. tintoria; Linn. Sp. Pl. 1399. Xanthoxylum aculeatum, carpinii folios, americanum, corte cineceo; Pluk. Phyt. t. 239. f. 3.)—Leaves ovate-oblong, pointed, serrated, nearly smooth. Spines axillary.—Native of the West Indies. Miller had it from Jamaica and the Bahama islands. Jacquin observed it in the vast woods near Carthagena. The former induced Linnæus to distinguish this from his M. tintoria, though the specimen in his herbarium is what he originally described for that species, and subfequently marked Xanthoxylon. The leaves of this are smooth beneath, slightly rough to the touch on the upper side; their form ovate-oblong, pointed, unequal at the base; the margin rather strongly serrated. Spines axillary,
MORUS.

axillary, solitary, scarcely the length of the footstalks, which
is about half an inch. Miller says there are two spines to
each leaf, which on the older branches extend to the length
of two branches. He observes that this tree does not grow to
so great a size as the last. The wood is sold for the fame
use, but Linnaeus mentions that its quality is inferior to that
of the real M. tinctoria. Pluver's Icones, t. 204, quoted
for this by Jacquin, is a rude representation of it, but the
spines are represented under the footstalk, not axillary.—
These two plants are well worthy the notice of some West
Indian botanists. Swartz has nothing on the subject.

Morus, in Gardening, comprehends plants of the decidu-
ous tree kind, of which the species cultivated are; the
common mulberry-tree (M. nigra); the white mulberry-
tree (M. alba); the paper mulberry-tree (M. papyrifera);
the red mulberry-tree (M. rubra); the Indian mulberry
(M. indica); and the yew's mulberry or fullick-wood
(M. tinctoria).

The first is the sort usually cultivated as a fruit-tree in the
garden.
A, and there is a variety with palmate or elegantly cut leaves
and a smaller fruit.

Speaking of the second kind, Miller observes that there
are two or three varieties of it, which differ in the shape
of their leaves, and in the size and colour of the fruit; but
as it is of no other use but for the leaves, the strongest shoot-
and the largest-leaved should be preferred.

This fruit is commonly cultivated for its leaves to feed silk-
worms in France, Italy, &c.; and in Spain, according to
Mr. Townsend, they prefer the white mulberry in Valencia,
and the black in Granada. But the Persians generally make
use of the latter, and Mr. Miller was assured by a gentleman
who had made trial of both sorts of leaves, that the worms
fed on the latter produced much the belt silk; but that the
leaves of the black should never be given to the worms after
they have eaten for some time of the white, left they should
burst. And for George Staunton states, that the tender
leaves growing on the young shoots of the black sort are
supposed in China to be the most succulent or juicy.

Method of Culture.—All the sorts are capable of being
increased by seeds, layer, cuttings, grafting, and inoculat-
ing or budding. But the best method is chiefly practiced
for the first, not intended as fruit-trees, as they are
very liable to vary in that way. It should be sown in the
early spring, as about March, on a bed of fine earth, in a
warm aspect, or upon a moderate hot-bed protected with
glasses, in drills to the depth of a quarter of an inch. Water
should be given lightly in dry weather, and in the heat of
the day shade; covering it in cold nights. When the plants
appear, they should be well guarded from fruit in the early
spring, and be kept clean during the summer, and properly
shaded and watered, protecting them the first autumn and
winter, removing them in the following March into nursery
rows two feet apart, and one distant, to continue a few
years, when they may be set out where they are to grow.
They should not be removed either from the feed-bed or
nursery-rows, till perfectly strong.

In cafes, where they are intended for feeding silk-worms,
they should be kept in a low, thrifty state of growth.

They appear, from Mr. George Staunton's account, to
survive well in China, on beds about a foot high in moist
loamy soils.

Where they are raised for fruit, great care should be taken
that the layers or cuttings be not only taken from old fruit-
bearing trees, but that the branches made use of be also
fruit-bearing.

The layers may be made from shoots formed for the pur-
pose, or by raising up large boxes, baskets, or pots of
earth, so as to lay the branches in them in the autumn, by
the slit method, heading them down to two eyes each.
When they have taken root in the autumn following, they
may be removed into the nursery and managed as the feed-

ings.

The cuttings should be made from the former year's shoots
of such trees and branches as bear well, and have fine fruit,
not being shortened, but planted their whole length, leaving
two or three buds above the ground. They should be planted
in March on light rich earth, precluding the mould well
about them, in order that it may be kept from getting too dry
and parched.

As soon as they have become well rooted in the following
spring they may be removed into the nursery, being regularly
trained to limbs by means of flaches fixed to each of them,
to which the principal shoots should be trained, removing
most of the rest, except such as are necessary to detain the
sap for the support of the tree.

And they may be trained to standards, half standards, and
division standards. See PRUNING AND TRAINING.

After three or four years in the nursery, they will be
ready to plant out freely.

But little fun should be admitted at the first planting of
the cuttings, but afterwards as much as possible, provided
the earth about them be prevented from becoming dry, by
moats or other means. The cuttings also succeed well when
planted in a hot-bed; and in all cafes when covered by hand-
glasses. It is, likewise, the practice with some to plant them
in October.

Grafting and budding, or inoculating, are certain meth-
ods of continuing the proper kinds, and should be prac-
ticed in the usual manner upon the feeding flocks of any of
the species. See GRAFTING AND BUDDING.

It is suggested by Mr. Forbynth, that "as the fruit is pro-
duced on the young wood, only such branches as are well,
and such as are decayed, or broken by accident, should be
cut out, applying at the same time the composition. When,
however, the heads become too full of wood, it will be ne-
cessary to thin them, as the fruit is larger and better flavoured
where the heads are kept thin of wood."

And the planting of these trees, when for fruit, in grafts
or orchards and pleuro-grounds is advised, as "the finest of
the fruit, when ripe, frequently drops, which, if it fall on dug or
ploughed ground, will be foiled and rendered unfit for use, as
the earth will adhere so to the fruit as to render the cleaning of
it impracticable; but if planted on lawns, or in gardens, the
fruit can be picked up without receiving any injury.

Another reason for planting these on lawns, or in orchards,
is, that when fully grown, they are too large for a kitchen-
garden. The foil in which they thrive best is a rich, light,
and deep earth."

"He has tried the efficacy of his composition on several of
these trees in a very decayed hollow stave of the trunk,
cutting out all the dead wood and cankered parts of same,
and heading down others that were flinted and sickly.
After these operations they put forth vigorous branches,
and bore excellent crops of fruit, more than double the size
of that which they produced in their former state."

And "those who have any old decayed mulberry-trees are
advised to treat them in the same manner: but those which
are very much decayed should be headed down; this will
throw them into a healthy bearing state, and in two or
three years they will produce plenty of fine fruit."

And as old trees of this sort bear better and have finer
fruit than the young ones, it is of importance to restore
them.
Both the fifth and sixth forts are tender, requiring the protection of the barkrove.

The fifth is raised for the fruit, but the others chiefly for the purpose of variety and ornament. The third is used for having the bark made into paper in some countries.

MORKI, the Indian name of a pettinent distemper, very common in Malabar, and in some other parts of the East Indies, frequently carrying off great numbers of people.

MORZEGORSKII, in Geography, a town of Russia, in the government of Archangel, on the W. side of the Dwina; 100 miles S.E. of Archangel.

MORZOVETZ, an island of Russia, in the fricts between the Frozen and White sea. N. lat. 66° 40'. E. long. 45° 38'.

MOSA, in Ancient Geography, a river of Gaul, near the "Meuse."

MOSABAD, in Geography, a town of Hindooftan, in Agimere; 13 miles S.E. of Rooopnagar.

MOSAIC, MOSAIC Work, or, as some choose to call it, Mosaic, an assemblage of little pieces of glass, marble, shells, precious stones, woods, or the like, of various colours, cut square, and cemented on a ground of flaece, &c. imitating the natural colours and degradations of painting.

In this tene, mosaic work includes marquetry, or inlaid work, veneering, &c.

The critics are divided as to the origin and reason of the name: some derive it from mosaikon, a corruption of mosaikin, as that is of mosaicum, as it was called among the Romans. Seager derives it from the Greek mosaic, and imagines the name was given to this sort of work, as being very fine and ingenious. Nebraeius is of opinion it was so called, because ex illa pictura ornabantur musae.

But, in its more proper and refined sense, mosaic only takes in works of stone, metals, and glass; those of wood being distinguished by the name of marquetry, or inlaying.

Others differ in the other name between mosaic and marquetry. In that properly called mosaic, they say the several stones are all of the same colour; and the changes and diminutions of colours and shades are made by applying different stones, one on another, but all of the same colour. Marquetry, on the contrary, confines of stones of different colours; and by the several colours, shades, degradations, &c. are expressed.

Mosaic leemzer to have taken its origin from paving: the fine effect and use of pavements composed of pieces of marble of different colours, so well joined together, as that, when dried, they might be polished, and the whole made a very beautiful and solid body, which, continually trodden upon, and washed with water, was not at all damaged, gave the painter the hint, who soon carried the art to a much greater perfection, so as to represent folages, masques, and other grotesque pieces of various colours, on a ground of black or white marble. In fine, observing the good effect which this kind of work had in pavements, and finding that it refilled water, they proceeded to line walls with it, and to take various figures by it, for the ornament of their temples and public buildings. But nature not producing variety of colours enough for them in marbles, to paint all kinds of objects, they beheld of counterfeiting them with gles and metal colours; which succeeded so well with them, that having given all manner of teents to an infinite number of little pieces of these two matters, to counterfeit stones of various colours, in order to get more colours, the workmen arranged them with so much art, that their mosaic seemed almost to vie with painting; this way of representing objects having this advantage, that it refills the impurities of the air as well as marble itself; and even grows more beautiful with time, which effects all other kinds of painting.

But the moderns have gone yet farther; and, setting aside glass and metals, as too mean materials, have introduced, along with the finest marbles, the richest of precious stones, as lapis lazuli, agat, cornelians, emeralds, turquoises, &c.

Of these three kinds of mosaic work, that of coloured glass and metals is now little in use; though of a surprising lustre and durability; of the other two, that of glass alone is in common use; the mosaic in precious stones being so very dear, that few workmen who apply themselves to it, make little else but petty works, as ornaments for altar-pieces, tables for rich cabinets, &c. Though out of these must be excepted that fumptuous chapel of the dukes of Tuscany, which will be a noble monument of the magnificence and piety of those princes, as well as of the patience and address of the workmen employed in it.

We shall, however, enter into some detail of the manner of working in these three kinds of mosaic; to which we shall add a fourth much newer, yet equally ingenious with any of the rest, made with a kind of gypsum or tale, found in the stone quarries about Paris.

MOSAIC Work of Glass. This kind they begin with little pieces of glass, which they provide of as many different colours as possible. To this end, the glaffe man's furnaces being distempered, and their pots or crucibles full of the matter of which glass is made, or rather of glass already made, they put what metalline colour or dye they think fit in each crucible, always beginning with the weakest, and augmenting the strength of the colours from crucible to crucible, till they come to the deepest dye, as in mixing of colours on a pallet to paint in oil. When the glass has had sufficient coction, and all the colours are in their perfection, they take out the glases hot, as it is, laying it on a smooth marble, flattening it down with another marble, and then cut it into slices of equal bigness, and about the thickness of an inch and a half. They then, with an instrument which the Italians call boccia dianes, make some pieces square, and others of different figures and sizes, as occasion requires; these they dispose orderly in cafes; as in painting in fresco, it is usual to range all the different teints in shells, according to their colour.

If it be desir’d to have gold, either in the ground of the painting, or in the ornaments, or the dresses, they take some of the pieces of the glases, formed and cut in the manner just mentioned: these they mount on one side with gum water, and afterwards lay them over with gold-leaf. They then put this piece, or several pieces at a time, on a fire-shovel, which they place in the month of the furnace, after having first covered them with another hollow piece of glass. Here they continue till such time as they become red-hot; after which the shovel is drawn out, all at once, and the gold becomes so firmly bound to the glass, that it will never afterwards leave it.

Now, to apply these several pieces, and out of them to form a picture, they first make a cartoon, or design; this they transfer on the ground or platter, by etching, as in painting in fresco.

As this plaster is to be laid thick on the wall, it will continue fresh and soft a considerable time, so that there may be enough prepared at once to serve three or four days. This plaster is composed of lime made of hard stone, with brick-dust ground very fine, gum tragacanth, and whites of eggs: when it is thus prepared, and laid on the wall, and the design finished of what is to be represented; with

E e
plyers they take out the little pieces of glass, ranging them one after another, and fill keeping tightly to the light; shadow, and different teints and colours reprented in the design: pressing or flattening them down with a ruler, which serves both to fink them within the ground, and to render the surface even.

Thus, in a long time, and with an infinite deal of trouble, they finish the work; which is still the more beautiful, as the pieces of glass are more uniform, and ranged at more equal heights. Some of these are executed with so much jaclnef, that they appear as smooth as a table of marble, and as finifhed and maitely as a painting in fresco; with this advantage, that they have a fine luirbre, and will hold almost for ever.

The neat works of this kind, that have descended to us, and thofe from which the moderns have retrieved the art, are loft, are thoie of the church of St. Agnes, formerly the temple of Bacchus, at Rome; besides Rome at Pifa, Florence, and other cities of Italy. The moft esteemed among the works of the moderns are thoie of Joseph Pine, and the chevalier Lanfranc, in the church of St. Peter at Rome. There are fome very good ones likewise at Venice.

Mosaic Work of Marbles, and Precious Stones: Thes two kinds bear to near a relation to each other as to the manner in which they are contrived, that to avoid repetition, we shall give them both under one: observing, by the way, wherein the one differs from the other, either in the fawing or ranging of the fones.

Mosaic of Marble is used in large works, as in pavements of churches, basilics, and palaces; and in the incrustation and veneering of the walls of the fame edifices. As to that of fones, especially precious fones, it is only used in small works, as before obferved.

The ground of mosaic works, wholly marble, is ordinarilily a mafs of marble, either white or black. On this ground the design is cut with a chiffel, having been firt called. When it is dug of a fufficient depth, i. e. an inch or more, it is filled up with marble of a proper colour, firt contoured, or fashioned to the design, and reduced to the thickefs of the cavities, with various instruments. To make the pieces thus inferted into the cavities hold, whole feveral colours are to imitate thofe of the design, they use a flucco, comofed of line and marble dust; or a maffe, which each workman preparently; after which, the work is polishd with a soft kind of fone.

The figures thus marked out, the painter or sculptor himself draws with a pencil, the colours of the figures, not determined by the ground, and in the fame manner makes strokes or hatchings, in the places where shadows are to be; and when he has engraved, with a chiffel, all the strokes thus drawn, he fills them up with a black maffe, composd chiefly of Burgundy pitch, poured on hot; taking off, afterwards, what is superfluous, with a piece of soft fone or brick, which, with water and beaten cement, takes away the maffe, polishes the marble, and renders the whole fo even, that one would imagine it only inferted of a fingle piece; it is this kind of mosaic we fee in the pompos church of the invalids at Paris, and the fine chapel of Versailles; and with which fome entire apartments of that palace are decoratfed.

For Mosaic Work of Precious Stones, there are required other and more delicate instruments than those used in marble: as wheels, drills, tin-plates, &c. used by lapidaries, and carvers in fone. As none but the richest marbles and fones enter this work, to make them go the farther, they are fawn into the thinnell leaves imaginarily, scarcely exceeding half a line in thicknefs: the back to be fawed is lattencd firmly with cords on the bench, only raised a little on a piece of wood one or two inches high. Two iron pins, which are fixed to the block, and which serve to fallen it, serve also to direct the faw. The pieces to be fawed are put into a vice contrived for the purpose; in which flate, with a kind of faw or bow made of a fine brafs wire, bent on a piece of springy wood, together with emery moifened with water, the leaf is gradually fashioned by following the frokes of the design made on the paper, and then glued to the piece.

When there are pieces enough fashioned to form an entire flower, or fome other part of the design, they are applied. The ground, that fupports this mosaic, is usually of ftone. The matter, with which the fones are joined together, is a flucco, or maffe, laid very thin on the leaves as they are fashioned; and the leaves in this flate are applied with pliers. If any contour, or fide of a leaf, he not either rounded enough, or squared enough, to fit the place where it is to be used, when it is too large, it is brought down with a brafs file or razp; and when too small, is managed with a drill, and other lapidary instruments.

Mosaic Work of Pygffum.—This is a kind of coarse tile, or thinning transparent fone, found in the quarries of Montmartre, near Paris, among the fones thence dug to make the platter of Paris. It is different from the platter; but retains the name which the Romans gave the platter, viz. pyffum.

Of this fone, calcined in a kiln, beaten in a mortar, and passed through a fieve, they make a kind of artificial marbles, imitating precious fones; and of these they compofe a kind of mosaic work which comes little short either of the durablenefs or vivacity of the natural fones: and which has this advantage, that it admits of continued pieces, or paintings, of entire compartments, without any joining visible.

Some make the ground of platter of Paris, others of freestone: if the former, it is fpread in a wooden frame, of the length and breadth of the intended work, and about an inch and a half thick. This frame is fpread, as that the teem being only joined to the mortifies by finge pins, they may be taken afunder, and the frame be difmounted when the platter is dry; this frame they mount on one fide by a flone or linnen cloth, nailed all round; and being placed horizon- tally, with the linen at bottom, it is filled with platter, palled through a wide fieve: the platter being half dry, the frame is fet perpendicular, and left till it be quite dry, and then taken out, by difmounting the frame. In this mosaic, the ground is the moft important part. Now, to prepare the lifted pyffum to be applied on this ground, they difolve and boil it in the bift English glue; and, after mixing with it the colour it is to bear, the whole is worked up together into the ordinary confifence of platter; and then taken and fpread on the ground, five or fix inches thick. It muft be obferved, that if the work be fuch, as that mouldings are required, they are formed with gooses, and other instruments.

It is on this platter thus coloured like marble, or precious fone, and which is to ferve as a ground to a work either of lapis lazuli, agat, abalbiter, or the like, that the design to be reprefented is drawn: having been firt pounced, or called. To hollow or imprfed the design, they use the fame instrument with the sculptors; the ground, whereon they are to work, not being much lefts hard than marble itself. The cavities, thus made in the ground, are filled up with the fame pyffum boiled in glue, only differently coloured; and thus are the feveral colours of the original repreffed. To have the neceffary colours and teints at hand, they temper quantities of the pyffum with the feveral
colours, in little pots. When the design is thus filled, and rendered visible, by half-polishing it with brick, or soft stone, they go over it again, cutting such places as are either to be weaker, or more strongly shadowed, and filling them with gypsum; which is repeated till all the colours, added one after another, represent the original to the life. The work being finished, is scored with soft stone, sand, and water; then with pumice-stone; and finally, polished with a wooden rubber, and fine emery; then a luffe is given it, by fmeared it over with oil, and rubbing it a long time with the palm of the hand; which gives it a gloss nothing inferior to that of natural marble.

If it be only required to make a variegated table, or other work of several colours, without mosaic figures, the process is somewhat different. To this end, they only prepare separately, in large bowls, as many different colours as nature inflows in the marble to be imitated; and, after incorporating them with the gypsum and glue-water, they take a trowel full of each, and dippose them in a trough, without any order; then, without mingling them, and only by cutting or scoring the gypsum of each trowel once or twice with each of the rest, they give them that beautiful confusion, for which natural marbles are so much valued: of these they then make their tables, or lay a mould, according to the work to be done.

As to Mosaic Work of Wood, more properly called marquetry or inted work, the ancients were well acquainted with it, and used it for the adorning of their beds, tables, and other moveables: employing, for this purpose, ivory, besides the richest woods.

There are, besides these, two other branches of mosaic work; the one called damaskening, or damask work, consisting in an assemblage of gold or silver threads, of which are sometimes formed flat works, and sometimes baflo relieves.

The other is called field-work; consisting of fields, artificial conglomera, petrifications, &c. used in grottoes.

MOSALA, in Geography, a town of Sweden, in the lapmark of Tornea; 18 miles N.E. of Kimi.

MOSALSK, a town of Russia, in the government of Kaluga; 48 miles W. of Kaluga. N. lat. 54° 20' E. long. 34° 34'.

MOSABA, the name of a particular kind of cotton, which appears to be the same with the capoc or mapu. According to Savary, this cotton covers the whole stem and the branches of the tree.

MOSBACH, in Geography, a town of Bavaria, in the Upper Palatinate; 20 miles E. of Amberg.—Alto, a town of the duchy of Baden, containing three churches, and some manufactures of cloth, salt, &c.; 18 miles E. of Heidelberg.—Allo, a town of the duchy of Wirzburg; 5 miles N. of Schweinfurt.

MOSBRUNN, a town of Aulria; 8 miles S. of Vienna.

MOSBURG, a town of the duchy of Carinithia; 6 miles N.W. of Cragenfurt.—Allo, a town of Bavaria, called alo 

MOSCHARA, in Botany, from moschus, musk, in allusion to its musky scent. Forsk. Copt. Arab. 138. Joff. 419. An herbaceous plant, found flowering in the middle of April, in the deserts about Alexandria. Forskall describes it thus. " Root perenial. Stems several, annual, spreading, but somewhat erect, square, a span long. Leaves opposite, crossing each other, fleshy, two inches long, linear, obtuse, villous, toothed at the end. Flowers axillary, from the very bottom of the stem, solitary, fleshy, the size of a small pea. Calyx globose, villous, five-toothed at the summit, closed, permanent. The place of the corolla is supplied by a pellucid membrane, enclosing the organs of fructification, like a bag, and necessary to be cut open before they can be investigated. Filaments none. Anthers four, two-lipped, surrounding the top of the stigma, combined, Germanus four, obvolute. Style thread-shaped. Stigma simple. Seeds four, naked, smooth. This paradoxical plant is placed by Joffe amongst those which he could reduce to no certain order, but with an indication of its being possibly allied to the Labiate, or Didynamia Gymnosperma. The learned Mr. Correa de Serra has haggled us, that it is probably a monolir series of the Linnæan Teatrum Io, more properly referred by Schreb to Auga. (See Wildl. Sp. Pl. v. 3. 11. Sm. Prodrt. Fl. Grec. Sib. v. r. 389.) Mr. Correa's conjecture strikes us with conviction, though we recollect no familiar metamorphosis in any other genus, particularly with regard to the stamens.

MOSCHALLCINIA, Myosbata of Cordus, Hift. 172, so called by that author from its musky scent, and humble stature. See Adoxa.

MOSCHEL, or Ober-Moschel, in Geography, a town of France, in the department of Me Tonnerre, and chief place of a canton, in the district of Kaiserslautern; 32 miles N.E. of Deux Ponts. The place contains 670, and the canton 8191 inhabitants, in 24 communes. N. lat. 49° 46'. E. long. 7° 43'.

MOSCHELAPHUS, in Natural History, a name given by some writers to a creature of a mixed nature, produced by the copulation of a female with a cow. Wagner tells us, that these creatures are sometimes seen in the mountainous parts of Switzerland; as also the hospitans, generated between a bull and a mare; but neither of these ever propagate their species. See Bucephalus.

MOSCHI, in Ancient Geography, a people who inhabited a territory north of the Euphrates, between that river and the Ccelebde, and the coasts south-east of the Euxine sea, according to Strabo. Pliny says that Phrixus built among the Mochi the rich temple of Leucothoe, and established there an oracle. This temple was pillaged by the fon of Mithridates. This people also occupied a part of mount Caucaus, where the river Phasis took its rise.

MOSCHIPERM ANIMAL, or Moschus moschifers of Linnaeus, musk, in Natural History, the name of the creature which affords us the perfume called musk. See Moschus.

MOSCHION, in Biography. Several ancient physicians of this name are mentioned by Galen, Pliny, Soranus, and Plutarch; some of whom were authors. But the only one, whose writings have been preserved, was a physician of the Medical sect, of an uncertain age, but who probably lived about the eighth century. His work is extant both in Greek and Latin; but it is supposed that the former edition is a translation from the Latin. It was first printed at Basle in 1538, in the "Libri Gynecomium" of Spachus, with the title of "De Melibrivus affectibus Liber unus;" and has been subsequently republished by Gasp. Wolff, with Gefner's Schola, 1538; and by J. O. Dewes, Vienna, 1793, with notes. The work is of little value, shewing a very imperfect acquaintance with the subject of which it treats. Elov Dict. Hist. Gen. Biog.

MOSCHO, or Massto, in Geography, a town of Africa, in the kingdom of Dongola, on the left bank of the Nile; 100 miles N.W. of Dongola. N. lat. 26° 26'. E. long. 30° 52'.

MOSCHOPULUS, Emanuel, in Biography, a Greek grammarian who flourished in the 14th century, was a ne
MOSCHUS, a celebrated Greek pastoral poet, was a native of Syracuse. It is not ascertained at what period he lived. Some authors make him a pupil of Bion (see his article); but Suidas and some others speak of him as the friend of Arístarchus, who flourished about 160 years before the birth of Christ. The tenderfees with which he speaks of Bion, in his beautiful elegy on that poet, is mentioned as a proof of his personal acquaintance with him. In the time of the latter Greeks, all the ancient Idylliums were collected, and attributed to Theocritus; but the claims of Moschus and Bion have been admitted with respect to a few little pieces. Moschus is a poet that possesses a great elegance of style, and more delicacy and ingenuity in his conceptions than usual among Bucolic poets. His piece entitled "Run away Love," in particular, deserves a high rank among sentimental pieces. His works, at least such as are usually attributed to him, are commonly printed in conjunction with those of Bion.

MOSCHIS, in Natural History, the musk, a genus of the order Pecora, and class Mammalia. The generic character is this: without horns; eight lower fore-teeth; the upper tusks are solitary, and projecting. Gmelin enumerates six species, but Dr. Shaw has mentioned seven, adding to those of Gmelin, the muschus delicatus, or Leverian musk. The musk is one of those quadrupeds, of which the true form and natural history continued in great obscurity, long after the introduction and general use of the celebrated perfume which it produces. It seems to have been unknown to the ancients, but is mentioned in the eighth century by the Arabians, who used the drug in their medical practice. At that period, and longer, the animal was by some considered as a kind of goat, by others as a species of deer, or antelope, and of course was supposed to be a horned animal. About the close of the 17th century, a pretty accurate description of its figure and habits was given.

Species.

MOSCHIFERUS, or Thibet Musk, has a follicle near the navel; the tail is short. The size and general appearance of this animal resembles, in some degree, that of the small roebuck. It measures about forty inches in length, and twenty-two in height from the top of the shoulders to the bottom of the fore-feet, thirty-three inches from the top of the haunches to the bottom of the hind-feet. The upper jaw is considerably longer than the lower, and is furnished on each side with a curved tusk about two inches long, and consequently exposed to view, when the mouth is closed. These tusks are thought to resemble a pair of crooked knives; their fibulation is a kind of ivory. The ears are long and narrow, of a pale yellowish cast in the inside, and deep brown on the outside. The general colour of the whole body is a kind of deep iron grey; the tips of the hairs being of a ferruginous cast, the remainder is blackish, growing much paler, or whitish, towards the roots; each hair is somewhat waved or undulated throughout its whole length, and is of a strong and elastic nature, growing rather upright on the animal, and very thick. The female is smaller than the male, and wants the tusks. These animals inhabit the Alpine mountains of Asia, Tonquin, and Siberia; they are also found about the lake Baikal, and near the rivers Jenefa and Argun. Their favourite haunts are the tops of mountains covered with pines, where they delight to wander in places the most difficult of access. In their habits and manners they resemble the chamois, and other mountain goats, springing with great celerity, and, when pursued, taking refuge among the highest and most inaccessible summits. They are hunted for the sake of their perfume, which is contained in a receptacle about the size of a small egg, hanging from the middle of the abdomen, and is peculiar to the male animal. This receptacle is found filled with a soft, unctuous, brownish fibulation, of the most powerful and penetrating smell, which is the perfume, in its natural state, so well known. As soon as the animal is slain, the hunters cut off the receptacle or musk-bag, and tie it up ready for sale. The perfume is found in animals at all seasons of the year, but not in those that are young: the quantity is about a quarter of an ounce. The celebrated musk-barks, or Tavies, lays he purchased, in one of his eastern journeys, no less than 765 musk-bags. The penetrating nature of the musk-perfume is generally known: its colour is brown, with an unctuous and granulated appearance. At a distance, the scent is agreeable; but when brought too close, and in large quantities, it produces alarming effects. It has been known to force the blood from the nofe, eyes, and ears, of those who have imprudently or accidentally inhaled its vapours.

INDICUS. The body of this species is tawny above, and whithin beneath, with purprous hoofs, and a somewhat lengthened tail. This is called the Indian musk, as being found in the East Indies. It has been defcribed by Briffon, and is larger than the Thibet musk. Its head is very like that of the horfe; the ears are erect and oblong, and the legs flender.

PYGMEUS, or Guinea Musk, has the body above brown-tawny, beneath white, and without purprous hoofs. It inhabits India and Java, is very small, as its specific name imports, not being more than nine or ten inches long from the nose to the tail. It is a most elegant little animal, of a bright bay colour, but beneath and on the inside of the thighs it is white. Its shape, as well as its colour, is beautiful, and the legs are so flender as not to exceed the diameter of a man's quill; the head, eyes, and ears, are rather large, and the aspect is mild. The natives of Java catch great numbers in snares, and carry them to markets in cages for sale; and some years since, they were purchased at as low a rate as two-pence or three-pence each. It obtained the name of Guinea musk from the opinion of Briffon and others, that it was a native of that country, which, it has been since ascertained, is not the case. The legs of the pigmy musk have been frequently capped at the upper joint with gold or silver, and in that state used as tobacco-foppers.

There is a variety of this species thus defcribed: body rufly, mixed with black; neck and throat with perpendicular stripes.

MENICONIA. Body above cineraceous-yellow, beneath white; flanks spotted with white, and with purprous or fulse hoofs. It is a native of the Indian islands, but is chiefly found in Ceylon and Java. It has been sometimes confounded with the M. pygmeus. It is readily distinguished by its remarkable colour and spots, and was raised into a distinct species by Mr. Pennant.

JAVAenus, or Java Musk, is, as its name imports, a native of the island of Java, and is the size of a rabbit. The specific character is, body above ferruginous, beneath longitudinally white; tail longish, hairy, white beneath at the tip; the nose and ears are naked; the neck is grey, mixed with brown hairs; beneath white, with two grey spots almost connected; under the throat there are two long divergent hairs; the crown is longitudinally blackish.

AMERICANUS, or Brazilian Musk. Body tawny-brown; mouth
mouth black; throat white. This species is found in Brazil and Guinea; is nearly as large as a roe-buck, with ears four inches long; it is timid, active, and swift; the hair is soft and short; the head and neck on the upper part brown, and under it is white; the hind-legs are longer than those in front. It can, like a goat, stand with all the four legs together on the point of a rock. The animals of this species are often seen swimming in rivers, and may then be easily taken. The Indians hunt them, and their flesh is esteemed very delicate.

A variety of this species is tawny-brown, spotted above with white.

Delictulus, or Leverian Musk, is ferruginous-brown, and spotted above with white. In the Leverian Museum it was called the "small spotted musk." Dr. Shaw says, that the animal so named appears to be nearly allied to one figured by Seba, who affirms it is a native of Surinam, and describes it as a ferruginous colour, thickly spotted with white, except on the head, breast, and belly, and that it is in all probability the same. In size it scarcely exceeds the pigmy musk, if the specimen referred to be of its full growth; of which there are doubts entertained, from the fine

Moscossa, or Moska, in Geography. See Muscka.

Moscow, the name of a tribe in the kingdom of New Granada, said to have been so called by the Spaniards, who, finding them more numerous than the other tribes, transferred the appellation from the fiesi, which abound in their country. Their conquerors found them governed by two elective princes, one of whom, named the "Zippa," ruled at Bogota, while the "Zequi," was established at Tunja. Others more judiciously infer, that the appellation of Mosco was a mere play of words upon the native name of Muscool. Next to the Peruvians, they were the most civilized people. They wore a coat of cotton, with a square cloak of the same fabric. On the head was a cap of the skins of animals, decorated with plumes of various colours; over the forehead hung a crecent of the gold or silver which abounded in their country, the points being turned upwards. Their arms were adorned with bracelets, formed of bone or bone; the nose-ring was of gold; and on gala-days, the face and body were painted with "achites," or ronceau, which yielded a vermilion tint, and with the juice of the "jagua," which produces a deep black. The women used a square cloak, called "chiricate," fastened with a girdle; and over the shoulders a small mantle, called "lipira," fixed on the breast with a large pin of gold. The men wore their hair long, and divided in what is called the Nazarnean form; while that of the women was loose, and darkened by art; the greatest affront being to cut off their hair. Both sexes were handsome, and of good dispositions. Their weapons were flags, swords of hard wood, and light darts. They believed in a great author of nature; and adored the sun, "Zulha," and the moon, "Chia," as their representatives. Their immortality was material, according to the customary opinion among savages; and they buried the dead with ornaments of gold, and the precious emeralds of their country. They were in constant warfare with the Muzos and Colimas, but were feared and respected by all. The Mucoo language, called "Cihualpa," was general throughout the kingdom; but it is now adulterated, and nearly lost, though most of the converted tribes of the kingdom of New Granada belong to this nation, and are generally of generous dispositions, bold, faithful, and robust, though inclined to ebriety.

Moscow, (11th of America, vol. ii.), we shall refer to the article Bogota.

MOSGOW, called by the Russians Moskva, a city of Russia, the capital of a government, is situated on a river of the same name. The approach to this city is announced at the distance of six miles, by spires over-topping an eminence, at the extremity of the broad avenue cut through a forest; and upon proceeding two or three miles farther, a superb prospect of this wide city bursts upon the sight of the traveller. It stretches in the form of a crescent to a prodigious extent; while innumerable churches, towers, guided spires and domes, white, red, and green buildings, glittering in the sun, form a splendid appearance; strongly contrived, however, by an intermixture of wooden hovels. The neighbouring country is undulating; and the forest, abounding with plantations of oaks, beech, mountain-ash, poplars, pines, and firs, reaches within a mile of the ramparts, and is succeeded by a range of open piaiures. In entering the city, or rather the suburbs, the river Moskva is crossed on a long kind of raft-floating, fastened to each bank, which the Russians call a "living-bridge," because it bends under the carriage. Before we give an account of the city itself, we shall detail some particulars respecting its origin, concerning which antiquaries have differed. The following account is received as the most probable. Moscow was founded by Prince Yaroslav, son of Vladimir, or Volodya Monomak, who reigned, says Chastreux, in 1147, but who ascended the throne of Russia, as Coxe says, in 1154. Being insulted by Stephen Kutchko, prince of Suifdal, he confiscated his domains, of which the lands, now occupied by this city, formed a part, and laid the foundation of a new town, which he called Moskva, from the river of that name. But under his successors, the town fell into such decay, that in the year 1255, when the empire was divided, and Daniel, son of Alexander Newiki, received as his share the duchy of Moscow, and fixed his residence at this place, he was under a necessity of rebuilding it, and may therefore be considered as its new founder. The spot, now occupied by the Kremlin, was at that time a moras, overgrown with wood, containing a small island, with a single hut. On this part Daniel constructed numerous buildings, confiding chiefly of churches and monasteries, and enclosed them with wooden fortifications. Here he first assumed the title of duchy of Moscow; and when he succeeded his brother, Andrew Alexandrovitch, in the great duchy of Vladimir, he continued his residence at Moscow, which became the capital of the Russian dominions. The new metropolis was considerably enlarged by his son Ivan; and in 1367, his grandson Demetrius Ivanowitch Doniki surrounded the Kremlin with a brick wall. Notwithstanding these fortifications, the town was taken, in 1382, by Tamerlane. This defunct conqueror soon evacuated it, and it again came into the possession of the Russians, but was frequently occupied by the Tartars, who, in the 14th and 15th centuries, over-ran Russia, and even maintained a garrison in Moscow, until they were finally expelled by Ivan Vasilievitch. To him Moscow has been indebted for its principal splendour, and under him it became the most considerable city of the Russian empire. Of Vladimir. Moscow continued to be the metropolis of Russia till the beginning of the last century; when, to the great diffusion of the nobility, but with great advantage to the state, the seat of empire was transferred to Peterburgh. Notwithstanding the predilection which Peter conceived for Peterburgh, Moscow is still the most populous city of the Russian empire. Here the chief nobles, who do not belong to
MOSCOW.

...and here they gratify their taste for a roder and more expensive magnificence in the ancient style of feudal grandeur, without being eclipsed, as at Peter-
burgh, by the superior splendour of the imperial establishment. This is the largest city in Europe; the circumference of the ramparts, which encloses the suburbs, being 39 miles, or 26 miles; but being built in a very unconnec-
ted and dragging manner, its population does not in any degree correspond to its extent. Some Russian authors have, by an exaggerated statement, estimated the number of inhabitants at 500,000. According to Bufcheh, who lived some years in Siberia, Moscow, in 1779, contained 708 brick-houses, and 11,840 habitations of wood; 85,731 males, and 67,059 females; in all, only 152,790 souls, a computation which much diminishes the true number. According to an account published in the journal of St. Peter-
burgh, for 1781, the district of Moscow contained, in the beginning of 1783, 217,873 hearths and the number of inhabitants included 137,695 males, and 134,918 females; in all, 272,616 souls. At the end of the same year, the popu-
lation of the district was found to be 143,445 males, and 137,592 females; in all, 277,937 souls. The accuracy of this com-
putation has been confirmed by the account received by an English gentleman from the lieutenant of the police, who informed him that Moscow contained within the ramparts 250,000 souls, and in the adjacent villages, 50,000. Dr. Clarke, in his "Travels," citing Mr. Heber's MS. journal, observes, that the population of Moscow has been greatly exaggerated; and that the intendant of police reckoned it at only 250,000 fixed inhabitants, and 70,000 retainers and servants of the nobles, who only reside in it during winter. Richter observes, that the population of Moscow differs ac-
cording to the season of the year. In winter, when the nobility and their retainers flock to the metropolis, the inhabitants exceed 300,000; but in summer, when they re-
tire to the country, they do not amount to 200,000. The births, deaths, and marriages at Moscow in the year 1790, appear, from a table published in the first volume of Mr. Tooke's "History of the Russian Empire," to be as follows:

<table>
<thead>
<tr>

</table>

The same writer states, that the government of Moscow, which was the most populous when he published his valuable work, including the metropolis, contained upwards of 1,130,000 persons.

Mr. Coxe informs us, that of all the cities that ever claimed his attention, he never observed any one so irregular, so uncommon, so extraordinary, and so contrived, as Moscow. The streets, he says, are in general exceedingly long and broad; some are paved; others, particularly in the suburbs, are formed with trunks of trees, or bordered with planks, like the floor of a room; wretched hovels are blended with large palaces; cottages of one story stand next to the most stately mansions. Many brick structures are cov-
ed with wooden tops; some of the timber houses are painted, others have iron doors and roofs. Churches in every quarter are very numerous, built in the oriental style of architecture, some with domes of copper, others of tin, gilt or painted green, and many roofed with wood. In a word, some parts of this vast city have the appearance of a squalid defiled; other quarters, of a populous town; some of a contemptible village; others of a great capital. Upon the whole, this city exhibits a motley mixture of discordant architecture. Dr. Clarke says, that "Moscow is in every thing extraordinary; as well as in disappointing expectation as in surpassing it; in causing wonder and derision, pleasure and regret. Numerous spires, glittering with gold, amidst burn-
hished domes and painted palaces, appear in the midst of an open plain for several miles before you reach the gate of the city. Having passed, you look about, and wonder what is become of the city, or where you are; and are ready to ask, once more, how far is it to Moscow? They will tell you, 'This is Moscow!' and you behold nothing but a wide and scattered suburb, huts, gardens, pigsties, brick walls, churches, dunghills, palaces, timber-yards, warehouse, and a refuie, as it were, of materials sufficient to flock an em-
pire with miserable towns and miserable villages. One might imagine all the states of Europe and Asia had sent a building, by way of representation, to Moscow; and under this im-
pression, the eye is presented with deputys from all coun-
tries, holding congresses; timber-huts from regions beyond the arctic; palatial palaces from Sweden and Denmark, not white-washed since their arrival; painted walls from the Tyrol; mosques from Constantinople; Tartar temples from Bucharia; pagodas, pavilions, and virandas from China; cabarets from Spain; dungeons, prisons, and public offices from France; architectural ruins from Rome; terraces and tumbled from Naples; and warehouses from China. Having heard accounts of immense population, you ap-
proach through deflected streets. Passing suddenly towards the quarter where the shops are situated, you might walk upon the heads of thousands. The daily throng is there so immense, that, unable to force a passage through it, or aflign any motive that might convene such a multitude, you ask the cau-
se; and are told, that it is always the same. Nor is the costume less various than the aspect of the buildings; Greeks, Turks, Tartars, Cossacks, Chinese, Muscovites, English, French, Italians, Poles, Germans, all parade in the habits of their respective countries."

Moscow is divided into the five following divisions, viz. Kremlin, Kitai-gorod, Bielgorod, Semilajgorod, and Sloboza, or suburbs.

1. The Kremlin was probably thus denominated by the Tartars, who, in possession of Moscow, from the word "krem," or "krim," which signifies a fortress. It stands in the central and highest part of the city, near the conflux of the Moskva and Neglia, which wash two of its sides; it is of a triangular form, and about two miles in circum-
ference; and it is surrounded by high walls of stone and brick, constructed in 1491. It is filled with domes and clock-towers; and though it contains the most irregular edifices, none of them are of wood, nor of mean appearance. A plan was proposed to the late emperors for uniting the whole Kremlin into one magnificent palace, which would, when executed, have exceeded every thing of the kind in ancient or modern days. A model of the proposed alteration was completed, and is preserved at Moscow; but the expense, even in that country of cheap labour, would have amounted to three millions sterling, and we therefore need not wonder that the design will proceed no farther than the preparation of the model.

2. The Kitai-gorod, denoting, by a Tartar derivation, the "middle town," is situated between the Kremlin and Biel-
gorod. It is bounded on one side by that wall of the Kremlin which runs from the Moskva to the Neglia, and on the other by a brick wall of lower height. This division of Moscow is much larger than the Kremlin, and contains the university, the printing-house, and many other public build-
ings, together with the shops of the tradesmen. The ed-
ifices...
fice are mostly stuccoed or white-washed; and it has the
only street in Moscow in which the houses stand contiguous
to each other, without any intervals.

3. The Bichgrod, or White-town, nearly encircles the
two preceding divisions, and is supposed to have derived its
name from a white wall with which it was formerly enclosed,
of which some remains still exist.

4. Semil'agorod environs the three other quarters, and
takes its denomination from a circular rampart of earth, with
which it is encompassed. This and the last division exhibit a
grotesque group of churches, convents, palaces, brick and
wooden houses, and mean bowels, in no degree superior to
peasant's cottages.

5. The Streda, or suburbs, form a vast exterior circle
round the parts already described, being invested with a low
rampart and ditch. These suburbs contain, besides numerous
buildings of all denominations, corn-fields, open pasture,
and some small lakes, from which the Neglina originates.

The Moscva flows through the city in a winding channel;
but, the season of spring excepted, it is only navigable for
rafts: it receives the Yaufa in the Semilagorod, and the
Neglina at the western extremity of the Kremlin; both
which rivulets are in summer almost dry. Beyond the Yaufa,
which is crossed by a raft bridge, is a palace, con-
structed for the late emperors, when they had occasion to visit
Moscow. This palace is not a single structure, but in the
true style of Atlantic grandeur, a vast assemblage of numerous
buildings, distributed into several streets, and bearing the
appearance of a moderate town. Paul converted this palace
into barracks for 2000 men. The gardens, which belonged
to the old palace, built by Elizabeth, near the spot where
the present structure was erecting, are still retained; they
are of considerable extent, and in some parts of them were
laid out in a pleasing and natural manner; but in general the
old style of gardening prevailed, and presented rows of
clipped yew-trees, long straight canals, and a profusion of
prepossessing statues. Under the arcipics of Catharine, all
these inlances of grotesque style were proposed to be re-
moved, and to give place to more natural ornaments. This
palace and gardens occupy the extremity of the suburbs
within the compass of the exterior rampart which encircles
the whole town.

The places of divine worship at Moscow are very nu-
merous; and exclusively of chapels, there are, according
to Mr. Coxe's account, 454 public churches, of which 199
are of brick, and the others of wood; the former are com-
monly stuccoed or white-washed, the latter painted of a red
colour. According to Heym, in 1793, Moscow contained
22 convents, 9 cathedrals, and 326 churches. The church
of the Holy Trinity, sometimes called the church of Jeru-
salem, which stands in the Khitaiagorod, close to the gate
leading into the Kremlin, has a kind of high steeple, and
nine or ten domes; it was built in the reign of Ivan Vass-
ilevitch II. The most ancient churches are generally square
buildings, with a cupola and four small domes; some of
bronze, or iron girt, others of iron timbered, either plain or
painted green. The cupolas or domes are for the most part
ornamented with crosses entwined with thin chains or wires;
such crofs (in the most ancient churches) has two transverse
bars; the upper horizontal, the lower inching, which, ac-
cording to the opinion of many Russians, is supposed to be
the form of the real crofs; under the lower bar frequently
occurs a crescent, the origin of which we have stated under
the article CRESCENT. The inside of the church generally
confists of three parts; that called by the Greeks προσωπο,
pronae, by the Russians trapeza; the body; and the lan-
cuary or shrine. In the body of the church are frequently
four square and massive piers, which support the en
cope; these piers, as well as the walls and ceilings, are painted
with numerous representations of our Saviour, the Virgin
Mary, and different saints. Towards the extremity of the
body of the church is a flight of steps leading to the shrine;
and between these steps and the shrine is usually a platform,
upon which the officiating minister stands and performs part
of the service. The shrine or sanctuary is separated from
the body of the church by the * Iconostasis, or ikre, which
is generally the part most richly ornamented, and on which
the most holy pictures are painted or hung. Before the
images of Jesus and the Virgin, and of some others, candles
or lamps are usually suspended, and kept continually burn-
ing. In the centre are the folding, called the holy, royal
or beautiful doors, which lead to the shrine, within which
is the holy table, as Dr. King (on the Greek church) describes
it, "with four small columns to support a canopy over it;
from which a peribolion, or dove, is suspended, as a
symbol of the Holy Ghost; upon the holy table the crofs
is always laid, and the gospel, and the pyxis, or box, in
which a part of the consecrated elements is preserved, for
visiting the sick or other purposes." Over the door of each
church is the portrait of the patron saint, to which the com-
mon people pay homage as they pass, by taking off their
hats, crossing themselves, and occasionally touching the
ground with their heads. In the Russian churches, bells
constitute no inconsiderable part of divine worship; for an
account of which, see the article BELL. Some of these
bells are of a fabulous size. The division of Moscow,
called the Kremlin, abounds with churches, of which the
two most remarkable, are St Michael's, and the Af-
famation of the Virgin Mary; he one being the place
where the sovereigns were formerly interred, and the other
that in which they were crowned. These edifices are both
in the same style of architecture, and were probably con-
structed by Solario of Milan, who built the walls of the
Kremlin. In the cathedral of St. Michael are the tombs of
the Russian sovereigns, which are raised sepulchres mostly
of brick, in the shape of a coffin, and about two feet high.
On great festivals all the sepulchres are covered with rich
palls of gold or silver brocade, studded with pearls or
jewels. From the time in which Moscow became the im-
perial residence to the close of the 16th century, all the
tzars have been interred in this cathedral, excepting Beris
Godunof, whose remains are deposited in the convent of
the Holy Trinity; the tzar, under the name of Demetrius,
who was destroyed in a tumult, and Vassili Shuilki, who
died in captivity at Warsaw. The cathedral of the Af-
famation of the Virgin Mary, appropriated to the coronation
of the Russian sovereigns, is the most magnificent temple in
Moscow. The ikre is in many parts covered with plates
of solid silver and gold richly wrought. From the centre of
the roof hangs an enormous chandelier of mossy silver, weigh-
ing 2940lbs., made in England, and presented, as Mr. Coxe
says, by Morofof, prime minister of Alexey Michaelovitch;
but, according to Storch, it was a present from the Vene-
tians to Beris Godunof, and weighs 2800lbs. The sacred
veils and episcopal veilments are extremely rich, but of
rude workmanship. Many of the painted figures, which
cover the inside walls, are of a colossal size; and were exe-
cuted towards the close of the 15th century. This church
also contains a head of the Virgin, suppos'd to have been
painted by St. Luke, and greatly celebrated in that coun-
try for the power of working-miracles. According to
the tradition of the church it was brought from Greece to
Kio, transferred from thence to Volodimir, and afterwards to
Moscow. It seems to have been a Grecian painting, and

W28

MOSCOW.
was probably anterior to the revival of the art in Italy. In this cathedral are deposited the remains of the Russian patriarchs, the first of whom was Job, before whose time the primate of the Russian church was suffragan to the patriarch of Constantinople. Job, being metropolitan archbishop of Moscov, was in 1538 installed in this cathedral patriarch of Russia, by Jeremias, patriarch of Constantinople. Philaet and Nicos were distinguished patriarchs, and died much regretted at an advanced age in 1653. The last of thefe patriarchs, who are reckoned to have been 11, was Adrian, at whose death, in 1609, Peter the Great refused to nominate a successor; and in 1721 the patriarchal dignity was formally abolished. In connection with this account of the churches at Moscov, we shall here insert a brief description of some of the more prominent ceremonies performed in this city, at the time of Easter. Dr. Clarke, who proceeded to the public a picture of the Russian manners, approaching to a caricature, and who, as we hope and believe, has incurred the charge of exaggeration in some of his details, furnishes us with several instances of the groffety of superstition, still prevalent in Russia. "All that has been said or written of the Roman Catholic bigothry," says this writer, "affords but a feeble idea of the superstition of the Greek church. It is the greatest libel upon human reason, the foremost scandal upon universal piety, that has yet disgraced the annals of mankind."—**

There are no people who observe Lent with more fervent and exccssive rigour than the Russians. Travelling the road from Petersburg to Moscov, if at any time, in poor cottages, where the peasants appeared flaving, I offered them a part of our dinner, they would fludder at the sight of it, and cast it to the dogs; daffing out of their children's hands, as an abomination, any food given to them; and removing every particle that might be left entirely from their sight. The fame privation takes place among the higher ranks, but in proportion as this rigour has been observed, to much the more exccssive is the degree of gluttony and relaxation, when the important intelligence that 'Chrift is risen,' has issued from the mouth of the archibishop. During Easter they run into every kind of excess, rolling about drunk the whole week. When Easter was proclaimed, the inn where we lodged became a Paudaemonium. Drinking, dancing, and singing continued through the night and the day. But in the midst of all these excesses, quarrels hardly ever took place. The wild, rude riot of a Russian populace is full of humanity. Few disputes are heard; no blows are given; no lives endangered, but by drinking. No meetings take place of any kind, without repeating the expressions of peace and joy, "Chriftos vosferjis!" "Chrift is risen!" to which the answer is always the fame, "Pa jifing vosferjis!" "He is risen indeed!" On Easter Monday begins the presentation of the Paschal eggs; lovers to their mistresses, relatives to each other, fervants to their masters, all bring ornamented eggs. Every offering at this feast is called a Paschala egg. The meanest pauper in the street, preparing an egg, and repeating this words "Chriftos vosferjis," trouble not a falsehood on the empress. All business is laid aside; the upper ranks are engaged in visiting, balls, dinners, suppers, masquerades; while hours fill the air with their fongs, or roll drunk about the streets. Servants sipper in new and taundry liveries; and carriages in the most sumptuous parade." During their easter festivals, the pomp of Moscov was displayed in motley processions on the public promenades. These processions are made in carriages and on horfesback; and the carriages surpass, in number at ball, any exhibition of the kind in Europe. On particular days, they exceed 1000, and have generally fix, but never fewer than four horses to each. Yet nothing can be more mean than the appearance of these equipages, when separately examined, whether we look at the awkwardness of the driver, the dust of the harness, or the clumsiness of the vehicle. During Easter week, the Russians indulge their predilection for finging; and the numerable bells of Moscov are tolled incessantly; the cathedral bell sends a hollow murmur over the city, like the tones of a vast organ, or the rolling of distant thunder. The diameter of the bell is 16 feet.

At Moscov carriages are so common, that almost every person makes use of them. The equipages of the nobility, with complete sets of horses, are frequently driving about the streets of Moscov. The number of these is exceedingly great; the hackney carriages are flattened in the streets for conveying passengers to the different quarters. These vehicles are without tops, have merely four wheels, and are furnished either with a long bench, or one, two, or three separate seats, like arm-chairs, placed side-ways: their fares are so reasonable, that servants occasionally use them upon errands to distant parts of the city. The coachman generally drives at the rate of eight or nine miles an hour. Notwithstanding the number of coaches with fix horses, that traverse the streets of Moscov, their accommodations are ridiculously mean. When a coach is procured with fix horses of different colours, the coachman and poftilion are drest like peafants, with high cylindrical hats; the coachman with a long beard and white linen robe, fits on the box; the poftilion in a coarse drugged garb, and mounted on the off-horse, according to the custom of the country. Behind the carriage is an enormous lack of hay, which, while the master is paying his bills, or regaling himself at dinner, is occasionally given to the horses. "Mafie during dinner generally makes a part of the entertainment at the tables of the nobility. Most of the Russian nobles have gardeners of our nation; and they are thus provided for their entertainments with pines, peaches, apricots, grapes, pears, cherries, and such fruits as can rarely in this country be obtained without the aid of hot-houses. According to Richter, in his Sketch of Moscov, pines are reared in great abundance in the hot-houses about this city, and may be purchased for a ruble a-piece. In the country-houfe of prince Gallitzin, grapes have been seen nearly ripe in the open air. The Russian nobles are fond to display a great degree of grandeur and magnificence in their houfes, domes, and mode of living. The wealth of the nobles is enormous. Some of them have 70 and even 100,000 peafants; and their fortunes are estimated by the number of their peafants, who pay them, upon an average, 10 rubles annually, in specie. They exalt labour, not merely from the masses, but from women, and children from the age of 10 and upwards. Tither are moreover demanded of linen, poultry, eggs, butter, pgs, sheep, lambs, and of every product of the land, or of domestic manual labour. Should a peafant by any misfortune be unable to furnish the tribute expected by his lord, he must beg, borrow, or steal to make up the deficiency. The only property a Russian nobleman allows his peafant to possess, is the food he cannot, or will not, eat himself; the bank of trees, chaff, or other refuse; quals, water, and fish-pond. Travelling the provinces south of Moscov, where the soil is singularly fertile and productive, the labourers are, never-
the chiefs, says Dr. Clarke, destitute of the common necessaries of life; the lord claims all the produce Mr. Heber differs in his statement of the condition of peasants from Dr. Clarke; objecting, that with regard to their comforts or means of sufficiency, they are not deficient. Their houses are well adapted to the habits of the people; their clothing is warm and substantial, and they appear to be sufficiently fed: but their political situation is very servile and distressing. They are hale to be levied as soldiers at the pleasure of their lords; for if a matter is displeased with his flave, he may lend him to the army whenever he thinks proper, and take a receipt from government. The wealth of the nobles is no where more conspicuously displayed than at their weekly fairs. Every parish, who is a bachelor, is excluded by the laws of the society, and though nobles only are admitted, the company occasionally consists of 2000 persons. The dresses are the most fumptuous that can be imagined; the favourite ornaments of the ladies are cameo stones, which they wear upon their arms, in girdles round their waists, or upon their bosoms. The drapery is disposed after the Grecian costume, and their hair is bound up round the head. The mode of drees in London and Paris are generally blended together by the ladies of Moscow; and in justice to their charms, it must be confessed, that no country in the world can boast superior beauty. The men on these occasions appear either in uniform or in coats of very rich embroidery, but neither men nor women evince the slightest degree of animation in the exercise of dancing. Dr. Clarke will not allow to the Russians the unqualified praise of hospitality. The dines and the wines, he says, correspond in gradation with the rank and condition of the guests. Those who fit near the master of the house are suffered to have no connection with the fare or the tenants at the lower end of the table. The chins, or as a Russian table are carefully placed at the upper end, and are handed down to those guests who are stationed near the owner of the mansion, according to the order in which they sit; afterwards, if any thing remain, it is taken gradually to the rest, so that persons at the bottom of the table are often compelled to remain satisfied with an empty dish. The wine also degenerates in quality, until at last it is deteriorated into simple quaffs. The number of attendants in waiting is prodigious. In the house of the young count Orlov 500 servants wait at table; many of them sumptuously clothed and many others in rags.

The palace inhabited by the ancient tsars stands at the extremity of the Kremlin; part of it is old, and remains in the same state in which it was, when it was built under Ivan Vassilievitch I. Additions have been made to it at various periods in different styles of architecture, so that it is a motley incongruous pile of building. This palace was the birth-place of Peter the Great in 1672. In the Kremlin there are two convets, one a nunnery founded in 1593; and the other a monastery for men. The nuns, who are prohibited the use of meat, live chiefly upon fish, eggs, and vegetables. The Russian archives are deposited in a strong brick building containing several vaulted apartments with iron floors, in the Khitaigorod. They were arranged by Mr. Muller in chronological order, and are enclosed in separate cabinets with glass doors. The MSS. relating to foreign kingdoms are also placed in separate divisions under the titles of the countries to which they belong. The archives contain also 13 volumes of letters, journals, notes, and other MSS. of Peter the Great, written with his own hand. The university is also situated in the Khitaigorod. It was founded, at the instance of count Shuvalof, by the empress Elizabeth, for 600 students, who are clothed, boarded, and educated at the expense of the crown. To the university belong a printing office, a library, and an apparatus of philosophical instruments. Besides the university, there are two gymnasia or seminaries for the education of youth, endowed also by Elizabeth.

Moscow is the centre of the inland commerce of Russia, and connects the trade between Europe and Siberia. The navigation to this city is formed solely by the Moskva, which, falling into the Oecas near Kolomna, communicates by means of that river with the Volga. But, as the Moskva is navigable only in the spring, on the melting of the snow, the principal merchandize is conveyed on flegdes in the winter. The whole retail commerce of the city is conducted in the districts of Khitaigorod, where, according to a custom prevalent in Russia, as well as in most of the East, the shops and ware-houses are collected in one spot. The place is like a kind of collection of booths for a fair; the dwellings of those, to whom those shops belong, are situated at a distance, in another quarter of the town. Every trade has its separate department. Furs and skins form the most considerable article of commerce in Moscow, and the shops vending those commodities occupy several streets. Among the curiosities of Moscow we may mention the market for the sale of houses. It is held in a large open space, in one of the suburbs, and exhibits "ready-made houses," scattered on the ground. The house, when selected, is sometimes paid for on the spot, and removed by the purchaser, or the vendor contracts to transport and erect it upon the place where it is designed to stand. In Moscow they have an admirable police for preventing riots, or filling the concourse of people in case of fires, which are very frequent in those parts, where the houses are mostly of brick built with timber. At the entrance of each street is a "chevaux de frise" gate, one end turning upon a pivot, and the other rolling upon a wheel; near it is a centry box, in which a man is occasionally stationed. In times of riot or fire the centry husts the gate, and thus immediately stops all passage. The Russians amuse themselves very much with playing at the game of chess.

Among the public institutions, the most remarkable is the Foundling hospital, endowed by the empress in 1764, and supported by voluntary contributions, legacies, and other charitable gifts. Benefactors have certain privileges granted to them by the empress, and a certain degree of rank proportioned to the extent of their liberality. The hospital is situated on a gentle acient near the river Moskva; and is capable of receiving 8000 children, who are admitted at the porter's lodge without recommendation. In the hospital is a theatre, of which the decorations are the work of the foundlings: they constructed the stage, painted the scene, and made the dresses.

The monastary, called "Troitsko Koller," or the monastery of the Holy Trinity, is distinguished in the Archives of Russia as the asylum for the Russian sovereigns in cases of insurrection; and is more particularly known to foreigners on account of the refuge which it afforded to Peter the Great, when he put an end to the administration of his sister Sophia. This monastery is about 40 miles from Moscow. At a little distance this monastery bears the appearance of a small town, and like many other convets in this country is surrounded with high brick walls, strengthened with battlements and towers. The parapet is roofed with wood, and the walls and towers are provided with embrasures for muskets and cannon; the whole is surrounded by a deep ditch. This place has withstood several sieges, and particularly baffled
all the efforts of Ladislaus, prince of Poland, who attacked it at the head of a large army. Besides the habitation for monks, the walls enclose an imperial palace, and nine large churches constructed by different sovereigns, which are splendid, and very rich in gold and silver ornaments, and costly vestments. The library of the convent contains a curious collection of books.

An eminence, called Sparrow-hill, and situated about four or five miles from Moscow, commands the belt view of the city; and from thence the land about it may be perceived to be low and swampy, abounding with pools of stagnant water, and of course unhealthy. The climate is also dangerous from sudden transitions. The rapidity of vegetation is here very striking. In and about Moscow the rivers freeze about the middle or latter part of November, and break up in March or the beginning of April. The birch trees come out in May, and shed their leaves in September. Fahrenheit's thermometer fluctuates at 68° on May 20th, and at 44° April 16th, and between these periods at intermediate degrees. At London on the same days it fluctuates at 51° and 55°. The French army under the command of Bonaparte, emperor of France, took possession of Moscow, after several engagements with the Russians, September 14th, 1812; but the place was previously set on fire by order of the governor, and so much defoliated, that it afforded no satisfactory accommodation for the emperor and his troops. After enhancing the diftrust of the city and its vicinity, the French were under a necessity of abandoning the city, and making their retreat homewards. History feebly records an event, that has been in every view so destructive to human life and to the possessions of individuals as the project, suggested by ambition, of invading and conquering Russia; but if the termination be auspicious, it may prove the salvation of Europe, the harbinger of peace, the extension of British commerce, and the prosperity of British manufacture. N. lat. 55° 45' 45". E. long. 37° 21'.

MOSE, or Villa de Moso, a town on the bank of the river Taba-fico, in the bottom of Campeachy gulf, from which great quantities of cocoa are shipped for Spain.

Mose, an island in the East Indian sea, about 30 miles in circumference. S. lat. 6° 20'. E. long. 132° 2'.

MOSECHE, a province of Angola, on the N. bank of the Cuanza.

MOSELLE, a river of France, which rises in the mountains of the Volges, joins the Rhine at Coblenz, and gives name to a department.

MOSELLE, one of the ten departments of the N.E. region of France, formed of the territory of Mellein, of French Luxembourg, and part of German Lorraine, and situated in N. lat. 19° 15'. It is bounded on the N. by the department of the Forest, on the E. by that of the Sarthe, on the S. by the departments of Mont Tonnerre and the Sarthe, and on the W. by that of the Meuse. It is 45 French leagues in length, 17 in breadth, and contains 6552½ square leagues, or 328 square leagues, and 353788 inhabitants; and is divided into 4 districts, 30 cantons, and 933 communes. The four circles are Brivy, including 49,552 inhabitants; Thionville, 98,436; Metz, 120,810; and Sarreguemines, 85,970. Its contributions in the 11th year of the French era were 3,508,285 francs, and its expenses 3,818,744 francs, 96 cents. According to Haffenricht, it is divided into 9 circles and 76 cantons, and its population is 328,568. The capital is Metz. This department is fertile in grain, wine, fruits, and pastures. It has also mines of iron and coal.

MOSENIA, a town of Peria, in Chusitan; 36 miles S.W. of Sauma.

MOSERADA, a town of Italy, in the Tresvign; 6 miles N.E. of Tresvign.

MOSES, in Scripture Biography, the son of Amram and Jochebed, was born in Egypt in the year 1571 before Christ. Pharaoh, the king of that country, perceiving that the Hebrews were becoming a very formidable nation, promulgated an order, under the several penalties, that every male child born of Hebrew parents should be cast into the Nile. By the operation of this cruel edict, the king hoped to extirpate, by degrees, the whole Israelite nation; parents were even enjoined to become the executioners of their own children, or at least to give such notice of their birth as to enable the officers of the king to perform the savage act. The rendition of this decree, according to Josephus, was the prediction of an Egyptian prophet, that a Hebrew child was about to be born who would hereafter diminish the power of Egypt, and increase that of the Israelites. Though there is no authority for this in the sacred scriptures, which will be our chief resource in this article, yet it does not appear at all improbable, that the king's mind was impressed with some such notion when he issued his command. At the birth of Moses, it is said that the natural reluctance of his parents to obey such a decree, was increased by the superior loveliness of the child; though mothers, probably, always feel beauty in their new-born infants, which, for obvious reasons, is a very wise provision of Providence, and they ventured to keep him in concealment during the space of three months. At length, the extreme danger of a discovery which would have proved fatal to themselves as well as the infant, reduced them to the cruel necessity of exposing him. His mother took a small ark, made of the ligneous part of the papyrus, and having bismected it with bitumen, to render it water-tight, placed the infant in it, and let it down among the rushes, on the marshy brink of the river. Anxious, however, about his fate, she placed her daughter Miriam, at a certain distance, to watch the circumstances that should occur. Soon after this, the daughter of Pharaoh, coming to the river with her female attendants in order to bathe, discovered the ark, and sent one of them for it. She determined to save the life of the child, and to adopt him as her own; at this moment Miriam approached the princess, and made an offer to bring an Hebrew nurse to suckle the child, which she ordered her to do. She accordingly brought the infant's mother, who with unspeakable joy received the child, and she was strictly enjoined to treat him as her own, under the promise of being amply rewarded for her services. About three years afterwards, the princess adopted him for her own, called his name Moses, and caused him to be diligently instructed in all the learning of the Egyptians. But his father and mother, to whom, as we have seen, he had been restored, were at great pains to instruct him in the history and religion of his country. It is highly probable that the manner in which his life had been faved led them to hope he was intended for some great work, and hence they would be doubly careful of his education; and when arrived at years of discretion they, probably, by relating to him the secret of his birth and of the attending circumstances, inspired him with a similar notion.

Many things are reported by Josephus and other historians concerning the early periods of the life of Moses, and though some persons consider them as entirely fabulous, yet we think it right to mention one or two, and the more so, as we are disposed to pay a considerable deference to the history of Josephus, and are not willing to suppress him capable
of introducing facts that were not authenticated by the best proofs that he was capable of obtaining. Unless we go thus far, we must lose much that Christians value as important, which he has transmitted in his History and Antiquities.

In the Acts of the Apostles, chap. vii. 20, we are told that Moses was "exceedingly fair," or, as the original may be rendered, "beautiful through or in respect to God," that is, perhaps, through the divine blessing. Joesephus relates, that when Moses was only three years old, that is, when he was specially introduced to Pharaoh's daughter as her adopted son, no one who saw him could avoid being struck with the singular beauty of his countenance, and he adds, people about their common business would leave it to gaze at him. Philo says, that at his birth he had a more elegant and beautiful appearance than denoted an ordinary person. According to Joesephus and Eusebius, Moses acted as a leader in the wars, distinguished himself, and obtained many signal victories. When he was about forty years of age he left the court of Pharaoh, and went to visit his countrymen the Hebrews, who groaned under the ill usage and oppression of that Almighty God, and complained "to have looked on their burdens," that is, he made himself acquainted with their condition and treatment, endeavoring to devise some means of relieving them from the intolerable oppressions to which they were subject. While he was thus occupied he perceived an Egyptian imitating an Hebrew; looking about and seeing no one near, he ran to the defence of the latter, and having killed the Egyptian in the struggle, he buried him in the sand. In consequence of this act, which we know not how to justify, he was obliged to fly into the land of Midian, in Arabia, there to seek that safety which he was aware he could not expect in Egypt. Here he married Zipporah, daughter of the priest of Jethro, by whom he had two sons. At this period he was employed by his father-in-law in attending upon his flocks. As he was following this business upon Mount Horeb, he had an extraordinary vision, which occasioned his return into the land of Egypt. In this vision he saw, or thought he saw, a bush in flames, but which was not consumed, and from the midst of the flames a voice proceeded, announcing the presence of the Most High, and commanding the shepherd to go and deliver his brethren from the state of bondage in which they had been so long involved. Moses was zealous of excusing himself from this high and very important office, till he was assured, by miraculous signs, that he should be accompanied in his mission by the divine power. Upon his return to Egypt, he, with his brother Aaron, went to the court of Pharaoh, and told him that God commanded him to let the Hebrews depart, and go three days' journey into the desert, for the purpose of celebrating a festival in his honour, without giving offence to the Egyptians by making them the witnesses of their peculiar rites and ceremonies. The monarch was deaf to their intreaties, and so far from regarding the message delivered by Moses and Aaron as one lent from a superior power, declared that he acknowledged no such power, and in contempt of them, he ordered the labours of the Israelites to be increased, instead of allowing them any relaxation of which they made a demand. In the anguish of their hearts, under an additional load of misery, the Hebrews now attributed their sufferings to Moses and Aaron, who had attempted to free them from their bondage. The want of success which had attended his first application to the king of Egypt, would have prevented Moses from appearing again before him, had not God encouraged him by fresh assurances of his determination to rescue the Israelites with a triumphant arm, and invested him with a miraculous power over Pharaoh, to be exercised in such displays of divine judgment on that proud monarch and his people, as should force him to dismiss them. Thus encouraged, Moses presented himself again before Pharaoh, and confirmed his former message by a miracle; which was followed, at different periods, by many others, as may be seen in the books of Exodus, inflicting the most dreadful calamities upon the Egyptians, as punishments for their continued oppression of the children of Israel. The tenth and last miracle, or plague brought upon the Egyptians, was the death of all the first-born in the land, who were all cut off in one night. This dreadful calamity seems to have subdued the heart of Pharaoh, and he consented to let the people of Israel depart from his kingdom. The Egyptians likewise were impatient to hurry them out of their country, dreading that a further detention of them would bring on themselves entire destruction; and to hasten them, they freely parted with their most valuable things, which the text says the Israelites wished to borrow. Dr. Geddes and others observe, that the word does not necessarily mean to borrow, and we are disposed to think that the Israelites conferred with Pharaoh in order to receive what the Egyptians gladly pressed upon them with the view of hastening their departure.

As soon as Moses had returned to Go'hen among his people, he made signals for collecting the entire body of the Israelites at a place of rendezvous, whence he began his march at their head before the break of day. They consisted of six hundred thousand men, besides women and children, and a multitude of strangers, who were probably peregrines of the gate, or persons who had renounced idolatry, though they were not yet circumcized, and all their flocks and herds. They proceeded on till they reached the borders of the Red sea; in the mean time Pharaoh had suddenly raised an immense army, pursuèd them and overtaken them in this position. The Israelites were now hemmed in by the sea, impassable mountains, and Pharaoh's army; there was no way of escape left, and they, reduced to the utmost distress, began to reproach Moses for leading them out of Egypt to perish under the swords of their enemies. Moses comforted them with the assurance that this would be the last time of their seeing the Egyptians; and he had no sooner dismissed them, than God commanded him to direct their march towards the sea, promising that upon his stretching out his rod over it, its waters would divide, and make way for the Israelites to go through on dry land, while Pharaoh and his mighty hosts, venturing to pursue them, should perish in the returning waves. The events having corresponded with this promise, Moses instituted a festival of seven days' continuance, in commemoration of the signal deliverance which the Israelites had experienced, and the total overthrow of Pharaoh and his army. For the occasion he composed a hymn to be sung alternately by the men and women, celebrating the greatness of God's power displayed in these wonderful events, and his amazing mercy towards his people. Moses now entered upon the arduous task of conducting his people towards the promised land. For an account of their march we must refer to the scriptures; it will be sufficient to observe, that the afflictions which they endured in the course of their journey, were intended to train them to a fitness for the divine blessings; to correct them of that fondness for superfluous and idolatry to which they were so strangely prone; to prepare them for a peculiar system of legislation which was to be formed and established among them, and which was calculated to preserve them from the corruptions of the sect of the world; and to maintain the belief in one living and true God, before they were to enter on the promised inheritance.

They arrived at the foot of Mount Sinai on the third day.
of the ninth month after their departure from Egypt. Moses having ascended several times into the mount, received the law from the hand of God, that is, in a miraculous manner, in the midst of thunders and lightnings, and concluded the famous covenant between the Almighty and the children of Israel. When he descended from Sinai, he found that the people had fallen into the idolatrous worship of a golden calf. Moses, shocked at such an instance of ingratitude towards the Almighty, and agitated at the alarming consequences that might follow from such a dereliction of principle, let fall the tables of the law which he was carrying in his hand, and caused all those to be put to death who would profane in the idolatrous worship. After this he again ascended into the mountain, and obtained new tables of stone on which the law was inscribed. On the descent of Moses his face shone with such brightness, that the Israelites did not dare to look upon him till he had covered himself with a veil.

The next act of Moses was to call an assembly of the people, in which he announced God's renewal of his covenant with them; enjoined the strict observance of the sabbath; declared the command which he had received to erect a tabernacle of the most costly materials; and invited them to liberality in their voluntary offerings for the completion of this undertaking. On this occasion there appears to have been a generous emulation in all the people to contribute their most valuable effects and ornaments towards the work. The tabernacle was finished in six months, when it was consecrated by Moses, who anointed Aaron as the high priest, and his sons as attendants in the worship, and thus commenced, in the year B.C. 1490, that pious worship of the Deity which was adapted to the then existing state of the Israelites, who were incapable of being affected with a purer and more spiritual one. This tabernacle served the Israelites instead of a temple till the time of Solomon.

After the camp had remained almost a year in the neighbourhood of mount Sinai, the Israelites recommenced their march through the wilderness, under the immediate direction of the most high God, who governed them immediately by means of his servant Moses, whom now he had chosen to be the interpreter of his will and the promulgator of his commands among the people; but he required all the honours belonging to their king to be paid to himself. He assumed to dwell in the tabernacle, which was always in the midst of the camp, and he denounced punishments against the transgressors of his laws. This was properly the period of the theocracy, taken in its full extent; for God was not only considered as the true and only proper object of religious worship, but as the sovereign to whom the honours of supreme majesty were paid. In their long journeys through the wilderness, every measure both of the leader and of the people was done by the direction of the Almighty, who rewarded their fidelity and obedience by a series of miracles, victories, and successes. After Moses had regulated every thing regarding the civil administration, and the marching of the troops, he led the Israelites to the confines of Canaan, to the foot of mount Nebo. It was from this mountain he was to take a view of the promised land which it was not permitted him to enter. Being apprized that he was to die on the mountain, he diligently employed his few remaining days in letting the affairs of the public in the best order in his power. His first care was to have Joshua confirmed his successor in the most formal manner, who, being filled with the spirit of Moses, undertook nothing without consulting his Maker. Moses also appointed the limits of the land which they were to conquer, and the distribution of it by lot according to God's command, and enjoined several other regulations relative to civil and ecclesiastical matters. He next assembled the people around him, and recapitulated to them, in a long and pathetic discourse, all that had taken place since their departure from Egypt to that time. In a subsequent assembly he caused the whole nation to ratify the covenant which their fathers had made with God in mount Horeb, and concluded with calling heaven and earth to witness the truth of what they had heard from him, the reafonableness of those laws which God had given them, and the certainty of the blessings or curses which would follow the observance or the breach of them. To impress strongly on their minds what he had delivered, he composed a psalm, in which the substance of his address is expressed in elegant and lively language, and it has been regarded as an imitable piece of ancient poetry. Having caused it to be read before all the people, he delivered it to Joshua to be afterwards learned by them and all their posterity. The last transfiguration of Moses with the Israelites, was to summon them again to receive his farewell and prophetic blessing upon the people in general, and upon each tribe in particular. As soon as he had delivered his last blessing, he went up alone to mount Nebo, and from Pisgah, its highest eminence, had a prospect of all those regions which God promised to the posterity of Abraham. Immediately afterwards Moses died, at the age of 120, in the year B.C. 1451, when his mental faculties were in perfect order, and neither his eye-sight nor his natural vigour was in the least impaired.

That Moses was an eminently great man will be readily admitted by those even who dispute his claims to supernatural communications with the Deity. We cannot, however, give up our belief in his miracles without materially affecting the credibility of the whole history, and of the other facts dependent upon it: and we see sufficient evidence to induce us to take the account as it stands in the seriptures, which, though not without difficulties, is not wholly irreconcilable with the dictates of reason and found sense. (See MIRACLE.) The zeal of Moses for the honour of the one living and true God, forms too conspicuous a feature in his character to be overlooked: it is indeed the principle which lies at the foundation, and constitutes the central point of all his institutions. The writings that bear his name, whether considered as historical documents, or as furnishing a system of legislation, are highly interesting and important. In the former point of view they supply us with the earliest records of the world from the creation to the birth of Abraham; and a particular history of the Hebrew nation, the descendants of Abraham, carried on in a regular series, till the death of Moses, a period all together equal to more than two thousand five hundred years. With respect to the system of legislation which these writings contain, as far as it is of a moral nature, it is unquestionably pure and excellent: its political and judicial regulations are wise and equitable, and the ritual part of it was adapted to establish and secure the worship of the one true God. Dr. Geddes, speaking of the great excellence of these writings, in point of composition only, says, "I know not if it would be too much to affirm, that whether they be considered as a compendium of history, or as a digest of laws, or as a system of theology, or as models of good writing, they are in some respects unequalled, in none overmatched, by the best productions of ancient times."

There seems little reason to doubt that the five first books of the Old Testament, commonly known by the name of the Pentateuch, were written by Moses, excepting the last chapter of Deuteronomy, which is generally thought to have been added by Ezra. Some few have refused to give
Moses, JOHANNES, in Biography, a celebrated Armenian archbishop, who flourished about the year 462. He was esteemed one of the most learned men of his nation, having studied Greek at Athens, from which language he made many versos into the Armenian: his principal work is "A History of Armenia," from the deluge to the middle of the fifth century, written in his native tongue. This was published with a Latin version, in 1736, by the sons of the famous William Whilton. It is thought to be a valuable piece of history, though mixed with no small portion of fable; it contains many national records, not to be met with elsewhere. We have, by the same author, "An Abriff of Geography," published at Amsterdam in 1668: and some "Sacred Canticles," to be sung in the Armenian language on the anniversary of Christ's presentation at the temple.

Moses, J. GOTTFRIED, organist of Auerbach, in Voigtland, a professor of singular abilities, both as a player and composer. In 1781 he published at Leipzig edes and songs; in 1783 a second part; and in 1789 he published at Dresden, Ein Harnisch fur Gott Spielt; the first part consisting of preludes and fantasias, the second of trios, and the third of fugues. These compositions manifest invention, science, and a complete knowledge of the genius and treatment of the organ.

Moses, in SEA LANGUAGE, is a very flat broad boat, used by merchant ships, amongst the Caribbean islands, to bring hogsheads of sugar off from the sea-beach to the shipping, which are anchored in the roads.

Moses Point, in Geography, a cape on the E. coast of Newfoundland; 5 miles S.W. of Cape Bonavista.

MOSHELY, in Geography, a town of Bengal; 28 miles S.E. of Kolkata.

MOSHKO, See MOSCHIO.

MOSINA, a town of South America, in the government of Caraccas; 15 miles S.W. of Cumana.

MOKSHO, or MOSHENES, an island in the N. sea, near the coast of Norway; S.W. of Marilrom. N. lat. 69° 4'.

MOSKOVSKAIA, a government of Russia, about 100 miles long, and 92 broad, the capital of which is Moskva, or Moscow. N. lat. 54° 50' to 56° 40'. E long. 35° to 38°. See Moscow.

MOSKVA, a river of Russia, which runs near Ruza, falls by Moscow, and runs into the Oka, near Kolsma. See Moscow.

MOSLY, a town of Poland, in the palatinate of Belze; 8 miles S. of Belze.

MOSON, Made nobile, in Biography, an opera-dancer in England during the seasons of 1780 and 1787; who, though a corporeal and pleasing performer in general, was chiefly distinguished by the arch and prudish manner in which he danced the pas raffa.

MOSONGO, in Geography, a province of Africa, in the kingdom of Anziko, E. of Pomboto.

MOSPONY, a town of the island of Ceylon; 24 miles E. of Candi.

MOSQUE, or Mosk, among the Mahometans, is a temple set apart for the exercises of their religion.

The word comes from the Turkish meşid, or meșhît, which properly signifies a temple built of wood, such as the Turks first used. Hence the Spaniards derive their meşhetas, and the Italians mosheetas, and the French and English mosque and mosque. Borel derives the word from the Greek μώσις, ταφ, because of the frequent mention of a cow
cow in the Alcoran; but others, with the greatest appearance of reason, derive it from the Arabic musjid, a place of worship.

There are royal mosques founded by the emperors, as the Soliman, and Velides, at Cosplantinople; and private mosques founded by mutties, viziers, bafias, &c. The mosque of Sanchi Sophia is now a magnificent edifice. That at Cordova in Spain was formerly much celebrated.

Mosques are built like large halls, with tiles, galleries, and domes; and are adorned on the inside with compartments, and pieces of Arabique work. On one side is always found a pool with several cocks; and on the top is placed a crecent.

The women are not allowed to enter the mosques, but stay in the porches without.

Most of the mosques have a kind of hospital belonging to them, in which travellers of any religion are entertained during three days.

The Turks have converted most of the Christian churches into mosques.

MOSQUITO BANK, or Mosquitos, in Geography, a cluster of small islands, near the coast of Honduras, which gives name to the tract of country called MOSQUITO SHORE; which see. N. lat. 14° 30'. W. long. 82° 10'.

MOSQUITO BAY, a bay at the S.E. extremity of the island of St. Christopher.

MOSQUITO COVE, a bay on the coast of Greenland. N. lat. 64° 55'. W. long. 72° 57'.—Alfo, a bay on the W. coast of the island of Antigua. N. lat. 17° 12'. W. long. 61° 35'.—Alfo, a bay on the N. coast of the island of Jamaica. N. lat. 18° 28'. W. long. 78° 5'.

MOSQUITO ISLAND, one of the smaller Virgin islands, near the N. coast of Virgin Gorda. N. lat. 18° 25'. W. long. 65° 15'.

MOSQUITO ISLANDS, small islands on the coast of Main. N. lat. 43° 55'. W. long. 69° 10'.

MOSQUITO KEY, a small island on the Spanish Main. N. lat. 14° 25'. W. long. 82° 35'.

MOSQUITO KEYS, a cluster of islets and rocks in the Spanish Main. N. lat. 12° 47'. W. long. 82° 45'.

MOSQUITO POINT, a cape at the entrance of Port Royal bay in Jamaica.—Alfo, a cape on the coast of Guiana, at the entrance of the river Ellequebo.

MOSQUITO SHORE, or Mosquito, a tract of country in North America, bounded on the N. and E. by the sea, on the S. by Nicaragua, and on the W. by Honduras. The Spaniards have claimed it as part of Honduras, though they have here no settlements. Having murdered most of the inhabitants when they first invaded this part of Mexico, those who fled into the mountains have retained an invincible hatred of them; and hence they have been ready to join with any Europeans, and particularly with the English, who touch upon their coast, against the Spaniards. As the Mosquito Indians are excellent marksmen, they are employed by the English to drive the Manati, and many of them fail in English vessels to Jamaica. When the duke of Albemarle was governor of this island, these Indians put themselves under the protection of the crown of England, and their king received a commissio from this crown. Since that period, when their king dies, the next male heir goes to Jamaica to receive his commissio, and before this ceremony he is not acknowledged by his countrymen. Some time ago offers were made by England for settling colonies on the Mosquito shore. The English evacuated this country in the years 1787 and 1788, after having had possession of it for about eighty years. Since the English have left it and the Spaniards have recovered it, the king of the Mosquito shore is absolute; for retaining their avertion to the Spaniards, they will not allow the king of Spain to be their matter, though they were satisfied with considering the king of England in this relation.

MOSQUITO INDIANS, Indians of North America, who inhabit a territory about N. lat. 46°. W. long. 94°.

MOSQUITOS, a town of the island of Cuba; 27 miles W. of Havana.

MOSS, in Botany. See Musci.

MOSS-BERRY. See Whortle-Berry.

MOSS, Heath. See CoRALLIGIDES.

MOSS-Tree. See Liverwort.

MOSS, Upright fr. See Lycopodium.

MOSS, Wall. See Bryum.

Moss, in Agriculture, a well-known vegetable substance or plant, that frequently spreads over the surface of old graz-lands in some districts.

This plant or vegetable is most apt to fix itself upon the surface of old graz-lands of the meadow and pasture kinds, in which it produces much injury by drawing away the nourishment of the graz-plants, and of course lessening in a high degree the graz-herbage. It affects such as are of the clayey moist description, in cold exposed situations, the most frequently, choking the graz by spreading closely over it. And it is observed by a late practical writer, that "various means have been proposed by writers on husbandry, for the removal of this moss destructive vegetable. But as it requires a considerable proportion of superficial moisture to promote its growth and extension on the soils which it infects, it is probable, that the application of such substances as have a tendency to absorb, and take up the superabundant degree of wetness by which it is supported, must be of great utility and advantage. In this view lime has been applied evenly over the surface, in such cafes, with much benefit. He has, however, experienced superior advantage, by covering moist graz-lands with a thin even coat of attenuated calcareous matter, in unyon with a sandy material, such as is scraped up from roads, when formed into a compost with about one-fourth part of well-rotted farm-yard dung; as by this application a new, and more vigorous description of graffes is brought up, which soon overpowers the moss plants, and thus wholly destroys them. For the same purpose, and at the same time promoting the improvement of the lands, as well as bringing the herbage into a finer state, the penning or folding of sheep has been advised by Mr. Kent. This method may probably be had recourse to with the most success either in the clove of the summer season, or early in the spring months; the latter is, however, to be preferred, as from the graz immediately covering the surface, more effect may be produced in mollifying and destroying the mossy vegetation. In this practice, advantage is obtained in different ways, as by the effect which the treading has in opening and removing the close nettled texture of the moss, and that of the urine and dung in promoting the more strong growth of the graz-plants. Harrowing with short, sharp-tined, light harrows, is likewise a practice that may be found useful in some cafes, especially previous to the application of such substances or composts as have been just mentioned, as by such means the matted nature of the moss is broken down, and rendered more open and fit for admitting the manure to the roots of the graz-plants, and exerting its full influence in promoting their vigorous growth, and at the same time the spreading of the moss in some measure prevented. After such harrowings have been performed, some have recommended it as an advantageous practice to few graz seeds and especially white clover over the surface. Different sorts of implements have been contrived for dressing the swards of graz-lands when in this condition; such as the above and different
different sorts of scariers and fward-cutters; but it may be very conveniently performed by a fward-dreffer lately in-vented by Mr. Amos, and represented in his Minutes on Agriculture and Planting. This is a tool which should be in the hands of all farmers where gras husbandry is much practised. See Sward-Dreffer.

But all old gras-lands, when much overrun with mofs, should be broken up for the purpose of tillage, in order to their being laid down again to gras after a proper course of crops; as it is probably impossible to render them good gras-lands again in any other method. In many situations this is a mode of proceeding which would produce great improvement.

Moss, a term frequently made use of also to signify a particular sort of earthy or boggy material, found in some low situations in different parts of the kingdom, but particularly in the more northern districts, being formed by the decay of different vegetable and other substances. This earthy material is of different natures in different situations, as wood mofs, black peat mofs, flow mofs, or red bog, &c. The drift, which is principally composed of ligneous substances, is probably the belt for manure; and the black peat, which is chiefly composed of heath, decayed sphagnum, and the roots of the eriophora, is the next in the goodnesh of its properties. The third, which is chiefly derived from the sphagnum in a more fresh state, is the least useful. Moffs are of very different depths, textures, and qualities, but all of them are greatly impregnated and loaded with water, holding it like a sponge; some have the depth of not more than three or four feet, while others have as many yards. They require much drainage and confolidating to bring them into cultivation. See MOSSY LAND and PEAT MOSS.

In the Survey of Pembroke, it is stated that, "in every flat, and on some slopes of the higher hills, there are moffs of various dimensions, of various depths, and of various degrees of firmness, according to the time that has elapsed since the mosses have been formed. In the high lands, mosses are so frequent, that it would be tedious to enumerate them. Their formation is uniformly owing to the same cause—fallen trees, the decidious parts of heath, and of strong aquatic plants. The largest tract of mofs, in a valley, any where in this county, and perhaps in Britain, is in Monmouth, which has given its name to a whole strewarty. It is also called Moss-Flanders, from its flat appearance, and is most commonly known by that name. This whole tract of mofs, from the bridge of Gartmore to the bridge of Drip, may be computed at 10,000 acres."

As it has frequently been found that "a tract of mofs is buried several feet below the surface of soils, of the rich kind, with a variety of timber lying in it, the mode of its origin seems evident.

"If the soil below Moss-Flanders and the other mofs in Strathmarn, have been formed by the agituation of the sea, which is very probable; whenever the waters retired, such a luxuriant foil could not long remain unproductive. It must have been sown without delay by the hand of nature, with the seeds of the plants growing around it. Of these, the oaks and other forest trees, being the most vigorous, would, in a few years, overtrop and choke the rent. "Time itself, and the violence of the winds, are sufficient to overturn any trees; and when trees are felled on flat land, where their leaves have been accumulating for ages, the leaves and branches dam the water; aquatic graffies grow; the place becomes a mora; and every moras composed of such substances, by acquiring solidity, becomes a mofs. These are the outlines of the most probable opinion of the manner in which Moss-Flanders was generated. The roots of oaks are found at this day, fitting in the very manner they grew, and adhering firmly to the clay and trunks of an immense size lying near the roots, at the depth of fifteen feet below the surface of this mofs."

Moss on Trees, in Rural Economy, a dissembler caused by the mofs plant fixing itself upon them, which is highly prejudicial to the growth and increafe of those both of the timber and fruit forts, and which much damages the fruit of the latter kind.

The best remedy is the scraping it off from the body and large branches, by means of a kind of wooden knife that does not hurt the bark, or with a piece of rough hair-cloth, after foaking rain. But the most effectual care is, the taking away the cause. This is to be done by draining off all the superfuous moisture from about the roots of the trees, and which may be greatly guarded against in the first planting of the trees, by not setting them too deep in the ground.

In cases where trees stand thick in a cold moist ground, they are always covered with mofs; and the best way to remedy the fault is to thin them. When the young branches of trees are covered with a long and flaggery mofs it utterly ruins them; and there is no way to prevent it, but that of rubbing it off, or cutting the branches away near the trunk, and even to take off the head of the tree, if necessary, when, if the cause be removed by thinning the plantation or draining the land, the young shoots continue clear afterwards.

This diseafe arises in consequence of the mofs plant etab-

lishing itself upon the trees which are in an unhealthy state of growth, or which have been planted too closely toge-
ther, by which proper circulation of air and drynesses are prevented. Of course, the trees are not merely injured by the plants etabllishing themselves upon them, and hindering their growth, but probably also by the large proportion of moisture that is attracted and the dampnesses induced in con-
sequence of it.

With the view of preventing and removing this affection, Mr. Forth advises the washing the trees with a mixture of fresh cow-dung, urine, and manures, in order that the etabllishment of the mofs plants may be prevented, and the bark be kept in a fine healthy condition. Where this diseafe proceeds from the unhealthy state of the trees in consequence of the unfriendly nature of the soil, Mr. Nichol thinks they should be removed as soon as possible, as this is the only certain way of guarding against their destruction.

Moss, in Commerce. Some kinds of mofses are used in medicine, in perfuming, &c.; among others, the fcan-mofs, called corallines, and the mofs of cedar and fir, which enter the composition of Cyprus powder.

The mofs of common trees, as oak, alh, poplar, &c. is used for caulking of vesels: it is also used by bird-

merchants, to prepare cages for certain kinds of birds to hatch in.

The soft marsh and bog mofs serve the poor in many places for stuffing their beds; and in the beulches of trans-

porting plants from other countries, nothing is of so great use as the stalks and leaves of these little vegetables; the succulent plants coming over in great beauty and vigour, when rolled up in dry mofs; and the trees and shrubs, by having their roots covered with such as is somewhat mofit.

The great quality of the mofses, which makes them so serviceable in this case, is, that they do not heat and ferment on being moistened, as hay and straw would.

Several species of the mofses and algae have been applied to medicinal use. Thus, several of the mofses are great and valuable medicines, used as delectatives and alterigents: that the common cup-mofs is one of the greatest remedies in the convulsive
convulsive coughs of children, called the chin-cough, is known to every one; and Dr. Mead has ennobled the grey ground-lichen, by publishing its virtues in one of the most terrible of all diseases, the bite of a mad-dog. The common green liverworts are known medicines in disorders of the breast, as are also all the species of polytricha. The seeds of our Lycopodium are given with efficacy in nephritic diarrhea; and the Indians give one of their species in many diseases, and, as they say, with great benefit. The common white ground coralloides serves the reindeer of Lapland for food, when all other herbage is lost; and the conserves serve for food to many of the fish both of the sea and rivers, and to several water-fowl. And these, as well as the land mosses, afford shelter and habitation to many insects, and their young. Many of the species of coralloides and licenoboides are found of great use in that profitable branch of commerce, the art of dyeing; and doubtless many others have also the same qualities, though not yet discovered; and we may be guided in searches of this kind by observing that many of them tinge the papers between which they are dried with very beautiful and lasting colours.

Moss, Silk, in Natural History, a name given by count Marigli to a species of sea-moss, or coralline, of a very remarkable fineness and softness, much more resembling silk than any other of the marine productions. It is wholly composed of a sort of tuft of fine hairs or filamenta, and is of a blueish-green colour, and almost transparent. It grows on rocks, stones, shells, or any thing else that lies in its way, and is found usually at small depths; it is not so tough and flexible as many other of the sea-plants, but is easily rubbed to powder between the fingers. When examined by the microscope, the single filamenta do not appear of the same equable surface and uniform texture; but they are seen to be jointed and made up, as it were, of a great number of pieces fastened end by end to another, in the manner of the beads of a lady's necklace. It is of a fine blue-green, and perfectly transparent before the microscope, and resembles a string of gems, such as the aqua marina, or some other like it.

Moss is also a name given in many parts of England to the ground called the bog, fen, marsh, or moors in other places.

Moss-Troopers, a rebellious sort of people in the North of England, that lived by robbery and rapine, not unlike the tories of Ireland, the buccaneers in Jamaica, or banditti in Italy: the counties of Northumberland and Cumberland were charged with a yearly sum, and a command of men, to be appointed by the juries of peace, to apprehend and suppress them. Stat. 2 Jac. I. cap. 1. 13 & 14 Car. II. cap. 22. 30 Car. II. cap. 2. See 6 Geo. II. cap. 37.

Mos, Robert, in Biography, a learned English divine of the disestablished church, was born at Gillingham, in Norfolk, in the year 1660. He received his classical education at the free school of Norwich, and in 1682 he was entered of Benet college, Cambridge, where he took his degree, and was elected into a vacant Norfolk fellowship in that house. When he commenced preacher his sermons made great impression, and he had full audiences whenever he was called to perform the duties of the pulpit. He offered himself as candidate for the office of public orator, and also for the mastership of his college, but was unsuccessful in both instances; it was, however, universally acknowledged that he left no credit by these competitions. In 1698, he was appointed preacher to the Society of Gray's-Inn, London, an office which he held through life. In the following year he was appointed preacher-assistant at the church of St. James, Wellminister, and was afterwards nominated chaplain in ordinary to king William III.: he continued to hold the same station under queen Anne, and being one of the chaplains in waiting when her majesty visited the university of Cambridge in 1705, he had the degree of doctor of divinity conferred upon him in the queen's presence. Soon after this an unsuccessful attempt was made to eject him from his fellowship, on account of non-residence. In the year 1712, Dr. Mos was nominated to the deanship of Ely, which led him to resign his fellowship of his own accord. Upon the accession of George I. Dr. Mos was sworn, a third time, chaplain in ordinary, which place he retained till 1715, when he was dismissed, on account of the part which he took in the Bangorian controversy. He died in 1729, in the sixty-third year of his age. He was author of a Collection of Sermons, published after his death, to which is prefixed a character of the author, which says: "He was of fo open and generous a disposition, and such a stranger to all artificial difguise, that he affirmed, and you believed him; he promised, and you trusted him; you knew him, and you loved him." Biog. Brit. vol. vii.

Moss, in Geography, a town of Norway, in the province of Aggerhusen, on the E. side of Christiania bay; 28 miles S. of Christiania.—Alto, a river of Norway, which runs into the sea near the town of Moss.

MOSSA, a town of Germany, in the county of Goritz: five miles S.W. of Goritz.—Albo, a town of France, in the department of the Seila; 23 miles N.N.W. of Versailles.

MOSSALE, a town of the duchy of Parma; 19 miles S. of Parma.

MOSSAR, a town of Lithuania, in the palatinate of Wilna; 28 miles S.E. of Breslaw.

MOSSAW, a town of Bengal; seven miles N.E. of Rajemal.

MOSEL BAY, a bay on the S.E. coast of Africa. The outermost point of the bay, called Cape Saint Blaise, lies in S. lat. 34 10' E. long. 22 18'. The variation of the compass in 1797, was 27 54' W. The time of high water at full and change about three o'clock, and the rise and fall of the tides six or seven feet. During the summer months, when the winds blow between E. and S., or directly into the bay, a heavy swell breaks upon the beach, which makes it dangerous, and frequently impracticable, for boats to land; but these winds are never so violent nor so lasting as at the Cape; and ships may ride at anchor in perfect security about three-quarters of a mile from the landing-place. The S.W. winds, that frequently blow with great violence from April to September, bring into the bay a most tremendous sea, setting round Cape Saint Blaise. At this season of the year it would be highly imprudent for ships to enter into Mossel bay. A roll of water glides over the sandy beach, where is the bell landing, and is easily conveyed into casks in the boats, by means of a hole. To the S.E. of this landing-place is another small cove tolerably sheltered, and deep enough to admit vellets of ten or twelve feet draught of water. At either of these coves, piers for landing and shipping of goods might conveniently be constructed, and at a small expense, as materials may be procured upon the spot. Boats, however, may land at every part of the bay; and the adjacent country would easily afford supplies for about 500 men. The mouths of the rivers that fall into the bay are generally blocked up with sand; they abound with various kinds of fish; and at the rocky parts of the coast musclers and excellent oysters are plentiful.
MOSSEL Bay gives name to a division of the district of Zwellendam, adjoining to it; and it is sometimes called " Droogeveldt," or dry country, extending from the Gou-ritz river to the Great Brakka river that falls into Mosfell bay. The surface is hilly and composed of a light sandy soil, which, when the rains are favourable, is sufficiently fertile in corn. The only natural product in the vegetable kingdom, that is useful as an article of commerce, is the aloe; but the heathy plants along the southern are more favourable for sheep than in the other parts of this division. Besides the fisheries mentioned under the preceding article, the aloe and barilla might employ the Hottentot's to advantage. As the former grows in every part of the district that surrounds the bay, that from the ashes of which the latter is procured is equally abundant in the plain through which the Olifants river flows to soak in water, they are in a fair degree recovered, and the variations are usually found to be owing to the joints and knots in the flakes, which interrupt the course of the general colour, and are often themselves either black, or of a dark and deep brown. See Coralline.

Mossel, Sea. These marine substanacies are very beautiful when viewed by the naked eye; but when examined with the microscope, they afford a very pleasing variety of structure and conformation.

The common kinds afford a great variety of colouring, the different parts of the same substanacies often appearing, some brown, some yellow, some red, and some grey. On drying, these colours become less elegant; but on putting the dried substanacies again to soak in water, they are in a fair degree recovered, and the variations are usually found to be owing to the joints and knots in the flakes, which interrupt the course of the general colour, and are often themselves either black, or of a dark and deep brown. See Coralline.

Mossombo, a town of Congo; 20 miles S. of Banza.

Mossy Land, a common name given to boggy peaty grounds in many parts of the kingdom. Those lands of mossy turf or turfy substanacies, below which is a black, moist, spongey earth, which rolls on a clay or marly bottom. The dark coloured under strata of mossy, after being dug up with spades, somewhat in the form of bricks, and dried, is what is called peat, and which is used as fuel in several districts.

The most certain and shortest method for the improvement of mossy land, if the ground be designed only for grazings, and its situation be such as admits of it, is this: first drain the motts, and if there be heath upon it, burn that off, and make the surface even. Then make a dam at the lowest part and a sluice, and work the water upon it through the winter. The mud which comes with the land.

Vol. XXIV.

food will bring a fine forward upon it in two or three years, and be afterwards a yearly manure; so that it will bear annual cutting, and, besides, be good pasture for cattle, after the sward is become strong enough to bear them. But Mr. Grzeze found that the improvement of mossy land may be endangered by draining it too much; for his crops were better where the surface of the water in the surrounding ditches was not above three feet lower than the level of the moss which composed it.

It may be observed, that the nature and origin of the foil of mossy's has been lately much inquired into and examined by different writers. In the second volume of Communications to the Board of Agriculture, Mr. Headrick states, that "Dr. Anderson, in a late treatise, advances an opinion which appears to him somewhat paradoxical. He affirms, that moss is a vegetable, or congeries of vegetables, which are growing, or being below; while he distinguishes the top, where we frequently see vegetables actually growing, by the epithet of dead moss. Thus, according to him, there are two species of mosses, viz. quick mosses, from which peats are dug, on which no vegetables are ever known to grow, and in which no animals are ever known to exist; that this, before it is cut out of its natural situation, is composed of a congeries of growing, or living plants. 2. Dead moss, which frequently covers the former at the surface, on which heat and fog and coarse grasses are seen in a growing state, while infects and other animals frequently mintle in it." He conceives, "the idea to have been suggested to the doctor by the vulgar dialect of some parts of the country where deep mosses, fit for making peats, is often distinguishes by the appellation of quick mosses. But, he apprehends, that this term, in the vulgar dialect of Scotland, no where indicates life in the sense affixed to it by the doctor, and he knows not of no term used among the vulgar that affixes life to vegetables of any kind. By the term quick, when applied to mosses, he supposes they mean only to express their mingled property, just as quick sands mean sands in which a passenger is in danger of sinking.

Dead moss, he conceives to be synonymous with firm mosses; those parts of peat-bogs which are covered with herbage being the only parts on which a passenger can walk when the moss is wet, as his feet are supported by the matted roots of plants." And that, "whatever may be the strict meaning of these terms in common language, the doctor must admit that, according to his hypothesis, this vegetable, during the whole period of its growth, is excluded from the influence of fun and air. No vegetable he ever heard of forms ligneous fibres, or acquires inammability, without contact of air and of the sun's rays during the period of its growth. Now, how comes it that a vegetable growing in such extraordinary circumstances, acquires the very high degree of inammability ascribed to it by the doctor? Inammability it cannot acquire from the action of the sun's rays, because it is soaked in water, and frequently covered with a thick coat of what the doctor calls dead moss. However ingenious, therefore, the hypothesis may be, this obstacle to its admission seems to him inexplicable." And further, "what seems decisive of the utter deadness, and partial disintegration of that species of moss to which the doctor imputes life and vegetation, is, that such moss emits light when kicked and tilled about in a very dark night. This is well known to those who live contiguous to peat-bogs, and is the cause of frequent terrors, which are ascribed to Will-of-the-wisp, & c. It is really owing to the slow inflammation of the ligneous or carbonic fibres, of which the moss is chiefly composed, in consequence of contact with atmospheric air in a mossy state. No plant, as far as he knows,
knows, is capable of spontaneous inflammation while it continues in a growing or living state; and most plants require all their mucilages, and other soluble parts, to be extracted by long soaking in water, before they are capable of exhibiting this phenomenon. If a piece of wood be well dried and seasoned, it cannot afterwards be rotted except very slowly; but if it be dunked in a green state, among moist earth, its soluble parts are extracted in the course of a few years. Its ligneous fibres become soft, and may be separated in every direction; each species of wood breaking in a way peculiar to itself, both laterally and perpendicularly, similar to the crystallization of salts. If this wood be suddenly exposed to the air, in a dark place, while moist, it will shine with great brilliancy; if it be dried, it will be found much more inflammable than fresh wood of the same species, which has been seafoned; as it conflits almost wholly of carbon. The property of shining in the dark is common also to leaves of trees, and to all vegetables, whose carbohydric fibres have been laid open in consequence of long soaking in moisture when they are first exposed to the action of atmospheric oxygen.

By frequent repetition of soaking, and exposure to the air, such bodies become entirely calcined, and they leave an un-inflammable earth, such as is produced by burning them in a common fire. No living plant, however, and no vegetable whose solution is not pretty far advanced, is ever seen to undergo this spontaneous inflammation; but mosfs adapted for making peats certainly undergoes this process, and therefore such mosfs, instead of being alive, must be dead. This may help us to explain a fact, which is ably illustrated by Dr. Anderfon, that mosfs, if frequently turned up to the air, and kept uniformly in a moist state, though not absolutely soaked, is gradually changed into a fertile soil. None of the succulent, or nutritious vegetables, are known to grow upon other vegetables, unless the putrefaction of the latter be pretty far advanced. Frequent turning of mosfs, in the given circumstances, exposes it to flow inflammation or putrefaction; both of these processes being of the same nature, which may also help to account for some facts which seem to have puzzled Dr. Anderfon, as appears from his treatise; that oak, which is never found to rot when sunk in moist clay, or moistur of any kind, should be found reduced almost to a pulp in mosfs; but the doctor may observe that the oak found in mosfs was never seafoned; it fell where it grew, and was inclosed by mosfs with all its natural juices, while a small quantity of additional juices, retained in the mosfs, soon inveted it on every part. The trees in this situation were in time robbed of all mucilage and soluble parts, which became food for the mosfs plants that invaded them; of course nothing at last remained but the carbon, or ligneous fibres, fatmer with the mosfs juices. Though the cohesion of these fibres are destroyed, they are insoluble in water, and do not easily rot in it; in other words, they do not readily decompose water. But another difficulty still occurs to the doctor. How come these ligneous fibres to retain their inflammableness, or even to have it considerably increased? A few facts will be afterwards stated which may help to account for this; at present it is only necessary to observe, that wood will retain its inflammableness a very long time, if buried green in any moist subflance, which eLife itisually excludes it from the action of the atmospheric air, provided it does not petrify, or change into stone. Its soluble parts may be extracted and diffused through the water; but they rather incerase than increafe the inflammable power of the wood. The ligneous fibres, however, remain, and are not rotted except by the joint action of air and moisture. It has often been observed, that the part of a flake fixed in the ground, which foucet rots,
MOSSY LAND.

were a naked rock suddenly thrown up from the sea, or from the bowels of the earth, the first plants which nature would place upon it would be the various species of lichens, and such as can subfist wholly upon what they imbibe from the air, without needing a foil in which to push their roots. These plants serve the double purpose of clothing the rock, and thus preventing the fine particles that are dissolved by air and moisture from being washed away, and, from their growth and diffusion, of accumulating vegetable foil for the sustenance of more succulent plants. The rock is thus gradually made to acquire such a depth of loam, that it becomes able to sustain, not only grasses and shrubs, but may become a receptacle for the oak itself. But, if we suppose this rock to be so situated, that moisture cannot easily run off from its surface, a great variety of the moss' plants will begin to grow upon it. As these accumulate, the moisture will rise along with them; for they retain it like a sponge, and obstruct its passage from the rock. Thus, as long as the moss' plants can accumulate moisture, they will continue to grow, until the rock comes to be covered with a deep moss. And the same effect will be produced upon a bottom of gravel or lime-stone, which does not easily admit the moisture to pass through it. Upon a bottom of aluminous or pyritical schilus, none but the most hardy plants, such as those which compose moss, can exist; and such plants will, therefore, accumulate upon such a soil if not checked, even though it should have a considerable declivity. It is added, that upon flat clay land, and in hollows that had been formerly covered with wood, we uniformly find mosses which have grown in confluence of the wood having been filled, or allowed to fall down. This is owing to the water having been obstructed by the trees, after they had been felled upon the ground, and which, consequently, caused the production of aquatic plants. But such trees as we find in the bottom of mosses, being deeped in water, throw out a considerable portion of the running principle; this is of such a nature, that no other but the hardy moss' plants can grow in a foil affected by it; such plants, therefore, rapidly grow in such situations, and accumulate as long as they can cause the moisture to rise as they rise. In the bottom of mosses that had been originally caused by the fall of woods, we find all those grasses and plants which commonly grow in woods in a state of preservation; we also find the leaves and other exuvis of the trees, which having been dropped during a course of ages, seem not only to have increased the dampness of the foil, but by their alluring juices to have predisposed the foil for the growth of moss' plants; thus, the moss' plants seem to have advanced a considerable way before the trees fell, and by the moisture which it retained, it seems to have chilled their roots, and rendered it easy for the winds to overthrow them.

And it is noticed farther, that "moss' plants in flat situations are generally highest in the centre, that being the point where the water finds most obstruction to its running off. The limit to the farther accumulation of these mosses is the point to which the water can be drawn up as the moss increases, and they have been known to cover until the column of water, contained in the moss, has burst its barriers, and conveyed the moss that retained it over the neighbouring fields. Many examples of this might be specified, but he will only mention that of the Solway moss, the facts relative to which are well known to the public. To this cause also moss-hags are to be imputed, or those dangerous chasms which frequently occur in deep mosses; these are produced by a part of the moss shifting its position from the column of water contained in it acquiring greater pressure than the lateral resistance. Thus moss may be considered as a fresh-water sponge, which grows as long as it can draw up and furnish water to nourish it." From these facts it is concluded, that "the predisposing causes of the growth of moss appear to be an extreme degree of dampness, or of altrigeneity in the foil, which render it an unit receptacle for any other but the moss' plants. He uniformly proceeds upon the supposition that the spem, the seeds, or the spores of the moss' plants are at hand, where a foil is thus predisposed for their production; it would be absurd to suppose, that these plants would begin to grow even in the most favourable situations, if there were no seeds or roots from which they were to spring. We are told, that in America and several other countries, peat-bogs are unknown; this he would account for in two ways; either the moss' plants are there, but never accumulate into a bog from want of a proper receptacle; or supposing situations favorable for their accumulation, there are neither seeds nor plants of mosses to occupy these situations. We know not all the causes which induced the Supreme Being to diversify the productions of different climates; but we know that they are exceedingly diversified, and that this operates as a powerful motive upon remote nations to cultivate a friendly intercourse with each other."

The writer adds, that "the moss' plants grow at the surface with their roots and stems immersed in moisture; but their leaves and branches are exposed to the air, and the sun's rays. Those mosses which discover no vegetation upon their surface, are either arrived at the utmost height at which they can sustain water, and have hence become dry, and are frequently blown about by the winds, or there are large spaces perpetually washed by the rains which fall, which are hence converted into water-courses. In such ruts every new accumulation of moss is washed away, if what was formerly accumulated be not also carried off to a considerable depth. In flat places, where the moisture does not readily get off, the genuine moss' plants may be seen growing somewhat similar to the green vegetation which arises in pure water, when exposed to the sun's rays. When a moss is interfacted by numerous water-courses, it appears to be divided into islands, on which heath and coarse grasses, with lichens and other moss' plants, are growing. When a moss has grown so high that it no longer retains a sufficiency of water to cause its further accumulation, the upper part, being between the wet and the dry, is partially rotted or decomposed into vegetable earth; hence the upper stratum of mosses is never, more inflammable than the parts below, having already, in some measure, suffered the flow inflammation which converts it into foil." And farther, "the moss' plants seem almost wholly composed of carboine fibres, and are so hardy that they continue to grow above, while their stems and roots are mouldering below. He has traced many of them to a considerable depth. Thus the yellow, or white fog, of which there are several varieties, is commonly fresh and vigorous at the surface; about a foot lower, it may exhibit marks of decomposition, though its organization remains entire. It may be frequently traced almost to the bottom of a deep moss, though its organization becomes constantly less distinct, until it is entirely lost. In the same way he has been able to trace the heath plant almost to the bottom of a peat moss; below it becomes lost, and is frequently bruised by the incumbent pressure, but its organization is seldom destroyed." And "the plants which compose mosses are doubtless exceedingly various. Botanists have enumerated more than 900 species of them, of the cryptogamia class; but it is probable that many species of these plants are invisible to the naked eye; and that there are many others, whose form and organization it is difficult to ascertain."
Mossy Land.

tain." But it is conceived, that "while the mossy plants are growing at the surface, they are not rotted below; they are only leaved, or macerated in water, which extracts their soluble ingredients, and reduces them to a soft and pulpy flate, in the same way as was mentioned respecting wood. As the water cannot get off, except by evaporation, in the lower parts, it is never changed, but the same water must continue for ever in the place which it occupies. Were it otherwise, that is, were the water frequently shifted, the moss would gradually rot, and moulder into earth,; hence the effect of watering mosses, which, by accumulating vegetable mould, causes the moss to throw up sweet herbage.'

Dr. Anderson thinks, that mosses could never accumulate to their present extent, by growing above, while they are rotted below; he thinks, that even an acre of the belt grafs could never accumulate hay sufficiently to cover the surface on which it grew, to such a depth as many mosses have attained, by the residuum left after it was rotted. But it is well known, that by the rottine of hay, and other succulent vegetables, by far the greatest part of their substance is conveyed away in those gasses which are emitted during the process, and there is nothing finally left but a light earth, together with some farts that are formed in the product. In moss no such rottine process takes place, for we never find that any of those gasses emitted by rottine vegetables are emitted by moss; on the contrary, moss will preserve succulent vegetable, and even animal substances. It is said, that in the Ards moss, in Airshire, bodies of persons have been found by the people who were cutting peats, which have remained in a perfect state of preservation ever since the percut of the covenanters by Charles II. The covenanters frequently held their conventicles, or field-preachings, on the borders of this moss: when surprized by the king's troops, they fled into the centre of the moss, where cavalry could not pursue them. As these meetings were generally held in the night, it appears that some of these people had dropped into holes, where they could not afterwards be found. It is, therefore, evident that moss, so far from being itself in a state of putrefaction, is a fptyc, whose juices are capable of preserving even those bodies which are naturally most liable to putrefaction; the two cafe are, therefore, altogether dissimilar, and the argument inconclusive. But if we were to suppose the grafs, like the mossy plants, growing as thick as it could stand, and every leaf so macerated, but not rotted, in water which fills up every interstice, it is apprehended it would soon accumulate, upon the soil that produced it, to a much greater depth than any now in existence; it may be further observed, that scarcely one-half of the densest moss is filled with vegetable matter. When peats are first cut out, they are nearly double the size they retain after they are dried; and when they are squeezed whilst wet, by a press, they go into a much smaller form.

The next question is, "how it comes that water only macerates the mossy plants, that is, extracts their soluble ingredients, and destroys the adhesion of their parts, without rottine them, as happens with succulent plants? He apprehends this must be partly imputed to the hardy nature of the mossy plants; for, being chiefly composed of ligneous or carbonic fibres, the water does not readily act upon them, or, more properly, is not easily decomposed by them. Thesel plants are callife rotten which abound in muscigenous plants, and parts that are soluble in water; even muscigenous plants do not callife rot, if they be wholly immersed in water, and excluded from the action of the air, which is precisely the situation of peat mosses. But independent of this consideration, we shall see, that the water which resides in mosses is impregnated with a portion of the tanning principle, which effectually prevents the rottine of the plants, in the proper sense of that word. Mossy plants, therefore, are macerated, or infused like tea in water, but not rotted; the organic texture may be destroyed, and the soluble parts diffused in water, without suffering any chemical change: as the same water always refides in the mosses, unless it be evaporated, there can be little or no loss of vegetable substance. As this maceration in water does not oxygenate the plants, it should, it is conceived, render them more independent than when in their organic flate, as was suggested respecting wood.

It is stated, that "the trees and shrubs he has found at the bottom of mosses are the following, and they are, perhaps, the only indigenous trees and shrubs of this country. Of trees, 1., the oak; 2., the elm; 3., the birch; 4., the willow; 5., the alder; 6., the fir. Of shrubs, 1., the hazel; 2., the dwarf-willow; 3., the gall-plant; 4., the heath-plant; this last frequently continues to grow upon mosses during the whole period of its existence. The 2d and 3d shrubs also frequently continue growing upon mosses in the western parts of Scotland: they are very hardy shrubs, and seem to prefer those situations where their roots are imbedded in the tanning principle, and the plants themselves abound in this principle. The shrubs which grow in mosses are always partially decomposed, if they have not entirely their organic form, when traced downwards to a certain depth; but he has also observed certain tubular roots, resembling large threads, which are evidently in a living flate from the top to the bottom. The roots belong to plants which are growing at the surface, and which do not seem to decay below, with the mats of other plants. In the commencement of many mosses, it would appear that the falling of leaves and decayed branches, together with the undergrowth of shrubs and coarse grafs, had obstructed the water, and caused the mossy plants to grow and advance before the trees fell down. The mosses, by its retention of moisture, and by creeping up the stems, seems to have chilled the trees, and brought on their decay, before they fell down; thus we frequently find a considerable depth of moss below the trees, which are often broken over a considerable way above the root, and they generally lie in one direction, owing to the prevailing current of the winds having first bent and afterwards cause them to fall in that direction. Mr. Smith showed the writer mosses, where oak and elm trees were lying near the bottom, and above them hazel and other shrubs had grown, which, in their turn, had been destroyed and clofed round by mosses." And, "as a proof that moss is composed of a congeries of plants, which had successively grown and decayed, though they had not rotted, we may observe, that it is always composed of thin layers, or frata, piled above each other, and the lower frata much more compressed than those above. This may be distinctly seen in many species of dried peat, and may also be observed in the face of a peat-bank, or wall, from which peat had been cut. The mossy plants, therefore, seem to be more analogous to wood, than to any other species of plants: they are paraflatical, and can grow either upon wood, or upon the wrecks and particles of their own substance. But if far from being in a state of putrefaction below, they will not grow in any soil where the putrefactive fermentation is excited."
Mossy Land.

*retains a white or yellow colour after it is dried;* the latter does not seem in such a perfect state of maceration as the former, as the fog of which it is composed still retains its organized form; and there does not seem to be such a great variety of the moss plants present in this species of peat as in the black. The prediluting cause of these variations seems, in his opinion, to be either the fog or species of wood on which the moss at first commenced its growth, or the climate in which it is situated. Thus, mosses growing on fir woods are generally of the soft and spongy kind, and the trees themselves may be split into slices, which are used, in many parts of the country, in place of candles; mosses growing upon oaks, and other alrignent trees, commonly produce a black and compact species of peat. Mosses in cold and elevated situations, as they grow very slowly, commonly produce a hard and compact peat. In this respect moss resembles wood, which is always hard and compact, in proportion to the climate, or rather to the length of time it takes to grow; mosses again, in low and warm situations, as it grows rapidly, is commonly soft and porous. Those several causes often act separately, and often co-operate; and thus mosses, considered as a soil, is found to possess the same varieties of quality which distinguish other soils. It is stated in conclusion, that "if these observations be well founded, it would appear that moss is not a plant which grows by a law peculiar to itself, and in direct opposition to the established laws of vegetable growth; but that it is a congeries of vegetables, of various species, which are adapted to grow in soils and situations where the more delicate succulent plants cannot subsist; that they are moist of the paractical kind, and grow either upon rocks and damp clays, where they receive little from the soil, or they can grow upon other plants, or even upon the particles that are formed from their own dissolution; that the prediluting cause of the growth of mosses are dampness and alrignent in the soil; that while these plants are growing at the surface, that the dissolving below, not indeed by a process of analogous to putrefaction, but by the simple diffusion of their parts in water, where they remain without any chemical change.

An analysis of the mossy material is afterwards given, but for which we must refer the reader to the paper itself.

It is concluded, however, "from a review of the whole of his analytical experiments; 1, that lime is the most powerful agent that can be employed for reducing mosses into soil. 2. That quick-lime is much more powerful than its carbonate in neutralizing the litpheric juice of mosses, because, being soluble in water, it continues itself through every pore of the plants, and while one part combines with the gallic acid, or litpheric juice, the remainder unites with the mossy matter itself, forming it into an infusible alkaline solution of mosses, or soil of great fertility. 3. That during the action of lime and alkalies on mosses, gases are generated. From the 25th experiment it would seem, that those gases are not chemically combined with the mosses, but, like the carbonic acid in yeal, are separable by pressure or agitation, and hence part of them at least remains in the same state as before, ready to promote the growth of plants. Indeed the same conclusion was inferred from examining the alkaline solution of mosses, though in a much higher degree. 4. That it appears that alkalies are much better calculated than lime to dissolve the mosses plants, and to generate gases in them beneficial to vegetation; but as they render the mosses very soluble, and enlarge its volume, they produce no soil capable of sustaining the plants. The same observation is applicable, in part, to putrefient manures." But, "5, the author has not ascertained the nature of the gases generated in the cases mentioned above. The reasons will appear why mosses and other soils, in given circumstances, are more apt to produce one species of plants than others. 7. What is here detailed concerning the action of lime and of alkalescent upon mosses, together with that of putrefent manures, is also applicable to the action of these substances upon other soils, in so far as they act upon vegetable matter." The writer concludes by suggesting its "admirable admiration for the beneficence of Providence, in having provided the mosses plants for the situations in which they grow: they afford an immediate supply of fuel; they produce the fuel from which pit-coal derives its origin, though, trees, and all the plants which abound in fuels and coal, also contribute to the supply of pit-coal. Were the places now occupied by mosses covered with vegetables, or scoured with vegetables of a different character, they would become noisome fens, which, by the emission of putrid gases would spread all around them pestilence and death. Mosses emit no noxious fumes; but rather, by growing at the surface, where the plants are acted upon by the sun's rays, they perpetually throw out oxygen, and thus contribute to the salubrity of the atmosphere. The only defect with which they are chargeable, is, forming magazines of moisture, which by its exhalation generates cold, and spreads rheumatism and intermitting fevers among all the animals within its reach. The perpetual evaporation of this moisture not only tends to chill the moss, but it defends, in hoar frost and mildews, upon all the lands that are lower in point of situation. These lat-mentioned disadvantages are more than amply compensated by the consideration that mosses are not only an inexhaustible magazine of manure for other soils, but may be converted into a molt fertile soil itself." And after it is so converted, none of the defects already stated are any longer applicable to it."

In considering the methods most adapted to the improvement of mossy lands, in different cases and under different circumstances, several things are necessary to be regarded as being necessary with different situations and conditions, in different places.

In cases where the mossy land is of considerable extent, and of the more deep kind, different modes have been in practice for bringing them into a state of cultivation. Some have attempted to remove the whole of the mossy substance by means of water, and a proper machine for the purpose while others have had recourse to lime in large proportions with clay or sand, and other similar matters. Mr. Headrick has, however, remarked, that "mosses were considered solely applicable to the uses of fuel, until the late Lord Kaims set on foot a project for floating away an extensive moss on his estate near Stirling. The project has been followed to a much greater extent by his son, who has constructed a bucket wheel, of great power, for raising water out of the Teath, to float the moss: the water is raised somewhat higher than the top of the mosses, passes some hundred yards in hooped wooden pipes eighteen inches diameter under ground, and then emerges upon a raised embankment of earth, by which it is conveyed to the mosses. It is stated by the author of the Report of Perthshire, that the expenditure for this machine and embankment was £1000, but that the people on that estate of Mr. Headrick that it cost £1000. When the water arrives at the highest part of the mosses, it is conveyed in a rut perpetually descending along the whole line of the uncleared mosses, at every part of this line, the people are employed in throwing the mosses into the stream with spades. Thos. at the part where the water first enters the mosses, keep the stream upon the surface, and they lift and throw into it all the mosses within their reach, until they uncover the clay below; they then cut
MOSSY LAND.

cut out a new water-course, and throw into it the embankment of mofs which sustained the water before; those lower down operate in the same way, only they precipitate the current of water on a lower level than those above them; those at the lowest part keep the water running upon the clay, and shift its course occasionally, so as to have it running along the bank, or face, of uncleared mofs; thus, at every point along the water-course, people may be employed in heaving in pieces of moss by the spade, and they constantly shift the position of the drifts, in proportion as the mofs is cleared away.

On this it is observed, that "the writer learnt that it required the labour of a man nearly a whole year to clear one Scotch acre of mofs, and reduce it into a condition to receive a crop. This labour cannot be estimated at less than 25/-; to which, when the price of feed, compound interest upon the original erection of the machine and embankment, &c. is added, the expense of this mode of cultivation cannot appear trifling."

And further, that: "the soil, after the mofs is carried away, being a rich carse clay, mixed in many places with peat-shells, is first formed into ridges by the spade, and commonly yields a few good crops: laying it up in drills, during the fall winter, by the spade, is found powerfully to increase its fertility. When it begins to lose its fertility, it receives a good dose of lime, and is afterwards manured with peat-sashes, and such putrefactive manures as are accumulated on the foot." The writer adds, "he has heard that the farmers upon the banks of the Forth raised, at first, a great clamour against the improver for waisting his mofs into the river, as, when it was met by the tide, it was thrown out, and covered up their gras-lands upon the banks; but he was told, that they afterwards became very earnest to collect what he had thrown away; for the mofs being washed and floated in this manner, is robbed of its ropy juice, and disposed to putrefaction; of course makes excellent manure for carse lands, more especially if made into compot with lime and flable dung." Mr. Headrick conceives that: "the whole of the plain, extending from Borrowstounnes to Gartmore, has once been covered by the sea; and the soil is composed of clay washed down by the Forth from the mountains of micaceous schistus, where that river derives its origin. This washed clay has gradually filled up, and towards the ferry is perpetually filling up, the bed of the sea: the carse clay is here and there interlaced by land and gravel, and other friable soils (called there dry-field land), which have been washed down by the various streams that run into the Forth, and partake of the quality of the mountains from which they have been washed; but the mere filling up of the bed of the sea would never cause dry land to rise above its surface, and would only raise the water to a higher level." When the plain of the Forth is examined from its origin to its termination, or indeed any part of the island that is near the sea, it is sufficiently evident that the sea has retreated into a lower level, by at least forty feet, than it formerly occupied; and that too, since the told land was placed in its present position; which accounts for the mud formerly deposited in this arm of the sea now appearing solid land. However, what chiefly deserves the attention of those who have an interest in this land is, that many parts of this carse clay are filled with oysters and other sea-shells, as he has observed them in many ditches, and frequently upon the surface. In some parts where a deep cut is cut by a rutlet, a deep bed of shells may be seen, which, taken in mass, is as rich in calcareous matter at the generality of lime-stone, and may be regarded as the material from which a future rock of lime-stone is to be conformed. It is easy to select these shells from the mud, when they would be much richer than any lime-stone. And as "lime is essentially necessary for this species of soil, and in many places difficult to be procured, on account of the distance from which it must be carried, and the badness of the roads, it would be very easy to supply its place, by burning the shells which here and there abound. Digging for lime-stone would be much less expensive than carrying lime-stone, and a flight heat would reduce them into very pure lime." Upon this principle it is conceived, that it would be more profitable to search for these shells, burn them into lime by means of peas, and employ them in the cultivation of the mofs themselves, instead of being at the expense of floating them away. Besides these dead shells left by the sea, as the Forth and Teath abound in fresh water muscles; these might easily be brofled by a stone rolling on its edge, and being mixed with mofs or earth afford an ample supply not only of calcareous, but also of purefect manure. They ought to be completely rotted before they are applied, and blended with a large proportion of earth."

And where clay marie could be procured, it would make an excellent dressing for the mofs land after it is thrown into pasture. But "the mofs have one advantage which seldom occurs, and which may have been the inducement to adopt this method. The soil, when got at, is excellent, being a rich carse clay, in many places reeking upon, or mixed with sea-shells. In most places the bottom of mofs is either a solid rock, or a whitish granite, or p r i c e l g r a v e l , or pyritical and aluminous clay." Which, after removing the mofs from such places, are worse than before, as the bottom either does not admit of culture, or requires an expensive far beyond its value in performing it.

In the Survey of Perthshire, it is stated, that this sort of land, when of "small extent, where there is a mixture of other earth, and the fall considerable, is generally pared and burnt, with profit; but if there be little or no fall, it may be planted with potatoes in lazy beds for a first crop, and the furrows left open for drains. With the first or second white crop, the feet of common grasses, which is always to be met with in meadow land, ought to be sown; which will yield a heavy crop of hay for some years, and after wards a plentiful spring of strong coarse pasture, confituting mostly of the aquatic plants." And, that "there is plenty of bruth-wood, deep mofs, with a good fall, are most frequently drained and drawn in ridges like other land. The drains may be made with faggots; put in either longitudinally and sloping, having the steps of the trancheal always in the direction of the fall; or they may be laid transversely, in the shape of a St. Andrew's crofs, and the land afterwards pared, burnt, and levelled." In these cases, "the spade for paring ought to be similar to that used in Scotland for cutting turf, provibly the spadus, which is to be very strong and deep, or a spade with a long hand and a short blade, or a slender spade with a large head; with a sharp edge. In the fore part, having a perpendicular knife, standing up at one side of the iron, to cut the sod, as the Highlanders have to the bagged spade, which they frequently employ in cutting peats in tough mofs." It is also stated, that a practice similar to this of improving mofs land, has been in use in Ayrshire, which is said to be borrowed originally from the practice in Ireland. The principal difference is, that the mofs is directed to be dotted or dug up with spades, and the manure to be chiefly lime. This is observed to be a method that is found by experience to be effectual. John Smith, Esq. of Sarsbridge Muir, near Keith, in the above county, has been very successful in following this mode. In this method the first thing to be done is to mark and cut proper manner-drains, eight feet in width by four and a half in depth, descending to two and a half at the bottom; which drains cut in Ayrshire at the rate of one

shilling
flinging per yard. In some instances it will be found necessary to cut these drains much deeper, and consequently at greater expense; and the drains are almost in every case too conducted, as to divide the field into regular inclosures, as well as to carry off the superficial water. Then the ridges are marked off regularly, and in breadth six or seven yards; seven yards are preferable; which ridges are formed with the spade in the following manner: in the centre of each ridge, a spade of about twenty inches is allowed to remain untouched; and on each side of that a furrow is opened, which is turned inward so as completely to cover that space, like what is called the firing of a gathered ridge. Thus begun, the work is continued by cutting with the spade, in breadth about twelve inches, and in length as may suit, till the whole be turned over, to appearance as with a plough, reaching back to the furrow that bounds the ridge. That furrow is a space about two feet, which is cut out and cast on the sides of the ridge. The depth of this furrow ought to be regulated by circumstances, so as not to lay the ridge at first too dry by being raised in the crown, and at the same time so as to bleed the moss and conduct the water to the main drains. The next operation is to top-dress the ridges with lime, the quicker the better, at the rate of from four to eight chaldrons to the acre: five or six chaldrons being the ordinary quantity. He has even been considerablv more applied with effect. The method thus prepared is ready to receive the feed, which is sown in the seafon, whether dry or wet is a matter of indifference, and harrowed in with a final harrow, drawn by two men. Four men, with cafe, will harrow at least five or six acres a-day; two and two by turns, drawing the harrow and breaking and dividing the mould with spades. But he would recommend planting potatoes, as preferable for a first crop, because oats for the first year frequently misgive. The potatoes are planted in what is called the lazy-bed way. The method is simple, and attended with little expense; and the moss is prepared for them in every respect and limited as before directed, for a first crop of oats. The beds are marked off across the ridges, in breadth from line to line six feet, with intermediate alleys of about two feet as a furrow. The beds are covered over with a thin stratum of dung. The fets of potatoes are laid on the dung and covered from the intermediate furrows; which is followed with another covering, in all about four or five inches." The planting of potatoes at first is not only considered as the most certain crop, but the most successful method at once of reclaiming the mosT, not owing perhaps so much to the influence of the dung in aiding the fermentation already begun in the moss, by means of the lime, as to the effect of the potatoe crop in over-shadowing the ground, and causing a stagnation of air, which prevents the evaporation of moisture, and thereby accelerates the putrefaction and decomposition of the moss; and also to the effect produced by the roots in dividing the moss, separating its particles, and rendering it into mould. This practice is now followed in general, wherever dung can be commanded; and the produce is between forty and fifty bushels from the acre. When the potatoes are removed, the ground is hoe'd, and a proper form, which is done, not by throwing the moulded surface into the trenches between the beds, but by making two or more cuts with a fpatel into the sides of the beds, which are pulled in opposite directions to close the lips of the trenches which have been made.

But if potatoes are not planted as a first crop, the field is prepared for a second crop of oats, by cutting the furrows across the ridge and turning them over, and by clearing out the division-furrows. To prepare for a third crop, the same operation is performed. The most proper feaston to prepare the moss for a first crop is early in the preceding summer, in which case, the lime, aided by the heat, the harvest rains, and the winter's frosts, has a powerful effect in promoting the proceeds of putrefaction: consequently a mould is formed to receive the feed the ensuing spring. Although mention is made of the preceding summer as the proper feaston to prepare for a first crop, the common practice is to prepare for it in the course of the preceding winter; and to prepare for the crop of the second year as soon as convenient after the removal of the former crop.

It is suggested, that "The first year's crop is sometimes good, but very uncertain, because the lime has not had time to exert its influence. The second year's crop will run from five to ten bolls the acre. A first crop after potatoes is seldom less than ten bolls; sometimes considerably more from the acre. Early oats, the small Dutch or Polish, are known to prefer. The grain is produced equal to any in the country. In general, four or five, or even six successive crops of oats are taken without any additional manure, and without any apparent signs of the soil being exhausted. On the contrary, the moss is now converted into a dark brown mould; and what alone renders it lofty productive of corn crops, is its running into sweet luxuriant grasses, the soft meadow grass, the daisy and white clover. Along with the fourth, fifth, or sixth crop of oats, grasses of which, in common produce an abundant crop of hay, and afterwards afford excellent pasture."

The moss is now considered to be in a permanent state of improvement; and if its own fodder be converted into manure, and applied to its own use, together with the occasional aid of lime, it will be for ever productive in potatoes and corn crops. In support of this opinion, a field of his has been in crop since the year 1788. When it began to run into grass, it was completely dived over, a fresh quantity of mosses turned up, top-dressed with lime, and planted with potatoes in drills, and hand-hoed. After the potatoes, a crop of barley was taken, and followed by a successions crops of oats; the last to be barley also with grass seed. The same rotation to be continued by way of experiment."

It is stated by Mr. Headrick, that "the expense of dving a moss for the first time, where the surface is tolerably smooth, is 2s. 6d. per fall, or 1l. 13s. 4d. per Scotch acre; but where inequalities occur, which must be removed into hollows, by wheel-harrows running upon boards, the first expense is greater, according to circumstances. The second delving, where potatoes have not been intervened, costs from 1l. to 1l. 6s. per Scotch acre, the division-furrows being at the same time cleaned out. The third delving and cleaning of the division-furrows cost 1l. per acre; but the moss is now so frable, that it may be wrought with the greatest ease and rapidity. At the above rates, an ordinary workman will earn 1l. 6s. per day; and an able and experienced one, from that to 2l. 6s. per day. They use a strong fpatel, edged with steel, and have always a grit-trowel near them, for sharpening the fpatel. In the evenings they repair its edge by rubbing it again with new steel. Sometimes the moss is so soft, that they walk upon boards while they are turning it over."

And it is added, that "Mr. Smith has found by long experience, that it is improper to make the ridges too high or too narrow; when they are made too high, they throw the water off from their sides, without admitting it to penetrate their substance; the top of course gets too dry; when too narrow, there is a lot of surface from too many division-furrows; the breadth already mentioned is found to be the
MOSSY LAND.

bead; and when the improvement is completed, the ridges appear like segments of wide circles, with a clean well-defined division-furrow between each of them. The moisture is thus caused slowly to filtrate through the mofs, rendered friable by lime, until it reaches the division-furrows and is discharged. As the mofs subsides for some time, and clohes in towards the furrows, it is generally necessary to cleanse them out before winter, and at the time the crop is sown until the mofs acquires solidity. And further, that "some mofs may be ploughed, the second year, to within two bount, or four ficles, of the division-furrows; and every operation performed by the force of hores, except turning over with the spade the narrow strips next to the division-furrows. In other mofs it requires three years before this can be done; and it seldom happens but every mofs may be wrought wholly by the plough; after it has been wrought four years by the spade. When mofs is wrought by the spade, it seems to be of no consequence whether it be wrought wet or dry; but when it is wrought by the plough, opportunities must be watched, as hores cannot walk upon it, for some years during wet weather."

With respect to "the quality of the potatoes thus produced upon mofs, the writer does not scruple to pronounce it most excellent. Potatoes have been tried with dung alone, but they were always watery, and frequently hollow or rotten in the heart; tho' raised upon mofs that have been well limed, are frequently fo dry and farinaceous, that it is difficult to boil them without reducing them to powder; and they are often obliged to lift them with spoons; they come clean out of the ground, keep remarkably well in heaps covered over with mofs in the field, and are remarkably well flavoured." Besides, "no such diffe as the curl was ever known among mofs potatoes:" and that if the opinion be true, that "the curl is caused by overloading the sets with too much earth, or from the earth becoming too hard around them, no such thing can take place in mofs; but to whatever cause the curl may be owing, it is certainly propagated by diseased seed; it would, therefore, appear disadvantageous to transfer the potatoes raised upon mofs as a feed for solid land. They have remarkably good species of potato in this distriet, which was brought from Virginia to Largs, about eight years ago; and whether it be owing to the benefial nature of a moffy soil, or to its own intrinsic merits, this potato has long been so much distinguished by the good quality and large quantity of its produce, that it has superseded the use of every other species. There seems to be no occasion for mofs improvers to change their feed. Some pertons in this distriet, who have but small patches of mofs, have kept them constantly in potatoes, more than ten years, without changing the feed, and that without any sensible diminution either in the quantity or quality of the crop."

I would seem from Mr. Headrick's paper, that in this fort of improvement much is owing to the great zeal and perseverance of Mr. Smith. And that "over all that county, the farmers and proprietors are busy in reclaiming mofs. In Renfrew, Lanark, and Dumfrieshire, this practice has made considerable progress. Major Majoribanks and Mr. Pitlow have got workmen from Ayrshire, and have commenced mofs improvements, upon a very extensive scale, in the neighbourhood of Bathgate. The culture of mofs has become, in many cafes, a distinct species of farming, to which individuals apply, to the neglect of every other pursuit." And "what may afflit the inexperienced to form some idea of the value put upon mofs by those who are acquainted with it, is, that a young man, son of a farmer on the eflate of Swinhird Muir, has taken 20 acres of mofs from William Patrick, esq. of Trelhorn, writer to the signet in Edinburgh for four crops, at 25s. per acre of yearly rent. All that was done by the proprietor was to dig the little drains, which also serve the purpose of fences; in other respects the mofs was delivered in its wild and unadulterated state, the tenant being at all the expense of working and manures, and obliging himself to lime, at the rate of 10 Ayrshire chaldrons per acre. The mofs was in crop in 1797; for the first time. The writer was several times upon it, and remarked, that where the lime had been early enough applied, which was the case with the greatest part of it, the crop (oats) was uncommonly good; even the worst was much better than some contiguous land which had been torn from Muir, and limed. On a small corner, which had got no lime, nothing grew. The proprietor himself expected no such rent, had it not been voluntarily offered by the tenant. The solid land there, which has been long in cultivation, does not average 20s. of rent, as the situation is not very accessible." And further, that "two small patches of cultivated mofs, contiguous to the town of Reith, were lately let at the rate, the one of 10l. per acre, per annum, for two crops of potatoes; the other let for 7l. per acre for two crops of oats, to be down with grass seeds. The first of these patches had been constantly in potatoes every since it was reduced to cultivation, and the occupants were to furnish what dung they chose for their crops, at their own expense. The second patch, of more than three acres, had been constantly either in potatoes, or oats, from the time of its first subjection, and would have given much more, had potatoes been permitted; but it was thought advisable to bring it into grass. It must be admitted, that land immediately contiguous to a town, fetches a rent for convenience, as well as for what it actually produces; at the same time it must be observed, that the said solid land, to which these patches of mofs belonged, and some of which had been long in pasture, brought only a rent of from 3l. to 6l. for two years' crops, the whole being let in parcels by public auction."

However, on minute examination, Mr. Headrick found in this district considerable variations in the practice of mofs improvers, induced by different circumstances. Those who have large tracts of mofs, and who are remote from markets, cannot afford to have any great proportion in potatoes, as those who have only a small patch. They go over as much land as they can with lime, not having dung for the whole. They take crops of oats until the land gets foul, and then leave it to gather grass as it can. Such land never being cleaned, abounds in weeds among the natural pasture. Others, who have a small patch of mofs, from four to six acres, have always a part of it in potatoes, with dung occasionally; another part in barley or oats, and another in cut grass. Many of these farmers never apply the plough to their mofs; for, though this may be done with safety, they say they have at least a third more crop with the spade than with the plough. After the mofs is completely reduced, it is turned over with great care, and they apply themselves to this work at intervals, either when the weather is so wet, or other circumstances occur, that they cannot work with their hores. As no plant yet tried contributes more to the improvement of mofs than the potato, and as it also affords an opportunity of cleaning the land, those portions of mofs on which it has been frequently repeated, are clean and fertile. In a word, some of the best land which he saw in this distriet was mofs of an unknown depth.

In concluding the account of this interesting fort of improvement, the writer thinks, that "it would be an improvement
promote to roll moss occasionally during the progress of its cultivation. Dr. Anderdon proposes to do this by a horse running upon planks, but he does not seem to advert that it would require more men to shift these planks, than would be sufficient to draw the roller in the way field-artillery are drawn." And that, “after moss is laid down into pasture, it would contribute much to its fertility to lay it all over with a good dose of earth, tarrins of quaries, sand, or clay pulverized by lime, and then to roll it; this could be done in dry weather, when there is no danger of poaching, or breaking the sward.” It is added, that “cattle of every kind should be kept from mosses, at first, during winter. This rule is also applicable to clay soils of every kind. Perhaps the best flock for pasturing on improved mosses would be sheep; but these have been banished from the improved moss districts, on account of the injury they do to young planting and hedges.” It is further remarked, that “he saw several mosses which were blilliery, and nacked of herbage, after they were thrown into pasture, on account of springs sifting from the out-crop of rocks that terminated below them. These may be cured by bored drains, and by no other method.”

The same writer states, that “hedges thrive remarkably well upon moss land, where a bank is thrown up, and lime is previously wrought and mixed among the moss in the thorn-bed; but in that district, with few exceptions, they plant hedges, and then abandon them to their fate: being seldom or never weeded, the grass and other plants soon overtop the hedge, and it never becomes a fence.” It is supposed that in extensive mosses, fences may be made out of the moss itself. Suppose, in place of one mafter-drain, to divide two fields, two drains were made, with an interval of ten or twelve feet betwixt them, and all that was taken out of each drain built up upon the surface of this interval; it would form a rampart, which no animal would attempt to pass. As the cultivation of the moss went on, its surface would sink, and then it would be necessary to deepen the mafter-drains, fill throwing what was taken out of them upon the top of the rampart. As no animal could see beyond this rampart, it never would attempt to cross, or get over it.

And in this district, “they have also roads running through the mosses, generally along the side of a mafter-drain, and cut off from the contiguous field by a small rut on the other side. These are generally too narrow, but they serve the purpose of conveying lime, &c. in dry weather, and of taking away the crop. Were the cultivation of an extensive flow moss attempted, he sees no other practicable plan but making very broad roads, drained to a great depth on each side, and laid with sile in the centre. This might intercept an extensive range of fields on each side, secured by the ramparts he has mentioned, and serve to convey lime, dung, &c. and take away the crop. At first it would be necessary to carry the corn-crop to the road upon hand-barrows; unless it was stacked upon the field, and taken away during frost. Potatoes, except such a portion as may be wanted for immediate use, are kept pressed upon the field, in heaps, covered with moss, and can be removed during frost. After land of this kind is sufficiently limed, and wrought during a number of years, it collapses so much, and becomes so solid, that it can endure cartage almost at any time of the year.”

Mossy Soil, that sort of soil which is principally constituted of peaty matters. See Soil.

MOST, or BRIEIX, in Geography, a town of Bohemia, in the circle of Sattz, on the Bila, containing three cloisters; 12 miles N. of Saatcz. N. lat. 50° 30'. E. long. 13° 40'.

Vol. XXIV.
white metal seems to have been better for all uses than the copper itself. As to their telling us that it was a fort of earth which they used on this occasion, very little regard is to be paid to the terms; for they had an inaccuracy in speaking that leaves us much in the dark, in many other things besides this. They call the colaminaris stone, which is an ore of zinc, by the name of Cadman earth, in their description of the manner of making brasses.

It has seemed absurd to some to call this white metal aurichalcum album, because they supposed the word aurichalcum to signify gold-coloured copper; but this is an error. The aurichalcum is but a false spelling of orichalcum.

MOTACILLA, the wagtail, and the warbler, in Ornithology, a genus of birds of the order Passeres. Though differing considerably in their manners, these birds are branded by Gmelin under one genus, of which he enumerates nearly two hundred species. The generic character is: bill fubute, straight; the mandibles nearly equal; nostrils suboval; tongue lacerate at the end.

Of the wagtails, it is observed that their movements are extremely alert, and that their tails are perpendicularly long, which they perpetually jerk up and down. Their progressive motion is by running rather than springing. They rarely perch on trees. Their flight is waving, and accompanied with a tittering sound, and their food consists of flies and other small insects, in pursuit of which they will often follow the husbandman with his plough, and the movements of flocks of sheep. The warblers are composed of a great variety of birds, differing in many of their particularities of habit as well as in size. They are found in almost all parts of the world, perch on trees, move by leaping, and rarely utter any sounds during their flight. They are more numerous than any genus of birds, and abound principally in the warm latitudes of the globe, where insects, their food, are found in never-failing supplies.

Species.

* LUSCIA, the Nightingale, of which three varieties are given: the specific character of the first is, rufous ahi; beneath white ahi; tail feathers rufous brown; bracelets cincereous. In the second the body is sometimber white; and in the third the body is entirely white. The nightingale is somewhat larger than a hedge-sparrow, which is known to every one, and on the upper part of its body it is of a rufly brown. It inhabits, in its several varieties, Europe, Asia, and Africa, and is, of all birds, most famed for its song, which is so melodious, in this country at least, more on account of the time in which it is heard, than in respect to the excellencies of its notes. It visits England in the beginning of May, sometimes sooner, if the weather be mild and favourable, and leaves it in autumn: it frequents thick hedges; evades the light as much as possible; sings late in the evening, and particularly during the time that the hen is hatching; breeds three or four times in the year, and lays four or five eggs, which are of a greenish-brown colour: it feeds on the larvae of insects. It is characterized by Gmelin as having a brown bill; head and back pale mouse colour, with olive spots; tail red-mouse colour; legs and quill-feathers brown-ah; the latter趁fatut on the outer edge. It is common in several parts of our own island, but is rarely heard in the northern parts of it, or even as far as Yorkshire, nor indeed so far west as Cornwall or Devonshire. It is not at all uncommon on the hills of Hampstead and Highgate, though we seldom not often heard to near the metropolis on the other sides of it. The males are said to arrive about a week before the females. Their winter residence has not been ascertained with any degree of precision; but is supposed to be in Asia, in various parts of which they are found, and are very highly prized, on account of their powers of melody. This is said to be particularly the case in Japan and Aleppa. In the latter place they are kept tame, and even hired out to give vivacity and harmony to almost every festival and entertainment. In Persia the nightingale sings in great perfection, and it is mentioned by a traveller in that country as the "sweet harbinger of the light: the conflagrant cheerer of the groves of Persia, charming, with its warbling strains, the heavest soul into a pleasing ecstasy." Another author describes the nightingale as beginning its song with a flow and timid voice, and, by degrees, opening its mouth and swelling it, till it bursts with loud and vivid flashes; and he adds, "it flows with smooth volubility; it faints and murmurs; it shakes with rapid and violent articulations. The soft breathing of love and joy are poured from the innomfoul, and every heart melts with delicious languor; pauses occasionally occur, to prevent fatiety, and give dignity and elevation; the mild silence of evening heightens the general effect, and no rival interrupts the happy and interesting scene." Nightingales build in low and close bushes. The female fults the undivided fatigue of incubation, while the male at a distance enlivens her with his fine strains. They are never seen in flocks, even of a very small number. If caught they may even be induced to sing in confinement; and will continue their song several months in the year.

CETIDUS: Hang-neat Warbler; so denominated from its building a hanging nest. It is the size of a robin, and is found chiefly in the island of Jamaica. Its specific character is: above greenish-brown, beneath tawny; has an ocular line, and one beneath black. The bill is blackish; lateral tail and quill-feathers within rufous; temples orange; wing-covers edged with yellowish; legs blackish.

PALMARUM; Palm Warbler. Brown, beneath dirty yellowish-white; belly yellowish; rump olive; two outmost tail-feathers with a white band near the tip. It inhabits the islands of St. Domingo; is about five inches long; feeds on seeds and fruits, has a fine note, and builds among palm trees, whence it derives its specific name.

BONARIENSIS; White-chinned Warbler. Black; throat and flanks ferruginous; face, chin, middle of the belly, and outmost tail-feathers white. It inhabits Bonaria: the bill is blackish; the hind claw large.

BANANIVOLA; Banana Warbler. Black-grey, beneath yellowish; arm-pits yellowish; vent varied with yellow and grey; chin cincereous; tip of the tail-feathers, spot on the wings and eye-brows white; lores black. It inhabits St. Domingo, is about three inches and a half long; feeds on seeds, insects, and fruits, particularly on bananas.

VERMIVORA; Worm-eating Warbler. Olive colour;
head, throat, and breast tawny; ocular band and arch over the eyes black; over the eyes a yellowish line, vent cinereous. It is found in Pennsylvania, and is of the fize of a common hedge-sparrow of this country: the bill is black, beneath flesh-colour; and the legs are of the same colour.

MADAGASCARENSIS; Madagascan Warbler. The name indicates the abode of the species: it is more than six inches long; of an olive brown; head rufous; chin white; breast reddish; belly brown-rufous. Bill and legs brown.

* MODULARIS; Hedge-Sparrow, or Hedge-Warbler. Above grey-brown; wing-coverts tipp with white; breast blueish-ah. The bill is blackish; checks striped with white; feathers of the back and wing-coverts edged with chestnut; wings and tail dull; rump greenish-brown; chin and breast cinereous; belly whitish; vent yellowish; legs flesh-coloured. It is nearly six inches in length. It inhabits this country and various other parts of Europe, and is one of the few of the warbler tribe that remains with us the whole year. It has a pleasing and plaintive song, which it begins with the year, if the weather is mild; breeds early, making in the month of March a nest composed of green-moss and wool, and lined with hair, which is placed in some low bush, or evergreen shrub, and sometimes in faggot-piles, or in mere bundles of pea-sticks. The female lays four or five blue eggs. For want of insects and worms, which in severer weather are rarely to be met with, the hedge-sparrow will pick up crumbs of bread, and seems to prefer situations near the habitations of man. The cuckoo frequently makes choice of this bird's nest for the purpose of depositing its egg.

JUNCOUS; Ruth Warbler. Brown, beneath paler; tail somewhat forked. It inhabits Virginia and Carolina, and is less than the last.

AQUATICA; Aquatic Warbler. Above pale rufous, spotted with brown; throat and breast reddish, belly and rump whitish. It inhabits Italy, and is migratory. It has a spot above the outer corner of the eye, and band at the base of the wing white; its tail-feathers are pointed.

SCIONOBANUS; Reed Warbler. Tefaceous-brown, beneath pale tefaceous; head spotted. It is found in marshy places, and in woods in many parts of Europe; it is very tame, and sings through the whole winter. The bill is blackish; quill-feathers brown, edged with rufous; tail is brown, and the legs are whitish.

CAMPESTRIS. Brown; head greenish-ah; tail the colour of the body; belly whitish. This is called the simple warbler. It inhabits Jamaica; is the size of a hedge-sparrow. The bill is black; the neck is greenish-ah; body beneath brownish-white, legs brown.

MACROURA; Green-tailed Warbler. Brown, beneath whitish-yellow, spotted with black; eye-brows white; tail wedge and long. It is found at the Cape of Good Hope, and widely distant in Cape Colony.

LONGICAUDA; Long-tailed Warbler. Olive; crown reddish; quill-feathers olive-brown; tail-feathers long, narrow, the middle ones longer. It inhabits China, is tame, and has a fine note.

CURRUCA; Babbting Warbler. Above brown, beneath whitish; tail-feathers brown, the outermost white on the thinner edge. It builds in hedges, and lays from three to five eggs. The bill of this species is blackish; crown and streak beneath the eyes cinereous; wing-coverts on the inner edge white, outer edge rufous-grey; tail-feathers edged with grey; legs brown.

PASSERINA; Pallierine Warbler. Cinereous, beneath grey-white; eye-brows whitish, wings and tail black. It inhabits France and Italy; has a simple note, and lays four whitish eggs spotted with green.

* HIPPOLAIS; Lesser Petty-chaps. Greenish-ah, beneath yellowish; belly whitish; limbs brown, eye-brows whitish. It is found in England and other parts of Europe; is larger than a linnet, builds under beams, or in a low shrub; eggs white, with small red spots. The upper mandible is black, the lower blueish; inside of the mouth red; above and beneath the eyes there is a yellow line; the quill and tail-feathers are of a mouse colour, edged with greenish, the shafts black; lower wing-coverts yellow; tail very. It has often been confounded with the yellow wren and wood-wren. It is the first of the many warblers that visits us in the spring, being heard early in April, and sometimes sooner than this. Its song consists of only two notes, which seems to express chip, chip. It is busy and restless, always active among the trees and bushes, in search of insects. The nest is oval, with a small hole near the top, composed externally of dry leaves and coarse dry grubs, and lined with feathers. For the most part, it is placed on or near the ground, frequently on the bank of a ditch, or in a tuft of grass or low bush. The eggs are five or fix, white, speckled with purplish-red at the larger end only, with a few spots on the sides. Its note is heard long after the yellow-wren is silent; and it remains with us not unfrequently till the latter end of October.

* SYLVA S; Wood-wren. Above oliv-green; throat and checks yellow; belly and vent of a fine flivery hue; tail-feathers brown, and, excepting the first, they are green on the outer webs, and white on the inner. The bill is of a horn colour; irides hazel; breast pale yellow; a yellow line through the eye; tail somewhat forked, and brown; the under part of the shoulder is of a bright yellow; the legs are of a horn colour. It inhabits England; frequents woods, and searches about trees for insects. It is very like the yellow-wren, and has not been much noticed as a distinct species, though it is not at all uncommon. It is partial to oak and beech-woods, where it may be observed by the singularity of its note, expressive of the word twice drawn out to some length, and repeated five or six times in succession, delivered in a hurried manner, and accompanied with the shaking of the wings. It makes an oval nest, with a small hole near the top, is constructed of dry grubs, a few dead leaves, and a little moss, and is lined with finer grubs and hair. It lays five eggs, which are white, and sprinkled with purplish spots.

* HORTENSIS; Petty-chaps, or greater Petty-chaps. Grey-brown above, white beneath; eye-brows whitish; quill-feathers brown-ah, edged with grey, the outermost on the outer web, and near the tip of the inner, whitish; the bill is blackish; lateral tail-feathers edged with grey-brown; the legs are also brown. Gmelin says it is found in France and Italy, chiefly in gardens, whence it derives its specific name; but other naturalists tell us, it is to be met with in the summer, in some of the southern counties of England, and even as far north as Lancashire. It frequents thick hedges, in which it builds its nest of goose-grubs, and other fibrous plants, covering it on the outside with green moss. It lays four eggs, of a dirty white blotted with brown. The song of this species is little inferior to that of the nightingale; some of its notes are not much unlike the black-bird's whistle; but in a more hurried cadence. It frequently sings after fun-fet.

RUPA; Rufous Warbler. It is rufous-grey, beneath white; eye-brows white. Inhabits France and Germany, is four inches long, and lays five greenish white eggs, with dusky spots. 

Hb 2

* SAI.
Sedge Warbler. Cinereous, beneath white; eye-brows white. It is found in many parts of Europe in reedy places; it sings in the night, and imitates the notes of other birds; the eggs are whitish varied with brown. It comes to us in April, and leaves again in September. Its notes partake of those of the sky-lark and swallower, as well as of the chatter of the house-sparrow: it builds among reeds and rushes, sometimes on the trunk of a low willow. The song of this species of warbler has sometimes been ascribed to the reed-bunting, a mistake which has originated from the circumstance of both species breeding in the same places, and the reed-bunting being conspicuous on the upper branches of a tree, while the warbler, concealed in the thickets, is heard aloud. It has been remarked, that if it be silent, a flute thrown into the bath will cause it to sing immediately, and that it will also sing during a moonlight night.

White Throat. Cinereous above, white beneath; first tail-feathers longitudinally half white, the second upright with white; bill black, white at the base; head brownish, with a black reddish. The female has a snow-white breast and belly. There is a variety which is thus described: reddish above, and reddish-white beneath, with the throat white; the outmost tail-feathers on the upper part of the inner side, and the whole of the outer side white. It is very common in the enclosed parts of our own country, and likewise in other parts of Europe. It arrives here about the middle of April, and enlivens the hedges with its song, when it erects its feathers on the crown of the head. It builds its nest in some low bushes, among nettles or other luxuriantly growing plants. It feeds on insects and berries, and frequents our gardens in the summer, for the sake of cherries and currants.

Leffier White Throat. Brownish, beneath white; breast spotted with cinereous. It is found in several countries of Europe, and its flesh is reckoned very delicious.

Fig-eater. Reddish-brown, varied with yellowish and cinereous, beneath white; breast yellowish, spotted with black; quill and tail-feathers blackish, edged with white. It is found in Italy, and feeds on grapes. The bill is of a chestnut colour; the legs are reddish, and the claws black.

Patagonia. Patagonian Warbler. This species, which takes its name from the country in which it is found, is cinereous, chin, throat, eye-brows, and outmost tail-feathers white; wings varied with brownish, the coverts with a brownish band; quill-feathers edged with brown. It feeds on lice, worms, and shell-fish. The bill is black; the body is streaked with white; the legs are black, and the hind claw very long.

Cheesman. Dartford Warbler. Cheesman, beneath terriginos, middle of the belly, edge of the quill-feathers, spurious wings, and outer side of the outmost tail-feathers white; eye-brows red. It inhabits Europe, and is about five inches long. The bill is black; iris scarlet; tail black, as long as the body; legs yellow.

African. African Warbler. Black; the feathers edged with rufous-grey, beneath whitish rufous; crown rufous spotted with blackish; each side the chin a longitudinal black streak; quill with four middle tail-feathers brown, edged with rufous colour. It is found at the Cape of Good Hope. Bill horn colour; tail slightly wedged; eggs grey-brown.

New York Warbler. Varied with cinereous brown, beneath yellowish, streaked with black, eye-brows white. This, as its name imports, inhabits New York; it is likewise found in Louisiana. Its bill is black, and legs of a pale chestnut.

Umbria. Umbrofle Warbler. Found also in Louisiana. Grey-brown, beneath white, with a few black spots, base with dirty spots; rump yellowish; wing-coverts, tail-feathers, and upper coverts black, edged with white. The bill is black, greater quill-feathers and legs blackish.

Yellow-throated Warbler. Grey, beneath white; throat pale yellow; front, eye-brows, and sides of the neck black; wings with a double white band. This is an American species, and may be found in Carolina. The tail-feathers are black, the lateral ones white on the inner side; bill black with a yellow spot on each side the base; legs brown.

Orange-thighed Warbler. Olive, beneath white; head with a transverse white bar; thighs and vent orange. This is found in Louisiana.

Rufous-tailed Warbler. Brown, beneath white; back inclining to the rufous; edge of the quill-feathers, wing-coverts, and tail rufous; chin white spotted with black, breast pale brown. It inhabits Cayenne.

Yellow-bellied Warbler. Greenish-brown; breast and belly yellow; tail greenish; wing-coverts and quill-feathers brown, edged with pale rufous. This is found likewise in Cayenne, and is of the size of a humming-bird.

Blue-grey Warbler. It is, as its name points out, of a blue-grey colour, beneath whitish; chin black; wing-coverts and quill-feathers brown; the former with a white spot, the latter edged with blue-grey. It is found in the island of St. Domingo.

Blue-grey Warbler. Throat and breast yellow; belly and tips of the wing-coverts white, tail pale at the tip. Is found in many parts of the American continent.

Penile Warbler. Grey, yellow beneath; belly and eye-brows white; lores spotted with yellow; wing-coverts alternate white and black bands. Nearly five inches long. Inhabits St. Domingo, and some of the West India islands, where it feeds chiefly on insects and fruits; and has a very delicate song, which is continued throughout the year. "The fagacity displayed by this bird," says Mr. Bingley, "in building and placing its nest, is truly remarkable. She does not fix it at the forking of the branches, as is usual with most other birds, but suspends it to binders hanging from the netting, which she forms from tree to tree, especially those which fall from branches that hang over the rivers and deep ravines. The nest consists of dry blades of grass, the ribs of leaves, and exceedingly small roots, interwoven with the greatest art; it is fastened on, or rather it is worked into, the pendent twigs. It is in fact a small bed rolled into a ball, so thick and compacted as to exclude the rain; and it rocks in the wind without receiving any harm. But the elements are not the only enemies against which this bird has to struggle; with wonderful fagacity it provides for the protection of its nest from other accidents. The opening is not made on the top or side of the nest, but at the bottom; nor is the entrance direct. After the bird has made its way into the well-made, it must pass over a kind of partition, and through another aperture, before it ascends into the abode of its family. This lodging is round and soft, being lined with a species.
MOTACILLA.

species of lichen, which grows on the trees, or with the silky down of plants.

ALBA; White-water Wagtail. Breast black; two lateral tail-feathers obliquely half white; bill, hind head, nape, throat, and legs black; front, orbits, sides of the neck, and belly white; body cinereous above; greater quill-feathers blackish; secondary, and wing-coverts dull, and edged with grey; middle tail-feathers black, and edged with grey. Female with the crown brown; length seven inches and a half. This species inhabits almost every where; is a very active bird, and continually in motion, running after flies. In this country, as the weather becomes severe, it is apt to haunt marshes that are subject to the flow of the tide. Early in spring they return to their usual summer situation; and from the number which are sometimes seen together at this time attending sheep-folds and newly ploughed fields, we may presume that they are gregarious in their flights. In the breeding season they seem to prefer pleasure-grounds that are conveniently mown, on which they run unincumbered, and where the insects have not sufficient cover to evade their flight. The nest is found in various places, sometimes on the ground, in a heap of flakes, the hole of a wall, or on the top of a pollard tree. It is composed of moss, dried grass, and fibres, put together with wool, and lined with feathers or hair. The eggs are four or five, white, and spotted all over with light brown and ash-colour; weighing about forty grains, and much resembling that of the cuckoo, which bird frequently makes choice of the wagtail's nest, in which to deposit her egg. It fings very prettily early in spring, and frequently gives the alarm on the appearance of a hawk, which it pursues in company with the swallows. The young birds have no black on the throat till the returning spring, the old ones lose it in winter. In this state they have been erroneously described as a variety.

MADERASSATINENSIS; Pied Wagtail. Black, beneath white; oblique band on the wings and lateral tail-feathers white. It inhabits Madras. The female is cinereous in the parts where the male is black.

CINERA; Cinereous Wagtail. Greyish, beneath white; breast of the male with a band; tail black, the two outermost feathers mottled white. It is found in many parts of Europe, and frequents watery places.

INDICA; Indian Wagtail. Greenish-grey, beneath yellow; breast of the male with a band; tail black, the two outermost feathers mottled white. It is found in many parts of Europe, and frequents watery places.

VIRIDIS; Green Wagtail. Greenish, head, wings, and tail cinereous; edges of the wings, tail, and belly white. It is found in Ceylon, and is about four inches long.

TCHUTSCHIENSIS; Tchutshi Wagtail. Olive-brown, beneath white spotted with a ferruginous tint; there is a spot between the bill and eyes, two bands on the wing-coverts, and the greater part of the outermost tail-feathers white. It takes its name from the flores of Tchutshi, where it is found.

AFRA; African Wagtail. Yellowish-brown, beneath yellow; lower tail-coverts white; bill, eye-brows, wings, tail, and legs black. It inhabits the Cape, and is less than the M. alba already described.

FRETICOLA; Yellow-headed Wagtail. Yellow; crested on the nape blackish; back blueish-grey; two lateral tail-feathers half white.

FLAVA; Yellow Wagtail. Breast and belly yellow; two lateral tail-feathers obliquely half white. There is a variety of this species; greyish, beneath and eye-brows yellow; quill and tail-feathers black; wings with a white band. It inhabits Europe and Asia. Visits this country in April, and departs in September. It frequents arable land, especially in the more champaign parts, and sometimes uncultivated ground, intersected with furze. It is also partial to beanfields; and breeds in all such situations, being more neglectful of water than the white or grey wagtail. The nest is always placed on the ground, composed of dried stalks and fibres, and lined with hair. The eggs are four or five; not very unlike those of the fedge warbler. Its note is more shrill than that of the white, and less so than that of the grey wagtail.

TIPHA; Green Indian Wagtail. Green, beneath yellowish; wings black, with two white bands. It is found in Bengal.

SINENSIS; China Wagtail. Green, beneath flesh colour; spot on the ears and liripie from the eyes to the nape pale; the tail is pointed. It is found in China; is six inches long; the bill and legs are black.

SINGALENSIS; Cingalese Wagtail. This species is of a changeable green; throat orange; breast and belly yellow; it inhabits Ceylon, is four inches long, and the bill is brown.

ZEYLONICA; Ceylon Wagtail. Green, beneath yellow; crown, grey, and wings black; the latter with a bield white band. It is likewise found in Ceylon; of the same size as the last, with a blue-grey bill.

OLIVACEA; Olive Wagtail. Olive, breast and belly white. It inhabits Ceylon; it lifts its tail into an acute angle; the bill whitish, covered at the base with yellowish feathers.

CARYOPHYLLUS; Pink-coloured Wagtail. Is, as its name denotes, of a pale pink; bill and legs reddish. It inhabits Ceylon; is very small; wings and tail growing dusky.

ALBICAPILLA; White-crowned Wagtail. It is black, beneath whitish; chin, spot on the crown, and eyes white. Found in China, and is full seven inches long.

GRISA; Grilly Wagtail. Greyish; crown, bill, throat, and breast black; ocular streak, tip of the quill-feathers, belly and vent white. Quill-feathers edged with grey; legs cinereous.

MAOULATA; Spotted Wheat-ear. This, as its name indicates, is spotted with black, above brown, beneath whitish; orbits pale ochre; rump brown; tail black with a white base; outermost tail-feathers without, and at the tip white. It inhabits France, and is the size of a lark.

MASSILIENSIS; Provence Wheat-ear; Rufous, beneath reddish-white spotted with blackish; crown and neck above brownish-rufous; under the eyes a pale yellow spot; tail-feathers black, the middle ones edged with rufous; four next each side white, outermost all white. It inhabits Provence, as its trivial name imports.

PILEATA; Black-headed Wheat-ear. Head, middle tail-feathers, and tips of the lateral ones black; eye-brows, front, chin, rump, tail and belly white. It is found in some parts of Africa and China; is about six inches long, and the bill is black.

AURANTIA; Orange-breasted Wheat-ear. Brown; beneath orange; throat whitish; varied beneath with black; greater wing and tail-coverts white; tail-feathers brown, the lateral ones tipped with white. It inhabits the Cape of Good Hope.

HOTTENTOTTA; Cape Wheat-ear. Tawny brown; rump with a yellowish band; chin and lower part of the belly whitish, upper tawny; upper tail-coverts yellowish, lower white; tail white at the base, black in the middle, and whitish at the tip. It inhabits the Cape.

LEUCORHOA; Rufous Wheat-ear. Reddish-brown, be-
neath whitish-yellow; rump, bafe of the tail, and coverts white. It inhabits Senegal, and is seven inches long.

*Stapazina;* Rufetf Wheat-ear. Ferruginous; wings brown; area of the eyes and tail black; outer tail-feathers white at the side. There is a variety of this species that is pale-rufous, beneath whifh; bands across the eyes black; two middle tail-feathers black; the outer ones white on each side, and fringed with black towards the tip. It inhabits Europe. Bill and legs black.

*Oenanthe;* Wheat-ear. Is diftinguished by its hoary back; its front, line above the eyes, rump and bafe of the tail white; through the eyes a black band. The distribution of these colours varies, however, fo as to produce four or five varieties. The bird is met with as far north as Greenland, and as far edf as India. It visits England annually in the beginning of March, and leaves us in September. It chiefly frequents heaths, warrens, and the edges of hills, feeds on insects, particularly earth-worms; grows prodigiously fat, and breeds in rabbit-burrows, or under a stone. The eggs are from five to eight in number, of a light blue, with a deep blue circle at the large end: the young are hatched in the middle of May. In some parts of England these birds are very plentiful. About Eastbourne, in Suffolk, they are taken in snares made of horse-hair, placed beneath a long turf; being very timid, the motion of a cloud, or the appearance of a hawk, will drive them for shelter into these traps. The numbers annually enfarm in the neighbourhood of Eastbourne, are fad to amount to 1,840, and they are usually fold at fixpence a dozen; the smaller are eaten in the country, the larger are fected for the London market, and when potted by the poulturers are by many as much esteemed as the ortolan on the continent.

*Rubreno;* Whin-chat. Blackish; eye-brows white; wings with two spots; chin and breast yellowish. This species is found in various parts of Europe. It lays five eggs, which are white, fotted with black.

†Fervida;* Sultry Whin-chat. Brown, the feathers edged with rufous; beneath pale ochre; wings with two white spots; tail blackish. It inhabits Senegal; its bill and legs are black.

Montanella;* Siberian Whin-chat. Pale tafeaceous, spotted with brown, beneath pale ochre; crown black-brown; eye-lids and chin ochre or white; ears with a black spot; wings brown; tail afy. It inhabits Siberia.

Magno;* Dark Warbler. Brown; crown and back paler black, beneath reddifh; chin whitifh; quill and tail-feathers half rufous, the outmott white on the outer webs. It is seven inches and a half in length.

Philippenis;* Philippine Warbler. Violet black, beneath reddenfwhite; wings with three white spots; head reddifh-white; neck dirty red, pectoral band bluefifh; outmott tail-feathers reddifh-white. This, as its name imports, inhabits the Philippine iflands.

Coromandelica;* Coromandel Warbler. Black; leifer wing-coverts with a yellow spot, the rcl with a white one, and edged with yellow; rump and belly pale rufous; wings and tail black. It is the rize of a titmouif.

*Perspicillata;* Spectacle Warbler. Black; wing-coverts with a white spot; tail even; orbits bladed, yellowfifh, wrinkled. It is found near the river Plate, and is the rize of a goldfifh. The irides are yellow; pupil blue; tail when extended forming an equilaterat triangle.

*Rubrica;* Stone-chat or Moor Titling. Grey, beneath pale rufous; throat with a white band; lores black. It inhabits hedges and dry moors in Europe and Siberia; is a reffifh, nofly bird, and builds under a stone, or in some low shrub; lays five or six bluefifh-green eggs, with pale rufous spots. The female is varied with blackifh and reddifh.

*Atricapilla;* Black-cap. Brick colour above, cinefrous beneath; cap dusky-black; bill brown; crown black, in the female chefnut; body greenifh-ah above, grey be nefh, gradually growing white; temples grey; quill and tail-feathers brown-ah, edged with greenifh-ah. The middle ones very fhort, legs lead colour. Of this species there are at feaf three or four varieties. Length full six inches. Inhabits Europe. It is a migratory bird, visiting us early in the spring and returing in September. It frequents woods and thick hedges, and feeds very partial to orchards and gardens, where it delights us with its charming melodi fous song, which is very little inferior to that of the nightingale, except in variety of notes. It makes a nest in some low bush or shrub, composed of dried flalks, generally of goose-grafs, put together with a little wool, and sometimes a little green moss on the outside, and lined with fibrous roots, on which are frequently placed a few long hairs. The eggs are four or five, of a pale reddifh-brown, mottled with a deeper colour, and sometimes sprinkled with a few ah-ah-coloured spots. On the first arrival of this bird, it feeds greedily on ivy berries, but forsakes that food as soon as the vernal fun has routed the infect tribe.

There are three varieties of this species, besides the one already defcribed. 1. Varied with black and white. 2. Above blackifh; fides grey; chin white. 3. Greenifh-brown; cap blackifh; neck above cinefrous; eye-brows white; wings and tail blackifh.

Melanocephala;* Black-headed Warbler. Greenifh-ah, beneath grey; crown black; eyes with a red band. It inhabits Sardinia.

Moscita. This species is of a lead-colour; cap pale rufous. This is likewise found in Sardinia. It frequently hatches the cuckoo's eggs, which are laid in its net.

Pennsylvanica;* Bloody-side Warbler. Cap yellow; flanks bloody-red. It is found in Pennsylvania; the rize of the M. Hippolais.

Ruschapilla;* Red-cap Warbler. Olive, beneath yellow; throat and breast longitudinal rufous spots; crown rufous; wing-coverts, quill and tail-feathers brown, edged with olive. Inhabits the island of Martinico. The bill is brown; two middle tail-feathers yellowish on the inner webs; legs grey.

Chrysoptera;* Golden-winged Warbler. Black cinefrous, beneath white; cap and spot on the wings pale yellow; chin black. This is an American bird, and found in Pennsylvania in the spring and the autumn.

Chrysocephala;* Orange-headed Warbler. Chfnet, beneath yellowish; head and neck orange; band above and beneath the eyes brown; wing-coverts white and black, tail-feathers black, edged with a yellowish fringe. It is found in Guiana.

Chitata;* Credled Warbler. Above brownifh-green, beneath greenifh-grey; rcl on the head blackifh-brown, edged with white. Inhabits Guiana.

Multicolor;* Rufous and Black Warbler. Black; bill and legs brown; breast, fides of the neck, tips of the greater wing-coverts, and half the tail rufous; belly and vent white. It is found in Cayennce.

Equinocialis;* Equinocital Warbler. Greenifh-brown, beneath pale ochre; chin and breast yellowish; wings, tail and legs brown. Inhabits Cayennce.

Photolitharhms;* Prothonotary Warbler. Yellow; rump cinefrous; vent white; wings and tail varied with cinefrous.
MOTACILLA.

cinereous and blackish. Found in Louisiana. The legs of this species are black.

Semiornata; Half-collared Warbler. Beneath pale-

aft; crown yellowish-olive; behind the eyes a cinereous

streak; wing-coverts and quill-feathers brown; tail-feathers

cinereous, pointed, the lateral ones white on the inner webs.

This is found in Louisiana.

Fulva; Orange-bellied Warbler. Olive-brown, beneath

yellow; quill and tail-feathers brown, edged with yellow,

the primary edged with pale grey. Inhabits also Louis-

iana.

Fusc a; Olive-brown Warbler. Olive-brown; varied

with whitish and grey; limbs brown; two outmost tail-

feathers within near the tip white. Inhabits Louisiana.

Pinguin; Grassiet Warbler. Grey-olive, a little spotted

with black; throat mixed reddish and ash; breast and belly

white; spot on the head and rump yellow; quill and tail-

feathers edged with grey. Inhabits Louisiana.

Cana; Grey-throated Warbler. Cinereous; quill-fea-

ters edged with whitish; tail-feathers black, the outmost

nearly white. Found in Louisiana.

Coronata; Gold-crowned Warbler. Spotted with

black; cap, flanks, and rump yellow. Found in Pennsyl-

vania only a few days in the spring.

Eisenostomus; Senegal Warbler. Brown; quill-fea-

ters rufous on the outer webs; tail-feathers black tipped

with white. Inhabits Senegal. Middle tail-feathers nearly

black.

Leucocela. Black, beneath white; crown whitish;

feathers of the cheeks and chin black bordered with whitish;

rump white; wing-coverts, quill and middle tail-feathers

blackish-brown, the lateral ones white with dusky tips. It

inhabits rocky precipices near the Wolga; feeds on worms

and wags its tail; lays ten eggs under stones, or in the

chinks of rocks.

Hirundinacea; Swallow Warbler. Black with a
gloss of steel-blue; throat, breast, and vent cinflow; belly

white with a longitudinal black band. Found in New

Holland.

Erythrogaster; Cheinut-bellied Warbler. Black be-

neath, belly, rump and tail cheinut; cap pale ash; quill-

feathers with a white spot; bracelets black. Is found in

the winter in the gravelly hollows of the Caucasan tor-

rents, and migrates southwards in the autumn. This is a

very restless bird, continually wagging its tail, and is about

seven inches long.

Maura; Moor Warbler. Dusky black, beneath white,
rump and sides of the neck white; throat bright ferrug-

inous; wings with an oblique yellowish-whitish blotch;
tail-feathers black, the lateral ones from the base half white.
A variety of this species is above rufous brown, beneath

rufous white. It inhabits Siberia.

Superciliosa; Yellow-browed Warbler. Above green-

ish, beneath pale; crown with a pale streak; eye-brows

yellow. It inhabits Russia.

Ferruginea; Gilt-throat Warbler. Above cinereous,
beneath whitish; neck ferruginous. Found also in Russia.

Canuca; Blue-tailed Warbler. Above yellow-ash,
beneath yellowish-white; throat and eye-brows yellow-

ish-white; rump bluish; vent white; tail-feathers bluish-

brown, the outer webs pale blue. It inhabits Siberia.

Aurorea; Daurian Warbler. Beneath tawny; crown

and neck above hoary; front whitish, throat dusky black;

back and wings black; the latter with a triangular spot;
tail-feathers tawny; the two middle ones black. Is found

in many parts of Siberia as far as China.

Striata; Black-poll Warbler. Streaked with black;

above cinereous, beneath white; crown black; cheeks

snow-white. Found at New York.

Incana; Grey-poll Warbler. Head, sides of the neck,

and upper tail-coverts grey; quill and tail-feathers black,
edged with grey; throat orange; chin and breast yellow;

belly whitish-ash. Found at New York.

Flaviphns; Yellow-fronted Warbler. Blueish-grey,
beneath white; crown, front, greater wing-coverts, and

tip of the lesser ones yellow; ocular band black, edged

with white; chin and throat black. Inhabits Pennsylvania.

Blackburnia. This is a New York bird. Crown

black, with a yellow line in the middle; ocular band and

lesser wing-coverts black; greater, vent, and lateral tail-

feathers white; the middle ones dusky-black; sides of the

neck, chin, and middle of the belly yellow.

Mitrata; Mitred Warbler. Olive, beneath and front

yellow; hind head and collar black. A variety of this

species is body above greenish-grey. Inhabits North

America. The bill is black, and the legs brown.

Cucullata; Hooded Warbler. Greenish, beneath

yellow; throat and cheeks black; tail wedged. Supposed
to be another variety of the Mitrata.

Littorea; Shore Warbler. Above dusky-grey, be-

neath pale ochre; quill and tail-feathers blackish. Found

upon the shores of the Caspian sea, and feeds on worms.

Longirostris; Long-billed Warbler. Cinereous, be-

neath dusky-black; bill long. Inhabits the mountains near

the Caspian sea.

Ochroura. Head cinereous; neck above and fore part

of the back dusky-black; throat and breast shining black;
belly yellow. Inhabits among the mountains of Persia.

Obscuro; Obscur Warbler. Upper feathers of the

body cinereous at the base, bay in the middle, and blackish

at the tips; beneath cinereous; quill and tail-feathers, the

outer edges bay. Found among the Persian Alps.

Susamica; Persian Warbler. Reddish-ash; chin and

throat black; breast and belly pale rufous; the feathers tipt

with white; vent snow; middle tail-feathers brown, lateral

ones tawny. Inhabits rocky mountains of Persia.

Murina; Murine Warbler. Mouse colour; head,

neck, and tail black; ocular streak, belly, and edge of the

outmost tail-feathers white. Size of a sparrow. Middle

of the belly black.

Spinicauda; Thorn-tailed Warbler. Cheinut, beneath

white; crown spotted with yellow; face and eye-brows

yellow; wing-coverts russet, varied with brown; the

greater and quill-feathers brown; tail wedged, the feathers

daggered. Found in Terra del Fuego.

Magellanica. Yellow-brown, waved with black, and

tinged with red; beneath yellow-ash, with blackish lines;
throat short, wedged, yellowish-brown, tinged with red, and

streaked with black. This also inhabits Terra del Fuego.

Cithina. Yellow, above streaked with black; cheeks,

throat, and breast white; tail tipt with yellow. Inhabits

New Zealand.

Aurata; Gilt-headed Warbler. Yellow; upper part

of the head and rump orange; throat deep blue; wings and
tail brown. This is an Indian species.

Longipes; Long-legged Warbler. Pale green, beneath

cinereous; beneath the eyes a white arch; front, temples,

cheeks and sides of the neck cinereous; vent greenish.

Inhabits New Zealand. Bill black; irides bluish-ash, and

leg grey-colour.

Munia; Lead Warbler. Not more than three inches

long; pale brown, beneath whitish; bill and very short tail

yellowish. Inhabits New Holland.

Varia;
MOTACILLA.

VARIA; White-pollled Warbler. Spotted with black and white; wings with two white bars. Found in several of the West Indian islands, particularly St. Domingo and Jamaica; and in the summer, in Pennsylvania, New York, and other parts of the American continent.

CAPENSIS; Cape Warbler. Brown, beneath whitish; pectoral band brown; eye-brows white; lateral tail-feathers obliquely white. Inhabits, as its name denotes, the Cape of Good Hope.

ICTEROCEPHALA; Quebec Warbler. Black, beneath whitish; cap pale yellow; ocular band black; wings with two yellow bars. Inhabits divers parts of North America.

DOMINICA. Notwithstanding its specific name, it takes the trivial name of Jamaica warbler, being common to that and to the island of Dominica. Cinnamon, beneath white; before the eyes a pale yellow spot, behind them a white, and beneath them a black one.

CINCTA; Belted Warbler. Pale-ah, beneath white; crown and band on the belly pale yellow; breast spotted with brown. Inhabits Canada.

MADAGASCARIENSIIS; White-eyed Warbler. Greenish, beneath whitish; chin and vent yellow; eye-lids white. Found in the isles of France and Madagascar.

BORBOICA. This is common to the islands of Bourbon and Madagascar. Grey-brown, beneath dull yellowish-grey; quill and tail-feathers brown, edged with a much lighter brown.

MAURITIANA; Maurice Warbler. Blue-grey, beneath white; quill and tail-feathers black, edged with white. Inhabits the isle of France. Bill blackish; legs blueish.

LIVIDA; Madagascar Warbler. Blue-grey; vent white; bill and legs lead-colour; quill-feathers blackish, edged with white; tail-feathers black, the two outmost white. Found in Madagascar, as its trivial name imports.

FLAVESCENS; Citron-bellied Warbler. Brown, beneath yellowish; temples whitish; equal tail and quill-feathers edged with rufous brown. Found in Senegal. Bill and legs dusky.

RUFICAGRA; Rufous-bellied Warbler. Olive brown, beneath yellowish-rufous; quill and tail-feathers brown. This, like the last, is an inhabitant of Senegal, and has been thought to be a variety of the Flavescens.

UNDATA. Black, the feathers edged with rufous; beneath white; rump rufous; tail wedged; quill and tail-feathers brown, edged with rufous white. It inhabits Senegal.

FUCATA; Dusky Warbler. Brown, beneath grey; tail long, equal. Inhabits Senegal; is six inches long; the bill is black, and legs yellow.

SUBPLAVA; Flaxen Warbler. Rufous-brown, beneath grey; rump pale; sides of the body pale rufous; tail wedged. Inhabits Senegal.

AUROCAPILLA; Golden-crowned Warbler. Olive, beneath white; crown golden; eye-brows, black; breast spotted with black. This is reckoned a North American species, but in winter it migrates southerly; eggs white, spotted with brown.

PETECHIA; Red-headed Warbler. Olive, beneath yellow, dotted with red; cap red. Found in Pennsylvania.

ALBICOLLIS; St. Domingo Warbler. Olive, beneath yellowish; throat and breast dull pale ochre, streaked with red; quill and tail-feathers brown, edged with greenish-yellow, lateral ones within yellowish. In this species, found in St. Domingo, the bill is of a horn colour; temples yellowish; legs grey-brown. In the female, the neck above is of a greenish-ah.

LUDOVICIANA; Louisiana Warbler. Olive; throat and breast yellow, spotted with red; belly pale ochre; two bands on the wings, and two outmost tail-feathers within, near the tip white. This inhabits Louisiana and St. Domingo.

CHLOROLEUCA; Green and White Warbler. Olive, beneath pale ochre; head cinnereous, varied with olive; greater wing-coverts and tail-feathers brown, edged with yellowish-green. Inhabits St. Domingo. Bill horn-colour; tail slightly forked, the lateral feathers varied with yellow: legs grey-brown.

AMERCOLLIS; Orange-throated Warbler. Olive, beneath orange; belly yellowish; vent whitish; greater wing-coverts and middle tail-feathers cinnereous, the lateral ones within white, without at the tip black. It inhabits Canada.

MACULOSA; Yellow-rumped Warbler. Olive, spotted with black; head and quill-feathers cinnereous; belly, vent, and two bands on the wings white; rump yellow; breast yellow, spotted with black. Inhabits Pennsylvania.

Fuscated; Brown-throated Warbler. Brownish, beneath varied with blackish and rufous-grey; bill, chin, and ocular band brown. Found in Jamaica.

TIGRINA; Spotted Yellow Warbler. Brown, the feathers edged with olive; beneath and rump yellow; lower part of the belly yellowish-white; behind the eyes a rufous blotch; quill and tail-feathers edged with olive. There is a variety of this species, which is characterized as of paler colour, beneath whitish; breast spotted with brown; wing-coverts without white. The first of these inhabits Canada, and the second St. Domingo.

PINUS; Pine Warbler. Olive, beneath yellow; lore black; wings blue, with two white bands. This species inhabits Carolina in the summer months. The female is wholly brown.

IRENS; Green Warbler. Green-olive, beneath white; cheeks, sides of the neck, and breast yellow; neck beneath white; wings with two white bands. It is found in Pennsylvania.

DEMETERUM; White-breasted Warbler. Ashy-brown; head blueish; chin and breast white. Inhabits Germany, and Russia.

NIGROSTRIIS; Black-jawed Warbler. Olive-brown; lores and chin rufous-yellow; breast rufous, spotted with blackish; belly white; wing-coverts tipt with reddish-white; quill-feathers edged with yellowish; tail-feathers pointed, the outmost white.

LUTESCENS; Buff-faced Warbler. Rusty-brown, beneath reddish-white; front and chin buff; ears with a red spot; breast spotted with black. This is about six inches in length; the bill is of a dusky black, and the legs brownish.

BOREALIS; Rusty-headed Warbler. Green, beneath yellow; chin and temples ferrugineous; tail rounded; the lateral feathers tipt with white. Found in Kamtschatka, as is also the next, from whence it takes its specific and trivial names.

KAMTSCHATKENSIS. Brown, beneath paler; middle of the belly white; front, cheeks, and chin pale ferrugineous. The bill is long and flender.

AWATCHA. This also inhabits Kamtschatka. Brown; chin and breast white, spotted with black; middle of the belly and lores white; primary quill-feathers edged with white; tail-feathers orange at the base.

CANESCENS; Van Diemen's Warbler. Hoary brown, beneath white; head black; front streaked with white; breast and vent streaked with black; spot on the wings and edge
edge of the tail-feathers at the base tawny. Inhabits New Holland.

*Nigrillosis;* Black-necked Warbler. Sub-crested; above pale grey, beneath flesh-colour; cap, neck above, quill and tail-feathers black. Inhabits India. Its bill and legs are yellow.

*Plumbia;* Lead colour; beneath cinereous; quill and tail-feathers dusky. This is a very small bird.

*Caniarissimus;* Cambay Warbler. Black-brown, beneath fine black; top of the belly and vent rufous; wing-coverts white. Found in India.

*Guurata;* Guurat Warbler. Greenish, beneath white; crown chestnut; quill-feathers and tail brown. Inhabits India. Bill and legs brown; quill and tail-feathers edged with green.

*Asiatica;* Asiatic Warbler. Brown, beneath yellowish; head and neck black; lores and chin white; tail long. A variety of this species is brown; front, eye-brows, and body beneath white; lateral tail-feathers half white. This is of the size of the nightingale, and inhabits Guurata. The bill is blackish, with a few small bristles at the base.

*Caprata;* Luzonian Warbler. Black; rump, vent, and spot on the wing-coverts white. It takes its trivial name from Luzonia, where it is found. The bill is blackish; legs brown. Female without the spot on the wings. A variety is thus described: head, neck, and body above black; beneath white-rufous; wings with a white band. Inhabits China. Bill and legs red.

*Phoenicus;* Red-flart. Of this there are three varieties: 1. Throat black; belly and tail rufous; head and back hoary; white front. 2. Breast spotted with rufous. 3. Body cinereous.

This species makes its appearance in spring, along with the other summer birds. It commonly alights upon old towers and uninhabited houses, choosing always the highest and most inaccessible pinnacles. It is found, too, in the most impenetrable recesses of dark woods, where it indiges, undisputed, its solitary habits, and utters its plaintive notes.

The red-flart nests in the holes of those old walls which it frequents, or in the hollow of a rotten tree, and sometimes in the cliff of a rock. The young ones are excluded in the month of May; they are five or six in number. While the female is employed in hatching and rearing them, the male is commonly flaited, as a sentinel, upon a point of the rock, or upon the top of the wall, whence he utters his unimpaired song; a pledge to the mother, that no danger is approaching her family. It is only when taken young, that the red-flart will acquire any familiarity with man; for, though this bird be frequently a near neighbour of the human race, he still prefers his native wildness and timidity. He acquires neither the confidence and intimacy that distinguishes the red-breast, the gaiety of the lark, nor the vivacity of the nightingale. His disposition is melancholy, and his manners wild. If taken when old, he refutes all food, preferring death to captivity; or if he forswears his freedom, his obstinate silence and fallen grief plainly indicate how deeply he is penetrated with the misery of his condition.

*Tityra;* Quill-feathers blackish; tail-feathers rufous, the two middle ones black, with a pale rufous web. It inhabits Italy.

*Gibaltarissimus;* Grey Red-flart. Hoary; front, temple, and chin black; hind-head and lower part of the belly white; rump and tail orange; two middle tail-feathers brown. Inhabits Gibraltar.

*Erythracus;* Red-tail Warbler. Back and quill-feathers cinereous; belly and tail-feathers rufous. Inhabits Europe; is something less than the red-flart; feeds on worms, and wags its tail: its eggs are white, varied with grey. The male has a spot of horn-like mark on the throat, and spot between the bill and eyes brown.

*Guianensis;* Guiana Red-tail. Grey, beneath white; wings and long tail rufous. Inhabits Guiana. The bill of this species is pale, and the legs flesh-colour.

*Attrata;* Black Red-tail. Black; crown plumbous; quill-feathers black, the secondaries white on the outer edge; tail-feathers rufous, the two middle ones dusky-black. The feathers of the back edged with dark brown.

*Gulia;* Guila Warbler. Green, beneath pale yellow; cheeks and chin black, surrounded with a pale yellow line. It inhabits Brazil, and is the size of a goldfinch.

*Sulcia;* Blue-throated Warbler. Breast ferruginous, with a blue band; tail-feathers brown, towards the tip ferruginous. A variety of this has a flivery spot on its breast. It inhabits Europe and Siberia; sings very sweetly, and does not migrate. The female has a white chin, with a broad blue band, and another black one terminated by black.

*Sialis;* Blue Warbler. Above blue, beneath red, belly white. Inhabits North America; migrates. The female has its secondary quill-feathers tint with white.

*Fulicata;* Sooty Warbler. Violet-black; vent chestnut; wing-coverts with a white spot. Inhabits the Philippine isles. Bill and legs brown.

*Canaya;* Cayenne Warbler. Blue; frontlet, cheeks, wings, and tail black. There are two varieties: 1. Head blue; chin black. 2. Head entirely blue. They all are found in Guiana.

*Cyanocephala;* Blue-headed Warbler. Green; head and upper wing-coverts blue; chin hoary; quill-feathers brown, edged with green. Found in Cayenne. Its bill is brown and legs grey.

*Lineata;* Blue-striped Warbler. Beneath and spot on the crown blue; front, three over the eyes, and sides of the neck of a shining blue; band on the breast and belly white. This is a Cayenne species.

*Cyanea;* Superb Warbler. Black-blue, beneath white; feathers of the head long, lax, turgid; front, checks, and lunule on the neck of a fine blue. A variety is described as blackish-grey; head, chin, and neck above blue; wing-coverts brown; quill and tail-feathers black. The first is found in New Holland; the second in Manilla. The female is somewhat different, being brown above, white beneath, and blue round the eyes.

*Vella;* Red-bellied Warbler. Of this species there are four varieties: 1. Blue; belly and rump tawny. 2. Front and rump golden; body beneath blue. 3. Lower part of the back and belly rufous. 4. Back blackish-brown; breast and belly scarlet. Inhabits Guiana, Surinam, and Cayenne.

*Canadensis;* Black-throated Warbler. Above blue, beneath white; throat, quill and tail-feathers black. Is found, in the summer months, in Pennsylvania.

*Carolus;* Carolian Warbler. Above blue, beneath white; wings and tail black. A variety of this species has its head black; quill and middle tail-feathers black, the rest white. It inhabits Pennsylvania; builds a cylindrical nest open at the top, and placed in the forked branches of a tree.
Cyanis. This species is of a fine blue, beneath it is snowy; from the bill to the wings there is a streak of black.

Arundinacea; Reed Wren. Above olive-brown, beneath whitish; lores and orbits whitish-brown; band in the middle of the wings beneath tawny-yellow; tail brown, slightly wedged. This species is found in the rocky places in England; is seven and a half inches long; builds its nest near the ground, with three or four reeds for its supports; and lays four whitish eggs, spotted with olive.

Sibilis; Sybil Warbler. Blackish, beneath white; breast rufous; wings with a white spot. Inhabits Madagascar, and flies very finely.

Sperata; Greenish-brown; beneath and rump rufous-grey; two middle tail-feathers blackish, lateral ones obliquely half tawny-brown. A variety has the chin white, and breast rufous. Inhabits the Cape of Good Hope.

Rubecola; Robin-red-breast. Grey; throat and breast ferruginous. The little birds of this name, on account of their near approaches to our dwellings, and their familiarity with man, are, perhaps, the best known of all the feathered race, except such as are kept in domestication. They are capable of enduring the most severe winters in this island; but, at the approach of such inclement feasons, they leave the woods, where they reside in summer, and are willing to acknowledge a kind of dependence upon man. It is remarkable, that a bird which remains in North Britain all the year round should migrate from France during the winter months. Such, however, is the case: in France the red-breast frequents the hedges and dwelling-houses, for a short time, in autumn and spring; but regularly, in the dead of winter, when the hard frost commences, disappears. In his spring visit he makes but a short stay, hastening, as he then is, to enter the forest, that he may there, amidst the spreading leaves, enjoy solitude and love.

The red-breast builds its nest at the foot of some thick shrub, or upon a tuft of grass, able to support it. The materials of which it is composed are oak-leaves, moss, and a bed of feathers within. Sometimes, after the edifice is finished, the bird covers it entirely over with leaves, allowing only a small passage to remain sufficient to admit its body. During the season of nelling and incubation, the male makes the grove resound with his soft and melodious lays. His warbling is soothing and tender, animated occasionally with notes of a louder tone, and sometimes, too, graced with those touching and engaging accents, that seem to express the ardour of his love. In the sweet society of his female, he seems to be wholly absorbed: at the interference of other company, he becomes fretful and enraged; for no stranger is permitted to intermeddle with his joy; even those of his own species he pursues with rage, till he banishes them from the district he has chosen for himself. His love exhibits a strange mixture of jealousy and attachment.

There is no bird more active, none satisfied with a smaller portion of rest, than this bird: he is the first that appears in the woods at the break of day, and the last that retires thither in the evening to enjoy repose. There are two varieties. 1. Chin white; wing-coverts varied with white, black, and rufous; quill and tail feathers black, edged with rufous. 2. Entirely white. The Rubecola species is spread over the whole of Europe, from Norway and Sweden to the Mediterranean.

Troglodytes; Wren. Grey; eye-brows white; wings waved with black and cinerous. Inhabits Europe and Asia. The ancients gave this bird the name of troglodyte, from a fancied resemblance between its manners and those of a race of men who were said to inhabit dens and caves of the earth. There is some difference among naturalists in classifying and distinguishing the tribe of wrens; a circumstance that might be expected in subjects so minute, and so slightly differentiated by nature. The common wren is known from its habitat. It frequents farm-houses and country villages, where it is seen hopping about, full of life and vivacity, even in the midst of winter, expressing, towards evening, its happiness in cheerful and well-toned notes. It appears upon the top of heaps of fire-wood, or by the sides of old walls, whence it disappears in a moment, by making its way into some small hole. It remains not, however, long concealed; but returns to make quick and inconstant movements with its little tail, always raised in an almost perpendicular direction.

The flights of the wrens are very short and expeditious. When flying, it moves its wings with such rapidity, that they become invisible. Its length is about three inches and a half, and its breadth, when the wings are extended, five. The whole plumage is transferrably barred with undulating lines of brown and black; on the belly and lower parts it inclines to grey.

This bird, slender as it is in form, is almost the only one that remains with us during the most severe winter; and it is the only one of the whole feathered creation which continues its warbling in a season in which the universal silence of the woods and groves is interrupted only by the croaking of ravens. During a fall of snow it is still better heard; for then it enters the courts-yards, the door of the stable, or dairy, seeking, among the garbage, for the dead bodies of insects, or their larvæ.

Platensis. Above varied with rufous and black, beneath white; quill and tail feathers barred. Inhabits Buenos Ayres.

Ludovisianna. Rufous-brown; eye-brows, cheeks, and body beneath whitish; quill and tail feathers barred with black and rufous. In this species there is over the eyes a band reaching to the sides of the neck; the cheeks are waved with brown.

Fulva; Brown Wren. Brown, beneath paler; back, wings and tail with blackish bars. Inhabits Surinam. It sings well; the bill and legs are of a yellowish-brown.

Calendula; Ruby-crowned Wren. Greenish-yellow; crown with a ruby line; belly and wings beneath whitish. It inhabits North America. The female is without the ruby vertical line, and varies in having a scarlet tincture on the nape.

Rugulosa; Golden-crowned Wren. Greenish; secondary quill-feathers yellow on the outer edge, and white in the middle; crown orange; bill black; crest orange, (of the female yellow,) each side edged with black; body yellowish-green above, reddish-white beneath; wing-coverts dark-brown, with two transverse white bars; legs yellow. Inhabit every quarter of the globe. This is the smallest British bird, its weight seldom exceeding eighty grains, and its length three inches and three quarters. It migrates from the Shetland islands in winter, but continues in the Orkneys the whole year. Its song is like that of the common wren, but its voice is weaker. It builds a nest nearly of a round form, with a hole in the side, and lays from six to eight eggs. It creets or depresses the creet at pleasure. Though not uncommon, it often escapes observation from the smallness of its size. It is also known by the name of Wren, and is frequently destroyed during the time of incubation; and the nest, with the eggs, left to decay.

Leata; Crested, greenish, beneath whitish; hinder-
head and vent pale yellow; wing-coverts at the edge, and lateral tail feathers at the tip, white. Inhabits Cayenne.

_Trochilus_; Yellow Wren. Dusky green above, yellowish-white beneath; wings and tail brown, and edged with green; eye-brows yellow. Four inches and a half long. Inhabits Europe and America. Frequents wooded and enclosed situations, especially where willows abound. Visits us early in April, and soon begins its usual song, which is short, with little variety. Makes an oval nest, with a small opening near the top, composed of moss and dried grass, and lined with feathers, either in the hollow of a ditch, or in a low bush, close to the ground. The eggs are six or seven, white, and spotted with light rufous. Has often been confounded with the lesser-petit-chat, and the wood-wren.

*Sylvicola_; Wood-wren. Greenish, beneath yellowish; eye-brows yellow; belly and vent gray. Is found in many parts of Europe, and in this country, particularly in the oak-woods of Carmarthen. It builds on the ground a roundish nest, with the entrance near the top; eggs white, sprinkled with ferruginous spots.

_Aestiva_; Yellow-paled Warbler. Olive-green, beneath yellow, and breast with reddish spots; lateral tail-feathers within yellow. A variety has its body above brown. It inhabits Guiana, but in the summer migrates to Canada. Bill and legs black; irides blue.

_Carolinensis_; Carolina Yellow-poll. Olive-green, beneath yellowish; quill and tail-feathers brown, the latter ones edged with yellow. Found in Hudson's Bay.

_Sutoria_; Taylor warbler, or Taylorbird. Entirely yellow, and very small, scarcely exceeding three inches in length. Inhabits India. Its nest is composed of two leaves, the one generally dead, which it fixes at the end of some branch, to the side of a living one, by fewing both together with some kind of gum. (Its bill, serving as a needle,) in the manner of a pouch or purse, and open at the top. Sometimes, instead of a dead and a living leaf, two living ones are sewed together, and, when thus connected, seem rather the work of human art than of an uninstructed animal. After the operation of sewing is finished, the cavity is lined with feathers, and soft vegetable down. The nest and birds are together so very light, that the leaves of the exterior and more slender twigs of the trees are chosen for the purpose; and, thus situated, the brood is completely secured from the depredations of every invader.

_Cappa_; Caffrarian Warbler. Olive; chin and tail ferruginous; eye-brows white. Is found at the Cape of Good Hope.

_Gularis_; Above ferruginous, beneath white; crown and rump cinnereous; area of the wings and lateral tail-feathers yellow, tipt with brown, the middle ones entirely brown.

_Flavicula_; Yellow-tailed Warbler. Olive, beneath white; crown and rump cinnamon; area of the wings and lateral tail-feathers yellow, tipt with brown, the middle ones entirely brown. Inhabits America, and migrates.

_Tsiecantchilla_; Above blackish, beneath ferruginous; head dark brown; nape whitish; collar and oblong spot on the wings white; back black. Inhabits Siberia.

_Melanops_; Bluish-ash, beneath yellow; lores and throat black; eye-brows and three lateral tail-feathers each side white; the outermost black on the exterior edge. There is in this species a white line from the gape through the neck; and the tail is even.

_Hudsonica_; Ruby-brown, beneath whitish; neck beneath with dusky stripes; outer tail-feather white, second white edged with black, third white on the disc. It is about six inches long, and inhabits Hudson's Bay.

**Borhula**; Grey Wagtail. Cinnamon, yellow beneath; first tail-feathers entirely, second, on the inner side, white; bill and legs brown; chin and throat black; wing-coverts brown, and edged with ash; quill-feathers brown, the secondaries white at the base; middle tail-feathers black, and edged with green. This elegant species inhabits Europe, visits us about the latter end of September, and departs in April. It is much in motion, continually floats the tail, fells perches, frequents waters, makes its nest on the ground, and sometimes on the banks of rivulets, and lays from six to eight eggs, of a dirty white, marked with yellow spots.

There is a variety; olive-brown, beneath yellow; lower part of the neck grey, first tail-feathers entirely, second and third on the inner side and tip white. This species is found in Java, and is seven inches long.

_Motia_, in Geography, a river of Sweden, in East Gotland, which runs from the Wetter lake to the Baltic; 22 miles E. of Nordköping.

_Motia ali lazites_. See MotiZaltites.

_Motio_ Acomolo, in Geography, a town on the W. coast of Madagascar; 18 miles S.E. from Cape St. André.

_Motching_, a town of Corea; 18 miles S.W. of Yang-tchen.

_Motchiama_, an island of Africa, in the kingdom of Angola, formed by the river Cuanza; about four or five miles long, and one broad, producing variety of roots and herbs, and breeding plenty of cattle. On this island were formerly settled five or six Portuguese families, who carried on a considerable trade in slaves.

_Motcho_, a town of Corea; 30 miles W. of Leng-Kouang.

_Mote_, a town of the county of Tyrol; 9 miles S. of Tyrol.

_Mote_, Motia is often in our ancient customs, for a meeting, court, or plea.

Of motes, by the Saxons also called gemotes, considered in the sense of assemblies, or courts, there were divers kinds; as coteragemotes, follegemotes, foliagemotes, hunded gemotes, hargemotes, scaldgemotes, &c. See each under its proper article.

_Mote_, Motia, was also used for a fortres or castle; as mota de Windsor, &c.

_Mote_ also denoted a standing water to keep fish in; and sometimes a large ditch encompassing a castle, or dwelling-house.

_Motea_ Cazez, in Geography, a town of Hindooistan, in Guzerat; 45 miles S. of Jugapur.

_Motentio_, Style. See Style.

_Motentius_ is defined by Tinctor in his "Diffinitum Terminorum Mulieres,"—"Cantus mediocri cui verba cujusuis materiae fecit frequentissimae divinis supplicantur." 

_Mottel_, in old _Musical Writers_, terms of the same import as Motetta; perhaps it was the diminutive of moteta.

_Moterana_, in Geography, a town of Naples, in the province of Otranto; 9 miles S.W. of Lecce.

_Mottet_, Fr., Moteto. Ital. formerly signified a fluided composition, enriched with all the beauties of the art; such were the motets of Baldi, regarded at the end of the 17th and beginning of the 18th century, at which time they were in the highest favour in all concerts where there was good singing. See Bassart.

At present the name of motet is given to every composition set to Latin words; such as hymns, psalms, or any small portion of scripture in the Romish church. As mot, in French, implies a phrase, or short sentence, so motet implies a verse.
a verse or short period taken from the sacred writings, as the text of what we should call an anthem, and the Germans a sacred cantata. Though a cantata in Italy and elsewhere, generally implies a vocal composition for a single voice, yet there are motets and cantatas in the service of the Romish church, from one to eight parts. As the verse or sentence is usually short, the more frequent repetition of the words is objected to in the construction of motets. (See Cantata.) In the Lutheran church, what the Roman Catholics call motets, and the church of England anthems, are called cantatas.

MOTH, in Zoology, an insect of the winged kind, which is very destructive to different sorts of crops of the garden kind, and other descriptions. See Papilio and Philaena.

Moth, Fuste, an insect which proceeds from a small caterpillar, the body of which is smooth and whitish. It has sixteen legs, does not lodge in the grains of corn, but contrives to fasten several of them together with a web which it spins, and with which it makes itself a dwelling-place. The sheath in which the caterpillar of the false moth usually abides, is generally in the middle of the little heap of grains which it has collected for its food, and which distinguishes it from the caterpillar of the true moth; it can quit this sheath at any time, to eat the grains around it, one after another. It generally attacks several grains at once, and always without order, eating sometimes of one and sometimes of another; so that several are gnawed, when not one is wholly consumed. When these insects are very numerous in a granary, all the grains upon the surface of the corn are linked together by a web, so as to form a crust, which is sometimes three inches thick. This caterpillar turns into chrysalids, or aurelia, in a grain which it has hollowed, or in the sheath of its web, and inflates thence in the month of June, in the form of a butterfly. When a heap of corn is fired, in which there are many caterpillars of the species of this false moth, those insects crawl up the walls; but they soon return to the heap, and by the next day, cover it all over with a new web. In the flate of moth it is grey, has six legs, and they are frequently seen in vast numbers, fluttering about the eaves of the windows of granaries, in the spring and summer, when the weather is very hot. The females lay their eggs upon the heap of wheat, and these eggs produce the caterpillars, or corn-worms, as some call them, which feed on the grain, and envelope it with their filthy web, so as to form over the whole surface a crust that is sometimes three or four inches thick. This entirely spoils the corn within that depth, besides communicating a bad smell to the loft. These worms, or rather caterpillars, for they have sixteen legs, are smooth, whitish, and seldom exceed a quarter, or, at most, a third part of an inch, when at their full growth. Breaking of their webs avails but little, for they are woven again by the next day: for which reason some have been of opinion that it is best to let them enjoy undisturbed the surface of the corn of which they have taken possession. But it should be considered, that three inches are a sixth part, and four inches upwards of a fifth, of any quantity of corn spread eighteen inches deep, which is the medium thickness at which it is laid; and that, independent of the bad smell with which the loft is tainted, this is a very considerable object, though it extend no farther. When this crust is broken, most of the grains which compose it are found either to be gnawed in their inside, or full of live worms, or of aurelia, according to the season; or the empty shells of the caterpillars, if the aurelia have been transformed into moths, are only seen.

Some have asserted that drawing the corn with power-dered lime, so as to form a sort of crust over it, will preserve it from the ravages of these insects: but from an idea that the surface would be spoiled, M. Dulamé did not try this expedient. From various observations and reflections, he was led to suspect that this insect, as it delights in none but very warm places, would not be able to live in the cold air of his ventilating granaries. After collecting the various wormy coats and webs formed by these insects, with their ova, he put them into one of his granaries, which contained seventy-five cubic feet, and was ventilated from time to time during all the winter. Towards the end of May, when the vents of the top of the granary were opened, a prodigious number of moths flew out, which showed that they did not like their situation. On being flung, and remaining in this state some time, afterwards, when emptied, all the moths and worms were dead, and there remained only a thin crust, not above the twelfth part of an inch thick, on the top of the corn, which had so far lost the bad smell it had when put into the granary, that it sold for the current market-price. But not satisfied with this method, he tried the effect of the flame upon another parcel of wheat known to be full of these worms. A heat from 45 to 50 degrees of Reaumur's thermometer (from 115° to 124° of Fahrenheit's) killed them all. This corn was then laid up in a common granary, where it remained two years without being attacked by any of these moths, and even in the third but very few of them appeared. It is therefore concluded that by either of these methods, this insect may be destroyed without injuring the grain in any great degree.

Moth, Field, Tinea campesiris, in Natural History, the name given by M. de Reaumur to a species of insect, which in all respects resembles the moth so destructive of clothes except in its food; as that feeds upon woolen, and makes its nest or covering of that substance; this eats the leaves of trees, and in the same manner makes itself a covering from the fibres and integuments of them.

Their changes are the same with those of the common moth, and performed in the same manner; they only seem to differ in having a more moist food.

M. Reaumur first observed thefe on the leaves of the alfalfa.

This creature for a great part of its life wants no covering, but, like the aphides, making its way through the upper integument of the leaf, it feeds on the parenchyma and juices; at length, when it has eaten away all the substance of the leaf, it bites out a piece from each integument of it, over and under its body, and festoons the edges all round with threads of its own spinning; thus making a complete case or covering, enabling it to bear the open air. This done, it marches from its place to find another leaf to supply it with more nourishment: thus it changes place several times during its life, and as often changes its covering, which requires but a very little time to make anew.

These are small animals of this genus; but there are others which are considerably larger, and which make their coverings of various matters and of different structure; they are usually very rough and rugged, and seem made of any matter that happens to be in the way; some species usually make them of pieces of flint, and particles of chaff, others of small twigs of bushes, others of the dry leaves of the oak, broom, and other plants.

All these animals might have been described as the dependents on the beetle and fly kinds; but as they have this remarkable quality of feeding in the same manner, and making themselves cases of different materials in the manner of the times, or clothes moth, while in the worm-state, and in this state they are much more obvious to the eye than the flies, beetles,
beetles, &c. produced of them, many of which are so small as to escape observation; this accurate author has chosen to describe them together, and in this their imperfect state. He adds an account of another set of animals somewhat allied to them, which he therefore calls the pseudo tima, or false moth. See Pseu-do-tima, and the preceding article.

Moth Mullein. See MULLEIN.

Moth other, that sort of moth which is so injurious to the hop plant. See Hop and Other-Moth.

MÔTHE-I-ÉVAY, FRANÇOIS DELA., in Biography, a learned French writer, born at Paris in 1585, was brought up to the profession of the law, and long occupied the post of substitute to the procureur-general in the parliament of Paris, which he inherited from his father. He was, probably, never pleased with his profession, and at length his attachment to letters induced him to quit the occupation, and he became one of the most considerable scholars of his time. In 1639 he was, on account of his works, admitted a member of the French academy, and appointed to the office of preceptor to the duke of Anjou, afterwards duke of Orleans; historiographer of France, and titular counsellor of state. He was supposed to have a strong disposition to scepticism, and bore with calmness the imputations to which his opinions exposed him: once, when walking in the gallery of the Louvre, he overheard a person whisper to his friend, "there goes a man without religion;" to which he replied, "I have religion enough, friend, to pardon your infidelity." He died in 1672, at the age of eighty-five. He is mentioned by Guy Patin as a Stoic, who would neither praise nor blame, and who followed his own fancies and caprices without regard to the opinions of the world. His draps and usual demeanour so distinguished him from other men, that he was taken, by strangers, to be an alchemist. In the court he lived like a philosopher, immersed in books, simple and regular in his manner of living, and void of ambition and avarice. He was a great writer; one of his works was a "Treatise on the Virtue of Pagans," which was answered by Arnaud, Le Mothe's bookeller complaining that his book did not sell. "I know a secret," said the author, "to quicken the sale," he procured an order from government for its suppression, which was the means of selling the whole edition. His works were collected in two volumes folio, and were afterwards printed in fifteen volumes 12mo. This collection does not include his "Dialogue after the Manner of the Ancients," in which he displayed his scepticism at large: nor his "Hexameron Rustique," Moreni.

MOTHER, MATER, a female, who hath borne, and flands in the relation of parent to another.

Thus Eve is called our common mother; Cybele, among the ancients, was the mother of the gods.

MOTHER, Queen, signifies the name with what we otherwise call queen dowager.

We meet with empresses on medals and inscriptions, with the title of mother of the camp, mother of the l-nate, mother of the country; mater femina, mater coelorum, mater patriae, &c.

MOTHER OF GOD, is an attribute commonly given to the blessed Virgin. It had its origin from the Greeks, who first called her Theotokos; in imitation of whom some Latins began to call her Deipara, Dei genitrix. The council of Ephesus first gave a sanction to the appellation; but the fifth of Constantinople decreed, that the Virgin should always be thus called. This gave rise to terrible disputes: Anatolius, a presbyter of Nestorius, patriarch of Constantinople, first affected, in a sermon, that the Virgin was by no means to be called Theotokos; upon which words, a great tumult arising, Nectarius took his presbyter's part, and taught the same doctrine.

MOTHER-Tongue is properly an original language, from which others are formed.

Of mother-tongues, Scaliger reckons ten in Europe; viz., the Greek, Latin, Teutonic or German, Slavonic, Etruscan, Scythian, or European Tartar, Hungarian, Cantabrian, Irish, and British.

MOTHER-Churches, are those which have founded or erected others. See PARISH.

In beneficary matters they say, it is not lawful for a man to enjoy, at the same time, both the mother and the daughter: meaning, that the son-law does not allow an abbey, and the benefices depending thereon, to be held by the same person.

MOTHER, Fits of the. See Hystera.

MOTHER-Water, in Chemistry, a name given to the solution of cryftalline salt, after no more cryftals will form in it without more of the water being evaporated. It will be easy to conceive, that when the cryftallization of a salt has gone on till the abstraction of the water for the salt is equal to the abstraction by which the cryftals are formed, that the procefs will stop. The affinity of cryftallization may be increased, and more cryftals may be formed, either by evaporating an additional quantity of water, or by expoying the mother-water to a lower temperature.

MOTHER of Nitre. See NITRE.

MOTHER-Thu-me, in Botany. See Thyme.

MOTHER-Wort, Cardiaea. See Leonurus.

Mother-wort has been used as an ingredient in some of the compound waters, intended against hysteric complaints; and the country people frequently make an infusion of it in the manner of tea, for the fame purpoze. It is also faid to be good in flatulenties and colics, to give great relief in epileptic fits, and to destroy worms. It promotes urine and the menes; but its power this way is greatly inferior to that of penny-royal.

The name cardiaea, improperly given to this plant, has led many into an opinion of its being a cordial; but experience does not shew any such thing.

MOTHER Of VITRIOL. See VITRIOL.

Mother Carey's chickens, a name given by the English sailors to birds which they suppose to be the forerunners of a storm. See Procellaria gigantea.

MOTHER Banks, in Geography, a bank in the Channel, between the isle of Wight and the coast of Hampshire, with from three to eight fathom water. N. lat. 50° 41'. W. long. 1°.

MOTHER Kilts, a river of the slate of Delaware, in Kent county, which runs into Delaware bay. N. lat. 39° 5'. W. long. 75° 30'.

MOTHER and Daughters, three remarkable hills on the coast of New Britain, in the Pacific ocean, situated W. of Cape Paliher.

MOT'I, a town of Persia, in the province of Segellan; 60 miles N. of Zareng.—Also a town of the island of Sardinia; 27 miles E. S.E. of Saffari. N. lat. 40° 42'. E. long. 9° 20'.

MOTIERS, a town of the Helvetian republic in the principality of Neufchatel, the seat of a court of justice; 13 miles S.W. of Neufchatel.

MOTIKLEI, a gulf of Russia, in the sea of Ochotkoi, between cape Dyuguikoi and the continent, about 40 miles long, and from 12 to 16 broad. N. lat. 59° 20' to 59° 36'. E. long. 147° 34' to 149° 14'.
MOTION, a town of Mexico, in the province of Mexico, situated on the foot of a mountain; 50 miles E.S.E. of Colima.

MOTION, primarily so called, or Local Motion, is a continued and successive change of place; or that state of a body, by which it corresponds successively to several different places; or the passage of the whole substance without separate parts.

Or, motion may be concisely defined as the change of rectilinear distance between two points.

In this sense the doctrine and laws of motion make the subject of mechanics, or statics. One of the ancient philosophers, in addressing a description of motion, is said to have walked across the room, and to have replied, you see it, but what is it I cannot tell you.

The ancient philosophers considered motion in a more general and extensive manner: they defined it, a passage out of one state, into another; and thus made the kinds of motion.

Some of the later schoolmen reduce these kinds of motion to four: the first is general, including any passage from one state to another; under which kind come creation, production, and mutation. The second is a puffsage of something already existing from one state to another; and thus generation is a motion. The third is a successive passage of something already existing from one term to another; and thus alteration and accretion are species of motion. The last is latum, or local motion; and thus walking is motion.

But the latest philosophers deny any other species besides local motion; and reduce all the above mentioned to this one. So that we have here only to do with latum, or local motion; of which the rest are only so many different determinations or effects.

Physical writers, both ancient and modern, have ever been perplexed about the nature and definition of local motion. The Peripatetics define it hy, Actus exitus in potentia, prole in potentia, Arist. 3. Phy. cap. 3. but this notion seems too abstract and metaphysical for our days, and is of no use in explaining the properties of motion.

The Epicureans explain motion by the migration of a body, or a part of a body from one place to another; on which definition the later Epicureans refine, and call it, the migration or passage of a body from space to space; thus substituting the word place, for that of space.

The Cartesians define motion, a passage or removal of one part of matter out of the neighborhood of other parts immediately contiguous to it, into the neighborhood of others which definition agrees, in effect, with that of the Epicureans: all the difference between them consisting in this; that what the one call body and place, the other call matter and contiguous parts.

Herein, and other late writers after him, define motion, more accurately and fully, the successive passage of a body from one place to another, in a determinate time, by becoming successively contiguous to the parts of the intermediate space.

Motion, then, is agreed to be the translation of a body from one place to another; but authors differ much when they come to explain in what this translation consists. And hence their divisions of motion become exceedingly precarious. Aristotel and the Peripatetics, divide all motion into natural and violent: the first is that which has its principle, or moving force, within the moving body. Such is that of a stone falling towards the centre of the earth. The second is that which principle is without, and against which the moving body makes a resistance. Such is that of a stone thrown upwards.

The moderns generally divide motion into absolute and relative. Absolute motion is the change of absolute place, in any moving body; whose celerity, therefore, will be measured by the quantity of absolute space which the moveable body runs through. Relative motion is a motion of the relative or vulgar place of the moving body; and has its celerity estimated by the quantity of relative space run through.

Others divide motion into proper, and improper, or foreign. Proper motion is a removal out of one proper place into another, which thus becomes proper, as being possessed by this body alone, in exclusion of all others. Such is the motion of a wheel in a clock. Improper, extraneous, foreign, or common motion, is the passage of a body out of one common place into another common place. Such is that of a clock when moving in a ship, &c.

The reason of all this diversity seems to arise from the not attending to the different meanings of the words, but confining all in one definition and division; which we should rather have distinguished into several parts.

Some, e.g. in their definitions of motion, consider the moving body, not as it regards the adjacent bodies, but as it regards immovable and infinite space. Others, again, consider the moving body, not as it regards infinite space, but as it regards other bodies very remote.

And others, stillly, consider the moving body, not as it regards remote bodies, but that surface only to which it is contiguous.

But these various meanings being once settled, the dispute is terminated. For, as every thing that moves may be considered in these several manners; there hence arise three several kinds of motions; of these, that which regards the parts of infinite immovable space, without consideration of the circumambient bodies, may be called absolutely and truly proper motion.

That which regards circumambient bodies very remote, which may themselves possibly be removed, we call relatively common motion.

The last, which regards the surfaces of the next contiguous bodies, as much as it may admit both absolute and common motion, we call relatively proper motion.

Motions, Absolutely and truly proper, then, is the application of a body to different parts of infinite and immovable space.

This alone is proper and absolute motion, being always generated and changed by forces impressed on the moving body itself, and by those only; and being to which the real forces of all bodies to put others in motion by impulse are owing, and to which those motions are proportioned.

But this motion we cannot investigate or determine accurately; nor can we distinguish, when two bodies are impressed on each other, in which of the two (e.g. that which appears to move the more swiftly), or the other, which appears to move the more slowly, and perhaps even to be at rest) the real motion, and, consequently, the real force whereas the impulse arose, is placed; nor being able to determine whether the centre of gravity of the whole system (which is but a point in infinite space) is itself at rest, or in motion.

Motion, relatively common, is a change of the situation of a body with respect to other remote circumambient bodies; and this is the motion we speak of, when we say, that men, cities, and the earth itself move round the sun. This is also the motion we mean, when we estimate the quantity of motion, and the force any body has to impel another.
another. For instance, if a wooden sphere, filled with lead, to make it the heavier, be dropped from the hand; we are accustomed to estimate the quantity of motion, and the force which the sphere has to impel another, by the celerity of the sphere, and the weight of the incli led lead; and that truly with regard to the force itself, and the effect of it, as it falls under our senses. But whether the real power or motion be in the sphere which appears to strike, or in the earth which appears to be struck, that, as has been observed above, we cannot determine.

Motion, relatively proper, is the successe application of a body to the different parts of the contiguous bodies.

And this is the motion usually understood in physical disputes about the nature of particular things; as when we say, that heat, found, fluidity, &c. consist in motion. This must be added, however, that by successe application of a body, it s whole surface, taken together, must be conceived successe applied to different parts of the contiguous bodies.

From these several definitions of motion arise as many definitions of place: for when we speak of motion (or rest) truly and absolutely proper, that place is that part of inanimate and immovable space which the body fills. When of motion relatively common; then place is a part of any space or moveable dimension. When of motion relatively proper (which is really very improper) place is then the surface of the next adjacent bodies, or moveable spaces.

The definition of rest is pretty well agreed on; but whether rest be a mere privation of motion, or any thing positive, is warmly disputed. Malebranche, and others, maintain the former side of the question; Cartes, and others, the latter. These last contend, that a body at rest has no power to perferv in that rest, nor to retifie any bodies that would destroy it; and that motion may as well be called a cessation of rest, as rest of motion.

The main argument urged by the former is this: suppose a globe at rest, and suppose God cease to will its rest; what will be the consequence? it will rest still. Let it be in motion, and let God cease to will its motion; what will be the consequence? it will cease to move; that is, it will be at rest; because the power whereby a body in motion perferves in that state, is the positive will of God; that whereby the quiescent body perferves is only his privative will.

But this is a petitio principii: for the force or conatus by which bodies, whether moving or quiescent, perferv in those states, is the mere inactivity of matter; and, therefore, were it possible for God not to will any thing, a body already in motion would move for ever; as a body at rest would rest for ever. To this inactivity of matter it is owing, that all bodies rest, according to their quantities of matter; and that any body striking another with any given velocity, will move in the same proportion which its density, or quantity of matter, has to the density, or quantity of matter, of the other.

For want of a precise definition of the term motion, many authors have fallen into confusion. Says Dr. Young, (Course of Lectures on Natural Philosophy, &c. vol. i.) with respect to absolute and relative motion. The definition of motion given, at the commencement of this article, as the change of rectilinear distance between two points, appears to be the definition of what is commonly called relative motion: but, on a strict examination, it will be found that what is usually called absolute motion is merely relative to some space, which is without motion, merely in our imagination. The space which we call quiescent is, in general, the earth's surface, but astronomy teaches us, that every point of the earth's surface is perpetually in motion. Moreover, when we assert, that a body is absolutely at rest, we only mean to compare it with some large space in which it is contained; for that any body exists that is absolutely at rest, in an strict a sense as an absolutely straight line may be conceived to exist, no one can positively affirm; and if such a quiescent body did exist, we have no criterion by which it could be distinguished. Supposing a ship to move at the rate of three miles in an hour, and a person on board to walk, or to be drawn towards the stern at the same rate, he would be relatively in motion, with respect to the ship, yet we might very properly consider him as absolutely at rest; but he would, on a more extended view, be at rest only in relation to the earth's surface; for he would still be revolving round the axis of the earth, and with the earth round the sun, and with the sun and the whole solar sytem, he would be slowly moving among the starry worlds which surround them. Now, with respect to any effects within the ship, all the subefquent relations are of no consequence, and the change of his rectilinear distance from the various parts of the ship is the whole that needs to be considered in determining these effects. In the same manner, if the ship appears, by comparison with the water only, to be moving through it with the velocity of three miles an hour, and the water be moving at the same time in a contrary direction at the same rate, in consequence of a tide or current, the ship will be at rest with regard to the shore, but the mutual actions of the ship and the water will be the same as if the water were actually at rest, and there was no motion. It is not sufficient, as our author proceeds, to observe the increase or decrease of distance of a moving point from another single point only; we must compare its successe situations with many other points surrounding it; and for this purpose, those points must be at rest among themselves, in order to be considered as belonging to a quiescent space or surface: which may be defined as a space or surface, of which all the points remain always at equal distances from each other, without any external influence. In this sense, we must call the deck of the ship a quiescent surface, whether the ship be at anchor or under sail; but we must not consider a surface revolving round a centre as a quiescent surface; for no such motion can exist without the influence of a centripetal force, which renders it improper for determining the affections of a moving body.

Motion has ever been esteemed a species of quantity; and its quantum, or greatness, which we otherwise call its momentum, is estimated partly from the length of the line which the moving body describes (as if a body pafs over a line of a hundred feet the quantity of its motion is greater than if it pafs over only ten feet), and partly from the quantity of the matter moved together, or at the same time; i.e. not from the bulk or extension of the body, but from its mass or weight; the air, and other subtile matters, with which the pores are filled, not entering into the account; as if a body of two cubic feet ran over a line of a hundred feet, the quantity of its motion is greater than that of a body of one cubic foot describing the same line; for whatever motion one whole has, that is had in one-half of the other; and the motion of the whole is the sum of the motion of all its parts. (See Force). Hence it follows, that for two unequal bodies to have equal motions or momentums, the lines which they pafs over must be in a reciprocall proportion of their masses or weights: i.e. if any body have three times the quantity of matter that another has, the line that it runs over must be one-third of the line run over by the other. If two bodies, then, fastened to the two extremities of a balance or lever, have their mass...
in reciprocal ratio of their distances from the fixed point, whence they are moved, they must describe lines in a reciprocal ratio of these distances.

For instance, if the body $A$, (Plate XXXIV. Mechanics, fig. 1.) has three times the mass or weight of $B$, and each be fastened to the extremes of the lever $AB$, whose fulcrum or fixed point is $C$, in such manner as that the distance $BC$ is thrice the distance $CA$, the lever cannot incline either way, but the space which the body $B$ moves, $BE$, will be thrice the space $AD$, which the greater movers: so that their motions will be equal. Nor is there any reason why the body $A$, tending downwards, and $B$, tending downwards likewise, with the same four degrees of motion, should raise the body $B$, rather than $B$, or any body $B$, tending downwards likewise, with the same four degrees of motion, should raise the body $A$: they will therefore be in equilibrium. On which foundation depends the whole doctrine of mechanics.

Hence that great proverb of Archimedes, with any given power, how small soever, to raise any weight given, how great soever. For by increasing the distance $CB$ infinitely, the power of the body $B$ will be increased infinitely.

It is allowed on all hands, that motion is no essential attribute of matter; and hence ariseth a dispute about its production, and to what cause its continuation is owing.

**Motion, for the general Laws of, see Laws of Nature.**

**Motion, Quantity of, whether always the same?** The Cartesianists maintain, that the Creator at the beginning imposed a certain quantity of motion on bodies, and that under such laws, as that no part of it should be lost, but the fame portion of motion should be constantly preferred in matter: and hence they conclude, that if any moving body strike on any other body, the former loses no more of its motion than it communicates to the latter.

This principle sir Isaac Newton overturns in the following words: *From the various compositions of two motions, it is manifest there is not always the same quantity of motion in the world, for if two balls, joined together by a slender wire, revolve with an uniform motion about their common centre of gravity, and at the same time that centre is carried uniformly in a right line drawn in the plane of their circular motion, the sum of the motions of the two balls as often as they are in a right line, drawn from their common centre of gravity, will be greater than the sum of their motions when they are in a line perpendicular to that other. Whence it appears, that motion may be both generated and lost. But by reason of the tenacity of fluid bodies, and the friction of their parts, with the weakness of the elastic power in solid bodies, nature seems to incline rather to the deduction than the production of motion; and in reality, motion becomes continually less and less.

And for bodies which are either so perfectly hard, or so soft, as to have no elastic power, will not rebound from each other: their impenetrability will only stop their motion. And if two such bodies, equal to each other, be carried with equal, but opposite motions, so as to meet in a void space, by the laws of motion they must stop in the very place of concourse, lose all their motion, and be at rest for ever; unless they have an elastic power to give them a new motion. If they have elasticity enough to enable them to rebound with $\frac{1}{4}$, or $\frac{2}{4}$, or $\frac{3}{4}$, of the force wherewith they meet, they will lose $\frac{2}{4}$, or $\frac{3}{4}$, or $\frac{4}{4}$, of their motion. And this is confirmed by experiment: for if two equal pendulums be let fall from equal heights, so as to strike full on each other; if these pendulums be of lead, or of soft clay, they will lose all, or almost all their motion; and if they be of any elastic matter, they will only retain so much motion as they receive from their elastic power." If it be asked, how it happens, that motion being thus continually lost, should be continually renewed again; the same author adds, that it is renewed from some active principles, "such as the cause of gravity, whereby the planets and comets preserve their motions in their orbits, and all bodies acquire a great degree of motion in falling; and the cause of fermentation, whereby the heart and blood of animals preserve a perpetual warmth and motion; the inner parts of the earth are kept continually warmed; many bodies burn and shine; and the sun himself burns and shines, and with his light warms and cheers all things": (as also from the cause of elasticity, by which bodies restore themselves into their former figures,)

"for we find but little motion in the world, except what plainly flows, either from these active principles, or from the command of the will." The preservation of the same quantity of motion in the universe, was a principle laid down universally by Des Cartes; but has been found false, and holds true only in the same direction, which is thus expressed by sir Isaac Newton: *the quantity of motion, which is collected by taking the sum of the motions directed towards the same parts, and the difference of those that are directed to contrary parts, suffer no change from the action of bodies among themselves.* Newt. Princip. lib i. See Collision.

Some philosophers, after Des Cartes, have supposed the preservation of the same force or vis viva. See the articles Force and Vis Viva.

But this holds only in elastic bodies, when there is a shock; and hence those philosophers have been led to maintain, that all bodies were elastic, at least in their elements, and that an inelastic body was impossible, being repugnant to the law of continuity. See Continuity.

**Motion, As to the continuation of, or the cause why a body once in motion comes to perserve in it**: this has been extremely controverted among physical writers; and yet it follows very evidently, from one of the grand laws of nature; *viz.* that all bodies perserve in their present state, whether of rest or motion, unless disturbed by some foreign powers. Motion, therefore, once begun, would be continued in infinitum, were it to meet with no interruption from external causes; as the power of gravity, the resistance of friction, &c. So that Aristotle's principle, every thing in motion affects rest, is groundless. Nor has the communication of motion, or the manner how a moving body comes to affect another at rest, or how much of its motion is communicated by the first to the last, been less disputed. See the laws of it under the words Collision and Pervusion.

**Motion, we have observed, is the subject of mechanics**; and mechanics is the basis of all natural philosophy, which hence becomes denominated mechanical.

In effect, all the phenomena of nature, all the changes that happen in the system of bodies, are owing to motion; and are directed according to its laws.

Hence, the modern philosophers have applied themselves with peculiar ardor to the consider of the doctrine of motion; to investigate the properties, laws, &c. of it; by observation, experiment, and the use of geometry. And to this we owe the great advantages of the modern philosophy above that of the ancients; who were extremely regardless of motion; notwithstanding that they seemed to sensible of its importance, that they defined nature by the first principle of motion; and rest of the falseness in which it is.

Among all the ancients there is nothing extant on motion, excepting some things in Archimedes's book, "De Equi-ponderantibus." To Galileo a great part of the doctrine of motion is owing; he first discovered the general laws of motion, and particularly of the defect of heavy bodies, both
both at liberty and on inclined planes; the laws of the motion of projectiles; the vibrations of pendulums, and stretched chords, with the theory of refractions, &c. which were things of which the ancients had little notion.

His disciple, Torricelli, polished and improved the discoveries of his master; and added to them divers experiments concerning the force of percussion, and the equilibrium of fluids. M. Huygens improved very considerably on the doctrine of the pendulum; and both he and Descartes on the force of percussion. Lastly, Newton, Leibnitz, Varignon, Mariotte, &c. have brought the doctrine of motion still much nearer to perfection.

The general laws of motion were first brought into a system, and analytically demonstrated together, by Dr. Wallis, Sir Christopher Wren, and M. Huygens, all of which at the same time: the first in bodies not elastic, and the two last in elastic bodies. Lastly, the whole doctrine of motion, including all the discoveries both of the ancients and moderns on that head, was given by Dr. Wallis in his "Mechanics, five de Mou;" published in 1670. See Mechanics.

Motion may be considered either as equal, and uniform; or as accelerated, and retarded. Equable motion, again, may be considered either as simple, or as compound; and compound motion either as retilinear, or as curvilinear.

And all these, again, may be considered either with regard to themselves, or with regard to the manner of their production, and communication, by percussion, &c.

Motion, Equable, is that in which the moving body proceeds with the same instantaneous velocity.

The laws of equal motion are as follow: the reader being only to observe, by the way, that mass, or quantity of matter, is expressed by M; momentum, or the quantity of motion or impetus, by T; time, or the duration of motion, by T; velocity, or its swiftness, by V; and space, or the line it describes, by S.

Thus, if the space be s, and the time = t; the velocity will be expressed by \( \frac{s}{t} \). And if the velocity = v, and the mass = m; the momentum will likewise be \( mv \).

Motion, Laws of uniform or equable. 1. The velocities \( V \) and \( v \) of two bodies, moving equably, are in a ratio compounded of the direct ratio of the spaces \( S \) and \( s \), and the reciprocal ratio of the times \( T \) and \( t \).

\[
V = \frac{S}{T}, \quad v = \frac{s}{t}.
\]

Therefore, \( V : v = \frac{S}{T} : \frac{s}{t} = \frac{sT}{t} \).

And \( V + v = \frac{S + s}{T + t} \); consequently \( V + v = \frac{S + s}{T + t} \).

Thus, and the following theorems, may be illustrated in numbers; thus: suppose a body \( A \), whose mass is \( 7 \); that is 7 pounds, in the time of 2 seconds, paffes over a space of 12 feet; and another body \( B \), whose mass is \( 5 \), in the time of 8 seconds, paffes over a space of 16 feet: we shall then have \( M = 7 \), \( T = 5 \), \( S = 12 \), \( m = 5 \), \( t = 8 \), \( s = 16 \). And therefore \( V = 2 \), \( v = 1 \). The case then will stand thus:

\[
V + v = \frac{S + s}{T + t} = \frac{12 + 8}{16 + 3} = \frac{20}{19} = 2.
\]

Hence, if \( V = v \), then \( S = t \); therefore \( S : t = T : t \). That is, if two bodies move equably, and with the same velocities, their spaces are as the times.

The corollaries may be illustrated by numbers, in like manner as the theorems. Thus, suppose \( S = 12 \), \( T = 6 \), \( t = 8 \), \( t = 4 \). Then will \( V = \frac{12}{6} = 2 \), and \( v = \frac{8}{4} = 2 \).

Consequently \( V \) being = \( v \),

\[
S : t :: T : t.
\]

If \( T = t \), \( V = v \), and \( s = S \), then will \( S = s \); and for the bodies, moving equably, will describe equal spaces in equal times.

2. The spaces \( S \) and \( s \), over which two bodies pass, are in a ratio compounded of the ratio of the times \( T \) and \( t \), and of the velocities \( V \) and \( v \).

For \( V : v = \frac{sT}{t} \)

Therefore \( V : v = \frac{S}{T} \).

And \( S : t :: V : v \).

In numbers, \( 12 : 16 :: 4 \times 3 = 2 \times 8 \).

Thus, if \( S = 12 \), \( V = 4 \), and \( s = 8 \), then \( S = 8 \); and for the bodies, moving equably, will on the forces of their times.

Hence, if \( S = 12 \), \( V = 4 \), and \( s = 8 \), then \( S = 8 \); and for the bodies, moving equably, will describe equal spaces in equal times.

That is, if two bodies, moving equably, describe equal spaces, their velocities will be in a reciprocal ratio of their times. In numbers, if we suppose \( S = 12 \), \( v = 3 \), \( T = 4 \), the velocities \( V \) and \( v \).

Thus, if \( t = T \), then \( V = v \); and therefore \( V : v = \frac{sT}{t} = \frac{S}{T} \).

And therefore \( S = \frac{V}{t} \).

3. The matter, or quantities of motion, of two bodies, moving equably, \( I \) and \( i \), are in a ratio compounded of the velocities \( V \) and \( v \), and the masses or quantities of matter \( M \) and \( m \).

For \( I = VM \), and \( i = vm \); therefore \( I : i = VM : vm \); that is, the ratio of \( I \) to \( i \) is compounded of the ratio of \( V \) to \( v \), and of \( M \) to \( m \).

Thus, if \( I = i \), then \( V = m \); and therefore \( V : v = m : M \). That is, if the momenta of two bodies, moving equably, be equal; the velocities will be in a reciprocal ratio of their masses.

And therefore if \( M = m \), \( V = v \); that is, if the momenta and masses of two moving bodies be equal, their velocities are also equal.

4. The velocities \( V \) and \( v \) of two bodies, moving equably, are in a ratio compounded of the direct ratio of their momenta \( I \) and \( i \), and the reciprocal one of their masses \( M \) and \( m \).

Since \( I = i :: VM : vm \)

Then \( i = vm \).

Therefore \( V = i = v \).

In numbers, \( 4 : 2 :: 28 : 8 = 10 : 7 = 4 : 1 = 2 \).

Hence, if \( V = v \), then \( I = i \); and therefore \( I = M = m \); that is, if two bodies move equably, and with the same velocity, their momenta will be in the same ratio with their masses. If \( M = m \), \( I = i \); and therefore \( I = i = \frac{M}{m} \).

5. In an equable motion, the masses of the bodies \( M \) and \( m \) are in a ratio compounded of the direct ratio of the
MOTION.

their momenta, and the reciprocal ratio of their velocities $V$ and $v$.

For since $i : : VM : : v m$

$\therefore M : m = i : : i V M$

In numbers, $7 : 5 : 28 \times 2 : 10 \times 4 : 7 \times 1 : 5 : 1 : 7 : 5$.

If $M = m$, then will $i = V = i V$; and therefore $i : : i V$. That is, if two bodies, moving equally, have their masses equal, their momenta will be as their velocities.

In numbers, suppose $i = 12$, $i = 8$, $M = 4$, $m = 4$; then will $V = \frac{12}{4} = 3$, and $v = \frac{8}{4} = 2$.

Therefore $i : : i V : : 12 : 8 :: 3 : 2$.

6. In an equal motion, the momenta $i$ and $i$ are in a ratio compounded of the direct ratios of the masses $M$ and $m$, and the spaces $S$ and $s$, and the reciprocal ratio of the times $T$ and $t$.

For because $V : : S t : : i T$ and $i : : i V M : : v m ; m$.

Therefore $V : : i V M S T : : v M s T$.

And $i : : M s T : : m s T$.

Hence, if $i = i$, then will $M s T = m s T$; and therefore $M : m = s T : s T$; $S : : m : T : : M t$; and $T : : T : = M s T : : m s T$; that is, if two bodies, moving equally, have their momenta equal, 1. Their mases are in a ratio compounded of the direct ratios of the times, and the reciprocal one of their spaces.

2. Their spaces are in a ratio compounded of the direct ratio of the times, and the reciprocal one of their momenta.

3. Their times are in a ratio compounded of their momenta, and their spaces.

Farther, if $M = m$, then will $i T = S t$; and therefore $S : : i T : : i t$; i. e., if two bodies, moving equally, have their momenta and their masses equal, their spaces are as their times.

Again, if $T = t$, then will $S = s$. The two moving bodies, therefore, whose mases and momenta are equal, describe equal spaces in equal times.

If befole $i = i$, $S = s$, then will $M = M t$; and therefore $M : m = i T : i t$; that is, if two moving bodies, whose momenta are equal, pass over equal spaces, their mases are proportionable to their times.

Farther, if $T = t$, then will $M = m$; and therefore bodies, whose momenta are equal, and which, moving equally, describe equal spaces in equal times, have their mases equal.

If besides $i = i$, $T = t$, then will $M s = m s$; and therefore $S : : m : T$; $M s$; and $i T : = i t$; that is, if two bodies, moving equally, describe over equal spaces in equal times, then their mases will be in a ratio compounded of the mases and the spaces.

7. In an equal motion, the spaces $S$ and $s$ are in a ratio compounded of the direct ratios of the momenta $i$ and $i$, and times $T$ and $t$, and the reciprocal one of the mases $M$ and $m$.

For because $i : : M s T : : m s T$,

$\therefore M : m = i T M s T i$.

Wherefore $S : : i T m : : i M s$.

In numbers, $12 : 16 :: 3 \times 28 \times 5 : 8 \times 10 \times 7 : 3 \times 4 :: 12 : 16$.

Hence, if $S = i$, $i T M = i M$; and therefore $i ; i$.

If two bodies, therefore, move equally over equal spaces, 1. Their momenta will be in a ratio compounded of the direct ratio of the mases, and the reciprocal one of the times. 2. Their mases will be in a ratio compounded of the momenta, and the times. 3. The times will be in a ratio compounded of the direct ratio of the mase, and the reciprocal one of the momenta.

If besides $S = s$, $M = m$; then will $i T = i t$; and therefore $i : : i t : : T$. That is, bodies whose mases are equal, have their momenta reciprocally proportionable to the times in which they move over equal spaces.

If besides $S = s$, $T = t$, then will $i M = i m$; and therefore two bodies, moving equally, and through equal spaces in equal times, have their momenta proportionable to their mases.

8. Two bodies, moving equally, have their momenta $M$ and $m$, in a ratio compounded of the direct ratios of the momenta $i$ and $i$, and the times $T$ and $t$, and the reciprocal one of the spaces $S$ and $s$.

For because $i : : M S T : : m s T$, $i = M s T = i M s$.

Wherefore $M : m = i T s : : i S$.

In numbers, $7 ; 5 :: 3 \times 28 \times 16 : 8 \times 10 \times 12 :: 3 \times 7 ; 2 \times 1 \times 10 \times 3 :: 7 : 5$.

Hence, if $M = m$, then will $i T S = i S t$; and therefore $i : : i S T : : S = i T S t$; $i T : = i T : = i S t$; $i S$.

That is, in two moving bodies, whose mases are equal;

1. The momenta are in a ratio compounded of the direct ratio of the spaces, and the reciprocal one of the times.

2. The spaces are in a ratio compounded of the momenta and the times.

3. The times are in a ratio compounded of the direct ratio of the spaces, and the reciprocal one of the momenta.

If besides $S = s$, $T = t$, then will $i S = i t$; and therefore $i : : i S : : s$. That is, the momenta of two bodies, whose mases are equal, are proportionable to the spaces passed over in equal times.

9. In equal motions, the times $T$ and $t$ are in a ratio compounded of the direct ratios of the mases $M$ and $m$, and the spaces $S$ and $s$, and the reciprocal one of the momenta $i$ and $i$.

For because $i : : M S T : : m s T$, $i = M s T = i M S t$.

Wherefore $T = i T S : : i M S = i M S t$.

Hence, if $T = t$, $i s M = i m s$, and therefore $i : : i T s : : m S : : m s T ; M m s ; i T ; i s S ; M i t ; S i M$. That is, if two bodies, moving equally, describe equal spaces in equal times; 1. Their momenta will be in a ratio compounded of the mases and the spaces.

2. Their mases will be in a ratio compounded of the direct ratio of the momenta, and the reciprocal one of the spaces.

3. The spaces will be in a ratio compounded of the direct ratio of the momenta, and the reciprocal one of the mases.

MOTION, Accelerated, is that which continually receives fresh accessions of velocity. It is said to be uniformly accelerated, when in equal times its accessions of velocity are equal.

MOTION, Retardated, is that whose velocity continually decreases. It is said to be uniformly retarded, when its decrease is continually proportionable to the time.

MOTION, Laws of, uniformly accelerated and retarded. It is an axiom, that a body once at rest will never move, unless some other body put it in motion; and when once in motion, it will continue for ever to move with the same velocity, and in the same direction, unless it be forced from its state by some other cause. This is evident from that fundamental axiom in philosophy, that nothing happens without a sufficient cause.

It follows, that a body, moved by one only impulsive, must proceed
MOTION.

10. If the action and reaction of two (unelastic) bodies be equal, there will be no motion ensuing; but the bodies, after colliding, will remain at rest, by each other.

11. If a body move with an uniform accelerated velocity, the spaces will be in a duplicate ratio of the times.

For, let the velocity acquired in the time $t$ be $v$, then will the velocity acquired in the time $2t = 2v$, in the time $3t = 3v$, &c. and the spaces corresponding to those times, $t, 2t, 3t$, &c. will be as $v^2, 4v^2, 9v^2$, &c. The spaces therefore are as $1, 4, 9$, &c. and the times as $1, 2, 3$, &c. that is, the spaces are in a duplicate ratio of the times. Hence, in a motion uniformly accelerated, the times are in a subduplicate ratio of the spaces.

12. The spaces passed over by a body uniformly accelerated, in equal times, according to the unequal numbers $1, 3, 9, 7, 5, 3, 1$.

For, if the times wherein a moving body, equally accelerated, proceeds, be as $1, 2, 3, 4, 5, 6, &c.$ the space passed over in one moment will be as $1$, in 2 moments as $4$, in 3 as $9$, in 4 as $16$, in 5 as $25$, &c. (Law 11). If, therefore, you subtract the space passed over in one moment, viz. $1$, from that passed over in two moments, viz. $4$, there will remain the space corresponding to the second moment, viz. $3$. In the same manner may be found the space passed over in the third moment, $9 - 4 = 5$. The space corresponding to the fourth moment, $16 - 9 = 7$; and so of the rest. The space of the first moment, therefore, is as 1, that of the second as 3, that of the third as 5, of the fourth as 7, of the fifth as 9, &c. Therefore the spaces passed over by a body, moving with an uniformly accelerated motion in equal times, increase according to the unequal numbers, $1, 3, 5, 7, 9, &c.$

13. The spaces passed over by a body equally accelerated are in a duplicate ratio of the velocities.

For, supposing the velocities to be $V$ and $v$, the times $T$ and $t$, and the spaces $S$ and $s$; then will $V : v :: T : t$. Wherefore, since $S : T = V : v$ (Law 10.), $S : s = V : v$.

Wherefore, in a motion uniformly accelerated, the velocities are in a subduplicate ratio of the spaces.

14. Heavy bodies descend with an uniformly accelerated motion, in a medium void of resistance, if the spaces be not very great. For, since heavy bodies descend with an accelerated velocity, the power of gravity mult continually impel them. But the power of gravity is found the same at all distances from the earth where the experiment can be made. Therefore heavy bodies must be driven downwards in the same manner in equal times. If then, in the first moment of time, they be impelled with the velocity $v$, they will be impelled with the same velocity $v$ in the second moment, and with the same in the third, fourth, &c. moments. Now the medium being suppos'd void of all resistance (by Hypoth.) they will still retain the velocity they acquire; and by reason of their equal fresh acquisitions every minute, they will descend with a motion uniformly accelerated.

Hence, the spaces of descent are in a duplicate ratio of their times, and also of their velocities, and the inerease according to the unequal numbers $1, 3, 5, 7, 9, &c.$.

The times, and likewise the velocities, are in a subduplicate ratio of the spaces. See the laws of accelerated motion, otherwise illustrated and evinced under Acceleration, and Laws of the Descent of Bodies.

15. If a heavy body fall through a medium void of resistance, and from a height not very great, the space it passes over is the subduplicate of that which it would pass over by an uniform motion in the same time, with the time in which it has acquired at the end of its fall.

For, let the right line $AB$ (Plate XXXIV. Mechanics, fig. 2.) represent the whole time of a heavy body's descent; and let this be divided into any number of equal parts; and the spaces $PM, QM, RM, &c.$ be drawn the right lines $P, Q, R, &c.$ which may be as the velocities acquired, in those times, in the descent. Since then $AP : AQ : AS : A$ $P : Q : R : A S : P : S : H$, &c. (Ex. VI. 1.) If then the altitude of the triangle $ABC$ is conceived to be divided into equal parts infinitely small, the motion being uniform in a moment of time infinitely small; the little area $AP \times PM$ may be considered as the space passed over in the little moment of time $P$. Therefore the space passed over in the time $AB$, will be as the sum of all the little areas, i.e. as the triangle $ABC$. But the space that would be described in the same time $AB$ with the uniform velocity $BC$, being as the rectangle $ABCD$, it will be to the other space as $2$ to $1$. (Eucl. I. 41.)

Hence the space passed over in half the time $AB$, with the velocity $BC$, is equal to the space which the heavy body passes over from a slate of rest in the whole time $AB$.

Hence, also, the time wherein a heavy body falls from any given altitude being given, it is easy to determine the space it passes over in each part of that time. For the method of doing this, see Laws of the Descent of Bodies.

16. If a body proceed with a motion uniformly retarded, it will pass over half the space which it would describe in the same time by an equal motion.

For, supposing the given time divided into any number of equal parts; and draw the right lines $BC, SH, QI, PM$, thereto, which are to be as the velocities corresponding to the parts of time, $BS, SQ, BP, BA$; so as letting fall the perpendiculars $HE, IF, MG$, the right lines $CE, CF, CG, CB$ may be as the velocities lost in the times, $HE, IF, GM, AB$; that is, $BS, SQ, BP, BA$. Since $CE : CF :: EH : FI$, $CG : CB :: GM : BA$, $ABC$ will be a triangle (Eucl. III. 17). If $B$, therefore, be a moment of time infinitely small, its motion will be uniform; and therefore the space described by the moving body will be as the little area $BC$. The space, therefore, described in the time $AB$, is as the triangle $ABC$; viz. as the sum of all the little areas $BC$. Now the space described by the body moving uniformly with the velocity $BC$ in the time $AB$, is as the rectangle $ABCD$; therefore the former is half of this. (Eucl. I. 41.)

17. The spaces described by a motion uniformly retarded, in equal times, decrease according to the unequal numbers $7, 5, 3, 1$.

For, supposing the moving body in the first instant of time to pass over seven feet; I say, that in the second, if it be equally retarded, it will pass over $5$; in the third, $3$; and in the fourth, $1$. For, let the equal parts of the axis of the triangles $BS, SQ, QP, PA$, be as the times; the semi-ordinates $BC, SH, QI, PM$, as the velocities at the beginning of any time; the trapezia $BSHC, SQIH, QPM$, and the triangle $PAM$, as the spaces described in those times. Let then $BC = 4$, and $BS = SQ = QP = PA = 1$. Then will $SH = 3$, $QI = 2$, $PM = 1$, $BSHC = (4 + 3 + 2 + 1) = 5$, $SQIH = \frac{5 \times 3}{2}$, $QPM = \frac{5 \times 2}{2}$, $PAM = \frac{5 \times 1}{2}$.
MOTION.

\[(3+2) \cdot 2 = 8\], \[QPM = (2+1) \cdot 2 = 3\] PAM \[= 4\] . Consequently the spaces described in equal times are \[= 1, 2, 3, 4\] ; that is, \[= 7, 5, 3, 1\] .

For the cause, \&c. of the acceleration of motion, see Gravity, and Acceleration.

For the cause, \&c. of the retardation, see Resistance, and Retardation.

The laws according to which motion is communicated by the collision and percussion of bodies, are very different, as the bodies are either elastic or inelastic, and as the direction of the stroke is either oblique or direct. See Collision and Percussion.

Motion, Simple, is that produced by some one power.

Motion, Compound, is that produced by several conspiring powers. (See Compound, and Composition of motion.)

Powers are said to conspire, when the direction of the one is not opposite to that of the other; as when the radius of a circle is imagined to whirl round on its centre, and a point in the same radius is at the same time suppurposed impelled straight along it.

All curvilinear motion is compound; as all simple motion is rectilinear.

17. If a moving body (Plate XXXIV. Mechanics, fig. 3.) be acted on by a double power; the one according to the direction A B, the other according to A C; with the motion compounded of both will describe the diagonal of a parallelogram A D; whose sides A B and A C it would have described in the same time with each of the respective powers apart.

For, if the body A were only acted on by the force impelled along A B; in the first instant of time it would be in some point of the right line A B, as in H, and so in the line H L parallel to A C; if it were only acted on by the power impelled in the direction A C, it would in the same instant of time be in some point of the line A C, as in I, and so in the line I L parallel to A B. But since the directions of the powers are not opposite to each other, neither of them can impede the other; and therefore the body in the same instant of time will arrive both at the lines H L and I L, and will consequently be in the point L, where the two meet.

In the same manner it appears, that if K M and M G be drawn parallel to A B and A C, the body in the second instant of time will be in M, and at length in D.

Q. E. D.

This important law of motion may be further illustrated by supposing the space E F G H, (Plate XXXIV. Mechanics, fig. 4.) to be carried uniformly forward in the direction A B, and with a velocity represented by A B. Let a motion in the direction A D, and measured by the right line A D, be impelled upon the body A in the space E F G H. To those who are in this space, the body A will appear to move in the right line A D; but its real or absolute motion will be in the diagonal A C of the parallelogram A B C D; and it will describe A C in the same time that the space by its uniform motion, or any point of it, is carried over a right line equal to A B, or that the body A, by its motion across the space, describes A D. For it is manifest, that the line A D, in consequence of the motion of the space, is carried into the situation B C, and the point D to C; so that the body A really moves in the diagonal A C. This law may also be confirmed by an experiment in the following manner: let there be a wooden square A B C D, (fig. 5.) to have the parts B E F C made to draw out or pull into the square at pleasure. To this part let the pulleys H be joined, to act freely on an axis, which will meet H when the piece is pulled in, and at H when it is drawn out. To this part let the ends of a straight wire be fixed, so as to move along with it, under the pulley; and let the ball G be made to slide easily on the wire. A thread is fixed to this ball, and goes over the pulley to I; by this thread the ball may be drawn up on the wire, parallel to the side A D, when the part B E F C is pulled as far as it will go into the square. But if this part be drawn out, it will carry the ball along with it, parallel to the bottom of the square D C. By this means, the ball G may either be drawn perpendicularly upward by pulling the thread m. or moved horizontally along by pulling out the part B E F C, in equal times, and through equal spaces; each power acting equally and separately upon it. But if, when the ball is at C, the upper end of the thread be tied to the pin L in the corner A of the fixed figure, and the movable part B E F C be drawn out, the ball will then be acted on by both the powers together; for it will be drawn up by the thread towards the top of the square, and, at the same time, carried, with its wire k towards its right hand B C, moving all the while in the diagonal line L; and will be found at g when the sliding part is drawn out as far as it was before; which will then have caused the thread to draw up the ball to the top of the inside of the square, just as high as it was before, when drawn up lyingly by the thread without moving the sliding part.

The converse of this law is, that the motion in the diagonal A C, (fig. 4.) may be reduced into the motion of the sides of the parallelograms A B and A D. For it is manifest, that if A K (fig. 6.) be taken equal to A D with an opposite direction, and the parallelogram A K B C be completed, the right line A B shal be the diagonal of this parallelogram; consequently, the motion A C, compounded with the motion A K equal and opposite to the motion A D, produces the motion A B; that is, if from the motion A C, in the diagonal, you subtract the motion A D in one of the sides, there will remain the motion A B in the other side of the parallelogram A B C D.

This doctrine will receive further illustration by resolving each of the motions A B and A D into two motions, one in the direction of the diagonal A C, and the other in the direction perpendicular to it; that is, by resolving (Plate XXXIV. Mechanics, fig. 7.) the motion A B into the motions A M and A N; and motion A D into the motions A K and A L. For the triangles A D K and B C M being equal and similar, D K is equal to B M, or A L to A N; so that the motions A L and A N, being equal and opposite, destroy each other's effect; and it being an obvious and general principle, that the motion of a body in a right line is no way affected by any two equal powers or motions that act in directions perpendicular to that line, and opposite to each other, it thus appears how the body A is determined to move in the diagonal A C; and because A K is equal to M C, it appears how the remaining motions A M and A K are accumulated in the direction A C, so as to produce a motion measured by A C. It appears likewise, how absolute motion is lost in the composition of motion; for the parts of the motions A B and A D that are represented by A N and A L, being equal and opposite, destroy each other's effect, and the other parts A M and A K, only, remain in the direction of the compounded motion A C: while, on the contrary, in the resolution of motion, the quantity of absolute motion is increased, the sum of the motions A B and A D, or B C, being greater than the motion A C. But the sum of the motions, estimated in a given direction, is no way affected by the composition or resolution of motion, or indeed by any actions or influences of bodies upon each other, that are equal and mutual, and have opposite directions.

For suppose that (Plate XXXIV. Mechanics, fig. 8.) the motions
MOTION.

Motions are to be estimated in the direction AP; let CP, BR, DQ, be perpendicular to this direction in the points P, R, and Q; then the motions AC, AB, AD, reduced to the direction AP, are to be estimated by AB, AR, and AQ respectively; the parts which are perpendicular to AP having no effect in that direction. Let AP meet BC in S; then because RS is to SP, as BC (or AD) to CS, that is, as AQ to SP, it follows that AQ is equal to RS, and that AR + AQ is equal to AP; that is, that the sum of the motions AB and AD, reduced to any given direction AP, is equal to the compounded motion AC reduced to the same direction. From which it is obvious, that, in general, when any number of motions are compounded together, or are resolved, the sum of the motions continues invariably the same, till some foreign influence affects them.

From the above reasoning it is plain that since about every right line, as AD, (Fig. 3.) a parallelogram, as ABCD, may be constructed, by making two equal triangles ACD and ABD, on one common base AD, every rectilinear motion, when it may be of service for the demonstration, may be considered as a compound one. But as the proportion of the sides A, C, and D may be various, so, also may the right line AD be divided by a motion compounded in various ways; and therefore the same rectilinear motion may be reduced to various compound motions.

Hence, if a moveable body be drawn by three several powers, according to the directions BA, AD, and AC, (Fig. 9.) two of which taken together are equivalent to the third; they will be to each other as the right lines DC, DA, DB, parallel to their directions; that is, reciprocally as the lines of the angles included between the lines of their directions, and the line of direction of the third: DB being to AD as the sine of the angle BAD to the sine of the angle ABD.

10. In an equalable compound motion, the velocity produced by the conspiring powers is, to the velocity of each of the two apart, as the diagonal AD (Fig. 3.) of the parallelogram ABCD, in the direction of whole sides they make, to either of those sides AB or AC.

In the same time that one of the powers will carry it over the side of the parallelogram AB, the other over AC separately, jointed together they will carry it over the diagonal AD. The diagonal AD, therefore, is the space described by the conspiring powers in the same time: but in an equalable motion the velocities in the same time are as the spaces; the velocities therefore arising from the conspiring forces are to the velocity arising from either force, as AD to AB or AC.

Hence the conspiring forces thereof being given; i.e. the ratio of the velocities being given by the lines AB and AC given in magnitude, and the direction through those lines being given in position, or by the angle of direction; the celerity and direction of the oblique motion is given, because the diagonal is given both in magnitude and position.

The oblique motion however being given; the simple ones are not, viz. the sides; given because the same oblique motion may be compounded of various simple ones.

20. In a compound motion produced by the same forces, the velocity is greater, if the angle of direction be less; and less, if this be greater.

For let the greater angle of direction be BAC (Fig. 10.) the less FAC since the powers are supposed the same, AC will be common to each parallelogram ACFE and BACD, and besides AB = AF. Now it is evident, that, in the case of the greater angle, the diagonal AD is divided; and, in the case of the less angle, AE: and both in the same time, became AB = AF. The velocities, therefore, are as AD to AE; whence, since AD is less than A F, the velocity in the case of the greater angle is less than that of the less angle.

Hence, since the legs AC and CE, with the included angle, being given, the angle CEA, and thence also AE, is found; the velocity of the conspiring powers, and the angle of direction, in any particular case, being given, the velocity of the compound motion, and consequently the ratio of the velocities produced by the same powers under different angles of directions, may be determined.

For the particular laws of motion arising from the collision of bodies, both elastic and unelastic, and that where the directions are both perpendicular and oblique, see Collision and Friction.

For circular motion, and the laws of projectiles, see Projectile.

For the motion of pendulums, and the laws of oscillation, see Pendulum.

MOTION, Altitude of. See Altitude.

Motion, Longitude of. See Longitude.

Motion, Perpetual, in Mechanics, a motion which is supplied and renewed from itself without the intervention of any external cause; or it is an uninterrupted communication of the same degree of motion from one part of matter to another, in a circle or other curve returning into itself, so that the same momentum still returns undiminished upon the first mover.

This celebrated problem of a perpetual motion consists in the invention of a machine, which has the principle of its motion within itself. M. de la Hire has demonstrated the impossibility of any such machine, and finds that it amounts to this, viz. to find a body which is both heavier and lighter at the same time; or to find a body which is heavier than itself.

To find a perpetual motion, or to construct an engine, &c. which shall have such a motion, is a famous problem that has employed the mathematicians of two thousand years; though none, perhaps, have professed it with attention and care, is equal to those of the present age.

Infinite are the schemes, designs, plans, engines, wheels, &c. to which this longed-for perpetual motion has given birth: it were as endless as impertinent to give a detail of them all.

In effect, there seems but little in nature to countenance all this affinity and expectation: among all the laws of matter and motion, we know of none yet, which seem to furnish any principle or foundation for such an effect.

Action and reaction are allowed to be ever equal; and a body which gives any quantity of motion to another, always loses just so much of its own; but under the present state of things, the resistance of the air, the friction of the parts of machines, &c. do necessarily retard every motion.

To keep the motion constant, therefore, either, first, there must be a supply from some foreign cause; which in a perpetual motion is excluded.

Or, secondly, all resistance from the friction of the parts of matter must be removed; which necessarily implies a change in the nature of things.

For, by the second law of nature, the changes made in the motions of bodies, are always proportional to the impressed moving force, and are produced in the same direction with it; no motion then can be communicated to any engine, greater than that of the first force impressed.
But, on our earth, all motion is performed in a resisting medium, and must, therefore, of necessity be retarded; consequently, a considerable quantity of its motion will be spent on the medium.

Nor is there any engine or machine in which all friction can be avoided; there being in nature no such thing as exact smoothness, or perfect congruity; the manner of the cohesion of the parts of bodies, the small proportion the solid matter bears to the vacuities between them, and the nature of those constituent particles not admitting it. This friction, therefore, will also in time sensibly diminish the impressed, or communicated force; so that a perpetual motion can never follow, unless the communicated force be in a much greater than the generating force, as to recompense the diminution made therein by all these causes: but *nil dat quod non habet*, and the generating force cannot communicate a greater degree of motion than it hath itself.

Or, thirdly and lastly, there must be some method of gaining a force equivalent to what is lost, by the artful disposition and combination of mechanic powers; to which last point, then, all endeavours are to be directed: but how, or by what means such force should be gained, is still a mystery.

The multiplication of powers or forces, it is certain, avails nothing, for what is gained in power is still lost in time, so that the quantity of motion still remains the same. This is an inviolable law of nature; by which nothing is left to art, but the choice of the several combinations that may produce the same effect.

Although it is allowed, that, by the resolution of force, there is a gain or increase of the absolute quantity of force, as the two forces in the sides of the parallelogram taken together exceed the force in the diagonal which is resolved into them, yet you cannot proceed resolving motion in infinitum by any machine whatsoever; but those you have resolved must be again compounded, in order to make a continual movement, and the gain obtained by the resolution will be lost again by the composition. In like manner, if you suppose two bodies to be perfectly elastic, and that the lefser body strikes the other at rest, there will be an increase of the absolute quantity of force, because the striking body will be reflected; but if you suppose them both to turn round any centre, after the stroke, for any time to meet again, the increase of force will be lost, and their motion will be reduced to its first quantity. Such a gain, therefore, of force, as must be afterwards lost in the actions of the bodies, can never produce a perpetual movement. There are various ways, besides these, by which absolute force may be gained; but since there is always an equal gain in opposite directions, and no final effect obtained in the same direction; in the circle of actions necessary to make a perpetual movement, this gain must be presently lost, and will not serve for the necessary expence of force employed in overcoming friction, and the resistance of the medium. We may observe, therefore, that though it could be shewn, that in an infinite number of bodies, or in an infinite machine, there could be a gain of force for ever, and a motion continued to infinity, it does not follow that a perpetual movement can be made. That which was proposed by M. Leibnitz, in August, 1690, in the Leipsic Acta, as a consequence of the common estimation of the forces of bodies in motion, is of this kind, and for this and other reasons ought to be rejected.

The possibility of a perpetual motion has been urged from the following specious argument. Let the height AB (Plate XXXIV. Mechanics, fig. 11.) be divided into four equal parts AC, CD, DE, EB; suppose the body A to acquire, by the descent AC, a velocity, as 1; and this motion, by any contrivance, to be transmitted to an equal body B: then let the body A, by an equal descent CD, acquire another degree of motion, as 1; to be transmitted likewise to the same body B, which in this manner is supposed to acquire a motion, as 2, that is sufficient to carry it upwards from B to A; and because there yet remain the motions which A acquires by the descents DE and EB, that may be sufficient to keep an engine in motion, while B and A ascend and descend by turns, it is hence concluded, that a sufficient gain of force may be obtained in this manner, so as to produce a perpetual movement.

But it should be considered, that two equal successive impulses, acting upon the same body, will not produce a motion in it double of that which would be generated by the first impulse; because the second impulse has necessarily a less effect upon the body, which is already in motion, than the first impulse which acted upon it while at rest. In like manner, if there is a third and fourth impulse, the third will have less effect than the second, and the fourth less than the third. Hence it appears, that a motion, as 2, in the preceding case, cannot be produced in B, by the two successive impulses transmitted from A, each of which is as 1. Maclaurin's View, &c. book ii. c. 3. See Orfey's Wheel.

**Motion, Rotatory. See Rotatory Motion.**

**Motion, Animal.** is that by which the situation, figure, magnitude, &c. of the parts, members, &c. of animals are changed.

Under these motions come all the animal functions: as respiration, circulation of the blood, excretion, walking, &c. Animal motions are usually divided into two species: *viv's spontaneous, and natural.*

Spontaneous or muscular motion is that performed by means of the muscules, at the command of the will; hence also called voluntary motion: or, according to the system of Dr. Hartley, voluntary motions are such as immediately succeed to volition (which fee), without the intervention of sensible impressions. See Muscular Motion.

Natural, involuntary, or automatic motion, is that effectuated without such command of the will: by the mere mechanism of the parts. Such is the motion of the heart and pulse; the peristaltic motion of the intestines, &c.

Semi-voluntary are those in which part, but not uniformly, follow the will; fuch, e.g. as breathing, vomiting, &c. These are excited sometimes by a stimulus independent on the will; and, at other times, they are partly restrained or accelerated by volition, a sense of decency, propriety, &c. with which they may happen to have been associated. There are other motions, originally automatic, which, after becoming perfectly voluntary, by utilisation become gradually voluntary, and in the end completely automatic again. Thus, a person learning to play upon the harpsichord, exerts an express volition for every motion of the fingers upon the keys of the instrument; by degrees the visible appearance of the notes will produce the motions without the intervention of volition; and at last the motions will, as it were, cling together, and produce each other in a manner perfectly automatic, without the intervention of volition, sensation, or idea, and even when the attention is wholly engaged upon a subject foreign to the performance.

**Motion, Intestinal, denotes an agitation of the particles of which a body consists.**

Some philosophers will have every body, and every particle of a body, in continual motion. As for *us it is the definition*
Definition they give of them, that their parts are in continual motion.
And as to solids, they infer the like motion from the effluvia continually emitted through their pores.
Hence intelligible motion is represented to be a motion of the internal and smaller parts of matter, continually excited by some internal, latent agent, which of itself is insensible, and only discovers itself by its effects; appointed by nature to be the great instrument of the changes in bodies.
Motion, in Astronomy, is peculiarly applied to the orderly courses of the heavenly bodies.
The motion of the earth, from west to east, is now generally granted among astronomers: see it proved under the article Earth.

Motion, Mean. See Mean.
The motions of the celestial luminaries are of two kinds: diurnal, or common; and secondary, or proper.
Diurnal, or primary motion, is that with which all the heavenly bodies, and the whole mundane sphere, appear to revolve every day round the earth, from east to west. This is also called the motion of the primum mobile, and the common motion; to distinguish it from that rotation which is peculiar to each planet, &c. It is about the various phenomena resulting from this motion, that astronomy is chiefly employed. See Diurnal.
Secondary, or proper motion, is that with which a star, planet, or the like, advances a certain space every day from west towards east.
See several motions of each luminary, with the irregularities, &c. to which they are subject, under the proper articles, Earth, Moon, Star, &c.
Motion, Angular. See Angular.
Horary Motion of the earth. See Horary.
Paracentric Motion of imputus. See Paracentric.
Motion of Trepidation, &c. See Trepidation, &c.

Motion, in Music, denotes the manner of beating the measure, to hasten or slacken the time of the words, or notes. See Time.
The motion, in songs composed in double time, differs from that in those in triple time. It is the motion that distinguishes courants and farabonds from gavots, borees, charconnes, &c.
Motion, Motu, or Motimento, in the Italian Music, has many significations; sometimes it means only a motion or pause from one note to another, at whatsoever distance, as a second, third, or any other interval; and is the same whether the intermediate degrees (if there are any) be founded, or only the extremes of them, as the first and last founded of any given interval. Sometimes it regards the quickness and slowness of such motions, as a brisk, slow, lively, or languid motion; and in this sense it is used with regard to minuets, gavots, farabonds, &c. See each article in its proper place.
But the most common, and indeed the most important acceptance of the word, is with respect to harmony; those above described only regarding melody.

With regard to harmony, it is the comparing the manner wherein an upper or treble part moves from one sound to another, with that wherein a lower or bass part moves; this is to be done three ways. The first is when the upper and lower parts both move the same way, either upwards or downwards, and is called moto retto. The second is when in comparing the upper with the lower part, the one ascends while the other descends, or vice versa; and hence called moto contrario. The last is when one of the parts holds out, or continues a sound, while the other rises or falls on any note whatsoever; and this is called moto obliquo.

Motion, in the Ancient Muse, was used to signify the transfiguration of the voice, from an acute to a grave sound; or the contrary. This they expressed by κατά τόν χώρον αναγεννησαν. See Locus.
Methonius translates it, moveri in loco.
Motion is also used, among Mechanics, for the inside of a watch, &c. more commonly called movement.

Motions, in Military Language, denote the marches, countermarches, &c. which an army makes in changing its post.
The great skill of a general consists in discovering the enemy's motions, and concealing his own. Nothing is more dangerous than to make great motions before a powerful enemy, ready to come to blows. See March.

Motion, in the Manage. A horse is said to have a pretty motion, when he moves and bends his fore-legs with great ease and freedom upon the manage. But if a horse trots right out and keeps his body straight, and his head high, and bends his fore-legs handsomely, then to say he has a pretty motion with him, implies the liberty of action of the head.

Motion, or Emotion, in Rhetoric. See Passion.

Motions, Rhythmical, a phrase used by Vellius, and other writers on the ancient rhythm, to express those motions which were made use of in the Greek and Roman entertainments to convey the ideas of the poet, or to affill music in outlining the syllables. Thence not only had great force when joined with sounds, but even without any voice or sound they were capable of conveying the pith of the orators of the times could do with their most laboured discourse.

Rofcius, the stage-player so famous in their pantomimes, which were all dumb-show, was so excellent an expreffe by these rhythmical motions, or gestures, that Cicero and he being contemporaries, there were many disputes between them, which could vary the same sentence molt: the one using all the power of words, the other being confined to gestures alone.

Motion in Court. In the courts of chancery, king's bench, &c. motions are made by barristers and counselors at law, for what concerns their clients' causes; and where any motion is made in chancery, that is not of course, generally an affidavit of the facts alleged must be read in court; and if motions are founded on the general rules or usage of the court, and are not of course, but granted or denied as the court thinks fit, on hearing counsel on both sides, notice is to be given in writing to the solicitor of the other party, or his clerk in court, expressing every thing to be moved for, which must be proved two days at least before the day on which the motion is to be made; whereof affidavit must also be made.

Motion of Plants, in Gardening, the course or direction of growth which is taken in different parts of them.

With respect to the roots and stems, the direction is totally opposite, the former either running directly downward into the ground, or horizontally under the surface; while the latter direct their motion towards the air and light of the sun, mostly in an upright manner, but sometimes horizontally along the surface of the ground. The caules which operate in promoting these are the quest of nourishment in the root, and the influence of the air, and light of the sun, on the item: for when any number of plants growing in pots is placed in a room, which only admits a small portion of light at one place, the items all incline towards that side; in close dark thickets, the young trees always lean to the part where the most light penetrates; and the new shoots of espailier or wall-trees detach themselves from those supports, in quest of free air and light.
And it would seem that the force of motion is greater in the roots than in the stems; the roots, without ever once going out of their way, pierce the hardest foils, penetrate into walls, which they overturn, and even into rocks, which they split; whereas the stems and branches surmount obstacles by leaving their natural direction, and over-topping them.

But though the natural tendency of most stems or trunks is to ascend, yet some by their weakness, or natural growth, descend: and occasionally by means of roots breaking out all along the stems and branches, as in the strawberry, pimpernel, and many other creeping plants, the stems are, by the roots, striking into the earth, tethered as it were to the ground, and only their extremities have the power of directing their course upwards.

The leaves and flowers of plants also direct their course towards the air, and light of the sun; the leaves always turning their upper surface outward to the air and light, which is very obvious in wall-trees, and when a branch is overturned, so that the leaves are inverted, they naturally direct their surfaces again gradually upwards to the light and air, though this often takes them several days' growth. Some flowers are also supposed to have a particular daily motion, so as to present their surfaces directly to the sun, and follow the diurnal course of it, as the sun-flower, and most of the compound flowers, in all of which the size or surface is believed to look towards the east in the morning, the south at noon, and the west in the evening.

And during the heat of the sun, the pinnated or winged leaves, particularly of the palmillicinous tribe of plants, rise vertically upwards, the opposite lobes or foilioles, which compose the leaves, rise so as to be generally applied close together by their upper surfaces; but in that state of the atmosphere which generally precedes a storm, or during a close, moist, cloudy air, the lobes of the same sort of leaves extend themselves commonly along the footstalk; and after fun-fct incline still lower, and hang directly down under the footstalk, being applied close together like the leaves of a book, by their lower surfaces; a state which by Linnaeus is called the sleep of plants.

Further, the simple leaves of many plants, when their surfaces are exposed to an ardent sun, also become concave above, but gradually recover as the heat declines. But, of all the motions of the leaves of plants, none is so sudden and rapid as those of the sensitive and humble kinds.

There is another kind of motion in plants; that is, elasticity; which is not infrequently in some sorts of seed-leaves, such as the yellow balsamine, and spurge-cucumber, &c. in which their fruits, when arrived at maturity, burst open like a spring, and dart out their seeds with an elastic force to a considerable distance in many cases.

MOT, in Geography, a small island in the East Indian sea, about 24 miles S. from Ternate. N. lat. 6 26'. E. long. 117 19'.

MOTIVE is sometimes applied to that faculty of the human mind, by which we purport good and avoid evil. Thus Hobbes distinguishes the faculties of the mind into two sorts, the cognitive, and motive.

Motive, in Metaphysics and Moral, denotes whatever power or influence the mind in its choice; which some writers have extended so as to include the bias of the mind as well as the end in view, and to comprehend both reason and inclination, and in a word, every circumstance immediately previous to the volition, and which in the best degree contributes to generate the choice. Others, however, conceive that it is absurd to say, that our inclinations act upon us, or compel us, and that our desires and fears put us into motion, or produce our volitions; that is, are agens. But though this notion be absurd, it is perfectly conceivable that they may be the occasions of our putting ourselves into motion. Accordingly it is alleged, that there is an essential and total difference between the ideas of an efficient cause and an account or occasion. What fence would there be in saying that the occasion of a body, which may properly be the occasion or account of its being struck by another body, is the efficient of its motion or its impeller? It is upon the influence of motives that the modern advocates for the doctrine of necessity lay the main stress of their case. Every deliberate action, they say, must have a motive. When there is no motive on the other side, this motive must determine the agent: when there are contrary motives, the strongest must prevail. We reason from men's motives to their actions, as we do from other causes to their effects. If man be a free agent, and be not governed by motives, all his actions must be mere caprice; rewards and punishments can have no effect; and such a being must be absolutely un governable. On the other hand, the advocates for liberty, considered as a power to act, or a power of self-motive, or self-determination, whilst they allow, that all rational beings are influenced, and ought to be influenced by motives, maintain, that the influence of motives is of a very different nature from that of efficient causes. They are neither causes nor agents. They suppose an efficient cause, and can do nothing without it. We cannot, without absurdity, as they argue, suppose a motive either to act or to be acted upon; it is equally incapable of action or passion; because it is not a thing that exists, but a thing that is conceived; it is what the schoolmen call an ens rationis.

Motive, therefore, may influence to action, but they do not act. They may be compared to advice, or exhortation, which leaves a man still at liberty. For in vain is advice given, when there is not a power either to do, or to forbear, what it recommends. In like manner, motives suppose liberty in the agent, otherwise they have no influence at all. With respect to matter, it is a law of nature, that every motion, and change of motion, is proportioned to the force impressed, and in the direction of that force. The scheme of necessity supposes a similar law to obtain in all the actions of intelligent beings; and this implies, that every action, or change of action, in an intelligent being, is proportioned to the force of motives impressed, and in the direction of that force. It is further alleged, that as the law of nature respecting matter is founded upon this principle, so that matter is an inert, inactive substance, which does not act, but is acted upon, the law of necessity must be grounded upon the supposition, that an intelligent being is an inert, inactive substance, which does not act, but is acted upon. In relation to this subject, it has been further alleged, that rational beings, in proportion as they are wise and good, well act according to the best motives; and that every rational being, who does otherwise, abuses his liberty. The most perfect being always infallibly acts according to the best motives; but to say that such a being does not act freely, because he always does what is best, is in effect to say, that the proper use of liberty destroys liberty, and that liberty consists only in the abuse of it. Whilst it is granted, that motives have influence, similar to that of advice or peroration, this influence is perfectly consistent with liberty, and indeed supposes liberty. In order to determine the question, whether or not every deliberate action must have a motive, it should be considered in what sense the word deliberate is used. If by a deliberate action, we mean, agreeably to the original meaning of the term, an action in which motives are weighed, there must be motives, and even contrary motives, otherwise they could
could not be weighed. But if a deliberate action means only, as it commonly does, an action done by a cool and calm determination of the mind, with forethought and will, many such actions are done without a motive. On this point, an appeal may be made to every man's own consciousness. Cafes do occur, and they are not unfrequent, in which a person who intends the end finds not the least difficulty in adopting one of various means for its attainment, though at the time he be firmly persuaded, that it has no title to be preferred to any of the others. To say that such a case cannot happen, is to contradict the experience of mankind; and to say that if it should happen, the person could not execute his purpose, is still more ridiculous, though the authority of some of the schoolmen has determined, that the acts between two equal bundles of hay, would stand still till it died of hunger.

If a man could not act without a motive, he would have no power at all; for motives are not in our own power; and he that has not power over a necessary means, has no power over the end. Although actions that are performed without any motive, can have neither merit nor demerit, and are, therefore, insignificant in a moral estimation, they are important, it is said, in the question concerning moral liberty. For, if there ever was any action of this kind, motives are not the sole causes of human action; and if we have the power of acting without a motive, that power, joined to a weaker motive, may counterbalance a stronger.

It has been further urged, that it can never be proved, that when there is a motive on one side only, the action must be determined by it. If there be such things as willfuls, caprice, or obstinacy, among mankind, a single motive, or indeed many motives, may be refuted. When it is said, that of contrary motives, the strongest always prevails, it is necessary, before the assertion can be either affirmed or denied, to ascertain what is meant by the strongest motive; but this cannot be easily done. Unlefs some sort of measure of the strength of motives, distinct from their prevalence, can be found, it cannot be determined, whether the strongest motive prevails or not. Every thing that can be called a motive, is addressed either to the animal or to the rational part of our nature; and, therefore, motives may be denominated "animal" when they are such as are common to us with the brutes, and "rational," when they are peculiar to rational beings. When a man is acted upon by contrary motives of the former kind, he finds it easy to yield to the strongest; but if it be inquired, whether the strongest of this kind of motives always prevails, this is probably the case with regard to brute animals. They have no self-command, and are, therefore, not accountable. But with men, posseffing rational powers, and any degree of self-command, the strongest animal motive does not always prevail. It is, however, to rational motives, that the term "motive" is more commonly and more properly applied. They do not give a blind impulse to the will as animal motives do, but they influence the judgment; they convince, but do not impel, unlefs they excite some passion of hope, or fear, or desire. But there may be conviction without passion; and the conviction of what we ought to do, in order to some end which we have judged fit to be pursued, is what is called a "rational motive." If there be any competition between rational motives, it is evident, that the strongest, in the eye of reason, is that which it is most our duty and our real happiness to pursue. This may be called the "rational test" of the strength of motives. The grand and the important competition of contrary motives is between the animal on the one hand, and the rational on the other. If it be asked, which of these is the strongest motive? The answer is, that the first is commonly strongest, when they are tried by the animal test. If it were not so, human life would not be a state of trial. But contrary motives being tried by the rational test, it is evident, that the rational motive is always the strongest. Hence it is inferred, that the strongest motives, according to either of the tests above-mentioned, does not always prevail. In every wise and virtuous action, the motive that prevails is the strongest according to the rational test, but commonly the weakest according to the animal. In every foolish, and every vicious action the motive that prevails is commonly the strongest according to the animal test, but always the weakest according to the rational. The writer, whose sentiments we are now stating, farther observes, that we reason from men's motives to their actions, and in many cases with great probability, but never with absolute certainty; yet we should be chargeable with weak reasoning, if we inferred from this circumstance, that men are necessarily determined by motives; nor is it better reasoning to conclude, that, if men are not necessarily determined by motives, all their actions must be capricious. It is equally insufficient to conclude, that if men are not necessarily determined by motives, rewards and punishment would have no effect. Upon the supposition of necessity, it is alleged, there can be neither reward nor punishment, in the proper sense. As those words imply good or ill defect. Reward and punishment are only tools employed to produce a mechanical effect. When the effect is not produced, the tool must be unfit or wrongly applied. Whereas, upon the supposition of liberty, rewards and punishments will have a proper effect upon the wife and good, but not on the foolish and vicious, when opposed by their animal passions or bad habits; and this is agreeable to fact. Upon this supposition, the transgression of the law implies no defect in the law, nor fault in the law-giver; the fault is solely in the transgressor; and it is upon this supposition only, that there can be either reward or punishment, in the proper sense of the words, because it is only on this supposition that there can be good or ill defect. Reid's Essays on the Active Powers of Man, Eff. iv. chap. 4 and 5.

Supposing a power of self-determination, says another excellent writer in evincing the consistency of liberty with acting from a regard to motives, it is by no means necessary that it should be exerted without a regard to any end or rule. On the contrary, it can never be exerted without some view or design. The power of determining ourselves, by its very nature, needs an end and rule to guide it; and no probability, or certainty, of its being exercised agreeably to a rule, can have the least tendency to infringe or diminish it. All that should be avoided here, is the intolerable absurdity of making our reasons and ends in acting the physical causes or efficient of action. This is the same with ascribing the action of walking, not to the feet (or the power which moves the feet), but to the eye, which only sees the way. The perception of a reason for acting, or the judgment of the understanding, is no more than feeling the way and is the eye of the mind, which informs and directs; and whatever certainty there may be that a particular determination will follow, such determination will be the self-determination of the mind; and not any change of its state from upon it, over which it has no power, and in receiving which, instead of being an agent, it is merely a subject, subject or object of their acting; but it is a contradiction to make them the mechanical efficient of their actions. Physical and moral causes.
causes differ in the following particulars: the one are beings, the others are only the \textit{virtus} of beings;—the one always \textit{do}; and the other may produce a certainty of event; but the certainties in these two cases essentially differ; and to ascribe a necessary and physical efficiency to motives, is (as Dr. Clarke has observed) the same with saying, that "an abstract notion can strike a ball," the certainty of event arising from the operation of \textit{physical} causes is always equal and invariable, but the certainty of event arising from \textit{moral} causes, that is, from the views and perceptions of beings, admits of an infinite variety of degrees; and sometimes passes into \textit{probability} and \textit{contingency}. Supposing contrary reasons equally balanced in the mind, it may be uncertain how a being will act. \textit{E. G.} If a temptation to an act of wickedness comes in the way of a man whose love of virtue is nearly equal to the strength of his passions, it may be doubtful which way he will determine. If his love of virtue exceeds the influence of passion, there will be a \textit{probability} of his acting virtuously, proportioned to the degree in which the love of virtue prevails within him; and it may be so prevalent as to make it \textit{certain}, that he will always follow his perceptions of virtue. Moreover, in the operation of \textit{physical} causes, it is always implied, that there is not in any sense a power to produce, or a possibility of producing any other effect than that which is produced; but the contrary is true of effects dependent on the wills, and occasioned by the views of free agents. A benevolent man will certainly relieve misery when it falls on him, but he may not relieve it. On the contrary, a stone thrown from the hand must move. The benevolent man \textit{acts}; the stone only \textit{suffers}. Who can deny, as the same author proceeds, even with respect to the supreme deity, that however certain it may be, that he will not make his creation miserable, he has the power to do it? It is, indeed, on this power, that all our notions of moral excellency in the actions of beings depend. Were the benevolence of a being no more his \textit{action}, or \textit{self-determination}, than the falling of rain is the action, or self-determination of rain, it would not be the object of moral approbation; or the ground of esteem and gratitude. It is added, that the \textit{causality} implied in the views and dispositions of beings is entirely consistent with moral obligation and responsibility; but all effects brought about by mechanical laws are inconsistent with them. Upon the whole, as our author argues, the question concerning liberty is not, \textit{whether} the views or ideas of beings influence their actions; but \textit{what} the nature of that influence is. This, as the advocate for liberty contends, is not any kind of \textit{mechanical} or \textit{physical} efficiency; for if it were, man would not be free to act. It would be folly to applaud or reproach ourselves for our conduct; and there would be an end of all moral obligation and accountableness. Price's Review of Morals, p. 410 to p. 415, ed. 2d; and A Free Discussion of the Doctrines of Materialism and Philosophical Necessity, in a Correspondence between Dr. Price and Dr. Prieaffley, p. 134, &c. See \textsc{Liberty}.

The advocates for necessity, on the other hand, maintain, that, if \textit{self-mot}ion or \textit{self-determination}, properly so called, be essential to liberty, man does not possess it; and if this, and nothing else, be called \textit{agency}, they deny that man is an \textit{agent}: because every human volition is invariably directed by the circumstances in which a man is placed, and what they call "motives." To this purpose Dr. Prieaffley says, it appears to me that we have no more reason, from \textit{fact} and \textit{observation}, to conclude that a man can move himself, that is, that he can \textit{will} without motives, than that a stone can move itself. And, if the will is as invariably influenced by motives as the stone is influenced by gravity, it may just as well be said that the stone moves itself, though always according to the laws of gravity, as that the will, or the mind moves itself, though always according to the motives; and whether these motives be called the \textit{moral} or the \textit{physical} causes of our volitions, is of no sort of figuration, because they are the only and the \textit{necessary} causes, just as much as gravity is the only and \textit{necessary} cause of the motion of the stone. Let the mind act contrary to motives, and the stone move contrary to the laws of gravity, and "I shall say," says Dr. Prieaffley, "but not before, believe, that they are not the only and necessary causes." The difference asserted by the Libertarians to subsist between \textit{moral} and \textit{physical} causes and effects, appears to me, says the same author, to be that which subsists between \textit{voluntary} and \textit{involuntary} causes and effects: and this indeed is a most important difference. Where involuntary motives are concerned, as is the case of a man dragged by force, it is absurd to use any reasoning or propugnation, or to apply rewards or punishments, because they can have no \textit{effect}; but where voluntary motives are concerned, as in the case of a man who is at liberty to go where he pleases, &c. reasoning and expostulation, rewards and punishments, have the \textit{greatest} propriety, because they have the greatest \textit{effect}; for they are applied to, and influence or move the will, as much as external force moves the body. On this circumstance, viz. the influence of motives on the will, it is said, that the whole of \textit{moral discipline} depends; so that if the will of "an were formed, as that motives should have no influence upon it, he could not be the subject of moral government; because the hope of reward and the fear of punishment operate in no other manner than as motives applied to the will. The ideas belonging to the terms \textit{accountableness}, \textit{praise}, and \textit{blame}, \textit{merit} and \textit{demerit}, all relate to the business of moral discipline, and therefore necessarily imply that men are influenced by motives, and act from \textit{fixed principles} and \textit{character}, though on account of our not comprehending the doctrine of \textit{causes}, and Stephenson where we ought not, we are generally under some mistake or misconception with respect to them. Dr. Prieaffley thinks, that in treating this subject philosophically, these words should be disdained. Correspondence, &c. ubi supra. Prieaffley's \textsc{Differ.} vol. ii. Bellahm's \textsc{Elem.} of the Philosophy of the Mind. See farther on this subject the article \textsc{Necessity}.

\textsc{Motivo}, in \textit{Italian Music}, implies the theme, subject, or two or three first bars of a composition. This technical term is chiefly used by composers in speaking of particular movements. It expresses the primitive and original idea upon which a composer forms an air or movement, and arranges his design. It is the \textit{motivo}, or first conception, that influences him to seize the pen in order to fix or imbibe one text or thought upon paper in preference to another; it resembles the \textit{prima intenzione} of painters. In this sense the principal \textit{motivo} or subject ought to be continually in the composer's mind, nor should he suffer it to be forgotten by the divers circumstances. A composer is said to "be beating about the bush," when he loses sight of the \textit{motivo}, and is flagging passages together without felle or connection with each other.

Besides the \textit{motivo}, which is only the leading idea of the piece, there are particular traits which naturally arise out of the subject and modulation, which, by being interwoven in the texture of the harmony, discover the author's ability and resources; or, if not perceptible, his want of science and invention.

\textsc{Moto}. I. al. motion: as \textit{Moto contrario}, contrary motion; \textit{con moto}, with motion, not dragged or too slow.

\textsc{Moto},
MOT

MOTO, in Geography, a town of Hindoostan, in Guzerat; 5 miles E. of Patann.

MODZIECNO, a town of Lithuania, in the palatinate of Wilna; 64 miles E. S.E. of Wilna.

MOTOL, a town of Lithuania, in the palatinate of Brefce; 66 miles E. of Brefce.

MOTOLA, a town of Africa, in the kingdom of Congo. — Alfo, a town of Naples, in the province of Otranto, the see of a bishop, suffragan of Tarento; 134 miles E. of Naples. N. lat. 40° 52'. E. long. 17° 2'.

MOTOORAH, a town of Bengal; 50 miles S.S.W. of Calcutta. N. lat. 22° 2'. E. long. 87° 48'.

MOTOTABBOO, one of the smaller Friendly islands; 5 miles N.W. of Tongatabou.

MOTORES OCEULONI, in Anatomy, the nerves of the third pair, which supply the muscles of the eye. See NERVE.

MOTORES OCEULORUM EXTERNI, the nerves of the fifth pair, distributed to the external straight muscles of the eyes. See NERVE.

MOTOS, motos, a piece of lint, or linen cloth, opened like wool, to be put into ulcers, to stop the flux of blood, &c.

Motos, in the Materia Medica of the Ancients, was a name given by Galen and others to a kind of caffia bark, the belt and smell that has been used at any time. The ancients were very fond of this drug, and ranged it, according to its different goodness, into several sorts.

MOTOUA, in Geography. See Mutova.

MOTOVSKAIA, a town of Ruffia, in the government of Archangel; 12 miles N.N.E. of Kola.

MOTRAPOUR, a town of Bengal; 10 miles N. of Mahmudpon.

MOTRICO, a sea-port town of Spain, in Guipuscoa, in the bay of Biscay; 18 miles W. of St. Sebastien.

MOTRILL, a sea-port town of Spain, in the province of Granada. From this town, along the coast as far as to Gibraltar, there are several sugar-mills, called "ingenios," and at Motril are four of them, which have been used from time immemorial for the manufacture of sugar; but the culture of sugar-canes has of late, from political motives, been superseded by that of the vine; 4 miles E. of Malaga. N. lat. 36° 45'. W. long. 3° 42'.—Alfo, a town of Walachia; 10 miles N.N.W. of Krajova.

MOTRIX, something that has the power or faculty of moving.

MOTRIX, Vf. See Vis Motrix, and Motion.

MOTTA RAPHAELLO, in Biography. See Raphaelino.

MOTTA, in Geography, a town of Italy, in the Trevisan; 18 miles E.N.E. of Treviso. — Alfo, a town of Italy, in the department of the Upper Po; 21 miles E. of Cremona.

MOTTA, La, a town of Sicily, in the valley of Noto; 11 miles W. of Calabria.

MOTTA di Braxiano, a town of Naples, in Calabria Ultra; 17 miles S. of Gierace.

MOTTA di Reina, a town of Naples, in Capitanata; 6 miles S. of Serviero.

MOTTA St. Gia, a town of Naples, in Calabria Ultra; 6 miles S.S.E. of Reggio.

MOTTA Sidroni, a town of Naples, in Calabria Ultra; 4 miles N.E. of Gierace.

MOTTABHEN, a town of Arabia, in Yemen; 10 miles W. of Bein el Pakih.

MOTTAPAR, a town of Hindoostan, in Travancore; 21 miles N.E. of Porab.

MOTTA, in Geography, a town of Italy, in the Paduan; 9 miles S.S.W. of Padua.

MOTTARELLE, a town of Italy, in the Paduan; a considerable French writer, was born at Paris in 1672. He was educated at one of the seminaries of the Jesuits, and was destined for the profession of the law. This was not suited to his taste, so that he quitted his legal studies, and devoted himself to polite literature. At the age of twenty-one he wrote a comedy, which was reprinted, but which proved unsuccessful. Mortified at the disappointment, he wished to take the habit of the order of La Trappe, and offered himself at the monastery, but after a stay of a few weeks he was dismissed, returned to Paris, and composed an opera, entitled "L'Europe Galante," that obtained for him great applause. This was the commencement of his fame; he afterwards published several other pieces, which proved that he had great talents for lyric poetry. In 1707, he published a volume of "Odes," that were pretty much read, but did not add to his reputation. In 1710 he was admitted a member of the French academy, and his discourse on his reception was reckoned a model of the kind. He next had a desire of being distinguished in the composition of tragedies, and wrote several, of which the most successful was "Ines de Castro." It proved, we are told, one of the most interesting pieces on the French stage, was acted a vast number of times on its first appearance, and is still popular. From tragedy he turned to comedy, and composed several pieces of that kind which were well received, particularly one entitled "Le Magnifique," which has retained a place among the most popular performances. In 1719 he published a volume of "Fables," which, though greatly criticized, were much read, and several of their lines became proverbial. He was author likewise of pastoral eclogues, cantatas, psalms, and hymns; but he has likewise attained to a high degree of excellence as a prose writer. His academical discourses have been much applauded, particularly an oration on Lewis XIV., which, among the number composed for the purpose, is the only one not entirely forgotten. He assumed also the character of a theologian, and drew up "A Plan of Evidences of Religion," which is thought to be a very valuable production. He maintained, through life, a perfect calmness in all the events of the world: although for many years he was reduced nearly to a state of blindness he bore the affliction with much patience and resignation, as he did the symptoms of a decline, which put an end to his life in 1737, at the age of fifty-nine. His works were published collectively at Paris in 1754, in eleven volumes, 8vo. An infirmity is given of the great mildness of his disposition; being in a crowded crowd he trod on the foot of a young man, who instantly slunk him a blow on the face: "Sir," said La Motte, "you will be very sorry for what you have done when I tell you I am blind." Morer.

MOTTE, in Geography, a small island in lake Champlain, about eight miles in length, and two in breadth, distant two miles from Hero island. It constituted a township of its own name in Franklin county, Vermont, named in 1802 Vineyard; which fee.

MOTTE, La, a town of France, in the department of the Vosges, placed on an eminence, not far from the Mouzon; 6 miles N.E. of Bourmont.

MOTTAYE-ARBAUD, La, a town of France, in the department of the Vexin, and chief place of a canton, in the diocese of Les Sables d'Olonne; 9 miles N.E. of it. The place contains 250, and the canton 753 inhabitants, on a territory of 3171 kilometres, in 12 communes.
MOT

MOTTE, Charlotte, a town of France, in the department of the Drôme, and chief place of a canton, in the district of Die; 16 miles S. of Die. The place contains 1,161, and the canton 7,546 inhabitants, on a territory of 362 square kilometres, in 17 communes.

MOTTE-Du-Caire, a town of France, in the department of the Lower Alpes, and chief place of a canton, in the district of Sisteron; 9 miles N. of it. The place contains 581, and the canton 4,435 inhabitants, on a territory of 1,775 square kilometres, in 12 communes.

MOTTE-HEBAY, a town of France, in the department of the Two Sevres, and chief town of a canton, in the district of Melle. The place contains 2,713, and the canton 8,536 inhabitants, on a territory of 165 square kilometres, in 8 communes.

MOTTE-Saint-Jean, a town of France, in the department of the Saone and Loire; 6 miles W.N.W. of Paray-le-Monial.

MOTTINE, a town of Arabia, in Yemen; 8 miles S.W. of Sana.

MOTTENHAGEN, a town of Prussia, in the province of Natangen; 5 miles E.S.E. of Konigberg.

MOTTEVILLE, Frances Berthaude, in Biography, daughter of a gentleman of ordinary of the king's bed-chamber, was born in Normandy about the year 1615. She was brought up at the court of queen Anne of Austria, with whom she ingratiated herself by her talents and agreeable manners. By the influence of cardinal Richelieu she was banished the court, and retired to Normandy, where the married Nicholas Langlois, lord of Motteville, first president of the chamber of accounts at Rouen. He was an old man, and left her a widow in about two years. After the death of Richelieu, queen Anne, then regent of France, recalled her to court, and kept her about her own person. The attachment which she had to the queen induced her to adopt the design of writing memoirs of her life, and with that view she began to note down every thing worthy of remembrance. The result was a work entitled "Memoires pour servir à l'Histoire d'Anne d'Austriae;" it was printed in 1723, in five volumes 12mo., and again in 1750, in six volumes 12mo. These memoirs display an intimate acquaintance with the court during the minority of Lewis XIV., and are regarded as true. She died at Paris in the year 1689. Motteville.

MOTTEUX, Peter Anthony, was a native of France, being born in 1660 at Rohan, in Normandy, where also he received his education. On the revocation of the edict of Nantes, he came over to England. He lived at first with his godfather and relation, Paul Dominique, esq.; but afterwards became a confidant of the duchess of Montrose, kept a large East India warehouse in Leadenhall-street, and had a very genteel place in the general post-office, relating to the foreign letters, being master of several languages. During his residence in this kingdom, he acquired to perform a masterly of the English language, that he not only was qualified to give a very good translation of Don Quixote, but also wrote several songs, prologues, epilogues, &c.; and what was still more extraordinary, became a very eminent dramatic writer in a language to which he was not native. He produced about 18 dramas. This gentleman, who seems to have led a very comfortable life, his circumstances having been perfectly easy, was yet unfortunate in his death; for he was found dead in a disorderly house, in the parish of St. Clement Danes, without suspicion of having been murdered. This accident happened to him on the 9th of February 1717-18, which, being his birth-day, exactly completed his 58th year. Biog. Dram.

MOTTLING, or METTLE, in Geography, a town of the duchy of Carlsruhe; 10 miles S.S.W. of Landstraes. N. lat. 15° 51', E. long. 15° 14'.

MOTTO, an Italian term, literally signifying word, or saying; used in arms, devices, &c.

Motto of an Armoury, is a short sentence or phrase carried in a scroll generally over, sometimes under the arms; sometimes alluding to the name of the bearer; sometimes to the bearing; and sometimes to some remarkable achievement of the bearer.

The motto, or word, says Guillim, is an external ornament annexed to coat-armour; being the invention or conceit of the bearer, succincly and significantly expressed, usually in three or four words, which are set in some scroll or compartment, placed at the foot of the escutcheon.

As the motto holds the lowest place in arms, so it is the last in blazoning. In friezes, it should express something intended in the achievement; but custom has now received whatsoever be the fancy of the deviser.

The use of mottos is very ancient; history, both sacred and profane, furnishing innumerable of them. Our ancestors made choice of mottos to express their predominant passions; as of piety, love, war, &c. or some extraordinary adventure that had befallen them; most of which, from some such original, have become hereditary in divers families.

The motto of the royal family of England is Dies & mon deus; of the royal family of Bourbon, Egressores; or of the Garter, Honi soit qui mal y pense, &c.

The motto of a device is also called the soul of the device. Motu—Ex meo Motu. See Ex.

MOTUARA, in Geography, an island in the Pacific ocean, between the islands of New Zealand, in Queen Charlotte's found, in which was a fortified village. S. lat. 41° 4', W. long. 184° 50'.

MOTUGOGOGO, a cape of New Zealand, called by Cook Cape Bret (which see) lying in S. lat. 35° 10' 30".

W. long.
On which, frequently, of be common, moveable

MOYSIN, a town of Ru§sian Poland, in the palatinate of Kiev; 20 miles W.N.W. of Kiev.

MOUAH, a town of Hindooftan, in Guzerat, on the gulf of Cambay; 54 miles S.S.W. of Gogo.

MOUAMILLADOORO, a town of Hindooftan, in the Carnatic; 30 miles N. of Nellore.

MOUCHA, Lai, a bay on the coast of Chili, on the west coast of South America.

MOUCHAM, a town of France, in the department of the Vendee; 20 miles N.N.W. of Fontenoy le Comte.

MOUCHEROLLE, in Ornithology, the name of a small bird of the size of the sparrow, and of the same colour, but longer bodied; its wings are of a dufkyer colour than the rest of its body, and its head is variegated with very small blackish spots; its throat and belly are white, but the throat and the sides of the breast and belly have a faint reddinefs; the beak is black, straight, and ridged, fo as to appear triangular; it feeds on flies and other insects, and is common in gardens and orchards in many parts of England, though it has no English name. It is confused by the common people with the common white-throat, but differs from it in that its tail is all of one colour, whereas the white-throat's is variegated. It somewhat resembles also the beecofaro, or petty-chaps, but differs from it in having no greenish colour, and in its bill being ridged and triangular. See Musucapa and Todus.

MOUCHERON, Frederick, called the Old, in Biography, was a landscape-painter, born at Embden in 1633, and the disciple of John Aelflyn; but at the age of 52, he went to Paris to practife the lefions he had learnt in his profession, and was fo fortunate as to obtain considerable applause, at an early period, by a freedom and boldness of hand, and a certain air of nature which his works poiffe, without, however, being highly meritorious, or ever being carried to any great degree of perfection. His choice of subjects was generally from the common scenes of nature; thefe he wrought with a full pencil, and a touch light and free. His colouring is generally of a negative call, with the fore-grounds wrought up clear and rich; but his middle distances are often pale and indiftinct, and have a little too much that is characteristic of the painter's not being decidedly well informed of his own intentions. From Paris he went to fettle at Amsterdam, and during his continuance in that city, the figures in his landscapes were frequently painted by Adrian Vander Velde; as during his residence in France, they were by Theodore Helmbrtcher. He died at the age of 53.

Moucoheron, Isaac, was born at Amsterdam in 1670, and having had the advantage of his father's inftuctions in the art of painting, till he arrived at the 24th year of his age, he then travelled to Rome, where he made defigns of the interesting, and often beautiful, fcenery around that city. Of thefe he carried back with him to his native place a very confiderable number, and was there employed in painting pictures from them, in halls, faloons, and the appartment of noble edifices; being affifted with figures for his fcenery by Verkolie and De Wit. He lived till the year 1744, having enjoyed great praise and benefit from the exercise of his talents; and his works are still very much esteemed.

MOUCHOU, in Geography, a river of China, which runs into the Eastern sea, N. lat. 36° 56'. E. long. 121° 54'.

MOUCI, a town of Afcatic Turkey, in Caramania; 30 miles N.N.E. of Akmalen.

MOUD, a town of Afcatic Turkey, in Caramania; 78 miles S.E. of Cogni.

MOUDON, Milden, Mildenum, a town of the Helvetian republic, which gives name to a bailiwick, in the canton of Bern. It is a handfome town, and was formerly the capital of all that part of the Pays de Vaud, which belonged to the duke of Switz. It was the ordinary residence of his chief bailiff, and the place where the fates were accufomed to meet. The town is inconveniently situated on the river Broye, part of it being level, and part of it lying on the declivity of a hill, from which a rivulet falls, and runs with rapidity into the Broye. In the upper town was formerly a church, dedicated to the Virgin Mary, of which nothing now remains but a tower or kind of free. In the lower part of the town is one church. Antonine mentions this place in his Itinerary, and it is thought to be one of those which the Swifs burned in the time of Julius Caesar. Some ancient medals and other curiosities have been found in this place. The district or bailiffage, in which it lies, is about ten miles long and eight broad, partly mountainous and woody, and partly fertile. The town, situated at the entrance of a narrow valley, is distant 11 miles N.E. from Laufanne. N. lat. 46° 42'. E. long. 6° 56'.

MUDYEL, a town of Hindooftan, in the circur of Cuddapah; 40 miles N.N.W. of Gaddipatta.

MOVE, in arref of Judgment. See Arrest.

MOVEABLE, something fuceptible of motion, or that is disposed to be moved. See Motion.

A sphere is the most moveable of all bodies, i.e. it is the easiest to move; a door is moveable on its hinges, the magnetic needle on a pin, or pivot, &c.

Moveable is frequently used in contradiction to fixed.

Moveable Feasts. See Feasts and Easter.

MOVEABLES, or Moveable Goods, by civilians called bona nobilita, are those which are capable of being removed from one place to another; or which may be concealed or perverted; as not being fixed to the ground, &c. See Goods and Chattels.

In England, we have two kinds of effects, moveable and immovable: the moveable are, ready money, merchandizes, bonds, book-debts, cattle, and household furniture, not fastened either with iron or nail, nor sealed in the pallet, but which may be transported without either friction or deterioration.

In the customary laws, they say, moveables follow the person, and his proper habitation; moveables follow the body, &c. which words have different meanings in different countries. Sometimes they signify, that moveables go according to the custom of the place where is the habitation of the deceased; though he die in another place; and sometimes they signify that moveables follow the custom of the place where the defunct died.

MOVEMENT, Motion, a term frequently used in the fame fenfe with automaton.

The most usual movements for keeping time are watches and clocks; the firth are such as move the parts of time, and are portable in the pocket; the second such as publish it by sounds, and are fixed as furniture. See Horologium and Chronometer.

Movement, in its popular use among us, signifies all the inner work of a watch, clock, or other engine, which moves,
MOUVEMEN T, is a term used by some writers to express the rise and fall, the advance and recede, with other diversity of form, in the different parts of a building, so as to add greatly to the picturesque of the composition. For the rising and falling, advancing and receding, with the concavity and convexity, and other forms of the great parts, have the same effect in architecture, that hill and dale, fore-ground and distance, swelling and sinking, have in landscape; that is, they serve to produce an agreeable and diversified contour, that groups and contracts like a picture, and creates a variety of light and shade, which give great spirit, beauty, and effect, to the composition.

MOVER, or First Mover. See Mobile.

MOYER, Perpetual. See Perpetual Motion.

MOUGDEN, in Geography. See Chen-yang.

MOUHAN, a town of Hindooftan, in Lahore; 10 miles S. of Koothaub.

MOUKI, a town of Arabia, in the province of Hedijas; 60 miles S.W. of Mecca.

MOUK, The, a cape of Scotland, on the east coast of the island of Shetland. N. lat. 60° 24'. W. long. 1° 10'.

MOUL-, Head, a cape of Scotland, on the north coast of the island of Papa Weirka. N. lat. 59° 13'. W. long. 2° 45'. Also, a cape on the east coast of the island of Pomona. N. lat. 58° 52'. W. long. 2° 34'.

MOULAMKENG, a mountain of Tibet. N. lat. 36° 46'. E. long. 99° 36'.

MOULAPUDDY, a town of Hindooftan, in the province of Dindigul; 7 miles N.E. of Dindigul.

MOULAR, a town of Hindooftan, in the Carnatic; 10 miles N. of Tuggar.

MOULAN, Laz, a town of France, in the department of the Po; 3 miles S.W. of Sofoa.

MOULD, or Mold, in the Mechanic Arts, &c., a cavity artfully cut, with design to give its form, or impression, to some fitted matter applied in it.

Moulds are implements of great use in sculpture, foundry, &c.

The workmen employed in melting the mineral or metallic globule dug out of mines, have each their several moulds, to receive the melted metal as it comes out of the furnace; but these are different, according to the diversity of metals and works. In gold mines, they have moulds for ingots; in silver mines, for bars; in copper and lead mines, for pigs or falmons; in tin mines, for pigs and ingots; and in iron mines, for bars, chimney-backs, anvils, cauldrons, pots, and other large utensils and merchandizes of iron; which are here cast, as it were at first hand.

Moulds of Founders of Large Works, as statues, bells, guns, and other bronze works, are of wax, supported with frames, by what they call a core, and covered with a fort with a cap or case. It is in the space which the wax took up, which is afterwards melted away to leave it free, that the liquid metal...
metal was, and the work is formed; being carried therethrough a great number of little cans, which cover the whole mould. See Foundery.

Moulds of Menners are frames full of sand, in which the plates of metal are cast that are to serve for the striking of species of gold and silver. See Coining.

A fort of concave moulds made of clay, having within them the figures and inscriptions of ancient Roman coins, are found in many parts of England, and suppose to have been used for the casting of money.

Mr. Baker having been favoured with a sight of some of these moulds found in Shropshire, bearing the same types and inscriptions with some of the Roman coins, gave an account of them to the Royal Society.

They were found in digging of sand, at a place called Ryton, in Shropshire, about a mile from the great Watling-street road. They are all of the size of the Roman denarius, and of a little more than the thickness of a halfpenny. They are made of a smooth pot or brick clay, which seems to have been first well cleaned from sand and dust, and well beat or kneaded, to render it fit for taking a fair impression. There were a great many of them found together, and there are many of them not unexceptionably found in Yorkshire; but they do not seem to have been made with in any other kingdom, except that some have been found to be once found at Lyons. They have been sometimes found in great numbers, joined together side by side, on one flat piece of clay, as if intended for the casting a great number of coins at once; and both these, and all the others that have been found, seem to have been of the emperor Severus. They are sometimes found impressed on both sides; and some have the head of Severus on one side, and some well-known reverses of him on the other. They seem plain to have been intended for the coinage of money, though it is not easy to say in what manner they can have been employed to that purpose, especially those which have impressions on both sides, unless it may be supposed that they coinced two pieces at the same time by the help of three moulds, of which this was to be the middle one.

If by disposing these into fame fort of iron frame or cafe, as our letter-founders do the braze moulds for casting their types, the melted metal could be easily poured into them, it would certainly be a very easy method of casting; as such moulds require little time or expence to make, and therefore might be supplied with new ones as often as they happen to break.

These moulds seem to have been burnt or baked sufficiently to make them hard; but not so as to render them porous like our bricks, by which they would have lost their smooth and even surface, which in there is plainly to close, that whatever metal should be formed in them would have no appearance like the found-holes by which the counterfeit coins and medals are usually detected.

Moulds of Founders of Small Works are like the frames of coiners: it is in these frames, which are likewise filled with sand, that their several works are fashioned; into which, when the two frames of which the mould is composed are rejoined, the melted braze is run.

Moulds of Letter-founders are partly of lead and partly wood; the wood, properly speaking, serves only to cover the real mould which is within, and to prevent the workman, who holds it in his hand, from being incommoded by the heat of the melted metal. Only one letter or type can be formed at once in each mould. See Letter-Foundery.

Moulds, in the Manufacture of Paper, are little frames composed of several braze or iron wires, fastened together by another wire still finer. Each mould is of the bigness of the sheet of paper to be made, and has a rim or ledge of wood to which the wires are fastened. These moulds are more usually called frames or forms.

Moulds, Furnace and Crucible Makers', are made of wood, of the same form with the crucibles; that is, in form of a truncated cone; they have handles of wood to hold and turn them with, when, being covered with the earth, the workman has a mind to round or flatten his vessel.

Moulds for Lead or Bullets are little iron pincers, each of whose branches terminates in a hemispherical concave, which, when shut, form an entire sphere. In the lips or sides, where the branches meet, is a little jet or hole, through which the melted lead is conveyed.

Moulds, Laboratory, are made of wood, for filling and driving all sorts of rockets and cartridges, &c.

Moulds, Glaziers. The glaziers have two kinds of moulds, both serving to cut their lead: in one they call the lead into long rods or canes to be drawn through the vice, and the grooves formed therein; this they sometimes call ingot-mould. In the other they mould those little pieces of lead a line thick, and two lines broad, fastened to the iron bars. These may be also cast in the vice.

Moulds, Goldsmiths'. The goldsmiths use the bones of the cuttle-fish to make moulds for their small works; which they do by pressing the pattern between two bones, and leaving a jet or hole to convey the silver through, after the pattern has been taken out.

Mould, among Majons, is a piece of hard wood or iron, hollowed within side, and wearable to the contours of the mouldings or cornices, &c. to be formed. This is otherwise called a calder.

Mould, a cavity formed in the external surface of a body, intended to be cast of liquid or soft matter, which after a certain time will acquire solidity.

Mould, in Majonery, is a templet made to a section of the bone intended to be cut. The ends or heading-joints being formed as in a cornice by means of the mould, the intermediate parts are wrought down by straight edges or circular templets, according as the work is straight or circular, upon the place. When the surface intended to be made is required to be very exact, a reverse mould is used in order to prove the work, by applying the mould in a transverse direction.

Moulds, among Plumbers, are the tables on which they call their sheets of lead. These they sometimes call simply tables. Besides these they have other real moulds, with which they call pipes without folding. See each described under Plumbery.

Moulds, among the Glass-Grinders, are wooden frames, on which they make the tubes with which they fit their perspectives, telescopes, and other optic machines.

These moulds are cylinders, of a length and diameter according to the use they are to be applied to, but always thicker at one end than the other, to facilitate the filing. The tubes made on these moulds are of two kinds; the one simply of palleboard and paper; the other of thin leaves of wood joined to the palleboard. To make the tubes to draw out, only the leaf or innermoit is formed on the mould; each tube made afterwards serving as a mould to that which is to go over it, but without taking out the mould from the fir. See Grinding.

Moulds used in basket-making are very simple, confiding ordinarily of a willow or other turnen or bent into an oval, circle, square, or other figure, according to the baskets, panniers, hampers, and other utensils intended. On these moulds they make, or, more properly measure, all their work:
work: and, accordingly, they have them of all sizes, shapes, &c.

Moulds, in Ship Building, are the shapes of the various timbers, knees, &c. made of board from the lines on the mould-loft floor, for the purpose of sawing out the various timbers, &c. to the shape required. Also thin flexible pieces of pear-tree or box, used in drawing the draughts and plans of a ship.

Moulded is a long even floor, on which the ship is laid-off to its full size, from the draughts and several other operations, which will be correctly explained in the article Ship-Building.

Moulds, among Tallow Chandlers, are of two kinds: the first for the common dipped candles, being the vessel in which the melted tallow is disposed, and the wick dipped.

This is of wood, of a triangular form, and supported on one of its angles, so that it has an opening of near a foot at top: the other, used in the fabric of mould candles, is of brass, pewter, or tin. Here each candle has its several mould. See each under CANDLE.

Moulded, among Gold Beaters, a certain number of leaves of vellum, or pieces of guts, cut square, of a certain size, and laid over one another, between which they put the leaves of gold and silver which they beat on the marble with the hammer. See Gold-Leaf.

They have four kinds of moulds; two of which are of vellum, and two of gut: the smallest of these leaves consists of forty or fifty leaves; the largest contains a hundred: for the others, each contain five hundred leaves.

The moulds have all their several cases, confining of two pieces of parchment, serving to keep the leaves of the mould in their place, and prevent their being disordered in beating.

Mould, or Mold, in Agriculture, the loose friable particles of earth or soil which are met with on the surface of the ground, called also natural or mother earth. (See Earth and Loam.) It is of different qualities in different situations. The properties of mould are in some measure distinguished by their appearance, those of a bright chucknut or hazel colour being generally good, as of this colour are the best loams, and also the best natural earths; and it is an advantage if they cut like butter, and do not flick obliquely, but are short; and tolerably light, breaking into small clods, and won't crumble or chopping in dry weather, or turning to mortar in wet. The next to these are the dark grey and ruflet moulds: the light and dark-coloured, such as is usually found on common heavy ground, is inferior, and the yellowish-red coloured the worst of all: this is commonly found in wild and waste parts of the country, and for the most part produces nothing but gorse, furze, and fern, according as the sub-folls are more or less of a light and sandy, or of a spewy gravel, or clayey nature. In all moulds of lands that are good, after rain, or breaking up, they emit a good smell. It is easily discovered by the touch whether they consist of sub-folls entirely arenaceous or clayey, or whether they be tender, fatty, detritive, or flippery; or more hard, gritty, porous, or friable.

Those moulds that have a blackish appearance, and contain much carbonaceous matter, are always found rich and good in the counties of the farmer.

It is of wall utility to have the mould of all the fliffer sorts of soil well broken down, and reduced before feeds of any kind are sown upon them. This is capable of being effected in various ways, as by turning them up in sharp ridges in the autumn, in order to have the action of the frost in the winter, and by frequent harrowing and rolling them with rollers proper for the purpose. Also by the proper use and application of the cultivator, scariifer, and furrower. See these different tools.

Moulds, according to Mr. Da Costa, are compound soils, of a loofe soft texture, somewhat ductile while moist, and composed of earthy particles, mixed with the putrefied remains of animal and vegetable bodies. He distinguishes them by their colours into the black, not acted upon by acids, to which belongs the common vegetable mould, or garden earth; the red, which is alkaline; and the brown, some of which are not acted upon by acids, and others alkaline.

Moulds, according to Kirwan, (Elem. of Mineralogy, vol. 1.) are loams (see Loam), mixed with animal and vegetable remains, particularly from putrefaction; generally of a black, brown, yellowish, or greyish-brown colour. The properties of these are highly interesting to agriculture, and may be pretty nearly determined by comparing their weight, when dried, at 140° Fahrenheit from the earth; at which they lose by being heated to redness in an open fire, continued as long as any coaly substance remains in them; yet not exactly, without some nicer operations, as the animal earths will retain undetermined, and also the vegetable ashes.

To analyse mould by means of water, Shaw proposes to wash it thoroughly in warm water in large quantities, and then to filtrate the liquor. Afterwards evaporate this to a considerable degree of concentration, and it is manifestly of a saline tarte, but making no alteration in syrup of violets; therefore the salt it contains is neither acid nor alkaline, but neutral. This analysis purified further, the particles may be difinuted and kept separate, and will be found to be a large proportion of sand, a quantity of a light mud, capable of remaining a long time suspended in water, and a heavier mud sinking immediately in water. By an analysis of any particular mould by this means, we may find its true constituent particles, and be able to mix up and compound a similar one for the growth of any peculiar plant it produces. But plants have the affability of heat as well as moisture, in the degree of temperature from the earth; therefore it may not be improper to try the effect of fire on the same subject. The common garden mould distilled in a retort in a naked fire, managed in its various degrees, affords a water, an oil and spirit like those yielded by animal subjests, and possibly arising from some extraneous particles mixed with the earth, and a dry caput mortuum, or indolent earth, remains in the retort.

The particles of animal, vegetable, and mineral substances, floating in the atmosphere, and thence precipitated on the earth, may give some of the properties to garden mould, and those different in different places; as is evident about London, where the mould is so impregnated with smoke, precipitated on it from the atmosphere, that it differs much from that of open countries. Shaw's Lectures, p. 64.

Mould, in Gardening, such earthly substances as constitute foils, when reduced into a fine pulverized state in their particles. It is of different qualities, according to the nature of the earth or foil in which it is found. But the best for the general purposes of gardening is probably that which contains a large proportion of carbonaceous or vegetable matter. It is of very different colours in different soils, as hazel, dark-grey, ruflet, ash, yellowish-red, and various others. But the first three colours are generally considered as denoting the best qualities, and the last the most unfriendly to the growth of vegetables.

Those moulds which are capable of working well at all seasons,
feasons, are rather light and dry, perfectly mellow and fine in their particles, being well enriched with vegetable and animal matters, are mostly preferred, and capable of affording the largest crops of good vegetables of the different kinds. See Earth and Soil.

Mould on Hops, in Rural Economy, a vegetable disease, which is liable to affect the hop plant in the more advanced periods of its growth, and produce much mischief to the crop. See Fenn.

Mould, Vegetable, in Agriculture, that sort of mould which is chiefly formed from the reements of decayed vegetables. It forms the surface stratum of molt foils, and is, in general, of a more dark colour than that which is below it. See Soil and Vegetable Mould.

MOULDINESS, a term applied to an appearance in bodies which are much exposed to the humidity of the atmosphere, and which show itself by a kind of white down, or lume, on their surface. It is liable to affect different articles of farm produce, unless guarded against by deposing them in proper dry places. See Mucor.

This mouldiness, when viewed with a microscope, affords a curious spectacle: being a kind of meadow, out of which arise herbs and flowers; some only in the bud, others full blown, and others decayed; each having its little root, stalk, and other parts; the figure of which may be seen in Hook’s Micrographia. The same may be observed of the mouldiness which gathers on the surface of liquid bodies.

Mr. Bradley observed this mouldiness in a melon very accurately, and found the vegetation of these little plants to be exceedingly quick. Each plant had its feeds in great abundance, which did not seem to be three hours before they began to shoot up; and in six hours more the new plant was complete and mature, and the feed ready to fall. When the fruit had been covered with a mould for fix days, its vegetation quality began to abate, and it was entirely gone in two days more; then came on a putrefaction, and the fleithy part of the melon yielding nothing but a flecing water, which began to have a gentle motion on its surface; and in two days’ time maggots appeared, which in fix more hid themselves up in their bags, where they continued four days, and then came out: These maggots were owing to the eggs of flies deposited in the putrefaction.

Moulding, any thing cast in mould, or that seems to have been so, though in reality it were cut with a chisel, or the axe.

Moulding, in Architecture, an ornamental surface, such that all its transverse sections are equal and similar throughout the length, the transverse sections being those which are everywhere perpendicular to the edge or edges of the said ornamental surface.

A regular moulding has either contrary, curved, circular, or elliptic sections. See Cymatium, Cyma-Retta, Cyma-Recta, Echinus, Ovolo, Quarter-Round, Cavetta, Scotia, Apophysis, Scape, &c. and Plate XXI. Architecture.

Mouldings in assemblage are used in the formation of cornices, architraves, bases, capitals, &c.

Mouldings are either plain or enriched with eggs, and with foliage displayed in a variety of forms. Some enrichments are peculiar to certain forms of mouldings, as eggs and anchors, or egg and tongue to the ovolo. See Plate XXI. Architecture.

Mouldings, in Gunery, are annexed to guns by way of ornament, and depend chiefly on the maker’s fancy.

It may be observed, in general, that they should be plain and simple, and the metal should be projected as little as possible, so that the piece may lie close on the carriage. See Cannon.

Moulding, the act of marking out the slope of any timber, &c. from a mould given, as when it is to cut, it is said to be moulded, which is the contrary dimension from fiding. See Sided.

Moulding, Bed. See Bed-Moulding.

Moulding, Plane. See Plane.

MOULE, Lé, in Geography, a town of the island of Guadaloupe, on the N. coast. N. lat. 16° 36’. W. long. 62° 27’.

MOULIN, Charles Duc, in Biography, a French jurist, was born at Paris, of an ancient family, in the year 1560. He was dilligentlich from his early years by the facility with which he took his education. He acquired the rudiments of learning at Paris, and went to study the law at Orleans and Poitiers. He was admitted an advocate at the age of twenty-two, and acted six years as a pleader; but an impediment in his speech obliged him to retire from practice. He now devoted himself to literature, and became greatly celebrated as an author. In 1539, he published a work, entitled “Commentaire sur les Matières Écclésiastiques de la Contumie de Paris;” and in 1551, “Observations sur l’Édit du Roi Henri II. contre les Petites Dames.” This edict had arisen from the hostility between the court of France and Rome; and Du Moulin, in his work, warmly advocated the liberties of the Gallican church, which gave so great offence to the papal court, that the parliament of Paris found it necessary to pass a decree for its suppression. The zealous Catholics found means to excite the populace against him as a favourite of heresy. His house was pillaged; he quitted Paris, and retired to Germany for safety. He employed himself several years at different towns in that country, and in Burgundy, in giving lectures on the law with great reputation. He returned to Paris, after having endured an imprisonment of four months for refusing to undertake an unjust cause; but in 1562, he quitted the metropolis, on account of the religious wars. Two years afterwards he came back, and was thrown into the Conciergerie, for a work which he printed that regarded the council of Trent. He died in 1566. He had for many years been considered in France as an oracle of jurisprudence, and of an authority equal to that of the greatest names in the science, ancient or modern. Of his own superiority he was fully sensible, and did not scruple to entitle himself “The Doctor of France and Germany;” and he would sometimes prefix to his opinions, “I, who am fecundo to no one, and whom no one can teach any thing.” His works were collected and printed in five volumes folio. Mancini.

Moulin, Peter Duc, a learned French Protestant divine, was born at Baith, in the Vexin, in 1553. He pursued his studies, first in Paris, and afterwards in England; and from this place he proceeded to the university of Leyden, where he became a professor, and taught philosophy with applause. Being admitted to the ministry, he undertook the pastoral duty of a Protestant church of Charenton near Paris, and was soon after appointed chaplain to Catherine de Bourbon, princeps of Navarre, and filler of Henry IV. In 1615, he visited England, and James I. presented him with a prebendary of Canterburia. He afterwards went to Sedan, and became professor of divinity, and had entrusted to him the principal management of the concerns of the Protestants in France. He died in 1578. He wrote a great number of works, of which the principal are “The Anatomy of Arminianism,” in Latin; “A Treatise on the Keys of the Church;” “The Capuchin, or Hillary of the Monks;” and
and "A Defence of the Reformed Churches." A vein of severe satire is said to run through several of his controversial pieces. Moreni.

MOULIN, PETER DU, son of the preceding, and a clergyman of the church of England, was born, it is supposed, at Paris, about the year 1600. He studied at Leyden, where he was admitted to the degree of doctor of divinity. He afterwards came to England, and was incorporated in the same degree at the university of Cambridge. He was patronized by Richard, earl of Cork, who appointed him governor to his sons, whom he afterwards accompanied to Oxford. Here Du Moulin remained two years or more, and preached frequently in the church of St. Peter in the East. After the restoration of Charles II. he was appointed chaplain in ordinary to his majesty, and given a prebend at Canterbury, where he spent the remainder of his life. He died in 1654, in the eighty-fourth year of his age. He was author of several works, of which we may mention, 1. The Peace of the Soul; 2. A Defence of the Protestant Religion. He was author of the famous work, entitled "Regii Sanguinis Clamor ad Coelum," which was published at the Hague, in 1672, by M. Alexander More. Anthony Wood gives him the character of an honest, zealous Calvinist. Moreni.

Wood's Athen. Oxon.

MOULIN. Fer de Moulin. See Fer.

MOULINET, a French term properly signifying a little mill, being the diminutive of moulin, mill.

It is used in mechanics to signify a roller, which, being crossed with two levers, is usually applied to cranes, capstans, and other sorts of engines of the like nature, to draw ropes, and heave up stones, timber, &c.

MOULINET is also a kind of turn-flite, or wooden cross, which turns horizontally upon a flake fixed in the ground; usually placed in the passages to keep out horSES, and to oblige passengers to go and come one by one.

These moulinet are oftenet near the outworks of fortified places, at the sides of the barriers, through which people pass on foot.

MOULINS, GUARDES, in Biography, a French priest and canon, who flourished towards the close of the 13th century. He is mentioned as being the first person who gave a translation of a considerable portion of the Scriptures in the French language. He was promted, in 1277, to the deanship of his chapter, after which we hear no more of him. His translation was printed in 1487, by order of Charles VIII. Moreni.

MOULINS, in Geography, a town of France, and principal place of a district, in the department of the Allier, before the revolution the capital of Bourbonnais, situated on the Allier, and esteemed one of the pleasanter towns in France, having broad and clean streets: its principal trade consists in cutlery; and near it is a medicinal spring. The E. partition contains 7000, and its canton, 11,074 inhabitants, in seven communes. Its W. division contains 6520, and its canton 10,525 inhabitants, in 10 communes. Its whole territory comprehends 355 square miles. N. lat. 40° 35'.

E. long. 3° 24'.

MOULINS-en-Gilbert, a town of France, in the department of the Nièvre, and chief place of a canton, in the district of Château-Chinon; seven miles S.W. of it. The place contains 1960, and the canton 8400 inhabitants, on a territory of 410 square kilometres, in nine communes. N. lat. 46° 59'.

E. long. 3° 53'.

MOULINS-la-Marche, a town of France, in the department of the Orne, and chief place of a canton, in the district of Mortagne; 18 miles N.E. of Alençon. The place contains 878, and the canton 7781 inhabitants, on a territory of 1925 square kilometres, in 20 communes.

MOULONGE, a cluster of small islands in the Indian sea, near the coast of Africa. S. lat. 1° 45'.

MOULTAN, a province of Hindostan, lying principally on the E. side of the Indus; bounded on the N. by Lahore, on the E. by Delhi, on the S. by sandy deserts, that separate it from Agimere, and on the W. by Persia. It belongs at present to the people called Seiks; and its productions are cotton, sugar, opium, galls, brimstone, &c. Its trade in the time of Aurungzebe was flourishing; but at present it is inconsiderable, on account of the rapacious diPersion of its poiffeItors.

MOULTAN, a city of Hindostan, the capital of the forementioned province, and one of the most ancient towns of Hindostan. Although it is a place of small extent for the capital of a viceroyalty, it is strongly fortified, and much celebrated for its pagoda, which is held in great veneration by the Hindoos. It has, or lately had, a great manufacture of cottons; but its trade has much declined, partly because the river that led to it has been in a great measure choked up, and its channel spoilt. This is the modern capital of the country designed by the historians of Alexander for that of the "Mall," although the ancient capital stood nearer to Toulumba. Moulton has been garrisoned ever since the year 1775, by the king of Candahar's troops. N. lat. 29° 34'.

E. long. 71° 21'.

MOULTING, among Farmers, a term signifying the changing of the feathers in animals of the domestic bird kind. It is a process which takes place annually towards the latter end of the year, when care should be taken to have them well fed, and kept as much as possible in a sheltered situation. In some forms of birds, as the goose, advantage is taken of this season for collecting the feathers for various useful purposes.

MOULTING in Horses, a term sometimes applied to horses, when they alter, change, or call their coats towards the latter end of autumn. As they become weak at this period, they should be well kept, and not have too much work. Great care should, likewise, be taken in the cleaning and dressing of them.

MOULTING, in Natural History. See Moulting.

MOULTONBOROUGH, in Geography, a town of America, in New Hampshire, now called New Hampton; which see.

MOULTRIE, Fort, See Sullivan's Island.

MOULTRIEVILLE, a town lately settled on Sullivan's Island, South Carolina. It is a place, containing 200 dwelling houses, much resorted to by the inhabitants of Charleston, during the summer and autumn, both for pleasure and health.

MOUND, a term used for a bank, rampart, or other fence, particularly of earth; or of earth and stone. Mound, or Mound, in Heraldry, is a ball or globe with a crois upon it; such as our kings are usually drawn with, holding it in their left hand, as they do the sceptre in the right.

MOUNEGES, in Geography, a cape on the S.E. coast of the island of Unk, one of the Shetland Islands. N. lat. 61° 41'.

W. long. 1° 2'.

MOUNT; an elevation of earth, called also mountain.

The words mount and mountain are synonymous; but the former is scarcely ever used in prose, unless when accompanied with some proper name; as mount Aetna, mount Gibe, mount Lebanon, mount Sinai, mount Atlas, mount Parasitus, &c.

Mount
Mount Airy, in Geography, a town of America, in Surry county, Carolina; 400 miles from Washington.

Mount Baker, a mountain on the W. coast of North America. N. lat. 48° 39'. E. long. 238° 50'.

Mount Battie, a mountain of Scotland, in the W. part of the county of Kincardine; 16 miles N.W. of Bervie.

Mount's Bay, a bay in the English channel, on the S. coast of the county of Devon, between the Land's End and Lizard Point. N. lat. 50° 7'. W. long. 5° 20'.

Mount Bethel, Upper and Lower, two townships of America, in Northampton county, Pennsylvania; both containing 2234 inhabitants.

Mount Calder, a barren mountain, which forms the extreme S. point of Port Protection, in the N.W. part of the Prince of Wales's Archipelago.

Mount Calvarya. See CALVARY.

Mount Camel, a mountain of New Zealand, at the N. extremity of Eaheinomauwe; 30 miles S.S.E. of Cape Maria Van Diemen.

Mount Campbell, a mountain on the N.E. coast of Kerguelen's land. S. lat. 45° 12'. E. long. 70° 20'.

Mount Carmel, Knight of. See Carmel.

Mount of Cocos, in Geography, an island in the South Pacific ocean, discovered by LeMaire and Schouten in the year 1616. The island is said to be high and covered with trees, particularly those of the cocoa-nut; the inhabitants are handsome, strong, and well proportioned, having hair of various colours, which is worn in different forms; they are thieves, and anxious to obtain iron. The navigators procured cocoa-nuts, bananas, yams, some small hogs, and fresh water. This island is called by the natives "Kootaaee." S. lat. 16°. E. long. 177°.

Mount Desert, an island, consisting of a valuable tract of land, on the coast of Hancock county, in the state of Maine. On the S.E. side are two considerable islands, called "Cranberry islands," which serve to form a harbour in the gulf that lets up on the S. side of the island. The whole island contains 1121 inhabitants. The northern part was formed into a township, called Eden, in 1796. The south-easternmost part of the island lies in about N. lat. 44° 12'. W. long. 68° 10'. On the main land, opposite to the N. part of the island, are the townships of Trenton and Sullivan. It is 353 miles distant N.E. from Boston.

Mount Edgecombe. See EDGECOMBE.

Mount Edgecumb, a mountain or eminence on the W. coast of the entrance into Plymouth harbour, on the coast of Devonshire. N. lat. 50° 21'. W. long. 4° 8'.

Mount Egg, in Mining. In the tin-works, after the tin from the burnt ore is melted down, and re-melted, there will sometimes remain a different slig in the bottom of the float; this they call mount-egg; and though of a tin-colour, yet it is of an iron nature, as hath been found by applying a magnet to it.

Mount Fairweather, in Geography, a mountain on the W. coast of North America; 12 miles N.E. of Cape Fairweather.

Mount Felix, a lofty cape on the N.E. coast of Africa, at the entrance of the Arabian gulf; 40 miles W.N.W. of Cape Guardafui. N. lat. 12°. E. long. 50° 40'.

Mount Gardner, a mountain and promontory on the S.W. coast of New Holland, forming the E. boundary of King George III's Sound. S. lat. 35° 4'. E. long. 118° 29'.

Mount Guard, in Military Language. See GUARD.

Mount Helby, in Geography, a mountain of considerable height in the island of Barbadoes.

Mount Hillary, or St. Hillary's Mountains, some mountains of Ireland, in the county of Cork, S. of the river Blackwater; between Mallow and Millstreet.

Mount Holly, a town, or rather a village, with a post-office, in Burlington county, New Jersey, on the banks of Anaconus creek, 12 miles S.E. of Burlington.

Mount Holly, a township in Rutland county, Vermont, formed out of a part of Wallingsford, a part of Ludlow, and a gore of land between them; containing 668 inhabitants.

Mount Hope Bay, a bay on the N.E. part of Narraganset bay.

Mount Jolin, lies on the northern coast of the gulf of St. Lawrence, in Labrador; and "Mount Island" lies on the same coast, in N. lat. 50° 5'. W. long. 61° 35'.

Mount Joy's, a Moravian settlement in Pennsylvania; 16 miles from Lititz.—Also, the name of two townships in Pennsylvania; the one in Lancaster, the other in Adam's county.

Mount Leinster, a high and rocky mountain of Ireland, in the county of Wicklow, on the borders of Wexford. It consists of granite. It is about 12 miles S.S.E. from Carlow.

Mount Major, a mountain of America, in New Hampshire, on the side of lake Winnipesaukee. N. lat. 43° 25'. W. long. 71° 20'.

Mount Misery, a mountain of the island of St. Christopher, near the W. end.—Also, a town of America, in the state of Connecticut; eight miles N.E. of Norwich.

Mount Olympia, in Ancient Geography. See OLYMPUS.

Mount Olympia, in Geography, a mountain on the W. coast of North America. N. lat. 47° 50'. E. long. 236° 24'.

Mount Orgueil Castle, called also "Gowray castle," from an adjacent village, derives its name of Orgueil from the promontory on which it is situated, which was given to it, according to vulgar tradition, by Henry V., or rather by the duke of Clarence. Of this edifice in the Isle of Jersey, we have historical record as early as the reign of John, before whose time it had been a considerable fortres, and by whom it was repaired and re-fortified. This castle still stands, and presents to the observer a grand appearance, though in a state of decline; five miles W. of St. Helier. Mount Parker, a mountain on the N. coast of Chatham, in the North Pacific ocean; 10 miles W. of Cape Young.

Mounts of Piety, are certain funds, or establishments, in Italy, where money is lent out on some small security. We had also mounts of piety in England, raised by contributions for the benefit of people ruined by the extortions of the Jews.

The name "mons pietus" came with the invention from Italy, and is equally old, if not older. Funds of money formed by the contributions of different persons, for some specified end, were long before called "montes." In the first century of the Christian era, free gifts were collected and preferred in churches by ecclesiastics, partly for the purpose of defraying the expense of divine service, and partly to relieve the poor. Such capitals which were considered as ecclesiastical funds, were by Prudentius, in the beginning of the fifth century, called "montes annonae," and "area nummis." Tertullian (Apolog. cap. 39) calls them "deposita pietus," and hence has been formed the denomination of "montes pietae."

In procures of these banks, that were employed in Italy, during the thirteenth and fourteenth centuries, to borrow money in the name of states, for which the public
MOUNTAIN and rivers; On the 799th mile this is a mountain of considerable elevation, and is celebrated for its picturesque scenery. The mountain is covered with forest, and the landscape is diversified by the winding courses of the streams that flow from its base. The mountain is a popular resort for hunters and sportsmen, and is noted for its deer and other game. The mountain is also a source of water power for the surrounding townships, and is a valuable resource for the community.

MOUNTAIN, a mountain of North America, in New Georgia. N. lat. 47° 3'. E. long. 238° 2'.

MOUNT ST. HELEN'S, a mountain on the W. coast of North America. N. lat. 46° 9'. E. long. 205° 1'.

MOUNT STEPHEN, a mountain on the W. coast of North America; five miles N. of Point Philip.

MOUNT TAMALPAIS, a small peak-town of Ireland, in the county of Roscommon, situated on the river Suck, and 76 miles W. by N. from Dublin.

MOUNT TURA, a place of America, in Parson county, North Carolina, having a post-office; 296 miles from Washington.

MOUNT TOM, a noted mountain of America, on the W. bank of Connecticut river, near Northampton.—Also, the name of a mountain between Litchfield and Washington, in Connecticut.

MOUNT VERNON, a town of America, in Kennebec county, and state of Maine; 17 miles N.W. of Hallowell.

MOUNT VERNON, the seat of the late George Washington, pleasantly situated on the Virginia bank of Patowmac river, in Fairfax county, Virginia, where the river is nearly two miles wide; nine miles below Alexandria, 127 from Point Look-out at the mouth of the river, and 280 miles from the sea. The area of the mount is 200 feet above the surface of the river; and after furnishing a lawn of five acres in front, and about the same in rear of the buildings, falls off rather abruptly in those two quarters. On the N. end it subides gradually into extensive pasture-grounds; while on the S. it slopes more steeply, in a short distance, and terminates with the coach-house, stables, vineyards, and nurseries. On either wing is a thick grove of different flowering forest trees. Parallel with them, on the land side, are two spacious gardens, into which one is led by two serpentine gravel walks, planted with weeping willows and shady shrubs. The mansion-house itself appears venerable and convenient; and viewed from the land side, the whole assemblage of buildings bears a resemblance to a rural village. A small park on the river, where the English, American, and the American wild deer are seen through the thickets, alternately with the woods as they are falling along, give a romantic and picturesque appearance to the whole scenery. On the opposite side of a small creek to the northward, an extensive plain, exhibiting corn-fields and cattle grazing, affords in summer a luxuriant landscape; while the blended verdure of woodlands and cultivated de- cilians, on the Maryland shore, varie gates the prospect in a charming manner. Such are the philosophic shades to which the commander-in-chief of the American army retired in 1783, at the close of a victorious war; which he again left in 1786 to dignify with his unequaled talents the highest office which his fellow-citizens could confer; and after again retreated in 1791, loaded with honors and the benedictions of his country. Here, in 1795, he again heard and obeyed the call of his endangered country, to command her armies, but was at length summoned on the 14th of December 1799 to join the heavenly hosts. More. See WASHINGTON.

MOUNT WASHINGTON, a mountain on the E. coast of New England. S. lat. 28° 27'.

MOUNT WASHINGTON lies in the upper part of the island of New York.—Also, one of the highest peaks of the White Mountains, in New Hampshire.—A fo, the south-western most township of Massachusetts, in Berkshire county, 236 miles W. by S. from Boston; incorporated in 1779, and containing 201 inhabitants.

MOUNTAGU, RICHARD, in Biography, a learned prelate of the church of England, and an excellent writer on ecclesiastical antiquities, was born in 1728, at Dorset. He was educated in the classics at Eton, and thence he proceeded, in 1754, to King's college, Cambridge. He rose rather rapidly in the church, and in 1680 he edited, in Greek, "Gregory Nazianzen's Inventions against Julian," with the notes of Nomiuss. In 1634 he published a piece in answer to a pamphlet, entitled "A Gap for the New Gospel." Mountagu's reply was entitled "A New Gap for an Old Goole;" this was viewed by some of his opponents in a very serious light, and a prosecution was commenced against him, but he had skill enough to evade it by applying to the king to be allowed to appeal to himself. James conferred, and the work was entitled "Appello Cæsarem." This appeal increased the number of his enemies, but in proportion to the odium hæpped upon him, he increased in favour at court, and in 1628 he was promoted to the bishopric of Chichester, though he was at that very time under the censure of the house of commons. He now applied himself to his favourite subject, church antiquities, and published, in 1635, "Originum Ecclesiasticarum Apparatus," Thomas the elder. In 1638 he was translated to Norwich, in which he became distinguished as a percursor of the Puritans. In 1640 he completed his "Originum Ecclesiasticarum," and died in the following year. He was author of many other works, enumerated in the Biog. Brit. to which the reader is referred.

MOUNTAINS, MOUNTAINOUS Country, &C. In the language of common life, the more considerable of those inequalities with which the surface of the earth is diversified are generally termed mountains, while those of inferior elevation are distinguished by the appellation of hills. It is unnecessary to point out the insufficiency of this popular but...
but vague distinction, for which, by the geologists of the present day, especially those of the Werreraian school, a division has been substituted, which is far better adapted to the present advanced state of geography and physical geography.

The inequalities on the surface of the earth may be divided into two great classes, viz. the bottom of the sea, and the dry land; for the former of these, see the article Sea. The dry land, with regard to its inequalities, is divided into high land and low land; the former denoting an uneven tract of land considerably elevated above the level of the sea; the latter conveying the idea of an extensive country quite flat, or of inconceivable elevation above the sea, chiefly composed of plains, but also hilly where it borders on alpine country; and if groups of mountains occur in it, these are always small, and occupy its central part.

High land is principally composed of alpine, mountainous, and hilly land; here and there also some plains occur in it.

Alpine land is formed of groups of mountains, which again are composed of mountain chains, or connected series of single mountains. Mountain groups are generally highest in the middle, and each of them, in an alpine country, takes a particular direction; they are separated from each other by plains and valleys, but more frequently by mountainous or hilly country. Each group constitutes a connected whole, both with regard to its base and its activity; it is not, however, an entire mass, but intermixed in many places, though never quite down to its foot or base: where the latter takes place, the mountain group is considered as terminated.

The second feature in the general aspect of high land is mountainous land; it is composed of single mountains collected into chains, which, however, not being joined together by a central or high mountain chain, are never seen to form groups.

The third component part of high land, is hilly land: which consists of gentle rounded undulated elevations; it is much lower than the preceding, and by means of the plains, which sometimes constitute a part of high land, forms a transition into low land.

In considering the various parts of which alpine land is composed, we observe that a mountain group always consists of several mountain chains, the highest part of which, extending through the whole group without being intersected, is called the high mountain chain, or also the high middle chain, in cafes where its situation is nearly in the middle of the groups, from which a great number of inferior chains proceed under various angles, which form the activity of the group, and are called subordinate and lateral chains. They vary in magnitude and extent; the most considerable, called also chief mountain chain, is that which, proceeding from the middle of the high mountain chain, reaches to the foot of the group; the other chains either from the foot of the group towards the principal mountain chain, but never reach the high mountain chain; or they proceed from the high mountain chain, without however reaching the foot of the group. The summit of a mountain chain is called its ridge, that of the highest chain the highest ridge. The concavities in a mountain group, which generally run parallel with its longitudinal direction, or separate one chain from another, are called valleys; which are.

Mountain groups, with regard to their extent, are divided into principal groups, or such as are from 30 to 30 geographical miles in length, for influence, the Alps of Switzerland, and Pyrenees into middle-sized mountain groups (Mattelgebirge), which have an extent of from 10 to 20 geographical miles, such as the Hartz mountains, the Riegengebirge, &c.; and into small mountain groups, which are only from two or three to ten geographical miles in length. With regard to their height, mountain groups are called high, if their elevation exceeds 1000 to 15000 feet, or 7000 to 10000 toises above the level of the sea; such as several mountain groups of Bohemia, Franconia, &c. Low mountain groups are from 100 to 500 toises, or from 700 to 2500 feet high. Generally the length of a mountain group is proportionate to its height, and to the breadth of its base. If the length and the breadth of the base be nearly alike, the mountain group is called massive; if, on the other hand, the length is very considerable in comparison of the breadth of the base, it is denominated a long mountain group.

Another distinction of mountain groups is derived from the difference in the form and the connection of the mountains and mountain chains of which they are composed. Thus we have common, alpine, and conic mountain groups. The common mountain groups have a middle-sized, lengthened principal mountain chain, which gives out shorter lateral chains, and the individual mountains of which these chains are composed are finely aggregated in rows; they are mostly mountain groups of an intermediate height and extent. In the conical groups the individual mountains are for the most part singly aggregated like the preceding, but only joined together at their foot, or not higher up than the declivity, by which the conical form is produced, which principally characterizes the mountains of the alps-vaux formation. The alpine mountain group does not consist, like the common group, of simple rows of mountains, the summits of which are finely projecting, but as it were of pyramidally aggregated clusters, and is therefore to be considered as a double aggregation. The alpine mountain groups are the most extensive, and their highest ridges and summits generally consist of granite.

With regard to the different parts of single mountains, we distinguish the foot, the acclivity, and the summit. The foot is generally very flat, and more or less extensive; the acclivity, or the space between the foot and the summit, is the most considerable and usually the steepest part of the mountain, sometimes even forming perpendicular precipices. The foot is generally gradual and the acclivity of a mountain, the richer it generally grows in ores. The summit varies both with regard to its steepness and shape, which latter is for the most part indicative of the nature of the rock of which it is composed; gneifs and transition rocks forming flat or round-backed; clay slate conical, and basalt, &c. short and obtuse conical summits. While granite and lime-flour mountains are often characterized by sharp-pointed summits or peaks. If several of the mountains in a group are flattened, such a ridge is called a plateforme. Very steep and lofty summits are called peaks, needles, (aiguilles,) horns. Sometimes the summit is marked by a depression; sometimes it is intersected by ravines, and the inequalities thus formed are called gaps or kappen.

Though mountains have been emphatically called "la charpente et l'ouvrage du globe terrestre," yet even the most elevated of them must appear as slight ruggosities only, when their proportion to the diameter of the earth is considered: for the highest mountain of Europe, the Montblanc, is, on the surface of our planet, what the protuberance of a line would be on the surface of a globe of about 21 feet in diameter. It is not a long time that we have obtained correct notions of the heights of mountains; before the barometer was applied to the measurement of altitudes, their
Table of the Heights of Mountains and Hills.

Jameson's Mineralogy, vol. iii.

The circumstance of one side of a chain of mountains, or of a single mountain, being in general steeper than the other, has given origin to an instructive paper by Mr. Kirwan, "On the Declivities of Mountains," of which the following is an abstract. The theory, according to which this natural attempts to explain the phenomenon in question, will constitute part of another article.

That one part of almost every high mountain is steeper than another, could not have escaped the notice of any person who had traversed such mountains; but that nature, in the formation of such declivities, had any regard to different aspects or points of the compass, seems to have been first remarked by the celebrated Swedish geologist, Mr. Tilsas, in his third volume of the Memoirs of Stockholm for 1758. Neither Virnemet, Ludolph, nor Buffon, in his Natural History, published in 1748, have noticed this remarkable circumstance. The observation of Tilsas, however, relates only to the extreme ends, and not to the flanks of the mountains. With respect to the former, he remarked that the steepest declivity always faces that part of the country where the land lies highest; and that in the southern and eastern parts of Sweden, they consequentially face the east and south-east, and in the northern west. The essential part of this observation extends, therefore, only to the general elevation or depression of the country, and not to the bearing of their declivities.

The discovery, that the different declivities of the flanks of the mountains bear an invariable relation to their different aspects, seems to have been first published by Bergmann, in his Physical Description of the Earth, of which the second edition appeared in 1773. He there remarked, that in mountains that extend from north to south, the western flank is the steepest; and that in mountains which run east and west, the southern declivity is the steepest, and the northern the gentlest. This assertion he grounds on the observation related in his first volume, namely, that in Scandinavia, the Svevoberg Mountains that run north and south, separating Sweden from Norway, the western or Norwegian sides are the steepest, and the eastern or Swedish the most moderate; the verticality or steepness of the former being to that of the latter as 40 to 50 to 4 or 2: that the Alps are steeper on their western and southern sides, than on the eastern and northern; that in America the Cordilleras are steeper on the western side, which faces the Pacific Ocean, than on the eastern. But he does not notice a few exceptions to this rule in particular cases, which will hereafter be mentioned.

Buffon, in the first volume of his Epoch of Nature, published in 1778, is the next who notices the general prevalence of this phenomenon, as far as relates to the eastern and western sides of the mountains that extend from north to south; but he is silent with respect to the north and southern sides of the mountains that run east and west: nay, he does not seem to have a just comprehension of this phenomenon, for he considers it conjointly with the general dip of the regions in which these mountains exist. Thus he tells us, that in all continents the general declivity, taking it from the summit of mountains, is always more rapid on the eastern than on the eastern side; thus, the summit of the chain of the Cordilleras is much nearer to the western shore than to the eastern; the chain which divides the whole length of Africa, from the Cape of Good Hope to the mountains of the moon, is nearer, he says, to the western than to the eastern seas. Of this, however, he must have been ignorant, as that tract of country is still unknown. The mountains which run from Cape Comorin through the peninsula of India are, he says, much nearer to the sea on the east than on the west: he probably meant the contrary, as the fact is evidently so, and it is stated in vol. ii. p. 295. The fame, he tells us, may be observed in islands and peninsulas, and in mountains.

This remarkable circumstance of mountains was, notwith-
MOUNTAINS.

flanking, so little noticed, that, in 1792, the author of an
excellent account of the territory of Carlsbad, in Bohemia,
tells us, he had made an observation, which he had never
met with in any physical description of the earth, namely,
that the southern declivity of all mountains was much fleeper
than the northern, which he proves by inflicting the Erzgebirge
of Saxony, the Pyrenees, the mountains of Switzerland,
Savoy, Carnith, Tyrol, Moravia, the Carpathian,
and mount Hemus in Turkey. (2. Bergm. Journ. 1792,
p. 385, in the note.) Hermann, in his Geology, pub-
lished in 1757, has at least partially mentioned this cir-
cumstance; for he says that the eastern declivities of all
mountains are much gentler, and more thickly covered with
secondary strata, and to a greater height, than the western
flanks, which he infers in the Swedid and Norwegian
mountains, the Alps, the Caucasian, the Appennine, and
Ouralian mountains; but the declivities bearing a southern
or northern aspect he does not mention.

Lamethier, in vol. iv. of his Theory of the Earth, pro-
duces numerous instances of the inequality of the eastern
and western declivities, but scarcely any of the northern
and southern, whose differences he does not seem to have no-
ticed; but he makes the remark, that the coasts of different
countries present similar declivities. With regard to eastern
and western aspect, he thinks that a different law has ob-
tained in Africa from that which he has observed in oth-
er countries; for in that vast peninsula he imagines the east-
nern declivities of mountains are the steepest, and the western
the gentlest. Of this, however, he adds no other proof
but that the greatest rivers are found on the western side.
This proof seems insufficient, as, if mountains be situated
far inland, great rivers may flow indiscriminately from any
side of them; and sometimes few rivers flow even from the
side whose depth is most moderate; for instance, from the
eastern side of the mountains of Syria. The Elbe and the
Oder, two of the greatest rivers in Germany, take their
course from the western sides, the first of the Bohemian,
and the other of the Moravian mountains, which yet are the
steepest. Many originate from lakes, as the Shannon in
Ireland. Many take such a winding course, that, from a
bare knowledge of the place of their disemboguement, it is
impossible to judge from what side of a mountain they issue,
if from any: their course at most discovers the deflexion of
the general level of the country.

In 1798 the celebrated traveller and circumnaviga-
tor, John Reinhold Forster, published a geological tract, which
merits so much more attention, as all the facts were either
observed by himself, or related to him by the immediate ob-
servers. In this he states as a fact universally observed, that
the south and east sides of almost every mountain are steep,
but that the north and west sides are gently covered and
connected with secondary strata, in which organic remains
abound, which he illustrates by various instances.

Having advanced these general remarks, Mr. Kirwan pro-
ceeds to state the principal observations relative to this
object, that have been made in different parts of the world;

In Europe: 1. The mountains that separate Sweden
from Norway extend from north to south; their western
sides are steep, and the eastern gentle (Bergm. Erdbeschreib.
ii. p. 157.) 2. The Carpathian mountains run from east to
west; their southern sides towards Hungary are steep, their
northern towards Poland moderate. (Forster, § 46.)—
3. Dr. Walker observed that the coasts and hills of Scotland
are steeper and higher on the western side than on the eastern.
(Jameison’s Mineralogy of Scotland, p. 3.) However,
Jameison observed that the south side of the isle of Arran is
the lowest, and the north side the highest. (P. 51.) 4. The
mountains of Wales are gentle on the eastern, and steep on the
western sides. 5. The mountains of Parnethy, in the county
of Mayo, are steep on the western side. 6. The mountains
which separate Saxony from Bohemia descend gently on
the Saxony or northern side, but are steep on the Bohemian
or southern side. (Charpentier, p. 75.) The southern
declivity is to the northern as six to two. (Bergm. Journ.
1792, p. 384.) 7. The mountains which separate Silesia
from Bohemia run nearly from east to west, yet are steeper on
the northern or Silesian side, than on the opposite Bohe-
man. (Alemann. Silesia, 335.) Such branches as run
from north-east to south-west have their western side
covered with primordial strata, and are consequently less steep. (New
Roz. p. 157.) 8. The Meiffner, in Hesse, is steeper on
the north and east sides, which face the Warra, than on the
southern and western. (Bergm. Journ. 1789, p. 272.)
9. The mountains of the Hartz and Habichtswald are steep
on the south, and gentle on the northern sides. (Forster,
§ 46.) 10. The Pyrenees, which run from east to west, are
steeper on the southern or Spanish side. (Carbonières, xim.
11. The mountains of Crim Tartary are gentle on the
northern, and steep on the southern sides. Forster, ibid.

In Asia: 12. The Uralis, which stretch from north to
south, are far steeper on the western than on the southern
side. (Herrmann Geol. p. 90, and Beschreib. des Ural,
p. 389.) 13. The mountain of Armenia, to the west of the
Uralis, is steep on its easter and north sides; but gentle on the
southern and eastern. (Forster, ibid. and Hermann, ibid.
p. 390, in the note.) 15. So also are the mountains of
Caucasus, (Schriften d. Berl. N. F. Gelifch. iii. p. 471.)
16. The mountains of Kamtchatka are steep on the
eastern sides. (Pallas Act. Petrop. 1777, p. 43.) 17. The
Ghauts, in the Indian peninsula, are steep on the western
side. 18. The mountains of Syria, which run from north to
south, skirting the Mediterranean, are said to be steeper on the
western side, facing the Mediterranean. Dalmatherie, iv.
p. 350.

In America: The Cordilleras run from north to south;
their western flank towards the Pacific are steep, their eastern
descend gradually. In Guinea there is a chain of mountains
that run from east to west; their southern flanks are steep,
their northern gentle. Condamine, p. 140. Kirwan in
Trans. Irish Acad. vol. viii.

Forster and Pallas account for the existence of unequal
declivities on the opposite north and south sides, by imagi-
nating that a great flood from the southward has given the earth
its present form; Mr. Kirwan, on the other hand, in the
memoir from which the above observations are extracted, has
evadoured to explain the origin of the inequalities, not
only of the northern and southern, but also of the eastern
and western declivities, by assuming a twofold violent motion
of the waters, by which the earth was originally covered,
mainly, the one from east to west, the other from north to
south; the former of these motions having been refuted by the
mountains which stretch from north to south, this oppo-
sition must have diminished the impulse of the water, and
deposited it to suffer the earthy particles with which it was
impregnated to be deposited on the eastern declivities, which
rendered them gentle, gradual, and moderate; while the
western sides, receiving no such accretions from depotions,
must have remained steep and craggy. The course of the
waters from north to south was in the same manner refuted
by the primeval mountains that run from east to west, which
occasional similar depotions on the northern sides of the
mountains, against which these waters impinged, and thus
smoothed them. Again, where mountains intersect each

other
other in an oblique direction, the north-east side of one range being contiguous to the south-west flanks of another range, there the efflux of adventitious particles on the north-east side of the one must have frequently extended to the south-west side of the other; particularly if that efflux were strong and copious, thus the Erzgebirge of Saxony, which runs from west to east, has its north-east side contiguous to the south-west side of the Riegengebirge, which separates Silesia from Bohemia, and hence these latter are covered with the same beds of gneis, &c. as the northern sides of the Saxons, and thereby are rendered smooth and gentle, comparatively to the opposite side, which, being sheltered, remains steep and abrupt. It is in this manner that Mr. Kirwan accounts for the above observation, N. 7. He also admits, that, from various contingent local causes, such as partial inundations, earthquakes, volcanoes, the erosion of rivers, the elapation of strata, disintegration, the diffusion of the lofty mounds by which many lakes were anciently hemmed in, several changes were produced in particular countries, that may at first sight appear exceptions to the operations of the general causes stated by him. Thus the mountains of Kamtschatka had their eastern flanks torn and rendered abrupt by the rupture of the general deluge, probably accompanied by earthquakes; and thus the Mesfiner has its east and north flanks undermined by the river Warra; thus, too, the eighth and sixteenth of the above cited observations are accounted for, as is the thirteenth, by the vast inundations so frequent in that country (Pallas, i. p. 172), which undermined or corroded its eastern side, while the western was smoothed by the calcareous depositions from the numerous rivers in its vicinity. Kirwan, loc. cit.

It should not be left unnoticed here that among the observations collected by Mr. Kirwan to support his theory, there are some that appear less correct, such as the tenth, in which the Pyrenees are said to be flatter on the southern or Spanish side; whereas, according to the observations of a late intelligent traveller in these parts, Professor Link, the northern flanks of most parts of that group of mountains are far flatter than those on the Spanish side.

More generally correct appears to be the observation made by several geologists, that all considerable chains are found to stretch from north-east to south-west; though, indeed, the Norwegian mountain chain, and that of the Ural, and part of the Cordilleran of the Andes, must be considered as exceptions to this rule. Professor Link endeavours to prove that the present form of the whole of Europe may be inferred from the general uniformity of the surface of the European chains of mountains, and the influx of the sea from west to east. See Link's Geolog. u. Mineral. Bemerkungen auf einer Reise durch das Sud weltsiche Europa, 1821.

For a history of the principal mountain chains on the globe, we must refer the reader to the articles Alps, Atlantic Mountains, Caucasus, Pyrenees, Ural, &c. as also to Pinkerton's Geographical Description of Mountains. We cannot, however, conclude this article without giving some observations on the mountains of Portugal and Spain, abridged from the work of professor Link above alluded to, and which have appeared the more worthy of a translation, as they principally relate to a part of Europe which had not before been examined with a view to its orology.

The northernmost part of Portugal, the province of Entre-Douro-e-Minho, is entirely composed of mountain chains which run nearly parallel to each other, from E. N. E. to W. S. W., deviating only now and then more towards N. and S. particularly in the north-eastern and eastern parts of this province. The valleys are rather narrow, and widen only towards the sea; perfect plains are not seen in this part of the country. The highest among these chains is that called Serra de Gerez (pronounced Sheréz); it enters the country at Montalegre, and following the course of the Rio Homem (principally in the direction from E. to W., inclining at last a little towards S. W.), branches out into the lower ranges of hills towards the Cavado: it also sends forth considerable ranges of hills to the southward. Almost all its valleys run in an ascending direction from S. to N., terminating at the ridge which separates Portugal from Spain. The most remarkable of these valleys is that called Caldas da Gerez, where are warm baths; and on its eastern side we find the most elevated situation of the whole range, viz. the Murro de Burgaré. The Gerez mountains consist entirely of granite, forming rugged and craggy summits; and in some parts (as in the valley of Caldas) the field of this rock is decomposed and converted into porcelain earth. There are no traces of real stratification observed in this granite. At the foot of one of the highest parts of this range, four warm springs issue from out of a granite unquestionably primitive: a circumstance which appears remarkable, as it is generally supposed that the heat of such springs is owing to the inflamed beds of coal, which cannot be in expectation in this situation like this. They are found in several other parts, such as at Guimarace, exactly under the face circumstances. On ascending the mountains that close the valley of Caldas at the western side, we arrive at an elevated mountain plain, whose western declivity is covered with a fine granitic sand, which renders it probable that the plain owes its existence to the detritus carried down by the waters. All detached rocks of quartz are found here, particularly near the village Coride; they are of considerable size, snow-white, and produce a beautiful effect. On the northern boundaries of this plain, the Serra Amarilla, a small range of hills rising from the Gerez, separates Portugal from Spain. The elevation of the Gerez mountain chain is estimated, by professor Link, at 3000 feet. There are frequent traces of metallic veins in the S. of this province, and on the banks of the Douro. At Oporto copper pyrites and malachite are found in the granite.

The mountains of Traz os Montes are less granitey, confining chiefly of flat sand-flone; their direction is from N. E. to S. W. The highest and most remarkable chain of this province is the Serra de Marao, which name it obtains near Amarante, although in the same range the mountains extend far to the N. E. The Marao, properly speaking, commences about Mirandela, proceeding in a south-westerly direction as far as the river Tamega. The rounded form of its ridge and summits, and the evenness and uniformity of its flanks, announce, even at a distance, a chain different from that of the Gerez. On approaching the Marao from the N. side, the traveller passes over a considerable tract of granitic ground. At the village of Lixe (Lithé) the granite is stratified; but in the neighbourhood of Amarante it appears again in craggy rock. On the summit of the Marao the granite becomes fine-grained, passing into flat sand-flone; this is succeeded by clay-flate, which forms the highest part of the mountain. This clay-flate has the peculiarity of separating, not only into flates, but also into flagges. It contains micaed clay. The elevation of the Marao is not inferior to that of the Gerez, and of the Serra de Foia in Algarve. The Douro is accompanied almost through the whole province by a range of hills of less height than the Marao; they all consist of a flat sand-flone passing into clay-flate. It is on these hills that the grape grows which yields the port wine; the steep declivities...
vies towards the S., with the black colour of the flate, produce very intense heat in the vineyards. These hills also contain chalybeate springs, such as those of Relva, in the parish of Guiaes, at Fermentose, in the parish of De Paços, &c.

The principal chain in Beira, and indeed in the whole kingdom, is the Serra de Estrela. It sends forth two rivers in two different directions; viz. the Zezere to the southward, and the Mondego towards the N. and E. It stretches from N.N.E. to S.S.W., commencing at Alorico, and extending to some leagues towards the S. of St. Roman. On the N. side the mountains rise very gradually, whence it is called Serra Brava; but the S. side has obtained the name of Serra Brava, the wild or bold mountain chain, on account of the rugged rocks and steep precipices by which it is terminated there, and which afford a most beautiful view on that side. The highest summit, called Malhao da Serra, is on the southern extremity. The Estrela is unquestionably the termination of the chain which separates New from Old Castile. The opposite Sierra de GTA is evidently connected with it by means of ranges of lower hills. Nor is there any material difference in the nature and appearance of these chains; for the Estrela, like the Castile mountains, consists of granite, and, like them, has a gradual acclivity on the N. and W. sides, and is steep on the S. side; whereas, the northern mountain chains of Spain and Portugal are either equally steep on both sides, or shew steeper acclivities on their northern flanks. Some distinct ranges, being continuations of the Estrela, are seen to proceed to the southward, towards the Tagus. These ranges of hills often exhibit common sand-flone without mica, covering the flat sandy-flone. These are various ranges of mountains in the vicinity of Coimbra; for to it extend the S.W. branches or continuations of the Estrela, as also some of its subordinate ranges, to which may be referred the Serra de Buffalo, and a branch of the southern calcareous chain likewise extends to this part of Beira; the others are composed of flat sandy-flone and flate-clay. The mountains on the coast, from the Manga to the town of Obidos, are calcareous, like those of Coimbra, but remarkable on account of the flat clay and flat sandy-flone, alternating with beds of coal (or rather brown coal) of upwards of four feet in thickness. Along the whole coast of Figueria, as far as above the Cape, traces of coal are observed, as also the Cape Espichel, of which more will be said hereafter.

The central part of Estremadura is occupied by a high chain of calcareous mountains, which principally stretches from N.N.E. to S.S.W., but send out branches at its two extremities, which unite with other mountain chains. At Condeixa, two leagues from Coimbra, it gives out several subordinate branches, which proceed beyond the Mondego to Coimbra, where they form the coast above Buracos. From Condeixa it runs to the southward of Pombal, from thence to the eastward of Leiria and Porto de Moz, along Alcobaca, and from here to the westward of Obidos and Torres Vedras, where it joins the range of Monte Junto. A very considerable secondary range at its eastern side is that of Louão, to the E.S.E. of Coimbra, and still in the province of Beira; it is elevated to very great heights, covered with snow, which is earned to Lisbon. All these ranges of hills are very closely grouped. The Monte Junto, which is more striking than the rest, on account of its superior height, appears, however, to be only part of the principal range. The lime-flone of these hills rests on sand-flone. At Rio Mayor, on the eastern declivity of this range of calcareous hills, salt-springs are found. The lime-flone of which the high central range is composed is of a very compact texture, and commonly of a smoky-grey colour, though in some places it constitutes very fine white, or black marbles, fusible of a good polish; the black variety of Porto de Moz and Leiria is of superior quality. Petrifications are seldom seen in this lime-flone. All these calcareous mountains of the principal chain are steep, and covered with small flones, from out of which a large rock is here and there seen to project. The sides and tops are rounded and covered with low underwood; their appearance is barren and dreary, while the lower secondary ranges are diversified by fine green shrubs, and display a luxurious vegetation. On the western side of the principal range, the sand-flone and lime-flone hills alternate, in the same manner as on the eastern side. Near Torres Vedras, and other places, beds of coal have been found. Two ranges from Obidos are the celebrated warm baths, Caldas da Rainha. On the eastern side of the calcareous chain, the plain of Golegão and Santarem separates the mountains belonging to the Upper Tagus, and to the chain just described. The granite mountains of Cintra constitute a lofty and rugged chain, which has been called a branch of the Estrela; but it may rather be looked upon as a protuberance of the above described distant granite chain, which here again emerges from a stratum of craggy rocks, steep forked summits, innumerable rivulets, and their fountains, and the woody acclivity on the north side, contribute to make these mountains one of the most romantic features of the richer inhabitants of Lisbon. The whole range from Cintra, to Cabo de Roca, has only two legsos in length; it is rather steep towards the N.E., but its descent is gradual towards the cape, where it terminates in a precipice, which is only from 50 to 80 feet above the level of the sea. The flanks of these mountains are covered with other rock-flones, of which compact lime-flone is the more common. The hills about Lisbon are principally composed of lime-flone, especially on the east side of the city; they run along the banks of the river as far as Villa Franca, where the country becomes less hilly, and from hence small hills of sand-flone, or only sand form, continue as far as Santarem. To the N. and S.W. of Lisbon, calcareous hills alternate with basaltic hills; but the basaltic range, properly speaking, only begins at Belém, near the banks of the Tagus, and extends over three legsos, as well as at the cape of Belem, and a range of broad mountains, extending from Lisbon, called in Portuguese Obidos, and down to the coast, where it forms the cape of Belem. This range has, however, a decided limestone formation, and is composed of grey limestone, which projects that rock; nor is it any white seen to exhibit columnar or other particular features, as is the case with the basalt of many other countries. On the banks of the river, the lime-flone overlies the basalt in horizontal strata. The elevated district of Alentjo stretches in general from N.N.E. to S.S.W., dividing the rivers of this province into two ranges, one of which takes its course towards the Guadiana, and the other towards the Tagus, and the western coast. We see here no chain, but a great number of small interrupted ranges of mountains, which generally run from N. to S., with a flat deviation to the westward. If we begin the survey of the elevated ground of this province with the plain of Badajoz, which extends to the westward as far as the hills on which is situated the fortress of Elvas, we find, at this latter place granite rocks, which generally form the base of these hills, while the tops are covered by granular lime-flone, or the whole in the same manner as in the mountains of Cintra, except that in these latter the granite projects over the lime-flone. The small hills from the Venda to near Estremoz consist of a flat sand-flone, which passes into flate-clay; the strata are often vertical.
At Elteemoz, the hills become more elevated; they are covered with black granular lime-flone, which may pass for one of the finest marbles in the kingdom. From the Venda to Montemor ó Novo, flaty sand-flone and granite are found to alternate. The neighbourhood of Montemor is entirely granitic. From here to the southward the hills decrease rapidly in height, and are lost in the great sand plain of Alentejo. To the northward of Montemor, the high land of Alentejo extends as far as Portalegre and the Tagus: granite is still alternating with flaty sand-flone. To the southward the granitic ground extends to Evora, Vidigueira, and Beja, and from thence uninterrupted to Serpa, on the opposite side of the Guadiana; the whole of this tract forming a very elevated plain with low hills. Between the Guadiana a range of low hills commences, consisting of flaty sand-flone, and forming the most dreary and barren tract of country in the whole kingdom; they run from N.E. to S.W., and are in fact only continuations of subordinate chains of the Sierra Morena in Spain. The Serra da Arrabida, which rises precipitously from a sandy plain, stretches from E.N.E. to W.S.W. towards the sea. It forms the southern cape at the mouth of the Tagus, or the Cabo de Espichel; where, to the southward, the mountains rise almost perpendicularly above the sea. This chain begins to the northward by a range of low hills at Aldea dos Mouros, which accompanies the main chain as far as Calheriz; to the eastward it begins with a rounded almost conical mountain, on which the monastery of Palhemala is situated: it suddenly rises to a considerable height (about 1500 feet), its sides are steep and its ridge is narrow. The highest point of the chain is between Azeitao and Aldea dos Mouros, and the sea; towards Cejimbra, and lastly, towards the Cabo de Espichel, it falls off considerably, (but not so much as the Cinfra chain does near the Cabo de Rocca,) and terminates as a precipice which overhangs the sea. The foot of this chain confines at its northern side of a kind of old sand-flone, which alternates with strata of a red-brown clay, which also traverses the former in various directions; this is succeeded up to the summit by compact lime-flone, with some petrifactions, which in some places forms beautiful varieties of marble. Near Calheriz and Cejimbra, where the chain begins to fall off in height, brown coal has been found.

Parallel with the Serra da Arrabida, an inselated, not very elevated chain, stretches towards the sea, viz. the Serra de Grandola; it forms two ranges, proceeding together from the southward of Grandola, both of which consists entirely of a close clayey sand-flone, which is here and there schilofic and micaceous. This chain, which in some maps is designated by the name of Serra Minas de Cobre, has considerable veins of copper ore, but they are not wrought, owing to the fecicity of wood in these parts. It is connected, by single ranges of hills, with the mountains of Campo de Oique, and the Algeverian mountains.

The chain of mountains which separates Algarve from Alentejo, begins to the northward of Cape St. Vincent, near to the coast; at first it constitutes the elevated Serra de Monchique; then, again falling, it forms Serra de Cadiz; and, lastly, it terminates in the mountains on the banks of the Guadiana near Mertola. On the northern side it has a great number of subordinate ranges, and these consist of granite and sand-flone; on the southern side it is accompanied, from Cape St. Vincent to near the Guadiana, by a chain of calcarious mountains. The Serra de Monchique appears to be of the same height as the Gerez and the Marao. On its northern side a range of mountains, composed of sand-flone, runs parallel to it. The highest part of the chain of Monchique is called Serra de Foja; it is a granitic ridge, emerging from out of the sand-flone mountains, which surround it on all sides. On the south side of Serra de Foja, near to its summit, is situated, in the midst of orange and chufa gardens, the romantic village of Monchique. On the steep woody side of the mountain, near this place, and to the southward, are the warm springs which issue from among granitic rocks, similar to those in the Gerez mountains. The chain of Algarve is covered on all sides by mountains of flaty sand-flone, which nearly ascends to its summit. The range of sand-flone mountains falls off to the eastward, but forms ridges at the Serra de Caldeirão. The highest point of this chain is between Faro and Os Padroes in Alentejo. Towards Vairina and Caiño Marin these mountains approach the sea, and to the eastward of them commence the mountains that run along the Rio Deleite, and those of Mertola. This whole eastern part of the chain, from Caiño Marin to Mertola, consists of a clayey massive sand-flone, not unlike the granuvace of the Hartz. Cape St. Vincent, which is elevated from fifty to eighty feet above the level of the sea, is formed by part of a range of calcarious hills, which proceeds from the principal chain: the same hills run along the sea to the eastward as far as Caiño Marin. Near Cape St. Vincent large masses of basalt are seen dispersed on the calcarious hills.

The very regular form of Spain is in great measure determined by two mountain chains, which may be considered as branches of the Pyrenees; one stretching from Guipuscoa and Navarra to Cape Ortegal, another from Catalonia to Murcia. Several other chains traverse the middle and southern part of the country: from E. to W. in nearly a parallel direction are the principal of them are the chain in South Galicia, the Cavilhanian mountains, extending as far as the Sierra de Gata and de Estrella in Portugal, the mountains near the Tagus, the Sierra Morena, and the Alpajara. From these arise a great number of lateral and more subordinate chains, and among them are seen single elevated plains or terraces, such as those of Alava, Old Cañile, and part of Leon, Arragon, New Cañile, and La Mancha.

The mountain chain which passes into Biscay may be considered as a continuation, or a branch, of the Pyrenees. The more elevated groups begin at that part where France is separated from Spain by the Bidalloa; they at first run to the northward, but soon take a more western direction, till at last they stretch exactly from E. to W. Compacted lime-flone is the rock of which the mountains of Guipuscoa are chiefly composed. They are rounded off, and are never seen to form acute ridges. On the boundaries of Guipuscoa and Alava, to the southward of the village Salinas de Lecy, a higher chain runs almost in a straight line from E. to W. The direction of the rivers and brooks of this chain indicates this to be the most elevated part of the province. On the foot of these mountains sand-flone appears for the first time. The mountain chain of Guipuscoa extends to the W. and N.W. through Biscay to the Aves; and it also appears to traverse the northern part of Galicia, and to form Cape Ortegal. On the northern sides of Salinas de Lecy the ascent is steep; the southern side is much less so, and runs out into the elevated plain or terrace of Vitoria. The principal rock in these mountains is compact lime-flone, resting flatly sand-flone and clay-flate. The plain of Alava, which is still considerably elevated, may be called the first terrace of the Pyrenees; the second terrace is the plain of Old Cañile, which extends as far as Leon, and is separated from the former by a range of calcarious mountains which here accompany the Ebro, and may be considered as the fore-runners of the chain of Biscay: they are craggy and
and steep, and at Pancorvo they have a considerable height.

In Galicia, to the northward of the Douro, and near the boundaries of Portugal, a chain commences, which runs in a parallel direction with the Gerez mountains, and to which belong the mountains of Monterey where tin is found.

The high mountain chain which separates Old from New Castile is one of the most considerable in Spain: it may be looked upon as a series of interrupted smaller chains, which, running between Old and New Castile, form here the Puerto de Guadarrama; farther to the S.W. the Sierra del Pico; still farther, de Montana de Griegos; and, lastly, the Sierra de Gata, and the Sierra de Ebreilla. The interior and the highest ridge of this chain (which cannot, with propriety, be called a branch of the Pyrenees,) consists entirely of granite, which, at the foot, is overlaid by masses of micaceous sand-flone approaching to mica flate. The granite of the summit is broken and craggy, forming wild and grotesque groups. The Puerto de Somofiera has still a rounded shape; but the less elevated mountains towards Madrid, the Pico de Miel, &c. present jagged and steep summits. The flanks of the Guadarrama are extremely dilacerated and rocky; and the Sierra del Pica probably derives its name from its pointed summit. In several parts this chain rises from the plain of New Castile with a steep ascent; this is the case with the Guadarrama, but still more strikingly with the Montana de Griegos. From the considerable cold on the highest summit, and the almost perpetual snow, in a latitude like this, we may infer that its elevation is about 8,000 feet above the level of the sea. This chain appears to be rich in minerals, but has not yet been scientifically examined in this respect. The smaller mountains contiguous to the base of this chain consist, on the New Castile side, of a solid sand-flone, separated into mountain masses; lower down the micaceous sand-flone is found; and, lastly, common sand-flone, overlaid by compact limestone; the latter, however, are often wanting, when the granite is seen to rise from the plain.

The plain of New Castile may likewise be denominated a terrace, or elevated plain, though it is less so than that on the Old Castile side of the chain. This terrace continues to eastward, as far as the ranges of mountains between the Ebro and Tagus, where, at first, it extends along both sides of the latter river, but lastly only on its northern side, as far as Placentia and Coria: it is, for the most part, covered with sand and rolled stones, but also diversified with ranges of hills composed of clay, with gypfum, limestone, and other fossils. The rolled stones of this plain consist chiefly of that fine granitic mixture of quartz, fomce feldspar, and much brasil-coloured mica, known under the name of avanturino. In the neighbourhood of Talavera alfo, porphry-flate, mica-flate, &c. are found among these as rolled stones. In the neighbourhood of Madrid, Arrajanes, and, indeed, in the whole northern part of New Castile, the hills consist of gypfum; those of the central part are composed of clay, which is generally mixed with sand and pebbles. Towards the banks of the Tagus they are of a coarze-grained old sand-flone; and these are immediately succeeded by granitic hills.

Nearly in a parallel direction with the Castilian mountains run the ranges of mountains which accompany the Tagus, and traverse the elevated country between this river and the Guadiana. With regard to length, these ranges are inferior to those of the last-mentioned chain; but they are an assemblage of several chains, which stretch parallel to each other. They do not attain the height of the Guadarrama, the Sierra del Pico, the Montana de Griegos; yet the elevation of the Sierra de Guadalupe is not inconsiderable. This mountainous tract has on its eastern and southern sides the elevated plain or terrace of La Mancha; on the south-west it terminates in the plain on the Guadiana. Parallel with it runs the Sierra Morena, with its continuations, the chains which traverse Cordova and Seville, and which join the Portuguese mountains near the banks of the Guadiana. These mountains are not very elevated, but rich in ores: they are principally composed of granite, as are the Montanas de Toledo, the Sierra de Guadalupe, and the range between the Tagus and the Guadiana. Near the Tagus, the granite hills give way to others composed of flaty micaceous sand-flone. Between Almaraz and Truxillo, beds of phofphate of lime have been found in this flaty sand-flone, and also in massive quartz. The country about Truxillo consists of a granitic plain; the town itself is surrounded by considerable rocks, which on this spot, otherwise open and flat, has a singular and striking appearance. On these granitic plains are also situated the craggy granite mountains of S. Cruz. The Guadiana at Merida has a granite bed; on the side opposite to this place the large granite hill is seen, when, at the place where the river enters Portugal, the plain of the Guadiana succeeds, which is covered with clay and sand. The low hills, farther up the Guadiana, consist, in the vicinity of Mejadus, of flaty sand-flone; and farther down, at the village S. Pedro, of old red sand-flone.

The chains of Catalonia and Valencia appear to be continuations of the Pyrenees; but the Alpujarra in Granada and the Sierra Morena should be kept distinct from them, for they belong to that series of mountains which runs in a parallel direction with the Castilian mountains. The mountains of Valencia, and those of Catalonia which join them, consist, according to Cavanilles, of lime-flone, generally containing petrifications. Catalonia appears to be very rich in rock flones, and it is the only province of Spain in which bafalt is found; a leaflet, a bafaltic column, in the museum of Madrid, is marked as coming from Catalonia. The principal rock-flone of the Sierra Morena, according to the specimens seen by professeur Link, is a flaty sand-flone. The Alpujarra in Granada is said chiefly to consist of lime-flone.

Mountains, Attraction of. See Attraction.

Mountains, Burning. See Volcano.

MOUNTAIN-MAFFER. This word, in the Wernerian system of geognosy, denotes a modification of structure observable in the rock formations that compose the crust of the earth, but demonstrable only in considerable masses, or whole mountains. To this structure belongs stratification (see Strata,) and what is called the veined structure, on account of the lines that indicate the distinct concretions, running parallel in one direction, but interfering each other in another direction, and thus conveying the idea of seams. A striking example of this latter structure is the columnar. The columns are sometimes regular, sometimes approach to the globular form, and occur even curved. They are from a few inches to many fathoms long. The islands of Staffa and Eigg present admirable examples of it, in those bafaltic columns which are sometimes collected into groups; and such groups are often separated from each other by rents, which render them more distinct. These groups may be considered as immense distinct concretions: the columns of which they are composed often tend towards a centre; others are parallel, or perpendicular; some are horizontal; and all these varieties sometimes occur in the same hill. Sometimes they are jointed, so that the convex extremity of the one column is fitted to the concave extremity of the other; and these columns are usually composed of globular...
Mounting a Cannon, Mortar, &c., is the setting it on its carriage, or the raising its mouth.

Mounting, in the Manufactories, something that serves to raise or set off a work. Thus the frame or border, and its dependencies, make the mounting of a looking-glass: the full, or butt, the mounting of a musquet, carbine, &c, and the hilt, &c., the mounting of a sword.

Mounting of a Fan, the ficks which serve to open and shut it, whether they be of wood, ivory, tortoise-shell, whalebone, Indian-cane, or the like. See Fan.

Mountmellick, in Geography, a poll-town of Ireland, in the northern part of the Queen’s county. The woollen buffets are carried on in it. It is 42 miles W.S.W. from Dublin, and nearly five miles from Maryborough.

Mountnugent, a small poll-town of Ireland, in the county of Cavan; 46 miles N.W. from Dublin.

Mountrath, a poll-town of Ireland, in the Queen’s county. It is also called Moyrath, a name which implies the fort in the bog. The wool-combing buffets formerly flourished here, but has much declined. Forges and furnaces for iron have been long established here, but from scarcity of charcoal, they are not often used: which is to be regretted, as there is an extensive bank of excellent iron ore. Mountrath is a good market-town, 47 miles S.W. from Dublin, and 6½ miles beyond Maryborough on the road to Limerick. Beaufort.

Mountshannon, a small town of Ireland, in the south-eastern corner of the county of Galway, and on the river Shannon, opposite to the island of Innis Colthear. It is about 8 miles N. by W. from Killaloe, and 105 miles W. by S. from Dublin.

Mountsorrel, or Mount-soar-hill, a small market-town in the hundred of Wet Gofcote, Leicestershire, England, is situated, as its name imports, on an eminence near the banks of the Soar, on the great turnpike-road from Leicesters to Derby, at the distance of seven miles from the former, and 104 from London. On the western side is the termination of a ridge of high hills which extend through Charnwood forest into Derbyshire. The highest point, almost overhanging the town, is called Calehill, where was formerly a fort, which is mentioned as early as the reign of King Stephen, and was of distinguished note in the contentions between the barons and the crown, in the time of King John and Henry III.; in the latter reign it was razed to the ground, and has never been re-edified. The town is partly in the parish of Barrow-upon-Soar, and partly in that of Rothley; and the vicars and proprietors of each are allotted their proportionate share of lands and tythes by an act of parliament which passed in the year 1781. Mountsorrell-hill is a rock of reddish granite, with pieces of which the streets are paved. They are commonly called Charley-forest stones, and in many places stand out bare, and are of such hardnes, after being exposed to the air, as to reftil all tools. Such pieces as can be got from under the ground are broken with a sledge, and used in buildings in the shape in which they are broken. Many houses are built with them, and make a very singular appearance. They are often imperfect cones, and being too hard to be cut or broken, the smoothest face is laid outermost, in beds of excellent lime. These stones, from their uncommon hardnes, are often used for painters' mullets.

At the end of Barrow-hill, which separates the parishes of Rothley and Barrow, formerly stood a curious crofs, which consisted of a slender, octagonal shaft, fluted, and ornamented with the flutes with carved heads, quatrefoils, &c.; the upper part of the shaft was terminated by a crocketted pediment and niches, supported by angels. This relic of monastic
monastic antiquity was taken down in 1792, and removed
into the grounds of Sir John Davies, who caused a small
market-house, in imitation of a pavilion, to be erected in
its stead. In this town were formerly two churches, but
it now has only one, which is subordinate to the church of
Barrow. Here are also three meeting-houses for Presby-
terians, Baptists, and Methodists. The population, in the
year 1801, was returned to parliament as 1223; the number
of houseties as 231. A weekly market is held on Monday,
which, with an annual fair, were first granted, in 1701, by
Edward I. to Nicholas de Seagrave and his heirs. Beauties
of England and Wales, vol. ix: from Nicholas's Hitory
and Antiquities of Leicestershire, 7 vols. folio.

MOUR, a town of Nubia, so called from a spring of
bitter water; 18 miles W. of Syene.—Also, a town of
Hindoostan, in Dowlatabad; 10 miles W. of Beder.—Also,
a town of Hindooftan, in Ouœ; 6 miles S.S.E. of Man-
nickpour.

MOURA, a town of Portugal, in Alentejo; containing
two parish churches, an hospital, several convents, and about
4200 inhabitants; 82 miles E.S.E. of Lisbon. N. lat. 58°
7'. W. long. 7' 21'.—Also, a town of Africa, on the Gold
coast; 5 miles N.E. of Cape Coast castle.

MOURAILLE, in Anjou. See BANCAIS.

MOURA, in Geography, a town of Portugal, in the
province of Alentejo, on the Guadiana, defended by a castle,
and containing about 1400 inhabitants; 90 miles E.S.E. of
Lisbon. N. lat. 58° 20'. W. long. 7° 8'.

MOURERA, in Botany, Abul. Guian. 582. t. 233.

See LACS.

MOURET, John Joseph, in Biography, chamber mu-
cician to Louis XIV., superintendent of the duchess de
Maine's band, and director of the Concert Spirituel, was
born at Avignon in 1682, where his father, a silk mer-
chant, gave him a good education, and cherishing his na-
tural passion for music, spared no expense in facilitating
the means of his making a great progress in the art.

He came to Paris in 1707, and had soon admission into
the belles lettres. His figure excited prejudices in his fa-
vor, his countenance was gay and cheerful, his conver-
sation lively and agreeable; and his voice in singing fine for
a composer made him sought after everywhere.

The duchess of Maine confided to him the conduct of her
magnificent festivals, known by the name of "Les nuits de
Seaux." Soon after, he married Mademoiselle Prone de
S Mars, daughter of the duke of Maine's silversmith, by
whom he had one only daughter. The many misfortunes
which he suffered two years before his death, occasioned him
to mortification as brought him to the grave, after having
so deranged his intellects, that his friends were obliged to
have him confined at the Fathers de la Charité at Charenton,
where he died in the year 1738, in the 56th year of his
age.

Mouret was not an able composer; but he had a good
taste, which supplied him with agreeable melodies. He
furnished the opera, as one of the succeffors of Lulli, with
six serious operas, published many cantatas and lively fongs,
three books of serious airs and bacchanalian fongs, many
entertainments for the comedie Françoise and the comic
opera, a set of fongs for two flutes, a book of military
pieces, and music expressly composed for many festivals at
Seaux, &c.

MOURGUES, Michael, a French mathematician,
was born in the province of Avengre about the year
1632. He became a professor of rhetoric and mathem-
atics in different houses belonging to his order, and was
at length appointed to the chair of professor-royal at
the university of Touloupe. He died, in 1715, a fascin-
ator to his exertions in the cause of humanity and religion,
during the dreadful pestilential disorder which then raged
in Touloupe. To very profound as well as extensive cred-
itation, he united the most polished and amiable manners,
and the most ardent piety, which made him zealous in his
attempts to reform the age in which he lived. He was
a considerable writer; his most celebrated pieces are, "New
Elements of Geometry, comprised in less than fifty Pro-
positions!" this work has never come into our hands, but we
are sceptical as to the value of a work of this kind being con-
tained in so small a space; "A Parallel between Chris-
tian Morality and that of the Ancient Philosophers!" "An
Explanation of the Theology of the Pythagoreans, and of
the other learned Sects in Greece, for the Purpose of illus-
trating the Writings of the Christian Fathers!" and "A Treatise
on French Poetry." Moreiri.

MOURI, in Geography, a town of Africa, in Foota
N. lat. 10° 43'. W. long. 11° 5'.

452. t. 180.)

MOURMIRO, in Geography, a town of France, in
the department of the Vaucile, and chief place of a can-
ton, in the district of Carpentras; 17 miles N.E. of Avog-
on. The place contains 1268, and the canton 8266 inhabi-
tants, on a territory of 280 kilometres; in 10 communes.

MOURNE, a barony of the county of Down, Ireland,
which is almost covered with a large mass of very high
mountains, generally called the Mourne Mountains, of which
Shelburne-Dondor is the chief. These are primitive moun-
tains, consisting chiefly of granite. The town of Newry
is situated at the base of them.

Mourne, a river of Ireland, proceeding from a lake of
the name in the county of Donegal, which falling into
the county of Tyrone receives the waters of the Derg, and
below Strabane runs into the Foyle.

MOURNING, a particular dress or habit, worn to sig-
nify grief, on some melancholy occasion.

The modes of mourning are various in various countries;
as also are the colours that obtain for that end. In Europe,
the ordinary colour for mourning is black; in China, it is
white; in Turkey, blue or violet; in Egypt, yellow; in
Ethiopia, brown. The ancient Spartan and Roman ladies
mourned in white; and the same colour obtained formerly
in Caflile, on the death of their princes. Herrera ob-
erves, that the last time it was used was in 1498, at the
death of prince John. Kings and cardinals always mourn
in purple.

Each person pretends to have his reasons for the particu-
lar colour of their mourning: white is supposed to denote
purity; yellow, that death is the end of human hopes, as
leaves when they fall, and flowers when they fade, become
yellow; brown denotes the earth, whither the dead re-
turn; black, the privation of life, as being the privation of
light; blue expresses the happiness which it is hoped the
deceased enjoy; and purple or violet, sorrow on the one
side, and hope on the other, as being a mixture of black
and blue.

Mourning, among the ancients, was expressed various
ways, by tearing their clothes, by wearing sackcloth,
laid of cedron and every other mark of joy. Plutarch,
in his Life of Cato, relates, that from the time of his leav-
ing the city with Pompey, he neither shaved his head, nor,
as usual, wore the crown or garland. Sometimes public
grief was testified by a general fall. See Fast.

Among the Romans a year of mourning was ordained,
by law, for women who lost their husbands.
In public mourning at Rome, the sheps were flut shut, the women laid aside all their ornaments, the sertors their laticial robes, and the confuls fat in a lower seat than usual.

The ancients had a remarkable way of mourning for soldiers slain in battle. The whole army attended the funeral solemnities, while the arms reversed, it being customary for mourners, in most of their actions, to behave themselves in a manner contrary to what was usual at other times. In those places where it was the fashion to wear long hair, mourners shaved; and where others shaved, mourners wore long hair. The conjecture of those, therefore, is frivolous, who imagine that the soldiers turned the heads of their shields downwards, left the gods, whose images were engraved upon them, should be polluted with the sight of a corpse; since not the gods only, but any other figures, were frequently represented on shields; nor did the few only near the corpse, but the whole company held their shields in the same position: not to mention that other arms were also pointed downwards. Potter, Archæol. Græc. tom. ii. p. 163.

The mourning of the Eastern nations of Indians are much more closely followed, though of much shorter duration than ours. After the death of a near relation, they mourn fifteen days, during which time they eat hardly but rice and water: they are not to chew betel, or to use the common washings in this time; but they are to do acts of charity, such as distributing food to the poor, and prayers are said, intreating the Almighty to forgive the sins of the dead person, and afflict him a good place in the other world. On the sixteenth day, that is, the day after the finishing of the time of mourning, they make a solemn feast according to their abilities, and invite to it all their friends and neighbours. After this, they annually, on this day, give food to the poor, and renew their prayers for the happiness of the dead person. Phil. Trans. N. 243.

MOUROU, in Geography, a mountain of Thibet. N. lat. 30° 20'. E. long. 83° 14'.

MOUROUCOA, in Botany, Aubl. Guiana. 141. t. 52. Juif. 135. Lamarck Illur. t. 103; a climbing shrub of the natural order of Convolvulœ, found by Aublet in the extensive forests of Guiana, where it ascends to the summits of the loftiest trees. Leaves alternate, stalked, elliptical, entire, firm, smooth, five inches long and three broad. Flowers in axillary tufts, large. Calyx in five deep rounded segments, two of them concealing the red, violet-coloured, permanent. Corolla blue, monopetalous, with a short funnel-shaped tube, and broad limb, in six deep rounded segments. Stamina five, infected into the tube, shorter than the limb, and opposite to each of its lobes: anthers incumbent. Germen superior, conical, violet-coloured like the style, which is thread-shaped, with a stigma of two rounded flat lobes. Capefle oval, punctured, with a fibrous coat, of two cells, one of the three which exist in the germin being abortive. Seeds solitary, reddish, polished, long, convex on the cuticle, flat on the inner. This plant is perhaps justly referred to Convolvulus by Willdenow. See Convolvulus Macropermerus, n. 91. Willd. n 62. Sp. Pl. v. 1. 860.

MOUROUCONGHE, in Geography, a town of Thibet; 76 miles E.N.E. of Lassa.

MOURTEAIL, a town of Kemaon; 25 miles E.S.E. of Kerigar.

MOUROUK, a city of Africa, and capital of the kingdom of Ffessan, is situated on the banks of a small river, and is also supplied with water from a multitude of springs and wells. It is surrounded by a high wall, which

not only serves to defend it, but enables the government to collect, at its three gates, a tax on all goods (provisions excepted) that are brought for the supply of its inhabitants. Being formerly built with stone, it still retains the appellation of a Chirilian town; but the medley which it presents to the eye of the vast ruins of ancient buildings, and of the humble cottages of earth and sand, that form the dwellings of its present Arab inhabitants, is singularly grotesque and strange. Its distance from Melurata, which borders on the well, and with respect to which its situation is nearly forth, is about 262 miles. N. lat. 27° 20'. E. long. 15° 35'.

MOUSA, a small island among the Shetlands. N. lat. 62° 24'. W. long. 1° 20'.

MOUSANAGUR, a town of Hindoostan, in Oude; 18 miles W.N.W. of Corah.

MOUSAR, a town of Perfa, in Larifan; 48 miles N.W. of Lar.

MOUSE, Mus, in Zoology. See Mous.

MOUSE, Dors. See Myoxus and Sciurus Striatus.

MOUSE, Sable, called also lemmer, or lemming, the name of an animal found in Lapland, and in other cold countries: many extraordinary things are related of the manner of living of these creatures. See Mus Lemmus.

They are of the bigness of a squirrel, and their skin is flecked with brown and black; there are also some fome few bodies of the fquirks; the black is a very fine deep colour, the brown is pale; they have two very sharp teeth above, and two below of the fame kind: their feet are like a squirrel's; they are usually very fat and fleshy, and are so quadrifome and fierce, that if a fhuck be held out to them, they will bite it at, and will hold it fo fmall, that they may be tofl'd and fwung about in the air by it, without letting it go. In their march they usually keep a direct line from north-east to south-west, and always travel in thofands in the fame troop. The whole number forms a square body, and they march only from the time of the twilight till the morning, lying idle all the day.

They march in lines, which are none ellls diffant, but always exactly parallel to each other, fo that the places they have gone over look like the furrows of a ploughed field. If they meet with any thing in their way that might deter another animal, it never ftops them; but though it be a fire, a deep well, a pond, a torrent, or a bog, they, without hesitation, venture through, and by that means many thousands of them are destroyed, and are found dead in the morning, in the waters or otherwife.

They never come into a house, nor meddle with any thing that we eat; if they chance to come to a house in their way, there they flop till they die; but if they come to a flack of hay or corn, they eat their way through.

When they march over a meadow, they do it great damage, by eating the roots of the grass; but if they encamp there, they wholly destroy the produce; the land looks like a place where there had been a fire, and the whole surface looks as if burned with ashes.

The Laplanders are always glad to fee fhese creatures on their march, for it always foretells plenty of more valuable creatures among them: the fame cold that fends thefe out, sending also a number of fowl, fquirrels, foxes, and other animals the fame way. Wormius has written a complete treatife on this animal, calling it mus Novergius: this is reprinted at large in his Muciem. Phil. Trans. N° 251. p. 112.

They commonly vifit the country once or twice in twenty years; Linneus luppofes that they come from the Norwegian Lapland Alps; but Pontoppidan thinks that Kolans rock, which divides Nordland from Sweden, is their native place.
MOUTH, in Anatomy. This part of the body is described in the article DENTITION, in which the figure, the openings, and the parts composing the fides of the cavity, are considered. The teeth are described under CHROMIUM.

Dr. Derham observes, that the mouth, in the several species of animals, is nicely adapted to the uses of each a part; and well-fixed and shaped for the catching of prey; for the gathering and receiving food, the formation of speech, &c.

In some creatures it is wide and large, in others little and narrow; in some it is formed with a deep incisure up into the head, for the better catching and holding of prey, and more easy commination of hard, large, and troublesome food; in others with a short incisure, for the gathering and holding of herbaceous food. See Anatomy of Birds, Fish, and Insects.

MOUTH is also used, in the courts of princes, for what relates to their eating and drinking. Hence, officers of the mouth, women of the mouth, &c.

Daviler defines mouth, an apartment composed of several rooms, as offices, kitchens, &c. where the meat intended for the first tables is dressed by itself. At court, this is called the king’s mouth.

MOUTH, in the Manage, denotes a horse’s feeling or sensibility in that part where the bit is applied. See Horse.

MOUTH, Ridges of a heart. See Ridges.

MOUTH, Opening or flushing the, of a cardinal, is a ceremony used in the confraternity of Rome; wherein the pope flouts a new-elected cardinal’s mouth, so that he may not speak at all, even though the pope should speak to him; and remains, in the meantime, deprived of all voice, both active and passive, till the calling of another confirmit, when the pope opens his mouth again, making a little harangue, to teach him how to speak, and comport himself in the confraternity.

MOUTHÉ, in Geography, a town of France, in the department of the Doubs, and chief place of a canton, in the district of Pontarlier; 13 miles S.W. of it. The place contains 1000, and the canton 8641 inhabitants, on a territory of 312½ square kilometres, in 24 communes.

MOUTIER, a town of France, in the department of the Upper Rhine, and chief place of a canton, in the district of Délemont. The place contains 467, and the canton 3977 inhabitants, on a territory of 163½ square kilometres, in 23 communes.

MOUTIERS, a town of France, in the department of Mont-Blanc, and principal place of a district; the town is divided into the northern and southern parts; the smaller contains 1470, and its canton 12,202 inhabitants, on a territory of 237½ square kilometres, in 24 communes; the latter has 535; and its canton 12,146 inhabitants, on a territory of 707½ square kilometres, in 20 communes.

MOUTIERS-les-Mausfrais, a town of France, in the department of the Vendée, and chief place of a canton, in the district of Les Sables-d’Olonne; 14 miles E. of it. The place contains 349, and the canton 10,634 inhabitants, on a territory of 352 square kilometres, in 18 communes.

MOUTIERS, Trois, a town of France, in the department of the Vienne, and chief place of a canton, in the district of Loudun. The place contains 1257, and the canton 7399 inhabitants, on a territory of 217½ square kilometres, in 16 communes.

MOUTON, JEAN, in Biography, a great musician, who flourished in the time of Louis XI. and Francis I., to both which princes he was maestro di cappella: several of his masses in four parts appear among the first that were printed.
with types, under a patent granted by Leo X., and signed by cardinal Benmo, his prime minister.

Gleaneus calls him a Frenchman; but Lud. Guicciardini claims him as a native of the Netherlands. Wherever he was born, it is certain that he spent the chief part of his life in the service of the French court, during the reigns of Louis XII. and Francis I. He was a disciple of Jofquin, and master of Adrian Willaert, not his scholar, as Printz, and others after him, have asserted.

Nowwithstanding the rapture with which Gleaneus speaks of this composer's masses, they seem to us inferior in melody, rhythm, and design, to those of Jofquin, de la Rue, and Fegg. It is in his fourth mass, that we first met with two flats at the elef, and an accidental flat to A. In scouring this composition from the Museum copy, in four separate books, we found it consisted of fourteen several movements, in which we can discover no variety of measure or subject: nor is there the want of melody compensated by richness of harmony, ingenuity of contrivance, or learning of modulation. His motets, however, if not more nervous and elaborate than those of his contemporaries, are more smooth and polished: he lived in a court.

His motet, "Non nobis Domine," is not only pleasing, but mallerly. It was composed in 1569, for the birth of Renée, the second daughter of Louis XII. by Anne of Bretagne, as appears in the body of the motet; and this is sufficient to confute the opinion of Mouton having been the scholar of Adrian Willaert, who, according to his own account, went into Italy very young, during the pontificate of Leo X. Zarlino, Initit. 44a parte, p. 346.

He composed another motet in 1574, on the death of queen Anne de Bretagne: but the bulk of his compositions that we have seen, is the motet, "Quam pulchra es amica mea," from the song of Solomon. It is composed for three tenors and a bafe: the subjects of fugue are pleasing, and treated with uncommon clearness and abilities, for so early a period of counterpoint.

Mouton d'Or, an old French coin. See Angel.

MOUTOUCHIA, in Botany, Jull. 365. (Moutouchi; Aubl. Guian. 74b. t. 299.) See Pterocarpus.

MOUVE, in Geography, a town of Hindoostan, in Guzerat; 60 miles N.E. of Nonagur.

MOW, a town of Hindoostan, in Allahabad; 60 miles N.E. of Chanderee. — Allo, a town of Oude; 20 miles S.E. of Azimgur.—Allo, a town in the circar of Chanderee; 8 miles S.E. of Seronge.—Allo, a town in Oude; 16 miles N.N.E. of Furruckabad.—Allo, a town in Bogleund; 30 miles E. of Rewah.—Allo, a town in Balbar; 12 miles N.E. of Hajypour. N. lat. 25° 49'. E. long. 84° 36.—Allo, a town in Oude; 18 miles E. N.E. of Fyzabad.—Allo, a town in Allahabad; 20 miles N. of Allahabad. N. lat. 25° 57'. E. long. 83° 48'.

Mow, in Agriculture, a pile, heap, or collection of corn, straw, hay, or any similar substance placed together for the purpose of being kept in a barn or other building. See Stack and Rick.

Mow-burnt, a term applied to such substances as are over-heated in the mow by the process of fermentation, as hay, corn, &c.

MOWAH, in Geography, a town of Hindoostan, in Balbar; 32 miles E. of Hajypour. N. lat. 25° 34'. E. long. 86.—Allo, a town in Oude; 20 miles of Fyzabad.

MOWDHILL, in Rural Economy, a provincial term applied to a mole-hill.

MOWDIARP, a provincial term sometimes signifying the mole.

MOWEE, in Geography, a town of Hindoostan, in Guzerat; 40 miles N.E. of Nonagur.

Mowe, one of the Sandwich islands, next in size and nearest in situation to Owyhee; lying at the distance of 8 leagues N.N.W. from it, and 140 geographical miles in circumference. This island is divided by a low isthmus into two circular peninsulas, of which that to the E. is called Whamadooa, and is double the size of the western peninsula, called Owlyrookoo. The mountains in both rise to a great height, being seen at the distance of upwards of 30 leagues. The northern shores, like those of Owyhee, afford no foundings; and the country presents the same appearance of verdure and fertility. To the S.E., between this and the adjacent islands, there are regular foundings of 150 fathoms, with a sandy bottom. From the W. point, which is low, runs a shoal, stretching out toward Rana to a considerable distance; and to the southward of this is a fine spacious bay, with a sandy beach, shaded with cocoa-nut trees. Here probably might be found good anchorage, with shelter from the prevailing winds, and the beach might afford a convenient place for landing. The country behind presents a very romantic appearance. The hills rise almost perpendicularly in a variety of peaked forms, and their steep sides, with the deep chains between them, are covered with trees, among which those of the bread fruit abounded. When La Perouse, in 1786, came within sight of this island, 200 canoes came out to meet him, laden with pigs, fruit, and fresh vegetables, which the inhabitants sent on board, and forced him to accept, without any futilation on their part. The inhabitants appeared to bear some resemblance to those of Eater island, and indicated a more robust constitution; but it had been impaired by disease. Their common height is about five feet three inches; their habit of body spare, their features coarse, their eye-brows thick, their eyes black, their aspect determined though not ferocious, their cheek-bones high, and their nostrils rather wide; their lips thick, their mouth large, as well as their teeth, which,
which, however, were fine and regular. Some of them had lost one or more of their teeth, which, as a modern navigator apprises, they had pulled out when mourning for their relations or friends. These people are more muscular, their beard more bushy, and their bodies more covered with hair than those of the Easter island. Their hair, which is black, is cut into the shape of a helmet, and the part, which they suffered to grow, representing the plume, was red at the extremity, having probably been coloured with the acid juice of some kind of vegetable. The women, instead of fixing the men, and are in general ill-made, with coarse features, a gloomy countenance, and rude, ill-minded awkward manners. The inhabitants of this island are gentle and persevering, and, in their manner, polite to strangers. They paint themselves, tattoo their skin, and pierce their ears and the cartilage of the nose, in which they wear rings, by way of ornament. They are not circumcised, but they use a kind of intumescence. The drefs of both sexes consists of a piece of cloth covering those parts which are commonly concealed, and are then wrapped round their bodies. These cloths, made from the paper mulberry, are beautifully variegated, being painted with great taste. Their houses, collected into villages, are built in the manner of those in Easter island, but their form is square. With regard to their government, it was observed that they were arranged into various tribes, each of which was under the control of its respective chief. The excellence of the climate and the fertility of the soil would afford the inhabitant's every means of happiness, did not leprosy and syphilis rage among them, very generally and with appropriate violence. The inhabitants of this island appeared in 1793 to be in a very dilapidated state, having suffered much by a war of 11 years' continuance with their neighbours of Owhyhee. N.lat. 20° 34'. E. long. 203° 40'.

MOWGUNGE, a town of Hindooistan, in Oude; 27 miles E. of Rewah.

MOWILGONGA, a river of Ceylon, which runs into the sea at Trinkomaly.

MOWING, in Agriculture, the art of cutting down corn, grasses, &c. by the scythe. In the mowing of grain crops, such as wheat, barley, oats, &c., the scythe acts as shorter in the blade than the common ones, and which, instead of a cradle, have two twigs of ozier put semicircular-wise into holes made in the handles, near the blade, in such a manner that one semicircle intercepts the other, are made use of. But for the cutting of grass longer and thinner scythes are generally in use.

A late practical writer states, that in "the cutting of grass crops for the purpose of being converted into hay, it is necessary that they be in the most fit state of growth and maturitv, for affording the belt and most nutritious fodder. With this view, it would seem, that they should neither be cut at too early a period, nor suffered to stand too long; as in the former case there will be considerable lofs in the drying, from the produce being in so soft and green a condition, and in the latter from a large proportion of the nourishing properties being expended. It is probable, therefore, that grass, when mown before it becomes in full flower, while the rich saccharine juice is in part retained at the juice of the flower-into, is in the most proper condition for being cut down, as at that period it must contain the largest proportion of nutritious materials, but which then begins to be absorbed, and taken up in proportion as the flowers expand, and the seeds ripen, so as to constitute the meal or flour of the seed lobes, and is either dispersed upon the land, or fed upon by birds; the grass crops with their leaves being left in a similar situation to that of the straw of ripened grain. But there are other circumstances, besides those of ripeness, to be attended to in determining the period of cutting crops of grass, as in some cases, while they are thick upon the ground, the bottom parts become of a yellow colour before the flowering fully takes place; under such circumstances it will always be the most advisable practice to mow as soon as the weather will permit; and, in this case, the bottom parts being of but little value. Where grass is very tall, as is often the case in moit meadows, it is liable to fall down and lodge, by which the fame effects are produced." In this case, also, the mowing should be performed as soon as possible, "as when much laid it then becomes rotten, and of little or no use as hay."

However, in cases where there is nothing of this fort, it appears evident, that "the most proper time for performing the bufinefs, is when the grass has begun to flower, before the feed flows become hard and wiry; at this period it would seem to contain the largest proportion of useful matter. Besides, when left to fland too long, the after-grasses is not only less abundant, but there is great lofs in it by the crumbling down of the flows, in the different operations of hay-making, as has been stated in the Pastshire Report."

It may be noticed, that the usual time of cutting for hay in the first crops, is from about the middle of June to the beginning of the following month, according to the nature of the land, or as the district is more early or late in the produce."

And in the operation of mowing, the chief art consists in cutting the crop as close to the surface of the ground as possible, and perfectly level, pointing the swathes well out, so as to leave scarcely any ridges under them.

But "in cutting rough, or second crops of grass, more attention in these different respects will be necessary than in the first, as the crops are more evenly lighter and more difficult to cut, the scythe being apt to rise and flip through the grass without cutting it fairly, except when in the hands of an expert workman. Crops of this fort should always be cut as much as possible when the dew is upon them; and as soon as ever there is a tolerable growth, as by waiting the season is constantly getting more unfavourable for reducing them into hay; and when not well made this hay is of little or no value. When the grass has been decided to be in the proper condition for being cut down, a lot of mowers proportioned to the extent of the crop should be immediately provided. In some districts, it is the custom to pay their labourers by the day, but a better and more general practice is, it is supposed, to let the work at a certain price by the acre. The extent or proportion of ground that can be mown in any given space of time, must obviously vary much according to the nature of the ground, the fertility of the crop, and the goodness of the workmen, but in general an acre is supposed a full day's work for an expert mower.

In mowing barley, oats, or other grain crops, the corn is generally on the right hand of the workman; but M. de Lisle had a method of mowing wheat, in which the corn was at his left hand: he mowed it inward, bearing the corn in his hand, then cut it, and then cut it, till it comes to that which is standing, against which it gently leans. After every mower a gatherer follows, who may be a lad, or a woman. The gatherer keeps within five or six feet of the mower, and being provided either with a hook or stick about two feet long, gathers up the corn, making it into a gavel, and laying it gently on the ground; this must be done with spirit, as another mower immediately follows: as to every mower there is a particular gatherer. And to do this work properly,
perly, the mower should form but one tract with his feet, advancing in a posture nearly as if he was going to fence, one foot chafing the other. In this manner the standing corn is mowed; and the workman should take care to have the wind at his left, as it bears the corn towards the scythe, and causes it to be cut nearer the ground. When wheat is bent, the workman takes the corn as it presents itself to him, which has the same effect as if the wind was at his left side. And when it is laid, it is more troublesome to the gatherer, because the cut corn is apt to be mixed with that which is standing; but a good mower takes advantage of the wind, and cuts it again in the way it is laid. No particular directions can be given for corn that is lodged and entangled, unless it be to take it as it is inclined, as if the wind were on the back of the mower.

The usual method of mowing grain is, however, in the same manner as for grass, the scythe only having a cradle or bow fixed upon the heel of the handle.

It is stated, in the tenth volume of the Agricultural Magazine, that in the "practice of every department of the kingdom, the farmer is working horizontally, or nearly level, leaving the stubble of almost an even height; or if it rise on either side, forming what are called swath-balks, the butts of the swaths are suffered to rest upon them, the heads or ears of the corn falling into the hollow or close mow part of the preceding swath-width. They are of course liable, in a wet season, not only to receive an undue portion of rain water, but to be fouled with the splinterings of heavy showers." But that in the Kentish practice, which is said to exceed those of other districts, "the position of the swaths is different. Here, the heads of the corn rest on the top of the swath-balk, provincially the beaver, which is left of extraordinary height, as ten to fifteen inches; so that the wind has a free circulation beneath the swaths. The workman, in performing this judicious operation, proceeds with his right foot forward, entering the point of his scythe with a downward stroke, and raising it as abruptly out, bringing the handle round to the left until it forms nearly a right angle with the line of the swath, carrying the corn in the cradle three or four feet behind the place where it grew, lifting it high and letting it fall on the beaver behind his left foot, and in the position above described." But "the disadvantages of the method are, the loss of some straw, the incumbrance arising from the length of stubble, and a little additional labour; but in a district where cattle are not numerous, the loss of straw is not felt, and in any country, the principle of leaving the heads, instead of the butts of the corn upon the swath-balk, whether left high or low, might be well adopted."

MOWLAY, in *Geography*, a town of Linchookan, in Baglana; 32 miles N.E. of Baffeen.

MOWRUD, a town of Candahar; 12 miles S.E. of Candahar.

JAPAN, a Japanese word, denoting a soft lustrous fabric prepared from the young leaves of a species of mugwort, employed by foreigners on the continent as a means of forming an ichihar, which is usually made in this country with canvas. A little cone of the moxa is laid on the part which has been previously muddled, and it is then ignited at the top, when it burns down with a temperate glowing heat, and produces a dark-colored spot, the exudation of which is said to be produced by the application of a small quantity of沥青. The ulcer is kept open, or healed, according as the indications of the case require. The moxa is famous in the East for curing several diseases, and the French are in the habit of using it; but whenever English

fugitives wish to produce a fough, they prefer camphor to actual fire.

*MOXES*, or *Moses*, in *Geography*, a province of South America, in the vicerealty of Buenos Ayres, situated between the diocese of Cauco and the country belonging to the Portuguese, on each side of the Marmora or Madera; of considerable extent, inhabited by Indian nations, and little known.

MOXVITO, a town of Portugal, in the province of Beira; 30 miles N.E. of Braganza Nova.

MOY, a town of France, in the department of the Aisne, and chief place of a canton, in the district of St. Quentin; nine miles S.E. of it. The place contains 948, and the canton 11,518 inhabitants, on a territory of 137½ kilometres, in 10 communes.

Moy, a circle of Bengal, bounded on the N.E. by Chindore, on the S.E. by Carrackdeagh, and on the W. by Rangpur and Bahar.

Moy, a post-town of Ireland, in the county of Tyrone; it is situated on the river Blackwater, which separates it from Charlemont in the county of Armagh. Near it is Clonfiele, the residence of Dr. Richardson, the celebrated advocate of Florin culture, which is there extensively carried on. It is 65 miles N. by W. from Dublin, and 3 miles from Armagh.

Moy, the name of two rivers in Ireland; one rises in the county of Sligo, after a winding course through that county and Mayo, forms the boundary between them for some miles, and runs into the bay of Killala; the other is in the county of Galway.—Also, a town of Scotland, in the county of Inverness; nine miles S.E. of Inverness.

MOY, a provincial word figuring muggy or close.

MOYNA, in *Geography*, a town of Spain; E. from Cenie; 37 miles E. of Cuenca.— Also, a town of Spain, in Cataonia; eight miles E.N.E. of Manresa.

MOYATTA, a river of the county of Cork, Ireland, which runs from Sheelby mountain to Bantry bay, into which it flows near Ballinlamey.

MOYEE, LA, a small island near the W. coast of Jersey; four miles W. of Noirmont Point.

MOYENNEVILLE, a town of France, in the department of the Somme, and chief place of a canton, in the district of Abbeville; four miles S.S.W. of it. The place contains 905, and the canton 9428 inhabitants, on a territory of 315 kilometres, in 14 communes.

MOYILE, Walter, in *Biography*, son of Mr. Walter of Cornwall, was born at Bake, near Looe, in 1672. He was greatly distinguished at school by his classical attainments; from school he went to Oxford, and having pursued his studies there, he was entered in the Temple, to obtain that kind of legal knowledge, which it behoves every gentleman to possess. He soon became acquainted with the wits of the day, and joined some of them in translating Lucan. He undertook to furnish versions of four of that author's pieces, which he executed with spirit and accuracy. He was warmly attached to the principles of liberty, and in 1695 he took his seat in parliament for the borough of Saltash, but probably the routine of the house of commons had no charms for him, and he appears never to have made any attempt at another seat. He was debarred of confining himself to his studies, and, at the desire of Dr. Davenant, he translated Xenophon's "Discourse upon improving the Revenues of Athens," which was prefixed to the doctor's work on "The Trade and Revenues of England," which was published in 1697. He next appeared as a co-adventor of Mr. Thomson in "An Argument against astanding Army," at that period the great object of the jealously
 Mozart, in *Geography*, a river of the county of Tyrone, Ireland, which rises in the northern part of the county, and flows through counties Down and Fermanagh, and is 15 miles N. by W. from Derry, and about 6 miles N. from Derry.

MOYNA, a small town of Ireland, in the county of Meath. It is situated on the river Boyne, and is 15 miles N. by W. from Dublin, and four miles N. from Kells.

MOYNE, a town of Ireland, in the county of Galway, which joins the town Clare six miles S. of Tuam.

MOYNOU, in *Fortification*. See MOISE.

MOYOBAMBA, in *Geography*, a town of South America, on a river of the same name, which runs into the Guallanca; 300 miles N. of Lima. S. lat. 7°. W. long. 76° 56'.

MOYOMBO, a town of Africa, in Congo; 10 miles S.W. of Bombi.

MOYOWIA, a river of Ireland, in the county of Londonderry, which runs into the north-western angle of lough Neagh, about two miles from Toome bridge.

MOYS, a river of Austria, which runs into the Danube, two miles above Orent Neuburg.

MOYSICWICZE, a town of Lithuania, in the principality of Mindik; 60 miles N.E. of Mindik.

MOZAISK, a town of Russia, in the government of Moscow; 56 miles W. of Moscow. N. lat. 56° 36'. E. long. 15° 44'.

MOZAMBIQUE or MOZAMBAR, a kingdom of Africa, subject to the Portuguese, situated on the E. coast, and on that part of the Indian sea which lies between the continent and the island of Madagascar. It takes its name from that of its chief town, which is seated on an island, the principal of three islands that form a part of the kingdom. This island is however very small, and distant about two miles from the continent. The bay is about three miles in circuit. The other two islands, viz. St. George's and St. James's, lie on each side of it, facing the continent. The city of Mozambar is said to consist of well-built houses, churches, and convents; and has a fort or castle, about a muquet-shot from the town, which is one of the strongest and best contrived belonging to the Portuguese on this coast. The soil of the island is a white barren land; over which an artificial mould has been formed, so that it produces very fine citrons, oranges, bananas, figs, and other fruits; but their pulse, roots, and other edibles, are chiefly brought from the continent, and the town is said to have been supplied with rice, wheat, and other provisions from Goa. On the land the soil is fat and fertile in rice, millet, variety of roots, pulse, fruits and plants. The natives breed a great number of cattle, large and small, particularly sheep with large tails. The country swarms with wild flocks of various kinds, such as elephants, as well as wild fowls and hares. In order to preserve themselves from the fierce and destructive elephants, the inhabitants kindle large fires round their town fields, to prevent their being devoured by them; nor do they shift from their habitations without lighted torches or firebrands to scare them away. The country has mines of gold, which is washed down their rivers and constitutes a great part of their commerce. Ivory, ebony, flaxes and cattle are likewise exchanged for European goods, such as little bells, knives, scissors, and razors. Besides the commodities already mentioned, they export silver, copper, wax, rice, and other provisions. The kings of Portugal have been at great expense in fortifying and garrisoning Mozambique, and providing it with an hospital for the sick, and a magazine well furnished with a variety of stores for shipping, &c. S. lat. 15° 5'. E. long. 46° 8'.
curious account of the musical feats of this child in London, during 1765, when he was no more than eight years and five months old, to which we refer our readers. His progress in talents and fame, contrary to all experience, continued to keep pace with the expectations of the public to the end of his life.

He went again to Paris soon after his return from Italy. But on the death of his father in 1778, he was called to Salzburg, and appointed principal concert-master to the prince archbishop, in his stead; but he resigned this office in 1780, and went to Vienna, where he settled, and was admired and patronized by the court and city; and in 1788 he was appointed chapel-master to the emperor Joseph.

It was not till the year 1782, that he began to compose at Vienna for the national theatre; at first chiefly instrumental music; but on its being discovered how well he could write for the voice, he was engaged by the nobility and gentry first to compose comic operas, sometimes to German words, and sometimes Italian. His serious operas, we believe, were all originally composed to Italian words.

There is a chronological list of his latter vocal compositions till the year 1790, in Gerber's Musical Lexicon.

In England we know nothing of his studies or productions, but from his harpsichord lessons, which frequently came over from Vienna; and in these he seems to have been trying experiments. They were full of new passages, and new effects; but were wild, capricious, and not always pleasing. We were wholly unacquainted with his vocal music till after his decease, though it is manifest that by composing for the voice he first refined his taste, and gave way to his feelings, as in his latter compositions for the piano forte and other instruments his melody is exquisite, and cherished and enforced by the most judicious accompaniments, equally free from pedantry and caprice.

It should be known, that the operas of this truly great musician are much injured by being printed in half scores, with so bully and contemptuously laid for a part in the piano forte. Some of the passages, we suppose taken from the instrumental parts in the full score, but that the editor, or in the fore, was not the author, has such a rage for saying something, when's there nothing to be said," (as was remarked of Dr. Warburton in his notes on Shakspere and Pope, by Dr. Johnson), that there is no contrast; the piano forte has a perpetual lesson to play, sometimes difficult, and sometimes vulgar and common, which, however soft it may be performed, disfigures the vocal melody, and diverts the attention from it, for what is not worth hearing. About the middle of the last century, Mondovini composed for the Concert Spirituel at Paris motets to Latin words for a single voice, accompanied by a very difficult and noisy part for the organ, obligato; and the effect was intolerable, though the organ part was well played by Balbatt; yet being a perpetual roullement, which said nothing to the heart, it was so loud, that it obliged mademoiselle Delcambre to scream to the utmost power of her lungs. There was neither taste, grace, solemnity, nor ingenuity to be discovered. These pieces abounded in notes, &c. que des notes, as Jean Jacques used to say of French music in general. Yet these performances were not only tolerated, but admired by the friends of the old school at Paris. But let us not level the productions of Mozart with those of Mondovini.

In "Idomeneo," which is full of fine things, the air in E, at the beginning of the second act, the chorus, "Alla Siciliana," in the same key, and the quartet in the last act, &c. are exquisitely beautiful, in different styles. But a commentary on the works of this gifted musician would fill one of our volumes. His reputation continued to spread and increase all over Europe to the end of his life, which, unfortunately for the musical world, was allowed to extend only to 36 years, at which period he died in 1791!

After his decease, when Haydn was asked in our hearing by Broderip, in his music-shop, whether Mozart had left any MS. compositions behind him that were worth purchasing, as his widow had offered his unedited papers, at a high price to the principal publishers of music throughout Europe; Haydn eagerly said, "purchase them by all means. He was truly a great musician. I have been often flattered by my friends with having some genius; but he was much my superior."

Though this declaration had more of modesty than truth in it, yet if Mozart's genius had been granted as many years to expand as that of Haydn, the attainment might perhaps have been realised in many particulars.

MOZDOZ, in Geography, a town of Ruffia, in the government of Caucaus, on the Malka; eight miles E. of Ekaterinograd.

MOZÉ, a town of France, in the department of the Maine and Loire; 15 miles W.S.W. of Angers.

MOZ, in Agriculture, a provincial word, sometimes applied to mofs, or a lake that is overgrown with moss or other aquatic plants.

MOZYR, in Geography, a town of Lithuania, in the palatinate of Minsk; 112 miles S.E. of Minsk.

MOZZANICA, a town of Italy; 12 miles N.N.E. of Lodi.

MRAKOTIN, a town of Moravia, in the circle of Iglau; 20 miles S.S.W. of Iglau.

MRATICK, a town of Bohemia, in the circle of Kauzim; 10 miles S.S.E. of Erle.

MRI, a town of Egypt, on the W. branch of the Nile; seven miles S. of Faoué.

MRITU, or MRTITU, in Hindu Mythology, a perfonification of death, and a name of Yama, the Pluto of the Hindoos; applied also to Kal, or Time, and to Siva, the destructive power of the deity. See those articles.

MSCHNO, in Geography, a town of Bohemia, in the circle of Polejlaw; 10 miles W. of Jung-Buntzel.

MSLAVL, or MSCHLAW, a town of Ruffia, in the government of Mogilev, on the Lern; formerly the capital of a palatinate of Lithuania, incorporated with Ruffia in the year 1773; 60 miles E. of Mogilev. N. lat. 53° 54'. E. long. 31°.

MSTI, a river of Ruffia, in the government of Novgorod, which runs into the Ilmen lake, near Lipinskoi.

MSTOW, a town of Poland, in the palatinate of Cracow; 44 miles N.N.W. of Cracow.

MTZENSK, a town of Ruffia, in the government of Orel; 24 miles N. of Orel.

MUAJKUSIN, a town of Asiatic Turkey, in the government of Diarbekir, on the Euphrates; 10 miles W. of Kerkisch.

MUANCES, in Music, the French term for the change in the names of the notes of the hexachords in tabulation, before the admission of the syllable fi. See MUTATION.
MUC

MUAR, in Geography, a river of Malacca, which runs into the Straits, N. lat. 2° 6'. E. long. 102° 27'.

MUSAFFA, a town of Arabia, in Yemen; 20 miles S. of Abu Arifh.

MUBAD, a town of Hindooftan, in Oude; 11 miles W.N.W. of Lucknow.

MUC de la Vix, Fr., the change or breaking of the voice of a boy at the time of puberty. Tiffot.

MUCARE, in Geography, a town of Arabia, in Hedejas; 80 miles S.W. of Mecca.

MUCARES, a small island among the Bahamas, surrounded with rocks. N. lat. 22° 13'; W. long. 77° 20'.

MUCCAPET, a town of Hindooftan, in Golconda; 32 miles S.S.E. of Comhamet.

MUCHEN, or MICHELA, a town of Saxony, in Thuringia; 37 miles N.E. of Erfurt. N. lat. 51° 18'. E. long. 15° 55'.

MUCHNOLO, a town of the island of Corfica; one mile N.E. of Cervione.

MUCHIMA, a town of Benguela, on the Coanza; 76 miles N.N.E. of Old Benguela.

MUCHODER, a town of Arabia, in the province of Yemen; situated on a hill and the seat of a Dola, between Taas and Jerim.

MUCHUNDRA, a town of Hindooftan, in Mylore; 12 miles E. of Bangalore.

MUCIDAN. See Mussidan.

MUCILAGE, in Chemistry, a name given to an aqueous solution of the vegetable product called gum, and to the mucilaginous matter extracted from several vegetables, such as the bulbs of the hyacinth, the lichens, and several others. From these sources it has recently been employed in calcico printing as a subliterate for gum arabic, to prevent the colours from running.

Dr. Thomson has tried the effect of a number of metallic solutions upon a solution of gum, few of which appear to produce any change. Nitrates of mercury produces a white coagulum, which, however, disappears by shaking, but returns when the solution is much diluted. Prussiates of mercury gives to a solution of gum a slight opaque appearance, but makes no precipitate.

He also found that potash, ammonia, solutions of lime, barytie and throntian alum, sulphate of magnesia and ammoniated potash, had no effect upon mucilage. Silicated potash produced a white flaky precipitate, although the solution was much diluted. Dr. Thomson recommends this substance as the best test of the presence of gum. It must be remembered, however, that an acid will produce the same effect upon silicated potash.

Mucilage is used by some writers to designate a peculiar principle distinct from gum. Mucilage, says M. Chapral, appears to constitute the first alteration of the alimentary juices in vegetables. Mucilaginous seeds are almost totally relatable into mucilage, and young plants seem to be entirely formed of it. This substance has the greatest analogy with the mucous fluid of animals. Like that fluid it is most abundant in the earlier periods of life, and all the other principles appear to be derived from it; and in vegetables, as well as animals, its quantity becomes less in proportion as the increase of magnitude, or growth of the individual, becomes less, or ceases. Mucilage is not only the nutritive juice of all plants and animals, but when extracted from either, it becomes the most nourishing and wholesome food with which we are acquainted. It is found in different flatus in plants; sometimes almost alone, as in linseed, &c. ; sometimes combined with substances insoluble in water, which it keeps suspended in the form of an emulsion, as in cuphorrhism, cedrine, &c. ; sometimes united with an oil and forming the fat oil; and frequently it is united with sugar, as in the granumose seeds, the sugar-cane, maize, &c. It is also found confounded with the essential fats, with excess of acid, as in barberries, tamarinds, forrel, &c. Mucilage sometimes constitutes the permanent flatus of the plant, as in the tremella, conferva, &c. It is also seen in this flatus in some animals, such as the medusa or sea-nettle, the holothurion, &c. The characters of mucilage are the following: viscid, insipidity, solubility in water, insolubility in alcohol, coagulation by the action of weak acids, and the emission of a considerable quantity of carbonic acid, when exposed to the action of fire; at the same time that it becomes converted into coals, without exhibiting any flame. It is likewise capable of passing to the acid fermentation when diluted with water. The formation of mucilage appears to be almost independent of light, for the plants which grow in subterraneous places abound with it; but light is required to enable mucilage to pass into other flatus, for without this principle, the same plants would scarcely obtain any confidence.

Of the vegetable mucilages the principal are gum arabic, gum senegal, and gum tragacanth. The gum arabic comes directly from Egypt and the Levant, and is obtained in a similar manner with the gum senegal. The principal marts for it were formerly Cairo and Alexandria, till the Dutch introduced the gum from Senegal into Europe about the beginning of the 17th century, which now supplies the greater part of the confumption of this article. The tree which produces the gum senegal is a species of mimofa, which grows in great abundance on the coasts of Barbary, and particularly about the river Senegal. The trees that yield it are from 16 to 20 inches high, with thorny branches, and the gum makes its appearance about the middle of November; the gummy juice oozing through the trunk and branches and in about a fortnight hardening into roundish drops of a yellowish-white colour. The quantity annually sold out of the Senegal country for European consumption is about 1,200,000 pounds weight. This gum is a wholesome nutritious food, thousands of the Moors subsisting upon it during the time of harvest. About six ounces are sufficient to support a man for a day, and it is also mixed with milk, animal broth and other victuals. Among other uses to which the gum arabic is applied, one is that of giving a fine glaze or glazing to ribs and vessels; for which purpose a thin solution is brushed over the skin, which rarely wafhes away with water, and occasions the appearance of spots in skins after being exposed to rain. See Gum Arabic, Gum Mucilage, Gum Senegal, and Gum Tragacanth. See also Mucous Acid and Pyro-mucous Acid, and Sugar.

MUCILAGE, Animal. See Animal Mucus.

MUCILAGE, in Pharmacy, &c. denotes a certain aqueous solution, which is very thick and adhesive; so called as resembling the mucus of the nose.

Mucilages are prepared chiefly from roots and seeds, pounded in a mortar, and infused in hot water, and strained through a cloth; and they are the most relaxing, emollient, and softening remedies in medicine.

The roots principally used for this purpose are those of aloes, mallows, symphymy, &c., the seeds are those of quinces, flaxwort, &c.
MUCILAGES enter the composition of several plasters. They are sometimes also made of gums and fruits; as figs, quinces, sfiglaf, tragacanth, &c.

The principal mucilages described in the Pharmacopoeias are the following:

Mucilage of acaica, Mucilago acacica, P. L. 1869, Mucilago arabicae gummi, P. L. 1787, is prepared by rubbing 4 oz. of acaica gum, powdered, in half a pint of boiling water gradually added, until it incorporates into a mucilage.

Mucilage of gum arabic, Mucilago gummi arabici, P. D. 1787, is prepared by digesting, with frequent agitation, 4 oz. of gum arabic, in coarse powder, in eight pints of boiling water, until the gum be dissolved; then straining the mucilage through linen.

This mucilage is chiefly employed for making pills and troches. This is omitted in the P. L. 1869, because it seems to possess no advantage over that of acacia gum, and is more difficultly soluble, and very thick, and apt to become lumpy in dilution.

Mucilage of quince feeds, Mucilago feminis cydonii, P. L. 1787, Mucilago femininum, P. L. 1745, is prepared by boiling over a gentle fire for ten minutes, two drachms of quince feeds in a pint of water, and then straining. This mucilage is coagulated by alcohol, acids, and most of the metallic salts; it is more apt to spoil than common mucilage, over which it poiffles no other advantage than its being more grateful, and its being sufficiently thin, without further dilution, to form the bulk of any liquid medicine. It is, however, often preferred to the other mucilages as a local demulcent in teneinmus, and in aphthous affections and excoritions of the mouth. A diluted solution of it injected beneath the eye-lids is useful for obtunding the acrimony of the discharge in violent inflammations of the eye. Thomson's Lond. Difpensatory, 1811.

MUCILAGE also denotes a thick pithitous mass, evacuated with the urine in the gravel and dysuria.

MUCILAGINOSA LIGAMENTA, in Anatomy, small membranous folds in the knee-joint, and the tendinous sheath of the fingers and toes. The term is employed by Witbrecht.

MUCILAGO, in Botany, a name under which Micheli has compriems some species of that kind of fungus called mucor, conflating of small bladders or vehicles, with seeds affixed to filaments on the inner part.

MUCIUR, in Geography, a town of Asiatic Turkey, in Caramania; 25 miles S. S. E. of Kir-fehr.

MUCK, in Agriculture, any sort of material, such as dung, straw, &c., which has undergone fermentation, or lies rotting. See DUNG, and MANURE.

MUCK. Midden, a term sometimes used to signify a dung-hill or compost heap.

MUCK-Weed, the common name of a troublesome weed in arable land, the common goose-foot.

MUCK, in Geography, a small island on the east coast of Ireland, near the entrance to Larme Lough. N. lat. 54° 51'. W. long. 5° 36'.

MUCK or MUCK, one of the smaller Hebrides, containing about 1000 acres of land; chiefly arable. N. lat. 56° 48'. W. long. 6° 12'.

MUCK. See MUCK.

MUCKDUMPollen. MUCKER, a town of Hindoostan; 30 miles N. E. of Moultan.

MUCKEARN, a town of Scotland, in the county of Argyle; 14 miles N. of Inverary.

MUCKBRENG, a town of Saxony, in the margraviate of Meissen; 28 miles N. of Dresden.

MUCKENHAGEN, a town of Pomerania, on the Mohlan; 7 miles S. S. E. of Dantzig.

MUCKENREUT, a town of Germany, in the principality of Culmbach; eight miles N. W. of Bayreuth.
MUCUCKER, a town of Prufilia, in the palatinate of Culm; 17 miles N.N.E. of Culm.

MUCKEROW GAUB, a mountain of Bahar; 23 miles W. of Sfaram.

MUCKISH, mountains of Ireland, in the northern part of the county of Donegal, W. of Sheephaven.

MUCKRAIR, a town of Hindoo, in the cirque of Hurup, 17 miles S.E. of Hurup.

MUCKRIS POINT, a cape of Ireland, in the county of Donegal, and on the northern coal of the bay of Donegal, not far from Tilen harbour. N. lat. 54° 35'; W. long. 5° 27'.

MUCKTERPOUR, a town of Bengal; 33 miles E. of Calcutta.

MUCKUNDGUNGE, a town of Bengal; 18 miles N. of Ramgur. N lat. 23° 57'. E. long. 8° 34'.

MUCOCARNEOUS, an epithet used by authors for a sort of ability, which are partly made up of flesh, and partly of a thick mucous matter.

MUCONI, in Ancient Geography, a people of Africa, in the eastern part of Mauritania Cesarinius, in the environs of mount Mamperus, according to Ptolemy.

MUCOR, in Botany, from mucor, to be mufy or mousy, an ancient Latin word, retained by botanists in its original acceptation, for that genus of minute and eaveefent fungi, found on decaying bread, vegetables, &c. known by the popular name of mould.—Linn. Gen. 460.—Schreb. 770.

Eff. Ch. Head membraneous, globose, ifalked; at first watery and pellucid; subfrequently opaque. Seeds naked, rather coherent.

Perfon enumerates nine species; three of them with a branched, six with a simplex, italk.—We subjoin an example of each.

M. flavidos. Perf. n. 1. Obf. Mycol. fac. 1. 95. t. 6. f. 5. (Byillus; Schimid. Ic. 203. f. 52. f. 2.)—Stalk branched. Heads yellowish; afterwards grey. Found in autumn upon rotten Fungi, especially Agaricus piperatus, on which it forms little indeterminate patches. At first this fland near upright, and is of a shining yellow; afterwards it lies down, and assumes the aife of a greyish aifh-colored Byillus. The heads are blafkifh when ripe, and appear somewhat granulated, from the protrusion of the seeds through the bulking coat. The latter are globular and wiffitive.

M. Muedo. Lion. Sp. Pl. 1655. (M. vulgarius; Perf. n. 4. &. M. vulgaris, caputulo lucido, per maturitatem nigro, pediculo griseo; Mich. Gen. 215. t. 95. f. 1.)—Stalks simple, crowded. Heads blackifh.—This is the most common mould, on all sorts of decaying food, vegetables, fruits, &c. It is at first greyifh, with some sparkling appearance; but in a few hours turns greenifh, and finally almost black, from the copious ripe fefds, which being gone, leave the expanded coat of the head, or receptacle, in a tar-like, jagged, flat form. This is well repreffented in Hook’s Micrografia, t. 12. f. 11, copied in Steerebeck’s Fungi, t. 31.—Perfon is firmly miltaken in confidering as a variety of this, Aelfphora Mucedo of Tode, fac. 1. 13. t. 3. f. 22; as Albertini and Schweinitz, in their learned Conflupus Fungorum, 356, well remark.

Mucor, a vegetable difeaseنتاج a foart of mould or mildew. See Mould, Mildew, and the preceding article.

MUCOSA, in Ichthyology, a name-given by the Italian so species of the ray-fish, called by the old authors, hiraria, and bos marinus; and by the later authors, raja, oxycephalus, and laevis. It is distinguished by Artedi by the name of the variegated ray, with ten prickly tubercles on the middle of the back. See Raja.

MUCOSA, in Anatomy, a name sometimes given to the ligaments which join the roots of the spinous processes together. See Sinne.

MUCOSUM LIGAMENTUM, a name sometimes given to the ligaments which join the roots of the spinous processes together. See Spinse.

MUCOUS Acis, in Chemistry, a peculiar acid formed by the mutual decomposition of the nitric acid and gum mucilage. This acid is found to be of the same as that discovered by Scheele to be produced by the action of nitric acid on sugar of milk. When nitric acid is moderately heated with half its weight of gum arabic, only till nitrous gas begins to be difengaged, there deposits on cooling a white powder, which, when collected and washed, is the mucous acid. Its feel is granular, and taffle slightly four. When heated per se to decomposition, it gives a red paffed oil, much carbonic acid gas, and a portion of it sublimates in brown flakes, smelling like the benzoic acid. The dry mucous acid is very sparingly soluble in water. The hot saturated solution deposits on cooling brilliant fealy cryfals. It decomposes the carbonated alkalies at boiling heat, expelling the carbonic acid, and forming perfectly neutral salts. For a further account of the properties of this acid, see Salicatic or Saccholistic Acid.

MUCRO, in Anatomy, the lower or pointed end of the heart. See Heart.

The word is Latin, mucro, where it properly signifies the point of a spear.

Hence, mucronated is applied to whatever tends to or terminates in a point, like that of a spear; as mucronata cartilago, &c.

MUCRONATUM OS, the flernum. See LUNG.

MUCUL, in Ichthyology, the name of a Brazilian kind of the lamprey kind; the Thymius lepturus of Linnaeus; which see.

MUCUCHIS, in Geography, a town of South America, in the vicerealty of New Granada; 15 miles E. of Merida.

MUCULLAGH ROCKS, rocks in Tralee bay, on the W. coast of Ireland; three miles N.N.W. of Fenit island.

MUCUNA-GUACU, the largest and most beautiful species of phaeolus growing in Brasil; it grows on a tree of the same name; the pod has a black shell, almost as hard as a stone, and covered with soft yellow hair, is a hand’s breadth long, and three fingers’ breadth wide. When broke open, it discloses three or four very beautiful globular beans, divided by intericles of a scarlet or red colour, round, smooth, and with a large eye, which being macerated in water, are deprived of some part of their noxious qualities; and being prepared with tipica de mandiloca, are eaten by the natives; so that their poisonous quality does not seem to neatly planted in them by nature, as not to admit of proper correctives; for though the interior fulstance of the bean, by its acrimony and biting property, venile the ficera, excites great perturbations in the body, and purges violently by dool and vomiting, the cooling and demulcent medicinal ingredient, prepared to be the medicinal effect of the tipica, leaves as an antidote, and is therefore preferable to other things employed to correct it. Ray.
MUD

MUCUND, in Geography, a town of Hindooftan, in Lahore; 14 miles S. of Lahore.

MUCUNDNAGAR, a town of Lamjung; 180 miles N. of Fyzabad. N. lat. 29° 27'. E. long. 83° 30'.

MUCUS, Animal, or Animal Mucilage, in Chemistry, a substance observable in many animal fluids, resembling vegetable mucilage, in being soluble in water, not coagulable by heat, insoluble in alcohol, inospid, and giving a filmy confluence to the fluids with which it is mixed; and on this account denominated mucous. Animal mucus is considered by Mr. Hatchett as merely a modification of gelatin; but Dr. Bolhoeck has pointed out a very decisive difference between the two with regard to the manner in which they are acted upon by Goulard's extract. A preparation of lead produced by saturating boiling vinegar with litharge. (See LEAD.) This liquid, when added to any fluid containing animal mucus, gives a copious white precipitate, whereas it is not rendered turbid by a solution of pure jelly. The infusion of galls or tan, which faintly precipitates jelly, has no or scarcely any effect on mucus. Neither gelatin nor mucus is altered by the solution of corrosive sublimate, which copiously precipitates albumen. Consequently, albumen, gelatin, and mucus mixed together, may be separated with tolerable accuracy by the successive application of corrosive sublimate, infusion of galls, and acetated litharge. Animal mucus is generally combined with gelatin and albumen, and always with some fats; upon the whole, it is one of the least abundant of the animal fluids. See GELATIN.

Mucus of the Joints, is a mucilaginous liquid, separated by its proper glands, conveniently placed in the interstices of the bones, where these glands are generally pressed by the motion of the parts; it serves to make the extremities of the bones or joints slide more easily.

Mucus of the Urethra, a viscous transparent liquid, forming in the bladder and ureter parts that the urine can move more freely, without either adhering to or lubricating the part.

It comes from glands lately discovered by Mr. Cowper, about the penis; and is that, which in women is often mistaken for semen.

Mucus of the Noftris, is a viscid excrementitious humour, separated by its proper glands placed in the internal membrane of the nostrils. It serves to moisten, lubricate, and defend the olfactory nerves; which being extremely soft and naked, would, without such provision, be soon spoiled. See NOSE.

Mucus of Fiba. The bodies of most of the fishes called alepidotes by authors, from their having either no scales at all, or only a few small ones, are covered in the place of scales with this mucus. It is a tough and thick viscous liquor, and thickly firm to the body, defending the thin motion of the parts from the motion of the parts; it serves to make the extremities of the bones or joints slide more easily.

MUD, in Agriculture, the sediment deposited at the bottom of rivers, ponds, ditches, &c. As much of this sort of material should be collected as possible, and be thrown up into heaps, in order to become mellow. It contains much carbonaceous matter, and is an excellent manure either in the simple or compound state. See DUNG, and MANURE.

Mud Creek, a river of Pennsylvania, which runs into the Susquehanna, N. lat. 39° 17'. W. long. 76° 20'.

MUDY, or Muddy, a town of a Saffatic Turkey, in the province of Natolia, situated in a gulf, in the S.E. part of the sea of Marma, and inhabited chiefly by Greeks or Jews, with some Turks. Here the archbishop of Burfa has a palace. The commerce of this place is considerable, and consists of grain, salt, salt-petre, white wine, a variety of fruits, and the manufactures of Burfa, which are brought either for exportation; 15 miles N.N.W. of Burfa. N. lat. 46° 14'. E. long. 28° 54'.

MUDAU, or Mudgee, a town of Germany, in the circle of the Lower Rhine; 10 miles S. of Miltenberg.

MUDBUNNY, a town of Hindooftan, in Bahar; 30 miles E.S.E. of Battiah. N. lat. 26° 33'. E. long. 83° 16'.

MUDD, in Ichthyology, a name given by the Swedes to the fish called by Schonefeldt and others aphra or apyes. See CYPHRUS Aphra.

MUDDAGO, in Geography, a town of Africa, in Futrë; 36 miles W. of Dar-Cooka.

MUDY, a river of Pennsylvania, which runs into the Susquehanna, N. lat. 39° 17'. W. long. 76° 20'.

MUDY, a river of Kentucky, which runs into the Ohio, N. lat. 36° 41'. W. long. 89° 18'. MUDY, a river of Kentucky, called "Pond creek," which runs into the Ohio, N. lat. 37° 16'. W. long. 83° 28'.

MUDY, a town of Georgia, situated between lakes Huron and George; about 25 or 30 miles long, and not very wide. On it are several small islands, the principal of which is St. Joseph's.

MUDY, a cape on the W. coast of Africa. S. lat. 17° 40'.

MUDEN, a town of Peria, in Segellia; 110 miles N.W. of Zareng.

MUDERER, a town of Hindooftan, in the gulf of Cutch; 18 miles S.E. of Boogebouge.

MUDERIS, in the Ottoman court. See CANDIESCHER.

MUDERNI, a town of Aflatic Turkey, in Natolia; 24 miles S.W. of Bolt.

MUDGURRY, a town of Hindooftan, in Bahar; 10 miles N.W. of Burwaah.

MUDJEA, a town of Bengal; 25 miles E. of Rugganpore. N. lat. 23° 32'. E. long. 87° 16'.

MUDNAGUR, a town of Hindooftan, in Oude; 16 miles E. of Bahiratch.

MUDNISKA, a town of Russia, in the government of Irkusth, on the Lena; 92 miles N.E. of Kirensk.

MUDO, HERNANDEZ EL, in Biography, whose real name was Juan Hernandez Navarette, was a native of Logrono, whose ingenuity in the art of painting acquired for him the honourable title of the Spanish Titian. Velasquez says, that he was born deaf and dumb, and, therefore, had the appellation of El Mudo, by which he was most generally known. He made himself master in the principles of his art by going to Italy, and studying there some time the works of the great men who then adorned it, particularly of Titian and the Venetian school. After his return to Madrid, he was in 1568 nominated painter to the king, and was employed by him to paint eight large pictures for the Escorial.
of which the most striking was the Decollation of St. James. He painted also for the cities of Valencia, Salamanca, and Eirella; but his hat and ball work, was of Abraham receiving the three Angels, and which was also deposited at the above-mentioned palace. He died at the age of little more than 40, according to P. Velasco, in the year 1572.

MUDWORTH, in Botany. See Liniocella.

MUEHRAU, in Geography, a town of the duchy of Stiria, on the Muehr, which divides it into two parts, defended by a citadel, situated on an eminence 32 miles W. of Judenburg. N. lat. 47° 7'. E. long. 13° 52'.

MUEL, a town of Spain, in the kingdom of Aragon; 12 miles S.S.W. of Saragossa.

MUENELUNA, a town of Mexico, in the province of Guusaxa; 60 miles S. of Nexapa.

MUEERAGAUT, a town of Hindooftan, in Oude; 54 miles N.W. of Lucknow.

MUERDUM, among the Turks, an officer belonging to their mosques, who, with his voice calls the people to prayers; thereby supplying the want of bells, which the Mahometans will not use. See Bell and Mosque.

MUERTZENSCHEL, in Geography, a town of the duchy of Stiria; 23 miles E. of Prueck.

MUEZIS, officers of the mosques among the Muffulmans, whose bufinefs it is to attend five times a day to the minaret, there to proclaim aloud the profefion of faith of Mahomet, invite the Muffulmans to prayer, and sing, on festivals, different hymns. In the little mosques, the muezins sweep and arrange the carpets, light the lamps, &c. But this function in the great mosques is referred for other young ones, called "cavins."

MUFFLE, in Metallurgy, is an arched cover, refilling the forgef with fire, and made to be placed over copels and tefts in the operation of affaying, to preserve them from the falling of coals or ashes into them; though at the fame time of fuch a form, as not to hinder the action of the fire on the metal, nor prevent the infpecion of the affayer.

The muffle may be made in any form, fo that they have these conditions; but that used with copels are commonly made semi-cylindrical, or when greater veffels are employed, in form of a hollow hemisphere.

The muffle must have apertures, that the affayer may look in, and the fore-part of it must always be quite open, that the air may act better in conjunction with the fire, and be incessantly renewed; for without this, scarcely any fumes are to be produced, and without the refpiration of lead is scarcely practicable; for when the air is once filled with a certain quantity of vapours, it scarcely admits any more afterwards; and for this reason a contiufion of fresh air is neceffary. The apertures in the muffle are also for the regimen of the fire; for the cold air rushing into the larger opening before, cools the bodies in the veffel; but if some coals are put in it and its aperture before be then flut with a door fixed to it, the fire will be increafed to the highest degree, much more quickly than it can be by the breathing-holes of the furnace. Another use of these apertures is also, that the aromatic vapours of lead and antimony, passing through the holes in the back part of the muffle, may not be offensive to the affayer, who stands before it.

As to the height, length, and depth of the muffles, thefe must be proportioned to the size and number of the veffels they are intended to cover; and care must be taken in this, that all parts of the inner surface of these veffels must be within the reach of the affayer’s eye. The most frequent size of the muffle, however, is four inches high, five or eight inches long, and four or six inches broad. The segments cut off at the bales, for the leffer holes, must be of fuch a proportioned height, that the least veffels put under it, may not be in the way of coals or ashes falling into them, for that always hinders the vitrification of lead, and the deftruc- tion of the other metals and semi-metals, and will sometimes entirely reduce them again when already destroyed; and the fcorie, softened by ashes, soften and retard the operation.

Wooden moulds of a proper shape are moft convenient for the making of these muffles, and the matter of which they are made is the fame with that of the German clay- tefts; this is, either a pure native clay, of a condition to bear the fire, which will be known upon the trial; or ftrong clay hardened by a mixture of the powder of ftones: and in order to the forming of thefe, the mafs must be made tolerably soft and pliant. Knead a fufficient quantity of this mafs with your hands upon a flat stone; spread it out evenly into a thin cake or plate, somewhat longer and broader than you thinke it be to be made; and ato thick, that two or more thin plates or lamina, of about two lines thick each, may be cut off from it. This is easily done by rolling the mafs on the stone with a rolling-pin, flrewed over lightly with ashes, or powder of chalk.

When the cake is thus rolled out, with a thin, fine, and perfectly straight brash-wi. cut off from the cake one thin plate; this maff must be done with great caution left it should break: take this up, and rubbing it over with oil or fat, lay it over the mould; then cut out a femicircular piece from the mafs, of the fame thicknefs with the former, and with this cover the back plane, or farther end of the mould, joining the edges of this plate to thofe of the former, closely and perfectly, by wetting them well with water.

Next cut off from the cake another thin plate, to be the bottom of the muffle; this may be either left lowe for the muffle to be placed on it occasionally, or the bottom edges of the already formed maffe may be joined to it all round by means of water, as the back was before jointed to the arched part of the muffle. But whether it be intended that the bottom should be thus fixed on, or left loose, it must be half an inch broader every way than the bottom of the muffle, that this may fland the more sure and firm upon its base.

When the muffle is thus made, wet your hand, and rub it carefully all over, that the small, and perhaps invisible, cracks and chinks in the plates may be closely joined, and the whole matter of it applied perfectly close to the surface of the mould.

When the muffle has been some time exposed to the air, and is somewhat dried, and hardenec on the mould, cut two or three hemispherical pieces on each side, to make the holes before described, at the basfs and back, and then draw away the mould from within it; for if the muffle is suffered to dry perfectly on the mould, it always cracks. When the whole is perfectly dry, let it be baked in a potter’s kiln, or in the affayer’s own; but without great care in the former method, and lighting the fire at top at first, it is apt to crack; so that the potter’s kiln, where at hand, is much the better way of baking it.

If there be adapted to the formerly defcribed convex mould, another concave one nearly fitting it, only leaving room for the thicknefs of the muffle between them, and the clay be placed between them, and formed by this means into its exact shape, by a strong and every way equal pre-
fure, this will make muffs not only with much les trouble, but they will be much stronger, les apt to crack, and more capable of refisting the fire, than those made by the hand in the other way.

The only cautions necessary for making these, are, that the clay be a little drier than when it is to be worked by the hand; that the sipes, both of the inner and convex mould, and of the outer concave one, be thoroughly oiled or greased, and the preffure on the surface of the outer or concave mould be as strong and equal as may be. There is no clay better for making these muffs than the Windflor-loam, an earth well known among the chemists and glaffmen, and always to be fold in London; and rubbing the infide of the mould with black lead in fine powder very well supplies the place of greasing them, to prevent the matter from flicking to them.

These are the muffs ordinarily ufed in affaying; but when very large tefts are to be covered, they use large pheriodial muffs, made of cad iron, or sometimes of the fame clay, and wrought in the fame manner, only made upon proportionally larger moulds. The clay is ually, for these large ones, only laid in a lump on the top of the mould, and with wet hands spread all over it to the bottom, and by this means a muff is made with little trouble. Cramer.

MUG. See Mupiti.

MUGA, in Geography, a town of Spain, in the province of Catalonia; 21 miles N. of Gerona. 

MUGALNOOR, a town of Hindooftan, in Coimbecore; nine miles E. of Darapurum. 

MUGARDOS, a town of Spain, in Galiacia; seven miles W. of Betanços. 

MUGDOOMPOUR, a town of Hindooftan, in Bahr; 30 miles N.E. of Monghir. 

MUGDUMPOR, a town of Bengal; 22 miles N. of Boglipour.—Alfo, a town of Hindooftan, in Bahr; 37 miles S.S.W. of Patna. 

MUGELN, New, a town of Saxony, in the circle of Leipfic; 25 miles E. of Leipfic. N. lat. 51° 15'. E. long. 12° 57'.

MUGELN, Old, a town of Saxony, in the circle of Leipfic; two miles N.W. of New Mugeln. 

MUGERES ISLANDS, called also Men-caters, or Women-caters, islands, are iflands situated in the bay of Honduras; to leagues S. of Cape Catoche, on the E. coast of the peninsula of Yucatan. On one of them to the S., towards the land, is good anchorage in a depth from seven to ten fathoms, and clear ground.

MUGGENT, in Ornithology, the name of a species of fresh water wild duck, called by many authors the myf- cania, from its catching flies that play on the surface of the water.

It is al about the size of the common tame duck; the beak is fhort and broad, and is of a faffron-colour: it is al over of a mottled colour, like that of the partridge, made up of black, white, brown, and grey, fo oddly mixed together, as to fhow neither separate; the crown of the head is black, and the feet are yellow.

Mr. Ray fuppofts this not to be different from our common wild duck. See Duck.

MUGGLETIONANS, in Ecclesiatical History, a religi- ous fect, which arose in Englaand about the year 1657, fo denominated from their leader Lodowick Muggleton, a journeyman taylor.

Muggleton, with his associate Revers, set up for great prophets; and, it is laid, pretendted to an absolute power of
MUGUL, a town of Nubia; 50 miles S. of Sennar.
MUGWORT, in Botany. See Artemisia.

MUGWORT, the common name of a very troublesome weed, the roots of which creep far under the surface of the ground, so as soon to overspread a large space, if they are not flopped. Its seeds are light, and easily carried to a distance by the wind, producing numbers of new plants the next spring. It has plain cut leaves, ending in many points woolly underneath, and fingle spikes of pale yellow oval flowers, which blow in June or soon after.

MUHES, in Geography, a town of Sweden, in East Bothnia, on the Ule; 20 miles S.E. of Ulea.
MUHKA, a town of Bengal; 13 miles W. of Toree.
MUHL, or Muhl, a quarter or division of the archduchy of Austria.

MUHLBERG, a town of Germany, in the territory of Erfurt; 12 miles S.W. of Erfurt.—Alto, a town of Saxony, in the margraviate of Meissen, seated on the Elbe containing five churches, a castle, and a cottage; 32 miles N.W. of Dresden. N. lat. 51° 25'. E. long. 13° 14'.
MUHLEBORN, a town of Baden; 6 miles W. of Durlach.

MUHLDORF, or Mieseldorf, a town of Saxony, in the Vogtland; 8 miles W.N.W. of Plauen. N. lat. 50° 27'. E. long. 12'.—Alto, a town of Germany, in the principality of Culmbach; 5 miles S.S.W. of Hof.

MUHLENBERG, a county of Kentucky, bounded N. and E. by the county of Ohio, N.W. by Henderson, S.W. and S. by Christian, and S.E. by Logan; 48 miles long, and 31 broad. It is watered by Green and Muddy rivers, with their branches, and contains 1517 people, 116 being slaves.

MUGR, a town of Africa, in the kingdom of Algiers; 85 miles S. of Algiers.

MUGRON, a town of France, in the department of the Landes, and chief place of a canton, in the district of Saint-Sever; 6 miles W. of it. The place contains 2135, and the canton 9182 inhabitants, on a territory of 1324 square kilometres, in 13 communes.

MUGROOR, a town of Hindoo-land, in Berar; 30 miles N.W. of Notchegong.

proceeds on each side. By Forficulae it is called the mugil magnum, or great mullet, as being much larger than the common mullet. By him it was first observed in the Red sea, of which it is a native. It is a yard long; body oblong and silvery, with soft cirri, but without teeth; scales are broad, rounded, finely irate. According to Gmelin a variety has been found nearly as large again. The head is narrower than the body; crown flat, glaucous, naked, upper lip longer, notched in the middle; lateral line recurved near the head and afterwards straight, nearer the back; tail much forked, and furnished towards the middle with two membraneous wing-like appendages on each side.

MALABARICUS; Grey Mullet. With large ciliated scales, and the first dorsoal and anal fin calcated. It is about two feet long; head small; nape sinking in a little before the rise of the back; scales large and ciliated, both on the body and gill-covers; thence on the head somewhat smaller. It is a native of the Indian seas.

TANG; Silver-grey Mullet. With yellowish longitudinal streaks, and scaled gill-covers. This is not more than a foot long; is a native of Guinea, inhabiting fresh waters, called by the natives long, and regarded by them as excellent food. Of this species there is a fupposed variety, in which the gill-covers were scaled, the colour of the fin brighter, the eyes more vertical, and the head fmialler. With wide mouth, and both dorsal fins fpiay. This is of the same length and shape of the other, but has a very large head, wide mouth, and fleshy lips, which appear better with a row of very small teeth round the edges. It is a native of the American seas, and was first noticed as an object for classification in natural history by Plummer.

CERULEO-MACULATUS; Blue-brown Mullet. With filly abdomen, nine rays in the dorsal fin, and a blue spot in the pectoral fins. This is the size of a common mullet, and is a native of the Indian seas.

MUGILAMERICANUS. See Gobius Gronovii.

MUGKOVSKOI, in Geography, a town of Russia, on the river Meksi; 190 miles E. of Archangel.

MUGLATORE, a town of Hindoo-land, in the circle of Rajamundry; 35 miles E.S.E. of Rajamundry.

MUGLE, a fort of Hindoo-land, in a pash of the Eastern Gatts, between the Carnatic and the Mysore; 12 miles W. of Chittore.

MUGLIA, or MUGLIA-Newa, a small town of Italy, with a harbour for barges, on the gulf of Trieste, about two miles N. of Capo d'Illiria, and about 10 miles S. of Trieste.

MUGLIA Vetelia, a town of Illiria; 2 miles E. of the former.

MUGLIANO, a town of Etruria; 24 miles N.W. of Sienna.

MUGLITZ, or Moel, a town of Moravia, in the circle of Olmutz; 15 miles N.N.W. of Olmutz. N. lat. 49° 49'. E. long. 16° 49'.

MUGORA, a town of Arabia; 35 miles N.N.E. of Ghezan.

MUGRA, a town of Africa, in the kingdom of Algiers; 85 miles S. of Algiers.

MUGRON, a town of France, in the department of the Landes, and chief place of a canton, in the district of Saint-Sever; 6 miles W. of it. The place contains 2135, and the canton 9182 inhabitants, on a territory of 1324 square kilometres, in 13 communes.
tritiated, smooth, the lower ones most compressed. *Stipa* small, membranous, crowning the contracted orifice of the sheath, accompanied by a tuft of fine short hairs. *Panicles* terminal, erect, much branched, close, three or four inches long, pale green; their flanks and branches triangular, finely downy. *Flowers* small, resembling those of an *Aegris* at first light, each about half a line long without the awn, which is straight, very strong, and about twice the length of the flower. Glumes of the *carola* with a few bristles at the base, angular, and strongly keeled; their keels rough. *Anther* dark purple.

2. *M. eretica*. Upright Broad-leaved Muhlenbergia. Schreb. M.S.S.— Stem erect, simple. Leaves broadly lanceolate, many-rhived. — Native of Pennsylvania. Sent by Dr. Muhlenberg with the foregoing, from which it differs widely in appearance and characters, though there is the trifled coincidence in the structure and habit of the fruitification. *Rust* perennial, tufted, hard, and rather woody, its buds invested with imbricated, polished, pale, strongly-rhived scales. *Stems* two feet high, erect, slender, unbranched, leafy, angular, jointed, smooth, except a few dense deflexed hairs under each joint. *Leaves* rather spreading, three or four inches long, and half an inch or more in breadth, flat, taper-pointed, rounded at the base, furnished with a mid-rib, and about four smaller ribs on each side of it, which half are finely hairy underneath; the intermediate *frise* of the leaf are still more minutely rough or downy. *Panicle* flat, erect, close, of much fewer *flowers* than the first species, but those are ten times as large, resembling some *Bromus* or *Festuca* in habit. Their glumes are hairy at the base, strongly fringed, and all the angles are rough. S.

**Mühlhausen**, in Geography, a town of Prussia, in the province of Oberland; 46 miles S.W. of Königsberg. N. lat. 54° 10'. E. long. 19° 40'.

**Mulhausen**, or Mulhausen, a city of Saxon, in Thuringia, on the Urntrutz; free and imperial till the year 1803, when it was elevated to the king of Prussia, and by him ceded to the kingdom of Westphalia at the peace of Tilsit. It is divided into the Upper and Lower Towns, and contains two Lutheran churches, and a Roman Catholic establishment of Augustinians; 50 miles S. of Goslar. N. lat. 51° 10'. E. long. 10° 32'.

**Mühlhausen**, or *Mühlau*, a town of France, in the department of the Upper Rhine, and chief place of a canton, in the district of Altkirch; 20 miles S. of Colmar. The town contains 6615, and the canton 14,701 inhabitants, on a territory of 120 kilometres, in 14 communes. N. lat. 47° 45'. E. long. 7° 25'.— *Alfo*, a town of Bavaria, in the principality of Aichlatt; 7 miles S.E. of Aichlatt.—*Alfo*, a town of Bohemia, in the circle of Schlan, on the Muldan; 10 miles N. of Prague.

**Mühlbach**, or Milbach, a town of Bohemia, in the circle of Bechin; 9 miles N.W. of Bechin. N. lat. 49° 28'. E. long. 14° 13'.

**Mühlau**: a town of Bohemia, in the circle of Leitmeritz; 13 miles N. of Leitmeritz.

**Mühlau**, a town of Germany, in the margraviate of Anspach, on the Altmühl.

**Mühlbau**, See Mühlbau.

**Mühlbeck**, a town of the duchy of Stiri, on the Mühl; 1-2 miles N. of Pettau.

**Müglaco**, a kingdom in the interior part of Africa, N. of Anzina, and about 450 miles from the sea.

**Mujjar**, or *Mucagra*, a former town of Spain, in the province of Granada, situated on a small bay of the Mediterranean; supposed to be the ancient "Murgis"; 35 miles N.E. of Almeria. N. lat. 37° 5'. W. long. 2° 11'.

**Muird**, a large measure, formerly in use among the French for dry commodities: as corn, pulse, salt, lime, coals, &c.

The muid is no real vessel used as a measure; but an estimation of several other measures, as the jeptier, or better, the minot, buflles, &c. At Paris the muid of wheat, pulse, and the like, is composed of twelve feters, each feter making two mines, the mine four minots, the minot three brushes, or buflles, the buflled four quarts, or sixteen litrons. A muid of wheat weighs about 2830 poids de marec; and a feter 240 lbs. The muid of oats is double that of wheat, containing 24 feters. The boifleau is a cylinder 8 inches 2½ lines in height, and 10 inches in diameter; its contents are, therefore, 644 French cubic inches, or 780 English; hence 11 feters of Paris = 6 English quarters, and 11 boifleaux = 4 English bushels. A muid of falt contains 12 feters, and a feter 4, 16 boifleaux, 256 litrons, 4906 meffures, weighing in all about 4000 lbs. poids de marec, or 432 lbs. avoirdupois. A muid of charcoal contains 20 mines, 49 minots, or 320 buflles.

*Muid* is also one of the nine casks, or regular vessels used in France, to put wine and other liquors in. The muid of wine divided into 2 demi-muids, 4 quarter-muids, and 8 half quarter-muids, contains 35 feters, each feter 5 pintes, Paris measure; so that the muid contains 388 pintes, but only 280 pintes without the lees. The pintone contains 2 chopes, or 4 demi-feters, or 8 pofitions, in all 47 French cubic inches, or 576 English; hence a French pintone is nearly equal to an English quart; and a muid of wine contains 781 English gallons.

Muir, in Geography, a term used in the northern parts of the kingdom to signify moor. It is the common term in Scotland.

**Muirirk**, in Geography, a town of Scotland, in the county of Ayr; in which are manufactures of iron and coal tar; 20 miles E. of Ayr.

**Muir**, Simon de, in Biography, a native of Orkney, born in 1537. He was educated for the church, and received promotion from Lewis XIII., who also nominated him professor-royal of the Hebrew language at Paris. He is considered as one of the ablest Hebrew scholars that France ever produced. He was distinguished likewise as a commentator on the Scriptures. He published a "Commentary on the Psalms," which is thought to be one of the best critical illustrations of that portion of the Bible. He died in 1644, leaving behind him many very learned works that do honour to his industry, talents, and erudition, the titles of which are enumerated in Moreri, and in the Gen. Biog.

**Mukar**, in Geography, a town of Hindoostan, in Bahar; 23 miles N.E. of Chaprah. N. lat. 25° 57'. E. long. 8° 13'.

**Mula**, a town of Spain, in Murcia, celebrated for its baths; 20 miles W. of Murcia.

**Mula**, a word used by some medical writers to express purules on the skin, which are owing to extreme heats, or to cold.

**Mulanter**, in Geography, a town of Hindoostan, in Tellangana; 32 miles W. of Warangol.

**Mulated**, a cluster of small islands in the Spanish main, near the islands of Dairen. N. lat. 9° 20' to 9° 35'. W. long. 78° 5' to 78° 30'.

**Muleatre Point**, a cape on the E. coast of the island of Dominica. N. lat. 15° 25'. W. long. 61° 17'.

**Malletto**,
MULATTO, a name given in the Indies to those who are begotten by a Negro man on an Indian woman; or an Indian man on a Negro woman.

The word is originally Spanish, mulata, formed of mula, a mul, as being begotten of two different species.

Those begotten of a Spanish woman and an Indian man, are called mulattoes; and those begotten of a savage by a mulatto, are called jambos. These are all very different in colour, and in their hair.

MULATTO Point, in Geography, the S. Cape of the port of Ancoa, on the W. coast of South America; 16 or 18 miles N. of Cadavalle river.

MULAZZO, a town of Genoa; 15 miles N. of Spezza.

MULBERRY Tree, in Botany. See Morus.

MULBERRY-Tree, in Agriculture, the common name of a tree of which there are several species, but those generally cultivated, are the white or filk-worm mulberry. For the cultivation of the mulberry-tree, see Morus.

The ripe fruit of this tree abounds with a deep violet-coloured juice, which in its general qualities agrees with that of the other acido-dulces, alloying thirst, partly by refrigerating, and partly by exciting an excretion of mucus from the mouth and fauces; a similar effect is also produced in the flamch, where, by correcting putrefaction, a powerful canle of thirst is removed. This is more especially the case with all those fruits in which the acid much prevails over the facharine part, as the currant, which we have already noticed; and to which the medicinal qualities of this fruit may be referred; but both these, and most of the other summer fruits, are to be considered rather as articles of diet than of medicine. The London College directs a syrups mort, which is an agreeable vehicle for various medicines.

The bark of the root of the mulberry-tree has an acrid bitter taste, and possesses a cathartic power. It has been successfully used as an anthelmintic, particularly in cafes of taenia. The dofe is half a drachm of the powder. Woodville Med. Bot.

The more general cultivation of mulberry-trees in England might be of greater use than is at present supposed in many respects. In Devonshire they have a way of mixing mulberry-juice with their cider in the making, and this makes the very bell of all English wines liquors.
