B. *Antennae filiform; shells fulvous, as long as the body.*

Species.

* THALASSINA. The thorax of this species is channeled; the body is green, legs black. It inhabits Germany, and is said to be twice as large as the next, viz. the

* VIRIDISSIMA. In this species the thorax is roundish; the body is green, and the fore-legs tesselaceous. It inhabits this and other European countries.

* CERULEAN. The thorax of this is roundish, and the body blue and nearly opaque. It is an European insect.

* VIRESCENTS. In this species the thorax is unequal; the body is of a dull greenish colour; the antennae and legs are black. It inhabits Germany, and is less than the N. thalassina. The thorax is impregnated on each side; the shells have two raised lines; the hind-thighs in one sex are clavate, and in the other simple.

Vol. XXIV.

CYANEA. Thorax ovate; blue; the antennae and legs are black. It inhabits Germany, and is the same size as the last, the thighs are blue.

SANGUINCOLLIS. The thorax of this is roundish and rufous; the body is brown. It inhabits Saxony.

BARBARA. Thorax uneven; greenish; tip of the shells and legs yellow. It inhabits Barbary. The hind-thighs are black.

SELADONIA. Thorax uneven; body green and poliished; the shells are blue and thickened at the tip. It inhabits Germany, and is something less than the N. virescens.

RUFICOLLIS. Thorax roundish, and with the abdomen rufous; head and shells brassy-green. It inhabits Italy. The head is green; the antennae and legs are black.

MELANOCEPHALA. Black; thorax and abdomen fulvous; shells tesselaceous. It inhabits Italy, and is the size of the last.

TRISTIS. Black; thorax roundish, and with the base of the thighs rufous. It is found in Van Diemen's Land. The shells of this species are very smooth.

ATRA. Shells tesselaceous, black; all the thighs are clavate. It inhabits the southern parts of Europe.

* HUMERALIS. Shells tesselaceous, black, yellow at the base. This is an English insect. The shells are without lines; body and legs black.

USTULATA. Black; base of the shells and broad future tesselaceous. It inhabits Germany.

MELANURA. Black; thorax and shells tesselaceous; the latter tipped with black. This is found on various plants in Spain.

NOTATA. Head and thorax ferrugineous; shells tesselaceous, tipp'd with black. It inhabits Germany, and is the same size as the last.

FULVICOLLIS. Black; thorax and tail fulvous; shells with a bluish shade. It inhabits Germany, and is less than the N. melanura.

* RUPA. The shells of this species are fulvous; the body is black; the thighs are clavate; the shells and antennae are rufous. This is found here and in other parts of Europe.

PREFUSTA. Black; shells tesselaceous, tipp'd with black; the thighs clavate. It is found in Barbary.

* CERULEA. Shells tesselaceous, body blue; hind-thighs clavate and arched. It is found in Europe and in other parts of Europe; and varies in having the legs sometimes simple.

PODOGRARIA. Shells tesselaceous, tesselaceous; body black; hind-thighs clavate and tesselaceous at the base. It is found in gardens in Europe.

FLAVESCENS. Shells tesselaceous; body black; hind-thighs clavate and curved. It is an European insect, and is thought to be a mere variety of the last.

BICOLOR. Blueish; edge of the thorax, abdomen, and legs tesselaceous. It inhabits the Cape of Good Hope.

CLAVIPES. Black; shells tapering, greenish; hind-thighs thickened and curved. This is found at Kiel, and is not above half the size of the others. The thorax is impregnated on each side black-green; shells with a ruffled dusky line reaching not half way down.

TESTACEA. Black; thorax and shells tesselaceous; legs rufous. This species is found in divers parts of Germany.

GLAUCESCENS. Shells tesselaceous and glaucous; body black; incision of the abdomen white. It inhabits the southern parts of Europe.

SIMPLEX. Shells tesselaceous and tesselaceous; the legs are simple. It is found in Europe, and is thought to be a variety of N. pedagraria.

41
QUERCUS. Shells subulate; abdomen and legs yellowish. It inhabits Denmark, on the oak, and is very small.

BREVICORNIS. The shells of this species are very minute; head and thorax brown, with a yellow line; the antennae are very short and thick. It inhabits Saxony.

GLAUCUS. Black; thorax and shells blue. This is found in Berlin.

MELANOCEROS. Shells testaceous; head and wings black; the antennae are brown. This inhabits Saxony.

GLAUCUS. Black; thorax and shells blue. This is found in Berlin.

COLLARIS. Black; thorax testaceous, with two punctures; the legs are simple. It inhabits North America.

EXUSTA. Brown; shells subulate and testaceous, darker at the margin; the legs are simple. It inhabits Europe.

CLAVATA. Black; shells subulate and testaceous; the outer margin brown; hind-thighs clavate and curved. It inhabits Europe.

This genus is generally found in woods, in their perfect form; but the refuscence and character of the larvae are unknown. In some individuals the thorax is black, in others yellow; the elytra or wing-sheaths are generally black, and lighter towards the middle, which contain a yellow, or lemon-coloured spot.

NEDA, in Geography, a town of Spain, in Galicia; five miles E. of Ferrol.—Allo, a river of European Turkey, which runs into the sea, 20 miles N. of Navarim.

NEDAS, in Ancient Geography, a river of Arcadia, S.W. of Megalopolis. It commenced at mount Ceraufius, and in its progress separated the Elide from Melfia. Near it was a celebrated ancient temple, consecrated to Eurynome, the pretended daughter of the Ocean: this temple was encompassed by cypresses-trees. Once a year it was restored to facricule, but at all other times it was flut.—Allo, a town of the Peloponnesus, in Arcadia.

NEDANORE, in Geography, a town of Hindoostan, in the circuit of Ello; 16 miles E. of Elleor.

NEDDAGOONTA, a town of Hindoostan, in the Carnatic; six miles S. of Pallamalifer.

NEDDEEK, a mountainous, narrow, and steep tract of Africa, about 70 miles W. of Augela, in the road to Mourzouk.

NEDDICK, or NEDDOCK, Cape, a cape of America, between York river and Well's bay, on the coast of York county, in the district of Maine.

NEDEBA, a lake of Egypt, on the borders of Libya, abounding in natron; 60 miles N.W. of Cairo.

NEDEHES, a town of Norway, in the diocese of Christianand; 24 miles N.E. of Christianland.

NEDERBRUKAL, a town of France, in the department of the Schlidt, and chief place of a canton, in the district of Audenarde. The place contains 3,145 inhabitants, and the canton 12,430 inhabitants, on a territory of 65 kilometres, in nine communes.

NEDERCRUCHTEN, a town of France, in the department of the Lower Mene, and chief place of a canton, in the district of Rumereonde. The place contains 3,525, and the canton 6,014 inhabitants, on a territory of 102½ kilometres, in three communes.

NEDIQULI, a town of Hindoostan, in Vifapour; 30 miles S. of Calberga.

NEDOSTRAILVA, a town of Russia, in the government of Irkuk; 32 miles N.N.E. of Vittimoff.

NEDRIGALLO, a town of Russia, in the government of Charkov; 80 miles N.W. of Charkov. N. lat. 50° 54', E. long. 34° 20'.

NED-ROMA, a town of Algiers, anciently "Celama," or "Salamium," situated near a small river, in a delightful country, and surrounded by magnificent ruins; 50 miles W.S.W. of Oran.

NEDSJEJED, a very extensive province of Arabia, comprehending all the interior parts of the country, and bounded on the N. by the desert of Syria, on the E. by Luchia, on the S. by Hadramaut and Yemen, and on the W. by Hadsjas. Niebouh has particularly described it; and from him we learn, that the soil is various; among the hills fertile, and bearing abundance of fruits, especially dates; but, being bounded by arid tracts of country, its rivers are short streams, the waters of which, after passing through the valleys, are absorbed in the sandy plains before they reach the ocean. On this account the inhabitants are, in many places, obliged to dig deep wells, so that it does not admit of cultivation. It is chiefly inhabited by Bedouins; and other parts are mountainous, full of cities and villages, and distributed among many petty sovereigns, so that almost every town has its own sheik. In their moral qualities the inhabitants of this province resemble the other Arabs; being at the same time robbers and hospitable. Travellers cannot pass with safety through this country, as they are liable to be plundered by the different sheikhs. The caravan indeed travels safely between Oman and Mecca, because it confines of beggars from whom nothing can be gained. But the sheikhs levy a contribution upon the caravan from Bagdad, on its way to Mecca, in the same manner as the sheikhs of Hadsjas lay contributions upon those from Syria and Egypt. Among themselves and with their immediate neighbours, they carry on a considerable trade; and it is probable that Europeans might travel in safety through this part of Arabia. The people seem to be warlike, and are almost constantly in arms; nor do they permit any of their young men to marry till they have performed some gallant action. Nedsjed is divided into two districts: El Arad, which joins Oman, and El Kherdsja, which stretches to the confines of Yemen. In the latter district, extending northward from Hadsjas to the desert, is the city of Imam, famous, even before the days of Mahomet, for being the native city of Meofelama, who assumed the character of a prophet. This district contains also many other cities. North from Nedsjed, and about ten days' journey from Bagdad, is the famous mountain of Schamer, confederate both in extent and fertility. Between this mountain and Syria is a hilly tract of country, denominated Dzof al Sirhan, which is populous and cultivated. This province contains Sabeeans, or Christians of St. John, and a few Jews; its other inhabitants are all Mahometans, who were once rigid Sunnites. At a late period, a new religion sprang up in the district of El Arad, which has already produced a revolution in the government of Arabia. Its founder was one Abd al Wahkeb, a native of Ajine, a town in El Arad. In his youth he studied those sciences which are chiefly cultivated in Arabia; and he afterwards spent some time at Bagdad, and made several journeys to Bagdad, and through Persia. After his return to his native place, he began to propagate his opinions among his countrymen, and having converted several independent sheikhs, their subjects became followers of this new prophet. The sheikhs who had been engaged in intestine contests were reconciled to one another by the mediation of Abd al Wahkeb, and mutually stipulated to undertake no future enterprise without consulting their apostle. By this association the balance of power in Nedsjed was destroyed: the wars became more frequent, and religion blended itself with other disputes. The new prophet reduced a considerable part of El Arad, and defeated
test the sheik of Lachfa, to whom the vanquished sheikhs of El Arad applied for assistence. The sheik Mehrami of Nedjseran, whose priciples resembled those of Abd al Wahkeb, joined the latter, or rather his son Mahomeck, called Mezemdi and imposed in order to reduce the Sunnite sheikhs. After the death of Abd al Wahkeb, his son retained the same authority and prosecuted his views. He fulfilled the supreme ecclesiastical character in El Arad, and became sovereign of the whole district, the hereditary sheikhs of the small independent states retaining only a nominal authority. With a view of carrying on the war against the infidels he imposed a tribute, under the name of "Sikka," or aid. The Sunnites have complained of his persecutions; and those inhabitants of Nedjseran who were unwilling to embrace the new religion, have retired to other parts of the country; and these refugees have peopled the ancient Bafra, now called Zobayer, so that from being a decayed hamlet, it is now become a large town. From the information obtained by Niebuhr from an intelligent Bedouin sheik, he has given the following account of this new religion Abd al Wahkeb taught, that God is the only proper object of worship, as the creator and governor of the world. He forbids the invocation of saints, and the mention of Mahomet, or any other prophet in prayer, as profaning the name of Mahomet, the Jesus Chrish, Moles, and many others, respected by the Sunnites or Sontimes in the character of prophets, as merely great men, whose history might be read with improvement; denying, at the same time, that any book had ever been written by divine inspiration, or brought down from heaven by the angel Gabriel. He prohibited, as a crime against Providence, the making of vows, in the manner of the Sunnites, to obtain deliverance from danger. This new religion is regarded as a reformation of Mahometanism, by which it is reduced to its original simplicity. He has probably gone farther than some other reformers; and it remains to be seen, whether a religion stripped of every thing that is adapted to strike the fenties, can maintain its ground among a people so rude and ignorant as the Arabs.

NEDJSERAN, a principality of Arabia, in the province of Yemen, three days' journey N.E. from Saade. This narrow territory is fertile in corn and fruits, especially in dates. It affords excellent pasturage; and its horses and camels are in high request through all Arabia. It is studded with villages of moderate size, and is said to have been of the stock of the ancient nobility. In his youth he travelled through all Arabia, Persia, and India; and upon his return, he was invested by the Imam of Saade with the government of the province of Nedjseran; but he had no sooner been entrusted with this office than he threw off his allegiance, and became formidable by his genius and valour, extending his possessions and traversing all Arabia with his army. Through the whole country he enjoys the reputation of a profound theologian, as well as that of a valiant warrior. In his religious opinions he differs essentially from the chief sects of the Mahometans. He honours Mahomet as the prophet of God, but entertains little respect for his successors and commentators. This heick, taking advantage of the rudeness of his countrymen, has impressed them with a fanatical idea of the efficacy of his prayers, pretending that he obtains in this way whatever he asks from God. Whenever, therefore, the country suffers by drought, he appoints a fast, and after it a public procession, in which a calum affifts, with an air of humility, without their turban, and in a garb suitably mean; and, it is said, that this ceremony never fails to procure an immediate fall of rain. Some of the more servile Arabs also say, that this sheik has found means to avil himself of heaven, even in this life; for, to use their expression, he bfields paradyse by the yard; and assigns more or less honourable places in that manifon, according to the sums that are paid to him in order to obtain such places.

The capital of this small kingdom is Nedjseran, an ancient city, famous in Arabian history. The other towns in it are places of little consequence.

NEDWASTA, a town of Bohemia, in the circle of Bohlelaw; 16 miles W.N.W. of Jung Buntzel.

NEDWIEITITZ, a town of Moravia, in the circle of Brunn; 20 miles N.W. of Brunn.

NEEDHAM. Marchmont, in Biography, a political writer, was born at Burford, in Oxfordshire, in the year 1620. He was educated in grammar learning by Mr. Glynn, vicar of Burford, who had married his mother on her becoming a widow. At the age of fourteen he left the roof of his father-in-law, and was admitted in All-souls' college, Oxford, where he took his first degree, when he removed to St. Mary's-hall. He afterwards became an usher in Merchant Taylors' school, which occupation he quitted for that of a writer to an attorney in Gray's-Inn. In 1643 he commenced a weekly paper of intelligence, under the title of "Mercurius Britannicus." Upon some occasion of dispute he quitted his party and repaired to the king at Hampton-court, whose pardon for the past, and promise of future favour he readily obtained, and began a new weekly paper, entitled "Mercurius Pragmaticus." In this paper, he indulged his satire as freely against the Presbyterians, as he had in the former against the Royalists. This freedom could not be allowed, and being discovered he was imprisoned in Newgat. Upon his release he joined the Independents, and in their service published a third weekly paper, entitled "Mercurius Politicus." This was commenced in 1649, and continued till 1660, when it was suppressed by order of the council of state. After the restoration he obtained a pardon, and began to practice physic with success and reputation. He was author of many works besides those already mentioned, but they were mostly fugitive and temporary political tracts. One work, however, requires to be noticed, entitled "A Discourse on the Excellency of a Free State above Kingly Government," which has passed through many editions, and was reprinted only as the work of a learned and methodical writer, full of illustrations from Greek and Roman history. It is founded on the natural sovereignty of the people, and the principle is ably supported and vindicated.

NEEDHAM, in Geography, a township of America, in Norfolk county, Massachusettts, 11 miles from Bollon; about nine miles long, and five broad, almost encompassed by Charles river, which, at a fall of 20 feet between Newton and Needham, divides Middlesex from Norfolk county. It was incorporated in 1711, and contains 1572 inhabitants.

NEEDHAM's Point, a cape on the S.W. angle of the island of Barbadoes in the West Indies, S.E. from Bridges-town, with a fort upon it called Charles fort.

NEEDHAM-Market, a small market-town in the hundred of Bosmere and Claydon, and county of Suffolk, England, is seven miles north-west from Ipswich, on the road to Bury St. Edmund's. It is said to have been, in former times, a place of considerable manufacturing importance, but now scarcely any trade is carried on in it. Indeed, so sunk was this place at the commencement of the last century, that the author of the Magna Britannia says, its poverty had become proverbial. The principal support of the town, at present, ...
arises from agriculture, and the number of genteel families either resident within it, or in its neighbourhood. The market-day is Saturday; and there are three fairs during the year, which privileges were obtained by the bishop of Ely in the reign of Henry III. The petty feisions for the hundred are held here. According to the parliamentary returns of 1801, this town contained 289 houses, and 1584 inhabitants, and in those of 1811, the former are stated to have been 284, and the latter 1301 in number, i.e. 26 more houses, and 47 fewer inhabitants, a circumstance that seems to indicate some mistake in one of the returns.

About two miles from Needham are the villages of Creeting-All-Saints, and Creeting-Olaves. The church of the former, which was anciently a cell to the abbey of Greifheim, in Normandy, is a very curious old building; as is likewise that of Olaves, which was a cell to the abbey of Bernay. Kirby's Suffolk Traveller, 8vo. Magm Britannia.

NEEDHAMIA, in Botany, received its name from Mr. Brown, in commemoration of Tuberville Needham, canon of Soigny, late director of the Academy of Sciences at Brussels, who published at London, in 1745, an octavo volume of 126 pages, with five plates, entitled "An Account of some New Microscopical Discoveries." In this is said to be the earliest account of the particular structure and economy of the pollen in plants. Some of his writings may be found in the Philosophical Transactions; and others, on the subjects of Ants and Bees, in the Memoirs of the Brussels Academy. He was born at London in 1713, and died, probably at Brussels, in 1781.—Brown Prod. Nov. Hull. v. 1549.—Clafs and order, Pentandria Monogyna. Nat. Ord. Epipadice, Brown.

Gen. Ch. Cal. Perianth inferior, of five linear-awl-shaped equal, somewhat membranous, coloured leaves, with a pair of oblong, coriaceous, external ones, of the same length. Cor. of one petal, salver-shaped; tube twice the length of the calyx; limb in five broad leaves equal segments, plaited in the bud, their finuses elevated. Nectary cup-like, surrounding the base of the germen. Stam. Filaments five, thread-shaped, inserted into the tube; anthers oblong, enclosed within the tube. Pif. Germen inferior, roundish, of two cells; style short, columnar; stigma obtuse. Peric. Drupa dry. Sied. Nut of one or two cells.

Eff. Ch. Outer calyx of two leaves. Corolla salver-shaped: its limb five-cleft, beardless, with elevated finuses; plaited in the bud. Stamens included in the tube. Drupa dry, of one or two cells.

1. N. Pumila. Dwarf Needhamia.—The only known species, gathered by Mr. Brown, in the south part of New Holland, and by Mr. Menzies, from whom we have a speci- men, at King George's Sound. The stem is shrubby, three or four inches high, divided from the very base into numerous, spreading, roundish, notched, leafy, compound branches, hoary when young. Leaves minute, opposite; somewhat imbricated, in two rows crossing each other alternately, sessile on the notches of the branches, triangular, obtuse, keeled, entire, concave, smooth; the upper ones finely fringed, and somewhat more dilated, or ovate. Flowers axillary, sessile, solitary, from several of the upper and broader leaves, beyond which, after flowering, the branch is subterminally extended, and clothed with the ordinary leaves, till it blusses again higher up. Calyx fringed, red-dish. Corolla white, turning reddish-brown in drying, about a quarter of an inch long.

NEEDLES, a very common little instrument, or utensil, made of steel, pointed at one end, and pierced at the other; used in sewing, embroidery, tapestry-work, &c.

Needles make a very considerable article in commerce; and the consumption of them is almost incredible. The sizes are from No. 1, the largest, to No. 25, the smallest. There is scarcely any commodity cheaper than needles; which will appear something extraordinary to the reader, after he has been shown the great number of operations they undergo, before they are brought to perfection.

Needles, Manufacture of. German and Hungarian steel is of most repute for needles. The first thing is to pass it through a coal fire, and under a hammer, and to bring it out of its square figure into a cylindrical one; this done, it is drawn through a large hole of a wire-drawing iron, returned into the fire, and drawn through a second hole of the iron, smaller than the first; and thus successively from hole to hole, till it has acquired the degree of fineness required for that species of needles; observing every time it is to be drawn, that it be greased over with oil to render it the more manageable. The steel, thus reduced into a fine wire, is cut in pieces of the length of the needles intended. These pieces are flattened at one end, on the anvil, in order to form the head and eye: they are then put into the fire, to soften them farther; and thence taken out and pierced at each extreme of the flat part, on the anvil, by the force of a punchen of well tempered steel, and laid on a leaden block, to bring out, with another punchen, the little piece of steel remaining in the eye.

The corners are then filed off the square of the heads, and a little cavity filed on each side the flat of the head. This done, the point is formed with a file; and the whole filed over.

They are then laid to heat red-hot, on a long, flat, narrow iron, crooked at one end, in a charcoal fire; and, when taken out thence, are thrown into a bason of cold water to harden. On this operation a good deal depends; too much heat burns them, and too little leaves them soft; the medium is only to be learnt by experience.

When they are thus hardened, they are laid in an iron shovel, on a fire, more or less brisk, in proportion to the thickness of the needles; taking care to move them from time to time. This serves to temper them, and take off their brittleness; great care, here too, must be taken of the degree of heat. They are then thoroughly rubbed, one after another, with the hammer; the coldness of the water, used in hardening them, having twisted the greatest part of them.

The next process is the polishing. To do this, they take twelve or fifteen thousand needles, and range them in little heaps against each other, on a piece of new buckram, sprinkled with emery dust. The needles, thus disposed, emery-dust is thrown over them, which is again sprinkled with oil of olives; at last, the whole is made up into a roll, well bound at both ends.

The roll is then laid on a polishing-table, and over it a thick plank, loaded with stones, which two men work backwards and forwards, a day and a half, or two days successively; by which means the roll, thus continually agitated by the weight and motion of the plank over it, the needles without, being rubbed against each other with oil and emery, are insensibly polished.

In Germany, instead of hands, they polish with water-mills.

After polishing, they are taken out, and the filth washed off them with hot water and soap; they are then wiped in hot brass, a little moistened, placed with the needles in a round box, suspended in the air by a cord, which is kept flaring till the brass and needles are dry.

The needles, thus wiped in two or three different brass, are taken out, and put in wooden vials, to have the good separated...
separated from those whose points or eyes have been broken, either in polishing or wiping; the points are then all turned the same way, and smoothed with an emery-stone, turned with a wheel.

This operation finishes them; and there remains nothing but to make them into packets of two hundred and fifty each.

Needles, Surgeons', are generally made crooked, and their points triangular; however, they are of different forms and sizes, and bear different names, according to the purposes they are used for.

The largest are needles for amputation: the next, needles for wounds; the finest, needles for future. They have others, very short and flat, for tendons; others, still shorter, and the eye placed in the middle, for tying together of vessels, &c. Needles for couching cataracts are of various kinds; all of which have a small, broad, and sharp point or longue, and some with the focus at the point. Surgeons have sometimes used two needles in this operation, one with a sharp point for perforating the coats of the eye, and another with a more obtuse point for depressing or couching the opaque crystalline lens: but care should be taken in the use of any of these, that they be first well polished, with cloth or leather, before they are applied to the eye. See Cataract and Couching.

Mr. Warner observes, that the blade of the couching needle should be at least a third part larger than those generally used upon this occasion, as great advantage will be found in the depressing of the cataract, by the increased breadth of the blade of that instrument. The handle, also, if made somewhat shorter than usual, will enable the operator to perform with greater readiness than he can do with a larger handled instrument.

It is to be observed, that needles of silver pierce more easily in itching arteries after an amputation, than those made of steel. Monro, in Med. Eff. Édlin. vol. v. art. 41.

Needle, Magnetic, in Navigation, denotes a needle touched with a loadstone, or sustained on a pivot or centre, on which, playing at liberty, it directs itself to certain points in or under the horizon. See Magnet. Magnetic needles are of two kinds; viz. horizontal and inclinatory.

Needles, Horizontal, are those equally balanced on each side the pivot which sustains them: and which, playing horizontally with their two extremes, point out the north and south points of the horizon. For their application and use, see Compass.

Needle, Construction of an Horizontal. A piece of pure steel is procured, of a length not exceeding six inches, left its weight impede its volubility; very thin, to take its verticity the better; and not pierced with any hole, or the like, for ornament fake, which prevent the equal diffusion of the magnetic virtue.

A perforation is then made in the middle of its length, and a brass cap or head folder on, whose inner cavity is conical, so as to play freely on the stile or pivot, headed with a fine steel point.

The north point of the needle, in our hemisphere, is made a little lighter than the southern, the touch always destroying the balance, if well adjusted before; and rendering the north end heavier than the south, and thus occasioning the needle to dip.

Now to give the needle its verticity, or directive faculty, it is to be rubbed leisurely on each pole of a magnet, from the south pole towards the north; first beginning with the northern end, and going back at each repeated rub toward the south. A rub in the contrary direction takes away the power communicated by the former.

Compass needles may acquire the magnetic virtue by means of magnetic bars in the following manner: lay two needles of equal length, about an inch asunder, with the north end of one, and the south end of the other pointing the same way, and applying two conductors in contact with their ends: then, with two magnetic hard bars, one in each hand, and held as nearly horizontal as can be, with the upper ends of contrary names, turned outwards to the right and left, let a needle be stroked or rubbed from the middle to both ends at the same time, for ten or twelve times, a north end of a bar going over the south end of the needle, and the south end of a bar going over the north end of a needle; then, without moving from the place, change hands with the bars. or, in the same hands, turn the other ends downwards, and stroke the other needle in like manner, and they will both be magnetic: but to make them still stronger, repeat the operation three or four times from needle to needle; and at last turn the lower side of each needle upwards, and repeat the operations of rubbing them, as on the other sides.

In the rubbings or touchings to procure magnetism, the hands should not return directly back the way it came, but should return in a kind of oval figure, carrying the hand about five or eight inches beyond the point, where the touch ended; but not beyond, on the side where the touch begins.

If, after touching, the needle be out of its equilibrium, something must be filed off from the heavier side, till it balance evenly. See Magnet.

The needles that were formerly applied to compasses, on board our merchant ships, were formed of two pieces of steel wire; each of which was bent in the middle, so as to make an obtuse angle; and their ends being applied together made an acute one; so that the whole represents the form of a lozenge. Dr. Knight, to whom we are indebted for the improvement of the compass, found, by repeated experiments, that these needles not only varied from the true direction, but from one another, and from themselves; and he has shown that these irregularities were owing to their structure: for the wires of which the needle was composed were hardened only at their ends; now if these ends are not equally hard, or if one end be hardened higher than the other, when they come to be put together, in fixing them to the card, that end which is hardest will destroy much of the virtue of the other; by which means the hardest end will have the greatest power in directing the card, and consequently make it vary towards its own direction: and as the wires are disposed in the form of a lozenge, these cards can have but little force; so that they will often, when drawn aside, stand at the distance of several degrees on either side of the point from whence they are drawn; for all magnetic bodies receive an additional strength by being placed in the direction of the earth's magnetism, and act proportionately with less vigour when turned out of it. Therefore, when needles of this kind are drawn aside from their true point, two of the parallel sides of the lozenge will confine more directly than before with the earth's magnetism, and the other two left in that direction: by this means the two former sides will very much impede its return, and the two latter will have that impediment to overcome, as well as the friction, by their own force alone.

The needles formerly used on board the men of war, and some of the larger trading ships, were made of one piece of steel, of a spring temper, and broad towards the ends, but tapering towards the middle. Every needle of this form is found to have six poles instead of two; one at each end,
two where it becomes tapering, and two at the hole in the middle. This inconvenience is owing to their shape; for the middle part, being very slender, has not substance enough to conduct the magnetic stream quite through from one end to the other. In order to avoid these inconveniences and errors, the needle, contrived by Dr. Knight for his compass, is quite straight and square at the ends, and consequently has only two poles, although the curves are a little confused about the hole in the middle. Needles of this construction, after vibrating a long time, will always point exactly in the same direction and if drawn over so little on one side, will return to it again, without any sensible difference. Hence Dr. Knight concludes, that a regular parallelepiped is the best shape for a needle, as well as the flimslest; with the holes for the caps as small as can be well contrived; or if it can be made to answer the purpose, without any hole at all, it will be still more perfect. — There is a peculiar advantage attending Dr. Knight's needles; for as they are tempered much higher than usual, they are able to contain a much greater quantity of the magnetic force. See Compass.

Mr. Michell fuggets, that it would not be amiss to cover the needles made use of in the sea-service, with a very thin coat of linseed oil, or some kind of varnish, that may keep them from rusting, which is generally reckoned to injure all magnetical bodies that are liable to it. Needles may be touched through such a coat, by applying a great number of bars, if not according to the common method of making magnets. He also apprehends, that coated needles may retain a greater degree of magnetism, than they otherwise would do.

Mr. Michell also proposes to increase the weight and length of mariners' needles; and he observes, that long needles, properly hung, traversing to a greater degree of exactness than the short ones, may be of considerable service on many occasions; particularly in mines for discovering the bearing of one place from another, that they may be able to sink a shaft from above, over any place at pleasure. In many sorts of mines, especially those of coal, there are often small quantities of magnetic iron ore, which draw the needle out of its proper direction; now the long needles are less liable to be disturbed by any small things, already magnetic, than shorter ones. Michell on Magnets, p. 42, &c.

A needle, on occasion, may be prepared without touching it on a load-stone: for a fine steel needle, gently laid on the water, or delicately suspended in the air, will direct itself to the north and south. Thus also a needle, heated in the fire, and cooled again in the direction of the meridian, or even only in an erect situation, acquires the same faculty.

The needle is not found to point precisely to the north, except in very few places; but deviates from it, more or less, in different places, and that too at different times; which deviation is called the declination.

Needle, Declination of the, is the variation of the horizontal needle from the meridian; or the angle it makes with the meridian, when freely suspended in an horizontal plane. See Declination.

Needles, Cleopatra's. See Porphyry.

Needles, Inclunatory or Dipping. See Dipping Needle.

Needle-Fish, in Ichthyology, the English name of the Syngnathus, with the middle of the body heptagonal, and the tail pinnated.

It is the same fish with the acus Aristotelis species altern major. See Syngnathus Acus.

Needle-Shell, in Conchology, the English name of a species of centromia, or echinodera.

Needle-Shell is also the English name of a species of turbo, which is flender, and has ventricose spines, and a small mouth.

Needles, Shepherd's, the name by which some writers call the fandoks, or Venus's comb.

Needles, Touch. See Touch Needles.

Needles, The, in Geography, rocks in the English channel, near the western extremity of the Isle of Wight. There were formerly three of these rocks, but towards the end of the eighteenth century, the most elevated of them, called "Lot's wife," and rising about 120 feet below low-water mark, disappeared. N. lat. 50° 44'. W. long. 1° 33'. See Isle of Wight.

Needle Rock, a needle in the Mergui Archipelago, about half a mile N.W. of Cat island.

NEEDUMARAN, a town of Hindoostan, in the Carnatic; 15 miles N.E. of Nattam.

NEEDWOOD FOREST, an extensive district of woodland in the hundred of Totmanflow, and county of Stafford, England. It anciently formed a portion of the property of the dukes of Lancaster, in whose right it belonged to the English monarchs for several centuries. It is divided into the four wards of Marchington, Yoxall, Barron, and Tutbury, each of them containing about five miles in compass, exclusive of Uttoxeter-wood. Boughay, &c. The aspect of this forest is finely varied with hill and dale, and, more particularly towards its northern parts, exhibits a series of deep glens, inclosed by steep and rugged precipices, covered with a profusion of trees. According to a survey made in 1765, this forest extends from the confines of Hanbury to Yoxall, about a mile to the north of the river Trent, and comprises 9920 acres of land, of which about 1000 acres contain oak trees of full growth and size. Among these is the Swilar oak, perhaps the most majestic tree in England, which is supposed to have stood upwards of five hundred years. There were formerly eight parks enclosed within the ring of this forest. The officers are a lieutenant and chief ranger, assisted by a deputy, four lieutenants, four keepers, and an axe-bearer. A court is still held every year by the king's lievour of the honour of Tutbury, in which Needwood is included, when a jury of twenty-four persons, reident within the jurisdiction, present and amerce all persons guilty of "encroaching on the forest, or committing offences in mart or venison." Some part of the forest has been lately inclosed for cultivation. Shaw's History of Staffordshire, 2 vols. folio. Pitt's Agricultural Survey of Staffordshire, octavo.

NEEF'S, Peter, in Biography, a painter of architecture, and a disciple of Henry Steenwick, was born at Antwerp in the year 1570. He was particularly skilful in perspective, and generally chose such subjects as required a considerable display of that science, such as the interior of churches and splendid halls, &c. These he drew with great neatness and effect, and painted very clear, gay, and agreeable, but he never equalled the truth of his master. His execution of the mouldings and masses of columns in the varied Gothic works which he chose as models, is too neat, and too much made up of lines for real imitation; but that very defect gives them lightness; and the truth with which he drew the forms of the building, and proportioned his figures, which are very freely wrought, though not unadorned by other artists, renders them very agreeable. Van Velden, Teniers, and Breughel, were often called upon to assist Neefs, and by their skilful execution made amends for his want of knowledge of the human figure. He died at the age of 81, leaving a son, whose name also was Peter, and who is denominated the Young, in contradistinction to his father,
father, whole excellence in the art of painting he never rivalled, although he had the advantage of his example and instruction, and practised in the same branch of the art.

NEEHEEHOW, in Geography. See Oneehow.

NEEKALLA, a town of Hindooftan, in Baghiana; 10 miles E. of Naderbar.

NEELGUR, a town of Hindooftan, in Orrif; nine miles W.S.W. of Balafoore. Also, a town of Hindooftan, in Golconda; 24 miles S.W. of Combarmet.

NEEMCUR, a town of Hindooftan, in Oude; 15 miles S.S.W. of Karrayabad. N. lat. 27° 20'. E. long. 81'.

NEEMDUR, a town of Hindooftan, in Agra; 13 miles E. of Kerowly.

NEELMA, a town of Candahar, on the Kemah; 50 miles S.E. of Cabul.

NEENEEVA, one of the smaller Friendly Islands; 28 miles N.N.E. of Annamooka. S. lat. 19° 47'. E. long. 185° 22'.

NEENY, a town of Algiers; 10 miles E.S.E. of Baggai, formerly Baggas.

NEEPO, a town on the W. coast of the island of Celesbes. S. lat. 3° 50'. E. long. 120°.

NEER, ARNOLD VANDER, in Biography, a landscape-painter, who was born at Amsterdam in 1619. His subjects are generally chosen from among the scenes of the Low Countries. A village, or a few hovels upon the banks of a canal or river; such a collection of forms as the eye of taste alone can combine agreeably; by a beautiful distribution of sky, of light and dark clouds, and reflections in the water, Vander Neer never failed to present with a pleasing aspect; and he executed his works, which are generally very small, with great brilliancy and neatness of pencilling. Very frequently his effects are chosen by moonlight; whole partial gleams breaking the formality of the canals, he imitated most beautifully. Owing to the simplicity of his manner, and his painting very thin, his pictures are now seldom found uninjured; when they are pure and well chosen, they are very valuable. He died at the age of 64, and left a son, Egton Hendrick Vander Neer, who practiced the art of painting in various branches with considerable success. His portrait, painted by himself, is, among those that adorn the gallery of Florence. He lived till the year 1703, dying at the age of 60.

NEERCASSEL, JOHN DE, a celebrated Dutch Catholic prelate, was born at Gorcum in the year 1626. He became member of the congregation of the Oratory of Paris, and after distinguishing himself for several years by his lectures on philosophy and divinity in their seminaries, was promoted to the archdeaconry of Utrecht, and appointed apostolic provincial in Holland and the other United Provinces. In the year 1662, he was created archbishop of Utrecht by the chapter of that place, but the pope refused to sanction the nomination, declaring that the vacant see should be filled by the abbe Catz, dean of the chapter of Haarlem. The two competitors, being alike friends to peace, agreed to compromise the matter by dividing the episcopal labours, and that Catz should govern the diocese of Haarlem, under the title of archbishop of Philippus, while Neercassel presided over the diocese of Utrecht, with the title of bishop of Caftoria. This arrangement was approved by the papal nuncio, and after the death of Catz, the subject of this article remained sole prelate of all the Dutch Catholics during the remainder of his life. His zeal and affability in discharging the functions of this post were unwearyed; and he fell a sacrifice to the fatigue occasioned by his exertions at Zwol, in 1686, when he was at the age of sixty.

He was author of many theological pieces, among which was his "Amor Punitus," a discourse on the love of God, as exercised in the sacrament of penance, which was cenured by pope Alexander VII., and prohibited by a decree of the sacred congregation. The Jesuits made some unsuccessful attempts to obtain a formal condemnation of it from Innocent XI. It has been translated into several languages. The most complete edition is that of 1684, in two volumes. It was published in 1741, in three volumes. The name of Neercassel was held in high veneration for a long series of years by the Catholics of Holland. Morer.

NEERDA, in Ancient Geography, a town of Babylonia, in Mesopotamia, where the Jews had a celebrated school.

NEERMUL, in Geography, a town of Hindooftan, in Dowlatabad; 70 miles N. of Warangule. N. lat. 19° 5'. E. long. 79° 5'.

NEERSEN, a town of France, in the department of the Roer, and chief place of a canton, in the diocet of Crete. It contains 608, and the canton 24,661 inhabitants, in 17 communes.

NEESOLY, a town of Hindooftan, in Oude; four miles N.N.E. of Gooracpour.

NEETA, a town of Idria; 12 miles E. of Pedea.

NEETAMUNDY, a town of Bengal; 16 miles W. of Beyhar.

NEEVAL, a town of Hindooftan, in the Carnatic; 50 miles S.W. of Madras.

NEEZEANT REGNO, in Law, is a writ to refrain a person from going out of the kingdom, without the king's licence. (F. N. B. 85.) It may be directed to the sheriff, to make the party find security that he will not depart the realm; and on refusal, to commit him to prison: or it may be directed to the party himself; and if he then goes, he may be fined. (3 Inst 175.) And this writ is granted on a suit being commenced against a man in the chancery, when the plaintiff fears the defendant will fly to some other country; and thereby avoid the issue and equity of the court; which hath been sometimes practised: and when thus granted, the party must give bonds to the matter of the roll, in the penalty of 1,000l. or some other large sum for yielding obedience to it; or to satisfy the court by anfrer, affidavit, or otherwise, that he hath no design of leaving the kingdom, and give security.

NEFASUS, a Latin term. The Romans used the appellation dei nefas, for those days wherein it was not allowed to administer justice, or hold courts; nor for the praeator to pronounce the three solemn words or formulas of the law. Do, dies, addicco; I give, I appoint, I adjudge. See Fasti.

These days were dignified in the calendar by the letter N. or N. P. nefasus primo, as when the day was only nefasus for the first part thereto.

NEFTA, in Geography, a town of Africa, in Biedulgerdi, seated on the lake of Marks, anciently called "Negata," near which are some vestiges of the Romans; 60 miles S. of Gafra. N. lat. 33° 30'. E. long. 8°.

NEFUS MUSA, a town of Abyssinia; 90 miles S.S.E. of Gondar.

NEGADA. See ANEGADA.

NEGANNOOR, a town of Hindooftan, in the country of Cooimatore; 20 miles S.E. of Cooimatore.

 NEGAPATAM, a sea-port town of Hindooftan, situated on the coast of Tanjore; so called in the language of the natives, and denoting the city of serpents, on account of the respect paid to these animals, which they deem it sinful to destroy. The Portuguese, feivable of the importance
portance of this city, as soon as they had possession of it, secured it by walls, and improved it in a variety of respects, so that it became a beautiful city, adorned with several fine churches, and a superb college, belonging to the Jesuits. When they lost the island of Ceylon, the Dutch became masters of it; by them it was fortified, and retained till, in the year 1783, it was captured by the English, to whom it was ceded by the treaty of peace in 1783. It has broad streets, convenient though ancient houses, handsome churches, and in its environs a great number of pagodas, some of which are richly ornamented, and others mean. Negapatam is a place of considerable trade, being inhabited by various descriptions of Indians, as well as Moors and Armenians, and guarded by a fortres. It is principally valuable on account of its local position. N. lat. 10° 40'. E. long. 79° 56' 35'.

NEGAPATLA, a town of Hindooslan, in the Carnatic; 30 miles N.N.W. of Bomrauzeepollam.

NEGARA, a town of the island of Borneo, and capital of the kingdom of Banjer-Malling, situated near a large river, which runs into the sea; 100 miles from the sea, and 60 N. from the town of Banjer-Malling.

NEGATION, in Logice, an act whereby the mind separates one idea from another; or affirms the one to be different from the other; as the soul is not matter.

NEGATION is also applied by logicians to not-being, as it has relation to modes, and denotes the absence of that which does not naturally belong to the thing spoken of, or which has no right, obligation, or necessity to be present with it. In this sense it is opposed to privation, and was denominated in the schools absentia habitus.

NEGATIVE, a term that denies, or implies a denial of any thing.

Logicians, &c. say a negative cannot be proved but by converting it into an affirmative.

Negative Heretics, in the language of the Inquisition, are those who, being accused of heresy, by witnesses whose evidence they do not deny, ill keep on the negative, make open profession of the Catholic doctrine, and declare their ignorance of herey.

There are also negative falsifications, as well as positive ones.—In the negative, it is sufficient to reject the errors of a church, without separating from it, or setting up a distinct society. Negative Penalties, the laws whereby certain persons are excluded from honours, dignities, &c. without inflicting any direct and positive pains on them.

Negative Power, in Algebra. See Power.

Negative Pregnant, in Law, a negative which implies or brings forth an affirmative.

As if a man, being impeached to have done a thing on such a day, in such a place, denies he did it, modo et forma declarata; which implies, nevertheless, that he did it in some form for.

Negative Quantity, in Algebra. See Quantity.

Negative Sign. The use of the negative sign, in algebra, is at an end with several confusions that at first sight are admitted with difficulty, and has sometimes given occasion to notions that seem to have no real foundation. This sign implies that the real value of the quantity represented by the letter to which it is prefixed, is to be subtracted; and it serves, with the positive sign, to keep in view what elements or parts enter into the composition of quantities, and in what manner, whether as increments or decrements (that is, whether by addition or subtraction), which is of the greatest use in this art.

In consequence of this, it serves to express a quantity of an opposite quality to the positive, as a line in a contrary position; a motion with an opposite direction; or a centrifugal force in opposition to gravity, and thus often saves the trouble of distinguishing, and demonstrating separately, the various cases of proportions, and prefers their analogy in view. But as the proportions of lines depend on their magnitude only, without regard to their position; and motions and forces are laid to be equal or unequal, in any given ratio, without regard to their directions; and, in general, the proportion of quantities relates to their magnitude only, without determining whether they are to be considered as increments or decrements; so there is no ground to imagine any other proportion of $-b$ and $+a$ (or of $-1$ and $1$) than that of the real magnitudes of the quantities represented by $b$ and $a$, whether these quantities are, in any particular case, to be added or subtracted. It is the same thing to subtract a decrement as to add an equal increment, or to subtract $-b$ from $a - b$, as to add $+b$ to it; and because multiplying a quantity by a negative number implies only a repeated subtraction of it, the multiplying $-b$ by $-n$, is subtracting $-b$ as often as there are units in $n$; and is therefore equivalent to adding $+b$ so many times, or the same as adding $+nb$. But if we infer from this, that $1$ is to $-a$ as $-b$ to $nb$, according to the rule, that unit is to one of the factors as the other factor is to the product, there is no ground to imagine that there is any mystery in this, or any other meaning than that the real magnitudes represented by $1$, $n$, $b$, and $nb$, are proportional. For that rule relates only to the magnitude of the factors and product, without determining whether any factor, or the product, is to be added, or subtracted. But this likewise must be determined in algebraic computations; and this is the proper use of the rules concerning the signs, without which the operation could not proceed. Because a quantity to be subtracted is never produced in composition, by any repeated addition of a positive, or repeated subtraction of a negative, a negative square number is never produced by composition from the root. Hence, $\sqrt{-1}$, or the square root of a negative, implies an imaginary quantity; and, in resolution, is a mark or character of the impossible cases of a problem, unless it is compensated by another imaginary symbol, or suppression, when the whole expression may have a real significature. Thus, $1 + \sqrt{-1}$, and $1 - \sqrt{-1}$, taken separately, are imaginary, but their sum is $2$; as the conditions that separately would render the solution of a problem impossible, in some cases destroy each other's effect, when conjoint. In the pursuit of general conclusions, and of simple forms representing them, expressions of this kind must sometimes arise where the imaginary symbol is compensated in a manner that is not always so obvious.

By proper substitutions, however, the expression may be transformed into another, wherein each particular term may have a real significature as well as the whole expression. The theorems that are sometimes briefly discovered by the use of this symbol, may be demonstrated without it, by the inverse operation, or some other way; and though such symbols are of some use in the computations by the method of fluxions, it may be concluded that they are not necessary to the arithmetic of the algebraic method. See Macaulay's Fluxions, book ii. chap. 1.

NEGATIVELY, Negative, in the school philosophy, is variously used, in contradistinction to positive. See Positive.

NEGELSTADT, in Geography, a town of Saxey, in Thuringia; 10 miles S.E. of Mühlhausen.

NEGEM, a town of Arabia, in the province of Hedjaz, or Hādjas; 30 miles W. of Goraffa.

NEGGADE. See NEKKADE.

NEGILA,
NEGILA, a tolerably well-built town, or rather a village, of Egypt, on the salt bank of the Nile, within one-fourth of a league from Zaire.

NEGKO, the name of a class of islands in the Eastern Pacific ocean, between Kamtschata and America, containing the sixteen that are called Andreanofic Islands; which see.

NEGOIESZTI, a town of Walachia, seated on the Arrich, where the Russians had a garrison in 1773; 25 miles S.E. of Bucharest.

NEGOMBO, Negombo, or Nigumbo, the largest village in the island of Ceylon, and containing, for its size, the greatest number of inhabitants, built by the Portuguese, and taken from them by the Dutch, is situated on the sea-coast in a highly picturesque spot, accounted one of the healthiest in the island; 24 miles N. of Columbo. Many Dutch reside in this place, on account of the pleasantness and salubrity of its situation; and warehouses and gardens are scattered up and down in delightful groves of cocoa-nut and other trees. The Dutch built a fort here for the protection of the cinnamon-cutters, as a considerable quantity of that spice grows in the adjacent district. Store-houses are also erected in the fort, where the cinnamon, after being dried, is lodged, till an opportunity offers for conveying it to Columbo. This cinnamon is reckoned equal in quality to any in the island. The fort is not strong, but is well defended; and within it are three long rows of buildings, which serve for barracks to the troops, and store-houses to the cinnamon. The command is now given to a field-officer, who acts as president of the "Landraad," or civil court, appointed to hear and determine differences among the natives, and take cognizance of the crimes committed within this district. These civil courts existed under the Dutch, and have been established by governor North at all the military posts and commands round the island. Negombo is very advantageously situated for carrying on inland trade, particularly with Columbo and its neighbourhood, as a branch of the Mulivadda here runs into the sea. At the mouth of it is a small harbour, where loops and other small vessels often put in and land their cargoes, which are afterwards conveyed up the Mulivadda, and then, by canals which communicate with it, to the lake which skirts the town of Columbo. One of the principal articles exported from Negombo by the inland communications consists of fish. This trade is considered as the property of government, and is annually farmed out for several thousand rupees. A Moor, or Malabar, is usually the farmer, who is allowed to dispose of the fish caught here, and he employs all the boats belonging to the place. The people employed are compelled by the authority of government to fish every day, when the weather permits. Sundays and particular festivals excepted. The fish, as soon as caught, are put into boats, conveyed by the rivers and canals during the night, and sold in the bazaars next morning. The fishermen go into the water up to the middle of the thighs, carrying in their hands a round basket, of a conical form, resembling our wire rat-traps without the bottom. This they plunge down into the water as far as the mud. They soon find whether they have caught a fish by its being against the sides of the basket, and when this is the case, they thrust down their arm through the hole at the top and take hold of it. They fling the fish, as they catch them, on a piece of rattan or bamboo, which is felled round their waist, while the operation of plunging the basket is continued. Other persons are employed in following the water all around, in order to make the fish go towards the basket. Besides the produce of the fisheries, other sorts of traffic are carried on at Negombo to a considerable amount. The inhabitants consist of Moors, Malabars, and Indian Portuguese; and it is remarked, that the women of those castes, as well as of the native Cingalese, are prettier here than at Columbo, and other more noted places. For its cool, healthy, and pleasant situation, Negombo is usually ranked next to Jaffnapatam; though some give the preference to Colaura, a delightful village about 30 miles S. of Columbo. The English landed at Negombo in February 1796, and made themselves masters of it without opposition. From Negombo southward the road is extremely pleasant; it is shaded the whole way, and there are many resting places provided for travellers. About half way to Columbo is a very large choultry or barrack, to which the officers of the garrisons frequently return on shorting parties. It is situated on a most agreeable spot, in the midst of a picturesque country; and snake and several species of game abound in this quarter. N. lat. 7° 12'. E. long. 79° 48'. Perceval's Account of Ceylon, p. 108. &c.

NEGRI, an island near the S.E. coast of Ava, in the mouth of the river Perfaim. The English had a factory in this island, chiefly for the purchase of teak timber. This island was taken possession of by the English, and a survey made of it, by a person named Weldon, in the year 1683; and in this island the government of Fort St. George established a settlement. But it does not appear that much benefit was derived from the acquisition. At a much later period, viz., about the year 1757, the English again took possession of the Negrais, but their affairs were not conducted with prudence, and the settlement continued in a state of wavering ferment; the Caffre slaves, who had been introduced for the purpose of cultivating the lands, rose against their masters, and, seizing upon the boats belonging to the island, effected their escape. Some time afterwards the English settlers became unhealthy; and though they did not evacuate the place, their exertions were rendered nugatory by the diminished probability of ultimate success. Afterwards the English settlers took a decided part with the Birman in their contest with the Peguans; but some circumstances occurred that led them to maintain a perfect neutrality, which created suspicion in the minds of the Birman; and this suspicion was proved not to be unfounded by clandestine negotiations which took place between the English and the Peguans. On the approach of a formidable armament belonging to the king of Pegue, the Birman fought the co-operation of the English. But they took a decided part with the enemy, and commenced a fire on the Birman fleet. The English attempted to support the Birman, notwithstanding this hostile attack, to recover the good will of the English, and instructions were given on the part of the latter to conclude a treaty of amity and alliance with the Birman monarch. In the progress of this treaty, one of the English deputies, after the king had granted permission to the company to establish factories at Dagon and Baffien, having determined on the total demolition of Syrian, made a further requisition of the island of Negrais. Whilst friendship and union were thus likely to be established between the Birman and the settlement at Negrais, the Peguans hazarded another attempt on the Birman port of Dagon, and were again affighted by the English ships. The attempt miscarried, nor was any other enterprise ever undertaken. In 1757, Negrais was neglected, though not abandoned. An English deputy from this island was admitted into the royal presence; and though the Birman monarch upbraided this deputy with the conduct of his countrymen in giving encouragement and protection to the disaffected Peguans, he referred him to the Portuguese interpreter and the Birman governor of Perfaim for a ratified and final
NEGRO Point lies on the E. coast of Brazil, 3 leagues S.S.E. from the Rio Grande, and 14 from cape St. Roque.

NEGRO River, the western boundary of Guiana, in South America.

NEGRO, in Ornithology, the name of a large bird, approaching to the crane kind, and more usually known among authors by its Brahamian name jabiru.

NEGRO Oil, in Botany. See PALM-TREE.

NEGROES, a kind of black slaves, which long constituted, to the disgrace of all civilized countries, a considerable article in the modern commerce; but which, by late laudable exertions, has been in a great measure abolished both in Europe and America. See SLAVE.

The Negroes, also called Blacks and Moors, are a people of Africa, whose country extends on each side of the river Niger, and is called Nigritia, though, whether the people communicated their name to the river, &c. or received it therefrom, is not easily determined. For an account of the discriminating disposition and characters of the Negroes exported from Africa to the West Indies, &c. see Eboes, KOROMANTES, MANDING, MOCDES, NAGOES, and PAPAWS. See also the article MAX. To the account occurring under the several articles here referred to, of different descriptions of Negroes, we shall here add some further particulars. The Negroes from Congo and Angola are suppos'd by Mr. Edwards (Hist. of the West Indies) to have been originally the same people with the Whidah negroes. They are in general a flender, slightly race, of a deep and glossy black, (a tribe of the Congoes excepted, who very nearly resembel the Eboes,) and of a disposition naturally mild and docile. They seem to be fitter for domestic service than for field labour. They are said, however, to become expert mechanics; and they are suppos'd to be more strictly honest than many other of the African tribes.

But whatever may be the general character and dispositions of the Negroes in their own country, they are influenced in a considerable degree, as we may naturally imagine, by their condition in a state of slavery; a circumstance that soon effaces the native original impression which distinguishes one nation from another in Negroes newly import'd, and creates a similitude of manners, and an uniformity of character throughout the whole body. Although the natives of the Gold Coast are reported to be firm and courageous, yet it is certain, that the Negroes in general in our islands (such of them as have for any length of time in a state of servitude) are of a dull and cowardly disposition. So degrading is slavery, that the fortitude of mind is lost as free agency is restrained. To the same cause may probably be ascribed their propensity to conceal, or violate the truth; which is so general, that the vice of falsehood is one of the most prominent features in their character. Their proneness to theft is also very prevalent. Cowardice and dissimulation have, indeed, been the properties of slavery in all ages. This unhappy condition necessarily suppreffes many of the best affections of the human heart. If it calls forth any latent virtues, they are those of sympathy and compasion towards perons in the same condition; and accordingly it is found, that the Negroes in general are strongly attached to their countrymen, but, above all, to those of their companions as came in the same ship with them from Africa. But their benevolence, excepting a few cafes, extends no farther. The foster virtues are seldom found in the bosom of the enslaved African. With sufficient authority, he becomes a remorseless tyrant. Their treatment of subordinate slaves, placed under their instruction and government, is in a high degree hard, oppressive, and cruel.

adjournment of the treaty. After some delay, an instrument was formally executed, consisting of nine articles. Some valuable commercial immunities were by these ceded to the India company; the island of Negrais was granted to them in perpetuity, together with a piece of ground opposite to the old town of Pernambuc, for the purpose of erecting a factory; in return for which, the company engaged to pay an annual tribute, consisting of ordnance and military stores. The king sanctioned this agreement. Negrais was, consequently, continued in the possession of the English, and the allotted portion of ground was actually measured. During the absence of Alompe, the Birman sovereign, upon a military expedition, the Pegnairs made an insurrection, and the English at Negrais were suspect of having been instrumental in producing it. Prejudices, of course, were excited against them, and they were represented to the Birman monarch as perfidious, hostile to his government, and conspiring to effect its overthrow. The affairs of the British government in India did not allow the necessary supplies for the support of the settlement at Negrais; and on the 14th of May, captain Newton, who was recalled, reached Bengal with 35 Europeans and 70 natives; having left a few persons to take care of the teak timber and materials for ship-building, that could not be conveniently removed, and to preserve the right of possession, if it should be determined at any future time to re-establish the settlement. Soon after this event, a deputy was sent from Bengal to execute the business above-mentioned, and to take up his residence. But, by treachery and malice, he and the former resident were put to death at a feast prepared for them, together with five other Europeans. Thus all the settlers were either murdered or dispersed by the savage contrivance of Antonio, Portugueze interpreter to the Birman monarch; and a horrid scene of unburied bodies some time after presented itself to those who visited the island. Notwithstanding this unaccountable conduct, attempts were afterwards made to con- ciliate the Birman monarch, and to obtain redress for the injury that had been committed, and they were not alto- gether ineffectual. N. lat. 16°. E. long. 97° 32'. Symes's Embassay to Ava, vol. i. See Birman Empire.

NEGRAIS, Cape, a cape on the coast of Ava, in the bay of Bengal. N. lat. 16°. E. long. 94° 25'. See AVA.

NEGARO, a town of Italy, in the Veronese; 6 miles N. of Verona.

NEGREPELISSE, a town of France, in the department of the Lot, and chief place of a canton, in the district of Montauban; 7 miles N.E. of it. The place contains 3,216, and the canton 10,004 inhabitants, on a territory of 230,000, square, in 8 communies. N. lat. 44° 43'. E. long. 1° 36'.

NEGRI, Don Francesco, in Biography, a Venetian ecclefeial, disciple of Lalli, an excellent performer on the harpfeichord and violin, a composer of instrumental music, of motets and cantatas; but a mark of his composition, which was performed at a concerto spirituale for Gemmiani's benefit in 1756, we thought at that time the finest music we had ever heard.

NEGRI HARBOUR, North, in Geography, a bay at the W. end of the island of Jamaica, having North Negri point on the N., which is the most westerly point of the island of Jamaica, and South Negri point on the S. N. lat. 18° 27'. W. long. 78° 21'.

NEGRILOS, a cluster of small islands in the Pacific ocean, near the coast of Peru.

NEGRO Cape and Harbour lie at the S.W. extremity of Nova Scotia.
Their conduct towards the inferior animal creation is severe and brutal. It has been said, however, that notwithstanding the selfish and unrelenting temper of the enslaved Africans, they are highly susceptible of love. The Negro, says Dr. Robertson, glows with all the warmth of desire natural to his climate. The tender passion, says another writer, is the most ardent one in the breast of the enslaved African. It is the only source of his joys, and his only solace in affliction. Mr. Edwards entertains doubts of the correctness of this statement. The Negroes in the West Indies, both men and women, would consider it as the greatest exertion of tyranny, and the most cruel of all hardships, to be compelled to confine themselves to a single connection with the other sex; and Mr. Edwards is of opinion, that any attempt to restrain their present licentious and diffusive manners, by introducing the marriage ceremony among them, which many persons in Great Britain have strenuously recommended, would be utterly impracticable to any good purpose. That passion, therefore, says this writer, to which (dignified by the name of love) is ascribed the power of softening all the mirreries of slavery, is mere animal desire, implanted by the great Author of all things for the preservation of the species. When, indeed, age mitigates the ardour, and diminishes theickleness of youth, many of them form attachments which produce an union for life; so that it is not uncommon to observe a venerable couple of this stamp, who, trotting under the load of years, contribute to each other's comfort, with a chearful affability, which is at once amiable and affecting. The situation of aged Negroes is said to be such as to compensate the hardships and sufferings of their youth. Their labour is diminished; and they derive their chief happiness from the high veneration which the Negroes in general pay to old age; and this is one of the most pleasing traits in their character. The greatest affliction that can be offered to a Negro is to curse his father and mother, or any of his progenitors. Many of them, it is said, attain to great longevity. Among other propensities and qualities of the Negroes, particular notice is taken of their loquacity. They are as fond of exhibiting set speeches, as if they were orators by profession; but their harangues are protracted and tedious, which they commonly introduce with a detail of their past services and hardships, particularizing the number of children which they have presented to "Mafa," or master, and the tokens of kindness they have received as evidences of their peculiar merit. In the imitative arts the Negroes have little knowledge. As practical musicians, they are generally very deficient, and it is said, that they prefer a long and continued noize to the finest harmony, and frequently confine the whole night in beating on a board with a stick; which is one of their favourite musical instruments. Besides this, they have the "banja," or "merriwang," which is a kind of violoncello, played on by the finger like the guitar, and producing a dismal monody of four notes, the "dundo," which is provided with a tabor, and the "goombay," which is a rude drum, formed of a hollow tree, one end of which is covered with a sheep's skin. Their songs are commonly impromptu, and among them there are individuals, who re semble the improvisatore, or extempore bards of Italy, but their poetry merits little commendation. Their tunes in general are characteristic of their national manners; those of the Eboes being soft and languishing, and that of the Koromantyns heroic and martial. At the same time there is observable, in most of them, a predominant melancholy, which, to a man of feeling, is sometimes very affecting. At their merrymakings, and midnight feptrivals, their songs, which are occasionally fraught with ridicule and derision, manifested to-wards one another, or their employers, abound with obscene ribaldry, and are accompanied with dances in the highest degree licentious and wanton. Their funeral songs are of the heroic or martial cast, and some of them exhibit a Pyrrhic or warlike dance, in which their bodies are much contorted by running, leaping, and jumping, with many violent and frantic gestures and contortions. In songs of the latter kind, it is thought by some, that the Negroes consider death as a welcome release from the calamities of their condition, and as a passport to the place of their nativity, by which they are restored to the society of their dearest, long-lost, and lamented relatives in Africa. Others are of opinion, that this representation is a mere figment of the imagination. The Negroes are so far from counting death, that they seem to dread approaching dissipation no less than others. Instead of rejoicing at a sudden death, they impute it to the malicious contrivances and diabolical arts of some practitioners, in what they call Obabu; which fee.

The origin of Negroes, and the cause of that remarkable difference in complexion from the rest of mankind, has much perplexed the naturalists; nor has any thing very satisfactory been yet offered on that head.

Mr. Boyle has observed, that the heat of the climates cannot be the true cause of the colour of Negroes; for though the heat of the sun may darken the colour of the skin, yet experience does not shew that heat is sufficient to produce a true blackness, like that of Negroes. In Africa itself, many nations of Ethiopia are not Negroes, nor were there any blacks originally in the West Indies.

In many parts of Asia, under the same parallel with the African regions, inhabited by blacks, the people are but tawny. He adds, that there are Negroes in Asia, beyond the southern tropic, and that a river sometimes parts nations, one of which is black, and the other but tawny.

Dr. Barrere alleges, that the gall of Negroes is black, and being mixed with their blood, is deposited between their skin and earl-skin. Diff. on the Phys. Caufe of the Colour of Negroes.

We have a dissertation on this head by Dr. John Mitchell, of Virginia, in the Philosophical Transactions, N° 476. Feat. 4, where he advances these propositions, and enters into a learned detail to support them.

1. The colour of white people proceeds from the colour which the epidermis transmits; that is, from the colour of the parts under the epidermis, rather than from any colour of its own.

2. The skins of Negroes are of a thicker substance, and denser texture, than those of white people, and transmit no colour through them.

3. The part of the skin which appears black in Negroes, is the corpus reticularis cutis, and external lamella of the epidermis; all other parts are the same colour in them with those of other people, except the fibres which pass between those two parts.

4. The colour of Negroes does not proceed from any black humour, or fluid parts contained in their skin; there being none such in any part of their bodies, more than in white people.

5. The epidermis, especially its external lamella, is divided into two parts by its pores and scales, two hundred times less than the particles of bodies on which their colours depend.

This is founded on Leeuwenhoek's observation, that a portion of the epidermis, no bigger than what can be discerned by the naked eye, is divided into 125,000 pores, and
thence pores must divide such a portion of the skin into as many particles. But the particles of bodies on which their colours depend, are, by Sir Isaac Newton's Optics, lib. ii. p. 3; prop. 7. 600 times less than those which can be discerned by the naked eye. Therefore, the particles of the skin must be about 200 times less than these; since \( \sqrt{250 \times 0.025} \approx 26\). It may also be observed, that such a small portion of the epidermis is divisible into 250 scales, which must increase the number of its parts.

6. From these propositions, and from Sir Isaac Newton's theory of light and colours, the doctor thinks he may conclude, that the proximate cause of the colour of Negroes is threefold; viz. the opacity of their skin, proceeding from the thickness and density of its texture, which obstructs the transmission of the rays of light, from the white and red parts under the skin, together with its greater refractive power, which absorbs these rays; and the smallness of the particles of this skin, which hinders it from reflecting any light.

7. The influence of the sun in hot countries, and the manner of life of their inhabitants, are the remote causes of the colour of Negroes, Indians, &c. And the ways of living in use amongst most nations of white people, make their colours whiter than they were originally, or would be naturally.

In support of this proposition, the doctor observes, that the skin is deprived of its white colour, by the force and influence of the sun, four ways. 1st. By being rendered opaque, from a dissipation of its more aqueous and pellucid juices. 2dly. By a concretion of its vessels and glands, from this dissipation of its more aqueous contents, which renders the skin both thicker and denser, or more callous and rigid. 3dly. By a new accretion of many new membranes, which render it thick and opaque. 4thly. By increasing those parts or principles, in the composition of the epidermis, which have the greatest refractive power; as the terrestial and fixed saline; but especially the teneacious sulphureous, which refract and absorb light more strongly than any other substances; while the more transparent and pellucid principles, as the aqueous, spirituous, and volatile saline, are evaporated by the heat, which causes the other more fixed principles to be accumulated; and these particles being likewise more committed by the sun, will, on this account, be blacker as happens, when well boiled. These effects, with those first mentioned, may, the doctor thinks, by confounding, make the skin quite black; especially if we add another effect of the sun's power, a peculiar necrosis of the epidermis, occasioned by the forcible vibrations, contractions, and excrecences of its fibres by the sun-beams, which cause it to turn black, as thence, or other parts do, by the heat of an inflammation, or a fever, in gangrene, black tongues, &c.

We cannot pretend to follow the author in all the detail of his observations on this subject, nor of his answer to a material objection already mentioned by Mr. Boyle, that the sun cannot be the cause of the colour of Negroes, because several nations, in the same latitude with those Negroes, are not made black by it. He seems to think the heat of Africa greater than that of other parts of the world. Whether it be so, or not, is, we apprehend, not easy to determine; but it would be a strong confirmation of his doctrine, if we could fee any people, originally white, become black and woolly by transplantation, or \( \text{vite tergo} \).

Mr. Buffon, and many other writers, have attributed the colour of the Negroes to the influence of the climate. See a statement and examination of this opinion under the article MAN. See also INTEGUMENTS. Concerning the corporeal form and mental capacities of Negroes, see MAN, and also CRANIUM.

Negroes have been brought from Guinea, and other coasts of Africa, and sent into the colonies in America, to cultivate sugar, tobacco, indigo, &c. and Peru and Mexico, to dig in the mines. This commerce, which is altogether indefensible on the principles either of religion or humanity, has been carried on by all the nations that have settlements in the West Indies; particularly by the English, Dutch, Spaniards, and Portuguese.

For an account of the slave, progres, and abolition of this infamous traffic in human beings, we refer to the article SLAVE-TRADE. See also ASSISTEN.

There are various ways of procuring these Negroes: some, to avoid famine, sell themselves, their wives, and children to their princes, or great men, who have wherewithal to furnish them. Some are born to slavery, and sold by great men as their property. Some are sold, together with their families, for debt. Adultery is punished by selling the offending parties. Obi, or pretended witchcraft, is also punished in the same manner. There are various other crimes, which subject the offender and his children to be sold. Others are made prisoners in war; and great numbers feizted in excursions made for that very purpose by the petty princes upon one another's territories; in which it is usual to sweep away all both old and young, male and female.

The Negroes make a frequent practice of surpising one another while the European vessels are at anchor, and dragging those they have caught to them, and selling them in spite of themselves; and it is no extraordinary thing to see the son fall, after this manner, his father or mother, and the father his own children, for a few bottles of brandy, or a bar of iron.

It is not easy to obtain a precise and satisfactory account of the means by which the market for slaves has been annually kept up and supported in Africa. Many nefarious practices were unquestionably recurred to for this purpose. But the instances that have been given of slavery arising from captivity in war, delinquency, and debt, seem to be inadequate to the regular supply that furnished an annual export of 74,000 persons. Besides this number multitudes were procured from the nations bordering on the rivers of Senegal and Gambia, for the emperor of Morocco and the states of Barbary. Caravans have also travelled from thence across the continent to Upper Egypt with considerable supplies of Negroes, some of which were sent afterwards to Conantinople. Great numbers of slaves have likewise been sent from Mozambique, and the ports on the eastern coast, to Persia, Goa, and other parts of the East Indies. Hence it has been calculated that Africa has been drained annually of no less than 150,000 of its natives.

As soon as the ship has its compleme, it immediately makes off; the poor wretches, while yet in fight of their country, falling into such deep grief and despair in the paffage, that a great part of them languish, fall into kickens, and die: while others of them dispatch themselves. The only sure means to preserve them, is to have some musical instrumet play to them, be it ever so mean. But this exellent love for their country abates as they get farther off. For other particulars, see SLAVE-TRADE.

It is now laid down, that a slave, or negro, the instant he lands in England, becomes a free man; that is, so far as that the law would protect him in the enjoyment of his person and property. But with regard to any right which the master may have acquired to the perpetual service of John or Thomas, this will remain exactly in the same state as before. Hence also it follows, that the infamous and unchristian
NEGROES, Island of, or Buglas, in Geography, one of the Philippine islands, about 240 miles in circumference, abounding in rice, for which the inhabitants pay tribute; it supplies Sebu and other adjacent parts. It derives its name from the blacks with curled hair, who occupy the mountains, and among whom the lands, both on the tops and the sides of the mountains, are distributed. Their intestine wars are frequent and fatal, as they use poisoned arrows, which are headed with iron, flint, bone, or wood hardened in the fire. The mouths of the river are occupied by another tribe of blacks, who have no intercourse with the others, and who give the Spaniards, to whom they are invertebrately hostile, no quarter. When the island is invaded by pirates, they defend it by their arms, and having accomplished this service, which they perform as the old lords of the island, they retire. The Bifaya, who live on the plain and are most numerous on the W. side, supply these blacks with rice, as an acknowledgment for permission to settle there, and the blacks in return furnish them with wax. The island contains about 3000 persons, who pay tribute, and are governed by a corregidore and a military commander. The cacao, which the island produces, was first brought to the Philippines from New Spain; the rice is produced in the mountains without watering. N. lat. 10° 10'. E. long. 122° 30'.

NEGROLAND, or NIGRITIA, an immense extent of country in the interior part of Africa, comprehending many large and populous kingdoms, and extending from W. long. 7° to E. long. 27°, and from 10° to 25° N. lat.; bounded on the N. by Sahara and mountains that separate it from Barbary, on the E. by Nubia and Abyssinia, on the S. by Guinea and unknown countries, and on the W. by Guinea. The Arabs call the country denominated by European geographers Nigritia, Soulan, and the natives give it the name of Asfoum, both words denoting "the land of the Blacks," but all these appellations alike apply only to a part of the extensive region to which their proper import belongs: but in this limited sense, the term Soudan is differently used: whilst some of the Africans restrict it to the empire of Calabar, N. of the Niger. (which see). Others extend it to the Negro states on the S. of the river. Some parts, especially near the Niger, are represented as very fertile; others are no less sandy and desert. The population must be very considerable, as it has been a source of ample supply to European traders.

NEGROPONT, a large and important island of the Greek Archipelago, about 100 British miles in length by 20 in breadth, formerly called Eubea, which see. It is divided from the continent by a strait anciently denominated Euripus, now the gulf of Negropont, of such narrow extent near the capital, that a galleon can hardly pass through; and joined to the continent by a bridge, as it was formerly thought to have been connected by an isthmus. The island is remarkable for its fertility, and the level parts produce in great abundance grain, wine, oil, and all kinds of excellent fruits. The mountains are for a great part of the year covered with snow; the highest is called Oche. The most noted of its capes are Capo d’Oro, or Capo Chimi, Capo Figara, anciently Caphareus, and Capo Liter, formerly Chalcis. This island had once many considerable cities; but the only places now worthy of notice are Negropont and Cafilet Roffio. It was taken from the Venetians in 1740 by Mahomet II. N. lat. 38° to 35° 10'. E. long. 23° 10'.

NEHAVEND, a town of Persia, in the province of Ispahan, of 638, Jezdegird, king of Persia, lost his life and kingdom in a battle at this place with the caliph Omar; 200 miles N. of Ispahan.

NEHEIM, a town of Welfphalia; 45 miles N.E. of Cologne.—Alfo, a town of Welfphalia, in the bishopric of Paderborn; 12 miles N.E. of Paderborn.

NEHEMIAH, sometimes called the second book of Ezra, a canonical book of the Old Testament, so called from the name of its author. Nehemiah was the son of Hilkiah, of the tribe of Levi, was born at Babylon during the captivity, and succeeded Ezra in the government of Judah and Jerusalem. He was a Jew, and was promoted to the office of cup-bearer to Artaxerxes Longimanus, king of Persia; when the opportunities he had of being daily in the king’s presence, together with the favour of either, the queen, procured him liberty to repair and fortify the city of Jerufalem, in the same manner as it was before its destruction by the Babylonians. On his going to Jerusalem, in the 20th year of the reign of Artaxerxes, he finished the rebuilding of the walls in 52 days, and dedicated the gates of the city with great solemnity. He then reformed some abuses which had crept in among his countrymen. The history of these transactions is the subject of this book.

Nehemiah, after dwelling twelve years at Jerufalem, returned to Babylon; and having continued in Babylon for several years, he obtained leave of the king of Persia to go and end his days in his own country; where he died about the end of the reign of Darius Nothus, or in the beginning of that of Artaxerxes Memon. To the chronology of this book it has been objected, that in chap. xii. 22. mention is made of the reign of Darius Codomannus, and of the high-priest Jaddua, who went to meet Alexander the Great; and that it is morally impossible that Nehemiah should have lived to that time; because from the 20th year of Artaxerxes Longimanus to the reign of Darius Codomannus and the priesthood of Jaddua, there was an interval of more than 100 years. For the solution of this difficulty it has been suggested, that it is not certain that Darius, mentioned in this place, was Darius Codomannus; probably this was Darius Nothus, who died about 40 years after the 20th year of Artaxerxes Longimanus; and it is not said, that Jaddua or Jaddus was high-priest already. He might have been born towards the end of the reign of Darius Nothus, or in the beginning of the reign of Memon, and might still have been alive in the time of Alexander. But it is probable, that what is said in this place, from the beginning to the 27th verse of the 12th chapter, was an interpolation, or added afterwards, as it has no connection with what goes before or comes after, and interrupts the series of the history. For Nehemiah, after he had related in what manner he had rebuilt the walls of the city of Jerusalem, in the 11th chapter, gives
NEI

us a catalogue of the families and persons who inhabited it. It was natural that he should afterwards give an account of the dedication of the city walls, which begins at the 27th verse; and the whole of that which is laid between these two accounts concerning the succession of the Levites and high-priests seems foreign to the purpose. Dupin's Hilt. Canon.

NEHERPOUR, in Geography, a town of Hindoostan, in Oude; 34 miles N.E. of Manickpur.

NEKHON, a principality of Yemen, in Arabia, which is a small district between Djasf and Hachlid-i-Bekil. The sheik is an independent prince, who possesses a few small inconsiderable towns, with a fertile mountain, on which are many villages. The inhabitants of Dieban are free; but they always join the sheik of Nehkon in his wars with the Imam.

NEHLA, a town of Hindoostan, in the circuit of Jyenagur; 10 miles N. of Jyenagur.

NEHOTENAN, a town of Cochinchina, on a river which runs into the Chinese sea, forming at its mouth a bay. N. lat. 1° 55'. E. long. 109° 9'.

NEHRWAILEH, a town of Hindoostan, and the ancient capital of Guzerat; which city, together with the whole of the peninsula, fell into the hands of Sultan Mahomed in 1044; four years before his death; 12 miles S.E. of Pottan.

NEHURSCHDORFF, a town of Bohemia, in the circle of Kauzem; 14 miles E. of Prague.

NEIA, a town of Naples, in Calabria Citra; 8 miles S.W. of Builgnano.

NEIDA, a town of the duchy of Stiria; 9 miles S.E. of Hardeburg.

NEIDADY, a town of Austria; 8 miles W.S.W. of Sonneberg.

NEIDEK, a town of Bohemia, in the circle of Elbe-hogen; 8 miles S. of Joachinthal.

NEIDENAU, a town of Wurtemberg, on the Jact; 9 miles N. of Heilhronn.

NEIDENBURG, a town of Prussia, in the province of Oberland; 80 miles S. of Königsberg. N. lat. 53° 12'. E. long. 20° 23'.

NEIDENSTEIN, a town of Germany, in the principality of Hesse; 9 miles S.W. of Caffel. N. lat. 51° 13'. E. long. 9° 15'.

NEIFALEN, a town of Austria; 10 miles S.S.E. of Aigen.

NEIFE, NATOVA, in our Ancient Cuffoms, a bond-woman, or the villain, born in one's house. 9 Rich. II. cap. 2.

Anciently, lords of manors fold, gave, or assigned their neifers, and natives. See SLAVE, VILLAIN, &C.

NEIFFEN, or Neuffen, in Geography, a town of Wurtemberg; 17 miles S.S.E. of Stuttgart. N. lat. 48° 52'. E. long. 9° 25'.

NEIFTY, Writ of, in our Ancient Cuffoms, is an ancient writ, whereby the lord claimed such a woman for his niece.

NEILSVILLE, in Geography, a town of America, in Tazewell county, Virginia; 342 miles W. from Washington.

NEIMPHY, a town of Meckley; 96 miles S.S.E. of Munnpour.

NE INJUSTE Vexet, in Law, a writ founded on Magna Charta, cap. 10, which lies for a tenant in fife simple against the lord forbidding him to detain on the tenant for more service than he ought to perform; particularly when he has formerly prejudiced himself by doing or paying more than he needed.

NEIR ibn Marend, in Geography, a town of Arabia, in the province of Nedjed or Neged; 110 miles N.E. of Mecca.

NEIRA, one of the Banda islands, the first in rank and seat of government, with a spacious and commodious harbour, but difficult of access; in which ships anchor under two farks. Its annual supply is about 5000 pounds of nutmeg, and 2000 of mace. In this island are two towns, one of its own name, and the other called Labetacka. S. lat. 4° 8'. E. long. 130° 37'.

NEISAPOUR, Nezaapour, or Ny,jafur, a town of Peria, in the province of Chorafan, which was destroyed, with a dreadful slaughter of its inhabitants, by Jenghis-khan; 150 miles N.W. of Herat. N. lat. 36° 20'. E. long. 57° 10'.

NEISCHLOT, a town of Russia, in the government of Vibriq, on the lake Saima; 40 miles N. of Viborg. N. lat. 62° 15'. E. long. 28° 24'.

NEISIG, a town of Bavaria, in the bishopric of Bamberg; 15 miles N. of Bamberg.

NEISS, a river of Westphalia, which runs into the Emmer, four miles S.S.E. of Blomberg, in the county of Lippur.

NEISSSE, or Neisse, a principality of Silefia, sometimes called "the principality of Grotkau." This principality, which is environed by thoie of Munflerberg, Brigg, Oppeln, and Jagernorff, as well as Moravia and the county of Glatz, is one of the largest in Silefia. The southern part is hilly; but the northern part, being less mountainous, is more fertile. Good horses are bred in the Neife and Grotkau circles. The latter also yields tobacco, and the former has several iron mills. The largest river is the Neife, but the principality comprehends eleven cities. It belongs to the king of Prufia; but that part which is contiguous to Moravia is annexed to the crown of Bohemia. Though Grotkau is neither a duchy nor principality, yet the bishop of Breilau is usually styled Prince of Neife, and Duke of Grotkau; and by virtue of this principality takes rank of all the other places in Silefia.

Neisse, or Neuffer, a city of Silefia, and capital of the above principality. It is a very strong place, and is situated on the river Neife, on the opposite side of which is a Prussian fort, erected in 1745. The king appoints a governor and commandant; but the prince and bishop possessed the palace, with a treasury, a court of justice, a demesne, and a confidtorial office. After the peace of Drefden, a new suburb was added to the old ones that were rebuilt, called Friedrichstadt, lying between Prufia and the Neife, in which is held a court, in the majesty's name; 42 miles S. of Breilau. N. lat. 52° 22'. E. long. 17° 13'.

Neisse, a river which rises in the N. part of Bohemia, and after passing through Lutatia and by several towns, enters the Oder about 12 miles N.E. of Guben.

NEISTIFT, a town of Austria; 16 miles S.E. of Steyr.

NEISTRIFT, a town of Austria; 8 miles S.W. of Sonneberg.

NEITH, in Mythology, the name of Minerva in Egypt.

NEITRA, in Geography, a town of Hungary, on a river of the fame name, the capital of a country, and the fce of a bishop.

NEITSOERSOAK, an island near the W. coaft of Greenland. N. lat. 63° 22'. W. long. 49° 26'.

NEIVANSKOI, a town of Russia, in the government of Ekaterinburg, on the Neiva, which runs into the Tura; this town has considerable iron works; 40 miles W. of Turinik.

NEKAR.
NEKAVIKBAN, a town of Perian Armenia; 39 miles S.E. of Erivan.

NEKEEL, a town of Egypt, on the left bank of the Nile; 4 miles S.E. of Aboutigue.

NEKKADE', or NAGUADA, a town, sometimes called a city, but rather a village, of Upper Egypt, on the W. bank of the Nile; almost entirely peopled by Copts, among whom are some Catholics, and the see of a Coptic bishop. The Copts have here a vicar, and two monks of the order of Recollets. This place has some manufactures of blue or striped cloth, of which they make an article of trade, that diffuses some degree of influence among the inhabitants.

NEKE', a town of Egypt, on the left bank of the Nile; 4 miles S. of Nomlot.

NEKOUNAUBAN, or KUBAN, a lake of Canada; 24 miles N.W. of Quebec. N. lat. 49° 55'; W. long. 75°.

NEKREST, a town of Afa, in the principality of Georgia, and province of Kakat; 65 miles N.E. of Tiflis.

NEKSHAB, or KARSHI, a town of Grand Bucharia; 60 miles E. of Bukhara. N. lat. 39° 5'; E. long. 63° 40'.

NELANJENUM, in Natural History, the name of a curious and peculiar fossil substance, found in the East Indies.

It has much the appearance of some of our fleck-grained lead ores, and is very ponderous, but it does not contain any lead; in this it approaches to the nature of that substance common in Europe, and called blende, or mock-lead; but this last is foliated, and resembles the plated lead ores, whereas this resembles the close ground ores. It is found in the beds of rivers; in many places; they calcine it, and reducing it to powder, mix it with the juice of herbs, and use it in ulcers.

NEKYANDA, in Ancient Geography. See NELISURAM.

—A town of Arabia, near the mouth of the Red sea; said by Arrian to have been a commercial place.

NELVANGELO, in Geography, a town of Hindooistan, in Myfore; 15 miles N.W. of Bangalore.

NELGOOND, a town of Hindooistan, in Viapour; 30 miles W. of Baddammy.

NELISURAM, formerly NELYANDA, a town of Hindooistan, and capital of a small country on the W. coast, S. of Canara. This town and district were ceded to Great Britain in 1799; 33 miles N.E. of Mangalore. The fort of Nelisuram is situated on a river named Cenganecora, whose course is from the N.E. and falls in about four miles to the north of mount Della. This Nelisuram, which is situated about 12 miles up the river, is confirmed by major Rennell as the place meant by Nelyanda, and Melynda by Pliny and Ptolemy; a place visited by the Egyptian and Roman ships. N. lat. 12° 20'. E. long. 74° 57'.

NELITRIS, in Botany, a name given by Gurtner to the Deaciformum of Forster, and apparently derived from νελιτρίς, a species of Pheidastis; an Afferalus, the cafe of a seed, because the absolute want of partitions in the berry, to separate the seeds, is said to be one of its chief distinctions from Guarana, or Psidium. Gurt. v. 1. 134. t. 27. The propriety of changing Forster's original name does not appear. Subsequent authors have, like fir Joph Banks and Dr. Solander, referred the plant to quellung of Psidium; fee that article.

NELIA CORVINDUM, in Mineralogy. See Adamantine Spar.

NELLEMB, of Nilemy-nehk, in Geography, a town of the island of Ceylon, about six or seven miles S. of Candy, which has occasionally afforded a retreat to the king, and in which he has a palace and flore-houses. N. lat. 7° 25'. E. long. 80° 50'.

NELLENBURG, a landgrave of Germany, which conformed formerly of the towns and prefectorates named from it, viz. Stockach, Aach, and Thengen, and contained about 30 boroughs, villages, and a district 32 miles in circuit. The landgrave, diminished by the dismemberment of Thengen, and deprived of the land-court which is held at Stockach, is governed by a landvogt; and it has its name from Nellenburg, a town with a citadel situated on a mountain, 16 miles N.W. of Conflance.

NELLER, GEORGE CHRISTOPHER, in Biography, a learned German writer on ecclesiastical antiquities, and on the science of medals, was born in Franconia in the year 1799. He attained some considerable rank in the church, and became canon of St. Simeon's at Treves, privy-councilor to the prince-elector, and doctor of laws. He excelled in the knowledge of ancient monuments and medals, of which he had amassed a fine collection; but his celebrity reeks on his various publications, which confit of dissertations that display great learning and laborious research, but not without paradoxical notions. He died at Treves in 1783. The titles of a great number of his works are given in the General Biography, to which we refer our readers.

NELLIPELLY, in Geography, a town of Hindooistan, in the circar of Rajamundry, situated on the coast; 30 miles S.E. of Rajamundry.

NELLON, in Botany, a name given by forome to rice. It is an Indian word, and properly signifies the grain of rice taken off from the stalks, but covered with its proper pellicle. The first operation to be performed upon this, is the beating it with large rones, or other more manageable tools, till this skin flies off. Then it is to be dried in the sun, and, after that beat a second time, to get off its thin, internal, reddish coat: when this is done it is in a flake to be used, and it is then only that the Indians call it arath, the word from which we formed our word rice.

NELLORE, in Geography, a town and fortress of Hindooistan, in the Carnatic, near the Nennar river, and within 16 miles from the sea; 85 miles from Macras. N. lat. 14° 26'. E. long. 79° 57'.

NELLY, a town of Hindooistan, in Myfore; 34 miles S. of Harponelly.

NELSON, ROBERT, in Biography, an excellent divine of the church of England, was the son of a considerable Turkey merchant, and born at London in the year 1656. He received the early part of his education at St. Paul's school, where he was taken home by his mother, the father being dead, and placed under the private tuition of the learned Dr. Bull, at that time rector of Suddington, near Cirenceller, Gloucestershire. At a proper age he was sent to Cambridge, and admitted a fellow-commoner of Trinity college. Here he secured the esteem and affection of all who knew him; and on one of his visits to London he became acquainted with Dr. (afterwards archbishop) Tillottan, and from the congeniality of their characters and dispositions, a close friendship took place between that celebrated divine and Mr. Nelson, which was only dissolved by the death of the former. In the year 1680, Mr. Nelson was chosen fellow of the Royal Society, and, being anxious to obtain the improvement which a residence in foreign countries is calculated to afford, he set out for Paris with his friend and school-fellow Dr. Halley. On their road to that city, they saw the remarkable comet which gave rise to Sir Isaac Newton's "Astronomy of Comets," and to Dr. Halley's "Synopsis Cometarum." While he continued at Paris he had an invitation to undertake an office at the court of Charles II.
NELSON.

of England, which he declined, on account of the aversion which his mother and other friends had for it. From Paris the travellers passed to Rome, where they separated, and Mr. Nelson, after completing what is called the grand tour, returned to England in the summer of 1682. At Rome he met with the widow of Sir Kingmilk Lucy, bart., second daughter of the earl of Berkeley; a mutual affection took place between them, and he married her soon after their arrival in England. Some time after this union had taken place, the lady, previous to her marriage with what she had previously concealed from him, viz. that she had become a convert to the Roman Catholic religion. This change in her religious sentiments had been effected by her conversations at Rome with cardinal Howard, grandson of the earl of Arundel, collector of the Arundel marbles, who had been raised to that high dignity by pope Clement X. Lady Nelson having once avowed an adherence to the Catholic faith, became a zealous advocate for the papal doctrines, made a convert of her daughter, by her former husband, and entered into the lists of controversy, and is supposed to have written a piece, published in 1684, under the title of "A Discourse concerning a Judge of Controversy in Matters of Religion, shewing the Necessity of such a Judge." Mr. Nelson was filled with grief when he learnt of the dereliction of his lady from the principles of the Protestant faith, and made every effort in his power to reclaim her, but his attempts, as well as those of his friends Tillotson and Hickes, were unavailing. The former, however, wrote a long letter to her on the subject, and the latter, on her account, published his collection of "Letters," which passed between him and a Popish priest in 1675. In this collection is a letter to an English priest of the Roman communion at Rome, which was written by Mr. Nelson for his lady's use. It was very similar in nature to a view which he took of the same subject in 1687, in a piece entitled "Transubstantiation contrary to Scripture; or the Protestant's Answer to the Seeker's Query." Lady Nelson, notwithstanding all the pains taken to bring her back to the church of England, continued in the Popish communion till her death. She was a person of fine understanding, and had cultivated her mental powers with great care and success. Dr. Tilboton not only lamented the loss of this lady from his own church, but probably dreaded the influence which the lady had over her husband's mind might have on him from the faith in which he had been educated. He, however, continued steady to his principles, though he travelled in foreign countries with his lady for the sake of her health, where the temptations to abandon the Protestant religion must have been much stronger than they could have been at home. In 1691 Mr. Nelson returned with his lady, entirely disaffected with the revolution that had taken place in the government three years before, and with a determination not to transfer his allegiance from king James. To that prince he threw his steady attachment while he resided at Florence, by keeping up a correspondence with the earl of Melfort, ambassador from the exiled James to the pope, and he now avowed himself a nonjuror, and withdrew from the communion of the church of England. His conduct in this particular did not disturb the friendship that subsisted between him and archbishop Tillotson, whose death he faithfully attended, and who at length expired in his arms. After that event he continued his kindness to his grace's widow, and was very instrumental in procuring her pension from the crown to be augmented from 400l. to 600l. per annum. As he now resided in or near the metropolis, a coincidence of opinions led him to form an acquaintance with Mr. Ketelwell, who appointed him sole executor and trustee to his last will, and in pursuance of that trust Mr. Nelson published some posthumous pieces of that worthy divine, with particulars of his life and character; and it was by the persuasion of this gentleman that he took up his pen in the service of piety and devotion. The principal works of Mr. Nelson are his "Companion for the Pilgrims and Faiths of the Church of England, &c," which has been exceedingly popular, and has passed through 20 or 30 editions: "The Great Duty of frequenting the Christian Sacrifice;" "The Practice of true Devotion, in relation to the End, as well as the Means of Religion, with an Office for the Holy Communion." Mr. Nelson for many years adhered to the communion of those bishops who had been deprived of their fees by the revolution, but upon the death of Dr. Lloyd, bishop of Norwich, in 1709, the last of that number, except Dr. Kena, he joined in communion with the church established by law. Mr. Nelson died at Kennington in January 1714-15, in the fifty-ninth year of his age. He left his whole fortune to pious and charitable purposes, to which he had devoted a great part of his income during life. He was author of many other pieces besides those already noticed, of which may be mentioned "The Life of Dr. George Bull, bishop of St. David's, with the History of the Controversies in which he was engaged, &c.:" also "The Scripture Doctrine of the most holy and undivided Trinity, vindicated from the Misrepresentations of Dr. Clarke." Biog. Brit.

NELSON, Horatio, Lord Viscount, one of the bravest and most successful naval commanders that ever appeared in the world, was the fifth son of the Rev. Edmund Nelson, rector of Burnham Thorpe, in Norfolk, in which county the family of Nelson had long been resident. His lordship's grandfather was rector of Hilborough, in the same county, of which living the family of the Nelfons have been for a great length of time the patrons. His father married, in May 1719, Catharine, daughter of Maurice Suckling, D.D., by whom he had eight sons and three daughters.

Horatio, the subject of the present article, was born on Michaelmas day 1758, in the parish-house of Burnham Thorpe. He was first sent to the high-school of Norwich, from whence he was afterwards removed to North Walsham. During the Christmas holidays of 1770, he read in the newspaper that his uncle, captain Maurice Suckling, was appointed to the Raisable of 64 guns. Young as he then was, it is said he felt a desire of relieving his father from the burden of supporting him; and it was the thought of providing for himself that actuated him in the request that he now made: "Do, brother William," said he, "write to my father, and tell him, I should like to go to sea with uncle Maurice." Mr. Nelson did not oppose the plan, but wrote to his brother-in-law, who had, previously to this, promised to provide for one of his nephews in his own profession; but this was not the lad he would have chosen, on account of the extreme delicacy of his constitution. "What," said he, in his reply, "has poor Horace done, who is so weak, that he, above all the rest, should be sent to rough it out at sea? But let him come, and the first time we go into action, a cannon ball may knock off his head, and provide for him at once." In the spring of 1771, his father sent him to join the ship, then lying in the Medway. When he got on board, captain Suckling had not joined, and the child, then but just turned of twelve years of age, paced the deck almost a whole day without being noticed by any one. "The pain," says one of lord Nelson's biographers, "is the felt when we are first transplanted from our native soil, when the living branch is cut from the parent tree, is one of the most poignant that we have to endure through life. There are after-grievings which wound more deeply, which leave behind them scars never to be effaced, which
which bruise the spirit, and sometimes break the heart; but never do we feel so piously the want of love, the necesse-
sity of being loved, the sense of utter desertion, as when we
first leave the haven of home, and are, as it were, pushed
off upon the stream of life. Added to this, the sea-boy
has to endure physical hardships, the privation of every
comfort, even of sleep. Nelson had a feeble body and an
affectionate heart, and he remembered through life his first
days of wretchedness in the service." The Raifonable,
by the termination of the dispute with Spain respecting
the Falkland islands, was foon paid off, and captain Suckling
was appointed to a guard-ship in the Medway. This he
considered as too inactive a service for his nephew, and ac-
cordingly fent him in a merchant-ship to the West Indies,
under Mr. Rathbone, who had formerly been master's mate
with him in the Dreadnought. On his return from this
voyage, he was received by his uncle on board the Triumph,
then lying at Chatham, in the month of July 1772. His
voyage to the West Indies, in the merchant service, had
given the youth a good practical knowledge of seamanship;
but it appeared that he had acquired an entire horror of the
royal navy. Captain Suckling beheld with the utmost
anxiety and diftrefs the prejudices of his nephew, and at first
attempted to win him over, by working upon his ambition,
a principle which he poifefled in an eminent degree, of be-
coming an excellent and thorough-bred fefman. It was
accordingly held out to the youth, that if he attended to
his duty, he fhould be permitted to go in the cutter and
decked long-boat, which was attached to the commanding
officer's ship at Chatham. This operated on the mind of
young Nelson as it was wished; and the confequence re-
Sulting from it was, that by degrees he became an excellent
pilot for vessels of that clafs, which failed from Chatham to
the Tower of London, and also down the Swin Channel,
and to the North Foreland. In each subsequent trial of
navigating difficult passages, or dangerous coasts, he became
more and more equal to the task, and felt that confidence
within himself which afterwards was a great comfort to him,
and which eflentially forms and eftablishes a great and un-
damaged mind.

In the following spring, an expedition of discovery to-
wards the north pole was fent out under captain Phips, in
confequence of an application from the Royal Society; and
though, on account of the extreme difficulty of the service,
itis ordered that no boys should be received on board, yet
the enterprising mind of Horatio Nelson anxiously solicited
to be appointed coxswain to captain Lutwidge of the Car-
cas. The captain, fhock with the unfuitable spirit which
he difplayed, admitted him to the office after which he
aspired. During the expedition, captain Phips, afterwards
lord Mulgrave, took particular notice of the youthful cox-
swain, and formed that high opinion of his character, which
his subsequent conduct has more than justified. The two
vessels, on the 31st of July, were in a most perilous situation,
off the Seven isles, which is a cluster in the Northern
Frozen ocean, situated in 86° N. lat., and nearly 19° E.
long., from becoming suddenly fall amidf immense fields of
ice. The labour of the whole ship's company to cut away
the ice proved ineffectual: their efertions, for a whole
day, could not move the ships above 500 yards. In this
dreadful flate they continued nearly five days, during which
the young coxswain, after much folicitation, obtained the
command of a four-gored cutter with twelve men; and he
took pride in imagining he could navigate her better than
any other boat in the service.

Soon after his return, his uncle recommended him to
captain Farmer of the Sea-Horse, of 20 guns, then going
to India, in a squadron under sir Edward Hughes. In this
ship young Nelson was stationed to watch in the fore-top,
whence, in due time, he was placed on the quarter-deck.
The matter foon perceived that he was extremely de
tious to make himself acquainted with the minutest parts of a
man's duty, and particularly recommended him to the
captain, who rated him as a midshipman. The service
which he went through strengthened his constitution, and he
feemed stout and athletic; but in India he caught one of
tabes malignant difeases which are frequently fatal to
European habits: it totally deprived him for a time of the
use of his limbs, and nearly brought him to the grave. In
confequence of this, he returned to Europe with captain
Pigot, in the Dolphin, 1776, in fuch a state of weakness
that his life was depair of; and he attributed the pref-
ervation of it, at this period, to the kindness of that officer.
He had, during this voyage, formed an acquaintance with
Thomas (afterwards sir) Trowbridge, and other diftinguished
officers, who, like himself, were entering upon
their career of glory, and had left them purfuing it with
full of health and enjoyment, while himself was returning with a
body broken down by ficknefs, and spirits dreadfully de-
preffed. Long afterwards he fpoke, almost with horror,
of the feelings which he at that time endured. "I felt im-
preffed," faid he, "with an idea that I fhould never rife in
my profession. My mind was ftaggered with a view of the
difficulties which I had to furmound, and the little interef I
poifefled. If, at a moment, I felt the emulation of ambi-
tion, I fhunk back, as having no means within my power
of reaching the object of my wishes. After a long and
glory reverie, in which I almoft wished myself overboard,
a fudden glow of patriotism was kindled within my breath,
and prefented my king and country as my patrons. Well
then, I exclaimed, I will be a hero, and, confiding in Pro-
vidence, I will brave every danger." From that hour his
depofitenne was changed into hope, and, as he told captain
Hardy, a radiant orb was fuspended before his mind's eye,
which urged him on to renown. Nelson, fays his biogra-
phers, fpoke of these aspirations of his youth as if they
had in them a character of divinity, as if

"The light which led him on,
Was light from heaven."

His fits of dejection, though not unnatural to a great
mind, were, as we shall see, altogether eafeful: his profefts were fair, and his proges almost as rapid as it
could possibly be. When he reached England, he found his
uncle comptroller of the navy, and was immediately ap-
pointed to act as fourth lieutenant of the Woreceler of
64 guns, captain Mark Robinfon, then on the point of
failing with a convoy to Gibraltar; and he was at fea from
this time, September 1776, to the beginning of April of
the next year: and though he had not yet completed his
18th year, captain Robinfon placed the moft unlimited con-
five in him, and declared that he felt equally easy during
the night, when it was Nelson's watch, as when the oldest
officer on board had charge of the ship. Mr. Nelson was
paffed as lieutenant on the 10th of April 1777, and the
next day received his commiffion as second of the Lowellotte,
32 guns; captain William Locker. During his examina-
tion, captain Suckling sat at the head of the table, and
when it had ended in a manner moft honourable to him, he
introduced him to the other members of the board as his
nephew. The examining captains eXpressed their surprife
that he had not apprized them of this relationship before.
"No," replied the comptroller, "I did not with the
young to be favoured: I felt convinced that he would pass
through
a good examination, and you see I have not been disappointed." In the Lowestoffe he arrived at Jamaica, but finding that even a frigate was not sufficiently active for his ardent mind, he solicited an appointment to the command of a fchooner, tender to the Lowestoffe; and in this small vessel he eagerly availed himself of the opportunity of becoming a complete pilot for all the intricate passages through the keys, situated north of Hispaniola. During Mr. Nelson's continuance in the Lowestoffe, she captured, in a strong gale of wind and a heavy sea, an American letter of marque. The captain ordered his first lieutenant to board her, which he infantly attempted, but was unable to effect, owing to the tremendous sea. On his return to the ship, the captain exclaimed, "Have I then no officer who can board the prize?" On hearing this, the matter immediately ran to the gang-way, in order to jump in the boat, when lieutenant Nelson suddenly stopped him, saying, "It is my turn now; if I come back, it will be yours." He no doubt had made up his mind not to return, unless he first accomplished his object; and the circumstance strongly prefigured his future character. He probably never saw a difficulty, in the mind of his father; that he did not think of, and, as it afterwards appears, the greater the obstacles with which he had to contend, the better was he pleased with the nature of his duty. After a year's active service, he was removed to the Brillo, the flag-ship of sir Peter Parker; and under this commander he finished his services as a lieutenant. It is observable that the late lord Collingwood, who succeeded to the command so many years afterwards, upon his glorious death, succeeded him now in the Lowestoffe, and again in the flag-ship, when, on the 8th of December, the same year, he was made commander in the Badger briz, at the age of 21. While captain Nelson commanded the Badger, his majesty's ship Glasgow, captain Thomas Lloyd, lying near, took fire from a cask of rum; but by the unceasing exertions and presence of mind of Nelson, the whole crew was saved from the flames.

Captain Nelson obtained his rank of post-captain on the 11th of July 1779; and during nine years that he had been in service, he had, by keen observation, and incessant application to every part of his known duty, not only become an able officer, but had likewise laid the foundation for forming a most skilful and successful pilot. This seems indeed, as has been already observed, from the first, to have been his constant ambition. After his advance to pilot rank, he was appointed to the Hinchinbrooke, of 28 guns. On this arrival of count D'Estaing, he superintended the landing of troops at Martinique, and led an attack upon Jamaica was expected. In this situation of the island, Nelson was entrusted, both by the admiral and general, with the command of the batteries at Port-Royal. This was the most important post in the whole island, as being at once the key to the naval force of the town of Kingston, and to the seat of government at Spanish Town. A plan was next formed for taking fort San Juan, on the river St. John, in the gulf of Mexico; and captain Nelson was appointed to the command of the naval department. His business was to have ended when he had conveyed the forces, about 500 men, from Jamaica to the Spanish main; but it was found, that not a man of the whole party had ever been up the river; he therefore displayed his usual intrepidity, quitted his ship, and superintended the transporting of the troops, in boats, 100 miles up a river which, since the time of the Buccaneers, none but Spaniards had ever navigated. Of all the services in which he had been engaged, this was the most perilous. It was the latter end of the dry season: the river was low, full of shallows, and sandy beaches; and the men were often obliged to quit the boats, and drag them through shallow channels, in which the natives went before to explore. This labour, and that of forcing the rapids, were chiefly sustained by the sailors; men at all times accustomed to rely on their own exertions, and at all times sure to do their duty. Seven or eight hours during the day they were exposed to a burning sun, rendered more intolerable by being reflected from dry flats of white sand; and at night their sufferings were not less severe, owing to the heavy dews that fell in that climate. On the 6th of April they arrived at a small island, called St. Bartholomew, which commanded the river in a rapid and difficult part, and was defended by a battery mounting nine or ten swivels. Nelson, according to his own phrase, resolved to board this out-poll. Putting himself at the head of a few sailors, he leaped on the beach. Captain Delpard, once driven to desperation, crimes, and an ignominious end, by neglect and ill usage, gallantly supported him; and they formed the battery, and fought and defeated the Spaniards with their own guns. Two days afterwards they came in fight of the castle of San Juan, and began to beleaguer it on the 15th: it succeeded in the second attack. Before that time they had a more formidable enemy to encounter, and against which even the prowess of a British sailor is of no avail. The bad weather had set in: failors, folders, and Indians, funk alike under it; the latter from exertions to which they had never been accustomed, and the Europeans from the deadly effects of a climate allotted by the distribution of nature to a race of different colour and complexion. All that victory procured them was a cessation from toil: no supplies were found, and the castle itself was worse than a prison. The hovels, which were used as an hospital, were surrounded with putrid hides; and when orders were obtained from the commander-in-chief to build one, the sickness had become so general, that there were no hands to work at it. The rains continued, with few intervals, from April to October, when they abandoned their baseless conquest. Of 1500, who were sent to different posts upon this ill-fated scheme, only 380 returned. Nelson narrowly escaped. His advice had been to carry the castle by assault; instead of which, eleven days were spent in the formalities of a siege. He returned before its surrender, exhausted with fatigue, and suffering under a dysentery; yet to him the commander-in-chief ascribed the principal cause of success in reducing fort Juan, in which were found one brass mortar of five inches and an half, twenty pieces of brass ordnance mounted, besides four guns, ten or twelve swivels, with a proportionable quantity of military stores. From the extreme fatigue which captain Nelson endured on this expedition, his health became visibly impaired; but he fortunately received an appointment to the Janus of 44 guns, vacant by the death of captain Glowr, son to the author of Leonidas. This promotion removed him from the fatal station just in time, and he reached Jamaica in such a state of sickness, that he was carried to his cot. The careful attention of a good old negroes, and afterwards of sir Peter Parker and his lady, saved his life; but his health had suffered so much and so severely, that he was foon compelled to return to England, which he did in the Lion, commanded by the Hon. William Cornwallis, through whose attention a complete recovery was effected.

In the month of August 1781, captain Nelson was appointed to the command of the Albemarle of 28 guns, and sent into the North Sea. During this voyage he gained a considerable knowledge of the Danish coast, and its foundings; a knowledge which afterwards proved of great importance to his country. On his return, he was ordered to
NELSON.

Quebec with a convoy, under the orders of captain Thomas Fringle. Here he became acquainted with Mr. Alexander Davison, who saved him from an imprudent marriage. Nelson was about to quit the station, had taken leave of his friends, and had gone down the river to the place where men of war usually anchor: nevertheless, next morning, as Mr. Davison was walking on the beach, he saw him coming back in his boat. He could not, he said, leave Quebec, without offering himself and fortune to the woman he loved. Davison remonstrated with him, and shewed that his utter ruin must of necessity follow such a step. "Then let it follow," was his reply; "for I am resolved to do it." His friend was, however, equally resolute that he should not; and after some disputes, Nelson consented to return to his ship.

Captain Nelson sailed from Quebec with a convoy to New York, in the month of October 1782, at which place he joined the fleet, under the command of sir Samuel Hood. Here he became acquainted with prince William Henry, the present duke of Clarence, who, at that time serving as midshipman in the Barfleur, under sir Samuel Hood. "I had," says his royal highness, "the watch on deck, when captain Nelson came in his barge along-side, who appeared to be the merest boy of a captain I ever beheld; and his dress was worthy of attention. He had on a full laced uniform; his band unpowdered hair was tied in a stiff Hef- tian tail, of an extraordinary length: the old-fashioned flaps of his waistcoat added to the general quaintness of his figure, and produced an appearance which particularly attracted my notice; for I had never seen anything like it before, nor could I imagine who he was, nor what he came about. There was, however, something irresistibly pleasing in his address and conversation, and an enthusiasm, when speaking on professional subjects, which shewed that he was no common being." In November he sailed with sir Samuel Hood to the West Indies, where he continued actively employed till the peace. By the commander-in-chief, Nelson says he was treated as if he were his son: "nor is my situation with prince William less flattering. Sir Samuel was kind enough to tell his royal highness, that if he wished to ask questions relative to naval tactics, I could give him as much information as any officer in the fleet. He will, I am certain, be an ornament to our service. He is a seaman, which you could hardly suppose: every other qualification you may expect from him; but he will be a disciplinarian, and a strong one." When Nelson was ordered back to England, he was directed, in his way, to attend his royal highness prince William on a visit to the Havana. On his arrival, the Albemarle was paid off at Portsmouth, on the 31st of July 1783. During the autumn of this year, captain Nelson went to France, where he continued till the spring of the year 1784, when he was appointed to the command of the Boreas frigate, 28 guns, and was ordered to the Leeward islands. While his velle was at anchor in Nevis road, a French frigate pulled to the leeward, close along shore. Nelson had received information that this frigate was sent from Martinico, for the purpose of making a survey of our West India islands. This he was determined to prevent. Accordingly he followed her to St. Eustatius, and being invited by the Dutch governor to meet the French officers at dinner, he took that opportunity of affurering the captain, that understanding it was his intention to honour the British poфессions with a visit, he had taken the earliest opportunity in his power to accompany him in his majesty's ship the Boreas, in order that such attention might be paid to an officer of his most Christian majesty, as every Englishman would be proud to shew. The French, with equal politeness, protested against giving him this trouble; but Nelson insisted upon paying them this compliment, followed them clove, in spite of all attempts to elude his vigilance, and never left light of them, till finding it impossible either to deceive or escape them, they gave up their intention in despair, and beat up to Martinico.

This fleet, moreover, opened a new scene to the officers of the British navy. The Americans, when colonists, possessed almost the whole of the trade from America to our West India islands; but on the return of peace, and when their independence was acknowledged, they forgot that they were then to be considered as having no more privileges in this trade than foreigners. The governors and custom-house officers pretended, that by the Navigation Act (which see), the Americans had a right to trade. He knew the meaning of that act as well as they, and though the commander-in-chief was disposed to wink at this commerce, he addressed a letter to the governor of the Leeward islands on the subject, who, in reply, told him that old generals were not in the habit of taking advice from young gentlemen. Nelson, in answer to this, said, "Sir, I am as old as the prime minister of England, and think myself as capable of commanding one of his majesty's ships, as that minister is of governing the state." He accordingly shewed that he could act for himself, and, in defiance of the judgment of those who thought themselves his superiors, ordered all the American vessels to quit the islands in forty-eight hours; declaring, that if they refused, or hesitated, or preferred to land their cargoes, he would seize them. The Americans, supported by the governors of the islands, did refit; and the admiral, unwilling to take an active part on either side, advised captain Nelson to be guided by the wishes of the presidents of the council. With respect to this advice of sir Richard Hughes, he said within himself, "I must now disobey my orders, or disobey acts of parliament: I determined on the former, trusting to the uprightness of my intentions, and believing that my country would not allow me to be ruined by protecting her commerce." He wrote to the admiral, and in very respectful language told him, he should decline obeying his orders, till he had an opportunity of seeing and conversing with him. The first feelings of sir Richard Hughes were those of anger, and he determined to supersede Nelson; but having mentioned the business to his own captain, the latter told him, he believed all the squadron thought he had issued illegal orders, and therefore did not know how far they were bound to obey him. The admiral submitted, and even thanked Nelson for having shewn him his error. At Nevis the Boreas found some American vessels deeply laden, with the colours of the island flying. They were ordered to hoist their proper flag, and leave it in eight-and-forty hours. At first they denied their country, and refused to obey; but upon being examined before the judge of the admiralty, they admitted that they were Americans, and that their vessels and cargoes were wholly American property. Upon this, Nelson seized them. Actions were brought against him, and the damages laid at 40,000£: he, however, triumphed, and the four ships and their cargoes were condemned. While the affair was pending, he lent a memorial to the king; in consequence of which, orders were forwarded to defend him at the expense of the crown: and upon the representation which he made at the same time to the secretary of state, the Regifter Act was framed. The treasury, upon this occasion, and certainly without much reason, transmitted thanks to sir Richard Hughes, and the officers under him, for their activity and zeal in protecting the commerce of Great Britain. Nelson felt indignant at their conduct: he, indeed, had protected the commerce of his country, in op-
NELSON.

position to the opinion and the express advice, which in military language always means order, of Sir Richard; and yet Nelson was palled over, and the admiral applauded. "I feel hurt," said the high-minded captain, "that after the loss of health, and the risk of my fortune, another should be thanked for what I did, and against his orders. I either deferred to be sent out of the service, or at least to have had some little notice taken of what I had done. They have thought the act worthy of notice, but they have neglected me."

During the whole time, captain Nelson scarcely ever quitted the ship, but was observed to carry on the duty with a strict but fullest attention. When orders were received for his ship to be paid off at Sheerness, he expressed his joy to the senior officer in the Medway, saying, "It is my determination never again to set my foot on board a king's ship. Immediately after my arrival in town, I shall wait on the first lord of the admiralty, and resign my commission." The officer, finding it in vain to reason with him against this resolution in the present state of his feelings, used his secret interference with the first lord of the admiralty to save Nelson from taking a step so injurious to himself, and which would ultimately have been so mischievous to his country. Lord Howe took the hint, sent for captain Nelson, and having had a long conversation with him, and probably expressed to him, with the feelings of admiration and a warm heart, the obligations that the country and government owed him, desired that he might, on the first levee day, have the honour of presenting him to his majesty. This thing was done: he was most graciously received at court, and the retection of captain Nelson was effectually removed. He now retired to enjoy the pleasures of domestic happiness at the parsonage-house at Burham Thorpe, which his father gave him as a place of residence. But the affair of the American captures was not terminated; he had, while amusing himself on his little farm, a notification that he was again to be liable for damages to the amount of 20,000l. This circumstance, as unexpected as it was unjust, excited his astonishment and indignation. "This affront," he exclaimed, "I did not deserve; but I will no longer be trifled with. I will write immediately to the treasury, and if government will not support me, I am resolved to leave the country." He accordingly informed the treasury, that unless a satisfactory answer were returned to him by return of post, he would immediately take refuge in France. Mr. Rofe replied, that he would assuredly be supported.

In the year 1790, during the armament occasioned by the dispute relative to Noviska found, captain Nelson offered his services, but they were not accepted. He made similar applications again and again, and with the same success; and he determined to quit the service, at least he affirmed this as his resolution: but he did not know himself; he was not aware that it was "his meat and drink" to serve his country; his peace, his comfort, his existence even depended upon his being able to serve.

On the 30th of January 1793, he was delighted with the appointment to the Agamemnon of 64 guns, and was very soon after placed under the orders of lord Hood, then appointed to command in the Mediterranean. The temper with which Nelson engaged in this war is manifested in the instructions which he gave to one of his midshipmen, probably his son-in-law, Joshua Nefbit. "There are three things, young gentleman, which you are constantly to bear in mind: first, you must always implicitly obey orders, without attempting to form any opinion of your own respecting their propriety (he probably did not recollect his own conduct in the American business); secondly, you must consider every man as your enemy who speaks ill of your king; thirdly, you are to hate a Frenchman as you do the Devil." This was naval morality!

The unbounded confidence which lord Hood always repose in captain Nelson, manifested the high opinion which he entertained not only of his courage, but of his talents and ability to execute the arduous services with which he was entrusted. If batteries were to be attacked, if ships were to be cut out of their harbours, if the hazardous landing of troops was to be effected, or difficult passages to be explored, we invariably find Nelson foremost on the occasion, with his brave officers, and the gallant crew of the Agamemnon. During the time that Nelson had the command of the Agamemnon, and previously to the commencement of hostilities with Spain, he put into Cadiz to water; and on beholding the Spanish fleet, exclaimed, "These ships are certainly the finest in the world. Thank God! the Spaniards cannot build men, as they do ships!" It was observed in the Mediterranean, that before captain Nelson quitted his old ship, he had not only fairly worn her out, there not being a mast, yard, sail, nor any part of the rigging, but was obliged to be repaired, the whole being cut to pieces with shot, but had exhausted himself and his ship's company. At Toulon, and the celebrated victories achieved at Baflia and Calvi, lord Hood bore ample testimony to the skill and unremitting exertions of captain Nelson, "which," said his lordship, "I cannot sufficiently applaud." During the memorable siege of Baflia, he superintended the disembarkation of the troops and flores, and commanded a brigade of seamen, who served on shore at the batteries. lord Hood had submitted to general Dundas, and afterwards to his successor D'Aubert, a plan for the reduction of Baflia; but they refused to co-operate, or to furnish a single soldier on the occasion. He obtained, however, only a few artificers, and began the siege with only 1200 soldiers, artillery-men, and marines, and 250 sailors. "We are but few," says the brave Nelson, "but of the right sort; our general not giving us one of the five regiments he has lying idle." They were landed on the 4th of April, under colonel Vil-letes and Nelson, who had obtained from the army the title of brigadier. The sailors dragged the guns up the heights, which was a work that could probably have been accomplished only by British seamen. The soldiers behaved with the same spirit. "Their zeal," said he, "is, I believe, almost unexampled. There is not a man but considers himself as personally interested in the event; and defreated by their general, it has, I am persuaded, made them equal to double their numbers." "This," says a biographer of Nelson, "is one of many proofs, that to make soldiers equal to our seamen, it is only necessary that they should be well commanded. They have the same heart and soul, as well as the same flesh and blood. Too much may indeed be expected from them in a retreat; but with their face towards a foe, there is nothing within which human achievement which they cannot perform." The siege continued nearly seven weeks, and on the 16th of May a treaty of capitulation was begun; and on that same evening, and not before, the
NELSON.

The troops made their appearance on the hills; and on the following morning, general D'Aubert arrived with his whole army to take Batavia. The event of the siege had justified the opinion of the fathers; and when the conquest was as good as made, then they had the assistance of the army, which they had solicited before in vain. "I am," said Nelson, when he got possession of the fortresses, "all astonished, when I reflect on what we have achieved: 1000 regulars, 1500 national guards, and a large body of Cortonian troops, lying down their arms to 1000 soldiers and marines, and 2000 men. The enemy were supposing to be far inferior in number, when it was resolved to attack the place; and it was not till every arrangement was made, that Nelson received certain information of their great superiority. This intelligence he kept a secret, fearing the attempt would be readily abandoned, if a fair pretext were afforded. The siege of Calvi was carried on by general Stuart, and Nelson had left responsibility here than at Batavia, but the bunglers was equally arduous. He certainly knew the importance of his services, and on no occasion scrupled to set a value upon them. When at Calvi, he had to Lord Hood, "We will flag ourselves to death, before any blame shall be at our doors. I trust it will not be forgotten, that twenty-five pieces of cannon have been dragged to the different batteries, and mounted, and all but three fought by them." He was employed full four months on shore, and the climate was more delirious to his health, and to the continuations of his brave comrades, than the war. Nelson described himself as the rendezvous of troops to 1000 soldiers and marines, when they were laid low. "All the prevailing disorders have attacked me," said the captain, "but I have not strength enough for them to fail on me. One plan I have, never to employ a doctor. Nature does all for me, and Providence protects me." It was at the siege of Calvi that he lost an eye; and yet, strange as it must appear, he was altogether overlooked; his name did not even appear among the wounded. "One hundred and ten days," said he, "I have been actually engaged in sea, and on shore, with the enemy: three actions against ships, two against Batavia in my own ship, four boat actions, and two villages taken, and twelve ships burnt. I do not know that any one has done more. I have had the comfort of being always applauded by my commanders-in-chief; but never rewarded: and what is more mortifying, for service in which I have been actually wounded, others have been praised, who, at the time, were actually in bed, and far from the scene of action. They have not done me justice; - but never mind: I'll have a gazette of my own." He lived long enough to take all the glory that he anticipated.

When lord Hood left the Mediterranean in October 1794, the command devolved on admiral Hotham, who confided in Nelson with the same alacrity as lord Hood had done before; and Nelson again distinguished himself in the actions with the French fleet of the 13th and 14th of March, and also on the 13th of July 1795. Under admiral Hotham, he had occasionally the command of a light squadron of frigates, with which he performed some valuable services; and he was rewarded with a colonelcy of marines. When sir John Jervis, now earl St. Vincenç, succeeded admiral Hotham in November 1795, he was too fethible of the merits of captain Nelson to part with him. He raised him to the rank of commodore, and removed him from the Agamemnon to the Captain of 74 guns; and on the 11th of August he had a captain appointed under him.

From the month of April till October, commodore Nelson was constantly employed in the most arduous services, viz. the blockade of Leghorn, the taking of port Ferrajo, with the island of Caprea, and, lastly, in the evacuation of Batavia: after which, he joined the admiral in St. Fineniza bay, and proceeded with him to Gibraltar. While the name of Nelson was hardly known to the English public, it was feared, respected, and highly honoured throughout Italy, and in other parts of the continent. A letter was sent to him, directed, "Horatio Nelson, Genoa." When the writer was asked, how he could address a letter so vaguely? he replied, "There is but one Horatio Nelson in the world." In the letter in which he mentions this circumstance to his lady, captain Nelson says, "Had all my actions been gazetted, not one fortnight would have passed, during the whole war, without a letter from me. One day or other I will have a long gazette to myself. I feel that such an opportunity will be given me. I cannot, if I am in the field of glory, be kept out of sight."

During the month of December 1796, commodore Nelson hoisted his broad pendant on board La Minerve frigate, captain George Cockburne, and was dispatched with that ship and La Blanche to Porto Ferro, to bring the naval stores left there to Gibraltar. On the passage thither, in the night of the 19th, the commodore fell in with two Spanish frigates. He immediately attacked the ship which carried the poop light, and directed the Blanche to bear down and engage the other. At forty minutes past ten at night, the commodore brought his ship to close action, which continued without interruption till half past one, when La Sabina of 44 guns, commanded by captain Don Jacobo Stuart, struck to La Minerve. Captain Preston in La Blanche silenced the ship he had engaged, but could not effect possession, owing to three more ships heaving in sight. Commodore Nelson's letter, on this occasion, to his admiral sir John Jervis, has been regarded as a noble example of a generous and modest spirit, insomuch as he assumes no merit to himself, but gives every praise to the captain, his officers, and crew. "You are, sir," says he, "so thoroughly acquainted with the merits of captain Cockburne, that it is needless for me to express them; but the discipline of La Minerve does the highest credit to her captain and lieutenants, and I wish fully to express the same I have of their judgment and gallantry. Lieutenant Culverhouse, the first lieutenant, is an old officer of very distinguished merit; lieutenants Hardy, Gage, and Noble, deserve every praise which gallantry and zeal justly entitle them to; as does every man in the ship. You will observe, sir, I am sure, with regret, among the wounded, lieutenant James Noble, who quitted the Captain to fight with me, and whose valour, and repeated wounds received in fighting the enemies of our country, entitle him to every reward a grateful nation can bestow." In this action, the captured ship had 164 men killed and wounded, and lost the mizen, main, and foremost; and La Minerve had seven men killed, 34 wounded, and all her masts shot through.

On the 29th of January 1797, commodore Nelson failed in La Minerve from Porto Ferro, on his return to sir John Jervis, with a mind irritated and depressed, through the fear that a general engagement would take place before he could join the fleet. He arrived at Gibraltar a few days after the Spanish fleet had passed the Straits from Carthagena. Impatient to join his admiral, the commodore only remained one day at Gibraltar; and on the 11th of February, while he was proceeding to the westward, to the place of rendezvous, he was chased by two Spanish line of battle ships, and fell in with their whole fleet off the mouth of the Straits. He fortunately effected his escape, and joined the admiral off cape St. Vincent, on the 13th of February, just in time to communicate intelligence relative to the force and state of
the Spanish fleet, and to shift his pendant on board his former ship, the Captain, 74 guns. Before six o'clock, the fires were made to prepare for action. At day-break, the enemy were in sight. The British force consisted of two ships of 100 guns each, two of 98, two of 90, eight of 74, and one of 64, with four frigates, a sloop, and a cutter. The Spaniards had one ship of 136 guns, fix of 112 guns each, two of 84, and eighteen of 74 guns, with ten frigates. The disproportion was very great, but the Spanish admiral Don Joseph de Cordova, had reason to believe it was still greater, or he would not have hazarded a battle. He had learnt from an American, that the English had but nine ships on that station, which was actually the case when the American had fallen in with them; and upon this information he fought an engagement, instead of going into Cadiz, as at first intended, relying with a fatal confidence upon the accuracy of the American.

Sir John Jervis, following the new system of naval tactics, determined to break the line of the enemy; and before the Spanish admiral could form a regular order of battle, of which he seemed very deftous, Sir John, by carrying a preface of fall, came up with them, passed through the fleet, then tacked, and thus cut off nine of their ships from the main body. These, in their turn, attempted to form on their larboard tack, either with a design of passing through the British line, or to the leeward of it, and thus rejoining their friends. One of the nine only succeeded; the others were so warmly received, that they took to flight, and did not appear in action till the close. The admiral was now enabled to direct the whole attention to the enemy's main body, still superior to his whole fleet. He made signal to tack in succession. Nelson, whose station was in the rear of the British line, perceiving that the Spanish fleet was bearing up before the wind, with an intention of forming their line, joining their separated ships, or flying; determined to prevent either of these schemes from taking effect, and accordingly, without a moment's hesitation, disobeyed the signal, and ordered his ship to be wore. This at once brought him into action with seven of the largest ships of the enemy's fleet, among which were the Santifima of 136 guns, and two others of 112. Captain Towbridge, in the Culloden, nobly supported him; and the Blenheim, captained Frederick, came to their assistance. The Salvador del Mundo and the San Isidro dropped after, and were fired into by the Excellent, captained Collingwood, to whom the latter lurked. But Collingwood," says Nelson, "distraining the moral of taking possession of the enemy, most gallantly pushed up with every fast sail, to fave his old friend and mersmate, who was to all appearance in a very critical situation." The Captain was at this moment fired upon by three frigate rates, and the San Nicholas and a 74 were within pisflot-shot. The Blenheim was a-head, and the Culloden crippled 8-tarm. Collingwood ranged, and passed within ten feet of the San Nicholas, giving her a most tremendous broadside, pushed on for the Santifima of Trinidad. At this time the Captain had lost her fore-top-mast, had not a sail, shroud, or rope left, her wheel was cold away, and thus left incapable of farther service in the line or the chase; her noble commander, Nelson, instantly resolved on a bold and decisive measure, and determined, whatever might be the event, to attempt his opponent sword in hand; and directed captain Miller to put the helm a-starboard, and the boarders were summoned. "Fortune," says colonel Drunk-water, the animated narrator of this battle, "favours the brave!" nor on this occasion was she unmindful of her favourite. Ralph Willett Miller, the commodore's captain, (who was afterwards in the battle of the Nile, where he gained great honour, and was slain in the Thefeus, under sir Sidney Smith,) so audaciously directed the course of his ship, that he laid her aboard the star-board quarter of the Spanish 84; her frist-fall-yard passing over the enemy's poop, and hooking in her mizen throuds: when the word to board being given, the officers and seamen, defined for this perilous duty, headed by lieutenant (now sir Edward) Berry, (who was afterwards lord Nelson's captain in the Vanguard, in the battle of the Nile,) together with the detachment of the 69th regiment, commanded by lieutenant Pearson, then doing duty on board the Captain, passed with rapidity on board the enemy's ship, and in a short time the San Nicholas was in possession of her intrepid assailants. The commodore's ardour would not permit him to remain an inactive spectator of this scene. He was aware that the attempt was hazardous, and he thought his presence might animate his brave companions, and contribute to the success of this bold enterprise. He, therefore, as if by magic impulse, accompanied the party in this attack; passing from the foremost of his own ship into the enemy's quarter-galley, and thence through the cabin to the quarter-deck, where he arrived in time to receive the sword of the dying commander, who had been mortally wounded by the boarders. The English were at this time in possession of every part of the ship, and a fire of musketry opened upon them from the stern-galley of the San Josef. The commodore was not long in resolving on the line of conduct which he should adopt. The two alternatives that presented themselves were, to quit the prize, or instantly to board the three-decker. Confident in the bravery of his seamen, he determined on the latter. Directing, therefore, an additional number of men to be sent from the Captain on board the San Nicholas, Nelson, whom no danger could appal, head himself the assailants in this new attack, exclaiming, "Westminster Abbey, or a glorious victory!" Success in a few minutes, and with little los, crowned the enterprise. For a moment, commodore Nelson could scarcely persuade himself of this second instance of good fortune; he, therefore, ordered the Spanish commandant, who had the rank of brigadier, to assemble the officers on the quarter-decks, and means to be taken instantly for communicating to the crew the surrender of the ship. All the officers immediately appeared, and the commodore had the surrender of the San Josef duly confirmed, by each of them delivering his sword. The coxswain of the commodore's barge, John Sykes, had attended close by the side of his commander throughout this perilous attempt. To him the commodore gave in charge the swords of the Spanish officers, as he received them; and the undaunted tar, as they were delivered to him, tucked these honourable trophies under his arm with all the coolness imaginable. It was at this moment, one of the sailors came up, and with an Englishman's feeling, and apologizing for the liberty, took his commander by the hand, and congratulated him on being safe on the quarter-deck of a Spanish three-decker. On this occasion Nelson had received only a few bruises. The Spaniards had fire eighteen or twenty ships, which had suffered little or no injury; but they did not think right to renew the battle. As soon as the action was discontinued, Nelson went on board the admiral's ship, who received him on the quarter-deck, took him in his arms, and said he could not sufficiently thank him.

Before the news of the action had arrived in England, Nelson had been advanced to the rank of rear-admiral; and now for his gallantry, on the 14th of February, he received the insignia of the Bath, and the gold medal from his sovereign. He was also prefented with the freedom of the city of London in a gold box.
NELSON.

In the month of April 1797, Sir Horatio Nelson hoisted his flag as rear-admiral of the blue, and was detached to bring down the garrison of Porto Ferrajo; and on the 28th of May, he shifted his flag from the Captain to the Thefeus, and was appointed in the command of the inner squadron at the blockade of Cadiz. During this service, his personal courage was, if possible, more conspicuous than at any other period of his former exploits. In the attack on the Spanish gun-boats July 3d, 1797, he was boarded in his barge, with only its usual complement of ten men and the coxswain, accompanied by captain Fremantle. The commander of the Spanish gun-boats, Don Miguel Trogovia, in a barge rowed by 26 oars, having 30 men, including officers, made a most desperate effort to overpower Sir Horatio Nelson and his brave companions. The conflict was long and doubtful: they fought hand to hand with their swords. His faithful coxswain, John Sykes, was wounded in defending the admiral; and twice saved his life, by parrying the blows that were aimed at him, and mortally wounded his adversaries; and at last actually interposed his head to receive the stroke of a fabre, which he could not by any other means avert. The whole of the Spaniards were either killed or wounded, and Nelson brought off the launch. Sir John Jervis, in his letter to the admiralty, dated the 5th of July, says, "The rear-admiral, who is always present in the most arduous enterprises, with the affluence of some other barges, boarded and carried two of the enemy's gun-boats, and a barge-launch belonging to one of the ships of war, with the commandant of the frigate. Rear-admiral Nelson's actions speak for themselves: any praise of mine would fall very short of his merit."

On the 15th of July, he was detached with a small squadron to make an attack on the town of Santa Cruz, in the island of Teneriffe, where it was imagined a Manilla ship had landed an immense treasure. The rear-admiral, on his arrival before the town, lol no time in directing a thousand men, including marines, to be prepared for landing from the ships, under the direction of captains Trowbridge, Hood, Thomson, Fremantle, Bowen, Miller, and Waller, who volunteered their services. The boats of the squadron were accordingly manned, and the landing was effected in the course of a dark night. The party were in full possession of the town of Santa Cruz in about seven hours; but finding it impracticable to storm the citadel, they prepared for their retreat, which was allowed by the Spaniards unmolested, agreeably to the stipulations made with captain Trowbridge. On this expedition, Nelson had orders on no account to land in peril with the forces, unless his presence was absolutely necessary; but no orders could restrain him, where there was danger to be encountered. That he was aware of the peril is evident from the letter which he wrote to the commander-in-chief: in this he says, "This night I command the whole force deputed to land under the batteries, and to-morrow my head will probably be crowned either with laurel or cypress." He was very disinclined, likewise, that his son-in-law, lieutenant Nebbit, should remain behind, saying, "Should we both fall, what will become of your poor mother? Besides, the care of the Thefeus falls to you; flay, therefore, and take charge of her." Nebbit replied, "Sir, the ship must take care of herself: I will go with you tonight, if I never go again." Nelson, in the act of stepping out of the boat, received a dis. through the right elbow, and fell. Nebbit, who was close to him, placed him at the bottom of the boat, and applied his neckbandkerchief as a tourniquet to the admiral's arm, and conveyed him to the Thefeus, under a tremendous fire from the enemy. The same night, at 10 o'clock, the admiral's arm was amputated; and immediately after, he began his official letter: and on the following day he wrote to lady Nelson, and says, "I know it will give you much pleasure, in finding that your son, under God's providence, was instrumental in saving my life." The loss of the English amounted to 250. But the admiral, in his official dispatches, did not mention his own wound; though in a private letter to lord St. Vincent, the first which he penned with his left hand, he says in the spirit of dependence, "I am become a burden to my friends, and degrade to my country. When I leave your command, I become dead to the world.—I go hence, and am never seen." He was obliged to go to England for advice, that he could not have abroad; and here honours awaited him, abundantly more than sufficient to recover his acquitained spirit: but what gave zest to every pleasure was the assurance, that he would be soon fit for active service. Letters were addressed to him by the first lord of the admiralty, and by his able friend, the duke of Clarence, to congratulate him on his return. The freedom of the cities of Bristol and London was transmitted to him; he was invested with the order of the Bath, and he received a pension of 1000l. a-year. Not having been in England since he lost his eye, he went to receive a year's pay as smart-money; but could not obtain it, because he had not brought a certificate from a surgeon, that the fight was actually destroyed. He was somewhat angry that this formality should be insisted upon, the fact being so notorious. He, however, complied; and on his return to the office, the clerk, finding it was the annual pay of a captain only, observed, he thought it had been more. "Oh," replied Nelson, "this is only for an eye; in a few days, I shall come for an arm; and in a little time longer, God knows, most probably for a leg." Accordingly he soon after went, and exhibited the certificate of the loss of an arm. On his first appearance at court, his sovereign received him in the most gracious and tender manner, expressing his sorrow at the loss which the noble admiral had sustained, and at his impaired state of health, which might deprive the country of his future services. "May it please your majesty," said the admiral, "I can never think that a loss, which the performance of my duty has occasioned; and so long as I have a foot to stand on, I will combat for my king and country." Previously to his having received the grant, already referred to, of a pension, custom required that a memorial of his services should be drawn up, and a more brilliant detail was never exhibited. He had been actually engaged against the enemy 120 times, and during the war then carrying on, he had affixed at the capture of seven sail of the line, six frigates, four corvettes, and eleven privates of different sizes; and taken or destroyed nearly fifty sail of merchant vessels.

In April 1798, Sir Horatio Nelson hoisted his flag in the Vanguard, and he was ordered to rejoin earl St. Vincent. Upon his departure, his father addressed him with affection and much solemnity. "I trust in the Lord," said the venerable rector, "that he will prosper your going out and coming in. I earnestly desired once more to see you, and that with has been heard. If I should presume to say, I hope again to see you, the question would be readily asked, How old are you? Vale, vale!" A gloomy foreboding of the future, it has been said, hung on the spirits of lady Nelson at their parting: this was, probably, through dread of losing him by the chance of war. No apprehension of losing his affection could possibly have existed: for we are assured, that all his letters to this time evince that he considered himself happy in his marriage; and his private life had hitherto been as spotless as his public one: and one of the last things he said to her was, that his own ambition was satisfied.
NELSON.

satisfied, but he was going to raise her to that rank in which he had long wished to see her.

As soon as he had joined earl St. Vincent, he was dispatched to the Mediterranean, that he might ascertain the object of the great expedition sitting out at Toulon. He failed with a small squadron from Gibraltar, on the 9th of May, to watch this armament. On the 22d, a sudden storm in the gulf of Lyons carried away all the top-masts of the Vanguard; the fore-mast went into three pieces, and the bow-sprit was sprung. Captain (afterwards Sir Alexander) Ball took the ship in tow, to carry her into St. Peters, Sardina. Nelson, apprehensive that this attempt might endanger both vessels, ordered him to call off; but that excellent officer, pooffing a spirit very like that of his commander, replied that he was confident he could save the Vanguard, and by God's help he would do it. Previously to this, there had been a coolness between the brave ships; but from that moment, Nelson became fully sensible of the extraordinary merit of captain Ball, and a sincere friendship sprung between them during the remainder of their lives. Being compelled to rest, the delay enabled him to secure his junction with the reinforcement which lord St. Vincent had sent to join him, under commodore Troubridge. That officer brought with him no instructions to Nelson, as to the course he was to steer, nor any positive account of the enemy's disposition; every thing was left to his own judgment. The first news was, that they had surprised Malta. He formed a plan for attacking them while at Gozo; but on the 22d, intelligence reached him that they had left that island on the 16th, the day after their arrival. He then pursued them to Egypt, but he could not learn any thing of them during his voyage; and when he reached Alexandria, the enemy were not there. He then shaped his course for the coast of Caramania, and feered from thence along the southern side of Canda, carrying a press of full both night and day, with a contrary wind. Irritated that they should have eluded his vigilance, the tediousness of the night made him impatient, and the officer of the watch was repeatedly called upon to declare the hour, and convince his admiral, who measured time by his own eagerness, that it was not yet break of day. "It would have been my delight," said he, "to have tried Bonaparte on a wind." Baffled in his pursuit, Nelson returned to Sicily, took in stores at Syracuse, and then made for the Morea. There, on the 26th of July, he learnt that the French had been seen about a month before, steering to the south-east from Canda. He rejoiced to return, and immediately, with every sail full, as soon as clear of the coast of Egypt. On the 11th of August, they came in sight of Alexandria; and at four in the afternoon, captain Hood, in the Zealous, made signal for the French fleet. For several preceding days, the admiral had scarcely taken either food or sleep; he now ordered his dinner to be served, while preparations were making for battle; and when his officers rose from table, and went to their separate stations, he said to them, "Before this time to-morrow I shall have gained a passage to Weemsbatter Abbey." It has never been explained, why Bonaparte, having effected his landing, should not have ordered the fleet to return. It is, however, certain, that it was detained by his express command; though after the death of Brueys, he accused him of having lingered there, contrary to his received orders. That admiral, not being able to enter the port of Alexandria, had moored his fleet in Aboukir bay, in a strong and compact line of battle; the mainmoat vessel being as close as possible to a shallow on the north-west, and the rest of the fleet forming a kind of curve along the line of deep water, so as not to be turned by any means on the south-west. This position the French admiral thought the strongest possible, in an open road; and he had no doubt that he could bid defiance to a force more than double their own. Instead of which, he had the advantage of numbers in ships, in guns, and in men: he had thirteen ships of the line and four frigates, carrying 1196 guns, and 11,230 men; whereas the English had the same number of ships of the line, and one 50 gun ship, carrying 1012 guns, and 8068 men. They had, however, Nelson for chief-in-command, who, in all cases, was a mighty host in himself. During the whole cruise, it had been Nelson's practice, whenever circumstances would admit of it, to have his captains on board the Vanguard, and fully explain to them his own ideas of the bell modes of attack, whatever might be the situation of the enemy. His officers, therefore, were well acquainted with his principles of tactics; and though he was not conspicuous in their abilities and zeal, that the only plan arranged, in case they should find the French at anchor, was for the ships to form as most convenient for their mutual support, and to anchor by the stern. His maxim was, "First gain the victory, and then make the bell use of it yourself." When he had fully explained his intended plan, captain Berry exclaimed with transport, "If we succeed, what will the world say?" "There is no if," replied the admiral; that we shall succeed is most certain; who may live to tell the story is a very different question."

The position of the enemy presented the most formidable obstacles, but the admiral viewed these with the eye of a seaman determined on an attack; and it instantly struck him, that where there was room for an enemy's ship to swing, there was room for one of ours to anchor. No further signal was necessary than those which had already been made. The admiral's designs were as fully known to his whole squadron, as was his determination to conquer or perish in the attempt. We cannot attempt to give a detailed account of this action, of which there is an excellent narrative in the first volume of the "Naval Chronicle;" neither can we wholly pass by an occurrence so important to the interests of our country. The action commenced at sun-set, at half past 6 o'clock, with an ardour that cannot be described. The Goliath, captain Foley, and the Zealous, captain Hood, received the first fire from the enemy. It was received with silence. On board every one of the British ships, the crew were employed aloft in furling sails, and below in tending the braces, and making ready for anchoring; a wretched sight for the French, who, with all their advantages, were on that element, upon which, when the hour of trial comes, a Frenchman has to hope but in escape; and here an attempt of the kind was impossible. Admiral Brueys was a brave and able man, yet he had, in a private letter, boasted that the English had miffed him, because not finding themselves superior in numbers, they did not think it prudent to try their strength with him. The moment was now come in which he was to be fatally deceived. The shores of the bay of Aboukir were soon lined with spectators, who beheld the approach of the English, and the awful conflict of the hostile fleets in silent astonishment. Admiral Nelson had six colours flying in different parts of his rigging, left they should be shot away;—that they should be struck, no British commander considers as a possibility. The two first ships of the French line had been dismasted within a quarter of an hour after the action, and the others suffered so severely, that victory was even now regarded as certain. The third, the fourth, and the fifth, were taken possession of at half past eight. In the mean time. Nelson had received a severe wound on the head from a piece of iron,
NELSON.

iron, called a langridge-flot; the skin of his forehead, being cut with it at right angles, hung down over his face. Captain Berry caught him in his arms, as he was falling. The great effusion of blood occasioned an apprehension that the wound was mortal. When the surgeon had examined it, he found there was no immediate danger, but urged him to keep himself quiet. He called for his secretary to write the dispatches, but he had been himself wounded. The chaplain was next summoned, but before he could get to the admiral's cabin, Nelfon seized the pen, and began himself. Suddenly a cry was heard on deck, that the Orient was on fire. In the confusion, the admiral found his way up, and, to the astonishment of every one, appeared on the quarter-deck, when he immediately gave orders that boats should be sent to the relief of the enemy. It was about nine o'clock that this fire broke out. Bruyere was dead: he had received three different wounds, yet would not leave his post: a fourth almost cut him in two; he refused to be carried below, being determined to die upon the deck. The flames soon overpowered every effort to save the ship. By the prodigious light of this conflagration, the situation of the two fleets were clearly distinguishable by the colours of each ship. About 10 o'clock the Orient blew up with a most tremendous explosion. This was followed with an awful pause, and a death-like silence. The firing instantaneous ceased on both sides, and the first sound was the fall of her shattered masts and yards; which had been carried to an astonishing height. The firing recommenced with the ships to leeward of the centre, and continued till three in the morning. At day-break, the two rear ships of the enemy were the only French ships of the line which had their colours flying: these cut their cables in the forenoon, and flew out to sea, and two frigates with them. The Zealous pursued, but as there was no other ship in a condition to support captain Hood, he was recalled. These, however, were all that escaped, and the victory was the most complete and glorious in the annals of naval history. Of thirteen fail of the line, nine were taken and two burnt; of the four frigates, one was sunk and another burnt. The losses on the part of the English, in killed and wounded, amounted to 895: on the part of the French, 522 were killed and 3105, including the wounded, were sent on shore by cartel.

Admiral Nelfon was now at the height of his glory. He had realized his hopes: he had nobly earned a peerage. Congratulations, rewards, and honours of every kind, were showered down upon him in great abundance, by all the princes and powers to which this important victory or splendid conquest was beneficial. The grand seignior, and his brother, the czar, the king of Naples and Sardinia, sent him presents, accompanied with letters, acknowledging his unequalled services to the common cause. In his own country he was created baron Nelfon of the Nile, of Buenos-Torpo, with a pension of 20,000l. for his own life, and those of two of his immediate successors. When this subject was brought before the house by Mr. secretary Dundas, he said, "Some victories had been marked with peculiar circumstances: some had been marked by the skill of the commanders; some by the particular bravery of the seamen; others by the great and extensive benefits resulting from them. But it was peculiar to this victory, that it united all those qualities by which other victories had been most distinguished." When he said, "we look to the extent of the consequences of this victory, both at home and abroad; when we behold the spirit with which it has electrified Europe from one end to the other; we must acknowledge that there never did exist a victory, which had produced so much at present, and which was likely to produce so many and such important consequences in future." It was on this occasion that general Walpole expressed an opinion, that a higher degree of rank ought to have been conferred. To this Mr. Pitt replied, that he thought it needless to enter into that question, which, after all, belonged to the crown, and to the crown only. "Admiral Nelfon's fame," he said, "would be coeval with the British name; and it would be remembered that he had obtained the greatest naval victory on record, when no man would think of asking whether he had been created a baron, a viscount, or an earl. True indeed, whatever title had been bestowed, he who received it would have been Nelfon still; that name he had ennobled beyond all addition of nobility. It was the name by which England loved him, France feared him, and Italy, Egypt, and Turkey celebrated him, and by which he would continue to be known while the present kingdoms and languages of the world endure." See Debates in the House of Commons for November 21, 1798.

The title of baron once obtained was not satisfactory to Nelfon; he had seen that sir John Jervis and admiral Duncan had obtained higher honours, and more splendid rewards for victories less decisive and important than that which he had achieved, and he did not hesitate to speak with indignation on this treatment of ministers.

On the twenty-second of September 1798 he arrived at Naples, where he was received as a deliverer by his majesties, and the whole kingdom. The king himself went among leagues to sea in his barge to meet him. The victory of the Nile had inspired the court with courage openly to declare against France, and a powerful army under general Mack was preparing to march against the French in Italy. Malta was at this time in a state of blockade by the English and Neapolitans, and lord Nelfon went hither to afflict in it. In the month of November he proceeded with a squadron to Leghorn, which town, with its fortresses, was delivered to the Neapolitan troops accompanying him. When the mismanagement and ill conduct of the court of Naples, and the cowardice of the troops, had rendered the French triumphant, and brought the capital into immediate danger, lord Nelfon zealously attached, by principle, to the royal family, took them with his friends sir William and lady Hamilton, on board his ship, and carried them safe to Palermo. He remained at that capital, directing the various operations of the fleet under his orders in the Mediterraneanc, not without some occasional altercations with sir Sidney Smith. Lord Nelfon had a punctious jealousy respecting any interference with him in the rights attached to his station, and felt a high sense of his own consequence and superiority, though, as it has appeared in various instances, no man was more ready to give due praise to others. His jealousy had no taint of envy in it, but it proceeded from his early habit of naval discipline; and it is not unfair to lay too much stress on the importance of his services. After the French had taken possession of Naples, and established a republic, on the ruins of the former monarchy, the dormant spirit of loyalty began to revive, and measures were taken for a counter revolution. In thebe lord Nelfon concurred with an enthusiastic zeal, and he sent Bamborough to cruise in the bay of Naples, and reduce the islands by which it is surrounded. On the 24th of June 1799 his lordship himself arrived in the bay, when the republicans had just entered into an armistice with the Neapolitan general Kuffo, signed by commodore Foote and the Turkish and Russian commanders, for the sailies which alone remained in their possession. The king of Naples, in this prosperous state of his affairs, was induced to dilate the authority of the cardinal to treat with subjects in rebellion.
NELSON.

and lord Nelson immediately put an end to the truce. The fortresses were afterwards obliged to capitulate, and a bloody execution, in spite of the treaty, took place of a number of the Neapolitan republicans, under the eye of the British admiral. For this part of lord Nelson's conduct, much has been said by his panegyrists, but it is not, and cannot be, justified. He submitted to be subservient to the passions of the court, and this, perhaps, the more readily as his own prejudices and paffions were all on the same side. That we have not spoken too strongly on this subject is evident from the vindication of commodore Poote, who shall speak for himself: "Nothing," says this much injured and insulted officer, "can be more evident than the fact that a folen capitalization had been agreed upon, formally signed by the chief commander of the forces of the king of Naples, by the Russian commander, and by myself, all duly authorized to sign any capitation in the absence of superior powers. This was not a treaty of peace, subject to ratification; it was not liable to be broken; it was a serious agreement for surrender, upon terms which involved the lives and properties of men, who might have chosen to forfeit those lives and properties, had they not relied principally upon the faith of a British officer. Parts of the agreement were performed, and actual advantage was afterwards taken of those parts of the capitation that had then been thus executed, to fleece the unhappy men who, having been thus deceived by a furred pledge, were sacrificed in a cruel and defpotic manner." "These facts," says the writer in the Quarterly Review, "are certain and undeniable. They cannot be defended: they cannot be excused; they cannot by any sophistry be palliated. A faithful historian has no alternative but to relate them with shame and sorrow."

On the ninth of August lord Nelson brought his Sicilian majesty safely to his court, having kept him some weeks in his ship out of the reach of peril, and on the thirteenth the king presented him with a sword most magnificently enriched with diamonds, and conferred upon him the title of duke of Bronté, and annexed to the title an estate supposed to be worth 3000l. per annum. Lord Nelson himself gave an account of the presents which he had received for his services, in the Mediterrenean, between the first of October 1798 to the same date in the following year. Besides what has been just mentioned he received from the king and parliament of Great Britain a peacree and 2000l. per annum, for his own life and two next heirs. From the East India company 10,000l.; from the Turkey company a piece of plate of great value; from the city of London a sword of exquisite workmanship and great worth; from the grand signior a diamond agirote, or plume of triumph, valued at 2000l.; also a rich pélisse valued at 1000l., and from the signior's mother a rofe fet with diamonds of equal value; from the emperor of Russia and the king of Sardinia boxes fet with diamonds worth 3700l.; besides many other presents of less value, but costly, and expressive of a high sense of gratitude in the donors.

It was at Naples, that lord Nelson suffered himself to be so far infatuated as to form a connection with lady Hamilton, which led to his separation from his own wife, and till which he had been an affectionate husband, and happy and amiable in all his domestic relations. This is inconceivable proved by the letters which passed between him and his lady, and which have been given in the life of his lordship by Mr. Clarke and Mr. Arthur.

After the appointment of lord Keith to the command of the Mediterranean fleet, lord Nelson made preparations to return, and proceeding, in company with Sir William and lady Hamilton, to Tfried, he travelled through Germany to Hamburgh every where received with distinguished honours. He embarked at Cuxhaven, and landed at Yarmouth on the fifth of November 1800, after an absence from his native country of three years. In the following January he received orders to embark again, and it was during this short interval that he formally separated from lady Nelson. Some of his laid words to her were, "I call God to witnesses that there is nothing in you or your conduct that I with otherwise." He was now raised to the rank of vice-admiral of the blue, and soon after hoisted his flag on board the San Josef of 112 guns, his own prize at the battle of Cape St. Vincent. About this time the emperor Paul of Russia had renewed the northern confederacy, the express and avowed object of which was to set limits to the naval supremacy of England. A revolution being taken by the English cabinet to attempt its dissolution, a formidable fleet was fitted out for the North seas under sir Hyde Parker, in which lord Nelson consented to go second in command. Having hoisted his flag to the St. George, of 98 guns, he failed with the fleet in the month of March, and on the 30th of that same month he led the way through the Sound, which was passed without any loss. When the fleet failed, it was known that its destination was Copenhagen; some Danish sailors who were on board the Amazon frigate went to captain Riou, and begged he would get them exchanged into a ship bound on some other service; they did not wish to quit the British navy, but they intreated that they might not be led to fight against their own country. The captain felt deeply for their situation, ordered his boat instantly, and did not return to the Amazon till he had procured their exchange. See Riou.

The battle of Copenhagen gave occasion for an equal display of lord Nelson's talents as that of the Nile. The Danes were well prepared for defence. Upwards of two hundred pieces of cannon were mounted upon the crown batteries at the entrance of the harbour, and a line of 25 two-deckers, frigates, and floating batteries, was moored across its mouth. An attack being determined upon, the conduct of it was entrusted to lord Nelson; the action was fought on the second of April; Nelson had with him twelve ships of the line, with all the frigates and small craft, the remainder of the fleet was with the commander-in-chief, about four miles off. The combat which succeeded was one of the most terrible on record. Nelson himself said, that all of the engagements in which he had borne a part it was the most terrible. It began at ten in the morning, and at one victory had not declared itself. A shot through the main-mast knocked a few splinters about the admiral; "It is warm work," said he, "and this may be the last cast to any of us in a momento; but mark you, I would not be elsewhere for thousands." Jut at this moment sir Hyde Parker made signal for the action to cease. It was reported to him, but he continued pacing the deck, and appeared to take no notice of it. The signallieutenant asked if he should repeat it. "No," replied Nel- son, "acknowledge it." Presently he called to know if the signal for close action was still hoisted, and being answered in the affirmative, he said "Mind you keep it so." "Doctor," said he to the Surgeon, "you know what's thrown on board the commander-in-chief, N 39?" He said he did, and asked what it meant. "Why to leave off action:—No—n n me if I do! You know Foley," speaking now to his captain, "I have only one eye, and have a right to be blind sometimes. D—n the signal! hoist mine for closer battle; that is the way I answer such signals. —Nail mine to the mast." Admiral Graves disobeyed that of the commander-in-chief in like manner, but whether intentionally, or by mistake, had not been explained. The squadron of frigates hauled off;
NELSON.

Nelson in the Amazon probably did not think himself sufficiently high in reputation to set at defiance the commands of his superior officer; but at the moment that the Amazon shewed her stern to the enemy the captain was killed— that he obeyed the signal for retreat with regret was evident from his last words, which expressed his sorrow, and he added, "What will Nelson think of us?" About two o'clock, great part of the Danish line had ceased to fire, and many of them had struck, but, though the victory was complete, yet it was difficult to take possession of the vanquished ships, on account of the fire from the shore, which was still kept up. Nelson was irritated at this, and the more so, as part of his own fleet was in a perilous state. The crown batteries were, as yet, untouched, as were the ships at the entrance of the arsenal; while two of his own were aground, and others in imminent hazard of a like fate. At this critical period lord Nelson, with the presence of mind of one familiarized to danger, instantly opened a negotiation, pretending that he had been urged to this step through humanity to the vanquished Danes: He thus wrote to the crown prince: "Lord Nelson has directions to spare Denmark, when no longer resisting; but if the firing is continued on the part of Denmark, lord Nelson must be obliged to set on fire all the floating batteries he has taken, without having the power of saving the brave Danes who have defended them." A wafer was given him for his letter, but he ordered wax and candle, saying, it was no time to appear informal, and he did not wish to appear that he was hurried. This measure put an end to further carriage; and on the landing of lord Nelson, the preliminaries of a treaty were arranged, which finally terminated the dispute. The death of Paul, though not then known, had happened about nine days before this dreadful engagement; and thus the northern confederacy was annihilated. For this signal service, in which lord Nelson has been applauded as well for his adroitness as a negociator and flateamn, as for his courage and talents as an admiral, he was raised to the rank of viscount. "There was some prudence," says a biographer, "in thus dealing out honours to him step by step; had he lived long enough, he would have fought his way to a dukedom."

The preparations made for the invasion of England from Boulogne, having now excited a great alarm in the nation, it was thought advisable to calm the public fears by entreting the marine defence to the popular hero, and lord Nelson was appointed commander-in-chief of a squadron, with the whole attached flotilla of gun-boats, bomb-velletts, &c. Refolving to attempt something that was worthy of his name, and the celebrity to which he had attained; something that should effect more than a temporary security, he planned a vigorous attack upon the enemy's velletts before Boulogne harbour. This was executed on the 16th of August 1801, but from a mistaken calculation of the enemy's preparations, and from the extreme difficulty of the entprise, it proved unsuccessful. He however received the thanks of the first lord of the admiralty in very warm terms: "I cannot," says lord St. Vincent, "sufficiently express my admiration of the zeal and persevering courage with which this gallant entprise was followed up, lamenting most sincerely the loss fullained in it. The manner in which the boats of the flotilla were made fast to the ground, and to each other, could not have been foreseen. The highest praise is due to your lordship, and all under your command, who were actors in this gallant attempt." The public at large, however, did not consider the matter in the same light; they beheld the loss of so many brave men with the deepest regret, and thought the persons who ordered the attack, or those who undertook it, ought to have been apprized of all circumstances before the attempt was made.

The ensuing peace restored lord Nelson to his friends on shore, and to the enjoyment of that renown which rendered all his journies of amusement to different parts of the kingdom so many triumphal progresses. On the termination of the short-lived peace, lord Nelson, more fitted for action than repose, accepted the command of the Mediterranean fleet, and in May 1803, failed for Gibraltar in his flagship the Victory. It was his particular business to watch the Toulon fleet; but he disdained a close blockade, and rather wished to give the enemy an opportunity of coming out, and trying his strength and fortune against him. This was not so successful as he anticipated, for after having been on the look-out for two years, with an inferior force they escaped him, formed a junction with the Spaniards, and ran for the West Indies, whither Nelson soon followed. The enemy's fleet consisted of eighteen sail of the line and six frigates, having 12,000 troops aboard, which Nelson did not hesitate to pursue with ten ships and three frigates. "There is just a Frenchman a-piece, he said to his captains, leaving the Spaniards to me: when I haul my colours down, I expect you will do the same, but not till then." This extraordinary chase across the Atlantic was conducted with singular order and expedition. The mere terror of Nelson's arm compelled them to fly before him; false intelligence, which he, and he alone, suscted to be false, misled them, and they feared their return to Europe, without having accomplished any other part of their purpose than that of reinforcing some of their own islands; ours were preferred from pillage, invasion, and perhaps conquest, by this pursuit, which, in all its circumstances, cannot be paralleled in naval history. Having pursued them to Europe, he delivered over his squadron to admiral Cornwallis, left them should make for Breff to liberate that fleet, and place him between two fires, and then returned to England with an intention to enjoy leisure and repose with his friends. He had scarcely been in Merton, his country seat, a month, when captain Blackwood, on his way to the admiralty with dispatches, called early in the morning. Upon seeing him, he exclaimed, "I am sure you bring me news of the Spanish fleets! I think I shall have to beat them yet." They had joined the fleet from Ferrol, and had got safe to Cadiz. "Depend upon it, Blackwood, I shall yet give M. Villeneuve a drubbing." After the captain had left him he was much agitated, but affected to be quite easy: his friends, however, perceived that he was anxious to be again in service; that his whole mind was bent upon meeting the combined fleet, which he considered as his own property, and that he would be the most miserable man living if any man but himself did the business. He again offered his services, which were readily accepted by the first lord of the admiralty, who gave him a lift of the navy, and bade him choose his own officers. He reached Portsmouth after an absence of only twenty-five days: he was hailed with joy wherever he went: numbers followed him to the shore, and many, when they saw him embark, knelt down to offer up their prayers for his success. The wind was against him, and blew strong, but such was his impatience to be at the scene of action, that he worked down channel, and after a rough passage arrived off Cadiz on his birth-day, September 29, on which day the French admiral, Villeneuve, received orders to put to sea the first opportunity. In point of preparation the two fleets were supposed to be on an equality; but in respect to force, the French were the stronger in the proportion of nearly three to two, they having 34 ships of the line of 74 guns
and upwards; and under Lord Nelson there were but 24 of the
tame rank; in frigates they out-numbered him in a simi-
lar proportion. Early in the month of October, Lord Nelson
received information which led him to imagine the enemy
would soon put to sea. He had already arranged a plan
according to which he determined to fight. He was aware
of the mischief of too many signals, and was resolved never
to distract the attention of his fleet on the day of action
by a great number of them. On the 4th of October he
assembled the admirals and captains of the fleet, and into the
hall of his ship, the Victory, and laid before them a new
and simple mode of attack. Every man comprehended his
method in a moment, and felt certain that it must succeed.
It proved irresistible.

Lord Nelson did not remain directly off Cadiz with his
fleet, or even within sight of the port. His object was to
induce the enemy to come out; with this view he stationed
his fleet in the following manner. The Euryalus frigate was
within half a mile of the mouth of the harbour to watch
the enemy's movements, and to give the earliest intelligence.
At a still greater distance he had seven or eight fails of the
tline. He himself removed off Cape St. Mary with the rest
of the fleet, and a line of frigates extended and a communi-
cation between him and the seven or eight fails off Cadiz.
The advantage of this plan was, that he could receive am-
ple supplies and reinforcement off Cape St. Mary, without
the enemy being informed of it, and thus they always re-
ained ignorant of the real force under his command: Vil-
leneuve had also been misled by an American, unintention-
ally on his part, who declared that he was sure Nelson could
not possibly be with the fleet, as he had seen him in London but
a few days before. Relying on this, and on their own superi-
ority, they put to sea on the 19th, and on the 21st Lord
Nelson intercepted them off Cape Trafalgar, about sixty
miles east of Cadiz. When his lordship found, that by his man-
œuvres, he had placed the enemy in such a situation, that
they could not avoid an engagement, he displayed
much animation, and his usual confidence of victory.

"Now," said he, "they cannot escape us; I think we
may make sure of twenty of them; I shall probably lose
a leg, but that will be purchasing a victory cheaply."
Notwithstanding this light way of speaking, Nelson never
went into battle but with a full sense of its danger, and he
seems, on all occasions of the kind, rather to have prepared
his mind for death, than to have taken any means to banish
the thought of it. On the morning of this, his last con-
test for glory and immortality, he wrote a prayer in his
journal, and solemnly bequeathed lady Hamilton as a legacy
to his king and country. He left also to the benediction
of his country his adopted daughter, defining that in fu-
ture she would use his name only. "Thine," said he, "are
the only favours I ask of my king and country at this
moment, when I am going to fight their battle." He had
put on the coat which he always wore in action, and kept
for that purpose, with a degree of veneration: it bore the
insignia of all his orders. "In honour," said he, " I
gained them, and in honour I will die with them." The
last order which his lordship gave previously to action, was
short, but comprehensive, "England expects every man
to do his duty." It was received with a shout of applause
throughout the whole fleet. "Now," said the admiral,
"I can do no more: we must trust to the great Disposer
of all events, and the justice of our cause. I thank God
for this opportunity of doing my duty." It had been re-
presented to him strongly, both by captain Blackwood,
and his own captain, Hardy, how advantageous it would be
for him to keep out of the action as long as possible, that
he contented that the Temeraire, which was then falling
abreast of the Victory, should be ordered to pass ahead,
and the Leviathan also. They could not possibly do this
if the Victory continued to carry all her sail; and yet so
far was Nelson from shortening sail, that he seemed
to take pleasure in baffling the advice to which he could not
but assent. As usual, he hoisted several flags, that they
might not be shot away. The enemy, on the other hand,
shewed no colours till late in the action, when they began to
feel the necessity of having them to strike.

Lord Nelson determined himself to fight the Santifima
Trinidad; and it is worthy of remark, that he gained
the highest honour in grappling with this ship in the action
off Cape St. Vincent. She was the largest ship in the
world, carried 136 guns, and had four decks. The Vic-
tory did not fire a single shot till she was close along-side
the Trinidad, and had already lost 50 men, in killed and
wounded. Lord Nelson ordered his ship to be lifted to his
rival, and in this labour the commander of the Trinidad
ordered his men also to assist. For four hours the con-
flict which ensued was tremendous. The Victory ran on
board the Redoubtable, which, firing her broad-sides into
the English flag-ship, instantly let down her lower deck
ports, for fear of being boarded through them. Captain
Harvey, in the Temeraire, fell on board the Redoubtable
on the other side; another ship, in like manner, was on board
the Temeraire, so that these four ships, in the heat of bat-
tle, formed as compact a tier as if they had been moored
together, their heads lying all the same way. The heu-
tenants of the Victory immediately depressed their guns,
and fired with a diminished charge, left the shot should
pass through and injure the Temeraire: and because there
was danger that the enemy's ship might take fire from the
guns of the lower-deck, whose muzzles touched her side
when they were run out, the fireman of each gun flooded
ready with a bucket of water, which, as soon as the gun
was discharged, he dafhed at the hole made in her sides by the
shot. In the prayer to which we have already alluded, and
which Nelson wrote before the action, he defines that hu-
manity, after victory, might distinguish the British fleet.
Setting an example himself, he twice gave orders to cease
firing upon the Redoubtable, supposing she had struck,
because her great guns were silent; and as she carried no flag,
there were no means of ascertaining the fact. From this
ship, whose destruction was twice delayed by his wish to
spare the vanquished, he received his death. Captain
Hardy, on perceiving frequent showers of musket-balls fired on
the Victory's quarter-deck, requested Lord Nelson to take off
the insignia by which he was exalted, as a mark, to the
sharpshooters placed in the main-round-top of the enemy's
ships. He answered, he would when he had time; but
paid no further attention to his safety. In a minute after-
wards, his secretary, Mr. Scott, who had been near him,
was killed. A musket-ball entered his head, and he fell dead
instantly. Another shot, a few minutes afterwards, struck
the epaulette on Nelson's left shoulder: he fell with his
face on the deck. "They have done for me at last,"
Hardy, he exclaimed, "my back-bone is shot through." He
did not, for the smallest portion of time, lose his pre-
fence of mind, but observed, as they were carrying him
down the ladder, that the tiller ropes, which had been
hoisted away, were not replaced, and ordered that new ones
should be fastened on immediately; and to prevent any de-
jection which the sight of their dying admiral might occasion,
it took out his handkerchief and covered his face, and the
insignia upon his coat; certain by the feat which he felt in his
back, that no human aid could benefit him.

After
After the surgeon had probed the wound, he defined him to return to afflict those to whom his services might be useful, "for," said he, "you can do nothing for me." From the severity of the pain he could not refrain from wishing to die, "yet," said he, checking himself, "one would like to live a little longer;" no doubt he heard the completion of a victory which he had seen so gloriously begun. Having been placed in a chair, he defined that captain Hardy might attend him, and during the hour that he lived he displayed all his coolness and recollection, and employed the time in dictating orders relative to the battle, in receiving reports, in enquiring what was the condition of the enemy, and what ships had struck. Upon hearing that fourteen or fifteen had certainly surrendered, "That's well," said he, "but I bargained for twenty." After a short pause, he exclaimed, "Anchor, Hardy, anchor." To this the captain replied, that he supposed admiral Collingwood would now take upon himself the command. "Not while I live," cried the dying hero, "no, do you anchor Hardy." He had foreseen the great importance of this; for, by the position in which the enemy waited for the attack, the ships of Trafalgar and St. Pedro were under their lee, and the port of Cadiz, with the exiting wind open to them, and it was on this account he had, before the action, made signal to prepare to anchor. The last ship that struck before his death was the Santissima Trinitada, of which he heard with the most lively emotions of joy. He felt himself now nearly at the last galp, and called for Hardy, and said in a low tone, "Don't throw me overboard," and defined that he might be buried at Burnham Thorpe, unless it should please the king to order otherwise. "Kiss me, Hardy," said he; "Hardy knelt and kissed his cheek, and the admiral said, "Now I am satisfied. I have done my duty. Thank God! I have done my duty." These were the last words that he uttered, and in the arms of his gallant captain he breathed his last.

The final event of this action was the capture of eighteen men-of-war, of the French commander-in-chief, and two other flag-officers, with a general. It was a blow to the maritime strength of the two powers that entirely ruined their present projects, and laffingly crippled their exertions. The maritime war might from this day be considered as at an end: the fleets of the enemy were not merely defeated: they were as good as annihilated, and with them the spirit of the French marine so completely depressed, as to forbid the hope of a revival, till a new race of men should arise, upon whom the terror of the name of Nelson would cease to operate. Well then might the death of lord Nelson be felt as something more than a public calamity: well might our countrymen, when the fatal intelligence was communicated to them, start and turn pale, as if they had heard of the loss of a dear friend; the object of their admiration and affection, of their pride and hopes, had been suddenly taken from them, and it is still [1813] in the remembrance of every one, that it seemed as if they had never, till then, known how deeply they esteemed and revered him. "It was not," says a writer already referred to, "from any selfish reflection upon our own loss that we mourned for him: the general sorrow was of a higher character. The people of England grieved that funeral ceremonies and public monuments were all which they could now bestow upon him, whom the king, the legislature, and the nation, could alike have delighted to honour; whom every tongue would have blessed; whom every village through which he should have passed, would have awakened the church bells; have given school-boys a holiday; have drawn children from their sports to gaze upon him, and old men from the chimney corner to look upon Nelson ere they died. The victory of Trafalgar was indeed celebrated with the usual forms of rejoicing, but they were without joy; for such was the glory of Nelson and of the British navy, in a great measure through his genius, that they scarcely seemed to receive any addition from this; that the most signal victory that ever was achieved upon the seas, and the destruction of so great a fleet, hardly appeared to add to our strength or security; for we felt ourselves as strong and secure while Nelson was living to watch them, as when they were destroyed."

Perhaps, in no country, have higher public honours been paid to the memory of a public benefactor than those that were enthusiastically given to lord Nelson. His body was brought home for interment: it was exhibited for several days in the proud pedestal at Greenwich; from thence it was conveyed to Westminster; and finally buried in the cathedral of St. Paul's. The funeral, made at the public expense, was the most solemn and magnificent spectacle ever beheld in this country, and was truly honourd by the presence of seven of the sons of his majesty. Honours and rewards were municipally bellowed on his relations, and an earldom was perpetuated in the family of Nelson, of which his brother was the first possessor.

Admiral Nelson died at the age of forty-seven, "yet he cannot be said to have fallen prematurely, whose work was done; nor ought he to be lamented who died fo full of honours, and at the height of human fame. The most triumphant death is that of the martyr, the most awful that of the martyred patriot; the most splendid that of the hero in the hour of victory; and, if the chariot and the horses of fire had been vouchsafed for Nelson's translation, he could fearlessly have departed in a brighter blaze of glory. He left us, not indeed his mantle of inspiration, but a name and an example which are at this hour inspiring hundreds of the youth of England—a name which is our pride, and an example which will continue to be our shield and our strength."

We cannot conclude without observing, that to the traits of character which have been already given, must be added a spirit of piety which he imbibed in his youth, and which distinguished him through the whole of his progress. It appeared in all his public dispatches, a fervent aspiration fell from his pen just as he was advancing to the final conflict: and expressions of true Christian resignation were among the last that faltered from his dying lips.

For this article, we have been, in part, indebted to the fifth number of the Quarterly Review, but principally to a very popular periodical work, entitled "The Naval Chronicle," to which his lordship communicated, under his own hand, all the particulars of the early part of his life and naval exploits, and from which, would our limits have allowed it, we could have selected a volume almost of interesting matter relating to lord Nelson.

NELSON, in Geography, a county of Kentucky, in America, containing 9287 inhabitants, of whom 1324 are slaves, its chief town is Bardstown.

NELSON's Quay, a town with a post-office in Charlestown county, South Carolina; 539 miles from Washington.

NELSON's Fort, a settlement on the W. shore of Hudson's Bay, situated at the mouth of a river of the same name; 250 miles S.E. of Churchhill fort, and 600 N.W. of Rupert's fort, in the possession of the Hudson's Bay company. N. lat. 57° 12'. W. long. 92° 42'.

NELSON's River, the N.W. branch of Hayes river, on the W. shore of Hudson's Bay, separated into two channels by Hayes island, at the mouth of which Nelson's fort is situated.

NELSONIA,
NELSONIA, in Botany, so named by Mr. Brown, in juft commemoration of the merits of the late Mr. David Nelfon, an excellent gardener and good practical botanist, who was fent out with captain Cook, in his laft voyage, and discovered many new plants, for which we have, in several places, had occasion to mention him. He afterwards accompanied captain Bligh, in the firft voyage of that able navigator, and unfortunately died in the ifland of Timor.—Brown Prod. Nov. Holl. v. 1. 480. Clafs and order, Di-andria Monogyinia. Nat. Ord. Personas, Linn. Acanthi, or Acanthacées, Jaff.

Eff. Ch. Calyx in four deep unequal segments. Corolla funnel-shaped; limb five-crefted, slightly unequal. Stamens two, shorter than the tube, without any barren filaments. Cells of the anthers equal in their infertion, divaricated. Capule femail, with an elftic point, the partitions from the centre of the valves. Seeds feparated in each cell, without any spinous pring. Brown.

A genus of herbaceous plants, with diffuse fliers, and a downy, somewhat hoary, habit. Leaves broadfided, undivided. Spikes terminal, defne, equal. Braheas broad, oppofite, fingle-flowered. Flowers small, each with a pair of filmer inner braheas. Anterior segment of the calyx emarginate, or divided half way down. Corolla either white or purple.

This genus is said to differ from Vahl's Elytraria, (with which it agrees in the want of an elftio spinous procfs under each feed,) in the want of barren flamas, as well as in the figure of its anthers, and espccially in habit. Mr. Brown, besides some hitherto non-described specifles from the East Indies, and others from the tropical regions of Africa, fufpects that Juficia bifurata, organoides, cajenfis and nummulariafla of Vahl, Enum. v. 1. 121, 122, properly belong to this genus. The two New Holland species, both tropical, are thus defined.

1. N. campfifrli.—Leaves elliptical, wooley. Braheas of the fpike acute. Anterior segment of the calyx cloven half way down; dorfl one acute, undivided. Segments of the corolla entire.—Gathered by Mr. Brown.

2. N. rotundifolia.—Leaves roundifh; fomewhat hairy when full-grown. Braheas of the fpike acute. Two broader segments of the calyx emarginate, as well as the divisions of the corolla.—Gathered by the Rt. Hon. Sir Joseph Banks, in whose herbarium only Mr. Brown has been fent.

NELUMBION, Jaff. 68. Willd. v. 2. 1258. Art. Hort. Kew. cd. 2. v. 3. 332. Curt. Mag. t. 993; see Nelumbo. See afo the article Cyamus, written by the late Rev. Mr. Wood.

NELUMBO, the name given by the natives of Ceylon, to the faced bean of India, and of Theophratus, Nymphae Nelumbo of Linnaeus. Adanlon, who firft, with unqueftionable propriety, feparated this plant from Nymphae, having no objecon to barbarous names, retained Nelumbo for a generic appellation, and he it followed by Curtier. It is not easy to fay why they preferred a very confined and local appellation, for a plant known throughout India by the name of Tamarind, by which it is dilguifhed in the Hortus Malabaricus, and celebrated in Hindu poetry and mythology. Juflies intended as an improvement the alteration into Nelumbium; fee that article. We wish to adhere, as much as poifible, to the Linnaean rejecon of barbarous generic names, and have no defire to eftablfh either Nelumbo or Tamarind, greatly preferring Cyamus; fee that article. It is much to be wished that botanifts, not totally illiterate and tafteless, would advert a little to the propriety of keep-
N E M

Ptolemy, who places it among the Vaconae between Andelan and Conmonum.

NEMARAM, in Geography, a town of Hindoostan, in Golconda; 32 miles S. of Comabate.

1 N. levigatum. The only known species. The leaves are ovate, very smooth. Capule oval, smooth. It is thought to be akin to the Lacelina myricoides. Swartz. Prod. 12; see Lacistema. The name alludes to the fitation and infection of the seeds.

NEMAUSUS, in Ancient Geography, the name of one of the richest towns of Galva Narbonence, which was the capital of the Arescanet. In the Notitia Imperii it is called "Prefectus thefaurum in Nemenia." See Nisies.

NEMBO, in Geography, a town of Italy, in the department of the Serino; four miles N. E. of Bergamo.

NEMS, a town of the duchy of Holstein; six miles N. of Sweberg.

NEMEA, in Ancient Geography, a town of the Argolid, situated at the foot of mount Apesos, upon which it is said that Perseus was the first who offered sacrifice to Jupiter Apacontius. In this town was a very beautiful temple of the Nemaiian Jupiter, surrounded with a grove of cypresses. The chief priest of the temple was named by the Argives. They also, as some have said, instituted in this place the Nemean games (see Nemea), in which the prize of the cause was referred for by persons completely armed. Here was shown the town of Otholstes, encompassed by a wall, within the compass of which they had four altars. It is also said that at a small distance from this place was the sepulchre of Lycurgus, king of Thrace, and particularly of Nemea—Alfo, a river of the Peloponneseus, which, according to Strabo, separated the kingdom of Sicyn from the territory of Corinth—Alfo, a country of the Peloponneseus, in the Eide.

NEMEN, in Geography, a town of Hindoostan, in Travancore; 15 miles N. W. of Travancore.

NEMERSDORFF, a town of Germany, in the principality of Calmbach; six miles N. E. of Bayreuth.

NEMESAI, in Ancient Geography, a country of the Peloponneseus, in which Hercules is said to have killed the lion.

NEMESAI, in Antiquity, a religion solemity in memory of deceased persons, so called from the goddess Nemesis, who was thought to defend the relics and memories of the dead from injuries.

NEMEIANUS, M. Aurelius Olympius, in Biography, a Latin poet, was a native of Carthage, and flourished under the emperors Carus, Carinus, and Numerianus. The last of these princes had a particular esteem for him. Under this prince he rose to high favour and fortune, and probably interested himself in behalf of his contemporary poet Calpurnius, who was reduced to indigence. Nemeianus was author of three poems, of which only the one entitled "Cynegeticon" has come down to modern times, and that in a very imperfect state. It was discovered by Sannazarius of Tours, and published by Paulo Manuzio at Venice in 1538. It has also been published in the "Poetae rei Veneticae," by Barthlet in 1613, and at Leyden in 1653, with notes. The "Cynegeticon" appears to have been well known in the dark ages; it was to highly esteemed in the eight century, that it was read among the classics in the public schools, in the time of Charlemagne. It cannot rank high as a poetical composition, but is said to deserve praise for its polished and elegance. The "Cynegeticon" is usually printed with that of Gratius Fahatus, and four "Eclogues" ascribed to him, with those of Calpurnius. Another poet of the same name and age, but of very inferior merit, wrote a work entitled "Icetica," of which some fragments have been published in the "Poetae Lat. Minor." Moretti.

NEMESIS, in Mythology, one of the infernal deities, represented by the ancients as watching for the punishment of the guilty, not only in this world, but also in the other, where the chastises them with the utmost rigour. For this reason she was exhibited with wings, sometimes too with a helm and a wheel, to signify that the pursuer of the guilty both by fire and land. As she was the daughter of Justice, she was, as Ammanus Marcellinus describes her office, appointed to revenge impiety, and at the same time to recompense virtuous actions. Several among the ancients, and some moderns, suppose Nemesis to be the same with Leda, the mother of Castor and Pollux, who obtained that name after her death, but the universal opinion is, that Nemesis herself was the mother of those two heroes, whom Jupiter, and that Leda was only their nurse. Nemesis was worshipped in several places, as well in Greece as in Italy, even in the Capitol itself; and it has been said that she had a temple at Rome; but her worship was at no place more pompous than at Rhamnus, a town of Attica, where she had a statue ten cubits high of a single stone, and so exquisitely beautiful that it was not inferior to the finest works of Phidias. Anciently the statues of Nemesis were without wings, as we learn from Paufanias, and the inhabitants of Smyrna were the first who gave her any. Paufanias speaks of "Nemeis" in the plural number. The Romans, before they fat down for war, offered a sacrifice to Nemesis, probably taking that goddes for Fortune, who ought to accompany and favour warriors.

NEMESIUM, in Ancient Geography, a town of Marma-rica, placed by Ptolemy between Aziaca and Tifarchi.

NEMESUS, in Biography, an eminent ancient Christian philosopher, supposed to have been bishop of Emaia in Phoe- nicia, and to have flourished towards the close of the fourth century. He was author of a treatise "On the Nature of Man," which has been ascribed, but erroneously, to St. Gre- gory Nyssus. It refutes the tenets of the Manicheans, Eunomians, and Apollinarists, and defends that of Origen concerning the pre-existence of souls. The opinions of the Greek philosophers on the subject of which he treats, he relates with great perspicuity of thought and correctness of language; but it is said to be chiefly curious, as it discovers a degree of acquaintance with physiology, not at all to be paralleled in any other writers of so early a date. The first Latin version of it was published at Lyons in 1583; it was afterwards published in Greek and Latin, at Antwerp. It is inserted in the second volume of the Ave. Bibl. Patr. The best edition is that of Oxford in 1671, in Greek and Latin, with notes, and a learned preface. Moreri. Enfield's Hist. Phil.

NEMESKO, in Geography, a town of Hungary; six miles W. of Ziget.

NEMESTRINUS, in Mythology, an ancient divinity who presided over forests, called "Nemora." He was probably the sovereign of the Dryads, Hamadryads, Fauns, Satyrs, and other gods, inhabitants of the woods.
NEMET, in Geography, a town of Transylvania, on the river Maros; 12 miles W.N.W. of Hunyad.

NEMETES, in Ancient Geography, a people of Germany, who named their capital Nemanus. In the time of Caesar, they occupied both sides of the Rhine. They were established along the Rhine, between the Vangiones to the north, and the Triboci to the south.

NEMETH-UYAR, or GLESSINGEN, in Geography, a town of Hungary, on the borders of Stiria; it is a populous walled town, having a castle seated on a high rock, detached from all the other mountains. It is delightfully situated among woods, corn-fields, and rising grounds, which are covered with vines; 45 miles S.W. of Raab.

NEMETOBIRIGA, in Ancient Geography, a town of Spain, in the Tarragonens, belonging to the Callaci, at some distance N. of the Aqve Flavize, on the route from Brera to Alturica.

NEMETZ, in Geography, a town of Hungary; 14 miles from Calichau.

NEMI, a town of Campagna di Roma; two miles S. of Albano.

NEMIA, in Botany, Berg. Cap. 160; see MANUELA. The name seems to be derived from NEME, to divide, alluding to the difference between the two uppermost of which are roundish, the two lowermost oblong.

NEMINE CONTRADICENTE, i.e. non contradicting it; a term chiefly used in parliament, or any public assembly, when any matter is carried with the consent of all the members.

NEMINPILLY, in Geography, a town of Hindoostan, in Mysore; 16 miles N.N.E. of Pungaroore.

NEMIR, a town of Persia, in Khorasan; 15 miles N. of Terhiz.

NEMLI, a town of Hindoostan, in Viliapour; 20 miles E. of Anamagur.

NEMOROW, a town of Mecklenburg; 60 miles S.W. of Stargard.

NEMOSSUS, in Ancient Geography, an ancient town of the Gauls, and capital of the Arverni. Strabo.

NEMOURS, MARY DE LONGUEVILLE, Duchess of, in Biography, was daughter of the duke de Longueville, and born in the year 1625. She was married to the duke de Nemours; and wrote "Memoirs of the Court of France during the Minority of Lewis XIV." which are composed with spirit, and with the fidelity of an historian who had an opportunity of becoming well acquainted with the facts recorded. They are commonly united with those of Joly, but have been printed separately. The duchess died at the age of 83, in the year 1707.

NEMOURS, in Geography, a town of France, in the department of the Seine and Marne, and chief place of a canton, in the district of Fontainebleau. The place contains 3766, and the canton 6475 inhabitants, on a territory of 260 kilometers, in 16 communes. N. lat. 48° 16'. E. long. 2° 47'.

NEMOURS, a town of Anatolic Turkey, in Nato'a, near the sea; 20 miles S. of Adramyti.

NEMTCHITZ, a town of Moravia, in the circle of Olmuz; 12 miles S. of Olmuz.

NEMTSCHITZ, or NEMEZIC, a town of Moravia, in the circle of Brunn; 15 miles from Brunn.

NEMUS, in Ancient Geography, a small town of Latium, E. of Aricia; which owed its commencement to a temple erected in honour of Diana Turane, by an inhabitant of Aricia. The Romans paid great respect to this divinity.

NEN, a town of Hindoostan, in Lahore; 74 miles E.S.E. of Bullaulpour.—Also, a river in the E. riding of the county of York, in Upper Canada, which rises several miles beyond York, and discharges itself into Lake Ontario; it abounds with fish.

nenag, a poet-town of the county of Tipperary, Ireland, is a large, regular, well-built town, situate upon a river which empties itself into lough Deircgerg. There is a handsome old castle, formerly of great strength, called Nenagh Round, and it was the seat of some monastic establishments. It is the chief town of the barony of Upper Ormond, and a military station; and is 75 miles S.W. by W. from Dublin.

NENEEVA, one of the Friendly islands, which is small and low; 20 miles N.E. of Annamooka.

NENESS, a cape on the S.E. coast of Shetland. N. lat. 59° 58'. W. long. 1° 20'.

NENGENGODD, a town of Hindooftan, in Myfore; 20 miles S.S.W. of Seringapatam.

Nenia, or Nenia, in the Ancient Poerty, a kind of funeral song, sung to the music of flutes, at the obsequies of the dead.

The word comes from the Greek ηνη, on which Scaliger observes, that it should be written in Latin Nenia, not Nenia.

Authors represent them as bad compositions, sung by hired women-mourners, called proseia. The first rite of these nenia is ascribed to the Sylurgians.

Guicciardi notes, that nenia was anciently the name of a song, sung by nuns, to lull children asleep; and conjectures it to come from the Hebrew לינא, nina, child.

In the heathen antiquity, the goddeus of tears and funerals was called Nenia, whom some supplement have given that name to the funeral song; and others to have taken her name from it. Some will have the one, and some the other, formed by onomatopoeia, from the sound or voice of those that weep.

NENNE, in Geography, a town of Persia, in the province of Irak; 50 miles N.N.E. of Nehavend.

NENNIUS, in Biography, an ancient British historian, abbot of Bangor, is generally said to have flourished about the year 620, and to have taken refuge at Chester, at the time of the massacre of the monks at that monastery. This, however, has been controverted, and bishop Nicholl says, that from his own book he appears to have written in the ninth century. He was author of several works, but the only one remaining is his "Historia Britonum," or "Eulogium Britannicum," which has been printed in Galle's Hist. Brit. Scru. Oxon. 1691. Great part of this work is suppos'd to have been compiled, or perhaps transcribed, from the history of one Elburus or Elvedogus.

NENORTOLIK, in Geography, an island on the S.W. coast of Greenland. N. lat. 59° 54'. W. long. 45'.

NENSLINGEN, a town of Germany, in the principality of Anspach, 20 miles N.E. of Anspach.

NENUFAR, a river of Natalia, which runs into the sea of Mariana; six miles E. of Mikalidi.

NENUPHAR, the ancient writers on the materia medica have all mentioned a peculiar species of this plant, under the name of nenuphar indicum. The roots of this they called fel, and Avicenna says, that they have the same virtues with the mandrake.

NENUPHAR, in Botany, is also a name used by some authors for the water-lily.

NENUPHARIN, a name given by the adepts to a kind of imaginary spirits which they suppos'd to inhabit the air, and to direct and govern many things on earth.

NEOCASAREA, in Ancient Geography, a town of Pontus,
Pontus, upon the Lyctus, N. of Comana, called by different authors Hadrianopolis. Ptolemy places it in the interior of the country between Abilata and Sarauriana.—Alfo, a town of Bithynia.—Alfo, a town of Syria.—Alfo, a town of Asia, upon the banks of the Euphrates.—Alfo, a town of Mauritania.

NEOCÆAREANS, in Ecclesiastical History, Christians of Neocaerae, in Capadocia, who were the disciples of Theodore, afterwards named Gregory, and called by Jerom a man of apostolical signs and wonders. These Christians were very troublesome to Bají, bishop of Caæarea, for in divers of his letters, he complains of them that they were all Sahellians, and he laments the strange avenion they had for him. They formed a small church in NEocaeraæ, as early as the year 230, to which Gregory made many additions about that period. His church continued steadfast in the faith after his death, which happened either in the year 265 or 270. Near the end of the fourth century, the Neocaeraeans were all Christians, having been favoured until that time with patiors, who were men of true worth. These people retained for a long while remarkable impressions of religion; and they had an affection for the primitive simplicity, almost singular at that time, when innovations came apace into the church. They seemed by no means to approve of the common zeal for the monastic life, of which Bají complained. Lardner's Works, vol. iii.

NECASTRO, in Geography, a town of European Turkey, in the Morea, at the mouth of a river which runs into the Mediterranean; 32 miles N. of Navarín.—Alfo, a town in Romania, strongly Garrisoned, whither Christian prisoners of consequence are sent; 12 miles N. of Constan- tinople.

NECORI, Nescori, among the Ancients, perfons whose business was to take care of temples, and other consecrated places. Theodoret (i. iii. c. 16.) mentions two other functions of the Neocori; these are, to stand at the gates of the temples, in order to sprinkle holy water for the purification of those who were entering into them; the other to throw some of the same water upon the meat served up at the emperor's table. They were otherwise called æidiu.

NEENIA, Neenia, in Antiquity, a festival celebrated in honour of Bacchus, when the new wine was first tasted.

NEETHO, in Ancient Geography, a small town of Italy, in Bruttium, towards the E., upon the Neetus, at a little distance N. of Croton.

NEOLA, in Geography, a country of Africa, N. of the Gambia, and W. of Dentilla. N. lat. 13° 30'. W. long. 11° 40'.

NEOLA, Nela, a river of Africa, which runs into the Gambia, N. lat. 13° 40'. W. long. 12° 25'.

NEOMAGUS, Novimagus, or Noviomagus, in Ancient Geography, a town of the Regni, in the Isle of Albion, according to Ptolemy. The Itinerary of Antoninus places it between Londinium (London) and Vagnicanius (Northfleet). The situation of this Italion is very uncertain; but Camden, Gale, and Horley, have agreed in placing it at Woodcote, near Crostden. Mr. Baxter, however, and some other antiquaries, contend for Ravenburn in Kent.

NEOMAGUS, or Noviomagus Batavorum, a town of Germany Secunda, at the extremity of Gaul. The Peutingerian table places it on the Rhine, between Castra Herculis and Arenatio.

NEOMENIA, Nomenia, in Antiquity. See Numenienia.

NEOMENIA, in Chronology, &c. A term used for the new mons. Some say, the Jews reckoned two kinds of neomenia, or new moons; the first on the day of her conjunction with the sun; the second on that of her apparition or phæn; and add, that they celebrated two festivals, on account of the uncertainty which of these days it should be held on.

F. Hardouin, on the contrary, maintains, they had no other neomenia but that of the moon's conjunction with the sun; which it was easy to ascertain by astronomical calculations; whereas the other was liable to mistakes; the moon sometimes not shewing herself till four or five days after conjunction.

NEOMINAS, in Geography, a large river on the coast of Peru, discharging itself into the Pacific ocean by two mouths: 12 or 14 leagues N.W. of Bonaventura river. N. lat. 4° 30'.

NEON, in Ancient Geography, a town of Greece, in the Phocide, placed on the ridge of Parminus, called Tithorea. At first a mere fort, it was a considerable town in the time of Platachus.

NEONE, in Geography, a town of European Turkey, in Theffaly: 20 miles W. of Zetton.

NEONTICHOS, in Ancient Geography, a town of the Etolie, placed by Strabo at 20 stadia from Larissa, but Herodotus places it at the distance of 30 stadia E. of that town, near the plain of Hermus. The appellation denotes a new-walled town.—Alfo, a town of Greece, in the Phocide. —Pauanias.—Alfo, a town of Thrace, on the Propontis.—Alfo, a town of Afia Minor, in Caria, between Ortolia and Bargafa. Ptolemy.

NEOPATRA, in Geography, a town of European Turkey, in Theffaly: 20 miles W. of Zetton.

NEOPYTHES, Noeopthi, in the Primitive Church, were new Christians; or the Heathens newly converted to the faith.

The word signifies a new plant: being formed of the Greek νέος; new; and φυτη, I produce; q. d. newly-born; baptism, whereby they commenced Neopythes, being a kind of new birth.

The fathers never discovered the mysteries of their religion to the Neopythes.

The term Neopythe is still applied to the converts which the missionaries frequently make among the infidels. The Japenese Neopythes, in the latter end of the sixteenth and beginning of the seventeenth century, are said to have been prodigious of courage and faith, equal to any known in the primitive church. See Catechumen.

Neopythes has formerly likewise been used to denote new prices, or those first admitted into orders; and sometimes, the novices in monasteries.

NEOPESCO Creek, in Geography, a river of America, in Virginia, which runs into the Potomack, N. lat. 38° 40'. W. long. 77° 10'.

NEOPTOLEMIA. Noeoptolemus, in Antiquity, a festival celebrated by the Delphians with much pomp and splendidness, in memory of Neoptolemus, the son of Achilles, who was slain in an attempt to sack Apollo's temple, which he undertook in revenge of his father's death, to which that god was afofactory.

NEOTS. St., in Geography, a parish in the hundred of Well, and county of Cornwall, England, is situated four miles from Liskeard, and 226 west from London. Its name was derived from Neotus (brother to king Alfred), who obtained the appellation of saint, and was buried in this church; a monastery was founded in honour of him, and subsidized till after the conquest, when, being dispossessed of its lands, it fell to decay, and only its name has defended it to the present age. All remains of the ancient church have likewise been long since destroyed: the present parish church, which consists of a nave and two aisles, with a tower at the
the well end, is apparently not older than the reign of
Henry VI.: the windows, seventeen in number, contain
representations, in painted glafs, of scripture history, and of
the events recorded in the legends of St. Neot and other
faints; but most of the windows are much damaged, and
the broken panes repaired with plain glafs, so that in some
influences the design can hardly be traced. The popula-
tion of this parish, according to the return in the year 1811,
was 1,041 persons, inhabiting 179 houses. Some Account
of the Church and Windows of St. Neots Cornwall, by
the Rev. Mr. Foster. Beauties of England and Wales,
vol. ii. Cornwall. The Life of St. Neot, the oldest of all
the Brothers to King Alfred, by the Rev. J. Whitaker, 8vo.
1829.

Neots, St., a considerable market-town in the hundred
of Tofedland, and county of Huntingdon, England, is plea-
santly feated on the north bank of the river Ouse. It
was anciently called “Enolsebury,” and had a palace, belonging
to earl Elfred, which was subsequently converted into a
monastery, in honour of St. Neot, whose relics are tradi-
tionally laid to have been removed hither from St. Neots in
Cornwall. The monks of this monastery were differed by the
Danes; but being restored again by earl Eofric, it con-
tinued a priory subordinate to Ely till after the conquest,
when the religious were expelled a second time by Gilbert
de Clare. Lady Roifia, wife to Richard, the earl’s son,
replenished it, however, about the year 1115, and granted
it, along with the manor, to the abbey of Beo, in Nor-
mandy. On the dilution of alien priories, this house
became a “prioratus indigena,” and remained so down to
the time of Henry VIII., when its revenues were ema-
culated at 256l. 13s. 4d. The ruins of this edifice, now remaining,
are very inconsiderable. St. Neots confits of a large mar-
tet-place, and several respectable streets intersecting each
other. The church is a very beautiful building in the pointed
style of Henry VIIth’s reign. At the well end rises an ele-
gant tower, 150 feet high. The windows are large, and bear
the remains of paintings on the glafs. In a chapel, called
Jcfsus chapel, lately laid open to the church, there was for-
merly a monument, supposed to have once contained the
relics of St. Neot, and removed hither from the priory.
This town contains, according to the population returns of
1811, 410 houses, and 1988 inhabitants. The market day
is Thursday.

On the opposite side of the river, and connected with the
town by a large handsome stone-bridge, is the village of
Eyelebury, which was the scene of an action between the
royalists, under lord Holland, and the parlementary forces,
in 1648. The church here has a separate tower on its south-
call side; and in the north wall of the chancel is a
stone coffin, in which Saar de Quincey is said to have been
buried. The parish-register records a curious licence to
eat fish on days not permitted by the statute. Beauties of

NEOTTIA, in Botany, a name which properly belongs
to the Ophrys Nidus avis of Linnæus, or Bird’s-nest Ophrys,
and which originated with Dodonæus, signifying a
bird’s nest. Linnæus retained this plant, along with the
Corallorrhiza, as a genus, in Aed. Upsal. ann. 1745, 32,
under the name in quellen; but that genus was afterwards
fung in Ophrys. Haller restored it under another appella-
tion, which is now established: see Epipactis. Neottia
therefore being unoccupied, was chosen by Jacquin and
Swartz, for the very distinct genus of which we are here to
speak; some of whose species had been previously referred
Aed. Holm. 1800. p. 224. t. 3. f. 1. Tracts on Botany,
151. t. 4. f. 1. Schrad. Neues Journ. v. i. 49. t. 1. f. 1.
Orchid. 5.

Gen. Ch. reformed. Cal. Perianth of three oblong
acute leaves, cohering below, spreading at the point; the
two lateral ones elongated at the base, in front, often con-
tected, running down, at the bottom of the lip, on each
side, in the form of a spur. Cor. Petals two, cohering
lengthwise with the upper leaf of the calyx. Nectary a lip
proceeding from the lower part of the style, tapering at the
base, swelling upwards, embraced by the lateral leaves of
the calyx; its margin bearded, rather dilated and spread-
ing. Stam. Anther parallel to the style and attached to its
back, erect, pointed, of two cells; masses of pollen linear,
powdery, granulated, half enclosed in two longitudinal fur-
rrows of the style, opposite to the cells of the anther.

Pet. Germen inferior, oblong, triangular; fylae erect, cylin-
drical, with a membranous point; stigma in front, near the
oblique summit of the fylae, convex. Peri. Capsule ob-
long, of one cell, opening between the angles. Seeds
numerous, minute, tuncate.

Eff. Ch. Calyx-leaves cohering, the two lowermost elon-
gated at the base, embracing the neckty. Corolla ringlet;
lip without a spur, bearded; petals cohering with the upper
calyx-leaf. Anther parallel to the fylae, inserted at the
back.

(Helleborus folis liliceas, radice alpinod, major; Plum.
1c. 184. t. 190. f. A.)—Lip lanceolate, pointed, undivided.
Bractae longer than the flowers. Stalk with numerous
feathery scales. Leaves elliptico-oblong, glaucous, undu-
lated, somewhat crisped.—Native of the West Indies. It
flowered for the first time in this country, at Mongewell, in
the Iove of the late Hon. Mrs. Barrington, who received
the plant from Jamaica, about the year 1793. Mr. Andrews’s
plant is certainly the same as that of Jacquin, though his
plate is, as Willdenow remarks, badly drawn and coloured.
Mr. Edwards’s in the Bot. Mag. is excellent. This is a
very handsome species, distinguished by the large spike
of numerous crimson flowers, each of which is subtended by
a very long concave bractea, of the same hue. The numerous
leafy scales on the flanks, which is 12 or 18 inches high, are
pale or reddish. Each flower, with its germen, is about an
inch and half. Root a clutber of oblong, cylindrical, blunt
knobs.

Swartz. Ind. Occ. 1409. (N. miner; Jacq. 1c. Rar.
Satyrium elatum; Swartz. Prod. 119. Helleboris folis
liliceas, radice alpinod, major; Plum. t. 184. t. 190.)
—Lip obovate, ciliata, fimbriata, of two cells. Stalk
long. Spike downy. Bractes shorter than the flowers. Leaves
elliptico-oblong, at the margin. Native of the West Indies.
It flowered in the Iove at Chelsea garden, under the care of
Mr. Fairbairn, in 1791. The leaves are all radical, nu-
merous, dark-green, even, not crisped, at the edges. Stalk
two feet high, with a few lanceolate scales, cylindrical,
downy, as well as the spike. Flowers numerous, small and
inconspicuous, drooping, turned to one side and rather spi-
 rally diposed. Corolla white, or bluish-coloured. Lip
broad and oblong, usuallv with a flight notch. Germen
downy.

Mag. t. 842.—Lip interfoliarily heart-shaped, concave, point.
Clutber downy, of few flowers. Bractes the length of the
partial flanks. Leaves elliptico-oblong, cinymat, recurved.—Na-
tive
It flowered in Mr. Woodford's flowes, in January 1805. In the flowers being racemose, not spikelike, to distinguish this from most of the genus; their colour is a mixture of green and white, and they are much more expanded, with broader petals and lip, than those of the last. Their figure is indeed so unlike all the species we have seen, as to excite suspicion of the genus, but we have never examined them alive.

4. N. lanceolata. Purple Lanceolate Neottia Willd. n. 3. (Lindomorum lanceolatum; Aubl. Guian. v. 2, 821. Helleborine purpurea, asphodel radiis; Plum. Ic. 179. t. 181. f. 2.)—Lip ovate, entire. Stem leafy at the base. Bracteas shorter than the flowers. Leaves elliptic-lanceolate, obtuse, erect.—Native of Guiana and the West Indies. Known only by Plumbier's figure. The flowers are about the size of the first species.

5. N. aureostrata. Orange-lanceolate Neottia. Willd. n. 4. (Epipactis floribus uno veris diploptosis, volgo Nalii; Feuillée Peruv. v. 2. 726. t. 17.)—Lip oblong, bluntish, crenate, reflexed. Spike turned one way. Bracteas about as long as the flowers. Leaves radical, linear.—Native of dry barren and mountainous places in Chili. Feuillée says the natives use this plant in retentions of urine, and gravely diffuso, which has been infused for a night. He speaks of the cylindrical knobs of the root as watery, with a sweetish and pungent flavour. The stalk is about 18 inches high, clothed with flowering stalks. Leaves few, linear, nearly upright, about five inches long, and half an inch wide. Flowers white, in a dense spike, all turned to one side, but apparently not in a spiral order.

6. N. quadridentata. Four-toothed Neottia. Willd. n. 5. (Ophrys peruviana; Aubl. Guian. v. 2. 816. Helleborine spiralis, flore albo; Plum. Ic. 178. t. 183. f. 1.)—Lip rounded, four-toothed. Spike spiral. Flowers turned one way, about equal to the bracteas. Stem leafy at the base. Leaves elliptic-oblong, obtuse, wavy.—Native of Guiana and the West Indies. Known only by Plumbier's figure. Willdenow has very properly distinguished this species from the last, with which Aoublet confounded it. The flowers appear to be about a foot long. Lip with four or five teeth. Bracteas enlarged after flowering.

7. N. fyrifera. Spiral Sweet Neottia, or Ladies' Traces. Willd. n. 6. Dr. Swartz. Ind. Occ. 1408. (Ophryis spiralis; Linn. Sp. Pl. 1340. Sm. Fl. Brit. 1854. Engl. Bot. 1855. Curt. Lond. f. 255 l. 557. Fl. Dict. 1857. Triorchis; Ger. em. 218.)—Lip ovate, obtuse, crenate. Spike lateral. Spike spiral, downy. Flowers turned one way. Leaves ovate, spreading, with broad footstalks.—Native of grassy open pastures, in various parts of Europe, flowering in August and September. Dr. Swartz gives its character in his West Indian Floria, but does not speak of this species as found in that part of the world. The flowers have a thick, almost ovate, downy. Stem spiral, about six inches high, bearing a few feathery scales. Leaves several, radical, lateral, about an inch long, ovate, spreading in a flary form, glaucous, ribbed. Spike two or three inches long, slender, downy, spiral, the flowers turned one way, small, highly fragrant. Calyx, as well as the corolla, white. Lip with a green rib; its margin more or less crenate or crisped. The bracteas are ovate, concave, taper-pointed, imbricated like a braid, whence the old name of Ladies' Traces. The variety 2 of Willdenow may belong to this species, but his figure and the writer in this instance differ in the length, and the writer in this instance differ in the fewness of the flowers.

8. N. azytnis. Summer Neottia. (N. spiralis γ and δ; Willd. n. 6. (Ophryis azythina; Juff. M.S. Michaux. Bozreal-Amer. v. 2. 157. Poir. in Lamarck Dict. v. 4. 557. O. spiralis γ; Linn. Sp. Pl. 1340. Orchis spiralis alba, odorata, longo angulotque folio; Vaill. Paris 147. Orchid. album palustris spiralis album odoratum; Mich. Gen. 30. t. 26. Epipactis n. 1294; Hall Hift. v. 2. 152. t. 38. ed. 2. t. 41.)—Lip obvolute, crenate. Spike central, leafy at the base. Spike spiral, slightly downy. Flowers turned one way. Leaves linear-lanceolate, erect.—In the moist pastures of France, Italy, and Switzerland, flowering in August, earlier than the last, from which it evidently differs in having the spike, or rather stem, from the centre of the leafless leaves, which are nearly upright, linear-lanceolate, full, thrice the leaf of the flower, and much narrower. The flowers too are rather larger; the spike less downy; the stem usually near a foot high. We never met with this plant in England, but we have it from near Paris; as well as from Switzerland, marked Haller's n. 1294, whose figure indeed accord with r, and not with the real spiralis. It seems to have confounded them, nor is it clear that it ever found the true spiralis in Switzerland. His citation of Micheli in his Nomenclator, p. 117, refers to the name of one, and the plate of the other. Gnaphalin's plate, Fl. Sib. t. 3. f. 1, seems taken from rather a large specimen of the spiralis.

9. N. flexuosa. Bending Indian Neottia. —Lip ovate, wavy, crenate. Spike central, wavy, leafy at the base. Spike spirally spiral, downy. Leaves oblong, spreading.—Gathered by Dr. F. Buchanan, May 19th, 1802, in wetty places, at Suembi in Upper Nepal. The roots of this plant are thicker than in the last-described; the flowers are more numerous, directed every way, in consequence of the remarkably spiral spike, which makes four or five turns between its base and summit. Their colour is whitish.

10. N. parviflora. Small-flowered Neottia. —Lip ovate, wavy, crenate. Spike central, leafy at the base. Spike spirally spiral, downy. Flowers turned one way. Leaves oblong, spreading.—Gathered by Dr. Buchanan, July 23rd, 1802, at Suembi in Upper Nepal. The flowers are more downy, feebly half so large, as numerous, but directed every way, in consequence of the remarkably spiral spike, which makes four or five turns between its base and summit. Their colour is whitish.
LEAVES

11. **fpan**. Drooping Neottia. Swartz. Orchid. n. 5. Willd. n. 8. (Ophrya fresnians; Linn. Sp. Pl. 1340. Michaux Boreal-Amur. v. 1. 125.)—Lip oblong, acute, undivided. Spike downy. Flowers turned every way, deflexed. Leaves radical, linear-oblong, bluntnish.—Native of various parts of North America, from Hudson's bay to Carolina. Michaux. Root of numerous, thick, cylindrical knobs. Leaves radical, linear, long. Stalk twelve or eighteen inches high, erect, smooth, with several long tubular sheaths. Spike two or three inches long, downy, of numerous, crowded, whitish, drooping flowers, above twice the size of **N. spiralis**, all turned to one side when they first expand, though their common flalk is then very much twisted. It appears, by our dried specimens, that the part in question from becomes less spiral, and that in confederation the flowers soon point every way.

13. **N. anellata**. Clefe-spurred Neottia. Swartz. Ind. Occ. 1409. Willd. n. 9. (Satyrium anellatum; Swartz. Prod. 115.)—Lip deflexed, two-lobed; its base, decurrent along the germin. Spike lax. Leaves radical, obovate, with very long footstalks.—Native of shady woods in the interior parts of Jamaica and Hifpaniola, flowering in May. Root of numerous, oblong, downy knobs. Leaves several, radical, elliptic-oblong, pointed, four or five inches in length, reticulated with veins, smooth; their footstalks red, channelled, half a foot long, or more, sheathing at the base. Stalk two or three feet high, downy, reddish, with remote, thin, coloured sheaths. Spike fix or eight inches long. Flowers rather flatter, almost erect, greenish white. Bractea linear-lanceolate, the length of the germin. Lip elongated at the base into an oblique spur, half the length of the germin, to which it is attached, and accompanied by a similar elongation of the two lateral leaves of the calyx; its fore-part rounded, deflexed, two-lobed, whitish.

15. **N. orchidoides**. Frosted-flowered Neottia. Swartz. Ind. Occ. 1411. Willd. n. 10. Curt. Mag. t. 1265.—Lip lancolate, pointed, undivided; its base, with the calyx, forming a pouch. Spike downy. Leaves radical, ovato-lancolate.—Gathered by Dr. Swartz, in very dry gravelly fields in Jamaica. It flowered in Mr. Woodford's stove at Rickmanworth, in May 1807. The colour and size of the flowers most resemble the first species, **N. spectabilis**, but the calyx, germin, and flalks are, as it were, frosted, with pellucid white dots, and are besides downy. The leaves are all radical, ovate or elliptical, tapering at both ends, widely spreading, or recurved, with numerous ribs. Stalk a foot or more in height, downy, and purplish near the flowers.

16. **N. refusa**. Creeping Neottia. Swartz. Orchid. n. 8. Willd. n. 11. (Satyrium refusum; Linn. Sp. Pl. 1338. Sm. Fl. Brit. 935. Engl. Bot. t. 209. Jacq. Alphr. t. 309. Palmu Chirlit, radice repente; Ger. em. 227.)—Lip inflated, with a lancolate, entire, deflexed point. Calyx-leaves lanceolate. Spikes downy, spiral. Leaves ovate, flaked, reticulated. Root creeping, with downy fibres.—Native of Alpine for woods, in Sweden, Siberia, Germany, Switzerland, and Scotland, flowering in July. The branched, downy, somewhat flabby roots creep among wet spots and decayed leaves, throwing out long horizontal shoots, leafy at the end, and at length taking root there. Leaves several, in tufts, obovate, full an inch long, smooth, marbled with many ribs and reticulated veins, and often chequered with dark brown, as in Mentzel. Pugl. t. 3. f. 45. 5. Footstalks as long as the leaves, broad and sheathing. Stalk terminal, from the centre of the leaves, near a span high, round, bearing a few sheaths. Spike two or three inches long, downy, spiral, the flowers following its direction, and rather drooping. Bracteas lanceolate, pointed, longer than the germin. Flowers flesh-coloured, fragrant, as is the whole plant in some degree, long after it has been dried. Lip inflated and almost globular underneath, terminating in a little reddish deflexed point.

17. **N. pubescens**. Downy American Neottia. Willd. n. 12. (Satyrium repens; Michaux Boreal-Amur. v. 2. 157.)—Lip inflated, with a pointed, deflexed point. Calyx-leaves ovate. Spike downy. Flowers spreading every way. Leaves ovate, flaked, reticulated. Root creeping, with downy fibres.—Native of North America, from Canada to Florida. We have it from Pennsylvania, but what Mr. Menzies found in Nova Scotia seems rather the chequerered variety of **N. refusa**, figured in Mentzelius, and in Morison, fed. 12. t. 11. f. 10. The plant of Willdenow and Michaux is taller, with a straight, not spiral, spike, the numerous flowers rather smaller, pointing every way, and erect, neither turned to one side, nor all drooping. The calyx-leaves are very broad, ovate, or almost orbicular. The point of the inflated lip seems very small.

18. **N. calcarata**. Spurred Neottia. Swartz. Ind. Occ. 1413. Willd. n. 13.—Lip lancolate, pointed; decurrent, with the calyx, at the base, forming an oval-shaped, curved spur. Spike of few flowers. Leaves elliptical, much shorter than their footstalks.—Native of shady woods on the mountains of Hifpaniola. Root of downy, thick, clustered fibres. Leaves radical, elliptical, ribbed, smooth, three or four inches long. Footstalks much longer than he leaves, erect, sheathing at the base. Stalk twelve or eighteen inches high, erect, round, smooth, pale red, bearing several taper-pointed sheaths. Spike upright, of a few, large, green, rather distant flowers. Upper leaf of the calyx erect; conical, keeled, pointed, forming, together with the petals, which are both half as long, and partly included within it, a hood or upper lip. The two lateral leaves of the calyx are very much elongated at the base, forming, together with the base of the lip, a long incurved spur, resembling the real spur of an Orchis, but very different in nature. The lip itself is lancolate, taper-pointed, undivided. German smooth.

19. **N. polyphylla**. Branched Red Neottia. Swartz. Ind. Occ. 1415. Willd. n. 14. (Serapis polyphylla; Swartz. Prod. 110.)—Lip ovate, recurved. Chilfer compound, terminal. Stem subdivided, jointed.—Native of woods on the high mountains of Clarendon in Jamaica, in a marly barren soil. Root of long, thin kish, whorled, brown fibres. Stem two or three feet long; round and somewhat branched in the lower part; the branches angular, jointed, as thick as a wheaten straw, flattened, rather stiff, leafy. Leaves alternate, folded and sheathing at the base, obovate, pointed at each end, entire, erect, ribbed, smooth, dark green, a foot in length; their sheaths slightly compressed, flattened, each originating from one of the joints of the stem, like those of griffes. Chilfer compound, supported by a falk which terminates the item, and is sometimes accompanied by a short leaf; its branches alternate, each confining
of from five to seven pale red drooping flowers, or very short filaments. Lip ovate, purple, flat, with a recurved point; its base inflated.

20. N. flavus. Branched Yellow Neottia. Swartz. Ind. Occ. 1417. Wild. n. 15. (Serapias flavus; Swartz. Prod. 119.)—Lip pointed, erect. Clusters compound, axillary. Stem subdivided, jointed.—Gathered by Dr. Swartz, with the last flowering in January, in marly woods, on the mountains of Jamaica. The roots, stem, and leaves are like those of that species, but twice or thrice as large Clusters from the sheaths of the terminal leaves, alternately branched. Flowers cropping all one way, yellow, larger than those of N. polyphylla. Lip lanceolate, erect, not recurved; its base concave, or channelled, embracing the style.

21. N. acutil. Stemless Neottia. Sm. Exot. Bot. v. 2. 91. t. 105.—Stem none. Flowers sessile, solitary, in the bole of each leaf.—Native of the island of Trinidad, from whence it was obtained by Mr. Evans of Stepney, and flowered in his house in June 1866. This plant is singular in its genus, and, as far as we know, in its natural order, for the superior members of the genus are known to bear no flowers, or are flower-leafs of any kind. The root consists of many thick fibres. The leaves are numerous, ovate, glaucous, glittering, pointed, ribbed, wavy, forming a dense tuft: their under side and base brown or purplish; their size and aspect most like the fist species. Flowers radical, large, sessile, erect, green and white, with an occasional sweet musty scent. German an inch and a half long; calyx half that length; both downy. Lip oblong, concave, downy, with a blunt point, and two dilated wavy lateral lobes, striped with green and bordered with white.

Mr. Brown obferves that Orbis floratematica of Linnaeus belongs to this genus; but we have no opportunity of examining it. There are some speci€es still undescribed in the herbarium of Sir Joseph Banks; and incomplete specimens of one or two others in our possession, which must be left for future consideration. S.

NEOU, the African name of a tree, found by Adanson at Senegal, which Johnson refers to the Pterocarya; see that article and MANIPATA.

NEOUNBENGZEICK, in Geography, a town of Ava, on the Irrawaddy, miles N. of P. me. O NEOUNDAH, a town of the Birman empire, on the Irawaddy, which is said to ruin the ruins of Paghan, to which it nearly joins.

NEP, in Botany. See NEFETA.

NEPA a word used by naturalists sometimes to express a crab, sometimes for a scorpion, and sometimes for a plant, called by the botanists genella Sparrman.

NEPA, Water-Scorpion, in Entomology. A genus of insects of the order Hemiptera: the generic character is this, the snout is inflected, and antennae short; it has f ur wings, folding crosswise, coraceous on the upper part; the forelegs are cheliform; the other four are formed for walking. There are fourteen species included in this genus, all which are divided into sections, according as they have no lip, or a short lip, or one that is projecting and round. Two of the species are common to this country.

The insects of this genus belong to the water, and their eggs are likewise deposited in water; they are of an oblong shape, and generally sunk and concealed in the flake of a bull rush. When they arrive at their full size, and become complete insects, they are sometimes nearly an inch in length, and nearly half as broad. The antennae appear in the usual place of the fore-legs; they are armed with a forceps adapted to the purpose for which they are applied. The nepas are, of all animals, the most tyrannical; like wolves, among a flock of harmless sheep, they destroy a vast number more than their wants require. It has been observed, that if a Nep be placed in a basin of water with thirty or forty warm of the livella kind, each as large as itself, it will destroy them all in a very short space of time, getting on their backs, and piercing them through the body with the rostrum. These animals, though they live upon the water by day, are capable of taking long flights from one pool or stagnant water to another, in quest of food; they are probably obliged to attempt from the fierceness of their manners, by which the insects in their vicinity must soon be destroyed. The nepas, so formidable to other creatures, are themselves nevertheless haunted by a little pediculus, which, perhaps, abundantly avenges the injuries that the water-scorpion so frequently commits upon others.

A. Antenna palmate, and without Lip.

Species.

GRANDIS. Chiefly brown, variegated with yellow. It inhabits South America. The antennae are four-cleft, and the divisions are curved. This is the largest species yet known, it measures more than three inches in length. It is said to prey on tadpoles and young frogs.

ANNOTATA. The tail of this species is unarmed, roundish, pale brown; the fore-feathers are pale, and annulate with brown. It is found in Coromandel, and is reckoned broader and more round than others.

RUSTICA. Tail unarmed, brown; the lateral and hind-margin of the thorax, and fore-margin of the upper wings, whitish. It is likewise found in Coromandel.

TUSCA. Tail ending in two bristles; scutel rugged; wings snowy. It inhabits the Eaf Indies. The body of this species is brown; and the tail is as long as the body.

GROSSA. Tail ending in two bristles; body ovate; and in this species the tail is longer than the body. It inhabits Tranquebar.

CINEREA. This is the common water-scorpion, whose specific character is this; tail ending in two bristles, half as long as the body; the body is ovate and brown. It inhabits this country, and many parts of the Crimea, chiefly on stagnant waters, measuring about an inch in length, and appearing, when the wings are closed, of a dull brownish colour; but when the wings are expanded the body above appears of a bright red colour, with a longitudinal band down the middle; and the lower wings, which are of a transparent white, are decorated with red veins; from the tail proceeds a tubular bifid process or flyle, nearly of the length of the body, and which appears single on a general view, the two valves of which it constricts being generally applied close to each other throughout their length. The animal is of slow motion, and is often found creeping about the shallow parts of ponds. In May, when the weather is warm and favourable, it deposits its eggs on the soft surface of the mud at the bottom of the water. They are of a singular shape, resembling some of the crowned feeds, having an oval body, and an upper part surrounded by seven radiating processes or curved spines; the young, when first hatched, are not more than the eighth of an inch in length. This insect flies only by night, when it wanders about the fields, in the neighbourhood of its native waters. The larva and pupa differ in appearance from the complete insect in having only the rudiments of wings, and being of a paler or yellowish colour.

MACULATA. Tail ending in two bristles; the body is black; the thorax and scutel spotted with ferruginous.
This is found in the East Indies, and is about half the size of the N. cinerea.

B. *Antennae palmate* ; Lip very short, and widely emarginate.

**Species.**

**Filiformis.** Tail ending in two bristles, shorter than the body; body linear; legs teltaceous; the thighs are annulate, and of a cinereous colour. It inhabits Tranquebar.

**Linearis.** The tail of this species ends in two bristles, as long as the body; the thorax is of one colour; the foreflanks have a spine down the middle. The infects of this species have a highly angular aspect, bearing a direct resemblance to some smaller insects of the genera Mantis and Phalma. It is about an inch and a half long, and the whole animal is extremely slender in proportion to its length. It inhabits the larger kind of flagrant waters, frequenting the shallower parts during the middle of the day, when it may be observed to prey on the smaller water infects. Its motions, too, are singular; often striking out all its legs in a kind of flitting manner at intervals. The eggs are smaller than those of the N. cinerea, of an oval shape, and furnished with two procefses or bristles diverging from the top of each.

**Elongata.** Tail ending in two bristles, flat, and longer than the body; the body is linear; the thorax teltaceous, with a brown dorsal line. It inhabits Tranquebar.

C. Lip projecting, and rounded.

**Species.**

**Cimicoidea.** Abdomen ferrate at the edge; head and thorax varied with yellow and brown. This, at the first appearance, is more like a notonecta than a Nepa, the hind legs being formed for swimming briskly, and furnished with an edging of hairs on the inner sides: it likewise bears a resemblance to the cicim in its broadly ovate shape.

**Estivalis.** Abdomen ferrate at the edge; head and thorax white. It inhabits France, and is about half the size of the last.

**Nepiformis.** Edge of the abdomen entire. It inhabits the South American islands.

**Curtitans.** The abdomen of this is black, the edge entire; all the legs are formed for running. It is a very small insect, and is found at Kiel.

**Nepaul, Nepal, or Nepaul, in Geography, a kingdom of Hindoostan, containing an extensive plain in a valley, enclosed in the great range of secondary mountains, which branch out towards the S. and W. from the gigantic ridge of Himalaya and the lofty regions of Tartary. On the cælæna fide, the poffeffions of the Ghhorhali, or present reigning family, are bounded by Boktan, or the country of the Deb Rajah; to the S.E. they touch upon our districts of Rangamutty and Coochbehcar; on the N.E. they are divided from Thibet by the Alpine ridge, in which the paffes of Phulak and Kooti are fettled. To the southward the Nepaul territories are bounded by the purgunahs of Durbungah, Tirhoot, and Chepparum. To the S.W. is Buirampore of Goroepore, adjoining to which is the tributary principality of Bootwal. To the westward, the Nepaul borders touch on various parts of Oude; and to the N.W. aredivided from various districts of Rohiylund by the Almorah hills. To the N.W. they are bounded by the dominions of the rajahs of Seringup and Siremor, and by parts of Thibet; all of them situated beyond the snowy ridge of Humhalé. While the Nepaul territories include between their eastern and western limits, as it feen in major Rennell's map, no lefs a space than twelve geographical degrees, they extend only two degrees from N. to S., and for the moft part exhibit a flip of even lefs than a degree in breadth. The extensive plain of Nepaul, situated N.E. of Patna, at the diftance of ten or eleven days' journey from that city, resembles an amphitheatre covered with populous towns and villages; the circumference of the plain is laid to be about 200 miles, somewhat irregular, and surrounded by hils on all sides, so that no perfon can enter or come out of it without passing the moutains. There are three principal cities in this plain, each of which was the capital of an independent kingdom; viz. Cath'mandu, on the eastern bank of the Bifhmutty, about one mile in length, and half a mile in breadth, containing nearly as many temples as houses, and as many idols as inhabitants. The number of houfes, according to Col. Kirkpatrick, in Cath'mandu, and its dependant towns and villages, is 22,000; and that of inhabitants in the town itself, allowing ten to a houfe, about 50,000; and the number of idol deities 2733. The other cities are Lelli Patan, or Patu; and Bhatano, or Bhatong; which fee respectively. Besides these three principal cities, there are many other large and lefs considerable towns or fortresses, one of which is Timi and another Gipoli, each of which contains about 500 houfes, and is very populous. (See also Kirtiplour.) All these towns, both great and small, are well built of brick, three or four stories high, with doors and windows of wood: the streets are paved with brick or stone, with a regular declivity for carrying off the water, but Kirkpatrick says, the streets of Cath'mandu are narrow and filthy; in almost every street of the capital towns are good wells of stone, from which the water paffes though several ftoncanals for the public benefit. In every town there are fquare varandas, called "Pali," well built, for the accommodation of travellers and the public, and there are many of these in different parts of the country for public use. On the outside of the great towns are small fquare refervoirs of water, faced with brick, with a good road to walk upon, and a large flight of steps for the convenience of thofe who choose to bathe.

The moft northerly part of Nepaul scarcely lies in a higher parallel of latitude than 27½°; and yet this valley enjoys, in certain respects, the climate of some of the southern parts of Europe. Snow, during winter, is sprinkled on the tops of the surrounding mountains for several days, and it sometimes falls in the valley below; and in this feaon a hoar froft commonly covers the ground, and the flanding water of the pools and tanks freezes, but the rivers are never frozen. Nepaul seems to owe its favourable climate to its great elevation; its height above the level of the sea, as indicated by the barometer, not being lefs than 4000 feet: the mean temperature, during Kirkpatrick's refidence towards the clofe of the year 1792, being, for a small interval of eight days, 67°. The feafons are much the fame with thofe of Upper Hindooftan. The rain commences a little earlier, and fets in from the S.E. quarter: it is ufually very copious, and ends towards the middle of October, and at this time the rivers are very difpofed to overflow their banks. On the fides of the mountains there is a conderable variety of temperature; and in three or four days the traveller may exchange, by moving from Noakote to Kheno, the heat of Bengal for the cold of Ruffia. The fallibility of the more elevated furnums is indicated by the aspect of the inhabitants. The guttural tumours, similar to the goiters of the Alps, and called in Hindooftan "ghaigha," and in Nepaul "ganoo," to which the inhabitants are subject, are a phencence of the imagination of their modest women, who confantly fea the protuberant pouches of moquitoes, with which part of the country abounds, and which,
which, according to a prevalent superstitious belief, it would be an act of the greatest impiety to defile.

It was formerly thought that Nepal contained gold mines; but although this is not the case, it produces almost every other metal; its iron is admirable; but copper scarce and dear. Near Ghorka there is said to be a considerable mass of rock-crystal; and limetone, as well as slate, abounds everywhere. However here are no lime-kilns, and the cement employed is mud, which is preferred for buildings. The cattle, generally speaking, are not much superior to those commonly met with in Bengal and the upper provinces. The honey is excellent; but the vegetables are of the worst kind. A species of yam, called "toraal," and a kind of wild asparagus, denominated "kurai," form a considerable part of the sufficiency of the poor.

The inhabitants consist principally of the two superior classes of Hindoos, and of a race called the "Newars," who are probably of Tartar or Chinese origin. The former are generally dispersed; but the latter are confined almost entirely to the valley of Nepal Proper. The "Dhenwars" and "Mhanjes" are the husbandmen and fishers of the western district; and the "Bhootias" occupy, generally speaking, such parts of the Kucha as are included in the Nepal territories. The "Bhantras" are a sort of sepoys from the Bhootias, and are supposed to amount to about 5000. They have their heads, like the Bhootias, shaved of the religious rites, as well as civil cullums, of these idolaters, in a dialect of whose language they are said to prefer their sacred writings. The total population is estimated at about half a million. As Nepal has been governed for many centuries past by Rajapoot princes, and as Hindoo in their various classes have constituted their chief population, it is natural to expect that a general resemblance would be still preserved, with regard to customs and manners, between this portion of its inhabitants, and the kindred facts and habits of the adjacent countries. The differences are slighter than might be expected, when it is considered that Nepal is the only Hindoo country that has never been disturbed by any Mughal power. The Hindus, however, and the Newars, differ very considerably: the latter are rarely employed in their armies; their occupations are agriculture, arts, and manufactures; they are capable of great labour, and evince a very considerable degree of skill in their mechanical operations. They are, in general, of middle size, with broad shoulders and chests, very flat limbs, round and rather flat faces, small eyes, low and somewhat spreading noses, and open cheerful countenances. At Bhatgong most of the women have a florid tint upon their cheeks, but, for the most part, their complexion, like that of the men, is between a fawn and copper-colour. The Newar men (like the "Nairs") have as many husbands as they please, being allowed to divorce them often on the slightest pretences. The popular religion of Nepal differs in no respect from the Hindoo established in Bengal, except that the Pashus are considered as the objects in which the country may have been intended to prefer it in a state of greater purity.

Father Giuseppe says, that the religion of Nepal is of two kinds: the one ancient, professed by many people who call themselves "Barysus"; these pluck out all the hair from their heads; their dress is of coarse red woollen cloth, and they wear a cap of the same: they are considered as people of the religious order; and they are prohibited by their religion from marrying, as it is with the Lamas of Tibet, from which country their religion was originally brought; but in Nepal they do not observe this rule, except at their own disposition. They have large monasteries, in which each has a separate apartment; they also observe particular festivals, the principal of which they call "Yatra," which continues a month, or longer, at the pleasure of the king. The ceremonies consist in drawing an idol, called at Lehit-Pattan "Baghoro," in a large and richly ornamented car, covered with gilt copper; round the idol fland the king and the principal Barysus; and thus the vehicle is drawn almost every day through some one of the streets by the inhabitants, who run about beating and playing upon every kind of instrument their country affords, which make an inconceivable noise. The other religion which is the most common of the two, is that of the Brahmins, or Hindoos, as already stated.

The government of Nepal is despotic. The chautra is the prime minister of the rajah, to whom he is invariably akin. He transacts the business of the country, and for his services he has, besides his jaghires, eight annas on every conteemperate rice plantation throughout the country; and their duties are subject to various other impositions. The law, and the administration of it, are in an equally imperfect state. The trade of Nepal needs better regulations, in order to render it more extensive. Some of the restraints by which it was shackled were removed by a treaty concluded with the East India company in 1792; but it still languishes under several impolitic restrictions. The exports of Nepal are elephants, elephants' teeth, rice, timber, hides, ginger, terra jasonica, turmeric, wax, honey, rhui, fruit, pepper, spices, ghee, lamp-oil, and cotton. The duties on articles passing between Tibet and Nepal are enormous. The company import into Nepal woolen goods, chinizas, shawls, raw silk, gold and silver lace, carpets, cutlery, cloves, sandal wood, alum, quicksilver, dyeing woods, tin, zinc, lead, soap, tobacco, coral, &c. &c. &c. The Newars, already mentioned, are almost the only artisans; their cloths are coarse; in iron, copper, and brass, and also in carpentry, they work well; they export some of their brazen articles to the southward; and their cutlery is in demand.

They gild extremely well, call bells of a large size; make paper, distill spirits, and prepare fermented liquors. The silver brought into Nepal by way of Tibet must be brought to the mint, as no silver is allowed to pass into Hindooistan; in exchange for his silver, the merchant receives rubies, losing from 10 to 12 per cent. by the transaction, 4 per cent. on account of coinage, and 8 per cent. for alloy. Gold has usually been a monopoly in the hands of government, which is supposed to be rich. Their artillery is contemptible. Their troops are armed with matchlocks, bows and arrows. The regular force consists of from 50 to 60 companies, each containing 140 firelocks; but their discipline is very lax. They are, however, as colonel Kirkpatrick says, brave, and capable of sustaining great hardships.

The Pundits of Nepal are not inferior to their brethren in such branches of science as are cultivated in Hindooistan. Astronomy, in connection with judicial astrology, is said to be their favourite study. In the valley of Nepal, and particularly at Bhatgong, which is the principal town of the Ghoorkah territory, a single private library contains 15,000 volumes. The Sanscrit is considerably cultivated by the Nepaul Pundits; and besides, there are eight vernacular languages spoken within the dominions of that kingdom. Besides his own immediate estates, there is hardly any division of the Ghoorkah conquests, in which the prince has not appropriated a share to himself. Some of these estates are cultivated by husbandmen, with whom he equally divides the produce; others are managed by agents of his own, and tilled by the neighbouring husbandmen, who are obliged to dedicate a certain number of days in the year to his service; and others are farmed out. Many of the kith lands yield three

NEPAUL.
three harvests, one of wheat, one of rice, and one of an excellent vegetable, called "tori." The sugar-cane is also cultivated in these lands. In the generality of them, land is reckoned to yield from 20 to 30fold; in fertility not much exceeding that of the belt arable land in this island. The plough is scarcely known among the Newars; the prejudice against the use of it originating in their reverence for the bullock, which they never approach but in the form of adoration. The expenses of the military establishment are for the most part discharged by afflictions of land; though in some instances, the fowler receives his pay, either from the treasury or the granary.

The kingdom of Nepal is thought to be very ancient; because it has always preferred its peculiar language and independence; but the cause of its ruin has been the dissension which subsists among its three kings. At length the king of Gorcha, taking advantage of the dissensions which prevailed among the other kings of Nepal, attached to his party many mountain-chiefs, and having poiffessed himself of the mountains which surround the plain of Nepal, defied into the flat country; but failing to subdue it by force of arms, he sought to effect his purpose by causing a famine. Not succeeding in this barbarous mode of conquest, he fomented dissensions among the nobles of the three kingdoms of Nepal, and he gained over to his party fome of the principal of these, for which purpofe he had about 2000 Brahmins in his service. He then laid feige to Kathmandu, or Kirtipour, a strongly town, containing of about 8000 houses, about a league from Kathmandu, which having long attempted in vain, he at last obtained by treachery. After the capture of this city, he proceeded against Lelit Pattan; but in the mean while he made himfelf master of Kathmandu, in 1768, and then compelled the inhabitants, with their king, to withdraw to the king of Bhatgan. Having gained Lelit Pattan, he got into his posseflion the perfons of the nobility. At the commencement of the year 1769, the king of Gorcha regained the city of Bhatgan, by the fame modes of violence and treachery by which he had fucceeded in his other conquests; and having thus in four years effected the conquest of Nepal, he made himfelf master also of the country of the Ciratans to the caft of it, and of other kingdoms, as far as the borders of Coochbehar. After his deceafe, his elfedft fon held the government of the whole country; but in about two years afterwards, when he died, a younger brother was required to accept the government, who began his reign with many dreadful massacres. Asiatic Re-arches, vol. ii. Kirtipour's Account of Nepal, 4to. 1811.

NEPEAN ISLAND, a small island in the South Pacific ocean, near the S. coast of Norfolk island, about half a mile from Point Hunter.

NEPEAN Sound, a bay on the N.W. coast of North America, in the North Pacific ocean. N. lat. 53° 32'. W. long. 127° 30'.

NEPEAN Township, lies in the eastern district of Upper Canada, being the eighth township in ascending the Ottawa river, and the first on the W. fide of the river Radeau.

Nepenthé, or Nepenthès, Nêpenthés, formed of the privative ren, non, or abfque, and évê, lucus, fources, in Antiquity, a kind of magic potion, which made perfones forget all their pains and misfortunes.

The nepenthé, mentioned in ancient authors, was the juice or infusion of a plant, now unknown: Homer fays it was a plant of Egypt; and adds, that Helena made use of it to charm her lovers, and make them forget their pains.

Some authors fay it was the plant we call belladonna; others begotis, whose juice inflamed in wine has this effect. M. Petit has a difputation on the ancient nepenthé.

Nepenthés, in Pharmacy, is a name given to a kind of opiate, contrived by Theo. Zwingerus, from the great opinion he had of his giving eafe in all manner of pain.

Nepenthés, in Botany, a name adopted by Linnaeus, or rather Breynus, from the ancient Greeks, which, being formed of the negative, ren, and évê, lucus, fources, expresses a plant furnished with the power of driving away care, in which fene Homer ufed the word. The Borage and the Elecampane have been fuppofed to poffefs this valuable property, and the above name has been applied to them, or to some potation in whole composition they had a share. The Nepenthés of Linnaeus is an herb, whose leaves bear a singular pitcher-like vefsel, into which a pure and fweet water is diffilfed through their flks, in great abundance; and this liquor might, in fome circumftances, prove a welcome re-freftment to travellers. We can give no further explanation of the matter.—Linn. Gen. 467. Schreb. 769. Mart. Mill. Dif. v. 3. Jull. 444. Poiret in Lam. Dif. v. 4. 458. Gärtn. t. 83.—Clafs and order, Dioecia Monadelphia. Nat. Ord. uncertain. Jullieu well remarks that it has no affinity to any other genus.

Gen. Ch. Male, Cal. Perianth of one leaf, coriaceous, in four deep, spreading, ovate, nearly equal segments, coloured on the inside. Cor. none. Stam. Filament one, columnar, cylindrical, erect, rather shorter than the calyx; anthers several, (fifteen or more), collected into a glabrous head, oblong, recurved.

Female, on a separate plant, Cal. as in the male, permanent. Cor. none. Pijf. Germen superior, fefill, ovate, with four furrows; Style none; fijgma large, peltate, four-lobed, each lobe marked with a hollow, permanent. Peric. Capsule oblong, columnar, abrupt, quadrangular, furrowed at the fides, of four cells and four valves, burling at the angles, each valve crowned with one lobe of the fijgma; partitions from the centre of the valves. Seeds numerous, oval, each enclosed in a long, membranous, angular tunic, tapering at both ends, inferted into the partitions in two rows, obliquely imbricated.

Female. Cal. and Cor. as in the male. Stigma fefill. Capsule superior, of four cells and four valves. Seeds numerous, tunicated.

Obfl. Linnaeus greatly erred in referring this genus to Gynandra Tetrandra, as it answers neither to that clafs nor order. Koegn trit ascertained it to be dioecious. Schreber describes the anthers as single-celled, of which we cannot satisfy ourselves.

1. N. diffilillatoria. Linn. Sp. Pl. 1354. (N. zeylanicum, flore minore; Breyn. Prod. 85; Cantharifera; Rumph. Amboth. v. 5. 121. t. 59. f. 2. Bandura zeylanica; Burr. Zeyl. 42. t. 17. Uticaria vegetabilis, zeylonenium Band. cingalenfibus difcia; Pluk. Phyt. t. 237. f. 3. — Native of Ceylon, Amboyna and Madagascar. Root perennial. Stems erect, rather zigzag, fimple, three or four feet high, round, smooth, leafy; very fpongy and vefcular internally. Leaves alternate, elliptic-oblance, smooth, entire, with one principal rib and several fmalI ones more or lefs parallel to it; tapering, and clasping the ftem, at their base; each terminating in a long twifted flalk, which bears an oblong, membranous, ribbed, upright bag, finely crenate at the margin, and clofed by an orbicular lid, attached at one fide. Flowers very numerous, fily or downy externally, in a long, terminal, fimple or compound flleru.

M. Poiret has diftinguifhed the Madagascar plant as a feparate species, by the fmalB tufs of the edge of the vefel at the end of the leaf. In our fpecimens from that country,
as well as from Ambroyna and Ceylon, the part in question is uniformly crenate. Perhaps the cluster of flowers being simple or compound may indicate a specific difference, but we perceive gradations that lead us to hesitate. The lateral ribs of the leaves too vary in distinctness and direction. The pitcher at their ends is one of the most curious appendages to leaves. It holds two ounces or more of clear water, distilled through the highly vacular flaks, and according to Rumphius is the refuge of a small aquatic shrimp.

**NEPER, or Napier, John**, baron of Merchiston, in Biography, is noted for the arithmetic of logarithms, was the eldest son of sir Archibald Neper of Merchiston, near Edinburgh, in Scotland, in the year 1550. He was educated with great care, and after going through the ordinary courses of philosophy at the university of St. Andrew's, he made the tour of France, Italy, and Germany. Upon his return home his talents and acquirements rendered him conspicuous, and might have raised him to the highest offices of state; but his love of science led him to decline all civil employments, and the bubble of the court, and to retire from the world to pursue literary researches, in which he made uncommon progres. Mathematics were his chief delight, next to the study of the holy scriptures. In every pursuit to which he applied himself he quickly discovered the most extensive knowledge and profound penetration. His work entitled "Plain Discovery of the Revelation of St. John," was published in 1593, and gives sufficient evidence that the author was accustomed to the most acute and diligent investigation, though the progress of time has shown that his calculations proceeded upon false data. This work obtained for Mr. Neper a high re-election at home and abroad. Neper of Merchiston, was translated into several languages. The French edition was eagerly bought up by the Protestant in France, on account of the zeal and erudition employed by the author to prove the pope to be antichrist. But what immortalized his name was his fortunate discovery of logarithms, and their application to all trigonometrical calculations, by which improvements in the sciences of astronomy, navigation, &c. have been wonderfully facilitated. The attachment of Mr. Neper to astronomy and spherical trigonometry led him to make many numerical calculations of triangles, with sines, tangents, &c. These, at first being expressed in large numbers, occasioned a great deal of labour and trouble: to shorten the operations many contrivances were resorted to, and some ingenious contrivances were invented, particularly the computation by Neper's rods, which fee. At length, the most complete one of logarithms was discovered in the actual construction of a large table of numbers in arithmetical progression, adapted to a set of as many others in geometrical progression. (See Logarithms.) Neper published his invention in 1614, under the title of "Logarithrorum Canonis Descriptio," containing a large canon of logarithms, with the description and uses of them; but the mode of their construction was still concealed. As soon as the inventor had communicated this discovery to Mr. Briggs, the mathematical professor of Gresham college, the latter set about the application of the rule in his "Imitatio Neiperiana," and in a letter which he wrote to the celebrated Usher in the same year, already mentioned, he says, "Napier, lord of Markinton, hath set my feet and hands at work with his new and admirable logarithms. I hope to see him this summer, if it please God; for I never saw a book which pleased me better, and made me more wonder. Briggs was too great a man to indulge the spirit of envy:" so far, indeed, was he removed from a feeling of that nature, that he afforded every facility to the reception of Neper's work, teaching the nature of the logarithms in his public lectures, and, at the same time, recommending a change in the scale of them, which he submitted to lord Neper. During a subsequent visit to lord Neper these two friends agreed upon a form, according to which the baron strongly urged Mr. Briggs to proceed with his computation, and hence they are denominated Briggs's logarithms. To Neper science is greatly indebted for considerable improvements in spherical trigonometry, particularly by his universal rule, or general theorem for the solution of all cases of spherical triangles, which is commonly known by the title of "The five circular Parts." He prepared for the press his "Construction of Logarithms," and "Rabdology and Promptuary of Multiplication," containing of infinitum tables for the more easy performance of the arithmetical operations of multiplication, division, &c. Neper died in the year 1617, when he was in the sixty-eighth year of his age. To him Kepler dedicated his "Ephemerides," regarding him as the greatest man of the age, in that particular department to which he applied his talents. Lord Buchan, in his account of the life, writings, and inventions of our author, says, "If we consider that Neper's discovery was not, like that of Kepler or of Newton, connected with any analogies or coincidences which might have led to it, but the fruit of unassisted reason and science, we shall be vindicated in placing him in one of the highest niches in the temple of Fame.

**NEPER's, Napier's, or Napier's, Bones, an instrument, by which multiplication and division of large numbers are much facilitated and expedited; so called from its inventor J. Neper, baron of Merchiston, in Scotland.**

**Construction of Neper's Bones.**—Five rods, plates, or lamellæ, are provided of wood, metal, horn, paleteboard, or other matter (Plate I. Algebra, fig. 7.) of an oblong form, and divided each into nine little squares; each of which is resolved into two triangles by diagonals. In these little squares are written the numbers of the multiplication-table, in such manner as that the units, or right-hand figures, are found in the right-hand triangle; and the tens, or the left-hand figures, in the left-hand triangle; as in the figure.

**Use of Neper's Bones in Multiplication.**—To multiply any given number by another; dispose the lamella in such manner, as that the top figures may exhibit the multiplicand; and to these, on the left-hand, join the lamella of units; in which seek the right-hand figure of the multiplicator; and the numbers corresponding thereto, in the squares of the other lamella, write out by adding the several numbers, occurring in the frame rhomb together, and their sums. After the same manner write out the numbers corresponding to the other figures of the multiplicator; let them be disposed under one another, as in the common multiplication, and lastly, add the several numbers into one sum.

Vol. XXIV.
For example; suppose the multiplicand 5978, and the multiplicator 937. From the outermost triangle on the right-hand (Plate 1. Algebra, fig. 8.), which corresponds to the right-hand figure of the multiplicator 7, write out the figure 6, placing it under the line. In the next rhomb, towards the left, add 9 and 5; their sum being 14, write the right-hand figure, viz. 4, against 6; carrying the left-hand figure, 1, to 4 and 3, which are found in the next rhomb. The sum 8, join to 46, already put down; after the same manner in the left rhomb, add 6 and 5, the latter figure of the sum 11, put down as before, and carry to the 3 found in the left-hand triangle; the sum 4 join as before, on the left of 1846; thus you will have the sum of 7 into 5978; and after the same manner will you have the sum of the multiplicand, into the other figures of the multiplicator; the whole added together gives the whole product.

Use of Nepet’s Bones in Division.—Dispose the lamelle so, that the uppermost figures may exhibit the divisor; to these, on the left-hand, join the lamella of units. Descend under the divisor, till you meet those figures of the dividend, wherein is first required, how oft the divisor is found, or at least the next less number, which is to be subtracted from the dividend; the number corresponding to this, in the place of units, write down for a quotient. By determining the other parts of the quotient after the same manner, the divisors will be completed.

For example; suppose the dividend 5601386, and the divisor 5978; since it is first asked how often 5978 is found in 56013, descend under the divisor (Plate 1. Alg. fig. 9.) till in the lowest lines you find the number 53802, approaching nearest to 56013; the former whereof is to be subtracted out of the latter, and the figure 5 corresponding thereto in the lamella of units written down for the quotient.

To the remainder, 2211, join the following figure of the divisor, 8; and the number 17934 being found, as before, to be the next less number thereto, the corresponding number in the lamella of units, 3, is to be written down for the quotient; and the subtraction to be continued as before. After the same manner the third and last figure of the quotient will be found to be 7; and the whole 937.

If the segments which border the throat be considered as part of the lower lip, it will then become three-lobed.

Eff. Ch. Corolla with the middle segment of its lower lip notched; orifice with a reflected margin. Stamens approaching each other.

The whole herb is covered with a very soft, hoary, velvet-like downiness, and has a strongly pungent, aromatic odour, like penny-royal or Valerian, that is peculiarly grateful to cats, whence its specific and English names. These animals are so fond of this species of Nepeta, especially when it is withering or boiled, that it is almost impossible to keep them from it, after being transplanted. Ray and Miller both assert however, that cats will never meddle with such plants as are raised from seed. Hence the old saying:—

"If you feed it, The cats will eat it; If you fow it, The cats don’t know it."

N. Catari a b, which Miller makes a species and calls N. minor, grows in Italy and the south of France. It is about half the size of the original species. The stalks are more slender, and their joints further asunder. Leaves narrower. Whorls more diluate, and the whole plant whiter.

3. N. crispa. Curled Cat-mint. Willd. n. 3. (N. racemosa; Lam. Dict. n. 12?)—Flowers in whorls, forming an interrupted spike. Leaves falcate, heart-shaped, toothed, rugose, hoary. All we know of this species is from Willdow, who says that it is extremely beautiful. Stem more than a foot high, branched, ascending. Leaves opposite, on longish stalks, scarcely an inch long, heart-shaped, obtuse, unequally toothed, undulated and curled or crisped, hoary with down. Flowers compounding a terminal, interrupted, clustered, whorled spike, of a blue colour, few in a whorl. Bracteae bristle-shaped, hairy.

4. N. lehongriophylla. Turnsole-leaved Cat-mint. Willd. n. 3. Lamarcq Dict. n. 14. (Cattaria orientalis, minor, folis Hichretopii; Tourn. Cor. 13.)—Flowers about five
in a tuft, on flalks. Leaves ovato-oblong, entire, rather downy.—Native of the East. Stem rather more than a foot in height, very much branched and forked. Leaves whiteish-green. Corolla terminal, small, forked, consisting of five flowers, the central one fertile, the rest on flalks. We are not acquainted with any figure of these last species.

6. N. carulescens. Blue Cat-mint. Willd. n. 6. Ait. Hort. Kew. ed. 2. v. 3. 378.—Cymes flalked, many-flowered, hairy. Leaves oblong, heart-shaped, villosa, nearly feffile. Lateral lobes of the corolla reflexed. Introduced to Kew in 1775, by Dr. Ortega, where it flowers in May and June; but from whence is unknown. Willdenow and Martyn adopt it solely from the Hortus Kewensis, without referring to any specimen, figure, or description of it.

7. N. violacea. Violet-coloured Cat-mint. Linn. Sp. Pl. 797. (N. montana, purpurea, major, farfana spicata; Barrel. t. 601. Bocc. Mus. v. 2. 46. t. 30.)—Cymes flalked, many-flowered, beftet with fine hairs. Leaves slightly flalked, almost naked. Lateral lobes of the corolla spreading. —Native of Spain, flowering from July to September. Stems two feet high, purple, with a few flender branches coming out of their sides. Leaves indented on their edges. Flowers in roundish whorls, pedunculated, blue; varying occasionally to white. Scopoli says the stem is frequently five or six feet high.

8. N. japonica. Japan Cat-mint. Willd. n. 9. (N. cinerea; Thumb. Jap. 244.)—Flowers in axillary panicles. Leaves flalked, ovate, notched, downy. —Native of Japan, on the highest mountains. It flowers in October and November. Stem five or six inches long, herbageous, decum- bent, erect, downy. Leaves acute, downy on both sides, but whiter underneath, gradually smaller on the upper part of the stem. Flowers in axillary panicles, in which respect it differs from N. Nepetella, as well as in having ovate, not heart-shaped, leaves.

10. N. uricola. Ukranian Cat-mint. Linn. Sp. Pl. 797. (Cataria betonica folio anguiforme, flore euralecente; Gerb. Tan. 87.)—Flowers in panicles. Leaves feffile, lanceolate, serrated, naked. —Native of Mufcovy. Introduced at Kew in 1780 by Dr. Pitcairn, where it flowers in July and August. We know not of any figure or description of this species.

11. N. Nepetella. Small Cat-mint. Linn. Sp. Pl. 797. Willd. n. 11. Allion. Pedem. v. 1. 37. t. 2. f. 1.—Leaves lanceolate, heart-shaped, at the base, toothed, downy. Clusters compound, each branch bearing about five flowers. —Native of the South of Europe. It flowers from July to September. —This species greatly resembles N. cataria in habit, being about one-third of its size. Leaves very narrow, acutely finncced or toothed. Flowers in loose clusters, as in N. violacea but not so numerous, when fresh of a red colour, not white or blue. Bracteas very narrow, spreading.

12. N. nudiflora. Naked or Spanish Cat-mint. Linn. Sp. Pl. 797. Jacq. Auth. t. 24. (Cataria hispanica, betonica folio anguiforme, flore cæruleo; item flore albo; Tourn. Infl. 202.)—Leaves heart-shaped, nearly seflile, serrated. Clusters whorled, naked. —Native of Spain, and of Greece on Mount Parnassus, flowering from June to August. Stems two feet high, smooth, straight, furrowed, the older ones dark purple. Leaves like those of Stachys palustris, blent, veined, naked, rugged on both sides. Clusters cossing each other. Flowers distinct. Corolla reddish or white, dotted with purple; according to Haller blue or white. Krocke is of opinion that this and uricola may be the same species.

17. N. Muffinii. Scopol'd-leaved Cat-mint. Marsh. Taur.-Caucas. v. 2. 39. (N. longiflora; Sims in Bot. Mag. t. 823.)—Cymes flalked, lowermoist flalked. Leaves heart-shaped, obtufate, downy, notched, rugose, not glandular; floral ones mostly flalked. —Native of Siberia. It flowers from May through the whole summer. Stem rather shrubby, decum-bent, branched, square, with obtuse angles. Leaves opposite, on longish flalks, hoary; upper ones seflile. Flowers whorled, three to five on a flalk, of a very rich light-purple colour. In young plants the leaves are rounder and less hoary.

numerous and conspicuous, violet-coloured. This is nearly allied in habit to 

Corolla pale purple. Bracteas large, ovate, pale, reticulated, frequently violet-coloured at the margin.

23. N. virginica. American Cat-mint. Linn. Sp. Pl. 799. (Clinopodium amarum folio, floribus albis; Pluk. Alm. t. 110. f. 85. f. 2.)—Tufts terminal. Stamens the length of the flower. Leaves lanceolate.—Native of Virginia. Stems two feet high. Leaves hairy, resembling those of Sweet Marjoram (Origianum) but larger. Flowers whorled, forming a terminal tuft, of a pale flesh colour. The lower lip of the corolla is ferrated but not concave.

27. N. multifida. Perennial Siberian Cat-mint. Linn. Sp. Pl. 799. (N. lavandulae; Linn. Suppl. 273.)—Flowers in spikes. Leaves pinnatifid, entire.—Native of Siberia. Stem erect, not branched. Leaves stalked; upper one sessile, oblong, three, four, or five-lobed. Flowers very small, white or purplish, in a terminal, sessile spike.

NEPETA, in Gardening, comprises plants of the herbaceous perennial kind, of which the species cultivated are, the common catmint (N. cataria); the Hungarian catmint (N. pannonica); the naked or Spanish catmint (N. nudica); the Italian catmint (N. italicca); and the tuberous-rooted catmint (N. tuberosa).

Method of Culture.—These plants are all capable of being increased by seeds, parting the roots, slips, and cuttings, but the firel is the principal mode.

And the seeds may be sown in the autumn or spring, on a bed of light earth, raking it in lightly; when the plants have attained some growth, they may be planted out in nursery rows, to remain till the autumn, when they may be set out where they are to remain; or they may remain where sown, only thinning them properly out.

The partings of the roots may be set out separately, where they are to remain, in the beginning of the autumn or spring, being afterwards kept free from weeds.

And the slips or cuttings of the branches may be planted out in the spring in shady situations, occasional supplies of water being given till they have firaken root perfectly.

It may be flated that the first form and varieties, as well as many of the others, may afford variety in the borders, clumps, and other parts of pleasure-grounds, in mixture with herbaceous plants of different descriptions. They are likewise some of them cultivated for medicinal use occasionally.

NEPHALIA, among the Greeks, a festival called the feast of sober men, at which the Athenians offered to the sun and moon, to Aurora and Venus, a drink made of water and honey. They burnt all sorts of wood on the occasion, except the vine and fig-tree.

NEPEUM, in Botany, from Nepenthes, a little cloud, feck, or spot, but of the reason of its application to the plant in question we can offer nothing more than conjecture. One of the specimens from Shinberg in the Linnaean herbarium is remarkable for a most curious Lichen, or Endocarpon, with which its leaves are spotted; but this is not an original specimen. Whether that from which Linnaeus took his description was so marked, we have no means of determining; as the plant does not exist in his old original collection. Such however might be the case, as he certainly described the genus from nature, perhaps in the herbarium of some friend, who had no duplicate to spare. Linn. Mant. 45. Schreb. 654. 857. Willd. Sp. Pl. v. 4. 37. Mart. Mill. Dict. v. 3. Jujif. 191. Lamarck Illuttr. t. 764. Poir. in Lamarck Dict. v. 4. 460. Gortn. t. 140. —Cladis and order, Monogilia Pentandria. Nat. Ord. Trionice, Linn. Corymbifera, Jull. Ammaceae, Gortn. Rather perhaps akin to the Sapindi, or to the Terebinthaceae of Julliet; it certainly can have nothing to do with his Corymbifere.

Female,
Female, in the same clumper, Cal. Perianth of one leaf, bell-shaped, with four teeth, the two opposite ones most remote; withering, permanent. Cor. none. Pfr. Germin two, superior, roundish, muricated, larger than the calyx; styles two, thread-shaped, recurved, originating from between the germs; stigmas thickish, obsolete. Peric. Drupas two, ovate, clothed with awl-shaped bristles, each of one cell, with a carnosaceous coat, containing a watery pulp. Sec. Nut solitary, roundish.

1. N. latipaxu. Rambutam. Lim. Mant. 125. - Native of the East Indies. A frbr or tree, with round smooth branches. Leaves alternate, flaked, abruptly pinnate, about a span long, smooth, coriaceous, of two or three pair of elliptical leaves, on short partial flasks; their upper side polished; the under paler and opaque; with one rib, fending off numerous oblique veins, connected by a multitude of reticulations. Stipulas papyraceous, axil and terminal, about the ends of the branches; their flaks, as well as the calyx, rusty. Bractes minute. Fruit about an inch in length, covered with innumerable projecting, curved, coloured, polished bristles. A considerable affinity may be traced between this fruit and the Chinefe Lin-chi; see Laphoria and Scatula. We can find no figure of the plant except Larracq's, cited above. The habit of the leaves, the inoffeence, pubeftence, form of the calyx, all are evidently akin to Scatula Longa; a specimen of which, brought by Lord Valetta from the botanic garden at Calcutta, is infefled with the fame Lichen which we have mentioned above, and which we have barely met with elsewhere.

N. Nephew, a term relative to uncle and aunt; signify- ing a brother's or father's son, who, according to the civil law, is in the third degree of confanguinity; but, according to the canon law, in the second. See Consanguinity.

The word is formed from the Latin nepos: which in the corrupt ages of that language signified the fame: though anciently and properly it denoted a grandchild.

Nepfihim, in Mythological History, a name given both to giants and to perons of diflinate manners. In the book of Genesis (chap. vi.) we read that the sons of God, that is, the succencers of Seth, had intercourse with the daughters of men, i.e. with those who defcended from Cain, and from this intercourse proceeded the Nepfihim, who fell into the grofteft enormities, as their name imports. The Centaurs were also called Nepfihim.

Nepfin, in Geography, a mountain of the county of Mayo, Ireland, which is 2640 feet high. It flands almost infolated, and appears round at all fides, and at top like a huge rath or barrow. Mr. Arrowmitch, in his Map of Ireland, has given the name of Nepfin Bog mountains to a range extending N.W., and lying to the westward of Nepfin, and also the name of Green Nepfin Mount to a hill south of lough Conn. This lake, which is nine miles long, is at the foot of mount Nepfin, which rises from its western shore.

Nephyalgia, in Medicine, from ρηγ, the kidnies, and παινον, pain, signifies every painful affection of the kidnies, except that which is connected with inflammation of these glands, the preference of which is indicated by a symptomatic fever, and constitutes the Nepfritis of the nophologist; which fee below. The absence of fever, therefore, distinguishes the nephalgia from nephritis.

The painful affections of the kidnies, which are not inflammatory, have been improperly termed nephritic colic; for, in strict propriety, the word colic is applicable only to the painful condition of the colon, or large intestine.

The cauf of pain in the kidnies, independently of inflammation in the substance of these organs, or in the membranes that furround them, are not very numerous. Sauvages, indeed, has enumerated fifteen species of nephalgia (see his Neoful Methodica, Ch. vii. Genus xxvii.; but if we examine accurately the grounds of these specific discriptions, we find that he has included several painful affections of the loins, in which the kidnies are not concerned; and which, therefore, are not affections of nephalgia. Thus, his fourth species, nephalgia rheumatica, is in fact lumbago, or rheumatism of the muscles and ligaments connected with the spine. His eighth, ninth, and tenth species, nephalgia a pancreata, N. vermiculata, and N. mefenterica, are obviously painful disorders of other organs in the vicinity of the kidnies; as well as his fifth, N. gravitarentum, originating from the dilatation of the gravid uterus. He defends this arrangement upon the principle, that the generic appellation does not necessarily denote the actual seat of the symptoms, but the part to which the patient's feotions refer them; but this is an incorrect view of the subject; as it tends to confound the practitioner in the choice and application of his remedies, by confounding together those things which it is the principal office of the physician to separate and to distinguish; namely, the diseases which have some symptoms in common, and are referred to the same situation, but which actually belong to different organs, and therefore require different modes of treatment.

The most frequent cauf of nephalgia, or pain in the kidnies, is the presence of small stones or concretions in the pelvis of the kidney, or in the ureters leading to the bladder, or of the sandy or gravelly matter irritating the same parts. The nature of these concretions, the symptoms by which their presence is indicated, the diagnosis between them, and the symptoms of other painful disorders affecting the loins, and the proper remedies to be administered for their cure, have been lated at sufficient length under the head of GRAVEL, in Medicine. These forms of the disease are included in the frill and second species of Sauvages, viz. the nephralgia, calciufa, and N. arastra; and the genit nephalgia, for the fame author (Spec. g.) should probably be referred to the same caufe, since that disease sometimes alternates with gravel, and the gravel is composd of the same matter with the external concretions, or chalk-stones, of gout.

Among the various acute spafmodic pains, which occur in the hystrical attacks of nervous women, a severe nephralgia is liable to come on suddenly, and suddenly disappear, like other symptoms of hysteria. The severe pain in the loins, which shoots along the course of the ureters, and is accompanied with violent vomiting, often mнимes the symptoms of calculus in the kidnies, and is only to be distinguished by an experienced practitioner, who examines the state of the pulse, and the presence of the other symptoms of hysteria, especially the globus hystericus, and the sudden transitions of mental emotion from one extreme to another. (See HYSTERIA.) This species of nephalgia, like other hysterical pains, is speedily relieved by opiates and antispasmodics.

The prufm of nephralgia, or rather the pains which are apparently seated in the kidnies, when the melonctery, pancreas, gravid uterus, and other contiguous visera are diseased, being secondary or symptomatic, can only be relieved by those means which alleate the primary disfase.

Nephritic, Nephritis, πρηγή, formed of ρηγ, reis, kidney, something that relates to the kidnies. See Kidney.
NEP

Nephritic Colic. See Nephralgia.

Nephritic Stone, Lapis Nephriticus, in Natural History, a sort of precious stone; so called from its extraordinary virtues against the stone and gravel in the kidneys.

It is a species of jasper, commonly of a uniform dusky green colour; but sometimes variegated with white, black, or yellow. It seems only to differ from jasper in its being harder, and always without any thing of red.

It is brought chiefly from New Spain, where it is sometimes found in pieces large enough to make moderate caps. There is none, likewise, found in Old Spain, and Bohemia.

This stone was once very dear, by reason of the wonderful virtues ascribed to it. A cup made of it was sold for 1600 crowns, in the time of the emperor Rudolphus II. The beld for medicinal use is of a greyish-green, fat and mucilaginous, like tule of Venice.

The Indians of New Spain, who first discovered its use, and taught the Europeans, wear it hung about their necks, after having cut it in various figures, chiefly of the beaks of birds: whence the charlatans take occasion to counterfeit it, by cutting other green stones into like figures; and sell them at great prices, to those who have an opinion of their nephritic faculty.

Nephritic Wood, Lignum Nephriticum, a kind of medicinal wood growing in New Spain, chiefly in the kingdom of Mexico; called by the Indians eulut and tapalcytapatli, as being reputed sovereign against nephritic pains.

Dr. Lewis says, he has never known its being given medicinally, and that it is not received in practice.

It must be chosen well cleared of its bark and rind; it is of a bitter taste, and a dusky yellow colour; but when infused with cold water, gives it a sky-blue tincture, when viewed by a false light, and a gold colour by a true one; a little of any acid being mixed with the tincture, both these colours disappear; but a little oil of tartar resorbs its sky-blue.

Some substitute ebooy, and others red Brazil wood, for lignum nephriticum; but the deceit becomes apparent by infusing it in water. See Transmutation of Colours.

Nephritics, Nephritica, in the Materia Medica, medicines proper for the relief of the diseaees of the kidneys, and especially, therefore, of the stone and gravel. See Gravel.

In addition to the alkaline and absorbent medicines, mentioned in the article just referred to, and which operate chiefly by preventing the formation of the uric or lithic acid, several drugs, possessed of a mucilaginous, anodyne, or diuretic quality, have been recommended as conducive to the relief of nephritic complaints (See Lithiontritic.)

The uva urdi has obtained considerable reputation for its virtues in this way; but it is very questionable, whether it possesses any other powers than the mallow, aparagus, sago, and other mucilaginous substances, and whether any of these are beneficial, except from the quantity of diluent fluid taken with them. The spirit of nitrous ether, turpentine, &c., when they act as diuretics, and therefore augment the dilution of the urine, occasionally produce relief. And opiates, camphor, and other soothing medicines, afford a temporary alleviation, by lessening the sensibility of the nervous system, and thus diminishing the degree of actual pain.

Nephritics, in Medicine, from νεφρός, the kidney, with the termination ἱτίς, signifies inflammation of the kidneys.

The local symptoms, which denote the presence of inflammation in the kidneys, do not differ very materially from those which belong to nephralgia, and which are principally the result of the irritation of calculi, or sandy concretions, formed in the urinary passages. (See Gravel.) For, in fact, inflammation of the kidneys is not very common as an idiopathic disorder, originating from the ordinary causes of inflammatory affections; but is usually an effect of the irritation of calculi in the same passages, when long continued, or particularly severe in degree: in other words, nephralgia is liable to terminate in nephritis.

The principal circumstance which marks the occurrence of inflammation in the kidneys, is the addition of symphomatic fever to the nephralic signs. The pulse becomes frequent and sharp in its beats; the skin grows hot; the tongue is dry, and loaded with a clammy fur; and there is considerable thirst, fits of appetite, languor, and depression of strength. Pain is felt in the region of the kidney, which is sometimes acute and pungent, but sometimes obtuse, and is most frequently confined to one of these glands. This pain is ascertained to be felt in the kidney, and not in the muscles of the loins, in the bowels, or the liver, by its shooting along the course of the ureter towards the bladder, and by the accompaniment of a flux or number of the thigh of the side affected, and of a retraction of the tendon of the same side in men, as well as of a sympathetic derangement of the stomach, which is troubled with sickness and frequent vomiting. There are also occasionally colic pains in the bowels, and often colicines, accompanying nephritis. The urine is voided frequently, and in small quantity at each time, and it is sometimes of a pale, but most commonly of a deep red colour. When pus is formed, by the progress of the inflammation, it may be known by its appearance in the urine, which will be more distinctly marked, in proportion to the quantity of the pus, or by the symptoms to be mentioned immediately.

The right distinction of this disease from the lumbago, from the mere spasmodic nephralgia arising from the passage of a calculus along the ureter, and from inflammation of other vescera contiguous to the kidneys, is of more importance in nephritis, than in the more chronic nephritic complaints; because the treatment required for its cure must be materially different. Thus, with respect to the spasmodic pain accompanying the irritation of a calculus, impacted in the ureter, a large dose of opium will sometimes at once relieve the pain, and allow the generation to pass into the bladder, by producing instantaneous relief; but if actual nephritis were present, the opium would confer no benefit; on the contrary, it would tend to augment the inflammation, and to carry it on to suppuration. From lumbago, then, the nephritis may be distinguished by the presence of acute fever; by the pain being little increased by moving the muscles of the back, but considerably aggravated by sitting, or lying, motion, especially when a calculus is present; and by the concomitant sickness. From opium, excited by calculous irritation, it is distinguished by the presence of fever; and from colic, and inflammation of the intestines, which are sometimes accompanied, more particularly the left, by sickness and vomiting, and the left always by fever, it is distinguished by the number of the thighs, and the pain and retraction of the tendon in male patients.

In addition to the ordinary exciting cause of nephritis above mentioned, some other circumstances occasionally give rise to it. Among these are mechanical injuries to the kidneys; as blows in the lumbar region; strains from violent muscular exertion, in raising weights, &c., and violent exercise in travelling, especially on horseback; even travelling in a carriage has induced it, and occasioned a discharge of bloody urine, where a calculus was already formed in the kidney. The influence of cold combined with moistures, especially
ically when applied to the loins and belly, has likewise excited nephritis as well as other acute inflammations. And certain stimulating substances, which have been swallowed, and exert a specific action on the urinary passages, such as cantharides, turpentine, and other acrid diuretics, have been said also to produce this inflammation. In some it has occurred, in the way of metalaffia, on the recollection of gouty inflammation from the extremities.

A predisposition to nephritis is obviously attached to peculiar mental conditions, especially to those which have a gouty tendency, or a disposition to calculous complaints; and these two maladies are so far connected, that they sometimes alternate with each other, and some individuals of a gouty temperament have been observed to be affected with gout, while others have suffered from calculous complaints. Compulosity seems also to predispose to these affections of the kidneys; or the predisposition may be produced, in cases of this nature, from the constant stimulus given to the urinary passages by the use of much high-gluten food and fermented liquors.

The treatment of nephritis, like that of other acute inflammatory diseases, is simple and obvious, when the existence of the complaint has been clearly ascertained by the presence of the symptoms above described. Where the pain and urinary symptoms are violent, general bleeding must be employed in proportion to the age and strength of the patient. In habits which are less robust, and in cases of minor severity, the free local detraction of blood from the lumbar region by means of leeches, or cupping must be substituted; or it may be resorted to after the general bleeding, where the circumstances of the patient render the repetition of the former less advisable. At the same time, a bilious may be applied to the loins, and removed as soon as it has produced any degree of vefication, lest the adsorption of the cantharides may occasion an irritation in the urinary passages. Dr. Cullen, Dr. Gregory, and other able physicians, however, have maintained, that such an irritation, which rather affects the neck of the bladder than the kidneys, is not much to be apprehended, while the effects are as beneficial as in other local inflammations. Mild cathartics, which fill empting the bowels, without irritating them and the contiguous organs, are likewise necessary; and their operation may be aided by the injection of warm emollient glivers, which will likewise afford a fermentation to the diseased parts, and thus contribute to the alleviation of the pain, as well as to the restitution of the inflammation. Saline medicines, whether used as castoraries, diuretics, or refrigerants, are on the whole to be deprecated, inasmuch as they are liable to irritate the urinary passages. The only diuretics that are admissible, are mucilaginous diluent drinks, which should be copiously administered, for the purpose of diminishing the acrimony of the urine, by diluting the fluids which it contains; to say nothing of the lubrication of the passages by the mucilages, which is a questionable hypothelis. At the same time, the antiphlogistic regimen, as it is called, should be rigidly enforced; i.e., all animal food, condiments, and heating liquors should be proscribed, and milk, whey, herb-tea, gruel, and vegetable and farinaceous matters be exclusively used.

With respect to the exhibition of opopium in nephritic inflammation, although during the early and active stage it is not to be trusted to; yet when the violence of the disease has been mitigated by these antiphlogistic measures, they may be employed with great advantage to relieve irritation. Fomentations and the warm bath may be also employed, under the same circumstances, with great benefit. Under the plan of treatment above recommended, if it be actively pursued within the first week of the disease, the nephritic inflammation will admit of a cure by resolution; and this event is sometimes accompanied by a copious discharge of urine, a diarrhoea, or hemorrhoidal bleeding. If, however, the inflammation continues unabated for twelve or fourteen days, suppuration is to be apprehended; the pain begins to remit, and is accompanied with a sense of throbbing; daily paroxysms of rigour and hectic fever, followed by perpiration in the night, occur; emaciation ensues; in a word, a fort of renal consumption, as Hippocrates calls it, comes on, and may terminate the life of the patient. In some cases, the whole subsidence of the diseased kidney has been reduced to a bag of pus, while the other kidney, being undermined by the specific of carrying off a larger proportion of the excrementitious fluids, has become considerably enlarged. In these cases of renal suppuration, the same light delusive diet, which is required in other varieties of flatus, is the principal remedy to be relied upon, as it affords the best means of supporting the constitution through the supplicative process, while it does not aggravate the febrile symptoms; we mean a milk and vegetable diet, especially of goat's milk, and the farinaceous vegetable substances. The most favourable termination of suppuration in the kidney is when the abscess opens into the proper urinary passages, and is discharged through the bladder; or when, in consequence of previous adhesion of the parts, it opens into the large intestine, and passes off by stool, as was observed by the ancients. See Hippocrates. Lib. de Intern. Affection. Aetius, ferm. xi. cap. 18.

Sometimes, though very rarely, nephritic inflammation is said to have terminated in gangrene, and sometimes in feverish disease. But this latter affection, by which the kidney is sometimes enlarged to an enormous bulk, is perhaps more commonly the result of a chronic simple inflammation of the kidneys, and is scarcely within the influence of medicine. See Van Swieten, Comment. ad Aphi. 902—906. Cullen, First Lines, vol. i. chap. x. Bailer's Morbid Anatomy.

The writer of the present article has long ago indicated this character in some of the old genus Polypodium as it stood in Linnaeus; see Mem. de l'Acad. de Turin, v. 5. 409, and Traits relating to Nat. Hist. 223. The part in question is nearly kidney-shaped in the Polypodium Filix mas, or Afpidium of Sverstz, and of Sm. Fl. Brit 1118, as well as in the North American Polypodium, or Afpidium, marginale. In these it however it most nearly approaches the orbicular form, which the authors who have founded Nephrodium with to consider as the mark of Afpidium. It is necessary to say the true genus Polypodium is now, by universal consent, agreed to have no involucrum at all. On the other hand, the involucrum in Afpidium Filix femina, Engl. Bot. t. 1459, and several others, verges towards a crenate, whole curve, in certain cases, is very flight, at some peri of its growth. Theefore their approach Afpelium and Darce (See Filices.) They are nevertheless distinguished from the two genera last mentioned, by the formation of the involucrum being at a limited point, or short fins, in one of its sides. If the formation of this part in any Afpidium were really central, or peltate, we might admit Nephrodium; but we believe such a character does not exist in any, there being always a lateral finns, however short or concealed by the expanding membrane;
membrane; in much that a regular series of species may be traced, from the most orbicular Aspidum, to the confines of Darea and Asplenum. S.

NEPHROMETRÉ, a name given by some authors to the muscles of the loins, called by the generality of medical authors nephromes.

NEPHROTOMY, derived from νεφρός, a kidney, and τομή, to cut, denotes, in surgery, the operation of extracting a stone from the kidney.

There have been surgeons who entertained the opinion that nephrotomy admits of being practised in two different cases: viz. 1. When the kidneys are entire, and no external sign indicates that these organs contain a stone. 2. When an abcess, or fistulous aperture, occurs in the loins. But, says Sabatier, it is easy to prove, that it is only in the second case that the operation is practicable.

The following reasons have been advanced for the purpose of proving that nephrotomy is practicable in the case first specified: 1. The operation has been recommended by Hippocrates: 2. It has been repeatedly performed: 3. Analogy is favourable to the practice. How little validity these reasons possess will next be considered.

1. Hippocrates says: "cum autem intumuet et elevatus fuerit, sub id tempus juxta renem fecato, et extra tum pure, arenam per urinam cietia fanato. Si enim fecus fuerit, fugit ipse et; his minus, morbus homini comminatur, &c."

2. "If the part should swell and become elevated, an incision must be made near the kidney in order to let out the matter, and the gravel is then to be got rid of by means of diuretics; for such an incision may save the patient's life, which otherwise would certainly be lost," Sabatier with reason contends, that it cannot be inferred from this passage that Hippocrates has recommended the performance of nephrotomy, when the kidneys are entire. On the contrary, he appears to have advised the operation only when the viscera are in a state of affections, and the matter tends to the surface of the body. There cannot be a doubt that Celsus and Galen have given this interpretation to the above passage in Hippocrates, inasmuch as neither of them makes any mention of extracting calculi which are included in the kidneys. Their silence upon this point has been imitated by the Greek and Latin writers, and it is in the Arabian authors that the first evidence in favour of such a proceeding is to be traced.

There are not many instances of nephrotomy being done when the kidney was supposed to be entire, nor are these well authenticated. The most ancient is fearfully known except by tradition. It is related in the Abrégé Chronologique de l'Histoire de France, par Mézerai. The doctors, (says this historian,) having learned that an archer of Bagnolet, who had been for a long while afflicted with the stone, was condemned to death for his crimes, requeded the magistrates to give him into their hands, in order that the experiment might be made, whether it was practicable to open the kidneys, and extract a calculus, without fatal consequences. This operation proved entirely successful, and the man lived several years afterwards, in excellent health.

This account seems, indeed, to shew, that an incision was actually made into the kidney. But, says Sabatier, if we refer to Ambroise Paré, who mentions the same case, it will not appear that such a proceeding was adopted. The following is the passage in the latter writer: "Je ne pus encore pâsser que je ne recenisse cette billeure Archer de Meudon, près Paris, qui estoit prifonnier au châtelet pour plusieurs larcins, à raison dequels il fut condamné à mort. Au même jour, fut remonté par les médecins de la ville, que plusieurs étaient fort travaillés et molletées de pierres, caliciques, passion, et maladies des côtés, dont étoit fort moleste l'Archer Franc Arache, et aussi deffites maladies étoit fort moleste monseigneur du Bouchage, et qu'il ferait fort requis de voir, les lieux ou lesdites maladies font concrées dans le corps humain, laquelle chose ne pouvoit être mieux vue qu'en enlevant le corps d'un homme vivant, ce qui pourroit être bien fait en la personne d'icelui Franc Arache; et dedans icelui fut perquis et regardé le lieu deffites maladies, et après qu'il eut été vu, fut reconstitué, les entailles mises dedans, et par ordonnance fut bien pâné; tellement que dedans quinze jours il fut bien, guéri, et eut fa rémission, lui fut donné avec ce argent."

This last statement proves how difficult it is to form a judgment respecting the disease under which the above archer laboured. Opinions upon the subject are considerably divided. Collot believes that nephrotomy was really performed upon the man. On the contrary, Méry thinks that the archer had a stone in the bladder, and was cut in a manner analogous to the apparatus major. Haller entertained the same opinion as Méry, in regard to the seat of the disease, but supposes that the operation performed must have been the apparatus altus, because, after the stone had been extricated, the bowels were replaced, and the abdomen closed up. Lastly, Tolet believes that the archer was afflicted with a volvulus, and that an opening was made in the abdomen, in order to disentangle the intestines. Besides these different opinions, it is proper to remark that historians do not concur respecting several other essential particulars of the event under consideration. Some represent it as having occurred in the time of Charles VII.; others in the reign of Lewis XI. Some describe the patient as an inhabitant of Meudon; others of Bagnolet. Some affirr that he lived afterwards a long while in good health; others that he survived only a short time, &c.

The second example of the operation of nephrotomy deserving notice, is that recorded in the Philosophical Transactions for 1696. It is there related, that Mr. Hobfon, the English consul at Venice, having been a long while afflicted with pain in the kidneys, in consequence of a calculus being lodged in one of those organs, went to Padua, for the purpose of consulting Marchetti, a very experienced physician, who told him that he knew of no other mode of relieving him, except that of making an incision, through which the extraneous substance that annoyed him might be extracted. There was no external sign by which the presence of the stone could be ascertained, and Marchetti did not conceal from the patient the difficulty and danger of the operation. Mr. Hobfon, however, shewed so much resolution, and so strong a desire to submit to any means of cure, that Marchetti could not decline the attempt. The parts were divided with a straight bistoury. The hemorrhage was to profuse, that the extraction of the stone was unavoidably deferred to the next day. In short, two or three calculi were then taken out, and the wound dressed. The subsequent symptoms were not serious, and Mr. Hobfon was soon well enough to return to Venice, although his wound was not completely healed, as a small fistula still continued, from which pus and urine were discharged. Some time afterwards, another stone presented itself, and was easily taken out. The patient at length experienced a radical cure. Ten years had elapsed, when Mr. Hobfon related his case to Dr. Bernard, who afterwards communicated it to the Royal Society.

That the operation was actually done, was proved by the cicatrix, which was visible in the loins; but the circumstances of the case could not be accurately known. Who, says Sabatier, can pretend to decide whether Marchetti was induced
induced to operate by the presence of a deeply-seated abscess, of which Hobson himself might be ignorant? This conjecture is rendered probable by the circumstance of this operation not having been mentioned by any body, though doubtless it must have been done before witnesses. Peter de Marchetti, who survived his son that died in 1673, takes no notice of it in his "Sylloge Observationum Medico-Chirurgicarum Rariorum."

According to Sabatier, there are some other influences recorded of nephrotomy being performed while the kidneys were entire; but the details are such as can claim no kind of confidence.

3. Analogy, says Sabatier, is not in favour of this operation. Considerable abscesses, indeed, are observed to form in the kidneys, and burst externally, and wounds to extend to these viscera, without dangerous symptoms being produced. But the nerves and blood-vessels are not injured in cases of abscesses, and, by great good fortune, a sword may pass through the texture of important viscera, without the injury being followed by dangerous consequences; but, in a deep incision made with a bistoury, every thing that precedes is divided to the edge of the instrument is divided.

The little validity of the reasons alleged in favour of nephrotomy, in the case in question, is not the only motive which should induce us to reject this operation. There are other considerations, deduced both from the want of symptoms by which the presence of an ilone is indicated, and from the difficulty of getting at the kidneys in consequence of their position, and the great number of parts which cover them. This difficulty is such, that James Douglas, a surgeon at Edinburgh, having attempted the operation upon the dead body of a calculous patient, aged fifty years, could not succeed, and was obliged to open the abdomen, in order to get at the kidneys, from which he extracted two stones; one of a triangular shape, weighing half an ounce; the other of an irregular square form, weighing not more than sixteen grains.

Besides, as Sabatier remarks, stones may form in different parts of the kidney. Frequently they are wedged in its substance, from which it would be impossible to extract them, without producing a dangerous degree of laceration. On the contrary, they often lie in the pelvis of the kidney; and occasionally, the upper part of the ureter is filled with particles of gravel, which cannot be readily taken out. Lastly, either only one kidney is affected, or both are. In the first case, the patient may live a long time; in the second, it would be useless to operate on only one of these viscera. But though nephrotomy is impracticable if the kidneys are entire, it may be undertaken when the ilone has produced an abscess in the loins; or when, in consequence of such an abscess, a fistula remains, within which the calculus can be felt with a probe. In these circumstances, the operation should be done; every body concurs upon this point: that is to say, all surgeons agree in regard to the propriety of opening the abscesses, and of introducing the finger, and endeavouring to feel the ilone, or of dilating the fistula, in order to get at the foreign body, and extract it. See Sabatier's Médécine Opéraire, tom. ii.

NEP, in Geography, a town of Italy, in the Patrimonio, the fee of a bishop, united to Sutri, containing five churches and five convents; 20 miles N. of Rome. N. lat. 42° 15'; E. long. 12° 24'.

NEPES, a town of East Greenland. N. lat. 60° 35'; W. long. 45°.

Nepizinges, or Nipisings, a lake of Upper Canada. 15 miles broad, and 36 leagues long, encompassed with rocks. Its shore is inhabited by the remains of a Christian tribe, called "Nepisingue," of the Algonquin nation. This lake discharges itself by the Riviere des Francois.

NEPISS, a lake of Canada, on the borders of Maine. N. lat. 45° 40'; W. long. 70° 31'.

NEPOMUK, a town of Bohemia, in the circle of Pilfen; 9 miles E.N.E. of Klattau.

NEPONSAT, a river of America, in the Massachusetts, originating chiefly from Muddy and Punkapog ponds in Stoughton, and Massapog pond in Sharon, and after uniting with several streams, meeting the tide in Milfor, whence it is navigable for vessels of 150 tons burden to Bolton bay, at the distance of four miles. There are fix paper-mills and others of different kinds on this small river.

NEPOS, CORNELIUS, in Biography, a Roman historian and biographer, who flourished in the time of Julius Caesar and Augustus. He was born on the banks of the Po, probably at Hildia, and like some other of his learned contemporaries, he flourished the favours, and enjoyed the patronage of the emperor. He was the intimate friend of Cicero and Atticus. We have no other account of his life. As an author, he is known to every school boy by his "De Vitis Eximiarum Imperatorum," which is his only work that has reached modern times. It consists of twenty-two articles of biography concerning Greek and other foreign generals, with a fragment of the life of Cato of Utica, and a more detailed memoir of Atticus. This work long passed under the name of Emilium Probos, who prefixed it to the emperor Theodosius in the fourth century, but the purity of the style, which is that of the best age of the Latin language, affirms them to their real author. According to some writers, he composed three books of "Chronicles," also a biographical account of all the most celebrated kings, generals, and authors of antiquity. The editions of Cornelius Nepos have been extremely numerous; the most valuable are the Variorum, of which that of 1673 is said to be the most correct. Lempriere speaks in high terms of that of Verbekey, 8vo. Lug. Bat. 1773, and that of Glasgow, 12mo. 1761.

Neros, FLAVIUS JULIUS, emperor of the West, was a native of Dalmatia, and having married a niece of Leo I., had, through the intimacy of the emperor Verina, who was anxious to promote the greatness of his own family, succeeded his uncle Marcellinus in the sovereignty of Dalmatia, a more solid position, says Gibbon, than the title which he was persuaded to accept of "Emperor of the West." In the empire he succeeded Olybrius, who had been placed on the throne at the time in which Anthemius was miscarried. Owing to the languid and irresolute measures of the court, it was some months before Nepos could shew himself, with a respectable force, to his Italian subjects. During that interval, Glycerius, an obscure soldiery, was invested with the purple by Gundobald, a Burgundian prince, who, however, was unable, or unwilling, to support his nomination by a civil war: the pursuits of domestic ambition recalled him beyond the Alps, and his client was permitted to exchange the Roman sceptre for the bishopric of Salena. After extinguishing such a competitor, the emperor Nepos was acknowledged by the senate, by the Italians, and by the provincials of Gaul. His moral virtues and military talents were loudly celebrated, and those who derived, or who expected to derive any private benefit from his government, announced in prophetic strains the reformation of public felicity. Their expectations were confounded in the space of a single year, and the treaty of peace, which ended Avarthe to the Visigoths, is the only event of his short and inglorious reign. The most faithful...
Subjects of Gaul were sacrificed by the Italian emperor to the hope of domestic security, but his repose was soon invaded by a furious sedition of the barbarian confederates, who, under the command of Orefes, their general, were in full march from Rome to Ravenna. Nepos trembled at their approach, and retired to his Dalmatian principality, on the opposite coast of the Adriatic. By this abdication, he protracted his life about five years, in a state between an emperor and an exile, till he was assassinated at Sartoria by Glycerius, who was translated, perhaps as a reward of his crime, to the archbishopric of Milan. This was in the year 480. Gibbon, vol. vi.

NEPOTISM, a term used in Italy, in speaking of the authority which the pope's nephews and relations have in the administration of affairs; and of the care the popes take to raise and enrich them.

Many of the popes have endeavoured to reform the abuses of nepotism: for some time past, nepotism is said to have been abolished. Leti has written expressly on this subject, Il Nepotismo.

NEPOTSKOII, in Geography, a town of Russia, in the government of Archangel, on the coast of the White sea; 24 miles W. of Archangel.

NEPTHALITES, a name formed by corruption from Ephthalites, and derived from the Oxus or Amus; by the Persians styled Abtelah, or the river of Gold. This was a denomination given to the people of Great Bucaria by the Byzantine historians; who called them White Huns, as all the western Barbarians were designated Scythians, or Huns.

NEPTUNIA, feasts held among the ancients, in honour of Neptune.

The Neptunalia differed from the Confulalia, in that the latter were feasts of Neptune, considered particularly as preceding over horses, and the manegge. Whereas the Neptunalia were feasts of Neptune in general, and not considered under any particular quality. They were celebrated on the roth of the calends of August.

NEPTUNE, in Mythology, the son of Saturn and Rhea, and brother of Jupiter and Pluto. He is commonly represented standing with his trident in his right hand, which was his peculiar sceptre, as lord of the Mediterranean seas, and seems to have been used by him chiefly to raise up the waters; for we find sometimes that he lays it aside, when he is to appease them; but he refrains it, when there is any occasion for violence. Virgil, Æn. ii. v. 162, makes him shake Troy from its foundations with it; and in Ovid, Met. i. v. 284, it is with the stroke of this that the waters are let loose for the general deluge. The dolphin is in his left hand, and he treads on the back of a ship, to show that he presided over the seas, or, more particularly, over the Mediterranean sea; which was the great, and almost the only scene for navigation, among the Greek and Romans. The poets have described this god as passing over the calm surface of the waters, in his chariot drawn by sea-horses. The fine original description of this is in Homer; from whom Virgil, Æn. i. v. 155, and Statius Achill. i. v. 60, have copied it. A tradition is sometimes preserved on each side, as guiding those that draw the chariot of Neptune. His emblem in all the best figures of him is majestic and serene. The lower part of the chariot exhibit him sometimes with an angry and disturbed air; and one may observe the same difference in this particular between the great and inferior poets, as there is between the good and bad artists. Thus Ovid, Met. i. v. 271, describes Neptune with a follen look; whereas Virgil, Æn. iii. v. 127, expressly tells us that he has a mild face, when he is representing him in a passion. Neptune had a great number

of temples erected to his honour, as well as feasts and games established in token of respect, both in Greece and Italy. Spence's Polytheism, p. 65. p. 215, &c.

Neptune's Gap, a name given by naturalists to a remarkable species of marine fungus, which is never found affixed to any solid body, but always loose, and rolling about at the bottom of the sea. Its usual size is about five inches in height, and six or seven in diameter at the base. It gradually becomes narrower from the base to the summit, where it terminates in a round end, ornamented with clusters of a foliaceous fort of frutices, resembling a cock's comb, but of the same matter with the rest of the frutice.

Its internal surface is very different from this: it is lightly furrowed down the sides, and belet with a number of small protuberances, with obtuse points. Some of these, when small, are found with a pedicle growing to them. This is always of a very brittle substance, and it is probable that all those found loose had originally such pedicles, by which they adhered to some solid body, in the manner of the corals, and other marine frutices; but that its extreme brittleness occasions it to be soon broken off by the motion of the water, after which it rolls loose about, and takes in its nourishment at its several pores, by means of the water, which every way surrounds it. It is not probable that these and the like marine frutices are nourished only by sea-water; but that there is in the sea a fort of mud continually formed out of the decayed particles of animals, and the fossil vegetables, which may be supposed much to resemble the common vegetable mould in its uses, as it has much the same origin; and this, or at least its finer and lighter parts, may be conveyed by water into the pores of these suppoed plants, and nourish them. Mem. Acad. Par. 1766.

NEPTUNINS, in Mythology, were sea-nymphs, so called, because they were the descendants of Neptune.

NEQUIT'AO, in Geography, a town of South America; in the province of Venezuela; 20 miles S. of Truxillo.

NEQUONQUIQUA, a river of New Brunswick, which runs into the St. John. N. lat. 46° 6'. W. long. 66° 55'.

NER, a town of Hindoostan, in the circuit of Aurungabad; 38 miles E. of Aurungabad.

NERA, or NEIRA, one of the Banda Islands. See BANDA.

NERRAC, a town of France, and principal place of a district, in the department of the Lot and Garonne, situated on the Blaye, which here becomes navigable; 12 miles S.W. of Agen. The place contains 5587; and the canton 11,876 inhabitants, on a territory of 185 kilometres, in 13 communies. N. lat. 44° 8'. E. long. 0° 25'.

NERAINSKOII Serebreni Zooid, a town of Russia, in the government of Irkutsk, on the Argun, near the borders of China; 118 miles E.S.E. of Nertschik. N. lat. 50° 28'. E. long. 120°.

NERBA, a town of Saxony, in Thuringia, on the Unnart; 15 miles N.W. of Naumburg.

NERBUDDAH, a river of Hindoostan, which, as well as the Sonne, has its rise in a pond or lake on the southern confines of the Allabahad province. These rivers, flowing from the same lake, make conjointly with the Ganges, an island of the northern part of Hindoostan, and pursue their course in opposite directions 1500 miles. The Nerbuddah discharges itself into the gulf of Cambay, 31 miles N. of Surat.

NERE, a town of Hindoostan, in the circuit of Ellichpour; 30 miles E.N.E. of Ellichpour.

NEREALELY, a town of Hindoostan, in Visapour; 25 miles E. of Anamgur.
NERECHTA, a town of Russia, in the government of Kolomna; 16 miles S.W. of Kolomna.

NEREIDS, NEREIDES, sea-nymphs, or fabulous deities of the ancients, supposed to inhabit the seas.

The Nereids were fifty in number, all the daughters of Nereus, by the nymph Doris. Their names and genealogies are described in Hesiod. Homer gives their names, with some variation, and reckons only thirty-two of them. The ancient monuments, as well as medals, agree in representing the Nereids as young women riding upon dolphins, and upon sea-horses, holding commonly in one hand Neptune's trident, and in the other a dolphin, and sometimes a victory and a crown; sometimes we see them half women and half fishes, conformable to this verse in Horace's Art. Poet.

"Definit in picem mulier formosa supra mare."

Such we see them on a medal of Marseillees, and upon some others. It has been a subject of inquiry with regard to the Nereids, whether they are to be considered as metaphorical personages, as their names signify, or as real beings. Tho' whom Hesiod and Homer name are mostly poetical personages; but some of them had real existence, as Callisto, the mother of Andromeda, Phaethon, the son of Phoebe, from whom the country into which she removed was called Phocis. Thetis, the mother of Achilles, and some others. It must be observed, however, that the name of Nereids was given to princesses who inhabited either some islands on the sea-coasts, and became famous for the establishment of commerce and navigation. It was transferred afterwards to some poetical personages, who owe their existence only to etymologies conformable to the qualities implied in their names, and even to certain fishes, that have the upper part of their bodies much like that of women. Pliny says, in the time of Tiberius, there were seen upon the sea-shore a Nereid such as the poets represent them, "humana effigie," and that an ambassador from Gaul had told Augustus that upon the sea-coasts several dead Nereids had been seen. See NEMEA.

NEREIS, in Zoology, a genus of the class and order Vermes, to which the generic character is; body long, creeping, with numerous lateral peduncles, or feet, on each side. The feelers are simple, but in certain cases there are none. It has sometimes no eyes, sometimes two, and sometimes four. Of this genus there are twenty-nine species, divided into three sections, according as the mouth of the worm is furnished with a claw or forceps; or with a proboscis; or with a tube. Most of the species are found in the North seas, but three or four are met with on our coasts.

A. Mouth furnished with a Claw or Forceps.

Species.

VERSICOLOR. This species is characterized with a body subdepressed; and with peduncles pointed, and furnished with bristles. It is about four inches long, and is found in European seas. The body has about eighty-five segments, growing wider and behind the colour of the worm is of an ochre yellow, with a dull red streak down the middle; the tail, and anterior segments of the body, are of a dirty green hue, but towards the middle it is shining, with various iridescent colours.

NOCTILUC. Body blue-green, with twenty-three segments; scarcely visible to the naked eye. This species is found in moss seas, and the animals are of that kind which frequently illuminate the water, making it appear as if we were on fire: the animals are extremely minute, pellucid, and highly phosphorescent, giving an uncommonly lucid splendour to the waves in an evening; by their extreme minuteness they elude observation, but may be detected by passing a small quantity of the water through blotting-paper.

Barburt, in speaking of this species of the Nereis, says, "I have observed with great attention a fish just caught out of the sea, whose body was almost covered with them, and have examined them in the dark: they twist and curl themselves with amazing agility, but soon retire out of our contracted sight; probably their glittering dazzles the eye, and their extreme minuteness eludes our search. It is to be observed, that when the unctuous moisture, which covers the scales of fishes, is exhausted by the air, these animals are not to be seen, nor are the fishes then noctilucent, the matter being perhaps, their nourishment when alive, as they themselves afford food to many marine animals. They do not shine in the day-time, because the solar rays are too powerful for their light, however aggregate or immense their number."

FABRIANUS. The body of this species is subdepressed; the peduncles are cirrate and glandular. It inhabits the Baltic, is about three inches long, and linear. The body is of a fulvous hue, with a blue line down the middle of the back and belly; the head is furnished with eight feelers; and the tail is terminated with two threads.

ARMILLARIS. The body of this also is subdepressed; the peduncles conic, with glandular cirri. This, like the last, is found in the North seas, borries itself deep in the sand, and is about an inch and a half long. The body is siliform, with three moniliform feelers on each side the head; it has about 120 articulations, all armed with a peduncle on each side the tail, ending in two long threads.

MOLLIS. This species has lateral falcis of hair above the peduncles. It is found in the seas about Norway.

PELAGICA. Body above convex; peduncles cirrate and warty. This is found in European seas, among the roots of alga, under stones, and in empty shells, is about seven inches long, and has a kind of flexuous motion.

TURricula. Body subdepressed, and peduncles slightly cirrate and globular. It inhabits the Northern seas. The body is linear, with five straight feelers on the head; it forms for itself a rough tube of the indurated moisture exuding from its pores.

NORWEGICA. The body of this is convex; the peduncles are cirrate and feathered. It is found in the bays about Norway, and is the size of a goose-quill. The body has 120 segments.

PINNATA. Body convex; peduncles cirrate and pinnate. This is found in the bays of Norway, on a bluish clay. The body is of a cheviot colour, with a blue gloss, the segments are from 100 to 122 in number; the head has five jointed feelers, and the tail ends in two thick filaments.

CORNICULATA. Body subdepressed, pinnate; the peduncles are furnished with a cirrus and long simple bristle. It inhabits the Norwegian seas, and is extremely minute and active.

PUSILLA. Body depressed; peduncles cirrate, with jointed filaments. Found also in the Norwegian seas.

INCISA. The body is convex; the segments dilatant; and the peduncles are simple and cirrate. It inhabits the Greenland seas, far from land, and among the roots of the larger alga. It is about two inches and a half long.

APHRODITOIDES. The body of this is depressed, and not grooved; the peduncles are cirrate, and furnished with papilae. It inhabits the Greenland seas, and is found among the mud at bottom; is an inch long.
NER

**B. Mouth furnished with a Proboscis.**

Species.

*Carulea.* Smooth, depressed, blueish-green, pellucid. This is found in the seas about our own coasts. The body is fish-shaped, about four inches long, with a groove along the belly.

*Viridis.* The body of this species is depressed; the peduncles have lanceolate lamellae, or scales. This is an inhabitant of the Northern seas, and has been found at Tenby; and is from two to three inches long. The body is siliform, and of a grass-green colour, with 130 equal segments.

*Maculata.* Body convex; peduncles with heart-shaped scales. It inhabits the North seas, and is from two and a half to four inches long.

*Crass.* Body depressed; proboscis cylindrical; peduncles red, with branched bristles. Inhabits the ocean; is seen on floating fucus, and is four inches long.

*Stellifera.* The body of this species is depressed; and the peduncles furnished with elliptic scales. It inhabits the Northern seas, particularly in the bays of Norway.

*Punctata.* Body slightly depressed; the peduncles furnished with very long cirri. This species is likewise found in the Northern seas, in oyster-shells, or under stones.

*Alba.* Body convex; front horned; peduncles bluish. Found in the seas about Norway, on a clayey bottom. The body of this species is white, annulate, and tapering behind; it has no eyes; and the proboscis is membraneous, very pellucid, and capable of being inflated to twice the width of the body; there are seventy-five peduncles on each side.

*Flava.* Body depressed; peduncles with oblong-ovate scales. It is found in the Northern seas, among the roots of alge, and is about two inches and a half long. The body is yellow, and is divided into about 140 segments.

*Longa.* The body of this species is slightly depressed, and furnished with conic papilla instead of scales of the peduncles. It inhabits the shores of Greenland, with a clayey or sandy bottom near the mouths of rivers.

*Prismatica.* Body triangular; peduncles distinct, with a single fissionary papilla cirrate above. This is found on the shores of Greenland, and is about half an inch long.

*Bifrons.* Body depressed; peduncles with a single fissionary papilla cirrate above, the middle ones also branched. This also is found in the Greenland seas, is an inch long, has fifty-fix segments, and is continually moving.

*Ceca.* Body slightly convex; it has two very short feelers, and the peduncles have double ciliate lamellae. It inhabits the sandy shores of Greenland, under stones, like the Lumbricus, (which see). It burrows very deep, and is about eight inches long. The body is divided into from 86 to 100 segments.

*Ebranchiata.* Body round, annular, and tapering both ways; peduncles cylindrical, short and double, pimice on each side; it has no feelers, and inhabits the German and Indian seas. The body is of a bluish or greyish-brown, and is divided into 269 segments.

*Laemelligera.* Body flatish, and tapering both ways; proboscis dilated, with four flesh-coloured flaps; the peduncles are compressed and furnished with a feminear scale above, and a larger leathern-shaped one beneath. This is found in the Indian, Mediterranean, and also in the Northern seas, among aquatic plants, and is nearly two feet long. The body of this species is said to be divided into from 200 to 250 segments; the head has four feelers.

*Ciliata.* Body depressed; mouth cylindrical, retractile; the anterior margin ciliate; it has no feelers.

NER

**C. Mouth furnished with a Tube.**

Species.

*Prolifera.* Body depressed; peduncles ciliate; front with a single feeler. It inhabits the bays of Norway, and its body is divided into from 32 to 46 segments. Instead of forcepts and a proboscis, it has a thick flexuous pellucid tube.

*Neresheim.* In Geography, a town of Germany, in the principality of Öttingen, near which is a princely abbey of the name of Neresheim; 12 miles S.S.W. of Óttingen.

*Neresi,* a town on the S. side of the island of Brazza, so called by Greek derivation from the referovs of water near it. Its situation is not pleasant, though it is the residence of the governor and a place of resort, and the only good land in the island are adjacent. The air is said to be intensely cold. This place was more considerable in a former period of piracy; but since other places near the sea have been inhabited, it has lost much of its population, and its deserted hovels are mouldering into ruins.

*Nerestbad,* a town of Perlia, in the province of Kerman; 90 miles N. of Malith.

*Nereos,* a town of Naples, in Abruzzo Ultra; 36 miles N.N.E. of Aquila.

*Nereus,* in Mythology, the son of Pontus and Terra, who, by Doris, produced the Nereids. The ancients reckon Nereus among the sea-gods, and, according to Hesiod, he was the son of Oceanus and Tethys. Hesiod highly celebrates this Nereus as a mild and peaceful old man, a lover of justice and moderation. From Apollodorus we learn, that Nereus commonly resided in the Ægean sea, where he was encircled with Nereids, who divested him with their songs and dances. Accordingly Paufanias takes the old man who was worshipped by the Gytheiates, and who according to them had his palace in the sea, to have been no other but Nereus, and in proof of it he cites these verses in Homer:

"Ye Sire! Nereids! to your deeps descend,
Half, and our Father's sacred feast attend."

Pope's Iliad, 18. 177.

Some authors have been of opinion that Nereus was the inventor of hydromancy, or of the science of prediction by water. whence he was represented as a great tooth-fayer: and this might have been the reason for ranking him among the gods of the sea.

*Nerfling,* in Ichthyology, the name of a fresh water fish of the leather-mouthed kind. common in some of the lakes in Germany, and there called allo the afford or oorre, and seeming to be the same with the common rudd.

There are two kinds of this fish, the flesh of the one of which, when dried, is white, and that of the other yellowish or redbitten. The latter kind is most valued.

*Nerfua,* in Geography, a small island in the gulf of Finland. N. lat. 60 12'. E. long. 28° 9'.

*Nerfeldes,* a town of Poland, in the palatinate or Kiev; 48 miles W.N.W. of Kiev.

*Neri, Philip de,* in Biography, an Italian writer, was born at Florence in the year 1415, of a noble family. In 1532, he was chosen by duke Alexander one of the magistrates, afterwards denounced senators. He died at Florence in 1536. He was author of "A History of Florentine Affairs," from 1215 to 1257, which was printed at Augsburg in 1528.

*Neri, Pompeo,* a native of Florence, who became professor of the law at Pisa, and was employed in state affairs by the duke of Lorraine, and the empress Maria Theresia. He founded the Academy of Botany at Florence, where he...
he died in 1776 at the age of 69. He wrote observations on the ancient and present state of the Tuscan nobility; on the imposts of Milan; on the legal value of the coin, and the difficulty of fixing and maintaining the same. There was also of this name and family Anthony Neri, well known by a work to which we have had occasion to refer, on the "Art of making Glasses."

NERIABAD, in Geography, a town of Hindostan, in Guzerat; 14 miles S. of Mahmoodabad.

NERICIA, or NEIRITA, a province of Sweden, bordering on three remarkable lakes, viz.: Wener, Wetter, and Hielmar, and bounded on the N. by Weftmanland, on the E. by Suddermanland, on the S. by Eaf and Weft Gothland, and on the W. by Warmeland. It is about 20 leagues in length, and 15 in breadth, and consists of mountains, forests, mines, lakes and rivers, with some level and tolerably fertile tracts. This country has iron and sulphur mines, quarries of lead-stone, alum, lime- stone, with iron-founderies, and also sulphur and lead works. It has been long famous for its flourishing manufactures of all kinds of hard-ware. Its inhabitants are principally employed in the mines and forges, in hunting, and in fishing; its chief town is Orebro.

NERILKERY, a town of Hindostan, in Mysore; 22 miles E. of Seringapatam.

NERITA, in Natural History, a genus of the Verme Teffaceae class and order, of which the generic character is this: the animal is a limax; shell univalve, spiral, gibbous, flattish at the bottom; the aperture is semicircular, or semilunar; pillar- lip transversely truncate, flattish. Seventy-five or fix species are enumerated as belonging to this genus, separated into three divisions, according as they are umbilicate, imperforate with tooth-like lips, or imperforate with lips that are toothed. The shells are generally very minute, seldom exceeding the size of a pea, usually polished, often banded, and the colours vary in the different species.

A. Umbilicate.

Species.

Crenata. The shell of this species is smooth, with a slightly pointed siphon and has a gibbous bifold umbilicus. It inhabits India, Africa, and America, in almost innumerable varieties of size, colours, and marks, being white, yellowish, or blueish, with variously disposed spots, lines, and clouds.

Cancellata. Shell with decussate flukes and impressed dots; the siphon subvalve; umbilicus gibbous and bifold. This species is found in several of the American islands. The shell is white with oblong spots, with sometimes a fulvous band and rays.

* Glauca. Shell smooth, glossy; siphon rather obtuse; umbilicus partly closed by the pillar-lip, which is gibbous and two-coloured. It inhabits the coasts of Barbary, and is sometimes found on our own shores. It is about two inches long.

Vittata. Shell subglobular, with a perforated equal umbilicus. It inhabits the Indian oceans. The shell is yellow, with white shades, and spots disposed in rows, above with a fulvous band, within and round the umbilicus it is white.

Albumea. Shell convex; umbilicus somewhat heart-shaped, with a flattened lobe. This species is found at the Cape of Good Hope, on the Barbary coast, and at the Nicobar and Molucca islands: it is, however, a very rare shell, but smooth and broad, of a pale yellow colour, beneath it is white and flat.

NER

Mammilla. Shell ovate, glabrous; umbilicus partly covered; aperture ovate. There are four different varieties of this species; found in India, and divers parts of America. It is more than two inches long.

Leucozonia. Shell subglobular and solid, of a bay colour, with white bands; the siphon is somewhat depressed. It is more than an inch long.

Spondylo. Shell subglobular and solid, chefnut colour, but beneath white; the siphon is blueish, throat with bands, one also on the back. Found in the island of Mauritius, and is rather large.

Rufa. Shell thin, rufous; umbilicus darker, with a white border; the back and base of the siphon have a white band on each, the throat with a reddish band; pillar with a brown filet.

Fulminea. Shell subglobular, with angular tawny lines, and flattened lobe. There are three varieties, found, though but rarely, in Africa. The shell is white or yellownish.

Stercus-Muscarum. Shell smooth, snowy, with rufous spots and siphons; the umbilicus is gibbous and bifold. It inhabits the Mediterranean and American seas; and is thought to be a variety of the N. cannera.

Orientalis. Shell subglobular, polished, very smooth, the siphon of the siphon a little wrinkled; the pillar is snowy. It is found in the Eastern seas. There are two varieties; the shell of the one is of a buff colour on each side, with a narrow white band in the middle; the other is entirely snowy.

Chrestata. Shell subglobular, white, with red spots and dots, the lip oblique and bluish, within blueish; umbilicus spiral.

Regosa. Shell wrinkled, within gibbous, pale tettaed, umbilicus bordered with white. It inhabits the American islands. The shell is covered with oblong, crowded wrinkles.

Marocchensis. Shell subglobular, smooth, light green, within brownish, and livid at the tip, a little wrinkled at the angle of the whorls. It is found in Africa. The shell is sometimes marked with feathered bands, the younger ones are thin and pellucid.

Sulcata. Shell subglobular, obliquely plated; siphon mucronate; umbilicus bifold. The siphon has four whorls.

Arachnidea. Shell white, reticulate, with reddish lines, and blackish at the tip; whorls convex; umbilicus nearly covered.

Vittata. Shell subglobular, brown, with a double white filet in the middle, reticulate and dentate on each side. This is an African shell.

Melanostoma. Shell thin, pellucid, smooth, oblong; the first whorl ventricose, flat, and very large, the others compressed; the umbilicus is half closed. There are five varieties of this species. It inhabits the Indian seas, and is two inches long.

* Pallidula. Shell semitransparent horn-colour, the whorls rather prominent; aperture semilunar, and very patent; the umbilicus is large. It inhabits the coast of Kent and Devon.

Papilla. Shell pellucid, thin, oblong, with decussate flukes; of a dirty yellow colour; the aperture is suboval; the pillar white, and the umbilicus half closed. It inhabits the shores of Tranquebar.

Clathrata. Shell depressed, ovate; transversely umbilicate, and longitudinally ribbed, the ribs flat, oblique, and semilunar; siphon papillary. Found in a fossile slate in Campania.

Valvata. Shell flattish, with a circinced aperture.
NERITA.

It inhabits the North seas; the inhabitant of the shell has two fleshy tentacula, bearing the eyes at the posterior angle.

Islandica. Shell globular, subacute, and rather thick; it has four whorls, separated by very deep grooves. It is found in the Northern seas.

Affinis. Shell globular, and rather thick, with a submucronate spine, and three whorls. It inhabits New Zealand, and is probably a Trochus; which see.

B. Imperforate, with toothless Lixis.

Species.

Corona. Whorls of the spine crowned with spines. It inhabits India and America, and is minute. The shell is sometimes blackish, with longer and shorter spines, thinly frigate.

Radula. Shell grooved, with equal tubercles. It inhabits the Indian islands, and is the size of a walnut.

Conoidea. Shell obtrumpeted. It inhabits the Red sea. The shell is fragile, brown, white, or pale violet, with longitudinal white or telfaceous bands.

* Fluvatilis. Shell rugged, spotted, streaked, or reticulate. There are four varieties that inhabit the rivers of Europe and Barbary; the shell of this species is not half an inch long.

* Littoralis. Shell smooth, with a circular crown, and four whorls. It inhabits the sea-rocks of Europe, and is the size of a horse-bean. The shell is yellow or ferruginous, with or without bands, spots, or dots of various colours.

* Loniceras. Shell smooth, horny or blackish, ending in an exquisitely fine point. It inhabits still waters, and the warm springs of Europe; it very much resembles the last named species, but is horny or blackish, and sometimes dotted with white.

Magdalenæ. Shell with wide grooves, black, but within white, the lip yellowish; the lid is smooth, and two-toothed. It inhabits the Magdalenæ island in the Southern ocean, and is more than half an inch long.

Marginata. Shell thin, with decurrent frizet, tuberculate, black, with ochraceous spots, subglobular; aperture margined outwardly.

Dumb. Shell thin, pellucid, ovate, polished, dull yellow, varied with black; outer lip acute, inner glabrous. This is a very rare shell, and its place of residence is not known.

* Pellucida. Shell smooth and pellucid, with three whorls. It is found on the coast of Pembrokeshire, and is very minute.

* Alba. Shell smooth, subpellucid, with two whorls. This is found, like the last, on the Pembrokeshire coast, and is very minute.

C. Imperforate, with Lixis toothed.

Species.

Pulligeræ. Shell smooth, coarse, with an excavated eye-like small spine; inner lip smooth, crenulated.

Undulata. Shell thin, smooth, undulate; crown obtuse; outer lip subfrizet and toothed; the inner one is a little denticulate.

Aterrima. Shell thick, opaque, globular, deep black with coloured lines, within white; outer lip glabrous, inner lip tuberculate, and wrinkled.

Larva. Shell smooth, subglobular, white, with yellowish-brown bands; the crown is obtuse; and the lip slightly denticulate. It is found at Amboina, though it is very rare.

Pupa. Shell smooth, roundish, milk-white, with transverse parallel black frizet on the whorls; the lip is flat, with hardly visible teeth.

Bident. Shell smooth; inner lip two-toothed. The shell is the size of a pea, and is either black or reddish, obtrumpeted, sometimes of a pale yellow, with whitish clouds, and three black bands.

Verris. Shell smooth and green; the inner lip is crenulate in the middle. It inhabits Minorca and Jamaica.

Virginiana. Shell smooth, ovate; inner lip denticulate. This is found in the rivers of India and South America, and is from two to ten lines long.

Polita. Shell smooth, with an obliterated crown; the lip is toothed on each side. There are four varieties, found in the Indian and South seas. The shell is ovate, solid, polished, variously ornamented with spots, clouds, and bands, or varied with black and white.

Peloronta. Shell frigate; lips toothed, the inner one flatish and wrinkled. It inhabits the American islands. It resembles the N. grotsa, but is of a red colour, the grooves are not so deep, the outer lip is not crenate, and the inner one not convex. See Groba farther on.

Albicilla. Shell frigate; lips slightly toothed, the inner one tuberculate. It is found in the Indian ocean, and on the shores of the Cape of Good Hope.

Histrio. Shell grooved and transversely frigate; inner lip toothed.

Placata. Shell grooved; lips toothed, the outer one with acute conic teeth on each side. This is found in divers parts of India.

Grossa. Shell grooved; lips toothed, the inner one convex and wrinkled. It is found about the Molucca islands. The shell is rounded, white, with black and cinereous veins; the crown is a little prominent; first whorl has thirteen or fourteen ribs; outer lip crenulate outwardly and toothed within; inner lip white, with a yellow spot, and three or four teeth.

Chameleos. Shell with twenty grooves; lips toothed, the inner one wrinkled and tuberculate. It inhabits the Indian ocean. The shell is varied with alternate, undulate, black and white rays, or yellowish, undulate with black and white, subglobular; the ribs are unequal, and croseted by very fine lines; the crown is depressed and lateral.

Undata. Shell with thirty grooves; lip toothed, the inner one wrinkled and tuberculate. It inhabits the Indian seas.

Exuvia. Shell groved; lips toothed; the inner one tuberculate. It is found on the Indian coasts.

Maxima. Shell solid, thick, glabrous, with undulate black and yellowish rays; outer lip toothed, inner one a little concave and four-toothed. The shell is very large, within and at the aperture flabby; inner lip smooth, and very broad.

Textilis. The shell of this species is marked with angular black lines, and sixteen crenate ribs and grooves; the outer lip is crenate without, and toothed within; inner lip wrinkled above and tuberculate beneath; the palate is toothed.

Artata. Shell deep black, glabrous, and very thinly frigate above; both lips white, the outer one very thinly grooved, and slightly toothed within, the inner one concave, wrinkled, and tuberculate. It inhabits the Atlantic, American, and South seas.

Ascensionis. Shell with sixteen grooves; the ribs are spotted with white, and the crown is a little prominent; the outer
NER

outer lip is glabrous on each side; and the inner one a little concave, yellowish, and toothed. It inhabits Ascension Island, hence its specific name; it is a larger species; the crown is generally worn down, rarely black; and the lid is thin and pellucid.

LINEATA. Mouth of the shell and both lips white; whorls round, surrounded with black parallel lines, the spaces between the frize 

VERSICOLO. Shell with blackish, blueish, red and white square spots, and bands spotted with red and white; the inner lip is fricate within, and toothed on each side. It inhabits the Antille islands. The shell is set round with whorls; the crown is a little prominent; inner lip wrinkled, with four-toothed beneath, the middle teeth larger.

FILA. Shell white, radiate with black without, with transverse, rounded, smooth frize; inner lip wrinkled, and four-toothed. This is found in the Indian seas. The crown is a little prominent; the outer lip crenate without, and fricate within.

COSTATA. Shell whitish within, subglobular, rounded with thicker frize; the interstices fuscous; both lips toothed, the outer one crenate without; inner one sub-convex, wrinkled and tuberculate. It inhabits the Nicobar islands.

QUADRICOLOR. Shell subovoid, with a whitish tip, within it is white, with elevated black frize; both lips toothed; the outer one grooved within, inner one wrinkled. It inhabits the Red seas. The shell has sometimes white lips, and is sometimes white within.

MACACCENSI.S Shell grooved, whitish within; crown a little prominent; outer lip unarmed and crenulate outwardly, inner lip whitish; smooth. This is found on the coast of Malacca.

ANTILLARUM. Shell subglobular, black, within it is whitish, grooved and fricate; the crown is obtuse; both lips are wrinkled and denticulate. This is a very common shell in the Antilles.

FLAMMEA. Shell subglobular, with crowded, transverse frize, white with purplish undulate rays; both lips toothed. There are two other varieties: the one shaded with red, the rays inclining to black; the other with bands partly livid, partly dotted with red. They are found in the American islands.

FULGURANS. Shell subglobular, with crowded transverse frize, deep black, with ochraceous rays; both lips lightly denticulate, the inner one tuberculate in the middle. It is found in the American islands.

TESSELLATA. Shell obtuse, transversely fricate, the frize are marked with nearly square white and black spots; both lips are denticulate. It is found in the several islands situated between Africa and America, and is of a middle size.

BEFACIATA. Shell blackish, with two grey bands; the crown is white. It inhabits India. It is uncertain to what sect it belongs.

LITHTERATA. Shell subglobular, white, with various characters; the inner lip is crenulate and toothed. A variety of this species is marked with bands composed of parallel lines. It inhabits India.

VIOACEA. Shell ovate, solid, smooth; it is of a violet colour, dotted with white; the inner tip is denticulate beneath. A variety is marked with chestnut spots, variegated with black. The shell is rarely red or whitish, sometimes dark grey or white.

SENEGALENSIS. Shell ovate, oblong, solid, and of a deep black colour, within it is white, grooved; both lips are toothed. This, as its specific name imports, is found in Senegal; an inch broad, and about half as wide.

PROMONTORI. Shell black, ovate, pointed; with thirty grooves. This is an African shell, is twice as broad as it is long, sometimes varied with white; the crown is composed of three whorls; the left lip is wrinkled.

TRICOLOR. Shell variegated red, black, and white; the first with fifteen elevated frize; both lips toothed. This is found in Africa.

PERVERSA. Shell surrounded with belts; spire con- trary; aperture eight-toothed. Hitherto it has been found in a foible slate only.

TURrita. Shell with alternate white and black bands, within white; crown very much elevated; the outer lip acute. This inhabits the Antille islands, in fresh waters.

ACULEATA. The shell is blackish, transversely fricate; the frize are flaminous; the inner lip is flatisht, smooth, and slightly toothed. It inhabits the rivers of India, and resembles the N. puligera above described.

Gen. Ch. Cal. Perianth inferior, minute, in five deep, acute, permanent segments, with small internal teeth. Cor. of one petal, falver-shaped; tube cylindrical, shorter than the limb; mouth inflated, crowned with five leaflets, cut into several narrow segments; limb large, in five deep, twilled, inequilateral, obtuse segments, without any appen- dage. Stam. Filaments five, aephal-shaped, short, inserted into the middle of the tube; anthers arrow-shaped, awned with long threads, cohering over the stigma. Pl. Germens two, superior, ovate; style one, common to both genders, thread-shaped, dilated at the top, the length of the tube; stigma at its base; seated on a small circular base. Peric. Follicles two, cylindrical, erect, long, pointed, burriling lengthwise. Seeds numerous, oblong, imbricated, each with a tufted crown.

Eff. Ch. Corolla salver-shaped, contorted; its mouth crowned with five divided leaflets. Anthers awned, coher- ing: Follicles two, erect. Seeds crowned with down. 1. N. Oleander. Common Rosebay. Linn. Sp. Pl. 303. Willd. n. 1. Ait. n. 1. Miller. Illustr. t. 12. (Nerium five Rhodendrum; Matth. Valgr. v. 2. 447. Duham. Arb. v. 2. t. 12. Ger. em. 1406.)—Leaves ribbed under- neath. Segments of the calyx prominent. Crown of the corolla with two flat cloven segments.—Native of Spain, Portugal, Italy, and the Levant, about the banks of ri- vulets, in low moist situations. Oriental travellers have, with great taste and probability, supposed this to be the bay-tree, to which the righteous man is compared by the royal psalmist. It was early introduced into our gardens, and is a hardy greenhouse shrub, flowering from June to October. In Italy it finitely decorates court-yards. The stem is arborescent, very much branched. Leaves three together, on short stalks, linear-lanceolate, acute, entire, smooth, coriaceous, evergreen, marked with numerous trans- verse ribs or veins beneath. Flowers numerous, terminal, corymbose, large and handsome, but inodorous. Usually of a rose-colour, occasionally white. There is also a much-admired double variety. Seed-vebels six inches long, ribbed, almost woody. One of the most beautiful of insects.
NER

Sphinx Nerii, feeds on this shrub, and is often taken on the coasts of Nice and Genoa.

2. N. odorum Sweet-scented Rosebay. Ait. Hort. Kew. ed. 1. v. 1. 297 ed. 2. v. 2. 67. Wildl. n. 2. (N. indicum angustifolium, floribos odoratus limbicibus; Herb. Lugd.-Bat. 447. t. 448; fl. plenis; t. 449. Tejoannae-arelii; Rheede Hort. Malab. v. 9. t. 1.)—Leaves ribbed underneath. Segments of the calyx erect. Crown of the corolla with numerous thread-shaped segments.—Native of the East Indies. Cultivated in Chelsea garden in 1683. Ait. It is kept in the house, flowering from June to August. During that time it will bear to hand in the window of a warm room, though much more tender than the former, from whose white flowers differ in the sweet almond-like scent, and paler hue, of its flowers, which have a yellow tinge in the middle, and a much-divided capitular crown.

3. N. falchium. Willow-leaved Rosebay. Vahl. Symb. v. 2. 45, Wildl. n. 3. (N. nn. 18. Ferk. /Egypt-Arab. 205.)—Leaves slightly veined beneath, obtuse.—Native of Arabia Felix.—A large tree, whose leaves are said by Forskall to resemble Salix fragilis.

Thee are all the species that Mr. Brown retains. N. zygianicum and antidyfericium of former authors constitute his Wrightia. He judges N. coronarium to be a Tabernemontana, and divaricatum to be the very same plant. N. obfum of Forskall and Vahl, (see as above,) is certainly no Nerium; perhaps a new genus.

NERIUM, in Gardening, comprehends plants of the evergreen, flowering, shrubby kind, of which the species cultivated are, the common rosebay, or oleander (N. oleander); the sweet-scented rosebay, or oleander (N. odorum); the oval-leaved rosebay (N. antidyfericium); and the broad-leaved rosebay (N. coronarium).

It may be remarked, that in warm dry summers the first fort makes a fine appearance, the flowers then opening in great plenty; but in cold moist feasons the flowers often decay without expidhing, unless the plants are placed in a greenhouse, or under a glass case. The variety with white flowers is the mock tender; but there are others, as the triple-leaved; the broad-leaved; double-flowered; the striped double-flowered, and with different shades of red, from purple to crimson or scarlet.

The second species has a variety with leaves, six inches long, and one inch broad in the middle, of a much thinner texture than those of the first, and their ends are generally reflexed; they are of a light green, and irregularly placed on the branches by pairs, alternately, or by threes; the flowers are produced in very large bunches at the end of the branches, upon long peduncles; they have three or four rows of petals one within another; they are much larger than those of the common fort, and fnmall like those of hawthorn; the plain flowers are of a soft red or peach colour; but in moist they are beautifully variegated with a deeper red, and make a fine appearance: the usual time of flowering is in July and August, but in a warm flower it will continue in flower till Michaelmas: from the flowers being double, they are not succeeded by seeds. They are all supposed to have a poisonous quality.

Method of Culture.—Thee different species and varieties of plants may be increased by layers, and suckers from the roots.

It is necessary that the layers should be made in the early spring months, as from March till May, but the earlier the better; the youngest lower branches being chosen for the purpose, which should be flat-layered, giving plenty of water during the summer, and they will be most rooted by the autumn following; but by plunging the pots in which they are laid in a bark hot-bed, their rooting may be greatly forwarded: when they are properly rooted, they may be taken off, and removed into separate pots for continuing.

But the cuttings should be planted in the spring, or the early part of summer, taking off the young shoots, five or six inches long, and planting them in large pots of rich mould, placing them under glasses, and giving water and shade occasionally: but, if plunged in a bark-bed, it will greatly promote and forward their rooting.

And the suckers arising from the bottom are sometimes furnished with roots; but when this is not the case, a small flit should be given at the lowest part; afterwards applying fresh mould around it, when fibres will be emitted by the root of furthers; they may then be taken off and potted separately in proper pots. With regard to the first fort and varieties, they are rather hardy; but should be kept cautiously in pots or tubs, to be protected through severe winters when necessary.

And the other sorts are often placed in the hot-house during winter, but when left tenderly treated, and supplied more freely with air in mild weather, they are faid by fome to succeed better, provided they be carefully screened from every effect of frost or severe cold.

These are very ornamental among other potted plants of fets tender kinds.

NERLI, Filippo, in Biography, an Italian historian, was born in 1485, and became a lector of the city of Florence. One of the fame names, and thought by fome to be the fame perfon, was governor of Modena for the church in 1526, and, attempting to return to Florence in 1527 with Guicciardini, was excluded from that city. He died in 1536. His work, entitled 'I Commentari de' Fatti civili occorsi nelle Città di Firenze del 1215 fino al 1537,' remained in manuscript till it was published in Florence in 1725.

NERO, Lucius Domitius, a Roman emperor, the son of Cneius Domitius Ahenobarbus, and Agrippina, the daughter of Germanicus, was born in the 37th year of the Christian era. Both his parents were notorious for the profligacy of their lives, and of this the father was so fnconscious, that he affirmed, at the birth of his fon, that, springing from such a flock, he must be a monfer born for some great public calamity. The favour of the people was mani- lated to him at his first appearance in the popular games, given by the emperor Claudius in the year 47. This emperor, having married Agrippina, adopted Nero, then only in his thirteenth year, as his successor, though he had a fon of his own. On the occasion, he received the names of Nero Claudius Caesar, and in the following year he assumed the toga virilis, was designated consul, and declared prince of the Roman youth. His marriage with Octavia, the emperor's daughter, took place in the year 53, and in the following year, the reigning emperor having been poisoned by his abandoned wife, Nero was raised to the throne. To Agrippina are to be attributed all the bad acts of the early part of his reign. His own conduct, as prompted by his tutor Seneca and governor Burrhus, appears to have been liberal and laudable, and his actions corresponded with the dicourages that were put into his mouth. Historians mention severall acts of clemency which are highly honourable to his memory, if they could be supposed to proceed from his own unbribed inclination. One of the earliest irregularities of this prince was an attachment to Ace, a freedwoman of a debauched character, who obtained a great ascendency over him, while he displayed the utmost aversion to his wife Octavia. His tutor indulged him in this passion, to keep him from more criminal amours, and his mother, finding
finding that her reproaches were of no avail, at length confined at his conduct. She, indeed, to keep her son in a state of dependence and subjection, affected to countenance the claims of Britannicus to the sovereignty, which led Nero to remove him out of his way by poison. The fatal dose was administered as he sat at table with the emperor, his wife, and mother. Its effects were instantaneously: he fell down speechless, and being carried out, very soon expired. After this he made an attack upon his mother's life. (See the article Achrippa.) The levity and turbulence of Nero's disposition were displayed in the amusements which he followed, of rambling about the streets disguised, by night, with a band of disorderly companions, robbing and abusing all that fell in their way, and carrying off all the pillage he could lay his hands on, which he fold the following day by auction in his palace. There was, in short, no species of brutality in which he did not delight; nevertheless, the public affairs of the empire were well managed during the first few years of his reign, and many salutary regulations took place at home and abroad. The senate was permitted to act freely on several occasions, and the political counsellors of the emperor were able and experienced. The Roman arms were successful in the East under the command of Corbulo, who subdued Armenia, and conferred its crown upon Tigranes. After the death of his mother, he plunged into a course of dissipate folly, that was highly derogatory to his rank: he exhibited his skill as a charioteer, and claimed public applause as an actor in the theatre. In the sixth year of his reign, he instituted games in imitation of those of Greece, which were at the same time gymnastic, musical, and equestrian. He named them Neronian games, and in his own person did dispense the prizes of eloquence and poetry, in which he obtained an easy victory, none venturing to give the palm to his competitors. In the year 62 he divorced his wife, whom he banished, and afterwards put to death, and took in her place Poppaea, a woman of distinguished beauty, but of truly infamous character. From this time, acts of cruelty and rapacity alone varied the scenes of indecent folly and abandoned debauchery, which constituted the habitual life of Nero. The terrible confederation of Rome in the year 64, is by Suetonius and Dio positively charged upon the emperor; but Tacitus expresses a doubt concerning its origin, and the probability is, that the fire was accidental. Nero was at Antium when it happened, but returned in time to see the palace in flames. He now opened his gardens, and caused flocks to be erected for the multitudes who were deprived of a home, and took measures to prevent a scarcity, and supply the wants of the people. The emperor might have gained credit upon the whole by this diffluence, had not the fulmination of his being its author still maintained its ground in the minds of the people. The method which he took to divert it has, perhaps, excited greater detestation of his memory than all his other enormities. He cauned the Christian to be accused as the incendiaries, and, without trial or inquiry, apprehended all whom he could discover in the city, and put them to death in the most horrible manner. This savage conduct, for which there was not the slightest pretence, has branded him most justly with the title of the first persecutor of the Christian church. In the re-edification of Rome, much attention was paid to order and convenience in the arrangement of streets, &c.; but, of all the new edifices, none could bear comparison with that which Nero constructed for his own residence, and which he denominated the "Golden Palace." This building was not more remarkable for the immense quantity of gold and other precious materials employed in its decoration, than for its magnitude. Nero, whose taste was entirely turned to the gigantic, and who enjoyed nothing but in proportion to its cost, laid, when it was finished, that he now began to be lodged like a man. His profusion of every kind rendered him always needy, and consequently rapacious; he plundered, without shame or remorse, every body, and the temples themselves were not sacred when his wants required their wealth. In the year 65, the people seemed weary of subjection to such a monster, and a conspiracy was formed against him; but it was discovered before the plan was executed, and much of the guilt blood in Rome was shed on the occasion. From this period Nero became fupicious of every human being, and placed no bounds to his cruelty: he mounted the public theatre at Rome, dispensed for the prizes of musician and actor, and inflicted cruel punishments on those who were tardy or careless in their applause. The death of his wife Poppaea was occasioned by a kick which she received from her husband while in a state of pregnancy. When his passion had subsided, his grief was excessive, of which he gave every demonstration in his power: he cauned her body to be embalmed in the Eastern manner, pronounced a funeral oration over her dead body, and burnt more perfumes at her obsequies than the annual produce of Arabia. A long and bloody list of executions, in which the victims were the least and greatest men of Rome, disfigured the annals of his subsequent years. These fanguinary scenes were contrived by the splendid ceremonial of Nero's conferring the crown of Armenia on Tiridates, in the presence of the Roman people, in which Oriental servility and Roman pride were equally conspicuous. The Greeks, about this period, sent a deputation to compliment Nero on his musical attainments, who gave him a favourable idea of their countrymen, that he determined on a tour into Greece. Carrying with him an immense train of persons attached to his theatrical establishment, he embarked for that country in the year 67, and before he left it solemnly proclaimed Greece free. This was, as he wished it to be understood, was counterbalanced by the pillages, confiscations, and murders, of which his visit was productive. To perpetuate his name, he undertook a project, often before conceived, but deferred through superflitious motives, viz., that of cutting across the isthmus which joins the Peloponnesus to the rest of Greece. The work had proceeded some length, when Nero was hastily recalled by the alarm of new conspiracies. On his return to Italy, he made triumphal entries into several towns, and a very splendid one into Rome, in which he is said to have displayed the most absurd vanity, although tooting on his throne, through the revolts of Vindex in Gaul, and of Galba in Spain. The latter, when he was made acquainted with its extent, particularly alarmed him, and though he was willing to make reparation, yet depair seems from the frist to have taken possession of his mind. Of all the reproaches heaped upon him, none made so deep an impression on his mind, as the title of a "paltry and contemptible musician," which Vindex bestowed on him. Upon entering the city, he convened a few of his creatures among the senate, and entertained them with a musical exhibition, instead of consulting them on the means of faying the state. At length the prætorian cohorts were detached from their allegiance by the perjuries of their prefect, and they proclaimed Galba emperor. Nero fled from Rome, and took refuge in the country-house of one of his freedmen. After his flight was known, he was declared a public enemy by the senate, and condemned to an ignominious end, such as was inflicted only on the vilest malefactors, viz to be dragged
Naked through the streets of Rome, and whipped to death; afterwards his body was to be thrown down from the Tarpeian rock. The execution of this sentence he prevented by a voluntary death. He pierced his throat with a poniard, but, being too irresolute effectually to perform the deed, his hand was aided by his secretary. As he was expiring, he begged that his head might not be cut off from his body, and exposed to the populace, but that the whole might be burnt on a funeral pile. This request was granted by one of Galba's freedmen, who performed the obsequies in the usual manner. This was in the 63d year of the Christian era, when he had attained to the age of 52, and after a reign of almost fourteen years. Rome was filled with acclamations at the intelligence. Their vengeance was not only exercised against the statues of the dead tyrant, but his friends were the objects of the public resentment. In him terminated the line of Augustus. Detestable as his memory has been in all ages, there were not wanting many in Rome among the people and soldiery, who, having benefited by his prodigality for several years, crowned his tomb with flowers, and cherished his name with fond regret. But such an attachment will not entitle him to credit for virtuous feelings, since it was the effacing of that levity of profusion which is always a vice in princes, and not unfrequently the parent of every other vice. In finishing the character of this emperor, it may be observed, that the name of Nero is even now, and will continue (so long as the facts of Roman history exist) to be used, to express a barbarous and unfeeling oppressor. Pliny calls him the common enemy of mankind, and in this he has been followed by all writers, who exhibit the savage tyrant as a pattern of the most execrable barbarity and unpardonable wantonness. Univer. Hist.

In the 63d year A.C. he mounted the stage himself at Naples as a public figure. This was his first appearance as a frottling minstrel. His second was in Greece, in 66, where, as we have seen, he pretended, in imitation of Flaminius, to restore to the Grecian states their ancient liberties. After entering the lists with common musicians at the Olympic games, and acquiring the prize of music by corrupting the judges or his competitors, he travelled through Greece, not prompted by the laudable curiosity of visiting the antiquities of that once celebrated country, but by the low ambition of displacing his skill in singing and playing upon the cithara. Here every where challenged the best performers, and, as may be imagined, was always declared victor. And that there might remain no memorials of other victors, he commanded all their statues to be pulled down, dragged through the streets, and to be either broken in pieces, or thrown into the common sewers.

At his return from Greece, he entered Naples, Antium, Albano, and Rome, through a breach in the wall of each city, as an Olympic victor, carrying with him in triumph, like spoils of an enemy, the prizes which he had extorted from the judges in musical contests; in the fame car in which kings used to be brought in triumph, who had been vanquished by Roman generals, and with the fame splendour, pomp, and solemnity, was Diodorus, a celebrated Greek performer on the cithara, with other eminent musicians, brought through the streets of Rome, leaving it doubtful which was the greater, the vanity of Nero in imagining himself superior to these proficient musicians, or their adulation in conferring themselves to have been vanquished by Nero. The sollicitude with which this emperor attended to his voice, was related by historians, curious, and will throw some light upon the practices of singers in different times. Suetonius informs us, that to prefer his voice, he used to lie upon his back, with a thin plate of lead upon his stomach; took frequent emetics and cathartics; and abstained from all kinds of fruit, and such meats as were thought to be prejudicial to fingers; and, at length, from the apprehension of hurting his voice, he ceased to harangue the soldiery or senate, contenting himself with inflaming his orders in writing, or by the mouth of some of his friends or freedmen. After his return from Greece, he established about his perforn a phonatus, or officer, to take care of his voice; he would never speak but in the presence of this vocal governor, who was first to admonish him, when he spoke too loud, or strained his voice; and afterwards, if the emperor, transported by some sudden emotion, did not listen to his remonstrances, he was to flop his mouth with a napkin. The most effectual means of acquiring his favour was to commend his voice, which, according to Suetonius, was both thin and husky; to pretend raptures while he sung, and to appear dejected and very important, if, like many other fingers, through caprice he deflected from doing what he himself most ardently defined.

Encouraged by the applause of the multitude, he appeared almost every day on the stage, inviting not only the senators and knights, but the whole populace and rabble of Rome, to hear him, generally in the theatre which he had built in his own palace. He frequently detained the audience not only the whole day, but the whole night; for till he was tired himself and defiled, no one was on any account suffered to depart; so that women are said to have been delivered in the theatre, and several perforns were so tired and disfigured with the performance, that, finding the gates of the palace shut, they either leaped over the walls at the hazard of their lives, or counterfeited death, in order to be carried out to their funeral. Some, by continuing night and day in the same posture, were seized with mortal distempers; these, however, they dreaded less than the repentment of the prince, which they would have unavoidably incurred by their absence. Besides the great number of secret observers employed to watch the countenances and behaviour of the audience, there were many open spies, who publicly set down the names and fashion as discovered the least symptoms of dissatisfaction: the vulgar were instantly punished by the soldiery for the least inattention; and upon perforns of rank, the vengeance of the emperor was vented in a still more dreadful manner. Vespasian, afterwards emperor, greatly provoked the anger of Nero, by escaping from the theatre during the time of performance; however, fearing the consequences of the offence which he had given, he returned, in order to make reparation; but, unfortunately falling asleep while the emperor was singing, this male failure was so enraged at his inattention, that he would have cost him his life, if his friends, men of the highest rank and merit, had not employed their prayers and mediation in his behalf.

NERONDE, in Geography, a town of France, in the department of the Loire, and chief place of a canton, in the district of Roanne. The place contains 1804, and the canton 8140 inhabitants, on a territory of 170 kilometres, in 10 communes.

NERONDES, a town of France, in the department of the Cher, and chief place of a canton, in the district of St. Amand; 17 miles E.S.E. of Bourges. The place contains 1417, and the canton 8265 inhabitants, on a territory of 207½ kilometres, in 13 communes.

NERSHIS, a town of Sweden, in Estf Bothnia; 10 miles N. of Christinablad.

NERSHINSK. See NERUTINSK.

NERSHCHN, a town of the duchy of Courland; 18 miles S.S.W. of Saulburg.
NERTCHINA, or NERTSHA, a river of Russia, which runs into the Amoor, near Nertchink.

NERTCHINSK, or NERTSHINSK, a city of Russia, in the government of Irkutsk, seated on the Nertcha, at its junction with the Amur or Amoor, built in the year 1658, on the borders of China. It took its name from a fort, and contains, besides some public edifices, 150 houses of mean structure. The Chinese caravans formerly paffed through this town, but they have of late taken a different route. However, the Russian envoys are still received and entertained by the Chinese, and those of China are treated in the same manner by the Russians, in this town. The adjacent country, though mountainous, yields excellent pasturage for cattle. In the vicinity of this town are considerable mines. N. lat. 51° 12'. E. long. 116° 44'.

NERTERIA, in Botany, derived from viginti, inferior, or lowly, in allusion to the humble and prolific growth of the plant. This genus was fent by Mutis to Linnaeus, under the name of Gomezia; but the latter, from an error in reading the manuscript, called it, in his Supplementum, Gomozia. The classical appellation therefore, bestowed on it by Solander and Gertner, is of course to be preferred. Indeed Gomozia would be hardly allowable, since no mention is made of its derivation in the manuscripts of Mutis, nor is any botanist of that name known. The genus is mostly allied to Maxtria. Sm. Plant. Ic. v. 28. Willd. Sp. Pl. v. 1705. Mart. Mill. Dicit. v. 3. (Nertera; Soland. MSS. Gerto. t. 26. Schreb. 821. Gomozia; Mutis. MSS. Gomozia; Linn. Suppl. 17. Julf. 198. Lamarck Illustr. t. 87.)—Clafs and order, Tetraandria Monogynia. Nat. Ord. Rubiaceae; Jull.

Gen. Ch. Cal. Perianth none, according to Mutis, except a very small, flightly four-toothed border to the germin. Cor. of one petal, funnel-shaped; tube gradually enlarging, short; limb cloven into four, acute, reflexed segments, shorter than the tube. Stam. Filaments four, equal, inserted at the base of the tube, thread-shaped, nearly erect, the length of the corolla; anthers oblong, two-lobed, erect, yellow. Pjft. Germin inferior, oval, slightly compressed, smooth; stylos two, adhering at the base, thread-shaped, smooth, as long as the flower; filaments acute, reflexed, divided. Pirc. Berry globose, unbillibrated with a small dot at the top, of two cells, succulent, very smooth, red, the size of a pea. Seeds two, oblong, flat on one side, convex on the other.

1. N. depolfa. Sm. Plant. Ic. v. 28. Willd. (Gomozia Granadenedis; Linn. Suppl. 129.)—Mutis observed this plant very frequently in wet and marshy situations at New Granada. It is also a native of New Zealand, according to Forth Prod. 8g. Root fibrous, annual. Stems herbaceous, procumbent, throwing out roots at the joints, branched, leafy, thread-shaped, somewhat angular, smooth. Branches axillary, opposite, erect, single-flowered, short. Leaves opposite, tallked, heart-shaped, roundish, rather oblong, entire, smooth; ifoie of the stem spreading, those of the branches more erect, or close-presses; flacks roundish, furrowed above, nearly as long as the leaves. Flowers foliary, at the tops of the branches, fife, pale-coloured.

NERTHINSKOI MOUNTAINS, otherwise called the mountains of Daouria, mountains of Ruffia, which extend from the Beikal and the fources of the Selenga and the Amoor, down the two sides of thee rivers; on the one side as far as where the Argoon falls into the Amoor, and on the other side up to the heads of the Niufa and the Oldclock, where it annexes itself to the fipuous range of Okhotz, or Krebet Stanovi. It consequently includes the whole space between the Selenga and the Argoon, takes the fame direction with the courfe of the Amoor and the Ingoa from W. to N.E. and runs due south from the Mongole under the name of Yabloko-Krebet, or Apple-mountain. It has its greatest elevations about the origin of the Amoor and the Ingoa, where it contains of very rugged granite tops, high and steep. Between the course of the Ingoa and the sources of the Khilok and Vitim it is much smaller, notwithstanding which it seems to stand very high. It here forms a ridge, partly uniform in its progress, woody, and well-watered, and contains for the most part of pure crumbled granite. The part of this range included by the Amoor and Argoon is properly called the Nerthinskoi chain of ore-mountains, and is found to be the richest in minerals of any of the mountains hitherto explored in these regions. It produces beautiful kinds of granite, porphyry, jasper, a great quantity of chalcedonies, carnelians, onyx, agate, hornstone, large smoky topazes, aqua marine, hyacinth, and topaz-coloured schorl, genuine topaz and beryl, &c.; granites, fine feldspar gneissus, serpentine, albustus, nephrites, chlorite, flate, gyptum, excellent fteffifer fpar; falt-lakes, vitriol-pyrites, alum-ore, native fulfur, coal, warm fprings, and numerous markable mines, iron, copper, and a remarkable quantity of lead-ore, containing silver and gold, of which, since the commencement of the fift century, a great many mines have been opened, and of which several are still in full work. These regions also prevalent numerous forests. The trees are pinus sylvestris, larch, birch, firs, cedars, &c. The principal rivers here are the Selenga, the Khilok, the Vitim, the Olekma, the Kairanga, the Niufa, the Oldekon, the Onon, the Ingoa, the Amoor, the Argoon, &c. &c. Tooke's View of the Ruff. Emp. vol. 1.

NERVA, COCELEUS, in Geography, a Roman emperor, descended from a Cretan family, that had become Roman in the time of Augustus, was born in the year 26 of the Christian era, and being fon, grandson, and great-grandson of consuls, entered with great success the career of civil dignities. He was prince when Nero conferred upon him triumphal honours. He was conful for the first time in the year 71, with the emperor Vespasian, and afterwards with Domitian in 90. The confpirators who had formed their plans for freeing the empire from the tyranny of Domitian applied to Nerva, who was at that time at Rome, to undertake the duties and office of emperor; to this he consented, and was accordingly raised to the imperial purple in the year 96. The praetorian band had been secured in his favour, and the Senate was happy to confirm the elevation of one of their own body, whom they highly respected. He soon rendered himself extremely popular by the mildness of his manners, and by the activity which he exhibited in the management of public affairs. The frift cares of his government were to repair the evils of the late tyranny; he abolished the odious law of trefon, and recalled the exiles, among whom were some of the most virtuous persons of the age. He restored to the enjoyment of their property those who had been the objects of unjust confipations, and punished with death the freedmen and slaves whose informations had caused the ruin of their masters. He suffered no statues to be razed to his own honour, and he applied to the use of the government all the gold and silver statues which had been erected to his predecessor. In himself he was the example as well as the patron of morals and ftrict virtue. He forbid the mutilation of male children. He made a solemn declaration that no senator should be put to death during his reign, which he observed with fuch fanftity, that, when two...
members of the senate had conspired against his own life, he was satisfied to tell them he was well acquainted with their evil intentions. He also conducted the very men to the public spectacles, and feared himself between them, and when a sword was offered to him according to the usual customs, he defended the conspirators to try it upon his body. Such confidence in the uprightness of his own intentions, and justice of his government, and such reliance upon the consequences of his lenity and indulgence, conciliated the affections of all his subjects. It was the spirit of his administration, to govern that he might render a good account of his actions, and return without apprehension to a private station. In some instances it must be admitted that his lenity, or perhaps timidity, forced him into disgraceful compliances. One of these was the reformation of licentious pantomimes, which Domitian had abolished, but which the people demanded with tumultuous shouts: another was the giving up the authors of the death of Domitian, who were, in fact, the instruments of his own elevation. It was in vain that he presented his own bare neck to the enraged soldiery, and entreated them rather to fatiate their vengeance on himself; he was obliged to consent to the sacrifice, and even to feem to approve it. The mortifying incident, however, was the cause of a great public benefit, for it produced the adoption of Trajan. Made felice of the necessity of a firm support to the throne, he passed by his own kindreds, and selected for his son, and successor, the man, in all the empire, best fitted for the high office. Had this choice been the only act of his reign, it would have entitled him to the remembrance of his subjects. (See Trajan.) He died in the year 98, after a reign of sixteen months, and at the age of 72.

Nerva has been charged with an impietate love and use of wine, and, perhaps, to have enjoyed the favour of Nero and Domitian may lead to a suspicion of the regularity of his morals, but his public virtues have deservedly placed him in the series of those good princes who have been respected and honoured by posterity. Tacitus speaks of Nerva as being the first person whom all the people before thought to be incompatible, viz. monarchy and liberty.

NERVA, in Anatomy and Physiology, is a solid chord of a round or flattened figure, sometimes fibrous; composed of a soft white or medullary substance, and a peculiar membrane; connected either immediately or remotely with the brain, spinal marrow, or certain small bodies called ganglia; and forming the instrument by which external objects act on the brain, by which the latter organ influences the voluntary muscles, and by which the involuntary organs and the brain or ganglia exert whatever influence they may possess on each other. The same term was applied by the older anatomists to the ligaments and tendons. See Nervous System.

NERVE, Capillaments of the. See Capillaments.

Nerves, Ganglion of the. See Ganglion.

Nerves Microscopically examined. Mr. Leeuwenhoek endeавoured by his microscope to discover the structure of the nerves in the spinal marrow of an ox; he saw there with great delight, minute hollow vesicles of an inconceivable firmness, invested with their proper membrane, and running out in length parallel to one another, and making up their composition; and though some hundreds of these vesicles go to the formation of the least nerve that can be imagined, he not only discerned the cavities in them, which he computed to be three times less than their diameters, but in some perceived the orifices as plainly as the holes in a pricked paper are to be seen when looked at against the sun. It requires, however, great dexterity and expedition to make this examination with success; for after a thin slice of the spinal marrow is placed before the microscope, in less than a minute’s time it becomes dry, and the whole appearance vanishes.

Baker’s Microscope, p. 145.

Nerves, in Architecture, denote the mouldings of projecting arches of vaults, or those arising from the branches of ogives, and crossing each other diagonally in Gothic vaults; serving to separate the pendentives. Nerves, in Botany, are long tough fibres, running either across, or lengthwise of the leaves of plants.

NERVI, in Geography, a town of Genoa; five miles E.S.E. of Genoa.

Nervines. See Neuritics.

NERUKA, in Geography, a port in the island of Cape Breton, where the French had a settlement.

NERVOSA CORPORA, in Anatomy. See Cavernosa Corpora.

NERVOSUM FOLIUM, in Botany, a leaf furnished with more than one longitudinal nerve, or rib; see Costa and Costatum.

NERVOUS COLIC. See Colic.

Nervous Disaffets, are those diseases which appear to arise independently of any organic change of structure, and are, therefore, ascribed to some indefinite derangement of the sensible and irritable powers of the animal frame, of which the brain and nervous system are the seat and channels of communication. Hence the epithet nervous is applied to all cramps and spasmodic pains, which, in fact, consist of inordinate and involuntary contractions of muscular parts; in all uncertain sensations, especially when they move from part to part, and have no determinate seat; to great depression or remarkable variations of the spirit; and especially to the tremors, fears, and anxieties, which accompany that depression of mind. Now these various symptoms, together with certain partial or general convulsive paroxysms, flatulence, globus hystericus, &c. which are commonly present, in persons of delicate constitution, in different degrees and combinations, when the stomach, or bowels, or the secretion of bile, happen to be disordered, or when some other important vicera are in a state of debility, as the uterus in women, have been mostly classed together under the appellation of Hysteria, Hypochondriasis, Indigestion, &c. under which articles an ample account of their nature and method of cure will be found.

It is worthy of observation, however, that this term, nervous disease, ought not to be taken in a literal sense; inasmuch as the nerves are not in fact the seat of any disease in these cases: on the contrary, there is usually some local disorder, most frequently in the organs of digestion, with which these general or nervous symptoms are connected. Hence it has been the fashion with some medical men to denominate them, with almost equal impropriety, bilious diseases. The treatment, however, which is suggested by the latter appellation, namely, the regulation of the bowels, is useful and proper: while the nervous or nervous medicines, as they have been called, which consist chiefly of stimulating andspiritious drugs, although they afford a temporary relief to the sensations of the patient, contribute nothing to the ultimate cure; but, on the contrary, undermine the strength of the constitution, and of the digestive organs in particular, and thus rivet, as it were, in the habit, the very evils which they are expected to cure. The "nervous cordis," and other empirical nostrums, which are sold under various names, are all spiritious liquors, tinctured with some grateful aromatic; in other words medicated drinks, which have not only contributed to injure the health, which they were taken with a view to improve, but also to convert many persons who were sober into dram-drinkers, by inducing them to take, under the
the name of medicine, what they would have been ashamed to swallow if undisguised. Too much caution cannot be recommended, in cases of nervous disorder, against the habitual use of what are called cordials.

Nervous Fever. See Fever, Nervous.

Nervous Fluid, Spirits, or Juices, hypothetical terms employed by the older pathologists, in order to express the medium of motion and sensation, as supposed to exist in the nervous system. It has been a common and almost universal error among philosophers, when they had traced certain phenomena up to certain material agents, the mode of action of which they were unable to comprehend, to invent some intermediate invisible agent, (generally a spirit, ether, or other fluid,) which they imagined was the organ of communication and connection between the visible agents. Thus the principle of gravitation, of electricity, &c. has been supposed to be an ethereal fluid, the framers of these hypotheses falsely imagining that they had acquired some new knowledge, when they had merely interposed some unmeaning words. A familiar hypothetical fluid was referred to, when the nervous chords and fibres, every where distributed through the animal frame, were discovered to be the channels of communication between the common senhorium and the extreme parts, the messengers of volition to the muscles, and the conveyers of sensation to the brain. We are obliged, from the poverty of language, to use these mechanical terms in speaking of the nervous system. But the mode of communication is peculiar and inarticulate; and we are concerned only with the fact. A more accurate anatomy has demonstrated that the nerves are not tubes and hollow canals, and therefore are not calculated for the transmiiion of any fluid; and a more accurate philosophy has taught us, not to interpose an imaginary agent, where we have no evidence of its existence, and where, if it were present, it could not enable us to understand, or to explain more satisfactorily, the phenomena which we observe. All considerations respecting a nervous fluid are, therefore, jutly discarded by modern physiologists and pathologists. See Nervous System.

Nervous Parts, Content of the. See Nervous System.

Nervous Spirit, or Juices, denotes a pure, subtle, volatile humour, better known by the name of animal spirits; secreted from the arterial blood in the cortical part of the brain, collected in the medulla oblongata, and thence driven by the force of the heart into the cavities of the nerves; to be conveyed by them throughout the body, for the purposes of sensation and animal motion.

Gall, Wharton, and Willis, first mentioned the nervous juice; but many of our modern physicians deny the existence of this juice. See Animal Spirits.

Nervous System, in Anatomy and Physiology. Under this expression are included the organs contained in the cavity of the cranium, or, in common language, the brain; the medulla spinalis; and the nerves, whatever of the kind that are connected to either of the two organs just mentioned, or those which are furnished with ganglia. A short account of the structure and functions of these parts is given under the word Brain: it will be the object of the present article to supply what has not been inferred there concerning the structure and functions of the nervous system, and to give a description of the ramifications of the nerves.

"The use of the senses in making us acquainted with the external world, volition and all its effects on the muscles, all the operations of the mind, our instincts, properties, and passions, and even the distinguishing characters of humanity, depend entirely on the nervous system, so that without it all nature would be in a manner dead and incapable of enjoyment, because we could not conceive the existence of any perception or idea under such a state. Without the physiology of the nervous system, neither psychology, nor any kind of philosophy can exist. If we consider further, that teachers, moralists, legislators, and judges cannot, without falling into error, overlook the influence of organisation on our propensities, passions, talents, and actions, we shall soon be convinced that there can be no object of greater, more general and permanent interest to all the educated classes of society. In animals of complicated organisation almost all the functions are more or less influenced by the nerves. Digestion, nutrition, the secretions and excretions, circulation, respiration, &c. are disordered or stopped when the nerves belonging to the different organs are compressed, injured, or divided. If the spinal marrow, or the nerves, which are the conductors of sensation and voluntary motion, are compressed or divided, all motion and sensation ceases in the parts below the injury. A fluid extravasated in the brain, or any kind of pressure on that organ, paralyses more or less completely the whole body, or the opposite side of the body to that on which the brain has been injured, and extinguishes in various degrees consciousness and the faculty of thinking. The more the influence of the nerves is weakened, the more easily are chemical and physical changes carried on in the body." Gall, Anat. et Physiol. du Syst. Nerveux, p. 12.

The brain has been regarded, in all ages, as the material instrument of the sentient and thinking principle; and the nerves are undoubtedly the medium through which the mind and external objects reciprocally influence each other. The anatomist and physiologist have always bestowed on the nervous system a degree of attention proportioned to the importance of the functions which it executes. The brain, in particular, has been its favourite study. By dissecting this part, they have hoped to solve the interesting problem of the connection between our organisation and the imaginary immaterial principle supposed to regulate its motions; and to develop the mysteries of sensation and of the various mental operations. Hitherto these expectations have not been realised. The extremely complicated structure of the encephalon has been represented with unrivalled beauty and accuracy, and described most clearly and elegantly by Vicq d'Azyr. His work, which is a splendid monument of the arts, confides entirely of anatomical details. The size, figure, connection, and structure of all parts in the brain, are unfolded with the greatest fidelity; but their uses receive no illustration. The labours of Soemmerring, the most accomplished of modern anatomists, who, like Vicq d'Azyr, has chiefly employed himself in investigating the contents of the cranium, have not been more successful in determining the uses of the different parts of the brain. Undismayed by the repeated failures of their predecessors, two German anatomists, Meck, and Spurzheim, have applied with unrestrained ardour to this interesting subject. They claim the merit of many new discoveries in the anatomy of the brain; they have founded certain physiological opinions on these; and have even attempted to draw a connection between certain points of structure and the moral and intellectual dispositions of individuals. The first of these gentlemen has attracted much notice of late years by the opinions delivered in his lectures in the principal cities of Europe. (See the article CRANIOLGY.) After confining himself for a long time to the oral promulgation of his doctrines, he at last submitted his alleged discoveries concerning the anatomy of the brain, to the final scientific tribunal in Europe, the French National Institute; and as they involve much minute anatomical detail, the account was very properly referred, for examination,
NERVOUS SYSTEM.

amination, by this learned body, to five of their own members, the most distinguished for their proficiency in anatomical science. Gall and Spurzheim dissected the brain in the presence of the commissioners of the National Institute, Meffro, Tenon, Portal, Sabatier, Pinel, and Cuvier, and gave the most ample explanations of their peculiar opinions. The dissections were repeated by these gentlemen, and the result of their investigations is contained in a report, of which an English translation was published in the Edinburgh Medical and Surgical Journal, January 1809, under the following title, "Report on a Memoir of Drs. Gall and Spurzheim, relative to the anatomy of the brain, by Meffro, Tenon, Portal, Sabatier, Pinel, and Cuvier, presented to, and adopted by, the classes of mathematical and physical sciences of the National Institute." The German anatomists have since published, on the same subject, "Recherches sur le système nerveux en général, et sur celui du cerveau en particulier; mémoire présenté à l'Institut de France, le 14 Mars, 1808; suivi d'observations sur le rapport qui en a été fait à cette compagnie par les commissaires, 4to. 1809."

This work was not designed to contain a development of all Gall's opinions: it is occupied almost entirely with anatomical details. He proposes to deliver the result of all his researches into the structure and functions of the nervous system in all animals, in a large work, with very numerous plates, of which one volume has been already completed, under the title "Anatomie et physiologie du système nerveux en général, et du cerveau en particulier, avec des observations sur la possibilité de reconnaître plusieurs dispositions intellectuelles et morales de l'homme, et des animaux, par la configuration de leurs têtes. Premier volume, Anat. et physiol. du fyl. nerveux en general, et du cerveau en particulier," Paris 4to., with atlas in folio. All these publications are subsequent in date to the time when the article Brain of this Encyclopædia was written, the doctrines delivered in them could not then be noticed.

The opinions of Gall with regard to the structure of the nervous system, and more particularly of the brain, totally change the common ideas and modes of investigating the subject. We should observe here, however, that he does not pretend to have discovered many new facts; the chief merit that he claims, consists in the connection that he has been the first to establish between known facts, and in the general conclusions which he has deduced from them. His doctrines concerning the special functions of different parts of the brain is in many respects new, ingenious, and important. Its intent is to prove, that there are in man and animals innate qualities and dispositions, connected with certain organs situated in the brain; that the brain is not so much the general organ of animal life, as the place in which the individual organs are collected, each innate quality having its special organ; that these organs threw themselves on the surface of the brain, and form eminences marked by corresponding expansions of the cranium; and that, from an observance of these facts, we may, under certain limitations, determine the existence of such organs, in a greater or less degree of development, answering to the greater or less degree of energy, in the intellectual or moral disposition with which they are connected. Its merit must rest on the number and importance of the facts which can be brought forward for its support. We cannot enter on this part of the subject, as the volume which is to contain Gall's detailed account of these matters is not yet before the public.

Opinions of Gall and Spurzheim concerning the medullary and cortical Substances.—Of the two substances, which compose the nervous system, commonly called the cortical and medullary, Gall and Spurzheim have taken a view somewhat different from the common one. They object very strongly to the term medullary, as implying a soft and pulpy texture in what they consider to be essentially fibrous. They regard the cineritious fibres as the source or origin of the white or fibrous matter. Their opinions on this subject may be collected from a series of anatomical corollaries appended to the second section of their great work. 1. The whole of the nervous system contains only two substances: one of these is pulpy or gelatinous, and generally grey-coloured, but it may be reddish, yellowish, &c.; the other is white and fibrous: consequently there is no such thing as a medullary matter. 2. The grey gelatinous matter engenders or produces the nervous fibres, that is, the matrix of these fibres. Wherever it exists, they are produced; and it exists, wherever they are produced. Whenever a medullary bundle crosses cineritious matter, it is enlarged by filaments received from the latter; and none of these bundles enlarge without the concurrence of this matter, whether it form a fenible enlargement, or only follow and accompany the medullary bundle. 3. The more abundant the gelatinous substance, the more nervous filaments are produced: consequently, the grey matter and the number of nerves are in a direct and reciprocal ratio to each other. 4. No nerve arises from another nerve; but each has its origin in a peculiar mass of gelatinous substance: consequently the nervous filaments of the cheek and abdomen cannot be derived from each other, nor from the brain, nor the spinal marrow. These anatomists regard the cortical matter as the name on the outside of the cerebrum and cerebellum, in the interior of these organs, and of the medulla oblongata, and in the ganglia and plexuses of nerves. They extend the analogy still further, and observe that 'the cineritious matter, and consequently the ganglia, may be compared to the mucous expansion, which covers all the extremities of the nerves of the skin, of the intestines, and even the pulp of the labyrinth, and the root of mucous varnish which covers the retina.' That the massies of cineritious matter, dispersed in the interior of the encephalon and spinal marrow, possest an identity of properties and functions with that which covers the surface of the cerebrum and cerebellum, is possible, nay perhaps even probable; for the sensible characters of the fibres are nearly the same. But we see no direct argument in proof of this point. We should hesitate still more in admitting the comparison between the parts just mentioned and the nervous ganglia. Anatomy detects great differences in their texture; and we are equally ignorant of the properties and functions of both. If we cannot acquiesce in those propositions, what shall we say when the cortical matter of the brain, and the substance of nervous ganglia, are pronounced to be the same in structure and office with the retina and membrane of the labyrinth, with the rete mucosum of the skin, and the lining of the alimentary canal? "Here, it has been truly observed, there can only be with respect to structure, texture, in short, physical nature, a resemblance purely hypothetical. In the absence of proofs derived from direct examination, this comparison could only be justified by some resemblance in the functions and mode of existence during life: but where do these appear?" The function assigned to the cortical matter, as far as we can understand the meaning of the phrases in which it is conveyed, does not seem to differ essentially from the old opinion, which supposes the medulla to be secreted from the cortex. Befide calling the latter the matrix of the medullary fibres, these are said to arise from and to be increased or reinforced (renforcé) by the cortical matter. If the origin of the medulla from the cortex mean anything more than the fact of connection, we object
ject to it on the grounds already stated. The notion of one part being produced by the other, is not supported by one fact or argument, and is not more probable, in our opinion, than that the skin should secrete the subjacent cellular substance or muscles. Our observations on the brain, in the early stages of fetal existence, threw that the two substances are coeval, and that the cortex enjoys no priority of formation to the medulla. Why should the latter posse numerous vessels, but for the purposes of its own growth and nutrition? And by what possible stretch of figuration can it be even imagined, that the medullary matter of the nerves in general is secrete, or in any way produced by the cortex?

General Summary of the Opinions of Gall and Spurzheim.—The commissioners of the Institute reduced to ten articles what they conceived to be the peculiar views of these anatomists, who acknowledged that they contain a true expression of their doctrine. We extract these as the most certain way to avoid misrepresentation.

1. The cincerelyous matter is the matrix of the medullary filaments; wherever it exists, these filaments are produced; it exists, wherever they are produced. Whenever a medullary bundle crosses cincerelyous matter, it is enlarged by filaments received from the latter; and none of those bundles enlarge without the concurrence of this matter, whether it form a sensible enlargement, or only follow and accompany the medullary bundle.

2. The spinal marrow is not a bundle of nerves descending from the brain. The spinal nerves arise by filaments, some of which ascend, others descend; this is observed especially in brute animals. The cincerelyous matter of the internal part of the spinal marrow is the matrix of their filaments; the spinal marrow swells whenever it gives off a pair of nerves; and the more, the larger the nerves are. Thus the spinal marrow of the larger animals, as well as that of insects and worms with red blood, is only a series of ganglia, which give off nerves; but all those ganglia communicate with each other.

3. The nerves commonly called cerebral, and which arise from the under part of the encephalon, and chiefly from the medulla oblongata, do not come from the brain any more than the others: on the contrary, when we follow separately the roots of each of them into the substance of the medulla oblongata, we see that they re-ascend from the medulla towards the point where they appear externally, and that they do not descend from the brain, to pass through the medulla oblongata.

4. The brain and cerebellum are themselves only developments of bundles, which have come from the medulla oblongata in the same manner as the nerves proceed from it. The brain, in particular, arises principally from the bundles called pyramidal eminences, which cross each other in passing out of the medulla oblongata, each going to the opposite side to that from which it comes. They swell out first in crossing the pons Varolii, again in passing through the tubercles called thalamo optic, and a third time in the corpora striata; always from the addition of medullary filaments, which the cincerelyous matter, contained in these three parts, adds to those originally contained of. The cerebellum comes from bundles called pro-eminiscs cerebelli ad medullam, or corpora retiforma, which receive an addition of filaments, once only from the cincerelyous matter of what is called the corpus ciliare.

5. Each of these two pairs of bundles, after receiving the additions just described, and having consequently afforded a diverging direction, terminates in two large expansions, covered externally by cincerelyous matter, which only here defers the name of cortical substance; and these expansions, folded in various ways, form what are called the hemispheres of the brain, the lobes, and the vermiform processes of the cerebellum.

6. From the whole extent of these expansions other medullary filaments are produced, which converge from the two sides of the brain and cerebellum towards the middle line, where the filaments of one side unite with those of the other, and form what are called the commissures. The corpus callosum, the fornix and its appendages, form the largest of the commissures of the brain; the anterior commissure is that which joins the middle lobes. The commissure of the cerebellum is composed of the transverse layers of the pons Varolii.

7. When we remove or lacerate the converging fibres which go to the corpus callosum, and which serve as ceiling to the lateral ventricles, there only remains, under the cincerelyous substance, a medullary part, lining it, and following all its folds. Each convolution of the brain and cerebellum, instead of forming a solid mass, as anatomists have hitherto supposed, contains in its middle a solution of continuity; and, by employing proper care, we may unfold this portion of the medulla, as we might unfold the cincerelyous substance, if it were alone. In a word, each convolution is a kind of small pure or canal, closed externally by a double layer of cincerelyous and medullary matter, and towards the ventricles by the converging medullary fibres.

8. As the pairs of bundles forming the brain and cerebellum have their commissures, those which form the nerves have often theirs also, which may very easily be demonstrated in the second, fourth, fifth, and seventh pairs, and very probably in the others.

9. The ganglia spread over the whole body are small masses of cincerelyous matter, which certain nerves pass through, and by which they are strengthened, as the pedunculi of the brain are increased in the thalami optic and corpora striata. These two pairs of tubercles, then, are true ganglia to thepedunculi. The cincerelyous matter of the cortical part of the brain and cerebellum may likewise be regarded as a ganglion of the commissures or converging fibres. That of the inner part of the spinal marrow forms, in like manner, the primary ganglia of the spinal nerves. The cerebral nerves have probably each of them a particular ganglion and it is easy to demonstrate it in several of them.

10. The cincerelyous matter, and consequently the ganglia, may therefore be compared to the mucous expansion, which covers all the extremities of the nerves of the skin, of the intestines, and even the pulp of the labium, and the fork of mucous varnish which covers the retina.

11. From these nine articles, all merely anatomical, all more or less susceptible of being verified, a tenth result, which completes and is the essential character of the doctrine of Gall and Spurzheim; viz. that each pair of nerves forms a particular system; that all these systems communicate together, and reunite in the great chord of the medulla oblongata and spinal marrow; and, lastly, that the brain and cerebellum, far from being the origin and source of this chord, are, on the contrary, an appendix or port of diverticulum, referred for certain functions, but receiving an influence from all the parts of the chord, and exerting one upon them by means of their communications."

The notions entertained by these anatomists on the nervous system in general, are at variance with those commonly received; and more particularly with the common opinions concerning the identity of origin and action of all the nerves. We believe, say they, that this system is composed of several particular systems, differing from each other in their intimate
NERVOUS SYSTEM.

Their Opinion about the Sympathetic Nerve.—They begin their view of the nervous sytem, with the examination of the intercostal or great sympathetic nerve, becaufe, in the more perfect classes of animals, the ganglions and plexues of the abdomen and thorax may be confidered as forming the sytem of an inferior order of functions. Their notions on the origins of this nerve will wear no appearance of novelty to fuch as are acquainted with the writings of later phyfio-logists. The opinion, which regarded the brain as the origin and point of departure of all the nerves of the body, either immediately, or by means of the spinal marrow, has been gradually departed from, in proportion as a better acquaintance with comparative anatomy, and a more accurate mode of reafoning in phyfiology, have fhewn its inconfistency. Many anatomists have remarked, in particular, the impropriety of deriving the great sympathetic nerve from the brain, and have confidered the ganglions as fo many separate origins of it. Bichat has entered more at large on the fame fubjeét, and in eftablihing the ganglions as fo many nervous centres, reckoning each an independent action, has inferred, exerted on the nervous filaments belonging from them to different parts, has given us occafion to admire the clearnefs of his conceptions, and the expressive language by which his theory is at once supported and adorned. To strengthen these opinions, our authors remark, that in ascending through a fcale of animats being from below "after the zoophytes, all animals properly fo called have an intestinal canal, and a heart, or at leaft distinct veifils. Here we fee the gelatinous bifubance collected into particular massés, and nervous-filaments arifing in them, and expanded over the different parts of the body; these collections and filaments are more or leaft numerous, according to the number of the vifcera. Sometimes there are only two or three. In the cuttlefish, the nerves of the abdominal vifcera, feet, &c. arife each from a particular collection of gelatinous bifubances. These nervous filaments, in animals of a lower order, are anagouvs to the correponding parts in those of the higher classes; in fact they are the nervous plexues of the abdomen and chelif, and the more or leaft interrupted filers of ganglia of the sympathetic nerve. As these nervous apparatuses exist already in certain animals, which have no spinal marrow or brain, the question whether they arise from that marrow, or from the fupposed cerebral nerves, is de-cided. Hence Winslow, Soemmerring, Cuvier, &c., and particularly Bichat, judged very correctly, when they regarded the nervous filaments, connecting these filsystems to the nerves of the brain and spinal marrow, as fimple branches of communication. When the lower sytems exit alone, they act in an inflated manner; but as foon as several organs are found in one individual, they muft have a reciprocal influence, eftablished by branches of communication: to accomplish this, nervous filaments pafs from one sytem to another, and form a net-work of communications. Thus the plexues of the vifera firft communicate with each other, then with the other sytems of the sympathetic nerve, and, by means of the latter, with the spinal marrow and some cerebral nerves. It follows from these confiderations, that the nervous sytems of the thoracic and abdominal vifcera cannot all execute the fame functions, and, consequently, ought not to be compared to a net-work. They are rather composed of as many particular sytems, each exercising a different function, as there are different origins of nerves; consequently, the sympathetic nerve cannot be regarded as a fingle pair." Ans. et Phyf. du Syll. Nerveux, fect. 1.

Towards the conclusion of this fection, the authors give us the following ftement of their opinion on the nature and ufe of the ganglions. This we have extracted as expressive of their opinions, on the origin of the nervous or medullary fibres, a very leading and important part of their doctrine. "We have obferved, in the lower classes of animals, two bifubances accompanying the nervous sytem; the greyifh gelatinous matter, and the nervous filaments. The former feems to compofe the polypus almofl entirely, and to charactefize the commencement of the animal kingdom, although nervous filaments have not yet been demonstrated in these creatures. In the next ftep, the vifcera are provided with particular collections of the gelatinous bifubance, and we can plainly perceive the nervous filaments arifing in them; the latter are diftributed in their respective organs. As these collections of gelatinous bifubance form knots or swellings with the nerves that arife from them, they are called ganglions. The larger the collections, the larger and more numerous are the nervous filaments. We do not fee the latter arifing immediately from the lymph, nor by a transformation of veffels; but they are produced wherever there is gelatinous bifubance. We acribe, therefore, the nutrition of the white filaments to the latter. As fimilar arrangements are found in the plexues and ganglions of the higher orders of animals, we muft equally regard them as the origin of the nerves. They are always interwoven with numerous veffels, and contain throughout an abundance of a reddifh-grey, gelatinous, pulpoy, uncious bifubance. They contain more or leaft cellular tiffue, and are fower or firmer in proportion to the structure of the coverings of the nervous filaments. Often the gelatinous bifubance is difperfed in a loofe cellular tiffue, fo that the nerves going from it form a kind of plexus. Sometimes it is collected into small masses in these plexues; between which and the ganglia there is no effential difference. The dilinations of number, form, conflation, and colour, obferved in the different fpecies of animals, or in different individuals, are not effential conditions, influencing the ufe of the organs; they are merely modifications of structure." Ibid. p. 44. 45.

The Spinal Marrow.—The common language, in which the spinal marrow is spoken of as a prolongation, or continuation of the medullary bifubance of the brain and cerebellum, and the common opinion, which regards this organ as a dependency of the encephalon, are entirely rejected by Gall and Spurzheim. The accephalous mutes, flew, that
it is formed and exists independently; and they endeavour to prove by comparative anatomy, that it is a series of ganglia, closely approximated, giving origin to the spinal nerves, as the ganglia of the chest and abdomen produce the respective nerves of those parts. Further particulars of their opinions on this subject will be given in our description of the spinal marrow, prefixed to that of the spinal nerves.

Nerves of the Brain.—The part immediately above the spinal marrow increases considerably in size, as soon as it enters the great occipital foramen; and this increase is more particularly distinct in the mammals, because most of the nervous systens arising at this point are much larger than in man. It has generally been regarded as a continuation of the white substance of the cerebrum, cerebellum, and tuberculum annulare, and, therefore, named medulla oblongata, the upper edge of the tuberculum being considered as its superior boundary. Other anatomists comprise under the medulla oblongata, the pons, crura cerebri and cerebelli, corpora tritae, and optic thalami. These anatomists refer the origins of all the nerves to the medulla oblongata, including under that term parts really belonging to the cerebrum; Soemmerring conceives, that all the nerves arise from the medulla of the brain; and derives them from the sides of the ventricles. All the proofs, say Gall and Spurzheim, that we have employed to shew that the medulla spinalis and oblongata are not prolongations of the brain and cerebellum, may be applied to the latter part in particular. They will also serve to refute the opinion, that the nerves called cerebral have their origins in the brain. They bear no proportion to the brain, which they would do, if they arose from it. In the calf, the pig, the horse, &c. they are generally much larger than in man, though the brain of these animals is much smaller than ours. These nerves, (called by Gall nerves of the head,) as well as the parts from which they arise, are found in acophilous fetuses, which have not originally possessed any brain; lastly, their direction from below upwards, or towards the openings, by which they go out of the cranium, proves manifestly, that they cannot be regarded as prolongations of the nervous substance of the brain. We must, on the contrary, consider them as nervous systens, not found in animals of a lower order, as not formed until after the systens of the sympathetic nerve and medulla spinalis, and as defined to the immediate functions of the fenens, as well as to the organs of motion, and their accessory organs. Anat. et Physiol. du Syst. Nerveux, p. 95.

The nervous substance referred to this part the first visible origins of most of the nerves of the fenens, of the fifth, sixth, and seventh pairs, as well as of the cerebrum and cerebellum. It has, in common with the medulla spinalis, (see our description of that organ in a subsequent part of this article,) the anterior and posterior filaments, the commissure or transverse layer of union, the internal stratum of ciceritious substance, and the canals that are demonstrable by inflation. Although it cannot be regarded as a continuation of the spinal marrow, its particular nervous system have an immediate connection, by communicating chords, with the nervous systens of the vertebral columns.

In the sympathetic and spinal systens, the nerves are detached, at their very origins, from the common fishes; but here the nervous filaments are collected into fasciculi, which continue united to the fishes for a longer or shorter extent. We must, therefore, be careful not to confound the point of origin with that of departure from the fishes. As long as a nervous bundle remains connected to the fishes, it is continually receiving augmentation from the ciceritious matter contained in it. Frequently the latter is collected into a ganglion, in order still farther to reinforce the nervous fibres. How far these gentlemen have been successful in their endeavours to trace all the nerves commonly called cerebral to the medulla oblongata, will appear in our descriptions of the origins of the nerves. We may state here, that they prove tolerably clearly, that the olfactory is the only one that can with any probability be derived from the brain.

In the conclusion of this section, they observe, that all these nervous systems originate in ciceritious substance, and by no means in what is called the medullary matter of the brain. That they are not perfect in the first instance, but strengthened and completed in their course. They are sometimes accompanied throughout by ciceritious matter, as in the case of the olfactory nerve, and thus go on constantly increasing. Sometimes they meet in their course with collections of grey matter, either in flattened plates, as above the decussation of the optic nerves, or in the form of ganglia, as the tubercula quadrigemina, corpora geniculata, &c. In both cases, the grey substance produces new nervous filaments, and the latter unite to what existed before, until each system is perfected. The ganglions and plexuses of these systens are also to be considered as the source of new systens, or as apparatus designed to strengthen them. The peripheral extremities of the nerves are not naked in the external organs of their functions; but are all covered with mucous substance of various colours. Of this kind is the mucous substance between the muscular fibres; the corpus mucosum of the skin; the pulpy substance in the nervous papille of the tongue; the mucous membrane of the nose; the soft covering of the retina and the labyrinth.

Gall and Spurzheim are very earnest in their objections to an opinion, entertained by most modern physiologists, that the nerves are all originally alike, and that the differences of their functions arise from the external organs connected with them. As a polyp may be divided into several pieces, of which each may become an animal like the original one, we may infer that all the parts of the polyp are perfectly alike. But it was an instance of bad logic to apply this conclusion, drawn from animals in whom no nerves have yet been discovered, to the complicated nervous systens of the more perfect animals. "Since it has been proved, that the different nerves are not derived from one source, from a common trunk, the opinion of their action being the same in all cannot be supported by any anatomical demonstration. There is a striking difference between the soft and whitish red nerves of the great sympathetic system, and the hard white spinal nerves; again, the delicate fibres of the cerebrum and cerebellum are distinguished by their whiteness and softness, from those of the vertebral column. The different nerves of the fenens bear no resemblance to each other in colour, confidence, form, and texture. Often the different filaments of the same nerve are visibly different. Not only the different nervous systens, but also the filaments of the same nerve arise from different collections of the grey substance. The ganglions of the different systens are more or less numerous, according as their form, confidence, colour, and texture, vary. All these points are the same in the same nerves; they must, therefore, arise from some original difference of internal structure, and be necessarily connected with the diversity of functions. Physiological principles support the anatomical facts, on which the differences of the nerves are grounded. It is allowed, that the external organs communicate different irritation to the nerves; but, if all these are of one nature, how comes it to pass, that the different impressions of their peripheral extremities are transmitted to the brain unaltered. Should not the impressions of the optic be, transported differently from those of the

Vol. XXIV.
AUDITORY OR Olfactory NERVE?" Anat. et Phyiol. du Syst. Nerveux, feét. 5.

We must observe, that this fact of the differences in structure of the particular nerves, has been already stated by Soemmerring and Bichat.

After a short phylogenial account of the different nerves, Gall presents us with the following general observations relative to all the nerves of the body.

**Anatomical Observations.**—1. Each nerve of the body has its particular origin. None arise from the brain, nor from any other nerve; but the filaments of each are produced from peculiar collections of grey substance.
2. Each differs from all others in size, structure, colour, and consistence.
3. The apparatuses of the same nerve are more or less numerous and complicated in the different kinds of animals.
4. There is no direct or constantly uniform proportion between the size of the brain and that of the nerves.
5. There is no determined proportion between the nerves of the same species of animals, nor in the individuals of the same species. Sometimes one, sometimes another nerve is the most developed.
6. The nerves of the same species cannot be said to be larger or smaller in the female than in the male.
7. They are developed and decay at very different epochs in the different kinds of animals, and in individuals of the same kind.
8. Hitherto we know of no destruction in the nerves of the female, excepting the optic, and this does not exist in all animals.

The corresponding nerves of the two sides (les nerfs correspondants des sens de chaque côté) communicate together by their commissures, and with the neighbouring parts of the brain by communicating branches.

**Physiological Observations.—1.** The functions of the nerves can only be executed by material instruments (ne font ren- dus possibles que par des instrumens materiaux).
2. The nerves of the same species are only employed in communicating the impressions of the external world to the brain, that it may modify them.
3. Each is capable of receiving only certain impressions: and the function of no nerve can be executed by another nerve of the same species.
4. The power (faculté) of each nerve, in respect to its acute sens of (finele), is, in the ordinary state, in a direct ratio to the perfection and development of the apparatuses, and probably to the greater or smaller number of them.
5. The particular functions have not the same degree of energy in the different species of animals, nor in the different individuals of the same species; acute sens of sight may be combined with dull hearing, &c.
6. The nervous systems of the different species, like others, may acquire unusual activity from extraordinary irritation, as in fever, inflammation, &c.
7. When the functions of the nerves are deranged from injury of the brain, as in paralysis arising from lesions of the spinal system, the effect does not take place on the opposite side of the body.
8. The powers of the different nerves are manifested at different periods, according to the development of their organs.
9. From what causes, and for what end, are some animals born with the nerves fully developed, or at least with the ears and eyes open, while others have them shut? This distinction does not always bear a relation to the power of using the extremities more early; for the newly-born child is as incapable of locomotion as the dog.
10. All the functions of the nerves are gradually weakened in old age. We cannot ascribe this to the effects of light, nor consider it analogous to our want of confidence of what palls in the organic life. Nature seems to have purposely deprived us of the power of perceiving the automatic processes; and to have accomplished this end by the flusterers of the communicating threads, which connect the thoracic and abdominal nervous systems to those of the spine, nerves, and brain. The functions of the nerves are weakened in old age, because the organs are changed in structure, and the nerves are diminished in size. But the change is not simultaneous in the whole system, so that the functions are gradually extinguished.

11. The double organs of each nerve do not interfere with the finele of the sense; as our consciousness is simple although the organs of sense are five in number.

12. Impressions, whether derived from the external world through the medium of the senses, or from the interior of our bodies by the general organs of feeling, are to be regarded as indispensable conditions, without which no perception or thought can take place. But no impression from without, nor any irritation from within, can become a sensation or idea without the concurrence of the brain. The power of perceiving impressions, of retaining and comparing ideas, bears no relation to the functions in man or animals, as is proved by idiots. Consequently, if it should be proved, that man has the most perfect nerves of all animals, it would by no means explain why he is made the most intelligent of all our species. Hence Condillac has been obliged to acknowledge "that the nerves are not sufficient to acquaint us with the objects in nature, since the same nerves are common to all animals, though we have not all the same knowledge." The author of the treatise on the nerves is therefore wrong in the following passage: "Tous les sens ont de même enfant des arts pour se satisfaire, ou se perfectionner, or se garantir des impressions fâcheuses. Quels arts n’a pas produit le sens du toucher? Ces habits, ces pabils, ces voitures commodes font les enfants de sa délicatesse." Le Cat, p. 39. Helvetius has a much more judicious observation on this subject. "L’expérience ne démontrera point que l’esprit soit toujours en nous proportionné à la finele plus ou moins grande de ces mêmes sens. Les femmes, par exemple, dont la peau plus délicate que celle des hommes, leur donne plus de finele dans le sens du toucher, n’ont plus d’esprit qu’un Voltaire, &c. Homère et Milton furent aveugles de bonne heure, cependant quelle imagination plus forte et plus brillante! Parmi ceux dont le sens de l’ouïe est le plus fin, en éel-le de supérieurs aux St. Lambert, aux Sarrin, aux Nivernois, &c. Ceux dont le sens du goût et de l’odorat sont les plus exquis, ont ils plus de grâce que Diderot, Rouillé, Marmontel, Dusols, &c. De quelle manière qu’on interroge l’expérience, elle répond toujours que la plus ou moins grande perfection des esprits est indépendante de la plus ou moins grande perfection des organes des sens." De l’Homme, &c. t. i. p. 185.

13. Bacon, Locke, Hume, Helvetius, Condillac found themselves obliged, in order to comprehend, in some degree, the possibility of the functions of the understanding, to have recourse not only to the senses, which fome of these authors had so much admired, but also to a knowledge of the relations of the sensations, or to attention, or experience, reflection, induction. Although they very much contradicted themselves, they were aware that none of the faculties, which we have enumerated, could belong to any of the senses. But if no faculty in this life can be exercised without a material condition, as we shall afterwards prove most incontrovertibly, we must necessarily suppose the existence of some material organisation for the exercise of the intellectual
Nervous System.

Nervous powers. At all times a high degree of importance has been attached to the researches concerning the organs by which man and the animals receive the material impressions of the external world. Will it be a less noble or less interesting task to attempt discovering the organs of the higher faculties of the mind? We ask whether the five senses and the properties, of which we have just spoken, are sufficient to explain the various propensities, and the different instinctive industries of animals, as well as the propensities and faculties of man? How shall we be able to explain on this principle, why the seal, the chamois, and the wild geese place sentinels to alarm them in case of danger? Why birds, the beaver, the rabbit, the ant, construct their abodes with such admirable artifice? Why the quail and the Iork emigrate, and return to the same places? Who will explain the attachment of females to their offspring, and the carelessneffe of the males; while in other species the males participate in this charge with the females? Why the crows are so strongly inclined to live in society, and the magpies alone? Why the cock and the bull are so jealous of their exclusive rights, the hen and the cow so impartial in distributing their favours? Who will shew us the meaning of those calls acuteness, courage, pride, rectitude, &c.? Is it experience? But all these sentiments proceed immediately from the spider spin, the beaver builds, before they have experience. Is it attention, reflection, induction? Why then does each species bestow attention on a particular object? Why do all individuals of the same species fix on the same object? Why is it even out of the power of man in many cafes to bellow great attention, or exercise highly the faculty of induction on certain objects? Mult we not perceive, that it is almost the same case throughout nature, as in the example of the monkey, who is careful to fill his cheeks with fruits, but does not know how to keep up a fire?" Anat. et Phyfiol. du Sytil. Nerveux. feet. 6.

The Brain.—Gal! and Spurzheim regard the brain as an assemblage of nervous systems, which, at least in the more perfect animals, are the particular organs of conceptions (conscience), instinctive industries, propensities, faculties of the mind and soul. Consequently the brain, like any other system, is a particular and independent fyltem, in a state of communication with, and of reciprocal action to, the other nervous systems, either immediately, through the medium of communicating branches. It no more arises from the nervous mafs of the spine, than that does from it. As we sometimes find the spinal fyltem without a brain, so it is possible for the brain to exist without spinal marrow. This must have been the case with the child born with a second head placed in an inverted position on the natural one. All the arguments against the common opinion concerning the origin of the nerves of the fenes, the medulla oblongata, and spinalis from the brain, militate equally against deriving the brain from the spinal fyltem." (Ibid. feet. 7.)

They proceed to shew, that the brain, like other parts of the nervous system, is made up of the two substances already specified; the cinneritious matter, and the nervous fibres. The details of their anatomical descriptions will be given in a subsequent part of this article.

"If we admit, say they, all the gross ideals that have been formed of the brain; that it is the source of all the nerves, and composed of all their extremities; how can we ascribe to it any other functions than those which belong to the nerves of the fenes, of motion, and of the organs of nutrition? Since it will present merely an union of the cerebral extremities of all these nerves." Recherches, p. 230.

"The history of opinions concerning the functions of the brain presents us only, with a succession of errors. Many of the notions did not even ascribe to it the operations of the mind. What connection could subsist between a spongy substance or mass of impure humours, and the spiritual faculties?" To the end of the 17th and even in great part of the 18th century, anatomists still adhered faithfully to the old doctrine of Galen respecting the vital spirits secreted in the cavities of the brain, and distributed to its various parts by the arteries. Such were the notions of Berenger, Spigelius, Veiling, Willis, Veuers, and most phlogiologists. After the beautiful discoveries of the lymphatic sytem and the structure of glands, an analogy of organisation was fancied to exist between the brain and glands; and similar functions were ascribed to them. A nervous fluid was then sought for, instead of vital spirits. Glafion even fancied, that he had seen this fluid distinctly transude from injured nerves. Malpighi thought the cortical substance like a collection of small oval glands. Pacchioni, Baglii, Lancisi, F. Hoffmann, Borelaave, &c. defended the nervous fluid. The organisation of the nerves was a point not less disputed: whether they are hollow or solid; whether they act by vibration or oscillation, &c. The seat of the soul was equally the subject of different opinions. For a long time it was conceived to be generally expanded through the body, and to reside principally in the nervous system at large; but this notion being at variance with the dogmas of the metaphysicians, the seat of the soul was confined to the brain, and even to some single point of the organ."—"The metaphysicians believed in the simplicity of thought, and consequently held that the organ of the soul must be single: with such views it was useless to inquire into the functions of parts of the brain, or to investigate the organs of particular faculties of the soul. They ought to have looked to anatomists and phlogiologists for proofs in support of their principles; instead of which the latter allowed the metaphysicians to dictate laws to them. Already there were isolated facts favouring the plurality of organs for the functions of the soul, but no means of rectifying them, or demonstrating their existence in the organisation itself; and the unity of conceptions formed an objection to this plurality. "The multiplicity of the vital organs, and of those of the fenices, which does not diminish the unity of life or of conception, ought to have shown that the want of power to explain a phenomenon does not destroy either the phenomenon or its cause. Philosophers were very unwilling to make the superior functions of the soul, such as thought, understanding, judgment, reason, imagination depend on material organs. The examples of idiots, cretins, hydrocephalic patients, the deranged, and injuries of the brain, were lost on these men. They willingly set down several intellectual faculties in animals, such as memory, which they could no longer dispute the existence of, as merely mechanical faculties."—"Instead of simply endeavouring to collect a sufficient number of phenomena, they gave themselves up to philosophical futilities with the view of finding hypotheses and explanations. They endeavoured to discover how the body and soul were united; whether immediately, or by the intervention of some substance. Even the nature of this substance, half body and half soul, was examined. Inquiries were instituted into the reciprocal action of the mind and body, the brain and nerves; whether fanciful and ideas are the result of impressions on the brain; whether wells of these are left behind, how they are renewed, &c." Anat. et Phyfiol. du Sytil. Nerveux. Introduction.

The insufficiency or absurdity of most of the notions that have hitherto prevailed concerning the physiology of the nervous system.
Nervous System.

nervous system, must make any extensive researches into its structure and functions peculiarly acceptable: we should receive with pleasure even an imperfect attempt to explain them, if it were grounded, like that of Gall, on actual observation. He has examined the anatomical structure most minutely in man and the various animals; he has attended to the organization of individuals, as connected with their talents, and has collected facts in the great establishments for education, in the hospitals for foundlings and idiots, in the houses of correction and in prisons, in courts of justice, and at the scaffold. We regret that the physiological part of his labours is not yet before the public: we shall present however some extracts to enable our readers to form a judgment on the kind of views which he takes of these most interesting subjects. And we confes, that so far as the anatomical descriptions go, they seem to us to profess a very decided advantage, in their clear exhibition of the organization and relative connections of the organs composing the encephalon, to the ordinary unsatisfactory exhibitions of horizontal sections and thin slices of the cerebrum. It will be seen, however, from the foregoing passage, that Gall does not pretend to derive his physiology of the brain from merely anatomical principles: he relies on observation of phenomena in animals and men for the former, as on the use of the knife in the dead body for the latter.

"There are few instances in which the structure of parts, as that of the bones, ligaments, &c. displays to the anatomist the functions depending on it: and when this happens, the ideas are only conjectural. The form of the muscles does not show us that they possess the power of contraction; and we only know this after seeing the motion they produce. There are neither muscles nor levers in the brain and different nervous systems; we can discern no excretery tubes, no extension, no relaxation, no oscillation, no refraction of luminous rays, no liquid in motion. If the medullary fibres exhibit various degrees of consistence and whiteness, various directions, &c. we could scarcely conceive the possibility of differences in the intimate nature and functions of these innumerable fibres, if we did not reflect that the millions of fibres of similar appearance in animals and in vegetables, are nevertheless proved to differ from each other by the diversity of their effects. Even if we saw any change in the arrangement of the elementary parts, what could we infer? To what conclusions would a knowledge of the structure of the eye and ear lead us, were not these organs connected with nerves, which alone are susceptible of impressions from light and found in a manner altogether incomprehensible to us? Would the most acute observer have been able a priori to ascribe the power of smelling to the putitary membrane, and the perception of tastes to the nervous papillae of the tongue. Generally the knowledge of functions has preceded that of the organs: that the power of vision resides in the eye was known before its mechanism or the optic nerve was understood. Indeed, for a long time the nerves were not supposed necessary to the functions of the senses, because it was believed that the blood-vessels carried impressions to the heart, the imagined seat of the soul. In the same way most of our own physiological discoveries have been independent of anatomical investigations. If we suppose a knowledge of organization to precede that of functions, it could at best only give rise to conjectures, that would have borne the marks of the prejudices of the time. Thus the heart was formerly made the seat of courage, love, sympathy, cruelty; the liver of anger and sensuality; and in modern times intellectual and moral qualities have been supposed to result from the mixture of humours or temperaments, and the passions to reside in the abdomen, about the solar plexus. If anatomy were a sure guide to the uses of parts, would Willis have imagined that the vital spirits concerned in motion were secreted in the cerebellum? Would Galen have placed the organ of smelling in the anterior ventricles? Would the soul, after being successively digested from the pineal gland, corpus callum, tuberculum annulare, &c. have been fed from by Soemmerring in the fluid of the ventricles, and by Ackermann in the medullary substance lining these cavities? Would a thousand other errors have been committed, such as placing memory in the cortical matter, judgment in the medullary substance of the hemispheres, &c.

It might have been expected that anatomists, seeing the great variety of parts in the brain, would have been the first to deduce from this circumstance the diversity, and consequently the plurality of organs for the intellectual and moral qualities. But when we see Vicq d'Azur, after gradually composing the human brain by ascending from the inflect to man, and decomposing it by the opposite course, till acknowledging a single organ of the soul, we find how insufficient the mere knowledge of the mechanical arrangement is to embrace the physiologist and philosopher. It is only by attending closely to natural phenomena, without paying any regard to metaphysical dogmas, that we can arrive at just notions concerning the structure of the brain, than most anatomists themselves have been able to form, even by the aid of the minutest dissection. Herder, struck by the intellectual phenomena of various animals and individuals, conceives the idea of a plurality of intellectual organs, and even the hope of being able to discover them by an attentive comparison of the brains and the various qualities. Bonnet regards the brain as a collection of fibres, each having a particular function, and looks to the possibility of discovering these functions.

We have been employed, for many years, in collecting anatomical and physiological facts, before we formed any reasonable induction concerning the nature of the brain and nervous system. But this collection would have been of no use to us, had we not previously supplied a close and necessary connection of them with their material conditions. When thus prepared in physiology and pathology, we soon made discoveries, which the scapul alone would never have unfolded. If we have gained an anatomy of the brain, which time cannot overturn, we owe it almost entirely to our physiological and pathological conceptions; and it is the perfect accordance of the intellectual phenomena with the material conditions of their existence, that affords us the permanence of our anatomical and physiological doctrine of the brain and nerves.

To say that the functions of the brain have been discovered, independently of the knowledge of its structure, is very different from ascertaining that the functions have no immediate and necessary connection with the structure. Would any one advance, for example, that motion and secretion have no connection with the organization of the muscles and viscera, and that digestion and circulation are not inseparably connected with the stomach and heart? Can we fail to refer the teeth and claws to the wants and instincts of animals? Is it to be believed that the hand of man has no relation to his brain, or the foot of the horse to his? Have the organs of the senses no necessary and immediate influence on the functions which depend on them? Are we to make an exception for the functions of the brain only, because its organization and faculties are different from those of the senses and of the organs of organic life? We should then ask if seeing is not altogether different from smelling and hearing, and if seeing, smelling and hearing are not different from moving, digesting, &c.? If it should be answered that all these
NERVOUS SYSTEM.

these phenomena require only one general vital principle, we
shall then inquire how this one principle produces contrac-
tion in the muscles, secretion of bile in the liver, sets the
heart in motion, and precedes over the sensations of taste and
smelling.

Is there a diversity of function in the senses be explained by
the variety of the external organs, and the different parts of
the brain be alleged to have no difference in function be-
cause they have no such external organs, we ask what be-
comes of the external organ when deprived of the partial
internal ones? Is vision kept up after the paralysis or atrophy
of the optic nerve? Whence come the sentiments and ideas
that agitate a man in a dream, or when he is re-
membering what is past? Since, then, all the nervous systems
exercize their functions in the interior of the organization,
why should the faculties of the brain be excited and limited
by the senses and external objects? What senses give us
the notions of benevolence and vengeance, love and hatred,
pride, duty, justice, art and science? The dog and monkey
have the same senses as man; are they therefore in the same
rank with him, in moral and intellectual qualities?

In vain do we attempt to explain the superiority of man,
by a higher degree of nobleness and perfection in the human
soul, since this soul is young in infancy, dull in old age,
inactive or nearly so in hydrocephalus, furious or frenzied in
certain diseases and injuries of the brain, impotent or out-
rageous in drunkenness and the effervescence of the passions.
From the consideration of these phenomena then, we cannot
help inferring the reality of a particular organization for the
faculties of the soul, an apparatus that emancipates the
mind from the slavery of the senses, gives to every animated
being a specific character, and measures out the world in
which each species is inclosed.

If any doctrine concerning the functions of the brain
were in contradiction with its structure, it would necessarily
be false. Let it be shewn that the brain is composed of
arms, and is an organ of sensation or excretion, it is then
shut out from all higher functions, and reduced to the clafs
of visceral. If a central point of termination of all the me-
dullary fibres be shewn; if there be pointed out in all ani-
mal, in spite of their varying faculties, a cerebral mass con-
stantly the same, the plurality and diversity of organs are
annihilated. Whoever proves that the brain is only the
central origin and termination of all the nervous sytems,
will have shewn that its functions are those of other organs.
If a constant identity of the constituent parts be shewn in
the different individuals of the same species, in spite of the
differences of their common faculties, it will then be impos-
ible to assign the feats of the organs by comparing the pre-
dominance of their physical development with that of their
psychological energy.

But if it is an irrevocable truth, that animals without in-
telligence have also no brain, and are provided only with in-
ferior nervous sytems; that these sytems are more numer-
ous, when the vegetative or organic life is more compli-
cated; that any faculty of the animal life, intellect, talent,
or aptitude of whatsoever kind is never perceived, except
in conjunction with a brain; that the constituent parts of
the brain, from the worm to man, are multiplied and diversi-
ed in a direct ratio to the faculties; that all facts concur
in proving that extraordinary energy of any faculty, always
corresponds with extraordinary excitement and particularly
development of some part of the brain; that the derange-
ment of any faculty is connected with injury or disease of a
part of the brain, as any affection or the loss of sense fol-
ows injury or disease of its physical apparatus; if, lastly,
it be invariably true, that the brain consists of a nervous
system different from all others, and divided into several
other sytems so distinct from each other, that the differences
of their origins, fasciculi, directions, points of union, &c.
can be clearly demonstrated, then there is no doubt that the
anatomy of the brain has an immediate connection and
perfect accordance with our doctrine of its functions; and
the metaphysician can no longer be justified for loving him-
self in the dark void of speculation, by saying that the
operations of the soul are too deeply hidden to allow of our
discovering their organs or material conditions." Recherches,
&c. p. 244, et seq.

On the generally received opinions concerning the com-
mon origin and identity of the acton of the nerves, Gall
and Spurzheim observe; "by substituting, on all occasions,
the metaphysical ideas of the schools, in place of the data
furnished by the observation of nature, physiologists and
even anatomists have supported these fabrics of error, which
have been regarded almost as sacred objects. The soul, say
the schoolmen, is simple: its material subsistence must
then be simple also, and all the nerves must end in one spot.
Aristotle, and several peripatetics of the 16th century,
having fixed the seat of the soul in the heart, derived all the
nerves from that organ: 'Thele, says Celsatus, can have
but one origin, because each individual has but one soul.'
Bonnet, Haller and others, having extended its seat
in the whole substance of the brain, were contradicted by
the metaphysicians; who thought it too considerable; not
considering that a little more or less room would not enable
them to explain the nature of the soul any better, nor that,
according to the remark of Van Swieten, Tiedemann, and
others, the simplicity of a material point, in which all sen-
fations and ideas should centre, is inconceivable, in con-
sequence of the confusion and disorder which would result
from such a concourse. Nothing appears to us more ridicu-
losous, than that the naturalist, to whom all nature lies open,
should direct his researches and inductions by the guidance
of such frivolous speculations. If the metaphysician would
employ himself in the observation of facts, and in ascertain-
ing the conditions on which they depend, his notions
would no longer be at variance with the inferences drawn from
anatomy, and one science would not arrogate the right of
settling bounds to the progress of another. The doctrine
of a single origin and centre for all the nerves is neither true
nor possible. As this point can be verified by examination,
it can no longer give rise to vague discussion. If, after this,
the metaphysician cannot comprehend the unity of his indi-
vidual consciousnesst (l'unité de fon moi), we ask him, if
he understands, in the organic life, how such different appar-
atuses concur, by their varied functions, in forming one
whole? if he can reconcile, in the animal life, the cir-
cumstance of double organs with unity of functions, and
simplicity of consciousnesst if he knows what life is, or
in general, if he can comprehend any single power in the
material world? These enigmas, which prove that our know-
iledge is limited, should not prevent us from using our sense
and mental powers in investigating the accessible secrets of

In summing up their peculiar views concerning the func-
tions belonging to different portions of the brain, they con-
clude; "Henceforward we may consider, in a much more
exalted point of view, that most important part of the ani-
mal organization, the assemblage of the nervous sytems.
The laws respecting their origin, successive increase, and
final expansion, are in part discovered and reduced to a ge-
neral principle. The nerve prefiguring over sensation and mo-
tion arises and is developed according to the same laws
which regulate the organ, by means of which the mind per-
ceives,
NERVOUS SYSTEM.

cereve, will, and reflects. The brain will become an intertingling subject, when it is no longer mechanically cut up, without any views like a mass of organic matter. We shall now find its dispositions for certain ends. All the old mechanical forms and connections will now be transformed into a wonderful collection of material apparatus for the faculties of the soul. As the actions of the various viscera, and the fanctions of our sensitive organs, are regulated by particular nervous organisation; so each instinct, and each intellectual faculty, in man and animals, will be found subordinate to some part of the brain. If, then, the mind eludes our grasp, we may at least retrace it in its organs, which indicate the degree of intelligence possefled by each species and individual. They not only form the line of demarcation between man and the brute, but, by flowing the development of the faculties, teach us how nature qualifies different men for wisdom or folly, for command or obedience.

"The time is not far distant when philosophers will agree with Bonnet, Condillac, Herder, Cabaris, Prochaska, &c. that all the phenomena of animated nature are founded on organisation in general; and that all intellectual phenomena flow from the structure of the brain in particular. A few drops of blood effused in the ventricles, a few grains of opium will prove sufficiently that volition and thought depend on the material conditions of the organs. Whoever wishes to understand completely the powers by which his machine is set in motion, to comprehend the nature of man and animals, and their relations to external objects, to establish a rational doctrine concerning the intellectual and moral functions, and the disorders of the mind, will find it indispensably to study the organisation of the brain, together with its functions. In this way the naturalist, the teacher, the moralist, and the legislator, may rectify their vague notions concerning human propensities and passions, and convince themselves, by sensible and evident proofs, that the human organisation is adapted to a superior order of intellectual and moral qualities; consequent that education, legislation, morality, and religion, are essentially connected with the nature of man; and, instead of being merely useful, are inseparable from his happiness: because they furnish motives to counterbalance his evil propensities, and increase more and more the moral freedom of his agency." Ibid. p. 272—274.

Membranes of the Brain.—We shall place under this head what is either omitted, or too curiously mentioned in the article Brain.

Dura Mater.—Although the dura mater adheres closely to the bone of the cranium, and numerous vessels pass from it to the latter, the facility with which it can be detached, so as to be exhibited entire, its thickness, its peculiar structure, and its nearly complete investment in the vertebral canal, form a broad line of demarcation between it and the pericranium.

Over the whole bony arch of the cranium, this membrane corresponds to broad bones, with few and inconsiderable eminences. Its adhesion is weak, except at the futures; it can therefore be easily detached from the frontal, parietal, upper part of the occipital, and squamous portion of the temporal bones. More or less difficulty is experienced in separating it from the futures, the intervals of which give passage to numerous fibrous clongations, establishing continuity between it and the pericranium; there are mass abundant in the fagittal future. The inequalities of the external or cranial surface of the membrane, are most conspicuous in the course of the futures. Through the fagittal, which is the only opening in the vault of the cranium, the dura mater sends a small canal, inclosing a vein, and continued with the pericranium.

Our account of the numerous inequalities and foramina, the disposition of the dura mater is much more complicated in the base of the skull. It fills and adheres closely to the foramen cecum, and is also firmly attached to the crista Galli, which it incloses. It forms the openings of the cribroform lamella; and the canals thus formed are continuous in the nose with the external or fibrous surface of the puitary membrane. It sends small canals to the internal orbital foramina. Its adhesion to the convexities of the orbits is but slight. In the phelephoidal region it lines and adheres very closely to the common channel of the optic nerves: then forms at the foramen opticum a canal accompanying the nerve into the orbit. This canal splits, at the orbital opening of the foramen, into two layers; one of which is continuous with the lining of the orbit; the other forms a sheath, including the optic nerve as far as the telerotica, and not adhering to it very closely. Behind the optic nerve, the membrane has a circular opening for the carotid artery, to which it adheres closely, and it forms a small separate canal for the passage of the opthalmic artery.

The dura mater then lines the fella Turcica, where it is covered by the puitary gland; on each side of this hollow it divides into two laminae, which form the cavernous funnels. The internal thinner layer lines the hollow of the bone behind the orbit, being for its period for the inner forms the exterior side of the fima. On the sides of the phelephoidal region, the dura mater passes over the lesser size of the phelephoid, and lines the middle fella of the basis cranii. It shuts up the superior orbital fissure, but lends into the orbit a thick and broad expansion, continuous with the period for of that cavity, which thus appears to be an extension of the dura mater. It can be seen felt by breaking the upper part of the orbit with a hammer; the lining of the cavity remains entire; it is perforated for the passage of the vessels and nerves which enter the orbit. The adhesion of the dura mater to the cerebral surfaces of the temporal and phelephoid bones is but slight. Towards the side of the latter bone it forms remarkable sheaths for the nerves of the third, fourth, and fifth pairs. Each of these nerves is contained at first in a distinct fibrous canal, lined by the arachnoid coat, reflected from the nerve in the form of a cul-de-sac: it then lies on the cavernous funis, from which it is separated by a thin cellular stratum, being covered externally by the dura mater, and, lastly, penetrates that portion of the membrane which cloaks the superior orbital fissure. The superior and inferior maxillary nerves are both accompanied by a fibrous prolongation of the dura mater. A cylindrical canal also lines the foramen spinosum, and is continuous with the external periorbital.

After this description it is easy to understand the disposition of the dura mater at the cavernous funis. One layer of the membrane is expanded, when the basis cranii is laid bare, and it has no attachment to the bone; the other forms a period for the bony hollow at the side of the fella Turcica, and behind the orbit. The lower and internal part of the interval between these is occupied by the cavernous funis properly so called, containing the internal carotid artery, and the nerve of the sixth pair: the upper and outer by the third, fourth, and fifth nerves, separated from each other, and from the funis by cellular feasts. At the upper and back part of this interval, the canals transmitting the above-named nerves end; while other fibrous tubes, through which they enter the orbit, the foramen rotundum and ovale, commence from the lower and front part.

The
The dura mater covers the upper surface of the petrous portion, as well as the upper branch of the Vidian nerve, from which it is easily detached. It adheres closely to the edge of the petrous portion, and then is continued towards the occipital region. In the middle and front of this it adheres very firmly to the channel of the basilary process, from which it is continued into the vertebral canal. Behind the foramen magnum its connections are comparatively loose. It has a simple fibrous opening for the passage of the nervus motor externus: it lines the meatus auditorm internus, at the bottom of which it is very thin, and the aquaeductus Fallopii, at the termination of which it is continuous with the periosteum.

It forms two canals at the foramen lacerum in both crania; one for the jugular vein behind, the other for the nerves in front; there is another similar canal at the foramen condyloideum anterius.

The internal or cerebral surface of the dura mater owes its smoothness, in the opinion of Bichat, to its being lined by a reflection of the tunica arachnoidea.

Processes of the Dura Mater.—The falx cerebri is placed in the middle line of the cranium: broad behind, and growing gradually narrower in front. Its upper convex edge corresponds to the frontal bone, to the middle of the frontal bone, and the anterior portion of the fronto-parietal suture, and the upper division of the internal perpendicular ridge of the occiput; its under concave edge is attached, and corresponds to the corpus callosum without touching it. The anterior narrow extremity is fixed to the crista Galli, which it incloses; the posterior broader end is continuous with the tentorium in its whole breadth. At the upper or convex edge of this process, there are three distinct portions of dura mater, one lines the cranium; two others, separate from this, are directed obliquely downwards and inwards, and unite into one, after leaving between them a triangular separation forming the superior longitudinal fissus. The single layer, which constitutes the greater part of the falx, is again divided below to form the inferior longitudinal fissus. It is also divided at the posterior end of the process, to form the torcular Herophilus.

The tentorium cerebelli bounds the posterior fossa of the basis cranii, and separates them, in great measure, from the rest of the cranium. It is broader behind than before; its upper surface supports the inner lobes of the brain, and the under division the cerebellum.

A layer of dura mater lines the great transverse groove of the occipital bone; two others, a superior and an inferior one, are detached from this, have a triangular interval for the lateral sinuses, and then unite into a single nearly horizontal layer. There is a similar arrangement in the anterior part of the production, the interval forming the superior petro-tympanic fissus.

The interval is much smaller than the external circumference of the tentorium, and has a form nearly oval. This edge is looser, and circumscribes the posterior and lateral parts of the opening, at which the posterior occipital hollows communicate with the rest of the cranium. The opening in question, which may be called that of the tentorium cerebelli, is not parallel to the great occipital hole. It is completed in front by the plate of the sphenoid bone; and entirely occupied by the tuberculum annulare. It is rounded behind, and terminated by a straight line in front; the membrane forming its folds ends in two elongated extremities, attached to the corresponding clinoid processes. At these extremities, the inner and outer circumferences of the tentorium are continuous.

The connection of the falx and tentorium maintains those processes in a state of tension, which is destroyed by cutting either of them. From this circumstance, anatomists have generally conceived that their use is to support the weight of the different parts of the encephalon, in the various attitudes of the body; e.g. that the tentorium bears the posterior lobes of the cerebrum, and prevents them from pressing on the cerebellum, and that the falx supports the right or left hemisphere of the brain in the recumbent posture. The position and attachments of these processes certainly enable them to perform the office alluded to; but we have some doubts whether this mechanical explanation is very just, because the falx has been entirely deficient (see a case quoted in the article Brain), and often is imperfect in front, without any inconvenience resulting to the functions of the brain.

The falx cerebelli is a small but thick triangular process of dura mater, placed under the tentorium, and in front of the perpendicular occipital ridge. Its front edge is loose, and corresponds to the interval between the two lobes of the cerebellum; the basis is continuous with the tentorium; the apex is placed downwards, and divided into two small secondary folds, which are infenibly lost at the foramen magnum.

Organisation of the Dura Mater.—Is it formed throughout of two laminae? Many anatomists have maintained this opinion, chiefly from the separations in many parts of the membrane for receiving the cerebral veins. In these, which are commonly called sinuses, we may distinctly see two, and sometimes three separate layers: but in other parts it is not possible to demonstrate two naturally distinct laminae, although we might artificially separate the membrane into several strata. No membrane has a more manifest fibrous texture: and the fibres are particularly numerous and well marked in the folds, as the falx and tentorium; they decussate each other in every direction; and are arranged in whitish irregular bundles, sometimes slightly prismatic. There is nothing muscular about them; the only foundation for ascribing such a nature to them was the motion observed when the membrane is laid bare during life; this arises entirely from the impulse of blood into the vellums of the brain.

The strength of the dura mater is very considerable; hence it is very easy to break the cranium with a hammer, leaving the membrane uninjured. This mode of removing the skull-cap, in examinations of the brain, is recommended by Bichat in preference to the use of the saw. After exposing the brain in the usual way, you strike with the thin edge of a tolerably heavy hammer, all round. Very rarely is the dura mater injured, even where considerable force is used, and the bone consequently much broken in. In deflecting the nerves of the head, where they are passing through canals or foramina of the bone, this way of proceeding is very advantageous; you break the bone into pieces, which are easily removed, the pericranium remaining entire.

It has no nerves, but numerous blood-vessels. Yet the capillaries, as in all the fibrous organs, are few in number. Its extensibility is proved by what happens in cases of hydrocephalus; we have no facts to show its contractility, although there is little doubt that the membrane enjoys this power. It has no animal sensibility in the natural state; hence it may be cut, or excited by chemical stimuli in living animals, without their giving signs of pain.

In the pha mater belongs not only to the external surface of the brain, as the dura mater does; not only to that surface and to the great cavities, like the arachnoid layer, but also to the small cavities in the organ. Hence it is continuous, and intimately adherent to the latter membranes by its external surface, at all the exterior prominences; but dilatant at the depressions, particularly at the basis. Between the brain and the pons Varolii, the latter and the medulla spinalis, and between the two lobes of the cerebellum, the...
the arachnoid is quite infuslated, and may be elevated alone, leaving the pia mater entire below.

- The internal surface of the pia mater corresponds everywhere to the subarachnoid cavity. Where the arachnoid adheres to the brain, the arachnoid lining is prolonged over the surface of the brain, and is adherent to it innumerable fine vessels pass between the layers, so that the membrane may be detached without injuring the organ.

- The external portion of the pia mater covers the convexities of the brain, and adheres to it innumerable fine vessels, which it also supports. The pia mater is continuous with the subarachnoid cavity. If it is detached from the outer surface of the brain, the arachnoid, which adheres to it, is left loose, so that the membrane may be detached without injuring the organ.

The pia mater is a delicate membrane, adhering to the brain, forming the external surface of the subarachnoid space, and being continuous with it. It is a thin, transparent, and delicate membrane, which is continuous with the subarachnoid cavity. It is a delicate membrane, adhering to the brain, forming the external surface of the subarachnoid space, and being continuous with it.

Structural features of the pia mater include:

- It is a delicate membrane, adhering to the brain, forming the external surface of the subarachnoid space, and being continuous with it.
- It is continuous with the subarachnoid cavity, and is a thin, transparent, and delicate membrane.
- It is a delicate membrane, adhering to the brain, forming the external surface of the subarachnoid space, and being continuous with it.
- It is a delicate membrane, adhering to the brain, forming the external surface of the subarachnoid space, and being continuous with it.
- It is a delicate membrane, adhering to the brain, forming the external surface of the subarachnoid space, and being continuous with it.
- It is a delicate membrane, adhering to the brain, forming the external surface of the subarachnoid space, and being continuous with it.
- It is a delicate membrane, adhering to the brain, forming the external surface of the subarachnoid space, and being continuous with it.
- It is a delicate membrane, adhering to the brain, forming the external surface of the subarachnoid space, and being continuous with it.
- It is a delicate membrane, adhering to the brain, forming the external surface of the subarachnoid space, and being continuous with it.
- It is a delicate membrane, adhering to the brain, forming the external surface of the subarachnoid space, and being continuous with it.
- It is a delicate membrane, adhering to the brain, forming the external surface of the subarachnoid space, and being continuous with it.
- It is a delicate membrane, adhering to the brain, forming the external surface of the subarachnoid space, and being continuous with it.

Hence we may form the following notion of the cerebral venous system. The great veins, that is the basilar and the middle cerebral arteries, lie at the base of the brain, and communicate with the subarachnoid space. The pia mater forms a free communication between the subarachnoid space and the choroid plexus. The pia mater is a delicate membrane, adhering to the brain, forming the external surface of the subarachnoid space, and being continuous with it.
to decide its nature by direct examination; we must therefore have recourse to analogy. In polishing a smooth, polished, and shining surface, moistened by serum fluid, contiguous to, and never continuous with, the surrounding organs, in the small number of blood-vessels, and abundance of exhalant and absorbent, in the essential basis of its texture, which is cellular, and in its transparency, when detached, the arachnoid resembles the serous membranes. Its tenacity is not more remarkable than that of the peritoneum. The vitreous properties of this membrane are exactly the same with those of the serous organs.

In forming to the brain a membranous limit, which isolates it from the surrounding parts; in constantly exhaling a serum fluid to moisten its surface, and absorbing it again, the arachnoid closely resembles serous membranes. When its surface is laid bare in a living animal, and wiped dry, moisture is quickly reproduced. It may be alleged that the dura mater is concerned in the exhalation and absorption of this fluid; but Bichat considers that its smooth surface is a reflection of the arachnoid. The proper tissue of the membrane cannot with any show of reason be supposed to exercise such a function. The fibrous membranes, to which it belongs, are never employed in that way, nor does the dura mater itself, where it lines the orbit, exercise such a function. We cannot suppose that the dura mater is concerned with the arachnoid coat in producing the fluid, as these secretions are in all instances furnished by one membrane only; and the arachnoid alone produces it in the ventricles.

The arachnoid, particularly in the ventricles, like the serous membranes, is liable to serous effusions or drops; it also exhibits adherences in consequence of inflammation, and becomes white and opaque like those membranes.

From this view of the organisation, vital properties, functions, and diseases of the arachnoid, we may safely draw the inference, that it belongs to the class of serous membranes.

Dissection of the external Arachnoid.—Every serous membrane forms a bag without any opening, covering the organs to which it belongs, and lining the cavity on which they are contained, affording sheaths to the vessels, and not penetrated by them; so that nothing is contained in its cavity, which would remain entire, were it possible to remove it by dissection. In this way the arachnoid covers the brain, its nerves and vessels, and lines the dura mater, none of these parts being contained in its cavity, which holds only the fluid that lubricates it.

It may be rendered evident by infiltration on the convexities of the hemispheres; here it affords a sheath to each vein entering the superior longitudinal sinus, and includes, in the same way, the granular bodies; in this situation; these sheaths are continued on the surface of the dura mater; consequently, it adheres to that membrane in numerous points along the course of the fins. It covers the opposed flat faces of the hemispheres, and the corpus callosum, separated from the latter by its arteries, and gives sheaths to the veins of the inferior longitudinal fins. It is then extended over the posterior lobes, and paves to the upper surface of the cerebellum, which it covers in the same way that it does the cerebrum. In this course it furnishes sheaths to the veins of the lateral and fourth sinuses. In passing from the cerebrum to the cerebellum, it may be seen distinct from the pia mater on both its surfaces; and a large portion is infiltrated in the same way at the fissure between the two lobes of the cerebellum.

It enters into the fissure between the two anterior lobes, at the front of their under surface, but paves directly over behind, so as to unite them closely. It covers the olfactory nerve, and forms a sheath for the optic; it includes the infundibulum, is extended over the surface of the pituitary gland, and surrounds the internal carotid at its entrance into the cavity of the cranium. The arachnoid then goes under the pons Varolii, lying quite detached from the surface, in a considerable extent between the union of the optic nerves, and the front edge of the pons. It is also completely infiltrated over the whole surface of the pons. It is extended to the sides of the cerebellum, and the commencement of the medulla spinalis, being quite loose and unattached at all the grooves about these parts. It furnishes sheaths to the various nerves in these parts, and to the vertebral arteries, and is continued into the vertebral canal.

These folds of the membrane may be seen most advantageously by lifting up the brain cautiously, for they are very easily torn, particularly those of the olfactory and optic nerves; they are loose, broader towards the brain, and narrower towards the nerve, and are reflected generally from the latter to the dura mater, so as to allow the nerve to pass on alone to its destination.

It will appear from the preceding description, that the whole mass of the encephalon is enveloped by the arachnoid, as the heart, lung, &c. are by their respective membranes, with this difference only, that the reflections are more numerous, on account of the greater number of nerves and vessels.

To complete the analogy, it remains for us to prove, that it lines the internal surface of the dura mater. Bichat describes the sheaths of the nerves and vessels as continued to the parts where they penetrate the dura mater, then united together and forming a general lining to the dura mater and its processes, corresponding to the pleura and peritoneum lining the thorax and abdomen. Thus we shall have a cranial and a cerebral division of this membrane, as we have a pleura costalis and pulmonalis.

It must be acknowledged, that this view of the subject is suggested rather by analogy, than by the direct evidence of dissection. Yet Bichat says, that the sheaths of arachnoid may be detached from the dura mater, and are thin and transparent, instead of exhibiting the fibrous texture of the exterior strata; and that this detachment is easier in the fetus and child, than in the adult. He says also, that the continuity of the two parts may be easily traced at the sheaths which have been mentioned. The polished surfaces of organs in all other situations are owing to serous membranes, which adhere sometimes very closely, as in joints, the sheaths of tendons, &c. We cannot detach the conjunctiva from the cornea, although no anatomist doubts of its being extended over that organ.

Internal Arachnoid.—It is the opinion of Bichat, that this membrane lines the cavities of the brain, and that the pia mater only produces the choroid plexuses. He acknowledges, that it is so extremely thin, where it covers the cerebral substance, that it cannot be raised and exhibited distinctly; its existence must, therefore, be inferred from analogy. He observes, that the surface has the same polish as that of the arachnoid; that it is the seat of an analogous serous exhalation and absorption; and that it is subject to dropsy, like serous membranes. He considers, that the water in hydrocephalus could not be confined to the ventricles, were they not lined by a membrane, but that it would escape where the choroid plexuses enter. He describes a continuity between the internal and external arachnoids, by means of an opening about the vena magna Galeni.

This opening includes the vein and its ramifications, and is formed in the process of pia mater that connects the velum; it paves between the veins and the pineal gland, and opens in the third ventricle. By it the arachnoid enters the ventricles. It appears, from his subsequent account, that...
NERVOUS SYSTEM.

that a small probe may sometimes be introduced along the
canal, but that this is not always practicable. In order to
discover it, the cranium should be carefully sawn, and the
fals removed without any violence, that the parts may not
be disturbed. The posterior lobes should be raised, and
gently separated, and the vein of Galen will be seen emerg-
ing from the opening which surrounds it. The internal
aperture may be found by turning back the velum and pineal
gland; on the under surface of the former is a triangular
arrangement of granulations in front of, and over the latter.
At the base of this triangle, and just above the pineal gland,
the opening will be found. Bichat conceives, that the in-
ternal arachnoid covers the choroid plexus, beides lining the
ventricles.

Glandula Pacchioni, (granulations cerebrales, Bichat.)—
Small whitish granular bodies, of unknown function, but
supposed by Pacchioni, whose name they bear, to be glands,
are found in clusters in different situations about the men-
branes of the brain. They are tolerably firm in their tex-
ture, and in size about equal to large pins' heads; they occur
chiefly in the funes, and the pia mater.

They are most abundant about the middle and posterior
portions of the superior longitudinal fissus, and appear naked
in the cavity when the veil is slit open. They are placed
principally round the orifices of the veins, and are fo con-
ected to each other, in the bundles which they form, that
they cannot be separated with an injustice. Some are found
in the lateral funes, at their posterior portion corresponding
with the occipital bone; and these are also placed at the
orifices of the veins. The other funes do not possess them,
excepting the fourth, where they are occasionally seen at
the opening of the vena Galeni. The granulations of the
funes are larger and less dense than those of the pia mater;
their texture and use is unknown. They are very rarely
affected by disease; Bichat mentions ossification as a change
occasionally exhibited in them.

These bodies are just the same as the pia mater as in the
funes, excepting their fize. They are placed at the fides
of the superior longitudinal fissus, and about the venous
trunks, and are continuous with those of the funus. They
lie in the sublinament of the pia mater, and the dura mater
adheres closely to them on the outside, being elevated by
them into small protuberances on each side of the superior
longitudinal fissus. They are only seen along the course
of the latter vessel; they are whiter, smaller, and more firm
than those of the funus.

The choridal plexuses contain feveral reddish or greyish
granular bodies, which are fatter than thofe just described;
and there are fome on the under surface of the velum, juft
in front of the pineal gland. They form two lateral rows,
converging fo as to form a triangle, at the base of which
Bichat describes his arachnoid foramen to open. Towards
the lower part and side of the fourth ventricle, there are
small foids of dura mater, containing feveral granulations.

Gall's Description of the Brain.—He concedes this organ
to be compounded of two substances, exactly similar to thofe
in other parts of the nervous system; viz. of grey, gelatino-
ous, or pulpy matter (the cortex), varying in its colour
and confistency; and of white nervous fibres (the medulla.)
The opinions of anatomists concerning these constituent
elements of the cerebral fabric have been very various, and
have agreed only in one point, that of being altogether un-
formed matter. Malpighi and his contemporaries generally re-
garded the cortex as composed of glands, defined to secrete
the nerves fluid; some affign to it the latter office, without
undertaking to determine the nature of its composition.
Raynich, followed by Halper and molt phvsiologists of that
time, regarded it as a tiffue of fine vessels; and others have
pleased themselves by imagining, that it was a very atten-
tuated prolongation of the blood-vessels entering into
the very subflanee of the nerves. Such theories are under
an-
NERVOUS SYSTEM.

We have proved also, that the nervous system is not formed, nor brought to perfection at once; but that, incon siderable at their origin, they acquire accesions in the grey substance and the ganglia, until they are completed. How then can we adopt a method more conformable to the course of Nature, than to begin our researches where she commences her work, to trace the various degrees of development, and to conclude them where the organ is completed? Can we expect by a contrary course, or by the violent separation of parts, to gain an exact knowledge of the means, by which Nature has attempted to arrive at a common end? In conformity with these views, they endeavor to follow the course of the nervous fibres from their origin to their termination, and employ only such sections as are calculated to illustrate this point? The texture of the brain renders the edge of the knife a very inconvenient means of accomplishing their purpose; they rather employ a blunt instrument, as the handle or back of the knife, and proceed by scraping.

Cerebellum. — Gall and Spurzheim begin with this organ, as it immediately follows the sytem of the spine and of the meninges. They refer its origin to the grey substance contained in the great swelling above the cervical nerves (medulla oblongata); the same point to which they trace the beginning of most of the nerves of the manæ, of the facial, trochlearis, and trigeminus. The origins of the cerebellum form two large bands, one on each side of the medulla oblongata, behind the corpora olivaria, hitherto known by the name of corpora retiformis, or crura cerebelli ad medullam. This band increases in size as it ascends, and the grey substance, or ganglion of the auditory nerve, lies upon it. When that is removed, its fibres may be easily traced into the interior of the hemisphere of the cerebellum. After penetrating a few lines, it meets a collection of grey substance (corpus dentatum, ciliare, or rhomboidum, zigzag) with which the white fibres are so closely interwoven, that they cannot be followed. This is the ganglion of the cerebellum, and the point of origin and increase of most of the nervous mafs of the organ. Many new fasciculi arise here, and branch out into the various subdivisions of the cerebellum; wherever a principal branch comes off, the circumventous matter riles into an eminence; and hence the dentated or fringe-like prominences of the ganglion. As this body is a principal origin of the cerebellum, its fibre is in proportion to that of the latter organ. In most mammals the cerebellum is much smaller than in man, and this ganglion is much smaller and less distinct. The corpus retiforme is also smaller in the same proportion.

The medullary fasciculi passing from the corpus ciliare ramify into the various subdivisions of the cerebellum; a principal one parallels towards the median line, and concurs, with the corresponding one of the opposite side, in forming the middle part of the cerebellum (proceccus verminiformis). This is the fundamental part (partie primitive ou fondamentale) found in all animals, whatever be the disposition of the brain in other respects. The lateral parts are superadded in different animals in various proportions. The band, which produces this middle portion, generally divides into seven principal branches, which are distinctly seen by a vertical section; the further divisions vary in number and length. In animals of the lower orders, and even in birds, this compo sely nearly the whole of the cerebellum; but in the mammals lateral portions are added, so that the part first mentioned becomes the middle piece (piecé mediane de Reil). The other fasciculi go out of the ganglion backwards, upwards, downwards, and outwards, expanding into their horizontal frata. The external surface of all these frata, as well as that of the similar layers composing the fundamental piece, is covered by cinetinous matter. A vertical section shows here, as in the middle piece, trunks of white substance dividing into smaller and smaller branches (arbor viseis). A fection carries through the middle of the ganglion generally discovers eleven principal branches: as we deviate from this middle line towards either side, the number diminishes. There is considerable variety in the further branchings and subdivisions. A transverse section exhibits merely a simple fractum of white substance bordered by the grey matter.

In order to exhibit these appearances, nothing more is necessary than to make a vertical section, in the direction of the primitive band, so as to divide the ganglion into two equal parts.

Thus far we have seen the nervous fibres of the cerebellum diverging from each other, expanding into the lamina which compose that organ, and always occupying a larger circumference. But there is another order of fibres, arising from the cinetinous matter of the surface, passing in the intervals of those first described, which cross, always converging towards the anterior margin, where they form a broad and thick fibrous layer. The posterior and middle filaments pass transversely through the longitudinal bands of the medulla oblongata, which go to diverge in the hemispheres of the brain. The anterior filaments lie in front of these bands in the form of a broad fibrous layer in man. They all unite in the middle line with their fellows of the opposite side, thereby joining the two hemispheres of the cerebellum, after the same manner as the hemispheres of the brain are united by the corpus callosum, &c. This part, which now goes under the name of the pons Varoli, or tuberculum amnii, is really the great commissure of the cerebellum; and is always in a direct ratio to the size of the hemispheres, as the primitive bands are to that of the ganglion. The mammals, having smaller cerebella, have also this commissure smaller. In man, where the cerebellum is so large and so fully developed, the commissure is particularly broad, covering the origins of many of the nerves, which are exposed in other animals. In fishes, reptiles, and birds, this commissure is not found, or, in common language, there is no pons; for these animals have no lateral parts to their cerebellum, and consequently no converging fibres to form it. But all animals have a commissure of the fundamental part, independent of the commissure of the lateral parts, or pons. This commissure is formed by the soft and fine fibrous layers from the inferior and inferior parts of the middle or fundamental portion, commonly called the inferior and inferior valves.

The two orders of nervous fibres described above are distinguished by the following names; in reference to their anatomical arrangement, the first, or those produced by the corpora retiforma, are called "files portans ou divergentes;" and the second, or those of the commissures, "files rentrants ou convergentes." In a physiological point of view, the first are called "appareils de formation;" and the second, "appareils de reunion."

The ordinary opinion, that the cerebellum contains more cinetinous substance, in proportion to its size, than the brain, is erroneous; the mistake arises from our generally making horizontal sections of the brain, and vertical ones of the cerebellum. The size and development of the cerebellum do not observe any determinate proportion to those of the brain; it may be small when the brain is large, and vice versa. Malacarne has found it to vary from the sixth to the eleventh part of the weight of the brain; and in a child he states that it is 1/9th, 1/12th, or 1/15th, or even 1/8th part of the whole weight of the brain.

Generally the cerebellum is smaller in the male than in the female, both in man and in animals; but this observation is not invariably true.
NERVOUS SYSTEM.

It will appear from the preceding description that the cerebellum is a symmetrical organ, or that it is divisible into a right and left corresponding half; although these do not always referring each other perfectly. The same parts are not invariably alike in different individuals. \textit{The same parts are not invariably alike in different individuals.} \textit{Reif has already shown that the length and breadth of the medullary ramifications, and the number, form, and direction of the plates in which they end, vary infinitely in different individuals.}

\textit{Cerebrum.—In describing this part, Gall and Spurzheim confine themselves principally to man, because the organisation is most perfect, and the various parts can be represented in the most intelligible manner. They state that there is no faculty, no mode of action depending on the brain, in animals, of which the type is not discoverable in the human subject; hence the brains of animals may be regarded as fragments of the human brain, and we find united in the latter, all the parts that are scattered through the different classes of animals. If we could remove some organs from the human brain, we should reduce it to the brain of animals; and by adding to the latter, it would be elevated to the rank of a human brain.}

As the cerebrum consists of many divisions, the functions of which are totally different, there are many primitive bands contributing by their development to form it. All these are composed gradually by fibres produced in the cineritious substance of the medulla oblongata (t. grand renflement). They are to be considered as the frill visible rudiments or commencement of the brain, having communication and reciprocal actions with the surrounding fylums. Among these primitive bands are placed the anterior and posterior pyramidal eminences, the bands which proceed from the corpora olivaria, the longitudinal nervous bands, which contribute to form the fourth ventricle, and some others which are concealed in the body of the medulla oblongata. The bands pass into the hemispheres on the same side in which they originate, with one exception; this is in the anterior pyramidal eminences. Here the fibres which arise on the right side, unite in the first instance into a few cords, which pass obliquely over to the left, in the same manner they pass from left to right; each cord giving over one and under another of the opposite side, so as to form a kind of weaving, like basket work. This decussation occupies a space of four or five lines at the lower extremity of the medulla oblongata. The bands afterwards pass up on the anterior surface of the medulla, gradually acquiring the pyramidal form. This appearance is very easily demonstrated, and is totally distinct from the transverse layer or commissure, visible both above and below this part in the anterior fissure of the medulla. The authors hint, that as the fibres of the anterior pyramids are the only ones which descollate, so it is only an injury of that part of the brain which is a continuation or development of those bodies, which affects in its consequences the opposite side of the body. Injuries of the cerebrum, of the posterior lobe, and of part of the middle convolutions of the brain, would affect the same side; these parts being continuations of fibres that do not cross.

The pyramids, as soon as they enter the tegumentum annulare, divide into many bands, which lie in a considerable mass of cineritious substance; from this many new fibres arise and join them. The bands are so much enlarged, when they pass out from the upper part of the pons, as to form nearly two-thirds of the crura cerebri (les grands faiciculs fibres). The pons then is to be regarded as a true ganglion, in which the corpora pyramidalis are strengthened and enlarged to as to form the crura cerebri. The transverse nervous bands of the pons are, as was before mentioned, the commissure of the cerebellum. This course of the pyramids may be seen by making an incision of about a line in depth in the pons, from the pyramid to the crus cerebri, and then turning aside a layer of the transverse fibres of the pons, of the depth already mentioned, with the blade of the knife.

The great fibrous bands composing the crura cerebri are then a continuation and further development of the pyramidal eminences. They contain in their interior much cineritious substance, from which they are constantly strengthened by new fibres. They receive the greatest accessions at their upper end, where the optic nerve turns round their external surface. The nervous threads and fasciculi formed at this part are prolonged into the hemispheres, and end at last in composing the atrata, of which the surface is covered by grey substance (the convolutions of the brain).

Thus the pyramidal bands may be traced from their origin until they are perfect and terminated in the inferior anterior and external convolutions of the front and middle lobes. The pyramids and their ganglion in the pons, the crura cerebri, and the convolutions which these form, are always in proportion to each other; the latter are much smaller in the mammalia than in man, and all the parts first mentioned are consequently smaller.

The same principle of structure is followed in the formation of the posterior lobe, and of the convolutions situated at the upper and internal edge of each hemisphere. The corpora olivaria are ganglia; a strong fasciculus proceeds from them on each side, and joins the posterior bands of the medulla oblongata. These cross the tuberculum annulare through the transverse fibres of the commissure of the cerebellum, and form the posterior and inner third part of each crus cerebri. They receive but little addition until they enter a thick mass of cineritious matter, known generally by the name of the laminae opticis. In this ganglion there is a large quantity of nervous filaments, which ascend, and unite at their exit from the upper part of the ganglion into bands that diverge in a radiating form (en manière de flammes ou de rayons). They then traverse another large mass of cineritious substance, the corpus striatum, where they receive fresh accessions, so that they are sufficient in number to form the convolutions of the posterior lobe, and those placed internally at the upper part of each hemisphere.

The thalamus opticis and corpora striata are in this view considered as true ganglia, in which the nervous fibres are increased in number and size, and are prepared by degrees to form their respective convolutions.

In examining under a general point of view the manner in which nature proceeds to the primary formation of the two hemispheres of the brain, we see that the original bands are produced in the cineritious substance of the medulla oblongata, and reinforced in different places by particular mals of the same matter, and that the same laws prevail here as in the nervous systeums of the abdomen, thorax, spine, nerves of the head and cerebellum. As all the preceding systems are gradually expanded in the internal and external organs of their functions, and then reach their final destination, the fasciculi of the brain undergo a similar successive expansion, and become the organs of the soul noble and important functions." Anat. et Phys. du Sysl. Nerveux, 11, p. 824.

The two sides of the brain communicate together by transverse fibres (fibres convergent ou appareils de reunion), as the systeums of the spine, cerebellum, &c. have their two halves brought into reciprocal action. The ascending or diverging fibres have been followed into the cortical or cineritious substance, which penetrate to some depth, making the internal part of a lighter grey than the external. How they finally terminate is not positively stated. Gall
Nervous System.

Gall and Spurzheim think it probable that new nervous fibres are produced in the cinerous matter, intimately connected with those whose course we have been following. The existence of the converging fibres may be more readily demonstrated than even that of the diverging: they may be seen at the bottom of every convolution decussating the latter, with which they are intermingled. In this way the two subjacent forms a very firm tiffue at the bottom of the convolutions, and at the circumference of the cavities. As the converging fibres draw near to the middle, they form distinct fasciculi and layers, which advance to the median line, and are there continuous with the corresponding parts of the opposite hemisphere forming the different unions or convolutions. The fibres are thicker in the outer layer than in the others; the two orders decussate each other, and form particular strata lining the interior of the cavities. The corpus callosum, with its dependencies, the fornix, lym. &c. the anterior and posterior commissures, are formed by these converging fibres. The fornix, lym. posterior edge of the corpus callosum, and the anterior commissure unite the inferior convolutions of the two hemispheres: the corpus callosum joins all the upper convolutions, and its two extremities are thicker than the middle, because they contain the convergent fibres belonging to those portions of the hemispheres which entered in front and behind beyond the boundaries of this body. The size of these bands of union is always proportionate to animals to that of the parts which they join. As certain parts are very small in birds, the commissures, corpus callosum, &c. are also insignificant in fize, and have commonly been said to be deficient.

Gall and Spurzheim proceed to describe the different cavities of the brain, and the structure of the convolutions. As soon as the diverging fibres have deccussated with the converging ones at the great cavity, the former begin to separate from each other, and are prolonged, like all the other nervous fibrines, into a fibrous expansion. But these fibres are not all of the same length: some end near the side of the ventricles; others are prolonged considerably further: thus the convolutions and their intervals are formed. They are all covered on their surface by a stratum of grey matter.

A vertical section of a convolutions shews the white fibrous substance broader at the basis of connection to the hemisphere and narrower at the opposite end: because the lateral fibres are gradually lost in the grey substance, while the middle ones only reach the end. "Yet the fibres of each convolution are not united into a single fiberulus, but they form two strata, each other in the median line, and slighty agglutinated by a mucous neurilema, or very fine cellular tisse. The same principle is observed in the plates of the cerebellum. At the same time each convolution contains fibres arising from the grey substance and proceeding towards the commissures; consequently each is composed of 1, diverging fibres; 2, of very fine converging fibres; and 3, of an exterior cortical covering. On this stratum is founded the possibility of separating the two strata without injuring them, and of extending the convolutions into a horizontal layer, so that the hemisphere may exhibit a continuus plane surface (le déploissement ou déplication des circonvolutions).

This unfolding of the convolutions is a point of the new opinions which has been very strongly contested, and on which we should conceive, from the data now before us, that it is not easy to decide certainly. The commissioners appointed by the National Institute did not admit the correctness of the representations made by Gall and his associate: the latter gentlemen argue the question at considerable length in their remarks on the report (Recherches, &c. p. 165—206), as well as in the 9th section of their great work, p. 207, et seq.

The following paragraph appears to exhibit most precisely the opinions of the authors. "Let it be observed, on this subject, that, in advancing that the two layers of a convolution are in contact (adoïfes), we did not affect that they are simply in contact. Moreover, we admitted between them an adhesion of contiguity, maintained perhaps by cellular substance; but not a connection of continuity produced by confusion of substance. In our opinion, then, the union is of that kind which might be denominated agglutination (anklebung, Germ.) but not concretion (verwachfung)." Recherches, p. 200.

They say, that if a piece of the hemisphere be taken, the pia mater removed, and the tisse that forms the sides of the ventricle destroyed, a very slight force is sufficient to unfold or extend the whole into a membranous expansion, without any destruction of fibres: the internal surface of this expansion is white, smooth and unjured (intacte), the external is cortical. An analogous process takes place in hydrocephalus: the tisse composing the sides of the ventricles is dissected into an enormous bag, by which the convolutions are gradually unfolded: their fibres, which in the natural state are vertical from the basis to the apex, are now extended horizontally with respect to the contour of the cavities, so that the bag holding the water is composed of a continuous flat stratum of the white fibres, covered by a similar layer of grey substance. It was the observation of what occurs in this dis ease, and particularly of the integrity of the intellectual functions in a remarkable case, indicating that the brain undergoes no effental injury, or is not destroyed, that led Gall to notice this fact in the structure of the convolutions.

If the convolutions are cut off on the outside of the cavities, they may be extended into a plane surface, without any injury of substance. If similar portions are hardened in alcohol, or in a mixture of nitric or muriatic acid and alcohol, or if they are boiled for a few minutes in oil, the two strata separate very easily, and only in the median line; no vestige of torn nervous fibres can be seen on the internal surface, although the fibrous expansion is very visible. When air is impelled on the cut surface of a convolution, or when a stream of water is directed on it from a syringe, a similar separation in the middle line takes place from the basis to the apex. If an opening be made on the side of a convolution from without, and fluid injected into the aperture, it produces a separation in the middle line for one or two inches on each side.

Gall acknowledges that there are some parts of the brain, as the pineal and pituitary glandes, &c. of which he cannot hitherto assign the connections and object in his system. He terminates his view of the organ by a series of general propositions, embracing the points, which we have already detailed, under the title of 'thèses générales anatomiques,' which conclude the tenth section of the fifth volume of his large work.

Physiology of the Brain. Its Motion. —When this organ is exposed in a living animal, its surface alternately rises and sinks: the elevation is synchronous with the pulsation of the arteries, and the subsidence with the diastole of the heart. In the young subject, while the fontanell is full membranous, a pulsation can be felt at that part, coinciding with that of the arteries, and arising from this motion of the brain. This phenomenon is owing to the projection of blood into the arteries of the brain. Some physiologists, as Senac, Bordeu, and Bislat, consider that it arises from the
the great arterial trunks being placed at the basis of the brain, between the latter organ and the bone; as their dilation is resisted by the skull below, it elevates the brain above, just as a tumour placed over a large artery is raised by the pulsation of the vessel, and as the whole lower limb is elevated by the influx of blood into the popliteal artery, when a person fits with one knee across the other.

It is an opinion of Bichat, that the impulse communicated to the brain by this motion of the arteries, is essential to the functions of the former; and he explains the death, consequent on tying all the four arteries of the brain, by the interruption of this impulse. See Heart; sixth column from the end.

This motion of the brain was ascribed, about the beginning of the last century, to a contraction and relaxation of the dura mater, to the fibres of which a power of contraction was granted for this purpose. If the fact of the intimate and universal adhesion of this membrane to the cranium had not been sufficient to show them the absurdity of the opinion, it might have been refuted by the no less obvious circumstance that the motion in question is exhibited just the same when the dura mater is removed from the surface. It must greatly diminish our confidence in names, when we learn that an hypothesis, so contrary to all the facts, was received with great and almost unanimous applause; and supported by Baglivi, Pacchioni, Miltichelli, Lancisi, Fred. Hoffmann, Santorini, Valfalva, and the school of Stahl.

Another kind of motion has been observed in the brain, not con\1\nt like the former, but occasional, and synchronous with the respirations. When we interrupt our breathing, as in training, or any violent efforts, the blood is collected in the venous system, and produces redness and venous distention over the head and neck. The internal vessels are affected in the same way as the external. Haller affirms that the brain rises at each expiration, and subsides at the following inspiration; and that this motion may be perceived in the infant before the fontanel is closed, or in man or animals, in whom the brain has been exposed. There is so little sign of venous distention in natural respiration, that we can hardly expect what has been just described to be a constant phenomenon; although it is easily conceivable that in coughing, crying loudly, holding the breath for some time, &c., a visible elevation should occur; that the finuses should swell, blood or matter be forced out from a wound of the brain, &c.

Sensibility of the Brain.—The cortical sufflance of the organ may be cut, pricked, or irritated by chemical stimuli, without the animal giving any signs of pain. Yet the pre\1\rure of a little blood, pus, or splinter of bone, on the surface of the brain, and other ca\1\tis of that desecration, often produce very severe sufferings. The result of experiments on animals has led physiologists to consider the cortex insensible. Haller Elem. Physiol. t. iv. p. 314.

If the instrument reach the white sufflance of the brain, signs of pain are observed; but these are very obscure on the convexities of the hemispheres. When you penetrate deeper, the animal eris and is convulsed; and these signs are increased in degree, in proportion to the depth of the injury. The pain is never so acute as when the medullary sufflance of a nerve is irritated. The consequences of injury or diffuse sufflance of the medullary sufflance in man are analogous to those effects of violence in animals. We find that tumours, absce\1\sses, effusions of blood, pus or water, fungusses, &c., excite the most excruciating pain.

A considerable quantity of the sufflance of the brain, including both cortical and medullary matter, has often been left in consequence of injury; yet the individual has re-

covered perfect health, and complete enjoyment of all his intellectual faculties. In experiments on animals, where the quantity of brain destroyed exceeds a certain limit, the opposite side of the body is paralyzed; and sleep with hydatids in the brain exhibit the same phenomenon. Dogs of a middling stature may lose from 50 to 70 grains of cerebral sufflance and recover; rabbits hardly 6, fowls and pigeons 12. After such wounds convulsions take place, difficult breathing with widely opened mouth, considerab?e secretion of saliva, and indications of great pain. If the wound reach the ventricles, death quickly ensues. Where an animal survives the loss of a portion of the brain, a yellowish soft sufflance rises up, and fills the vacancy; a limit can be easily perceived, distinguishing this from the proper sufflance of the brain. The ventricle at the same time is expanded towards the wound. Soemmerring, de Corp. Hum. Fab. t. iv. p. 113, note 7.

The brain is the seat of sensation, or the point to which all impressions, whether external or internal, are conveyed: it is the organ of the mind, or the place in which the intellectual operations are carried on; and it is the source of volition, or the part from which the determinations of the will are sent to the voluntary muscles. If the brain be found, any part of the body, any limb, any intestine, any organ of sense, even the spinal marrow, may be injured or diseased, without the power of perception, thinking, remembering, willing, &c. Being affected. On the contrary, injuries and diseases of the brain suspend or entirely destroy the powers just mentioned. Pressure on its surface, as by effused blood or pus, by depressed bone, by the finger of an experimenter, by tumours, &c. make the individual insensible to all external objects, and incapable of motion, although the organs of sense, the muscles, and the nerves are all found. After a blow on the head, or a stroke of apoplexy, you may pinch or cut the skin, bring a light to the eye, or make a loud noise, and nothing is perceived: the limbs and trunk are motionless, like those of a dead body. Irritation of the organ, as by inflammation, generally increases the sensibility; all impressions on the meninges produce a more lively effect: but the mental operations are generally suspended.

The preceding observations apply principally to cases affecting the organ suddenly, as in injuries or apoplexy. When the pressure comes on more slowly, as in hydrocephalus, or in tumours or abscesses produced very gradually, the functions are often not disturbed, although the diseased be considerable. Again, the brain has a great power of accommodation; so that sensation and volition, which are at first suspended in apoplexy, gradually return, although the effused blood still remains. When the pressure is removed, when the blood or pus is evacuated, the depressed bone re-\1\rlored to its former level, or the diseased state of the organ remedied, the functions of the meninges, the mind, and the will are recovered.

In some cases, injury or diseased brain is followed by more partial loss of its powers: as loss of speech, sight, hearing, memory, &c. Concussion of the organ has been followed by fatuity, although sensation and volition were perfect: Haller mentions a man, who remained an idiot for eighteen months, from depression of the parietal bone, and recovered when this was removed. (Lec. cit. p. 317.)

The influences of particular meninges being destroyed, when the brain is compressed or diseased near the origins of their respective nerves, are numerous.

We have shewn, that the impressions of external objects on the organs of sense are conveyed to the brain, and that the cause of motion passes from that organ through the nerves to all the muscles of the body. Some have suspected that
all parts of the organ are not equally concerned in these functions, and that the whole brain is not necessary in the business of sensation: they found that extensive injuries and diseases were suffered, and the individuals nevertheless recovered with entire preservation of their senses, memory, intellectual faculties, and volition. This point is most fully established by an immense collection of examples in Haller's great work. (bid. x. sect. 7. § 32.) Hence different physiologists have endeavored to fix the seat of the fault to some particular spot of the brain: but there is no part, which has not often been found either greatly injured or destroyed by disease, without natural affection of the powers of sensation, &c. Thus the corpus callosum, which several anatomists fixed on as the part essential to the functions of the brain, was wounded in animals by Zinn, with no other effects than such as wounds of the brain in general produce: the power of sensation and voluntary motion remained for many hours and days after such injuries, (Haller, loc. cit. § 33 and 34.) Nor is there any more satisfactory proof that the cerebrum ought to be regarded as the organ of the soul, or as essentially necessary to life. The common notion of the greater danger attending injuries and diseases of this part is unfounded; and Haller shows clearly, that both in it, and in the cerebrum, the lighter injuries are not very dangerous, while more serious ones are usually fatal. (Ibid. § 35 and 36.) The pretensions of the pineal gland, centrum ovale, &c. to the honour of lodging the soul, are not more clearly made out.

Pressure or disease on one side of the brain destroys the power of motion in the opposite side of the body, and this kind of paralysis, which attends apoplexy, as well as various injuries and diseases of the brain, is called hemiplegia. The nerves of sensation are not in general affected in these examples, like those of motion: the eye, the ear, the nose, and the tongue usually retain their powers, although the voluntary muscles of the same side are completely paralyzed. The skin, too, which is supplied by the same nerves as the muscles, is still more or less sensible. Even those nerves, which are concerned in mere motion, as the 36, 4th, and 6th pairs, which go to the muscles of the eyes, have their powers but little affected; and this is more remarkable in the sixth or abducent, which originate from the upper part of the medulla oblongata, and therefore may be regarded as similarly situated with the glossopharyngeal and the hypoglossal, both of which are affected by pressure on the opposite side of the brain. As all the voluntary muscles of the side are paralyzed in hemiplegia, the nerves implicated are those of the spinal marrow, the hypoglossal, accessory, glosso- and pharyngeal, facial, and trigeminal.

In experiments on living animals, the muscles are convulsed on the side which is injured, and paralyzed on the opposite side. Sometimes, however, it happens that the paralysis occurs on the same side, and the convulsions on the opposite.

It may be inquired whether this paralysis of the opposite side be a circumstance belonging to affections of all parts of the encephalon. The effects of pressure on either hemisphere in producing paralysis of the opposite side of the body have been noticed by almost every pathological writer since the time of Hippocrates; and hence has been deduced the general law as to the whole encephalon. The preceding quotation from Haller makes it doubtful whether this always happens.

Injuries and morbid changes of the cerebrum are so much less frequently the subjects of observation than those of the cerebellum, that we cannot speak with much certainty on this point. Morgagni has cafes, in which the paralysis was on the opposite side; but Bianchi saw the same side affected.

In the first vol. of the Medico-chirurgical Transactions, Dr. Yelloly has related a case, in which a tumour pressing on the tuberculum annulare caused paralysis of the opposite side of the body, and of the abductor muscles of the eye of the same side, the nerve of which it also compressed.

We cannot explain how this phenomenon takes place: the decapsulation of the corpora pyramida is inadequate to the solution, because a very small part of the chord is involved in that decapsulation; and, even if this were otherwise, it would only account for the phenomenon in the nerves below the decapsulation, whereas these above it are equally concerned.

The loss of motion is sometimes partial: the face may be affected, when the limbs are not, and vice versa. This, as well as many other phenomena, in which the functions of sensation and motion are disturbed, is quite inexplicable.

For an account of the influence which the brain exerts over the muscles, both of the voluntary and involuntary kinds, see Muscle.

Although the sensations, and the voluntary motions are subject to the influence of the brain, and cannot be carried on without that influence, the involuntary organs are very differently circumstanced. When the action of the brain has suffered a complete intermission, as in sleep, and when, consequently, the senses and voluntary muscles are quite inerte, the heart still contracts, the motions of the alimentary canal go on, all the secretions and exhalations, and the busines of nutrition, are not at all interrupted. Again, when a stroke of apoplexy or depression of the skull has suddenly annihilated the power of sensation and motion, and this has cut off the connection with the external world, the processes of the internal life still continue, respiration, circulation, digestion, absorption, &c. go on, and support life until the brain has recovered from the mischief. The independence of the heart upon the brain has been placed in the clearest point of view by Mr. Brodie, in the papers which we shall quote presently.

This gentleman found that when an animal was pitch, by dividing the spinal marrow in the upper part of the neck, respiration was immediately destroyed, but the heart still continued to contract circulating dark-coloured blood, and that in some instances from ten to fifteen minutes elapsed before its action had entirely ceased. When the head was removed, the divided vessels being secured by ligature, the circulation still continued, apparently unaffected by the entire separation of the brain. When respiration was artificially maintained, by a pipe introduced into the trachea, after the head had been cut off, the contractions of the heart were maintained for one and two hours, and even longer. The cephalic structures, which attain their full growth in the uterus, and polish all their other organs in perfect size and structure without a brain, shew that nutrition, secretion, and absorption, are not under the influence of this organ.

The generation of animal heat, which hitherto has been referred to respiration, is very much influenced by the brain.
After dividing the medulla spinalis under the occiput, and the nerves of the neck, or after cutting off the head entirely, Mr. Brodie maintained artificial respiration by means of a tube tied in the trachea. The action of the heart was continued, and the blood underwent its usual change from the venous to the arterial state, and vice versa. The air employed in respiration also exhibited the change that occurs in common breathing; viz. the removal of its oxygenous portion, and the substitution of carbonic acid gas in its place. Yet the animals on whom these experiments were performed, cooled faster than those which were killed, and exposed to the same temperature. In an experiment on two rabbits of the same size, in which they both had the medulla spinalis divided, and artificial respiration was afterwards maintained in one, while the other was merely left to cool, the thermometer in the rectum stood, at 30 minutes after the operation, at 97; at 60 min. at 94; at 100 min. at 90, in the former; in the latter, the temperatures at these periods were respectively, 99, 90, 94, and 93.

See the Croonian lecture on Some physiological researches respecting the influence of the brain on the action of the heart, and on the generation of animal heat; Philos. Trans. 1811, pt. 1. And further experiments and observations on the influence of the brain on the generation of animal heat; Philos. Trans. 1812, pt. 2.

Towards the end of the latter paper, this gentleman observes, that his experiments "warrant the conclusion, that in an animal in which the brain has ceased to exercise its functions, and the circulation of the blood is kept up to the natural standard, although the usual changes in the sensible qualities of the blood take place in the two capillary sytems, and the same quantity of carbonic acid is formed, as under ordinary circumstances, no heat is generated, and (in consequence of the cold air thrown into the lungs) the animal cools more rapidly than one which is actually dead." Mr. Brodie's experiments tend to establish the conclusion, "that the influence of the nervous system is not necessary to the production of the chemical changes, which the blood undergoes in consequence of exposure to the air in the lungs. He notices some experiments of Mr. Dupuytren, which lead to a different result. After dividing the nerves of the par vagum, this physiologist found "that the blood returned from the lungs had a darker colour than natural, and that the animals on whom this operation is performed, die sooner or later with symptoms of asphyxia, notwithstanding the air continues to enter the lungs; and hence he concludes, that the changes which are produced on the blood in respiration, are not the result of a mere chemical process, but are dependent on the nervous influence, and cease to take place when the communication between the lungs and the brain is destroyed. Mr. Provence, in prosecuting this inquiry, ascertained that the animals subjected to this experiment give out less carbonic acid than before. Mr. Blainville observed, that the frequency of the respirations is much diminished; and Mr. Dumas restored the scarlet colour of the arterial blood by artificially inflating the lungs, and from these and other circumstances, he has arrived at conclusions very different from those of Mr. Dupuytren. My own observations (says Mr. Brodie) exactly correspond with those of M. M. Dumas and Blainville. After the nerves of the par vagum are divided, a less quantity of carbonic acid is evolved, the respirations are much diminished in frequency, and the blood in the arteries of the general system assumes a darker hue; but its natural colour may be restored by artificially inflating the lungs, so as to furnish a greater supply of air to the blood circulating through them. We may suppose, that on the division of these nerves, the sensibility of the lungs is either extremely impaired, or altogether destroyed, so that the animal does not feel the same desire to draw in fresh air; in consequence, its respirations become less frequent than natural, and hence arise the phenomena produced by this operation.

The facts contained in the two papers, Mr. Brodie continues, "go far towards proving, that the temperature of warm-blooded animals is considerably under the influence of the nervous system; but what is the nature of the connection between them? Is the brain directly or indirectly necessary to the production of heat? These are questions, to which no answers can be given, except such as are purely hypothetical. At present we must be content with the knowledge of the inflated fact; future observations may, perhaps, enable us to refer it to some more general principle. We have evidence, that when the brain ceases to exercise its functions, although those of the heart and lungs continue to be performed, the animal loses the power of generating heat. It would, however, be absurd to argue from this fact, that the chemical changes of the blood in the lungs, are in no way necessary to the production of heat, since we know of no influence in which it continues to take place, after respiration has ceased."

Concerning the mode in which the brain operates in perceiving, reflecting, and willing, as about the manner in which the nerves convey the impressions made on the senses to the brain, and the commands of the will from the brain to the muscles, we are profoundly ignorant; not indeed for want of attempts at explanation, for they have been abundant in all ages of physiologist; but because the operations are not cognizable by our senses, any more than those which take place in matter, when it exhibits the phenomena of gravitation, electricity, magnetism, and so forth. We refer those, who are inclined to look over the hypothetic dreams about these matters, to the Elementa Physiologicorum of Halle. He has wisely separated them, under the title of "conjectura," from the "phenomena vivi cerebi," and he introduces them with the following observation; "non periit loco fuiter, ab errore fibi in ipsis carere, quae nunc dicenda superfluent. Eorum pars minus fenibus patet, reliquam ex collectis nu- duque probabilibus argumentis erurere opore, quorum tanta fit vis, ut nobis speratiam ruri, non ca vero confianitia, ut ad alium convencionem sufficiat. A nervis facimus dubiis serios initium." Lib. x. sect. 8.

From the experiments of Mr. Brodie, which we have related above, it appears clearly, that the brain exerts no immediate influence on the heart and lungs; but that those organs continue to execute their functions, when artificial respiration is employed, for some hours after the brain has been removed. The brain, however, has the means of influencing the lungs, as it is necessary to the action of the muscles employed in respiration; and through the lungs it affects the heart. For a particular account of the mode in which these three important organs act on each other, in producing death, see Death, Heart, and Lungs. We have only to add here, the manner in which, according to Bichat, the phenomena of general death succeed, when it begins in the brain. 1. Annihilation of the action of the brain. 2. Sudden cessation of the sensations and voluntary motions. 3. Paralysis of the diaphragm and intercostal muscles. 4. Interruption of the mechanical phenomena of respiration, and consequently of the voice. 5. Interruption of the chemical phenomena. 6. Paucity of black blood into the fyllem of red blood. 7. Retardation of the circulation by the contact of this blood with the heart and arteries, and by the absolute immobility of all the parts, particularly.
particularly of the chert. 8. Death of the heart, and ceasing of the general circulation. 9. Interruption of the organic life, particularly in those parts which are habitually penetrated by black blood. 10. Abolition of animal life, which is the produce of all the functions. 11. Termination of the action of the white organs, which die more slowly than other parts, because their fluids are more independent of the general circulation.

The division to the stomach, or rectum, or to the surface of a wound, of various poisons, causes death by their action on the brain. Opium, alcohol, effusive oil of bitter almonds, empyreumatic oil of tobacco, and juice of aconite, are of this number, and probably many others. Life may be prolonged by keeping up respiration artificially in these cases; and in some instances this process has enabled the animal to recover from the effects produced on the brain. Of mineral poisons, arsenic, emetic tartar, and muriate of barytes, act on the brain, but they act also on other organs. For further particulars on these subjects, and especially for an account of the very interesting researches of Mr. Brodie, contained in the Philosophical Transactions for 1811 and 1812, see Poisons.

Of the Nerves.—These organs have generally been regarded by anatomists as all of one kind, both in structure and functions; they have been considered every where as designed to establish a communication, for the purposes of sensation and volition, between the brain and the organs of our body. More accurate inquiry shows that there are numerous differences of colour, strength, form, and interior organisation between the particular nerves; and the analogies furnished by the lower orders of the animal kingdom, lead us to doubt whether some of them depend at all on the brain in the execution of their functions. These circumstances are considered at greater length in the preceding review of the doctrines of Gall. We have to notice here, the arrangement of Bichat, which, although not rigorously correct, points out a broad general distinction of the nervous system, in respect to some of its leading phenomena. He divides it into two parts, having for their respective centres; one, the brain and its dependences; the other, the ganglia. The former, belonging to the animal life, confits of the encephalon, medulla spinalis, and nerves connected with those organs; and is the agent by which external impressions, defined to produce sensations, are transmitted to the brain, and by which the volitions emanating from the latter organ are conveyed to the voluntary muscles. The latter, including the ganglia and the nerves belonging to them, is almost every where distributed to the organs of digestion, circulation, respiration, and the secretions, belong to the organic life, and executes a much more obvious office than the other. He calls the first the nervous system of the animal, and the latter, that of the organic life. The cerebral nerves, however, send some branches to the glands, involuntary muscles, &c; while filaments from the ganglia proceed sometimes to voluntary muscles. Again, the numerous nerves included under each of these classes differ from each other in many respects.

The nervous system of the animal life is symmetrical, like all the organs of this life; but the correspondence of the two sides is not always rigorously exact. A line drawn through the middle of the brain and spinal marrow, would divide them into right and left similar halves, and corresponding nerves would be connected with each of them. Hence arises the expression "pair of nerves," which denotes the corresponding trunks of the right and left sides; an expression, which, in general, is inapplicable to the nerves of the ganglia. We may state then that there are two animal nervous systems; a right and a left, separated by the median line. The distinction is rendered apparent, not only by definition, but by diseases; one half of the body may be paralyzed, or subjected to convulsions, while the other is unaffected.

General Account of the Origins, Course, and Distribution of the Nerves.—When we speak of a nerve arising or deriving its origin from the brain and spinal marrow, running, palling, or proceeding through various parts, dividing into branches, being continued, prolonged, or separated, having a peculiar course, &c. These expressions are employed merely for the sake of describing position and connection, of pointing out the mechanical arrangement of the parts; and not to express any succession in the formation, or any dependence of one organ on another. There would be just as much propriety in describing the olfactory nerve to arise or begin at the pituitary membrane, and to end in the brain, as in the ordinary method, in which this order is inverted. That the nerves, which are connected both to the brain and medulla spinalis, are formed quite independently of those parts, is evinced by the influences of monitory features, in which these organs are wanting, yet the different nerves are perfect. See Monster.

The origins of the nerves are very different; and the nerves themselves exhibit very different appearances in their commencements. The third, fourth, fifth, and facial nerves adhere so lightly to the brain at their connection with its surface, that a very little force detaches them; the other cerebral nerves are more strongly connected, and those of the spinal marrow are firmly attached to that organ. Some arise by numerous threads, which may either come off separately, or in one body; others by one mass of white substance. Some are very soft, others firm, &c. The dura mater lines the foramina, through which they proceed from the skull; the arachnoid forms a process surrounding each nerve, and is then reflected to the dura mater. The length of the nerves within the cranium and the vertebral canal, and their direction, are various. All these points will be more minutely considered in the description of the particular nerves.

Some of the nerves of the brain proceed to their respective organs without communicating with any other nerve; e.g. the olfactory, optic, auditory, trochlear. The par vagum, glosopharyngeal, accessor, and hypoglossal nerves are joined, immediately on leaving the head, to the surrounding trunks. But these communications are the most remarkable in the spinal nerves; the cervical, brachial, lumbar, and sciatic plexuses result from these unions. A similar kind of plexus is formed by the constituent nervous filaments of each trunk. If you examine the cords that make up a large spinal nerve, and separate them, you will find that they are not firmly applied laterally to each other, but that they frequently interchange branches. Each cord of a nervous trunk consists of filaments, some of which are frequently detached from one cord and go to another. In both the kinds of communication now described, there is simply juxtaposition of the nervous trunks or filaments, and not confusion of them.

After forming the communications just described, the nervous trunks separate from each other, and proceed to their respective organs, passing through the cellular interfaces in a longer or shorter course. Their form is generally round; but it may be flattened, as in the sciotic. This does not seem to influence their functions; as a naturally round nerve flattened by a tumour performs its functions in the usual way. The trunks vary in length, according to the distance of the parts to which they are distributed; sometimes they go with the arteries and veins; sometimes alone.

Vol. XXIV.
Nervous System.

alone. As they proceed, they send off branches, which produce others, and so on until they are reduced to very fine twigs, that can hardly be traced by the naked eye. The angles of these divisions are very various; but the acute is the most common. At these branchings a certain number of cords or twigs is separated from the trunk; hence the former are longer or shorter in proportion as they arise later or sooner from the nerve. In the limbs most of the nervous branches are accompanied by an artery and a vein: but there are many exceptions to this rule in the head and trunk: so that we cannot attach any importance, in the functions, to this juxtaposition.

The small branches end in two different ways: they communicate with other nerves, or are lost in the organs.

The communications already noticed are simple juxtapositions: the filaments of one nerve join another, and concur with them in constituting the trunk. This is the most common kind of connection. But there is another, analogous to the anastomoses of blood-vessels, in which two branches from two different nerves meet and join together. This is seen in the union of the hypoglossal and cervical, of the facial and infraorbital. Here the nervous filaments are continued into each other. The different branches of the same nerve may communicate together, as in the trigeminal. It is said that the right and left pairs are joined at the median line in the chin and neck; but it is not easy to demonstrate this.

The nerves of the animal communicate with those of the organic system.

The terminations of the nerves in the organs present considerable varieties: the skin, muscles, and mucous systems have many nerves; the cellular and glandular systems fewer. In the serous, medullary, and part of the fibrous system, we know little of them. Tendons, cartilage, hair, epidermis, &c. have none.

We do not know what form the nerves assume at their terminations; whether they lay aside the neurilema, so as to form a pulpy expansion, or not. The former is evidently the case with the optic and auditory nerves.

Organisation of the Nerve of the Animal Life.—We have only a few points to add to the general account in the article Brain.

The threads composing a nervous trunk differ in size in the different nerves: in the sciatic and cranial they are more slender than in the brachial nerves. Some, as the nervus vagus, consist of a single cord marked with grooves. The cords may be of uniform or of different size. The optic does not exhibit that interior intertexture which we have mentioned above. The eye, and many other circumstances, which have been chiefly noticed by Reil, show that there are great differences in the internal arrangement of the nerves; that each hath something peculiar, and, consequently, that they cannot be compared to arteries or veins, which are alike everywhere.

"The neurilema, says Bichat, forms to each nervous filament a true canal containing the medullary substance, as the veins and arteries contain blood, with this difference, that the former flagellates, while the latter circulate."

This membrane is continuous with that covering of the medulla spinæ which is called its pia mater. Hence, if the medulla be squeezed out of the spinal marrow, the nerves remain connected to its pia mater. A similar connection seems to subsist in the head; for the nerves are generally torn away when the pia mater is detached. The optic before its junction and the olfactory have no neurilema; the former acquires the covering after the union; the canals are particularly large in it, and the medullary substance therefore abundant. The neurilema bears considerable analogy to the pia mater. Arising in the way we have mentioned, it accompanies the nerves in their passage through the foramina of the head and vertebral canal. It is of the same nature on the outside as within, but it is here surrounded by cellular substance.

The neurilema exhibits the phenomenon of cripitation or corrugation in a very remarkable degree, particularly on immersion a nerve in tolerably strong sulphuric or nitric acid. The nerve is immediately contracted in size, and twisted in different directions. Boiling water has an analogous effect. But continued ebullition or immersion in acid softens it and produces a yellowish tint; at last it is almost dissolved. Water hardens it at first, and this effect lasts for a month and a half: the nerve is afterwards softened, like all other animal tissues.

The density of its tissue renders it very strong: hence, a flender nerve will bear a great weight, because this membrane composes a considerable part of the whole cord.

The medullary substance is very abundant in the optic nerve; also in the auditory. It composes the whole of the optic behind the junction, as well as the entire olfactory nerve within the cranium. In the latter cavity, the medulla of the nerves in general seems to predominate over the neurilema; while on the outside these proportions are reversed. Hence the nerves are weaker within the skull than without.

The great power of the nerves to resist gangrene during life, and putrefaction after death, seems to be owing to the neurilema. The water, in which they are macerated, has very little fætor; while that of the brain is very offensive.

The medullary substance of the nerves or brain is not susceptible of corrugation by acids or hot water; but, in consequence of the contraction of the neurilema, the medulla is expressed from the cut end, fo as to form a small rounded tubercle.

Bichat enters at considerable length into a parallel between the medullary substance of the nerves and of the brain; and exposes, in a comparative view, the effects of different chemical agents on each. The result of the whole is, that there is great general resemblance; but the great proportion of neurilema in most of the nerves occasions them to exhibit very different phenomena from the brain under the application of chemical agents.

The nerves have no cellular substance on the inside of the cranium and spine; but contain much of it in other parts. A copious stratum usually connects them to the surrounding parts. The same tissus joins together the different cords of the nerve; and this generally contains fat in the large nerves, always in the sciatic, as may be shown by drying them. A finer kind of tissus connects together the minute filaments.

We have no remarks on the blood-vessels of the nerves to add to what is stated in the article Brain. The function of nutrition proves the existence of exhalants and absorbents. Bichat doubts the correctness of the opinion, which assigns to the neurilema the office of secreting the medulla of the nerves. He conceives that this membrane supports and protects the medullary part; that the vessels are first minutely ramified in it, and then enter the latter substance, as those of the brain are dipped on the pia mater before they go into its substance: and that these interior vessels in both cases deposit the materials of the organ. He observes, that the olfactory, and a part of the optic nerve within the cranium have no neurilema.

Properties of the Nervous System of the Animal Life.—A nerve possesses very little extensibility; when force is applied
Nervous System.

Applied to it in a living animal, it can hardly be stretched beyond its natural state. This is probably owing to the neuralame, for the medullary substance undergoes a great extension in hydrocephalus. When a large nervous trunk is pressed on by a tumour, its fibres are separated, and it assumes a flattened form; in which state, according to the degree of pressure, it either continues or ceases to transmit sensations and volitions. Sudden dilatation acts much more efficaciously in interrupting these functions, than that which comes on gradually. Thus the pressure of the head of the bone in dilatation of the humerus causes numbness of the limb, when a much more considerable tumour in the axilla has no such effect. A slight depression of the cranium from a fracture disturbs all the functions of the brain, when large swellings, fungusses, &c. of slow growth hardly exert any sensible operation. A similar contrast is seen in the sudden effusion of a little fluid in the ventricles, and the enormous collections of chronic hydrocephalus.

There is still a concurrency: when a nerve is cut transversely, the two ends are hardly separated.

The facility of the nerves is to be considered under two points of view: 1st, that which is inherent in them; 2dly, their concern in the facility of other organs.

The effect produced in the mind, when any foreign body acts on our organs of sense, or on any parts of the frame pitting nerves; or when certain internal changes of an unknown nature are produced in our organs, is called a sensibility. The nature of the mind being unknown to us, as well as the impressions, actions, motions, or whatever they may be, of the nervous system, which produce mental phenomena, we cannot arrive at a more clear definition or description of sensibility than what we have just given.

"Sensitivum dicimus," says Haller, "populorum omnino significatione ejus vocis ut, quamcumque mentis nostrae mutationem, quae ex corporis humani cum mente connexi contactus ortur."—"Sensit adere nervus, nemp fi a copore quocunque contingatur, nascetur in anima mutatio, per quam ejus contactus conficta redditur." (Elem. Physiol. lib. x. sect. 6. § 1.) This effect is caused not only by the contact of the grocer kinds of matter, but also by those, of which the existence is not immediately obvious to the senses: such as light, electric fluid, the air, and its modifications producing sound, &c. According to the violence of the impression, the state of the organ, &c. sensations may be pleasurable, painful or indifferent.

Generally, the body causing a sensibility is not in immediate contact with the nerve. The surface of the body has an insensible external covering. The nerves of the teeth feel through the substance of these organs. In the eye and ear there is a large apparatus between the nerve and the part impressed: in the nose and mouth the surface is covered by mucus. These media are necessary to some kind of sensation: when the cuticle is removed, acute pain is felt by the contact of foreign bodies, but their properties are not discerned. If the tongue be made quite dry, tastes are not perceived.

Again, different alterations in the condition of the organ modify the sensibility: the slightest contact is acutely painful, when a part is inflamed; the stream of water is not felt in the healthy urethra, but is intolerably painful when that canal is inflamed, &c.

The different nerves are affected by different kinds of impressions; and each is insensible to those which act on others. Light is perceived only by the optic; it affects no other nerve in any form. The loudest sound produces no sensation in the nerves of the eyes, tongue, skin, &c.

Animal sensibility is the most strongly marked property in these organs: the acute pain is produced, when they are exposed and irritated, as on a blistered surface, or by tying, stretching, pricking, cauterizing, or applying chemical fumigations to denuded nerves. We cannot believe much in referring this sensibility to the medulla of the nerves; for simple contact, without any pressure, is hardly painful, and the filaments may be actually separated in a large nerve, by very careful division, with little pain to the animal. But the moment that the instrument penetrates, acute pain is produced.

This property of animal sensibility is gradually exhausted by repeated experiments: and the nerve is renewed after some interval of rest. The animal sensibility of the nerves is different in its kind from that of other organs; at least, the feelings produced when these organs are the source of disorder are altogether peculiar. This is seen in the tie douleurs; in the sciatica, as compared with rheumatism; and in the tingling and numbs caused by pressure on nervous trunks, as in the familiar example of the foot going to sleep when the great sciatic is compressed, &c.

Another peculiarity in the nerves is, that local irritation of a trunk often affects all the branches; if the ulnar nerve is stripped or compressed at the elbow, we feel it in the fingers, and the whole leg and foot are affected when the sciatic is compressed in fitting. When a superficial nerve is injured, the lower part of the limb frequently swells and becomes painful. A ligature has not the same effect; for that intercepts the communication with the brain. Why is this disturbance always propagated downwards, and never towards the brain, which is the ordinary course of sensation? In the arterial, venous, absorbing, mucous, &c. we have no examples of this propagation of irritation.

The nerves are essential to the animal sensibility of the other organs; external impressions, whether of that general kind common to all the external surface of the body, or the particular ones confined exclusively to the organs of sense, produce no effect, unless the nerves are found and communicating with the brain. If the optic, auditory, or any other nerve be compressed, tied, divided, or in any way considerably injured, light or sound will cause no sensation, although the organ and the brain may both be in a perfectly natural state. If all the nerves of a limb be cut or tied, the skin may be pinched, pricked, burned, or irritated in any way without sensation being produced. Nothing is more acutely painful than the irritation of a nerve; let the trunk be cut through or finely tied, and you may irritate it beyond the point of division or ligature (that is, in the portion of which the continuity with the brain is interrupted) without the animal feeling what is done. If a divided nerve should unite again, or the ligature be removed from a tied nerve (supposing it should not have derged too much the texture of the part) the power of feeling is restored.

The organs of the sense profess the general power of feeling, as well as the particular faculty of receiving and transmitting the impressions from their respective external agents. Now the latter may be lost, while the former continues unimpaired; the eye may be insensible to light from injury or disease of the optic nerve; yet it is still susceptible, like the external surface of the body in general, of the impressions of heat and cold, hardnes and softness, &c. The sense of smelling is lost in a cold, while the general feeling remains, &c.

We may then lay it down as a general position, that the nerves are necessary to all the external sensations, of what
ever kind they may be. All the organs, with which external objects can come in contact, as the skin, the beginnings of the mucous surfaces, and the organs of sense, are more or less abundantly supplied with cerebral nerves. None derive any nerves from the ganglia. This division of the nervous system of the animal life is very considerable: when to this we add what is employed in supplying the voluntary muscles, there is very little left.

Whether the impressions producing internal senfations are all conveyed to the brain by the nerves, is a more doubtful point: the phenomena here are more obscure. We find also, that parts with few nerves have acute sensibility, that others with a considerable portion of cerebral nerves have little or no feeling in the natural state; we must, therefore, hesitate in admitting that the nerves are the only media by which impressions producing senfations can be conveyed, and that the acuteness of feeling is always proportioned to their number and size.

The concurrence of the brain is essential in these internal senfations, as well as in the exterior ones. However the internal organs may be affected, the action of opium, wine, &c. on the brain, will suspend all senfation.

Some organs have the most exquisite sensibility, yet possess hardly any perceptible nerves: such is the medullary membrane of the long bones. The liver and lung, which receive nerves from the brain, may be irritated in living animals, without signs of pain being produced. The voluntary muscles, which have so many and large nerves, may be cut or irritated with very little pain, if the actual nervous ramifications are avoided. Ligaments, which have no nerves, when twisted or diffused cause considerable pain. Tendons, aponeuroses, ligaments, and all other organs, which receive no visible nerves, are acutely senfible when inflamed.

This question concerning senfibility engaged Haller in a long and laborious controversy. He subjected the different textures and organs of the body to experiment in living animals: he cut, pricked, compressed them, applied chemical stimuli, as acids, alkalies, &c.; and inferred that the parts were insensible, when the animals gave no signs of pain. In this way he determined that tendons and aponeuroses, ligaments, bones, membranes of all kinds, as the pericardium, pleura, peritoneum, &c. are insensible; and that the viscera have only an obscure sensibility. This, however, is too limited a view of the subject: diffuse often develops in these supposéd insensible organs the most exquisite power of feeling: The epidermis, hair, and nails, and the substance of the teeth, are the only parts which can be irritated with certainty to be insensible; but we cannot trace any nerves into the following organs, viz. the bones, cartilages, tendons, ligaments, membranes, fat, and the medulla of bones, the seccundines, the corne, crystalline lens and humour.

The nerves have no perceptible motion, but they are essential agents in those movements of the voluntary muscles, which depend on volition. When they are cut, tied, or severely injured in any way, the muscles no longer obey the will. See the article Muscles.

How do the nerves transmit impressions and the determinations of the will? What is the manner in which their influence is exerted? “The opinions of physiologists,” says Bichat, “have been much divided on these points. Some have admitted a kind of vibration in the nerve, some talk of impulse, some of action, some speak of a fluid contained in tubes in the nerve, others of an insensible fluid not held in any visible canals. The latter hypothesis is still very generally upheld; and long discussions are maintained whether it be of an albuminous, electric, magnetic nature, &c. In most treatises of physiology, the chapter on the nerves is principally occupied with such discussions, which I shall not enter into here, because we have no data concerning it founded on experience. Moreover, cannot we study and analyze the phenomena connected with the nerves, without knowing their mode of action? All the old physiologists committed the error of willing to begin at the point, in which some day or other we may be able to end. The science was still in its cradle, when all the discussions were directed to the primary causes of the vital phenomena. What was the result? Long trains of unsubstantial reasoning, and a necessity to come at last to the rigorous study of phenomena, leaving that of their causes, until we have collected observations enough to form the basis of theories. In the same way, the nature of light, fire, heat, cold, &c. was discussed for centuries, until at last philosophers found out that they wanted bases for their reasonings, and thus created experimental philosophy. Endless disputes agitated the schools about the soul, the judgment, &c. before metaphysicians discovered, that instead of attempting to discover the essence of the intellectual faculties, they ought to employ themselves in analyzing their operations. Each of the natural sciences has had two periods: the first, in which first causes were almost the only object of investigation; the second, the experience and observation were relied on for divulging the phenomena. Physiology has still one foot in the former, while she has placed the other in the latter: the physiologists of the present day must make her complete the step.” Anat. Gen. t. i. p. 175.

The organic properties exist in the nerves in a low degree; they are merely subservient to their nutrition. Hence all the principal diseases of these organs affect their animal sensibility: tumours, funguses, ulcerations, &c. are very rare.

When the power of transmitting senfations and motion is lost, nutrition still goes on, and the nerves remain as large in a paralyzed as in a healthy limb. Perhaps they may be diminished in size, when the whole limb begins to be reduced. We know nothing of any changes in these organs, after long continued painful diseases, as cancers, &c. Bichat has examined them in cancer of the flomach and uterus, without finding any change.

The cerebral nerves do not seem to exert any influence over the organic properties of other parts, and hence the leading distinctions between the animal and the organic senibilities. In the capillary circulation, in secretion, exhalation, absorption, nutrition, the fluids make on the solids an impression, of which we are not conscious, and by virtue of which the latter react. The influence of the cerebral nerves does not seem to be essential in any of these cases.

Capillary circulation goes on in cartilages, tendons, ligaments, which possess no nerves. These parts are as much liable to inflammation, as those which have large or numerous cerebral nerves. Indeed the tongue and the retina are parts seldom inflamed; while in the cellular tissue and serous membranes, which have very small nerves, the capillary circulation is brought into increased activity very frequently. In paralytic limbs, as in animals where the nerves have been cut, the capillary circulation goes on as usual; inflammation, ulceration, &c. may take place.

That the exhalation from the skin is independent of the cerebral nerves, is proved under the article Interstuments. In the synovial and serous membranes, and in the cellular tissue, exhalation constantly goes on; but the nerves are very few, if any. Irritation of the nerves, brain, or medulla
dulla spinalis, has no influence on the exhalations. The
fame observations hold good of aborption, which, as well as the
eelation of the secretions, goes on in sleep, when the ac-
tion of the brain and voluntary nerves is intermitted. On
the subject of the secretions, see GLAND.

Nutrition is carried on in parts that have no cerebral
nerves; and it goes on in limbs completely paralysed.

The nerves have some influence, of a kind and degree not
yet clearly ascertained, on the production of animal heat.
The ligature of a nerve, in an operation, will produce a
general sense of cold in the limb: the little finger and ring-
finger remained constantly colder than the others, after the
ulnar nerve had been divided at the plisiform bone. Com-
pression of the nerves, as by the head of the bone in lu-
xtion, produces analogous effects. The temperature of the
affected limb in hemiplegia is below that of the found one,
although there is no perceptible difference in the pulse. Yet
the heat is not always increased, when the activity of the
nervous system is augmented; nor, vice versa, do these
experience decreafe, when that is diminished. The cures in
which it seems independent of that system are as numerous
as the others.

SYMPATHETIC. We have to consider here the relations of the
different nerves to each other, and the share which they have in
the sympathies of other organs.

1. Sometimes the two nerves of one pair sympathetic; that
is, when one is affected from any cause, the other becomes
disturbed without any obvious reason. This is seen in
the eye frequently. Or, an injury of one nerve may be
attended with disorder of another on the same side of the
body, either belonging to the same trunk, or to one entirely
different.

The nerves, when disturbed, may affect other organs:
thus, in tic douleursux, there are pains in the head and
other parts. When a nerve is iritated, many muscles are
thrown into convulsion, besides those which receive their
supply from the irritated trunk. Vomiting and increased
action of the heart often attend attacks of nervous pains;
and irritation of the nerves, in living animals, may cause
vomiting. Again, these parts may be sympathetically
acted on by various organs: hence the pains, particularly
of the limbs, in various acute or chronic disaffections,
have been much divided in opinion concerning the
causes which produce sympathies. How can an organ,
which has no obvious relation or connection to another, act
on it, so as to produce in it very serious disturbances, for no
other reason than because it is affected? This singular phe-
nomenon often occurs in health; but the instances are so
numerous in diseafes, that, if we take from every affection
what does not depend immediately on the disorder of the
function particularly disturbed, diseases would be reduced
to a state of simplicity very favourable to their study and
treatment. But no sooner is one organ affected, than many
or all the others seem to feel the attack. Most authors
have regarded the nerves as the general medium of communi-
cation in these cases; and the communications have been
considered as an arrangement connected with this object.
Some consider that the brain is always affected in an inter-
minate manner; others do not see the necessity of this.
The communications of organs by means of the blood-
veffls, or by the cellular tissue, or the contiuity of mucous
surfaces, have all been adduced in explanation of the phe-
nomenon. None of these are supported by sufficiently
strong arguments, to induce us to consider them at length;
and they are all exposed to the objection of placing the sub-
ject in too general a point of view.

Bichat observes that sympathies may be divided into as
many kinds as there are different vital properties, and that
these may be excited in different ways. When the animal
fenibility of an organ is sympathetically excited, this does
not always depend on nervous communications: for the
part, in which the primary affection occurs, may be one not
fuppied with nerves, as a tendon, cartilage, &c. and con-
sequently cannot communicate with that in which the pain
is felt by means of nerves. Again, it is uncertain whether
the nerves are the only media for conveying internal fen-
sations. This author considers that the brain produces these
sympathies; that the power of perception is disturbed; that
there is an "aberration of the internal fenentient principle,
referring to one part a fenation of which the cause exists in
another." Thus, when the end of the nerve is irritated in
a stump, pain is felt in the amputated limb; a fume in the
bladder causes fuffering in the clasus penis. Perception is
subject to numerous irregularities, which have not yet been
analyzed with sufficient accuracy.

When the voluntary muscles are thrown into convulsions
in sympathies, we conceive that the nerves are effentially im-
plicated, according to the views which we have preftented
of the dependence of the animal contraboutivity on those or-
organs. (See MUSCLE.) The affected organ must act on
the brain, which re-acts through the nerves. If the latter
are divided in the limb of an animal, the muscles are not
thrown into convulsion by irritations, that would otherwise
certainly produce this effect.

The brain and nerves cannot be the agents of communi-
cation in sympathies, where irritability, or, according to
Bichat, the fensible organic contraction, is concerned; be-
cause the former has no power over the involuntary muscles.
In fakes, then, where the heart, flomach, or other internal
organs, are sympathetically affected, we must acknowledge
our ignorance of the mode in which this is brought
about.

The fame observation may be applied to the sympathies of
the organic fenibility and infeble contraction. The
nerves have no influence over these fpecies; by acting on
these organs, you neither increase nor diminish the functions
over which they predile; and these are equally free from
disturbance in diseases of the nervous system. Hence the
sympathetic exhalations, as phatical fweats and feral
fweats; the fecretions and abfolutions of a fimilar na-
ture, which occur frequently in fepafl, are evidently out of
the influence of the nervous system of animal life. The
cellular and vascular influences are equally inadequate to a
solution of the phenomenon. What positive datum can we
rely on, in explaining, by these means of communication,
why fweats occur when the lung is diseased, why saliva is
poured into the mouth when the membrane of the palate is
iritated, &c.

"The fecret to be collected from the preceding obser-
vations," says Bichat, "is, that the sympathies of the
animal fenibility are, in most fakes, an aberration of that
principle in us, which perceives, and which is deceived con-
cerning the place in which the causes of our fenations act.
Gally. That the sympathies of the animal contraction re-
quadr the intervention of the brain; and that we do not
know how the part affected acts upon that organ, although
it is clear that the nerves are the media by which it re-acts on
the muscles gally. That the causes of the two kinds of or-
ganic sympathy are absolutely unknown."

"We must observe here, not to confound the natural con-
nection of phenomena with sympathies. In syncope ap-
oplexy, and afphyxia, the heart, brain, and lung are respec-
tively affected, and their functions suspended. This pro-
duces, as a natural consequence, suspension of action in all
other
other parts. But the cafe is quite different in sympathies. When the functions of the skin are interrupted, the lungs, stomach, or intestines may be affected. The sympathetic phenomena either may or may not be exhibited; whereas, in the preceding cafes, the suspension of all other actions follows inevitably that of either the heart, brain, or lungs. On the reproduction of the nerves, see the article Brain.

Progressive Development of the Nervous System of the Animal Life.—The brain is of a very large size, in comparison with the rest of the body, from the earliest periods of gestation. Its size, indeed, in the first months, is monstrous, in comparison with its relative bulk in an adult. It is soft, and even semifluid at this time; and the two component matters are much less distinct than they will be afterwards. The nerves are also very large. The latter organs present an appearance just the reverie of what takes place in the arteries. The size of these vessels is in proportion to that of the organs; while, on the contrary, the small organs of the foetus have very large nerves.

There is every reason to suppose that the brain and the nerves of the animal life, although so large, are quite inactive in the foetus. The body may be completely formed, and arrive at its full size, although the brain be deficient.

At the time of birth, the brain is excited by the circulation of red blood in its arteries, as well as by the impressions of surrounding objects on the organs of sense. The former circumstance is essential to the performance of its functions, which either do not begin at all, or only in an extremely feeble manner, and for a very short time, unless the lungs begin to act, and thus cause the proper change in the blood. Long after birth, and even during the whole period of growth, the nervous system, and the brain, which is the centre of it, predominate in their development over the other parts. But this predominance is gradually diminished until the time of puberty, when the generative organs assume the primary importance in the system.

The novelty of every thing which surrounds the infant, keeps his nervous system in constant action; and hence it requires longer, and more frequently repeated intervals of repose. The numerous sensations of the child lead to frequency of motion. The great development, and constant exercise of the nervous system in the child, expose it to the action of causes that produce disease. Slight pain will produce convulsions, and disturbances of this system are the predominant affections of this age. The structure of the brain is frequently affected, as well as its functions; as the occurrence of tumours, hydrocephalus, spina bifida, &c. demonstrate.

When the growth is completed, the brain and nerves have arrived at their just proportion to the other systems; and their functions are then in equilibrium with those of the other organs.

As old age advances, the functions of the nervous system are gradually diminished. The sensations are less lively, both because long habit has rendered them familiar, and because the perceptive power of the nerves is blunted. As the nerves transmit fewer and fewer acute sensations, the brain has less to perceive; and the motions are consequently diminished. Changes of structure coincide with these changes in the functions. The brain, which was so soft in the foetus, is very firm in the old subject; it is less red, and has a more tawny colour. The nerves also grow harder; but the disproportion in point of firmness between the two ages is not so remarkable in these as in the brain. It follows from these circumstances, that pain is less acutely felt by the old. As age advances, partial losses of power often occur in the nervous system; and hence hemiplegia, which are very common in the aged.

Nervous System of the Organic Life.—There is an obvious difference in structure between the nerves just described and those which belong to the present division; and there are no striking differences in the functions of the parts to which the two kinds of nerves belong. The arrangement of Bichat is well calculated to show these distinctions; although, as we have already observed, they cannot be applied rigorously and satisfactorily throughout the nervous system. The ganglia of the spinal nerves, which belong to organs of animal life; and the branches of organic nerves, distributed in some cases to parts of voluntary motion, interfere with the arrangement.

Bichat regards each ganglion as a particular centre, independent of the others in its action, furnishing or receiving its particular nerves, as the brain furnishes or receives its nerves, and only connected with the animal nerves by communications. Hence, while the brain is the common centre in the animal life, to which all sensations are conveyed, and from which all motions proceed; there are as many particular centres, and as many small secondary nervous systems in the organic life, as there are ganglia. He observes that all anatomists, even those who, without attributing any precise meaning to the expression, have called the ganglia small brains, have regarded these bodies as dependencies, or swellings of the nerves, in the course of which they are found; and, as they moly occupy the great sympathetic, they have been represented as a distinguishing character of that nerve. But that nerve cannot be laid to exil, according to the view which he gives of the ganglia; and the continued cord, which may be traced from the neck to the pelvis, can only be regarded as a series of communications between the ganglia.

The following were the considerations that first induced him not to regard the sympathetic as a nerve like others, but merely as a series of anastomoses. 1. The continuity is sometimes interrupted, particularly between the last thoracic and first lumbar ganglion; sometimes two adjoining ganglia in the loin or sacrum have no communication. 2. Cuvier has found that the superior cervical ganglion is always inflated in birds; and in many other animals there are interruptions in the series of ganglia composing what is called the great sympathetic nerves. 3. The ganglia sometimes communicate by two or more branches, which is a different disposition from that of the cerebral nerves. 4. What can be called the origin of this nerve? Is it the first pair? But the cerebral nerves decrease in size as they become more distant from the brain, and the caudal would be reversed in the sympathetic on this supposition. Does it arise from the spinal marrow? Then the branches produced in one region would come from the branches furnished by the spinal marrow in that region. But the sympathetic nerves are much larger than the branches from which they must be supposed to arise on this supposition.

The properties of these are also different from those of the cerebral nerves; they do not transmit sensations, nor have they any concern in voluntary motion; they are distributed only on the organs of the internal life. Hence they are concentrated in the trunk, particularly in the chest and abdomen; hardly any are found in the head, where nearly all the organs belong to the animal life; and none in the limbs, which belong exclusively to this life.

As the ganglia and their nerves are distributed generally to the organs of the internal life, they partake with them in their want of symmetry, and they are exposed to numerous varieties in number, form, &c. This, indeed, is not a very
very rigorous distinction between the two nervous systems; there is as great a want of symmetry in the par vagum as in the sympathetic.

From the view which we have given of the opinions of Gall, it will be seen that that anatomist nearly coincides with Bichat in his notions about the ganglia and the great sympathetic nerve.

Ganglia.—A general account of these bodies is given under the article Brain, and in the view of Gall's doctrines. We have some particulars to add.

The greatest number of these bodies is found along the vertebral column, where we see, in regular succession from above downwards, the cervical, dorsal, lumbar, and sacral ganglia, which, with their communicating nervous branches, form the great sympathetic nerve of most anatomists. Besides these, the head contains the ophthalmic or lenticular, the sphenopalatine, and the maxillary; the oval swelling of the olfactory nerve, and the ganglion Glaseri of the nerve trigeminus, both placed within the cranium, do not resemble the other ganglia in many points. There are the cardiac or splanchnic ganglia in the abdomen; and sometimes a small one at the base of the heart in the chest. The posterior root of each spinal nerve swells into a ganglion as it passes out of the vertebral canal. The bodies thus formed are acknowledged by Bichat to have the greatest analogy to the other ganglia, yet they are situated on nerves of the animal life.

Some ganglia are found constantly, others are only accidental; in the hypogastical plexus, and in the middle of the neck, there is sometimes a small ganglion. The maxillary, or some of the lumbar or sacral ganglia, sometimes do not exist.

They are generally deeply seated, so as to be protected by their situation from external injury; this circumstance renders it difficult to make experiments on them, and will therefore drive us from clearing up the obscurity in which their functions are enveloped. They possess all kinds of figures; and the individual ones vary greatly in this respect in different subjects.

Very different views have been given by anatomists of the internal structure of the ganglia; this may have arisen in some degree from actually existing differences in the organs. In the oval swelling of the olfactory nerve, we can distinctly see medullary fibres involved in and separated by cortical matter. The fibres of the nerve trigeminus are expanded and separated, and mixed with many blood-vessels, in the ganglioniform swelling of that nerve. Neither of these has any firm general exterior investment. In the other ganglia we find a loose cellular substance round them, and this seems to be conformed into a clover flavatum, which is soft, thin, and tolerably smooth on the surface; it has no analogy to the neurula. This covering is thicker in the spinal ganglia, and those of the neck, than in other situations. Scarpa and Soemmering consider the ganglia to be formed by an expansion of the nervous filaments, which are separated into very small threads, interwoven and mixed with a peculiar vascularity substance; and affirm that the structure becomes matted, by dissecting these bodies after they have been mace-rated for some time. "Filia nervorum, noti oculi habitus, in ipso ganglii massa quadam mollis, fusculentum, purpurea, lutea, vel cinerea, vasfique plena, tale cellulo-filo-filis, in ganglio nervi olfactus vero massa cerebris contrahit interponitur." (De Corp. Hum. Fab. t. iv. p. 148.) These anatomists state, that the nervous filaments pass directly through the ganglia, although separated from each other, and mixed with others; that the different nerves connected with a ganglion have their component fibres so intermixed, that they may be all laid to communicate with each other; that the nervous fibres may sometimes be seen running over the surface without mixing with the masts; and that the nerves going from a ganglion are generally larger than those which come to it, as if they derived some accession in it. "Ganglia igitur," says Soemmering, "articulae plebeae, tenerum florum postulo atque molliste, maffa quadam valis divine interposita fervatis representant." Ibid. p. 149.

Bichat finds for the ganglia both soft, spongy, homogeneous tissue, not at all resembling either the substance of the brain, or that of the nerves. He cannot discern in them that expansion of the nervous fibres, which is described by Scarpa. He states that chemical agents have a different operation on the nerves and on the ganglia; and that the difference of colour, consistence, and properties tend still further to establish the distinction. If the ganglia are merely expanded nerves, why do the spinal branches, after forming one of these bodies, not transmit sensation and voluntary motion? Why do not the branches coming in and going out correspond in size: why is there not a constant proportion between the nerves and the ganglia? We have already shown that Gall regards the ganglia as masses of semi-cerebriform matter, giving origin to nervous fibres.

Scarpa asserts that the ganglia contain cellular tissue and fat: but Bichat says that they have very little of the former, and none of the latter.

The ganglia are curled up by the action of boiling water; and a continuation of the ebullition afterwards softens them. Alkalies, when strong, act upon them, and have a slight solvent effect: but this is much less considerable and rapid than their action on the brain. They resist putrefaction even longer than the nerves.

Properties of the Ganglia. These are very obscure. Bichat states that he has opened the abdomen of an animal, and exposed the femoral ganglion, after allowing him to recover from the first alarm of the operation; that he has then irritated the ganglion without the animal becoming at all agitated, while the irritation of a lumbar nerve, as a point of comparison, caused howling and violent struggles.

This author considers it probable that hysteria, hypochondriasis, melancholia, and the long train of nervous disorders, may probably be traced in the ganglia: the feelings and pains attendant on these have a very different character from those which arise from affections of the animal nervous system.

We may state that the mode of action of these organs, and the effects they produce on parts which derive their nerves from them, are entirely unknown. We agree with Soemmering, who, after enumerating the opinions on this subject, concludes; "Ergo genus unuum gangliorum usus adhuc in obscurat latet." (Neurologia, § 161.) A very copious enumeration of opinions concerning the structure and functions of the ganglia may be seen in the first section of Gall's large work.

Development of the Ganglia. They are not more advanced than the other organs in the fetus; and in this respect are remarkably distinguished from the brain. In the young subject, those affections which are supposed to reside in the ganglia hardly exist. They are as firm in their texture in the fetus or young person as in the adult. Our want of knowledge of the functions of these organs prevents us from flating anything further concerning their changes at different periods of life.

Nerves of the Organic Life. Each ganglion is a centre, from which nervous branches go off in different directions. The connection of the ganglia and the nerves is different from what we observe in the brain and spinal marrow. The
adhesion is very firm, so that if force be applied, the nerve will give way in any situation rather than at the point of connection. Sometimes the nerves coming from the ganglia remain distinct; sometimes two or more unite into one trunk.

After leaving the ganglia, the nerves are disposed in various ways. 1. Some communicate with those of the animal life: and such exist in every ganglion. 2. Each ganglion communicates with the two neighbouring ones, with that above, and that below it; the ophthalmic, maxillary, and sphenopalatine are however excepted from this rule; and there may be exceptions in other situations. 3. Several go to voluntary muscles. All the nerves hitherto enumerated agree entirely with the cerebral nerves in structure.

4. Most of the nerves, arising from the ganglia by separate filaments, are interwoven as to form plexuses with those of the contiguous ganglia, in the neighbourhood or upon the large vessels. The most remarkable of these are in the abdomen. The nerves of the animal life are generally found in small proportion in them. These plexuses compose a tolerably close network, altogether unlike any thing in the nerves of the animal life, imbedded in cellular tissue, and accommodated to the form of the surrounding organs: the number of small nervous filaments entering into their composition is very considerable. Of these nerves have a reddish or greyish colour, softer texture, and often a knotted appearance. The plexuses divide into subdivisions, which go to the various organs, particularly of the internal life. These subdivisions consist of numerous small filaments, which communicate more frequently, so as to form networks, but never unite into large cords, and surround the arteries of the organ to which they are distributed. Some of them merely accompany the vessel, without lying close to it: others adhere firmly to the arterial coats, communicate very repeatedly with each other, and seem to form almost an additional covering to the vessel.

When the artery is short, these two orders of branches continue distinct from each other, until they have arrived at the organ: but if the vessel be longer, the exterior filaments gradually join, and are lost in the internal plexus. This plexus may be followed in the large trunks: it divides at the origin of branches, but the filaments become so minute that it is not possible to trace them far. They may be followed further on the spermatic than on any other artery. When we set aside those branches of the ganglia, which communicate with each other, and with the nerves of the animal life, the remainder are distributed almost entirely on the arteries. This circumstance, together with the close and almost inseparable adhesion of the nerves to the arterial trunks, indicates some influence of those parts on the secretions, exhalations, nutrition, &c. of which these vessels convey the materials: the nature of this influence is entirely unknown to us.

Neither the veins, nor the absorbing vessels, are accompanied by such an apparatus of nerves.

The nerves of the ganglia may be divided into two kinds, with respect to their organization: 1. those which in appearance and texture resemble the cerebral nerves; and 2. the soft reddish or greyish filaments so abundant in the plexuses. The nature of these has not been particularly examined; we do not know whether they have neurilema and medullary fulfulness.

Properties of the Organic Nerves.—They possess much less animal sensibility than the other kind of nerves. Bichat has irritated them in animals, after opening the abdomen, and has also irritated the cellular stratum on the outside of the mucous membrane of the intestine; yet the animal gave very slight signs of pain. The process carried on in the organs, to which these nerves are distributed, do not excite sensations. “Every thing,” says Gall, “is carried on in these systems without consciousfuefs, by a blind necessity, and under the direction of laws, which they cannot either obey or oppose voluntarily. The vifera have motion: they felect the nutriment that is suitable to their nature, and reject what is heterogeneous; secretions and excretions go on in them. But plants exhibit similar phenomena. We know that the same functions take place in acephalous monsters; that the re-action of an organ does not prove that it is the seat of true sensation, which is essentially characterized by perception, or the consciousness of an impression; and that no irritation is felt without the co-operation of the brain: consequently, that we can no more ascribe the property of sensation to the nervous systems of the abdomen and head, than admit its existence in acephalous monsters and plants. Again, the superior and inferior systems exert their reciprocal influence without consciousfuefs, and without the participation of the will: the affections and passions operate on the vifera, and derangement of the functions of the vifera disturbs the faculties of the mind and of the soul; yet it is equally beyond our power to discover how this mutual influence is exerted, or to arrest its operation.” Anat. et Phys. du Syst. Nerveux, t. i. p. 37.

Under certain circumstances, however, the nerves of the ganglia appear to transmit impressions to the brain: at least the organs, to which they are sent, are the seat of the most acute pains in various diseases. Independently of the sufferings caused by the more obvious derangements of these organs, they are the seat of various indefinable internal feelings, when not visibly diseased. “I conceive,” says Bichat, “that the sensibility of the organic nerves is much exalted in disease. It can hardly be doubted that the cardiac plexus performs an important part in the various sensations which we experience in the epigastrium: the acute pains often accompanying the formation of aneurisms probably arise in part from the dilatation of the nervous filaments that surround the artery; and the organic nerves are probably much concerned in the sensations experienced in certain nervous diseases.” Anat. Generale, t. i. p. 241.

The motions of the organs, to which the nerves of the ganglia are distributed, are never subject to the will; they may probably be disturbed by the influence of the brain in cases where the organs of the internal life have their functions affected by the condition of that organ.

It is natural to inquire how far the organic nerves are concerned in the phenomena of the internal life. Are the internal sensations referred to these parts, or the pains produced by their diseases, suspended when the nerves are tied or divided? How are the motions of the organs affected by such operations on the nerves? The deep situation of the ganglia, the great number and small size of the nerves, have hitherto opposed insuperable obstacles to the experimental investigation of these points.

We must not forget that the preceding observations are not applicable to all the ganglia; that the spinal nerves and some nerves of the head have these bodies, and convey sensations and voluntary motion in their ordinary state.

Description of the Cerebral Nerves.—The olfactory nerve; or nerve of the brift pair.

The origin of this nerve has been generally assigned to the corpus striatum, which Chauflier has accordingly named couche du nerf ethmoidal. Soemmerring observed that there was no proportion in animals between the nerve and this eminence; and Cuvier showed that the cetasca (as the dolphin
dolphin and porpoise), in whom there are no olfactory nerves, nor organs of smelling, have nevertheless corpora fimbriae. It is the only nerve which can be affected, with any probability, to arise from the hemispheres of the brain; and even if this be allowed, it has no connection with the white substance. It proceeds from the grey substance on the under surface of the organ, and its filaments are perceived towards the front of the inner convolutions of the middle lobes. They are soft, and appear for some time enveloped in the grey matter: they come together and form three principal roots, an outer longer, and two internal shorter ones. The external may be followed to the bottom of the fifth ventricle.

Gall and Spurzheim are inclined to refer the origin of this nerve to a fasciculus, arising at the side of the corpora pyramidalia, passing through the pons Varolii to the telencephalon, and thence to the corpus geniculatum internum, and then passing under the optic nerve, beyond which they cannot trace it. Recherches, p. 99.

The three origins, of which the middle is cortical and the two exterior medullary, unite into a very soft nervous chord of a triangular prismatic figure, which runs in a longitudinal groove of the under surface of the anterior lobe, confined by the tunica arachnoidae. It advances from behind forward, inclining more and more towards the nerve of the opposite side, and increasing gradually in size, until it arrives on the upper surface of the cribriform plate of the ethmoid bone; here it quits the groove of the anterior lobe, and swells into an oval ball of a greyish colour and very soft consistence, in which the medullary fibres appear separated by cortical matter, as in a ganglion. For a description of the remaining course of this nerve, see Nosse.

When a section of the olfactory nerve is made at right angles to its course, crenated substance is observed in its middle, and sometimes towards the sides: and it may be also partially seen on the external surface. The latter has a peculiar laminated and striated appearance, compared by Soemmerring to the pili of the lily: this is best seen by immersing the recent nerve in spirits of wine.

Besides its origin, the olfactory nerve has the following peculiarities: 1. folded and striated external appearance; 2. softness, in which we can hardly distinguish any thing fibrous; 3. triangular prismatic figure; 4. position in a groove of the brain; 5. approximation of the right and left nerves before they penetrate the dura mater; in all other cases the corresponding nerves diverge; 6. the crenated bulbus; 7. the crenated substance within the nerve; 8. passage through the skull by numerous foramina.

It is the largest nerve of the brain in an embryo of three months, and hollow: in the fetus at full time it has a crenated appearance and rounded figure; it is shorter, softer and fibrous, and large in comparison with the other nerves.

The nerve of one side is sometimes larger than the other; but an appearance of this kind may arise from its lying deeper in the groove of the anterior lobe.

Optic Nerve, or nerve of the second pair.—The large hemispherical eminences of the lateral ventricles have been generally regarded as the origin of these nerves; and hence the names thalami nervorum opticorum, couches des nerfs optiques, &c. applied to these parts. The optic nerve, says Soemmerring, arises by very minute roots or fibres from the posterior and inferior part of the thalamus, from the corpora geniculata, and the corpora bigemina: and these origins are visible when the parts are merely exposed by opening the ventricle, without any further direction.

Gall observed that there is no proportion between the size of the thalamus and of the nerve arising from it; that the fibres is much smaller in the horse, the cow, the deer, than in man, while the latter is much larger: hence he doubted the justice of the common opinion, and further anatomical investigation justified his suspicion. "A broad band," says he, "composed of nervous filaments, is seen in man and animals, but more distinctly in the latter, as in the horse, cow, sheep, pig, dog, &c. to proceed from the upper or anterior pair of the corpora quadrigemina (mammals). It turns round the outer edge of the optic thalamus, then joins a considerable collection of grey substance, called the corpus geniculatum externum, in which it is increased. Hitherto the whole band adheres to the optic thalamus; afterwards it simply lies upon the crus cerebi, where it is no longer attached, except by its external anterior edge, which is connected to the neighbouring substance of the brain." Anat. et Physioll. du Syr. Nerv. 184, p. 112.

In support of this opinion concerning the origin of the optic nerve, Gall observes, that in animals it bears a proportion in its size to that of the naris, although there is no such proportion observed between it and the thalamus. He also found the nerve unaffected, where an ulcer had destroyed half the thalamus: when, on the contrary, when the nerve has been diminished in size, the naris has experienced an analogous change.

When it is dilated from the thalamus, the optic nerve makes an extensive sweep (tractus opticus) over the surface of the crus cerebri, advancing towards the nerve of the opposite side. In this course it has a flattened figure, is unconnected with the crus on its inner edge, but receives filaments on the outer, and is enveloped in the vascular ramifications about this part. Towards the front it grows rounder, becomes adherent to the cernuus pyramidal prominence (tuber cinereum) that closes the front of the third ventricle, and joins the root of the opposite side, the substance of the two appearing completely mixed. Several filaments are received from the tuber, so that the nerves are larger after than before their union. The united portion lies on the smooth space in front of the sella Turcica between the two anterior clinoid processes. From this point the nerves, visibly enlarged, again separate to proceed respectively through the right and left foramina optic. Their course in the orbits is described under the article Eye.

The degree of union between the two nerves at their apparent conjunction has been a matter considerably disputed. (See DUCHASSON.) Apparently the right and left have their substance completely confounded in the middle portion. The following is the account given by Soemmerring, who has bestowed much attention on the subject. "The right and left nerves decussate, which sometimes, but not always, can be observed, when one is disfigured or considerably smaller than the other; for the nerve of the opposite side is found disfigured, discoloured, or smaller before the junction. Sometimes, but not always, the thalamus of the opposite side, and sometimes the thalamus of the same side, is changed in structure, or smaller. For example of the latter, see Meeckel's note to Soemmerring's Version of Haller's Praxis Litterar. § 509, and Medicina, über die Durchkreuzungen der Schenennere, Halé 1790. The optic nerve may be altered as far as the union, and no change perceptible beyond that point. Therefore we cannot determine whether all the fibres, or some only decussate." The mode of decussation, he adds in a note, "can be best observed in animals, as the horse, dog, pig, cat, racoon, squirrel, birds, amphibien, &c. In the horse, one nerve penetrates the other in fibres one lies on the other; and they are connected merely by loose cellular substance. In the deer the nerve is sometimes altered from the affected eye to the junction, and no further.
NERVOUS SYSTEM.

further. Nöthig has adduced in his "Differtatio de Decuffatione Nervorum Opticorum," various cases and authorities which cannot be detailed here. The specimens mentioned in that dissertation are in my possession. Several anatomists, as Ackermann, Billmann, Leveling, Michaelis, Ronge- mont, Walter, Wenzel, and Clofiss and Ebel in the horse, have adopted my opinion." (De Corp. Hum. Fab. t. iv. § 215.) Cuvier and Gall adopt the same view: "Cuvier has the brain of a horse, in which one optic nerve is diminished in size (atrophic), and the same change is continued behind the union on the opposite side. All our observations on the human subject, the horse, hare, and fox, confirm this fact, and make us doubt the authenticity of the cases alleged on the opposite side, which we cannot admit without attributing inconsistency to nature." Anat. et Physiol. du Cerveau, &c. p. 114.

The optic is finer than the olfactory or auditory nerve, but softer than the rest: it is the largest cerebral nerve after the fifth.

It is peculiar to the optic nerve, 1, to arise from a distinct eminence of the brain; 2, the junction or decussation with the opposite nerve; 3, the surrounding sheath of dura mater in the orbit; 4, the contraction in its passage through the coats of the eye, before it expands into the retina; 5, its expansion into a membrane, inadherent on all sides, and the foramen in that membrane. From their origin to the point of their union the optic nerves are soft and pulpy; they contain no cinnerous matter internally, nor are they frizzled on the surface, like the olfactory. They are covered by the middle lobes throughout all the first part of their course. They become firmer about their junction, but have no neurilema within the cranium, being made up entirely of medullary fulblance. The orbital portion, besides its covering of dura mater, has a dense neurilema, forming a general external investment, so that the nerve represents a single thread, and is not divisible, like other nerves, into secondary filaments: this neurilema sends productions from its inner surface, forming several canals, in which the medullary fulblance is contained.

Nervus Optico-motorius; or nerve of the third pair. — It arises from the crus cerebri, or its inner or anterior edge, where the divergence of these two processes leaves a vacancy, named by Vicq d'Azyr la folie des nerfs oculo-musculaires, just in front of the pons Varolii. Its filaments may be followed in firmer brains to the under surface of the pons: they come through the black fulblance of the crus cerebri, and are increased, according to Gall, in their passage. The threads, coming out of the crus cerebri, are collected together into a roundish nerve by the pia mater: it separates from the opposite nerve, passes between the profunda cerebri and superior cerebelli arteries, and is sometimes perforated by the trunk or by a large branch of the former. It separates very easily from the crus cerebri, when the surrouding pia mater or vessels are torn off from the brain: so that caution is necessary, when we wish to demonstrate its origin. This soft part, however, is very small, as the nerve immediately becomes covered with neurilema, and acquires considerable firmness. It goes obliquely forwards and outwards, unconnected to the surrouding parts, and therefore easily brought into view near the edge of the tentorium by elevating the brain. Just at the point formed by the posterior termination of the tentorium cerebelli, it enters a canal of the dura mater, which surrounds it as far as the foramen lacerum orbitale. This canal is formed on the outside by that portion of dura mater which constitutes the cavernous sinus: on the inside, a thin lamintum of cellular tissue separates it from the carotic artery. Arriving in a direction slightly oblique at the level of the foramen lacerum, it divides into two branches before penetrating that opening. In most of its course under the dura mater it is situated more internally and higher than the trochlearis and ophthalmic nerves: but when it has arrived under the anterior clinoid process, and has divided, its superior branch is covered by those two nerves, which crofs obliquely, and become situated on its inner side. Of the two branches, one is superior, the other inferior: both enter the orbit by the broadest part of the foramen lacerum, and penetrate, together with the nervus motorius externus and the ophthalmic nerve, between the two origins of the external straight muscle.

I. The superior and smaller branch mounts over the optic, the nasaf, and the ophthalmic nerves to the under surface of the rectus superior muscle, in which it is distributed, with the exception of a small branch sent to the levator palpebro superioris.

II. The inferior branch, much larger than the preceding, passes under the optic nerve, and divides into, 1, an internal branch, which supplies the rectus internus muscle; 2, a middle shorter one for the rectus inferior; and 3, an external, the longest and slenderest of the three, which sends a small branch to the outer side of the optic nerve, where it joins the ophthalmic ganglion, and then terminates on the obliquus ocular inferior.

We notice nothing peculiar in its structure; it has a firm neurilema, both in the cranium and orbit. The peculiarities of the nerve are, that the origins of the right and left are very near together; that it supplies five muscles of the globe; and, through the ophthalmic ganglion, gives branches to the iris.

Nervus Trochlearis; nerve of the fourth pair: n. patheticius.—This nerve is the smallest of those which arise from the brain, and has the longest course within the cranium. It arises, under the tubercula quadrigemina, from the valve of the brain, by a single, double, or triple root; and is sometimes joined, by a tranverse communication, to the opposite nerve. The origin, soft and unprovided with neurilema, may be torn very easily: but the nerve soon acquires greater firmness. It runs round the crus cerebri, between the cerebrum and cerebellum, covered by the arachnoid coat, which must be cut in order to expose it: it then continues its course along the edge of the tentorium cerebelli to the posterior clinoid process. There it enters a canal of the dura mater, separated from the cavernous sinus by a peculiar dense tissue. It goes horizontally forwards between the oculo-motorius, and the ophthalmic, and crosses the former obliquely, as it approaches the orbit, which it enters at the broad part of the foramen lacerum, through a fibrous hole in the lining of dura mater. In this cavity it passes over the two elevator muscles, and immediately under the membranous lining of the orbit, to the superior oblique muscle, in which it ends.

It is the flenderest nerve of the brain, almost equalling in size a large fwenth thread: it has the highest origin; and pursues the longest course within the dura mater: finally, it supplies only by a single muscle.

Nervus Trigemini; nerve of the fifth pair: pair mixte of Gall.—This is the largest nerve of the brain, particularly in individuals who have a large face: at all events, it is equal in size to the optic. Its'origin has generally been referred to the side of the pons Varolii, from which it is detached just at the front of the crus cerebri. Gall traces its roots backwards from this part, through the pons to the outer edge of the corpus olivare: it is divided, within the pons, into three principal fasciculi, and its fibres arise from the
the grey substance in various places. When it is difter-
gaged from the crus cerebii, it forms a thick flattened
cord made up of numerous (from 70 to 100) distinct pa-
allel threads, loosely united. Each of these is dense and
firm, and covered on the outside by the neurilem covering it: but they are feebly connected to the medullary substance, and just at
the point of connection the nerve is firmer than in its sub-
sequent course. It consists of two portions connected by
loose cellular tissue, and sometimes separated by the passage of
blood-vessels; viz. a larger posterior and exterior, a
smaller anterior composed of fewer, fatter, and whiter, but
larger threads. It goes forwards and outwards, surrounded
by the arachnoid coat, passes under the front of the teno-
rhion cerebii, and enters a peculiar canal of the dura mater
by an oval aperture towards the anterior and upper part of
the petrous portion of the temporal bone. This canal is
situated on the outside of the cavernous sinus: as the nerve
enters it, it becomes broader and flatter; the filaments of the
larger portion are separated from each other, divided, and
formed into a plexus, so that the whole trunk undergoes a
kind of conical enlargement, and presents a flattened band
instead of a round cord. After a short course, it swells
into a knot or ganglion (ganglion Glaeni), concave above,
where the filaments enter, and convex below, where they
de-part, having a redish colour from the distribution of nu-
umerous vessels in it; and presenting a kind of middle ap-
pearance between that of a ganglion and a plexus. The
dura mater has a very close adherence to this knot; in which
the nerve is more than six times its original thickness.
The ganglion is fatter than those of the spinal nerves; but
firmer than the bulb of the olfactory: although the con-
nection of the dura mater is so close, that it hardly admits of
separation without injury, it has beenascertained that no
filaments enters that membrane to be distributed on it.
After the ganglion, the nerve refines its original appear-
ance, and divides into three branches, surrounded by the
dura mater, and passing out of the cranium by distinct fora-
mina: the nervous fibres are however so completely inter-
 woven in the ganglion, that the continuity between the
threads of the trunk and of its three branches is completely
interrupted.

When the nerve and its ganglion are raised from the sur-
face of the cranium, and turned over, we perceive that the
whiter filaments, which form the anterior or smaller division
of the nerve, go along the under surface of the swelling
without being at all concerned in its formation. Their size,
whiteness, and want of connection with the ganglion, imme-
diately strike us: they join the inferior maxillary nerve, and
constitute the crotaphitic and buccinator branches of that
nerve: Palleta, therefore, divides the trigeminus into five
branches, adding the two last mentioned to the three ordina-
dry described.

The three branches of the trigeminus separate from the
ganglion as follows: the ophthalmic is the smallest, and the first
towards the front: it separates from the others from its ori-
gin, and goes obliquely forwards and upwards towards the
outer side of the cavernous sinus. The second, which is
larger, arises below this, and is called the superior maxillari:
it goes horizontally forwards, and after a passage of some length enters the foramen rotundum. The third and
hindernent is the largest, and descends almost perpendicu-
larly into the foramen ovale.

I. The ophthalmic nerve, covered by the dura mater, is
separated from the cavernous sinus by cellular tissue, and
retains the fibrous character of the trunk. Placed at first be-
low the eculo-motorius and the treccleirii, it runs with the
latter above the former, and divides, before it enters, or as it
enters the orbit by the foramen lacrream, to three branches:
an external small one, the lacrimal nerve; a superior, which
is the largest, the frontal nerve; and a middle one in situ-
tion and fize, the nasal nerve.

The lacrimal nerve runs along the outer side of the
orbit between the perissima and the adductor muscles: it is
divided into several filaments accompanying the lacrimal
artery, and entering the gland. It is difficult to determine
whether these end in the substance of the gland: but several
manifestly terminate on the integuments of the eyelid and
forehead. It has a communication with the subcutaneous
male.

2. The frontal nerve, which by its size would be regarded
as the continuation of the trunk, enters the orbit between
its superior surface and the corresponding extreme of the
rectus superior: it goes obliquely forwards and inwards,
over all the contents of the cavity, and immediately under
the bony arch, and divides sooner or later into two branches,
which vary in their relative size. 1. The internal or supra-
trecheiries, is commonly the smallest, and quits the orbit
between the suprachylic notch and the cartilaginous pulley.
to distribute its branches on the superior eyelid, the internal
part of the forehead, the corrugator supilcrii, orbicularis
palpebrarum, epicranii, and integuments. A smaller fila-
ment of this nerve joins the infraoachleiries, and gives
a twig to the frontal sinus. Its branches on the forehead be
rather deeper than those of the following branch 2. The
external or proper frontal branch quits the cavity by the
supraciliary notch either in one or two branches, and fends
flenderer superficial, and larger deep-seated ramifications to
the epicranii, orbicularis, and integuments of the up-
per eyelid, eyebrow, forehead, temple, and top of the
head. It may be detached most conveniently by detached
all the soft parts from behind forwards, towards the supera-
ciliary arch, and thus making it out from below; we find its
ramifications of two orders, deep-seated muscular, and super-
facial cutaneous. Some unite with ascending branches of
the facial nerve, others form a minute network round the
frontal arteries. They may be traced almost to the occupant.
As the trunk and ramifications of the frontal nerve lie fo
the skin, and are placed against the bone on the other
side, they must be exposed to external pressure: the painful
feelling caused by wearing a tight hat is ascribed by Bi-
chat to this cause.

3. The nasal branch, naso-ocularis, the lowest and most
interior of the three, divides from its very origin into two.
(a) A small twig, the lowest in situation produced from the
ophthalmic, joining the ophthalmic or lenticular ganglion,
but previously communicating with the smaller branch of the
eculo-motorius. The ganglion formed by the conjunction
of this with the branch already described of the eculo-mot-
orius, is very small, of a nearly square figure, placed on the
outer side of the optic nerve among the fat. The root
of the ganglion from the nerve of the third pair is short
and thick, that from the ophthalmic long and slender, and
sometimes detached from the trunk before it enters the orbit:
sometimes the latter does not exist. Two fasciculi of cuti-
ary nerves are produced from the ganglion, and separated
from each other more widely as they come nearer to the globe. The
superior and smaller fasciculi, lying close on the optic nerve,
constitute a small bundle, and then of small twigs of different size:
the inferior larger bundle is made up of eight or ten small fila-
ments, lies closely adhering to the nerve; one leaves the reil,
and enters the sclerotics about its middle, under the rectus
externus. 4 U 2 The
The ciliary nerves, thus produced, differ in size, do not communicate together, but proceed in a tortuous direction to the back of the sclerotica, where, increased in magnitude and connected with the ciliary arteries, they obliquely perforate the membrane, running for some length within it. They then follow a straight and nearly parallel course, between the sclerotica and choroid, giving no branches to either of these, to the iris. They are very rarely united to each other by transverse threads. At the orbiticus ciliaris they divide into smaller branches, which are again subdivided, and the minutest threads, having a serpentine direction, are interposed between the ciliary vessels like white radiated fibres. When the vessels are well injected, and the part examined in water, a series of white points is observed in the orbiticus ciliaris, receiving the ciliary nerves on one side, and sending twigs towards the pupil on the other, thus resembling ganglia.

b. The nasal branch lies close on the sheath of the optic nerve, which it crosses, under the rectus superior and levator palpebrae; it produces one or two ciliary branches, which resemble in their distribution those just described, and then is divided into two branches. One of these passes through the foramen orbitarium internum anterior to the cavity of the cranium, where it is covered by the dura mater; it goes out of the skull through the front of the cribriform lamella, and is distributed towards the anterior part of the septum nasi, and of the outer side of the cavity. The other, sometimes called infraorbicularis, goes to the inner corner of the eye, below the trochlea, and distributes several very small twigs to the integuments of the forehead, and the neighbouring muscles, communicating with the facial and infraorbital nerves.

II. The superior maxillary nerve holds a middle place in respect to size between the other two branches of the trigemini. It goes forwards and rather outwards from the middle of the ganglion, preferring at first its greyish hue and fibrous appearance; after a short course it enters the foramen rotundum, losing those characters and becoming more round in its figure. After penetrating that foramen, it runs horizontally through much cellular tissue, in the space between the maxillary and pphoid bones, sometimes called the pterygo-maxillary fossa. It then enters the infraorbital canal, and passes through that to its termination on the face.

1. In passing through the foramen rotundum, the superior maxillary nerve sends off a small branch, the infraorbital nerve, which enters the orbit by the maxillary-maxillary fissure, passes along the outer side of the cavity, externally to the perioidea, and then penetrates the canal of the malar bone to appear on the cheek, where it is distributed superficially, communicating sometimes with the facial and infraorbital nerves. It produces a twig running towards the lacrymal glands, and communicating with the nerves of that gland; and another, which enters the temporal fossa by a foramen of the malar bone, and communicates with the deep-seated temporal nerves.

In the pterygo-maxillary fossa the nerve produces one or two branches, which go downwards and inwards, surrounded by much fat; if there is only one, it is larger; when there are two, they are united again in a kind of ganglion, named the sphenopalatine, and first described by Meckel. This does not resemble the ganglion on the nerves of the ventera, and sometimes it is not perceptible at all. When there is one branch, it swells a little, and produces from the enlargement the numerous branches of the neighboring parts; if there are two, they unite together, and this union gives the appearance of a ganglion, placed just on the internal side of the sphenopalatine foramen. From this point, whether it exhibits a ganglion-like swelling or not, the numerous following branches proceed.

a. Sphenopalatine or nasal branches. (Nervi nasiis priores) passing through the foramen of the same name, in variable numbers, into the nose. Some of these are distributed on the two superior turbinate bones, particularly on their concave surface; but the largest, discovered by Cotunni, and since called nato-palatine, goes in front of the phehnoideal sinus along the upper surface of the nasal cavity to the back of the septum, along which it runs obliquely forwards and downwards to the foramen incisivum. It passes to the palate through a small peculiar canal immediately behind the foramen incisivum, and is distributed on the neighbouring part of the palatine membrane.

b. Three palatine nerves, one large and two smaller. The former enters the pterygo-palatine canal, formed between the maxillary, palatine, and phehnoideal bones, and passes through it. The different filaments are often separate at this part, and connected only by a loose tissue. The great palatine nerve sends off two branches (nervi nasales inferiores); a smaller to the middle, and a larger to the inferior turbinate bone: the ramifications of the latter pass from behind forwards in grooves of the convex surface. It produces also a branch, which descends in a peculiar canal of the palate bone to the soft palate. The trunk of the nerve quits the pterygo-palatine canal by the foramen palatinum posterius, bends forwards in an irregular groove of the palate arch, and divides into several branches, which supply the whole of the palatine membrane and gums of the upper teeth. The middle palatine nerve (n. palati minor postrior), placed behind the former, runs along a separate canal nearly parallel to the pterygo-palatine, and comes out of it behind the curved procres of the pterygoid plate to be distributed on the amygdalae and in the substance of the palate. The small palatine nerve (n. palatinus minus inferior), which is not confluent, goes through a short canal, which terminates between the maxillary tube and the pyramidal procres of the os palati; it is lost on the tonsil, uvula, and palate.

c. The pterygoid or Vidian nerve goes off horizontally backwards from the sphenopalatine ganglion, and immediately enters the bony canal at the bafa of the pterygoid process, having first given two extremely small branches to the phehnoideal nerves. In the canal it produces two or three nasal branches (nasales superiores posteriores) distributed on the upper and back part of the septum, the neighbouring arch of the pharynx and orifice of the Eustachian tube. The trunk then quits the pterygoid canal by its posterior aperture, passes through the cartilaginous substance that occupies the irregular defectency at the side of the body of the sphenoid, and close to the second turn of the carotid artery divides into two branches, a superficial, pterofal or cranial, and a deep-seated or carotid. The former enters the cranium between the petrous portion and the neighbouring edge of the sphenoid bone; passes over the surface of the former in a peculiar groove of the bone, covered by dura mater, and enters the squamosa Fallopini by a broken aperture on the surface of the bone, to join the trunk of the facial nerve. The latter runs closely upon the internal carotid artery, accompanies that vessel in its passage through the cranium, and joins in the carotid canal a branch of the abductor nerve; the trunk formed by this union runs the upper extremity of the superior cervical ganglion. Sometimes the two branches enter the ganglion separately; and several other varieties are observed.
observed in the distribution and connections of this branch, and that of the abductor nerve.

Having produced the nerves above described, from the pheno-palatine ganglion, in the pterygo-maxillary fossa, the superior maxillary nerve advances horizontally to the pheno-maxillary fissure, and enters the infraorbital canal, at the same time taking that name. Just before it passes in, it gives off one or two branches to the teeth; d, nervus alveolaris, or dentalis posterior, which descends on the maxillary tubercle, and enters a bony canal above the molar teeth. It communicates with the anterior dental nerve, supplies the three grinders, the membrane of the maxillary sinus, and part of the buccinator.

2. The anterior dental branch (alveolaris or dentalis anterior) enters a canal of the superior maxillary bone, communicates with the posterior branch, and sends filaments to the m'elior, canine, and bicuspid teeth.

The infraorbital nerve divides in its canal into several branches, which continue parallel; when they emerge at the infraorbital foramen, they immediately separate, like radial from a centre, and are spread over all that part of the face, which is described as not having any bony structure below, the nose on the inside, and the maxillothe on the outside. The multiplicity of these ramifications, many of which are very large, would render it very tedious to enter into a detailed account of them. They may be divided into 8, the superior or palpebral branches, distributed to the lower eyelid, the integuments of the cheek, and muscles at the root of the nose, and communicating with the facial nerve, the infraorbicularis, and sometimes with the lacrymal; c, inferior or labial branches, which are large, expanded on the surfaces of the upper lip, and communicate very freely with the facial; 3, internal or nasal branches, to the eye, septum, and muscles of the external nose; and 4, external branches to the zygomaticus major, levator anguli, and commissure of the lips, joining branches of the facial.

111. Interior maxillary nerve; nervus glossoptericus. This is composed of two distinct portions, an external and a larger, which is the most considerable of the three branches produced from the ganglion Glosferi, and has a very short course before it arrives at the foramen ovale; an internus and 5, maxillary, which is described as not having any bony structure in composing the ganglion. Both these go together through the foramen ovale, where the fibrous plexiform arrangement of the former distinguishes it very clearly from the latter. As the nerve quits the foramen ovale, the smaller portion gets in front; the two are sometimes intimately united, at others distinct, in which case the smaller part produces the buccinator and one of the temporal nerves. Below the foramen ovale, the trunk of the nerve is placed between the zygomatic fossa, and the external pterygoid muscle; there it divides into two portions, a superior and external, an inferior and internal. From the former proceed the temporal, maffetic, buccinator and pterygoid nerves; from the latter, which is the largest, the superior maxillary, lingual, and auricular.

a b. The external and internal deep temporal nerves pass at first horizontally between the external pterygoid muscle and the bone, then turn upwards and upwards into the substance of the temporal muscles in which they are distributed, communicating with the neighbouring superficial ramifications.

5. The maxillary nerve is a considerable branch passing between the pterygoideus externus and the bone, close on the articulation of the lower jaw; it then goes between the condyle and the coronoid process, and enters the internal surface of the maxilla, in which it terminates.

6. The buccinator nerve, or nerve of the cheek, proceeds forwards and downwards between the two pterygoidei, to the external of which, and to the temporal muscle, it gives branches; it then comes on the buccinator, and splits into several filaments, which reach as far as the corner of the mouth, and communicate with the facial nerves.

6. The pterygoid nervé is the smallest branch of the superior division; it supplies the pterygoideus internus and circumflexus palati.

7. The lingual or glossoptericus nerve, is commonly rather smaller than the dental. It receives the chorda tympani, a little below the sphenoid Glaseri, and a very acute angle pointing downwards is formed by their union. The nerve then descends between the pterygoideus internus and the jaw, goes between the submaxillary gland and the membrane of the mouth, accompanies the excretory duct of this gland, between the upper surface of the mylo-hyoideus and hypoglossus, and passes very close upon and above the sublingual gland, to the side of the tongue, where it lies between the hypoglossus and the linguals. It runs along the side to the very point of the tongue. It gives a branch to the pterygoideus internus, and two or three very slender ones to the back part of the gums; several branches, which either form a small ganglion (ganglion maxillare), or are united into a plexus, to the submaxillary gland and neighbouring parts; branches of communication with the hypoglossal nerve; four or five twigs to the sublingual gland and neighbouring part of the gums. At the level of the latter gland, considerable branches begin to be detached from the trunk for the tissue of the tongue, and continue to arise, to the number of ten or twelve, until the whole nerve is consummated. These penetrate between the genioglossus and linguals, and are distributed in the proper tissue of the organ; they may be traced through the muscular fibres, to the membrane covering the back, sides, and apex of the part, and even into the papillae of the membrane in which the fenes of tongue reside. Thus this nerve constitutes the organ of the sense of smelling, while the hypoglossus belongs to the motions of the part; that these two functions belong to distinct nerves, is rendered probable by the pathological cases, in which the fenes or the motion of the organ is separately destroyed.

8. The inferior maxillary or dental nerve (mandibulopalatini, or maxillaris inferior) is a very large nerve, descends by the side of the former, first between the two pterygoideus muscles, and then between the internal and the lower jaw, corresponding on the inside to the internal lateral ligament of this bone. Near the orifice of the inferior maxillary canal, it produces the nervus mylo-hyoideus, which runs along a groove or even an entire canal of the lower jaw from behind forwards, is distributed principally on the mylo-hyoideus muscle, but gives also some branches to the submaxillary gland, genio-hyoideus, and digastricus. The trunk of the inferior maxillary nerve then enters the canal of the lower jaw, in company with an artery and a vein, and runs completely through it, giving branches to the molares and bicuspides. At the foramen mentale it divides into two portions; a smaller, which passes backwards in a canal under the canine and incisor teeth, and supplies those teeth; and a much larger, which comes out of the foramen mentale, and divides immediately into numerous filaments, communicating freely with those of the facial.

The twigs sent to the teeth are very small; they can be followed with considerable difficulty to the pores at the extremities of the fangs, and are left on the pulpy substance filling the cavities; whether they feed any branches to the bone of the tooth, and whether that part possesses any sensibility, are questions considered in the description of the tooth, under the article Cranium. The size of the trunk is very little diminished in its passage through the jaw;
Nervous System.

"egregius foraminit, vix exilior," Soemmerring; yet in the Anatomic Descriptive of Bichat, t. iii. p. 188, it is said to be diminished by one half.

The branch that comes out at the foramen mentale, sometimes called nervus mentalis, may be most advantageously observed by dividing the membrane of the mouth, and dissecting from within. It either comes out in two branches, or divides very soon after its exit into an exterior smaller, and an interior larger branch. These are again very soon subdivided in a radiated manner; the branches first ascend between the membrane and the muscles, supplying the depressor anguli oris and labii inferioris proprius, the levator menti, orbicularis and buccinator, and then enter into the submaxillary muscle of these muscles. They ascend to the very edge of the lips, and terminate in the orbicularis, the mucous glands and the skin. In a careful dissection, the whole margin of the mouth is found to receive numerous filaments, which are distributed abundantly on the integuments, where they exhibit the beautiful papillary structure; these nerves come from the mental in the lower lip, and from the superior maxillary in the upper.

b. The superficial temporal or auricular nerve turns horizontally along the back part of the neck of the condyle, between it and the meatus auditorius externus, produces in this situation branches that communicate with the facial, then ascends in front of the meatus, covered by the parotid gland, giving branches to both of those parts, and to the concha, and arrives at the back of the zygomatic process. It passes through the parotid towards the temple, and is distributed superficially, communicating with the facial and subcutaneous muscles.

It appears from this description, that the nervus trigeminus supplies all the muscles of the face, the forehead and its muscles, the eye-brows and their muscles; the external and internal parts of the nose; the iris; the external ear, skin of the cheeks, lips and their muscles; the mucous surface and the muscles of the tongue; the salivary glands and the teeth. Its various branches are not only united by communications to each other, but are also joined to the third, fourth, and sixth cerebral nerves; to the facial both in the skull and face, to the great sympathetic, and the second and third cervical.

The abductor nerve, motor externus, abducens, nerve of the sixth pair, is of a middle size, between the third and fourth, and extends from the upper part of the medulla spinalis to the rectus externus occuli. It comes out of the groove that separates the pons from the medulla spinalis, and its origin is referred, sometimes to the pons, sometimes to the corpora pyramidula. "If we examine it," says Gall, "in the calf, deer, and particularly in the horse, its origin cannot be mistaken. It appears as a small filaculus, lying by the corpus pyramidale, and generally dividing behind the pons into two smaller, which are separately disengaged from the surface. The pons being much larger in man than in animals, some small transverse fibres cover the origin of this nerve, and cause an appearance, as if the nerve arose from this pair, although its origin may in fact be traced to the same point as in the animals already named." (Anat. et Phys. du Syll. Nervens, p. 102.)

The nerve has a fibrous texture at its origin, and consists usually of a larger exterior, and a smaller internal portion, which sometimes penetrate the dura mater separately, and are not joined until they arrive in the cavernous sinus.

It passes behind forwards, upwards, and outwards, between the pons and the biliary excavation of the cranium, presenting a flattened form, and adhering closely to the former. It penetrates the dura mater below the posterior clinoid process, and enters the cavernous sinus, in which it lies on the outside of, and is closely connected to the carotid artery; it goes through the sinus, in contact, as well as the artery just mentioned, with the blood in its cavity, and hence presents a red colour after death. Opposite the internal orifice of the cavernous canal, one, two, or more slender and redilatated filaments are connected to it, at an angle rather acute forwards, and oblique backwards. These filaments pass with the internal carotid through the cranium, communicate with the Viridian nerve, and join the superior cervical ganglion. The abductor nerve is larger in size in front of this connection than behind it. It enters the orbit at the foramen lacrima, in company with the oculo-motorius, and the nasi branch of the ophthalmic, between the two origins of the rectus externus, and proceeds between this muscle and the optic nerve, dividing into several filaments, which are entirely lost in the muscle. It appears, therefore, that the abductor nerve, and the filaments produced from the cervical ganglion, are confused in that single muscle of the eye.

All the nerves distributed on parts contained in the orbit, and the ganglion of the fifth nerve, are represented in the plates illustrating the anatomy of the eye. See Plate III. figs. 3, 4, 11, and 12. The description is contained in the article Eye.

The facial nerve, with the auditory, which follows it, have generally been clasped together as composing a single nerve of the seventh pair; the former was called portio dura, and the latter portio mollis of the seventh cerebral nerve. The two nerves, although lying for some part of their course in contact, are perfectly distinct throughout; in a numerical arrangement the former will be the seventh, and the latter the eighth.

The facial nerve is detached from the brain behind the crus cerebri, and its origin has been generally referred to the posterior and lateral part of the pons. Gall states, that its origin has no connection with the pons; that in animals its commencement is seen under the appearance of a broad fasciculus between the corpus olivare and the gloso-phaenageal nerve; that it ascends towards a transverse band placed at the lower edge of the pons, pales under it, and then comes out by the side of the auditory nerve; if it appears in the human subject to come from the pons, it is because some portion of that organ is placed over it. Anat. et Phys. &c. p. 104.

Two or three filaments are placed between the facial and auditory nerves; but they join the former sooner or later.

It is very soft at the situation of its connection with the brain, but it soon becomes covered by neurilema, and acquires a firmer confidence. It enters the internal auditory meatus, in company with the auditory nerve, and goes with it to the bottom of that palsea; it enters and pales through the aquaeductus Fallopian, which is lined by a thin fibrous layer, and filled completely by the meninges, which, in some authors, as in the case of all nerves traversing bony passages, is loose and unconfined in the tube. It quits the aquedvoid at the foramen labyrostaloidenum, pales outwards and forwards under the parotid gland, and divides into two branches, which will be described presently.

In the aqueduct it produces no branch until it has arrived at the hiatus Fallopian, and there it is joined by the superficial or petrosal branch of the Vidian nerve; it afterwards gives a branch to the external muscle of the malleus, and another very small twig to the flaps. It then gives rise to the chords tympanic, a considerable nerve, of which the palsea across the tympanum is described in the article Ear. This goes out of the cavity of the sifuro Gaferi, and joins the lingual
lingual branch of the inferior maxillary nerve at a very acute angle; the latter nerve is obviously larger after the junction.

As soon as the facial nerve has quitted the aqueduct, it分支es off, in the postauricular, auricular, and auricular (nervus auris posterior, or occipitalis, or externus profundus), which mounts in front of the mastoid process, and is distributed on the convexity of the concha, and the neighbouring part of the occipital region: 2, a branch to the styloidal muscles (nervus ilio-hyoideus) communicating with filaments from the superior cervical ganglion; and 3, another to the back of the digastricus, communicating with the glosso-pharyngeal, and the laryngeal branch of the par vagum.

After giving these branches, which can only be dissected well from behind, after having removed the vertebral column, the facial nerve enters the parotid gland, and is at first very deeply buried in it, but descends obliquely and comes nearer to the surface. About the lower third part of the gland, that is, nearer to the angle of the jaw than to the mastoid processes, it divides into two branches, which may be called temporofacial (ramus major, superior, or ascending), and cervico-facial, (ramus minor, inferior, or descending.) Sometimes there are three branches, or even more, but the various subdivisions correspond always to the arrangement just indicated.

1. Temporo-facial branch. Concealed, like the trunk from which it arises, in the parotid gland, it passes forwards and upwards towards the neck of the maxillary condyle, which it crosses at an acute angle. A twig or two in this situation penetrate behind the condyle, to communicate with the auricular branch of the inferior maxillary nerve. Very soon after the trunk divides into seven or eight diverging branches, which are spread out on the face and temple, and may be distinguished in superficial temporal, malar, and nerves of the cheek.

a. The superficial temporal are generally two in number; give some twigs to the parotid, and then mount over the zygoma; they are distributed very extensively to the integuments of this region, and communicate with the auricular, deep temporal, and lacrymal nerve.

b. There are commonly two malar nerves, which go towards the os max, and divide into numerous filaments distributed on the surrounding muscles, and communicating freely with the lacrymal, subcutaneous, malar, and particularly the infraorbital nerve.

c. Three branches generally pass transversely over the malleus to the cheek, communicate with each other, and with the filaments of the cervicofacial branch. The upper one goes towards the root of the nose; the second, which is the largest of this division of the facial nerve, passes over the buccinator nearly to the corner of the mouth, communicating very freely with the infraorbital; the third is often only a branch of the latter.

All these ramifications are superficial in the situation of the malleus, and become deeper seated towards the front of the face, where they are covered by the muscle.

Bichat states that he could never discover any communications between the right and left nerves; and that he finds the same remark applicable to the nervous filaments in general.

2. The cervicofacial branch goes obliquely downwards in the fibres of the parotid gland, and concealed by the ramus of the lower jaw; at the angle of the bone it comes forwards, lies under the temporalis, and divides into branches, which communicate with the superficial cervical nerves, and of which some are distributed above, others below the basis of the jaw. The former, generally two in number, pass over the edge of the bone, come through the parotid gland, run directly across the malleus, and proceed towards the lower lip, distributing numerous filaments to the skin and muscles, communicating with the other branches of the facial, and with the mental nerve. There may be one or more branches running under the basis of the jaw, and reaching the front of the neck; they communicate with the mental, and with the superficial cervical; the latissimus coli and skin of the neck are the parts principally supplied by them.

Soemmerring enumerates and describes the following branches of the portio dura: 1. Of the ascending branch: a, zygomaticus, or jugalis primus, or temporalis posterior; b, temporalis, or jugalis secundus; c, temporalis prior, or jugalis tertius; d, orbitalis superior, or jugalis quartus; e, orbitalis inferior, or jugalis quintus; f, facialis superior; g, facialis medius, or magnus; h, facialis inferior. 2. Of the descending branch: a, nervus prior facialis minus; b, nervus marginis maxillae inferioris, dividing into a superior and an inferior branch; c, d, e, nervi pterygoidei et superioris subcutanei coli, primus, alter, tertius.

Thus it appears that the facial nerve is distributed over the whole face, in a space beginning with the temples above and extending to the upper part of the neck below: the car and a part of the occiput, the zygomatic process of the cranium of which is much firmer than the auditory nerve; but the latter is considerably firmer in the aqueduct, and in its distribution on the face, than in the cranium. Its multiplied anastomoses are a very remarkable feature in its anatomy: it is not only joined to the neighbouring nerves, as the three branches of the fifth, the nervous vagus, glosso-pharyngeal, and accessory nerves, third cervical and great sympathetic, but its branches frequently communicate with each other, and thus form a network of nervous communications on the face, which, although in reality very considerable, has been rather exaggerated in some plates, as in that of Meckel, Mem. de l'Acad. des Sciences de Berlin, tom. vii. In no nerve of the animal life are the communications between the different filaments so numerous.

The auditory or eighth nerve; nervus auditorius or acusticus; portio mollis of the seventh pair.

Several white medullary filaments may be seen in the anterior surface of the fourth ventricle, where their colour distinguishes them from the cimeritious matter in which they lie. They are sometimes almost imperceptible, and at others strongly marked; they vary in number from one to six or seven. They are sometimes radiated, sometimes parallel, and sometimes in the form of a pencil: they may form small bands, or be rounded and prominent. Often they are different on the two sides; being higher or more numerous on one than on the other. Modern anatomists have generally regarded these filaments as the origin of the auditory nerves, and, in fact, some of them usually join these nerves; but, as Prochaska and Soemmerring have remarked, they have often no connection with them, being lost in the crura cerebelli. "In the mammals," says Gall, "even when they have an auditory nerve much more considerable than that of the human subject, the medullary filaments are entirely deficient. The filaments of the nerve derive their origin in great measure from the cimeritious matter so abundant in the fourth ventricle: this matter is more thinly deposited in man, and forms the grey band (ruban gris) placed towards the middle and outer part of the ventricle, and forming in the sheep, pig, horse, &c. an elevation of the face of a pea. Consequently this is a true swelling (relentef), place of origin, or ganglion for the auditory nerve, which there receives its most considerable enlargement. This ganglion is placed precisely at the spot where the auditory nerve turns round the corpus rethiforme of the cerebellum, and its size..."
fize is always proportioned to that of the nerve. Most anatomists, such as Cuvier, Portal, Sahatier, Dichter, are contented with affirming the origin of this nerve to the medullary tissue of the fourth ventricle, without even mentioning the "ruban gris," or the oblong elevation in animals. In animals a broad band extends immediately behind the pons from one auditory nerve to the other, and paves over all the affending nervous fasiculi, excepting those of the corpora pyramidalia. We consider that it consists of communicating fibres from one nerve to the other, and that it forms a commissure between them. It is covered in man by the posterior part of the pons." Anat. et Phys. du Syft. Nerveux, p. 105.

The filaments of the nerve are collected together, from the origin just mentioned, into a soft and roundish band, which turns forwards and outwards round the back edge of the corpus reftiforme, and comes in contact with the facial nerve. It then goes more directly outwards, being in size about equal to the third, firmer than the olfactory, but softer than all the others, affumes a more fibrous appearance, and forms a kind of groove, in which the facial is lodged. It enters the meatus auditorius internus, in company with a blood-vejlel, and is much smaller than that canal, so that it is contained quite loosely. The rest of its defcription will be found in the article Ear; and its course and distribution are represented in the plates of the ear. It has two very different distributions; one to the cochlea, the other to the semicircular canals and ventribulum. The latter is analogous to the retina formed by the optic nerve; the expansions of the veltibular branch very much resembiling that membrane. The distribution on the cochlea may be rather compared to that of the olfactory nerve; yet the softness and shortness of the ramifications are points in which it differs from those of the olfactory, which have a very firm neurilema, and a long course.

This nerve is distributed exclusively to the organ of hearing; and has no communication with any other nerve.

The four following pairs of nerves, although they arise within the cranium, have much analogy to the spinal nerves; they separate from the general mafs, like them, by several distinct threads, and pass by one or more openings in the dura mater. Their origin is referred by Gall to the cineritious substance placed within the part from which they go off; consequently they cannot be regarded as prolongations or productions of the cerebral mafs. The nerves, which we have hitherto described, have the threads, produced in the grey substance, united into one falcuculus before they are detached.

The gloffo-phyaryngeal, or ninth cerebral nerve, arises by feveral more or less distinct threads immediately below the pons, and below the corpora olivaria. Girard and Soemmerring have mentioned that filaments may sometimes be traced from the fourth ventricle; but Gall has not been able to discover them. An artery or a vein, or both are generally interpoled between it and the nervus vagus. It goes under the smaller lobe of the cerebellum and the choroid plexus, with which it is slightly connected, separates more and more from the nervus vagus, and enters a peculiar canal of the dura mater. It quits the cranium by a membranous canal in females, and a bony one in males, placed under the meatus auditorius internus, and above the jugular fora; being separted from the nervus vagus by the internal jugular vein. Some anatomists (Aderich and Huber, quoted by Soemmerring Neurologia, § 368.) describe a small ganglion formed just after the nerve has quitted the head, and contained in a groove of the bone; but Bichat has never met with this. (Anat. Descriptive, t. iii. p. 207.) It then goes downwards and forwards over the internal carotid and under the stylo-phyaryngeus; afterwards between that muscle and the stylo-glossus. It is connected pretty closely by cellular substance to the former of these two muscles, of which it follows the direction to the posterior part of the tongue.

In this course it produces the following branches: 1. Filaments communicating with the stylo-hyoidal branch of the facial, and with the nervus vagus. 2. A branch or two depeeding over the internal carotid, and united with the pharyngeal branch of the nervus vagus, with the nervi mollis of the great sympathetic, and the nerves of the heart. 3. One or two branches to the stylo-phyaryngeus. 4. Two pharyngeal nerves to the upper constrictors of the pharynx, the tonsil, and the surface of the posterior lateral part of the tongue. 5. Branches forming a plexus about the pharynx, and sending ramifications over the branches of the external carotid.

At the basis of the tongue the gloffo-phyaryngeal nerve pafs under the stylo-glossus, and on the inside of the hyglossus, and is divided into, 1, superior filaments going forwards to the lingualis, where its fibres are united to those of the constrictor illimi faucium, and to the mucous glands about this part; 2, inferior ones to the hystro-glossus, and to the mucous membrane continued from the back of the tongue to the epiglottis; middle ones distributed principally on the mucous glanda. The muscular fibres of the tongue receive very little from this nerve, of which the ramifications become superficial, and supply the mucous surface behind as the gulfatory nerve does in front.

The nervus vagus, tenth nerve, though commonly called the eighth or par vagum, surf vocal of Gall, arises immediately below the glofio-phyaryngeal between the corpus reftiforme and olivare, but nearer to the former than to the latter, by many separate threads, of which the number varies, placed in a perpendicular line. Soemmerring and Santorini speak of its deriving fibres from the fourth ventricle; but Gall denies the existence of these. Sometimes, according to Soemmerring, its origins are arranged in a double series, (anterior and posterior,) like those of the medulla spinalis; sometimes it arises in one mafs, like the fifth nerve. The minute threads, by which it arises from the medulla spinalis, are collected into fix, eighth, or ten larger filaments, which form a thin and flat band, without communicating together, placed under the cerebellum, and going outwards and forwards to a peculiar canal of the dura mater, of which the opening is placed under that of the glofio-phyaryngeal nerve, and separted from it by a distinct fibrous septum. It goes out of the cranium by a peculiar openhole in the fora of the jugular vein; it approaches to the glofio-phyaryngeal nerve in its course, but leaves it again, and passes outwards and forwards close to the jugular vein. The filaments of the nerve remain rather distinct in their passage through the cranium, but they unite at their exit into a single rounded cord, which is sometimes rather swollen and grey, so as to have been taken for a ganglion. It is always closely united, after leaving the skull, to the hypo-glossal, accessoriy, and glofio-phyaryngeal nerves, by a dense cellular tifiue containing no fat, and including also the afferding filaments of the superior cervical ganglion. It is at first situated in front of the hypo-glossal, but soon becomes posterior to that nerve, and quits it to descend along the neck, between and behind the carotid artery and internal jugular vein. A loose but tolerably firm cellular tifiue, never containing fat, joins the artery, vein, and nerve together; they are here closely connected to the great sympathetic nerve.

At
NERVOUS SYSTEM.

At the lower part of the neck, the nervus vagus leaves its position between the artery and vein, enters the chest, and goes backwards to the posterior part of the bronchial, descending immediately in front of the subclavian artery on the right, and along the back of the aorta on the left side, and manifestly increasing in size. It goes along the back of the root of the lung, between the bronchus and the pleura, and becomes attached, lower down, to the oesophagus. The left nerve is found towards the front, and the right at the back of this tube, in company with which they penetrate the superior or cardiac orifice of the diaphragm, to be distributed on the stomach in the manner which we shall presently describe.

Its branches may be conveniently arranged under the divisions cervical, thoracic, and abdominal.

Cervical Branches.—It communicates with the accessory and gloso-pharyngeal nerves, and then produces the pharyngeal branch, which descends obliquely inwards, crossing the carotid, communicates with the gloso-pharyngeal, and separates about the upper part of the middle constrictor into several filaments, which form the pharyngeal plexus; the latter is augmented by twigs from the superior cervical ganglion, the laryngeal, and gloso-pharyngeal nerves. The branches composing this plexus are tortuous, of a greyish color, and communicate frequently; they are distributed on the muscles of the pharynx.

The superior laryngeal nerve is larger than the preceding, and arises under it; goes behind the internal carotid, and along the outer side of the superior cervical ganglion, producing some twigs of communication with that ganglion, the hypo-glossal nerve and the plexus just described, and then divides into two branches. The external (nervus laryngeus externus) descends to the lower constrictor, the crico-thyroides, thyroid gland, &c.; the internal (nervus laryngeus internus) enters the larynx between the os hyoideus and the thyroid cartilage, is distributed on the membrane and glands and some of the muscles of the larynx, and communicates with the inferior laryngeal nerve.

After producing the superior laryngeal, the nervus vagus descends along the neck without giving off any other, until it reaches the confines of the chest; it then sends off branches, which join the cardiac plexus, two, three, or more on the right, and generally one on the left side.

The inferior laryngeal or recurrent nerve arises in the chest, but is distributed principally in the neck: it is rather different in the two sides of the body. On the right it arises at an acute angle below the subclavian artery, and turns immediately round that vessel, so as to include it in a kind of loop: it then goes inwards and upwards, under the carotid and inferior thyroid arteries, and ascends in the depression between the trachea and oesophagus to the larynx. From the convexity of the loop two or three cardiac nerves come off, and join the filaments from the inferior cervical ganglion and the nervus vagus, forming a remarkable plexus between the subclavian and the trachea. Some pulmonary twigs are then produced, descending in front of the trachea to the pulmonary artery, and following its ramifications in the lung.

As it ascends by the side of the trachea, the nerve sends off twigs to the oesophagus, thyroid gland, and trachea. At the lower part of the larynx, it goes under the inferior constrictor, after giving it some filaments, and often divides here into two or three principal branches, which are spread out on the mucous membrane of the pharynx, and of the larynx, and particularly on the muscles of the arytenoid cartilages, communicating with the branches of the superior laryngeal.

VOL. XXIV.

The left inferior laryngeal nerve arises lower down than the right, bends under the arch of the aorta, and consequently forms a more considerable loop. It then ascends in a perpendicular course, and lies more immediately on the oesophagus, as that tube in the neck is placed rather to the left of the trachea. Its cardiac and pulmonary filaments go towards the back of the heart and pulmonary artery, of which the front is supplied by the right branch.

Thoracic Branches.—After the origin of the recurrent, the nervus vagus goes behind the root of the lung, and lies in close contact with the posterior surface of the bronchus. Here its filaments are loosened and separated from each other, so that the nerve seems considerably increased in size: they put on a plexiform appearance, and there are sometimes intervals between them occupied by cellular substance and vessels: opposite to the lower end of the trachea several filaments arise, forming a plexus in front of the bronchus and trachea, and pulmonary vessels, (plexus prior nervorum pulmonalium,) and communicating with the branches of the recurrent, and of the inferior cervical ganglion. Some branches go to the back of the trachea, and neighbouring part of the oesophagus, and communicate with the other pulmonary plexus. Behind the bronchus several branches come from the enlarged part of the nerve, and constitute a considerable plexus, named the pulmonary (plexus posterior nervorum pulmonalium), which receives filaments from the inferior cervical ganglion, and sends numerous branches surrounding the pulmonary and bronchial vessels, and distributed more particularly on the air-tube and its ramifications. Bichat considers that these nerves are distributed entirely on the mucous membrane and glands of the lungs, and not in the proper tissue of the organ; and that they may easily be traced penetrating the posterior membrane of the air-tubes.

The right nervus vagus, while it is producing the pulmonary plexus, and afterwards, divides into four or five large branches, which descend along the side and back part of the oesophagus, communicate and divide again, so as to constitute a plexus (plexus nervorum gulae posterior), and unite again below into a single branch passing behind the oesophagus into the abdomen. On the left side the nerve divides into two or three branches (plexus nervorum gulae prior), which are united again below, and penetrate the diaphragm on the front of the oesophagus. The two trunks communicate freely on the oesophagus, and send several filaments to that tube, and some to the descending aorta.

Abdominal Branches.—The right trunk enters the abdominal on the side and back part of the oesophagus, and soon divides into numerous filaments, which form a considerable plexus on the superior orifice of the stomach, and are then distributed to that organ and to the neighbouring parts. The flomachic branches are ramified first on the back of the cardia, where they are continuous with the oesophageal filaments produced in the chest, then on the posterior surface of the organ. Near the small curvature they are near together, lie immediately under the serous membrane, and are consequently very visible: they diverge towards the great arch, and penetrate the muscular fibres as they descend. Several branches go behind the coronary flomachic artery, communicate with branches of the left nerve, and pass beyond the pylorus to terminate in the neighbouring parts.

Other branches behind these go to the hepatic and gastro-epiploic arteries: to the right colic ganglion, the pancreas, duodenum, vena portarum, gall-bladder, and liver, connected with various filaments from the colic ganglia: others go to the colic plexus.
NERVOUS SYSTEM.

The left nerve enters in front of the oesophagus, divides on the cardia into several filaments, which are at first situated superficially under the pericardium membrane, and go along the small curvature in front of the coronary stomachic artery. Branches from these descend obliquely over the anterior surface of the organ, being at first situated superficially, and then penetrating the muscular fibres. They communicate, at the pylorus, with those of the opposite side, and pass on towards the liver, joining the hepatic plexus.

The nerves vagus, therefore, supplies the pharynx and oesophagus; the larynx, trachea, and thyroid gland; the arteries of the neck, large vessels of the heart, and the lungs; the stomach, duodenum, liver, gall-bladder, and spleen. It communicates freely with the opposite nerve, with the glosso-pharyngeal, hypoglossal, accesorius, great sympathetic, and frill cervical nerves.

Accessory, or eleventh cervical nerve, nerves ad par vagum accessorius, nerf spinal. This, and the two preceding, compose the eighth pair, or par vagum of most authors.

The accessory nerve arises from the upper part of the medulla spinalis, between the anterior and posterior falciceuli of the upper cervical nerves. The point of its commencement is uncertain, and varies from the third to the seventh cervical nerve: it may be different in length on the two sides. It arises by a small point on the side of the medulla, and ascends between the ligamentum denticulatum and the posterior roots of the cervical nerves, receiving at each interval between two nerves an additional branch, arising by three roots, and thereby increasing in size. Sometimes it communicates with the posterior root of the frill cervical nerve. As it ascends, it is directed obliquely outwards, and enters the cranium at the foramen magnum: at this part it receives four longer twigs, each of which arises by several minute threads, and then turns outwards to the opening which receives the nervus vagus, under which it quits the cranium, sometimes by a common fibrous canal with that nerve, sometimes by a separate one. It communicates, towards the lower end of the canal, with the nervus vagus, to which it adheres so closely, that they might be taken for a single trunk. As it quits the canal, it separates from the nervus vagus, becomes connected by a dense cellular tissue to the hypoglossus, then leaves it to go behind the internal jugular vein, and afterwards turns outward under the flasco-masculi. It traverses the fibres of the posterior part of this muscle, at about one-third from its upper end, becomes more superficial, and then runs along the anterior surface of the trapezius, on which it is lost. Its branches are not very numerous: in its passage through the cranium it divides into an exterior and an interior branch.

The interior (rameau accesorice du nerf vague) gives off a superior and an inferior branch, which unite together above the ramifications of the nervus vagus, and there receive a considerable branch from that nerve. The union of these three composes the pharyngeal nerve, which is, therefore, formed between the nervus vagus and accessorius, and which is already described in the account of the former. The trunk then goes behind the nervus vagus, closely connected to it, and augmented by two branches from it. Below the origin of the superior laryngeal nerve it divides into several filaments, joining the trunk of the nervus vagus, which affixes here a very manifest plexiform arrangement for the reception of these threads. Sometimes it communicates with the hypoglossal.

The exterior branch penetrates the fibres of the frerno-mastoideus, sends two or three branches to that muscle, and communicates here by one or more twigs with the cervical plexus. The remainder of the trunk is lost on the trapezius.

Thus, besides the pharynx, two muscles only, the frerno-mastoideus and trapezius, have branches from the nervus accessorius: and these muscles derive branches from other quarters.

The hypoglossal nerve, or twelfth, nervus lingualis medius, commonly called nerve of the ninth pair, has its origin placed in front of that of the nervus vagus and glosso-pharyngeus: it comes from the groove between the corpus olivare and pyramidal, and arises by ten or twelve slender threads, generally united into three or four fasciculi placed in a vertical line, one under the other, in front of the vertebral artery. They converge towards the anterior condyloid foramen, and penetrate the dura mater by one, two, or three openings; but unite in the canal of the foramen, which is sometimes double. When it quits the cranium, the hypoglossal nerve is connected by a dense cellular tissue to the nervus vagus, and placed on its outside: it soon quits this situation to pass obliquely forwards and downwards, becoming conflantly more superficial. It lies at first on the internal carotid and the superior cervical ganglion, and afterwards goes over the external carotid and its branches: it is covered by the stylo-hyoides, the posterior portion of the digastric and the occipital artery, and soon appears between the branches of the internal jugular vein. In this place it forms a remarkable turn, sweeping forwards and upwards under the tendon of the digastric.

Immediately under the cranium it forms a twig to communicate with the arch formed by the junction of the frill and second cervical nerves; and it communicates, by one or two filaments, with the nervus vagus and accessorius. When it begins to bend forwards, a considerable branch arises from its convexity, (ramus descendens, branche cervicale descendante,) defends perpendicularly in the neck, along the internal jugular vein, and, about the middle of the part, turns outwards to communicate, by a considerable arch, with a similar branch formed by two twigs of the two frill cervical nerves. There is a small plexus at the point of communication. Just before this communication, the descending cervical nerve sends off two twigs to the omohyoides and frerno-hyoides. The branches of the plexus are long and slender, and are lost on the omohyoides, frerno-hyoides, and frerno-phyoides: it communicates with the third and fourth cervical, and the phrenic nerves.

The hypoglossal nerve lies nearly in company with the lingual artery, where it begins to turn forwards; it penetrates between the mylohyoides and hypoglossus, and is afterwards separated by the latter muscle from the artery, and enters the substance of the tongue, in which it terminates. It sends a small twig to the thyro-hyoides, and has some communication with the nervi molles. When it has arrived under the mylo-hyoides, its filaments are separated, so that it seems to increase in size, and it gives off a great number of branches in a radiated form. 1. A few go to the superior constrictor of the pharynx and the stylo-pharyngeus. 2. Five or six very slender, but easily discernible ones, ascend on the external surface of the hypoglossus, and communicate freely with each other, as well as with branches of the glosso-hyoides. 3. Inferior filaments to the genio-hyoides, genio-glossus, and mylo-hyoides. The trunk afterwards penetrates the genio-glious, distributes its filaments in its posterior part, and follows the course of its injection into the muscular fibres of the tongue, distributing successively to it, as well as to these fibres, other filaments, almost to the point of the organ, but having no concern with the papilla. In this passage, along the middle of the tongue,
the hypoglossal nerve lies very near that of the opposite side.

The hypoglossal nerve supplies all the muscles of the os hyoidei, the genio-glossus, and sternio-thyroides, and the muscles of the tongue. It is connected with the fifth cranial nerve, with the vagus, the accessory, the sympathetic, the phrenic, and some cervical nerves. It belongs to the motions of the tongue, and seems to have no connexion with the bifurcations of taste.

Anatomy of the Spinal Marrow, and of the Parts connected with it.—The membranes covering this organ are continuations of those which belong to the brain, and they enter the vertebral canal through the great occipital foramen.

Dura Mater.—The canal is lined in the first place by a production of dura mater prolonged to its inferior extremity. This production forms a membranous canal, differing in its form from the bony canal: it is rounded, while the latter is triangular, and consequently broader. Independently, too, of this difference in form, the membranous canal is smaller than the bony one, and consequently unattached to it in the greater part of its surface. A similar disproportion is observed between the membranous canal and the included organ; the latter appearing quite loose in its sheath. Yet there is not more fluid observed here than in the brain.

The outer surface of the sheath corresponds to the canal, but does not adhere to it, as the dura mater does to the cranium: the front of the plates, that meet to form the spinous processes, is covered by periooeum, and the front of the canal is covered by the posterior ligament of the vertebrae. A loose cellular tisue intervenes between the canal and the sheath, except in front, where the latter adheres closely to the ligament. In the facrum this tisue contains fat.

On each side of the sheath there is a series of small canals surrounding the spinal nerves as they pass through the corresponding foramina. These vary in size, length, and direction, according to the differences of the nerves. They are manifestly enlarged at the foramina, on account of the ganglia formed on the nerves in that situation. They are gradually lost in the cellular membrane on the surface of the nerve, instead of being continuous, as in the head, with the periooeum. The internal surface of the membrane is polished, as in the head, and every where contiguous to the arachnoid. Bichat conceives the polished surface to be owing to a reflection of the arachnoid. Each side offers a series of openings, which are the beginnings of the canals for the nerves; and in the intervals of these, the points of attachment of the ligamentum denticulatum. At the upper end, the sheath is continuous with the dura mater of the cranium; it is perforated, immediately below the occipital foramen, for the passage of the vertebral artery. It terminates below in forming fibrous sheaths for the facial nerves.

The structure of the membrane is the same as in the brain: yet the fibres are less distinct, and the thickness is not so considerable. The latter diminishes gradually to the end of the canals that contain the nerves.

Pia Mater.—The organs contained in the cranium are surrounded by a vascular network, to which the appellation of membrane can hardly be given with propriety. The medulla spinalis, on the contrary, is most closely enveloped by a firm membrane forming with it one substance; and to this, in spite of the differences of texture between the two parts, anatomists give the name of pia mater. If this covering be slit up lengthwise, and the medullary substance be then scraped away, the former is left alone, under the appearance of a dense semitransparent membrane; or if, after dividing the medulla spinalis, we press it towards the cut surface, the medulla may be squeezed out, and the membrane is left. Its external surface corresponds to the arachnoid, which does not adhere to it, but may be separated throughout by inflammation. The spinal arteries lie on it, and distribute their branches over it. At the sides it is continuous with the neurilema of the nerves, and gives attachment to the ligamentum denticulatum. The internal surface corresponds every where to the medullary substance, and seems to be continuous with it, so that the two form one organ. It consists of a thick, solid, and very firm tissue, with an appearance, towards the sides, of distinct fibres. Its density is greater in the lower than in the upper part of the organ. But few vessels belong to the substance of the membrane; a great number, after being first minutely subdivided, enter the medulla, and this probably contributes to its very firm adhesion. It has a yellowish-white colour, different from the pure white of the medulla, which is seen when the membrane is divided.

Immersion in cold water for a few days makes it rather harder; but prolonged maceration softens it. It contracts and curls up considerably under the action of boiling water, and thereby squeezes out the medulla from its cut end. If openings are previously made in it, a similar phenomenon is exhibited at these. It refits putrefaction for a long time; and assumes a yellowish colour when dried. Acids and heat corrugate it; and the former afterwards reduce it to a fluid flake.

It seems to be analogous to the neurilema of the nerves. It does not commence abruptly: the pia mater acquires on the pons a greater constance than it has in other parts of the cerebral organ: this increases on the corpora olivaria and pyramidalia, where it seems to have nothing in common with the pia mater, except its continuity.

The ligamentum denticulatum is a narrow, whitish, and dense layer, affixed to the side of the medulla spinalis; and apparently continuous with its proper membrane. It lies between the anterior and posterior origins of the spinal nerves throughout the whole length of the organ. The outer edge presents a series of small pointed processes, from which the name denticulatum was derived, attached to the dura mater. These are narrow rounded cords, very dense, and are fixed at the intervals between the exits of the nerves. They are short above, and longer below. The outer edge of the ligament presents a series of concavities between these. Bichat contends, that this organ is distinct both from the arachnoid and the proper membrane of the medulla; indeed its density and firmness sufficiently distinguish it from the former; and it is connected to the latter, according to the anatomist just mentioned, by a cellular tissue. At the point of adhesion to the medullary membrane it is very thin, and becomes gradually thicker towards its outer edge. It is not easy to flake any thing positive about its nature; its texture is very close, but not manifestly fibrous. It has the effect of fixing the medulla spinalis in its situation.

The Arachnoid.—This membrane palies from the skull at the occipital foramen, and descends into the vertebral canal.

It is almost unattached on its internal surface: a small number of cellular threads form its only connection to the proper membrane of the spinal marrow. Hence, if the spinal marrow with its coverings be carefully taken out of the canal, the dura mater laid open, and air impelled under the arachnoid, the latter will be raised throughout and form a tube interrupted only at the points where it furnishes prov-
longations to the nerves. This want of adhesion on the internal surface distinguishes it essentially from the cranial portion of the membrane. Its external surface is free, like that of the arachnoid in the head, and in contact with the dura mater. It affords at the sides a conical covering to each of the spinal nerves, accompanying the nerve to its fibrous canal, and then reflected to the dura mater.

The Medulla Spinalis.—The term spinal marrow, by the import of the words, denotes the nervous mass contained in the vertebral column from the foramen occipitale downwards; but anatomists have differed in respect to its posterior boundary. Varoli, Willis, Bartholin and others, include under this expression the medulla oblongata, pons, crura cerebri, and even higher parts; Haller makes the occipital foramen the boundary. Soemmerring, Bichat, and Chauffier make it extend to the back edge of the pons, and consequently include the corpora pyramidalis and olivaria, and the origins of the three last cerebral nerves. The latter anatomist calls the part situated within the cranium "le bulbe supérieur du prolongement rachidien." This division is an arbitrary one; the groove forming the separation is not made by any interruption of the ascending falciculi, but by the thickness of the transverse falka of the pons, and does not exist on the posterior surface; it is much less strongly marked in the mammalia than in man, and, as these transverse falka are wanting in birds, amphibia, and fishes, the separation also does not exist. We think, therefore, with Gall, that the foramen of the occiput is the best distinction.

"We cannot indeed say, that the organization of the part is changed immediately on its becoming contained in the cranium. Some pairs of nerves are still detached from it, in a manner similar to the origin of the cerebral; the line of demarcation occupying the middle of the organ is continued beyond this point on the posterior surface, but interrupted in front by the decapsulation of the corpora pyramidalia. The spinal marrow is intimately connected to the parts, which begin at the foramen magnum. But in this part the anterior fissure is interrupted, the nervous masses become swollen in a very visible manner in man, and still more so in the mammalia. The first rudiments of the nerves called cerebral, of the brain, and of the cerebellum, are very distinctly perceived at this part. These reasons seem sufficient for making the spinal marrow end above at the beginning of the great swellings of the pyramids."

It were to be wished, as this author states, that the term marrow (medulla or medullary fabric) were entirely discarded, as there is no more analogy in structure, than in functions, between the medullary texture and the two matters that compose the nervous system. In the medulla spinalis, as in other parts of this system, we meet only with the grey gelatinous matter, occupying the middle of its whole length, and nervous fibres comprising the white exterior part.

The nervous cord terminates below about the first or second lumbar vertebra. In common language the spinal marrow is spoken of as a prolongation or continuation of the medullary substance of the cerebrum and cerebellum; if it is meant by such expressions to denote any actual formation of the one part from the other, any dependence of one on the other, or any thing further than the simple fact of connection, we entirely agree with Gall in considering them as incorrect. The spinal marrow does not become smaller in proportion as the other nerves are sent from it; on the contrary, it is largest in the situations where the largest nerves come from it, as at the origins of the nerves of the extremities; and this fact is particularly observable in birds. Again, in animals, it has been often noticed that the spinal marrow is larger in proportion to the brain than in man. In the same way the nerves are much more considerable in their relative size to the brain in animals, than in man. All these facts shew the independence of the various organs on each other, although anatomists have still continued to describe the large and small spinal marrow and nerves of man and animals equally as prolongations of the brain. Whence comes the spinal marrow of acephalous monsters? Further proofs of the independent existence of these organs are afforded by comparative anatomy. In the lower classes of animals, as worms and caterpillars, there are as many origins of nerves or ganglions, as there are rings or segments; these knots of cineritious matter are joined together by nervous branches; and form a nervous cord divided at intervals with small tumours of various form and size, but all divided into two parts, so that all is double. The number and size of the nervous threads proceeding from these swellings are always in a direct ratio to the size of the latter. In fishes, amphibia, and birds, the principle is the same; there is no essential difference; only the ganglions are in general closer to each other, forming with their uniting bands a cord nearly uniform in size, but swelling out in distinct knots, wherever large nerves pass off; and if closely examined, we may perceive throughout alternate swellings and contractions. This is very visible in the fowl, each pair arising from cineritious substance, and communicating with those on each side by connecting branches. The same law obtains in the mammalia and in man, although the facts are not so immediately evident. Where the large nerves of the extremities arise, the ganglions are larger and more abundantly supplied with the grey pulpy substance. But, besides these principal swellings, there are others at the origins of the particular nerves (one for each nerve), less manifest than in insects, but still sufficiently perceptible. Gall and Spurzheim demonstrated these swellings in the calf, and affirm, that they are also very perceptible in the human subject, particularly at the back part, from which the largest falciculi arise. If the dura mater and arachnoid coats are removed, and the size of the spinal marrow viewed in profile, the outline is distinctly undulated.

A very distinct fissure runs along both the anterior and the posterior surface of the spinal marrow in their whole extent; the anterior is broader and more conspicuous, the posterior deeper. Into both of these the vascular membrane extends. The former is interrupted, at the beginning of the medulla oblongata, by the decapsulation of the pyramids. The two halves of the spinal marrow are united at the bottom of the fissures by a nervous layer, which consists behind of two falciculi directed longitudinally; on the front the falciculi are transverse, and directed from each side towards the middle line, but they do not come opposite to each other, those of one side ending at the intervals between the opposite ones. Gall and his associate consider these nervous layers as the apparatus, by means of which the two halves of this part of the nervous system communicate with and act on each other, in the same manner as takes place in the brain and cerebellum by their several communi- cations. Some animators have admitted the existence of two lateral grooves; but we reject these, with Gall and all other correct modern anatomists.

The production of the spinal nerves has been generally represented, as if the medulla were only a medium through which they are derived from the brain. This representation is quite ungrounded; there is a quantity of cineritious matter
in each lateral half of the medulla spinalis, from which the nervous filaments are produced; when a transverse section is made of the medulla spinalis, this crenated matter represents on each side an arch, of which the convexity is turned towards the median line.

The existence of a canal in the middle of the spinal marrow has been casually mentioned by several writers. Gall and Spurzheim give the following account of it. They first observed it in examining a cafe of spinis bifida, attended with hydrocephalus. "In order to know positively if there existed any communication between the face and the internal part of the spinal marrow, we divided the latter transversely in the neck; it exhibited its natural appearance. Blowing gently through a pipe on the cut surface, we perceived an opening as large as that of a common quill in each half of the spinal marrow, separated by the commissure. They were the openings of two canals, which, by dividing lower and lower down, were found to terminate about three inches above the end of the spinal marrow, having no communication whatever with the face. Doubtful whether this appearance might be the effect of dissection, we examined the part in children and adults. We found the same structure, with this difference only, that in the adult and older children these canals did not open so freely as in younger subjects. The structure is most easily found in children just born. In other respects they are alike. If we continue to blow gently into these canals, from below upwards, and if, after having opened by this operation the length of five or eight lines in the spinal marrow, we expose only four or five, in order to maintain the opening, we may follow these canals through the medulla oblongata, the pons, crura cerebri, and as far as the optic thalami, in which these canals are depicted as a cavity as large as an almond when blown up. They are closed at the anterior margin of the thalami, at the commencement of the corpora striata, and they have no communication with the cavities of the brain. Their surface is smooth; but they contain no fluid." P. 72.

The filaments by which the spinal nerves arise are numerous and delicate; they unite into two, three, or more fasciculi, which go out by two or more openings of the dura mater; the anterior and posterior fasciculi of each nerve, separated at first by the ligamentum denticulatum and above by the spinal accessory nerve, approach to each other, but they penetrate the membrane separately, and are contained in two distinct tubes.

The anterior origins consist of very numerous fine roots, which unite together into larger fibres, and these again into full larger ones, which join ultimately into two cords. The posterior are simple and round, and run to the opening of the dura mater without joining the neighbouring ones. The lowest thread of one nerve often joins the highest of the nerve immediately preceding on the posterior aspect of the medulla spinalis.

The posterior origins are larger and more numerous than the anterior, throughout the whole vertebral column. Gall and Spurzheim explain this by the greater force required for extending than bending the trunk; and consider, that the extended condition of the body after death indicates this preponderance in the extensor muscles. P. 66.

The two first cervical nerves have on the front an ascending and a descending fasciculus; in all the other nerves, all the fibres are directed from their origins downwards to the openings of the dura mater. The posterior origin of the second nerve goes entirely downwards. Hence the two first spinal nerves go out transversely from their origins, while all the red run obliquely downwards. The former are the shortest, within the sheath; the others increase in length as we trace them downwards. The inferior and longest are loosely contained, lie in close apposition to each other, are tortuous in their course, but not connected by any communications; they form below the termination of the medulla spinalis, a large bundle of threads called the cauda equina.

In younger individuals, the fibres, by which the spinal nerves arise, follow each other very closely; in the adult these are small intervals. The arrangement, the height, size, and number of the fibres are often different on the two sides.

After passing through the openings of the dura mater, and receiving a firm fibrous covering, the posterior origins of the spinal nerves swell out, at different distances from their commencement, into small reddish oval ganglia, to which the anterior fasciculus is closely connected by cellular tissue, without being included in it. These ganglia have usually been described in general terms, without noticing the mode of their formation. Scarp a demonstrated, that they belong to the posterior fasciculus only. Yet we meet sometimes, particularly in the neck, with such a firm and red interweaving of the anterior fasciculi, that we are tempted to regard them as gangliform productions.

The size of the nerves is much below that of the common lateral holes of the vertebral column, through which they go out of the vertebral canal; cellular tissue and vascular ramifications fill up the rest of the space.

The medulla spinalis serves for conveying sensations to the brain, and for producing voluntary motions. Hence preference on this organ, or division of it, causes the same effects on the sensations and motions of the parts, which receive sensibility, as the division of the motor portion of the nervous system, on the nerves, or as injuries of the brain. The powers of sensation and motion are sometimes recovered when the medulla spinalis is restored to its former state: this depends on the degree of injury it has received. Although the same nerves are employed for sensation and motion, the latter power may be destroyed while the former remains. The effects of injury are confined to the parts whose nerves arise below the point affected; the sensibility and mobility of other parts is not impaired.

That the medulla spinalis is only a conducting organ, and not the immediate seat of sensation and volition, is proved by the ceasing of these functions, when its connection with the brain is cut off, although it remains uninjured in other respects. The suddenly fatal effect of cutting through the spinal marrow high up in the neck, depends on the paralysis of the respiratory muscles caused by this operation; if the section be above those cervical nerves which give rise to the phrenic nerves, the operation is fatal; if below, the animal may for a longer or shorter time. By maintainning artificial respiration, we may also keep an animal alive after having divided the medulla spinalis above the origin of the phrenic nerves.

The same law does not obtain in the medulla spinalis as in the brain, with respect to the paralysis of the muscles on the side opposite to that of the injury. On this point there have been contrary opinions. Galen has not expressed himself very clearly; but he seems to state that division of one half of the spinal marrow paralyses the muscles of the same side. Sommerring confirms this statement; but Haller contradicts himself in different parts of his Elementa Physiologic. In the first volume of Medico-Chirurgical Transactions, Dr. Yelloly mentions a case of tumour passing on the side of the spine which it had rendered curious; the paralysis was much more considerable on the same side with the tumour,
tumour, than on the opposite; p. 195. Mr. Aftley Co-  
oper divided one-half of the spinal marrow in a dog, imme-  
diately below the occiput; the muscles were paralysed on  
the same side. P. 198.

According to Galen, a longitudinal incision in the middle  
of the spinal marrow has no paralyzing effect.

Prelire or irritation of the part excites very severe pain;  
if it comes on gradually, as in disease, it does not cause  
pain, but gradual loss of feeling and motion in the parts  
below.

For an account of the effect which irritation of this part  
has on the voluntary muscles, see Muscular.  

Description of the Nerves of the Medulla Spinalis.—There  
are thirty pairs of these: viz. eight cervical, of which the  
first paffes between the occiput and atlas, and the last be-  
tween the seventh cervical, and first dorsal vertebra; twelve  
dorsal, of which the first paffes under the first rib, and the  
others, in succession, under the remaining ribs; five lumbar,  
bearing the fame relation to the lumbar vertebrae, as the dor-  
sal nerves do to the ribs; and five sacral, of which four pen-  
nerate the four sacral foramina, and the fifth the foramen  
formed between the facrum and the coccyx.

Sometimes there are only twenty-nine pairs; and some-  
times only twenty-eight: in which the latj ganglion divides  
to two nerves.

First cervical Nerve.—The distribution of this nerve ac-  
cords generally with that of the cervical, from which it dif-  
ers in being much smaller; in often wanting the posterior  
root, which, when it exists, is not in the fame line with the  
corresponding roots of thefe nerves; in having its anterior  
branches much smaller than the posterior; and in having no  
connection with the cervical plexus. These circumstances  
have led many anatomists to feparate this from the remain-  
ing cervical nerves, and to describe it under the name of  
sub-occipital nerve: sometimes, indeed, it is clasped with  
the nerves arising in the head; of which, in the common ar-  
arangement, it would form the tenth, in that which we have  
adopted from Soemmerring and Viciq d’Azyr, the thirteenth.

It arises from the side of the upper part of the medulla  
spinalis, juft under its superior enlargement, and about half  
an inch below the origin of the hypoglossal. Seven or eight  
filaments unite into two or three falciculi in front, and two  
or three threads only behind, form the two origins, which  
are feparated by the ligamentum denticulatum, and some-  
times by the spinal nerve, which more frequently goes behind  
both origins of this nerve, and sometimes communicates  
with the anterior. They penetrate the duræ mater at the  
point where the vertebral artery paffes, and run clofe to that  
artery in the fame canal, on leaving which, a small greyish  
enlargement, similar to what we shall defcribe in the other  
cervical nerves, but lefs ilrongly marked, is obferved. The  
two falciculi united together form a fingle trunk, lodged  
in the excavation behind the articular procfs of the atlas,  
running on the inner fide of the vertebral artery, and divided  
immediately into an anterior and a posterior branch. The  
former is the fmalleft, runs along the articular procfs of the  
atlas, between it and the rectus lateralis, from behind for-  
wards, then descends in front of the transverse procfs, and  
unites with a branch of the cervical plexus, fo as to form  
an arch. It produces only fmal twig, to the lateral and an-  
terior recti, to the superior cervical ganglion, and to the  
nervus vagus and hypoglossus.

The posterior and larger branch goes backwards and up-  
wards, through the triangular space bounded by the obliqui  
and rectus pollicis major, and divides, after a short courfe,  
into, 1, an internal occipital branch; 2, an external occipital  
branch; and 3, a cervical branch, which are distributed on  
the obliqui, the posterior recti, and the complexus. Instead  
of thefe three, six or even seven twig may be produced im-  
mediately from the trunk.

It appears from this defcription, that the first cervical, or  
the sub-occipital nerve, is principally concerned in the mo-  
tions of the head.

Of the remaining seven cervical nerves, the anterior or-  
gins are placed in a vertical line, and conflit of two portions  
or threads, which arife from the medulla spinalis by feven  
or eight filaments, dillinct at the point of origin, but imme-  
diately uniting to form the two threads. These origins in-  
crease in fize from above downwards. The posterior roots,  
more much more considerable than thefe, arife in a vertical  
line from a cleanly marked groove, by a variable number of  
threads: there are commonly three or four in the fecond, fix  
or seven in the three following, and eight or nine in the re-  
mainder. Between the roots of two neighbouring nerves,  
there is very commonly a middle thread, which bifurcates,  
one branch joining the upper, and the other the lower nerve.  
Like the anterior origins, thefæ become larger as they  
are situated lower down: and the threads converge from  
their origin towards the dura mater, fo as to acquire a tri-  
angular figure.

The two roots, separated at firft by the ligamentum den-  
ticulatum, and above by the spinal nerve, approach towards  
each other as they pafs outwards. They have a more  
oblique and larger curve in the canal, in proportion as they  
are placed lower down: the firft goes out oppofite to its  
origin, but each of the fucceding penetrates the dura ma-  
ter below this point: the difference between the origin  
and the exit of the lat is not lefs than the depth of a ver-  
tebra.

When they come to the orifice of the fibrous canal  
which is to transmit them, the two origins are united, and  
enter: but a thin partition still seperates them, forming, as  
it were, two tubes. After a short courfe, the filaments of  
the posterior root swell into a greyfih, denfe, oval body,  
extremely analogous in its appearance to the ganglia of the  
organic nerves. The canal is enlarged for lodging this dwell-  
ing, in which the anterior root has no conccrn. The latter  
joins the cord after the formation of the ganglion, and forms  
with it a trunk, proportioned in fize to that of the two roots  
which give it origin: this trunk paffes through a very fhort  
courfe, when it ends by dividing into an anterior and a po-  
terior branch.

The fecond cervical nerve goes out backwards between  
the atlas and the second vertebra, and divides into the branches  
of which the posterior is the moft conccrable.

The latter paffes under the lower edge of the obliquus  
majus, turns over it upwards and backwards under the com-  
pexus, and perforates that muscle at its infcription in the occi-  
put to become sutfctaneous. It communicates, at the edge  
of the obliquus major, with the sub-occipital and the fecond  
cervical nerves; and fends branches to the complexus and  
splenius. Where it becomes superficial, the trunk is some-  
times called the great occipital nerve: it divides into a vast  
number of branches, distributed to the occipital muscle, and  
to the fcin of the posterior, lateral, and upper parts of the  
head, reaching as far as the termination of the frontal  
branches of the ophthalmic nerve, with which they commu-  
nicate.

The anterior branch turns over the articulation between  
the atlas and the fecond vertebra towards the front, paffes between  
their transverse procfses, covered by the levator scapulae,  
the splenius, and intertransversariil prior, and divides into  
1, upper branches, of which one forms an arch with the  

NERVOUS SYSTEM.

anterior branch of the first cervical, and others go to the superior cervical ganglion: 2, lower branches, of which one or two go to the rectus major anticus, and two or three, rarely one, to communicate with the second cervical, and thus contribute to the cervical plexus.

The third cervical nerve divides, like the preceding, immediately on its escape from the vertebral canal, into two branches, of which, however, the posterior is smaller by half than the anterior.

The posterior turns immediately backwards, over the articulation, between the second and third vertebrae, first defends a little, then ascends, and becomes attached to the anterior surface of the complexus, on which it mounts a little, penetrates it and the trapezius, and becomes subcutaneous towards the upper part of the neck. It communicates with the posterior branch of the second nerve, gives branches to the complexus and neighbouring muscles, and ends at last in the upper part of the neck, and back of the head.

The anterior branch goes forwards and outwards, covered by the splenius and levator scapulae, gives a filament to the superior cervical ganglion, forms an arch above and below with the contiguous nerves, and then joins the cervical plexus.

Fourth cervical Nerve.—Its posterior branch goes backwards, along the articular processes, penetrates between the inflections of the complexus and semispinalis colli, descends between these two muscles, distributing to them several filaments, and then pierces the muscle, to terminate on the skin of the neck. It communicates with the third. The anterior branch goes first outwards, then turns forwards, round the anterior tubercle of the fourth vertebra, sends a communicating branch to the superior cervical ganglion, forms nervous arches with the branches above and below it, and then enters the cervical plexus.

The cervical plexus is formed by the union of the anterior branches of the second, third, and fourth cervical nerves, which, as they leave the vertebral column, communicate with the superior cervical ganglion, then divide each into two branches, which communicate respectively, so as to form nervous arches at the side of the neck, from which other branches arise that are again united more externally. By the upper branch of the second cervical nerve, this plexus is connected with the sub-occipital; and by the lower branch of the fourth, with the first nerve of the brachial plexus.

There is a marked interval in the neck between these two plexuses; the cervical is placed at the back edge of the sternoclidomastoideus, and corresponds to the second, third, and fourth cervical vertebrae: it lies in front of the posterior scalenus, and on the outside of the carotid artery, jugular vein, and nervus vagus. A large quantity of cellular tissue is placed about it, and many blood-vessels and lymphatic glands are interwoven with it, occupying often the arcades formed by its communications. It produces twigs of communication with the cervical ganglia, and with the spinal nerve, and then divides into the following branches.

1. Defending cervical nerve, arising by two roots that remain separate for some time, from the second and third cervical, passing downwards and inwards, and communicating in the manner already described with the defending branch of the hypoglossal nerve.

2. Phrenic or diaphragmatic (nervus septi transversi), arising from the lower part of the plexus. The fourth nerve furnishes its most considerable root, and a flaccid twig is sometimes added by the third. The brachial plexus also adds two or three twigs lower down in the neck. It defends on the front of the anterior scalenus, to which it is closely tied by cellular tissue, enters the chest between the subclavian vein and artery, passes inwards and forwards in the mediastinum before the great vessels of the lungs, and then becomes connected to the pericardium, over which it runs, covered by the pleura, to the convexity of the diaphragm. Its white colour enables us to trace its course, without any division, by simply opening the chest: the pleura is so thin, that the nerve is seen through it on either side of the pericardium.

The right nerve is more anterior, and follows a straighter course: it divides, before reaching the diaphragm, into several branches united by communicating filaments, and then diverging. They give twigs to the convexity of this muscle, and others which descend through the opening occupied by the vena cava to the inferior surface, whence they communicate with branches of the aortic arch. Other branches, longer than thefe, pierce the muscle, join the arteries, and are distributed with them, communicating also with the aortic nerves.

The left phrenic nerve lies farther back in the chest, and is longer, because it turns round the point of the heart. Its branches, like those of the former, are distributed on both surfaces of the diaphragm: some go with the aortic arch into the abdomen, and communicate below with the aortic arch. Ganglia have been described at the point of connection between the phrenic and aortic nerves.

Innumerable experiments on living animals have shewn that this nerve is concerned in the motions of the diaphragm. Injury or irritation of it induces dreadful symptoms; convulsions of the diaphragm, anxiety, distress of breathing, &c. When it is divided, the motion of the diaphragm ceases, and great difficulty of breathing follows; the abdomen falls in when air is taken into the lungs, and swells on expiration. Divisions of the spinal marrow above the origin of the nerves, which produce the phrenic, is instantly fatal, as all the respiratory muscles are instantly paralysed; below that point, it is only fatal after the lapse of hours, or even days; because the diaphragm can still act.

3. Defending external cervical branches, two, three, or four in number, quickly subdivided into numerous other ramifications, which pass over the clavicle and acromion to the integuments and muscles on the neck and shoulder, as the pectoral and deltoid, (supraclaviculares interni & externi; susclaviculares & sus-acromiostes of Bichat,) behind that bone into the axillary, where they are distributed to the omohyoideus, subclavieus, and serratus anticus, (subclaviculares, sus claviculares of Bichat,) and deeper in the neighbourhood of the cervical muscles, particularly of the levator scapulae, along the edge of which a large branch defends ramified in it, and in the neighbouring muscles, (cerveaux profonds, Bichat).

4. Defending branches. Of these there are two principal; a maffoid and an auricular, particularly produced from the second cervical nerve. The maffoid branch (nervus occipitalis minor) descends along the posterior edge of the sternoclidomastoideus, between the integuments and the splenius, to the back of the mastoid process, where it divides into several filaments, distributed to the integuments on the side and back of the head, to the external ear and the occipital muscles, and communicate with the auricular branch of the facial, and the great occipital branch of the second cervical.

The
NERVOUS SYSTEM.

The auricular nerve (superficialis collis, Soemmerring) is a very considerable trunk, twice as large as the preceding, first directed outwards as it leaves the plexus, then bent forwards over the back edge of the ilio-mailloleus, and crossing the upper part of its external surface, in close contact with the muscle, obliquely upwards and forwards. It reaches the anterior edge of this muscle, and divides, opposite to the angle of the jaw, into, 1. anterior auricular branches, spread out on the surface of the cartilage, giving some filaments to its substance, and then ramified on the external ear: one of them communicates, in the gland, with the facial nerve. 2. Posterior auricular branches, of which there are sometimes two, sometimes only one, ascending in front of the ilio-mailloleus and of the multifid processes, and distributed on the ear and neighbouring integuments.

3. Middle cervical branches. There is either a single trunk or two, produced chiefly by the third cervical, reflected over the back edge of the ilio-mailloleus, and distributed to the skin and latissimus colli. The superior filaments communicate with the lower twigs of the facial nerve.

The fifth, sixth, seventh, and eighth cervical nerves, so far agree in their distribution, that they may be considered together. They divide into two branches, as they quit the foramina of the vertebral column. Their posterior branches are remarkable for their smallness, when compared to those of the preceding nerves: they go backwards between the semispinalis colli and complexus, penetrate the splenius and trapezius, and are left on the skin.

The anterior branches, particularly of the three last nerves, are very large: they pass obliquely downwards and outwards from the side of the spine, between the scaleni muscles, which cover their exit from the vertebral foramina, and very soon communicate together. The fifth communicates also with the fourth cervical, and the eighth with the ninth dorsal. Each sends a filament to the cervical ganglia: from the fourth, the phrenic derives a root already mentioned; and various twigs are sent on the surrounding muscles: they then unite to compose the brachial plexus.

The brachial or axillary plexus is composed of the anterior branches of the four last cervical nerves, and of the corresponding branch of the first dorsal, which ascends from the chest. Its extent is considerable; broad at its origin, contracted in the middle, and again expanded towards its termination. The fifth and sixth cervical nerves unite immediately into a common trunk, which descends very obliquely outwards. The eighth cervical and first dorsal join into one trunk, which runs nearly horizontally. The seventh cervical passes between these two trunks as far as the first rib, before it joins them. The plexus descends in the form of a flattened sacculus, between the subclavius and the upper portion of the serratus anterior; it then expands, and divides into numerous branches passing downwards, as we shall describe presently.

The different nerves are all joined together in this plexus, mutually giving and receiving filaments; so that the branches produced from it may be considered as arising from all the five spinal trunks that enter into its composition. In this great plexus another smaller is observed, produced by the union of the origins of the median and ulnar: several small twigs of a soft texture descend from the trunk of the former, and, after a more or less intricate plexiform arrangement, join the latter, constituting the plexus brachialis minor of Searpa, who first described it. See the excellent representations of the whole axillary plexus in his Annot. Anat. lib. 1. tab. 2. figs. 2 and 3.

At its origin, the brachial plexus is placed between the scaleni, of which the anterior conceals this origin, especially towards the lower parts. It then is surrounded by the abundant loose cellular tissue of the axilla below the clavicle, lying first between the subclavius and the first rib, and then upon the serratus: it goes through the axilla to the upper and lower part of the arm. Both pectoral muscles, the subclavius, and the clavicle, cover it in its passage through the cavity. Towards the upper part, the axillary vein is in front, the artery in the middle, and the nerves behind. In the cavity of the axilla, the nerves produced from the plexus surround the artery, almost like a sheath. Besides the branches of communication with the cervical ganglia, and the phrenic nerve, and the muscular twigs already mentioned, the plexus produces the following nerves.

1. 2. Anterior and posterior thoracic nerves, accompanying the arteries of the same name, and distributed on the pectoral and serratus muscles, and through the former to the gland and skin of the breast.

3. Supraclavicular nerve (superficialis, furcula-plicare), going backwards, through the notch of the clavicle, to the dorso of the scapula, and distributed to the subclavicular, supraventricular, and trapezius.

4. The axillary nerve passes under the lower edge of the scapula, and round the head of the humerus, in company with the posterior circumflex artery. It is lost on the surface of the deltoid. Its branches are sent to the subclavicular teres major and minor, rhomboidei, infraspinatus, latissimus dorfi, and deltoid. It communicates with the cutaneous pectoral nerves arising from the dorsal; and it sends off the external cutaneous branch of the shoulder, which goes to the skin of the outer part of the shoulder, and has communications with superficial branches of the radial nerve. Sometimes one, two, or more separate branches come from the brachial plexus to the subclavicular musculi.

5. The internal cutaneous (cutaneous medius of Soemmerring) is the smallest branch of the axillary plexus. It lies in the axilla, between the median and ulnar nerves, then runs along the inner side of the arm, under the brachial aponerous, and in the same general direction with the brachial vein, as far as the bend of the elbow. It lies, however, more superficially and posteriorly than the vessels, and generally very close upon the bicipital vein. It sends off some very inconsiderable twigs among the cellular substance, to terminate on the skin. One of them is more considerable, and descends towards the internal condyle. Near the middle of the arm, or rather higher, the trunk divides into an internal and an external branch.

The external branch penetrates the aponerous, goes obliquely downwards and forwards over the median nerves, as far as the end of the biceps, then passes over the bend of the elbow, about its middle, and continues its course superficially as far as the wrist, distributed to the integuments, and communicating with the neighbouring superficial nerves. The trunk of this nerve is connected at the elbow with the superficial veins, going generally behind those vessels; and the ramifications on the fore-arm are interwoven with the plexus of cutaneous veins.

The internal or larger branch is continued in the direction of the trunk, and accompanies the bicipital vein. This divides at the bend of the elbow, and is distributed superficially on the forearm, over the ulna.

6. The external cutaneous or myelo-cutaneous nerve (nervus perforans) is of a middle size between the preceding and the other brachial nerves: it separates from the plexus, opposite to the common origin of the biceps and coracochabialis, and is directed outwards. It descends obliquely, and penetrates the middle of the coraco-brachialis muscle, then
then goes between it and the brachialis internus, and escapes at the outer edge of the lower end of the biceps. It then lies parallel to the tendon of that muscle, under the median cephalic vein, and becomes superficial. It descends through the forearm, between the aponeurosis and the skin, in the direction of the radius, and reaches as far as the wrist. The musculo-cutaneous nerve sends off muscular branches to the coraco-brachialis, biceps, and brachialis internus. A small twig sometimes joins it to the median. Numerous small twigs are distributed superficially in the forearm, but have nothing remarkable about them. The trunk terminates at the wrist by dividing into two branches, of which one goes backwards, principally to the thumb; and the other forwards, to the eminence formed by the muscles of that member.

There are communications in the forearm, particularly near the wrist, between the internal and external cutaneous trunks.

The trunks of the two nerves just described, (the internal and the musculo-cutaneous,) are deeply seated in the arm; but become quite superficial in the forearm; being placed, with all their branches, in the subcutaneous cellular tissue, in company with the superficial veins. At the bend of the elbow they are closely connected to those veins, particularly to the median basilic and cephalic: the trunks usually pass behind those vessels, but branches occasionally go over them. These are the nerves exposed to injury in varicelion.

7. The median nerve (radial of some authors) is the largest branch of the plexus, after the radial, and comes from the lower and anterior part of it. The trunks, from which it arises, surround the axillary artery. The median nerve descends along the inner side of the arm, in company with that artery, but placed more superficially, to the elbow, which it passes on the inner side of the biceps, and behind the production which its tendon lends to the aponeurosis of the forearm. Here it lies parallel and close to the artery, but on its outside. The trunk then plunges under the muscles of the forearm; it goes first behind the pronator teres, and then between the two flexors of the fingers along the middle of the limb, and arrives in this situation at the wrist. Here it becomes more superficial, and passes with the tendons under the annular ligament of the carpus, becoming apparently increased in size. Having entered the palm of the hand, where it is covered by the palmar aponeurosis, it divides, opposite to the carpal ends of the metacarpal bones, into the branches, which will be presently described.

In the arm, the median nerve distributes no branches; it sends off, in the forearm, several muscular branches to the numerous muscles which occupy the internal or palmar aspect of the limb, and one of which penetrates the interosseous ligament, near the pronator quadratus, to be distributed on the back of the hand. A cutaneous palmar branch comes off near the wrist to be distributed on the skin of the palm.

In the situation already mentioned, the median nerve divides into five digital branches, which may come off all together, or through the medium of two principal primary ramifications; an external forming three, and an internal two secondary branches. The first (reckoning from the outer or radial side) digital branch goes obliquely outward and gives several branches to the muscles of the thumb; these sometimes come off in one trunk from the median itself. The first digital nerve passes along the radial side of the thumb to its extremity. A small twig arising at the first phalanx goes to the back of the thumb.

The second digital nerve is at first parallel to the former,

Vol. XXIV.

but separates from it, and runs along the ulnar edge of the thumb, giving posterior branches, and terminating, at the extremity of the organ, by communications with the former.

The third follows the first lumbrical, to which it lends a twig, as far as the root of the forefinger, and then runs along the radial edge of that finger to its extremity.

The fourth goes to the interval between the fore and middle fingers, and then divides into two secondary branches, which follow the opposed edges of their fingers.

The fifth is distributed in an analogous manner to the ulnar edge of the middle, and the radial edge of the ring finger.

The trunk of the median nerve, and the digital branches produced from it, are covered by the palmar aponeurosis, as well as by the skin of the palm. The latter pass in company with the digital arteries of the arcuri sublimis; they are further accompanied by these arteries in their passage along the sides of the fingers, but they lie nearer to the inner (meatal) or anterior part of the fingers. All of them give branches to the lumbricales muscles, and posterior ramifications turning round the fingers towards their back part; numerous filaments are sent to the skin of the fingers, but the trunks, which retain a considerable size to the ends of the organs, are principally distributed to the cutaneous palmar convexitities of the hand phalanges, where they communicate together, and follow on the parts that more acute sensibility, which qualifies them to act in a more especial manner than the rest of the skin, as organs of touch. The same observations will apply to the distribution of the digital branches of the ulnar nerve.

8. The ulnar or cubital nerve separates from the inner or back part of the brachial plexus, and descends almost perpendicularly over the triceps muscle, to which it is closely tied by cellular tissue, at some distance behind the brachial vessels. It goes behind the elbow, in the channel between the internal condyle and the olecranon, and passes, in the interval between the two origins of the flexor carpi ulnaris, to the front of the forearm. Here it becomes connected to the ulnar artery, and passes in company with it, but rather on the inside, between the flexor ulnaris and flexor profundus. Within two or three inches of the wrist it divides into two branches, a palmar and a dorsal.

In its course along the arm it sends off some slender twigs to the skin and muscles. There is a more considerable branch given off in the axilla, distributed to the integuments covering the triceps and the olecranon, communicating with the internal cutaneous, and described by Soemmerring, under the name of cutaneous internus, as a distinct branch of the plexus. From four to fix muscular branches are produced between the olecranon and the bifurcation of the trunk.

The palmar branch (volaris) is the largest of the two, into which the nerve divides; and it continues its course, in company with the ulnar artery, in the direction of the trunk. It accompanies that artery in its passage over the annular ligament and on the inside of the os pisiforme, and enters the palm of the hand; where it is placed, with the artery, under the palmar aponeurosis. It divides into a deep-seated and a superficial branch.

The deep-seated palmar branch goes under the lumbricales and the flexor tendons, and bends outwards or towards the thumb, so as to describe an arch, from the convexity of which numerous branches go off to the muscles of the little finger, to the interossei, to the adductor indicis, adductor and flexor brevis pollicis.

The superficial palmar branch, after sending a twig to the muscles of the little finger, divides into an external and an internal digital branch. The former, which is the largest, goes to the interval between the ring and little fingers, having
Nervous system.

The dorsal nerves have an anterior origin composed of two or three filaments, and a posterior of more numerous threads but uncertain in their number. They descend obliquely, and are longer in the canal, in proportion as they are situated lower down. These nerves are smaller than those of the lower cervical nerves, or of the lumbar. From the common trunk, which is short, two branches (a dorsal and an intercostal) arise in each nerve.

The dorsal branches are much smaller than the intercostal; they go immediately backwards between the transverse processes, and under the multifidus spinus, and divide into an internal and external series of branches. There is one or two internal branches produced from each nerve; they penetrate the multifidus, and the muscles that cover it, giving branches to them, and then terminate on the integuments, to which however all of them do not reach. The external branches are the largest, go obliquely outwards, escaping at the triangular spaces under the levatores colliarum, and then between the longissimus dorfi and faciolumbii. Afterwards they run under the latissimus dorfi, trapezius, rhomboideus, &c. and end on the skin; having given branches to the different muscles, near which they pass.

The intercostal branches resemble each other in some points, and differ in others. They come out of the vertebral canal under the corresponding ribs; the first under the first rib, and the last under the twelfth. They all go nearly horizontally outwards, except the fifth; pass in the interval of the two transverse processes, and then between the two ribs; and communicate with the thoracic ganglia by one or two branches, which turn inwards and upwards, on the sides of the vertebral column. The intercostal branches then continue their course outwards, covered only by the pleura, to the angles of the ribs, where they pass between the two strata of intercostal muscles, approach the lower edge of the upper rib, and run on in the intercostal interval, where they are distributed as we shall describe.

1st Intercostal Nerve.—This differs much from the succeeding ones. Immediately after its origin it goes obliquely upwards and outwards over the first rib, and joins the axillary plexus, as we have already described. Where it turns over the rib, it sends off a small branch, of which the course and distribution correspond to those of the following nerves. This branch goes along the under surface of the first rib, and arrives at the anterior extremity of the first intercostal interval, where it penetrates the muscles, and is distributed on the upper and anterior part of the chest. It gives branches to the intercostal muscles of the first interval.

The 2nd intercostal nerve runs along the inner surface of the second rib, through the posterior third part of the intercostal interval, and then divides into an intercostal and a brachial branch, previously sending a branch to the back part of the intercostal muscles. The former continues its course along the second rib to the front of the chest, and passes out between the margin of the sternum and the external intercostal muscle, to terminate on the pectoralis major. The latter pierces the external intercostal muscle, passes through the axilla, and divides along the inner and back part of the arm to the elbow, being lost on the integuments.

The 3rd intercostal goes along the lower edge of the third rib to the middle of the bone, and there divides like the former. 1ts intercostal branch is distributed like that of the former: the brachial branch pierces the external intercostal muscle, goes along the lower part of the axilla, and is soon lost upon the arm.

The 4th, 5th, 6th, and 7th branches are nearly alike in their distribution. Each of them runs along the lower edge of
NERVOUS SYSTEM.

of its corresponding rib to about the middle of the chest, giving in its passage many branches to the intercostal muscles. They then divide into intercostal branches, which follow the lower edges of the ribs, supply the intercostals and triangular ligament, pass out at the edge of the sternum, and are lost upon the pectoralis major, mammary gland, and integuments, and into internal pectoral branches which come through the intercostal muscles, and terminate on the neighbouring skin and muscles.

The 8th, 9th, 10th, and 11th branches follow the same course, towards the posterior part of the chest, as the last, supply the intercostal muscles, and divide into external and internal branches. The latter continue in the course of the trunk, and, at the ends of the intercostal spaces, pass over the origins of the diaphragm, and enter the abdominal peritoneum between the transversus and the obliquus internus, to both of which they send branches. They reach the rectus, and there divide into twigs, which enter that muscle, and others which penetrate its sheath to end on the integuments. The external branches go through the external intercostal muscles, and are distributed to the surrounding muscles and skin.

The 12th branch sends first a communicating twig to the first lumbar nerve, soon leaves the last rib to go outwards and downwards, passes along the front of the quadratus lumborum, giving branches to it, and to the diaaphragm, and divides, at the outer edge of the muscle, into a superficial abdominal branch, which first goes between the two oblique muscles, giving them branches, then penetrates the outer, and descends on its surface as far as the crista of the ilium; and a deepseated abdominal branch, passing downwards and forwards between the obliquus internus and transversus, as far as the edge of the rectus.

Lumbar Nerves.—The first pair passes out between the two upper lumbar vertebrae; and the fifth between the fifth vertebra and the sacrum. Their origins are much closer together than those of the dorsal nerves; and are all found in that part of the medulla which is within the last dorsal and first lumbar vertebra. All of them are much longer within the canal than the dorsal nerves, and they become longer in proportion as they are lower down; the last nerve arises opposite to the first vertebra, and its length is equal to that of the intervening space. The lumbar nerves increase in size from above downwards.

Immediately after quitting the canal, each divides into a posterior or lumbar and an anterior or abdominal branch.

1st Lumbar nerve. Its posterior branch is large, goes backwards between the transversus muscles, gives branches to the muscles situated upon the spine, and terminates on the integuments of the loins and buttock.

The abdominal branch goes forwards, and is hidden by the origin of the psoas; it communicates with the branches of the lumbar ganglia, receives the communicating branch from the last dorsal nerve, and sends one to the anterior branch of the second lumbar nerve. It then enters the lumbar plexus.

2d Lumbar nerve. Its posterior branch, like that of the former nerve, goes backwards, and is distributed to the multifidus spinæ, and to the integuments of the upper and back part of the thigh. The anterior is hidden by the psoas, communicates with the lumbar ganglia, and with the nerve above and below it, so as to contribute to the lumbar plexus.

3d Lumbar nerve. The lumbar branch is small, but distributed in a manner similar to the former; the abdominal reflexes in all respects that of the second nerve.

4th and 5th Lumbar nerves. The posterior branches are small, and terminate in the multifidus, and common origin of the sacroiliacalis and longus dorsi, without becoming superficial.

The abdominal branches communicate with the lumbar ganglia: that of the fourth enters into the lumbar plexus, while the fifth descends into the pelvis to join the sacral plexus.

Lumbar plexus (plexus lumbo-abdominalis of Bichat.) This is produced, as we have already mentioned, by the union of the abdominal branches of the lumbar nerves, which form, on leaving the vertebral column, a series of communications with each other, behind the psoas muscle, and in front of the transverser process. It is narrow above, but grows broader below. It begins, in the former situation, by the connection of the first lumbar with the last dorsal nerve; and it ends by three nerves, of which one descends into the pelvis, to communicate with the sacral plexus, and give off the superior gluteal nerve; one passes through the foramen ovale; and the third descends in front of the thigh. Besides these, the plexus sends off other branches to the upper part of the thigh, and to the neighbouring muscles.

1. External or musculo-cutaneous branches. There are usually three, situated between the peritoneum and the iliacus internus; they run over that muscle to penetrate the abdominal muscles, and terminate on the skin. There is considerable variety in their origin and course. The superior penetrates the upper part of the psoas, passes obliquely downwards and forwards, in front of the quadratus lumbarum, and then continues along the crista of the ilium, giving branches to the quadratus, iliacus, and transversus. It penetrates the latter, and divides into an outer branch, which is lost on the lower part of the three broad muscles of the abdomen, and an inner, which descends between the transversus and internal oblique to the anterior superior fisure of the ilium. Then it continues behind the aponeurosis of the external oblique, in the course of the crural arch, to its ring, and terminates in filaments expanded on the integuments of the groin, pubes, and even scrotum.

The middle branch comes from the plexus near the former, penetrates the psoas, passes in front of the quadratus and iliacus to the crista ili; pierces the transversus, and soon after the obliquus internus, and is lost upon these muscles. One branch follows the crural arch to the ring, and is distributed like the corresponding branch of the former nerve, and more particularly to the scrotum.

The inferior branch arises lower down, passes over the iliacus to the anterior and superior pubis of the ilium, and descends into the thigh between that process and the anterior and inferior pubis. It divides into two branches, which penetrate the fascia lata, and are distributed to the integuments of the anterior and outer part of the limb: the inner reaches nearly to the knee.

2. Internal branch (genito-cruralis of Bichat.) It arises from the upper part of the plexus, descends in the substance of the psoas, and then penetrates that muscle entirely, so as to lie on its surface, covered by peritoneum. It descends to the crural arch and divides into two branches. The internal of these is the largest; it follows the spermatic vessels through the ring, and terminates on the integuments of the inner part of the thigh and of the scrotum. The internal goes with the vessels behind the arch, and is lost in the skin of the thigh.

3. Inferior or crural branches. The lumbar plexus, after sending off the nerves already described, ends in three large trunks distributed to the lower extremity.

a. The anterior crural nerve (cruralis; femoralis prior) is

The
the most external of the three trunks: all the lumbar nerves, except the fifth, contribute to its formation. Completely detached from the plexus at the level of the fourth lumbar vertebra, it follows the course of the outer edge of the psoas, concealed by it above, and partly uncovered below. It descends to the front of the thigh, under the crural arch, in front of the common mass formed by the union of the psoas and iliacus, and on the outer side of the femoral artery, from which it is distant about a quarter of an inch. Below the arch it divides into a great number of branches; some of which are superficial, the others deep-seated. There are great varieties in the arrangement of the trunk: sometimes it is single as far as the arch; sometimes the divisions begin about its middle: often the superficial branches are separate through the whole course of the trunk, and merely connect to it. Several small twigs come off in the abdomen, form a network, and are afterwards loft upon the iliacus internus; others go about the crural artery; but the latter are frequently deficient.

The cutaneous branches of the anterior crural (from two to fix in number) are the smallest and least numerous of its ramifications. The point of their origin from the trunk varies: after a short course under the fascia, they pierce it, and are fixed upon the skin of the inner and anterior part of the thigh, where they reach as low as the knee.

The muscular branches are numerous and large, but the number varies: they may be divided into external and internal. The former go outwards in the space between the iliacus, sartorius, and rectus, and then between the latter and the cruralis. We may notice the following: 1, some branches to the lower end of the iliacus; 2, three or four to the sartorius, partly lost in it, partly penetrating that muscle to terminate superficially; 3, a large branch to the rectus; 4, three or four branches to the vastus externus; 5, an equal number to the cruralis; 6, a branch to the tensor vaginae femoris.

The internal branches have the following distribution: 1, several to the vastus internus, of which the inferior descends low on the musles, before entering its substance; 2, some to the pectineus; 3, a cutaneous branch, descending at first in front of the femoral artery, then separating from it to follow the inner edge of the sartorius as far as the knee; it gives some twigs to that muscle, and terminates on the integuments; 4, the largest of these external branches is called the internal saphenic nerve, from its accompanying the great saphena vein. This nerve lies close to the artery on its outer side; it passes the knee joint between the sartorius and the bone, and joins the saphena vein on the inside of the leg. In the thigh it sends branches to the surrounding muscles; its twigs are distributed in the leg to the skin, and they reach on the foot to the ankle, or even the great toe.

b. The obturator nerve arises particularly from the second and third lumbar; sometimes also from the fourth. It descends between the psoas and the latum lumbar vertebra, and traverses obliquely the upper and lateral part of the pelvis, accompanied by an artery and vein of the same name, and surrounded by much cellular tissue. It passes out through the hole under the pubes, and lies between the pectineus and the adductor magnus, where it divides into an anterior and a posterior branch. Before this division it only sends off one twig near the notch of the bone. The two branches just mentioned are distributed to the adductor muscles, vastus internus, obturator externus, and ilium.

c. The large branch joining the facral plexus (nerf lombosacré of Bichat). This trunk descends obliquely into the pelvis, and produces, before it joins the facral plexus, a considerable nerve for the glutei muscles (the superior gluteal nerve). This nerve receives some twigs from the facral plexus, then goes out of the sacro-sciatic notch, above the pyramidalis, and divides into several filaments for the gluteus medius and minimus.

The facral nerves are commonly five, but sometimes six pairs. The first pair comes out through the first facral foramen, and the last at an opening formed between the facrum and the coccyx. They all arise close together, from the considerable swelling which terminates the medulla spinalis, and within a space not greater than the interval of the two vertebrae; yet their origins are perfectly distinct. Each nerve, as in the case of the other nerves of the spinal marrow, has a distinct anterior and posterior origin, composed of several separate threads. They descend perpendicularly, and are very long within the canal, because the spinal marrow terminates at the second lumbar vertebra, and each nerve must go from this point to its respective facral foramen, before it pales out of the sheath of dura mater. They unite at the aperture of the latter membrane; one of the fasciculi then forms, as in the other vertebral nerves, a small oval ganglion, and the common trunk passing from this divides into two branches, an anterior and a posterior. The ganglia of the facral nerves are contained in the bony canal, instead of being situated, as those of the other spinal nerves are, at the external apertures. The ganglia of the upper nerves, however, are nearer to the openings than those of the lower.

The first pair is as large as the last lumbar nerve; they gradually decrease to the fifth, which is very small, considerably smaller than the first cervical.

The anterior branches decrease successively in size, from above downwards, like the trunks themselves: they go out of the canal by the anterior facral foramina. The posterior foramina transmit the posterior branches, which are comparatively very small.

First facral Nerve.—The posterior branch is very small and short; it communicates with the second, and is distributed to the muscles on the back of the bone, and to the skin. The anterior branch, which is large, communicates with the facral ganglia by two considerable but short filaments, then descends obliquely backwards, and joins, above the pyramidalis, with the first lumbar nerve above, and the second facral below, to contribute to the facral plexus.

Second facral Nerve.—Its posterior branch is distributed to the muscles occupying the back of the facrum, and extends beyond them to the posterior surface of the gluteus maximus. The anterior branch comes out between two portions of the pyramidalis, communicates with the facral ganglion, and crofles the muscle obliquely to join the facral plexus.

Third facral Nerve.—The posterior branch is larger than those of the preceding nerves, joins the nerve above and below it, penetrates the gluteus, and is distributed to the skin of the buttock. The anterior communicates with the facral ganglion, and joins the plexus, communicating with the two nerves immediately adjoining.

Fourth facral Nerve.—Its posterior branch is the largest of all produced from the facral nerves. It descends obliquely forwards, communicates with the two branches, between which it is placed, gives filaments to the gluteus maximus, and terminates in the integuments of the buttock. The anterior branch communicates with the ganglia, and joins the facral plexus.

Fifth facral Nerve.—Its anterior branch passes out between the facrum and coccyx; it communicates with the fourth, but has no other share in the facral plexus. It goes to the levator
has an analogous distribution to that of the male subject; it terminates upon the clitoris.

The anterior branches of the femoral plexus are very variable in size and number, but are in general small and numerous; they arise from the lower part of the plexus, and especially from the third and fourth nerves. They may be named after the parts which they are distributed to.

The hemorrhoidal branches ramify on the whole length of the rectum; they appear to end partly in the muscular fibres, and partly on the mucous membrane.

The vesical nerves pass along the side of the rectum, and are partly derived from the hemorrhoidal. They terminate on the bladder, prostate, and vesicle, and can be followed in the female to the urethra.

The uterine and vaginal nerves ascend by the side of the rectum, diverge, and are distributed to the whole length of the vagina. The upper ones go to the neck and body of the uterus, but in much smaller number than to the vagina. They are connected with the vesical nerves.

All these nerves, which are small and very numerous, are so minutely divided, and so much interwoven with each other, that we give only a general view of them. They are also very intricately connected with the abdominal and femoral ganglia, and from this union results the hypogastric plexus, which shall describe afterwards.

The femoral plexus generally produces one or two branches, passing over the lesser facio-femoral ligament to join the pudendal nerve.

The sciatic or ischiatic nerve (nervus ischiadicus), the largest trunk in the body, is the true termination of the femoral plexus; and there is such complete continuity between them, that we cannot assign any exact limit. All the femoral nerves entering the plexus contribute to the formation of the sciatic. It descends in front of the pyriformis, and passes through the lower part of the great ischiatic foramen, between the edge of that muscle and the bone, then goes along the back of the limb towards the knee. Sometimes two trunks go from the plexus, instead of one; the smaller penetrates the fibres of the pyriformis, and joins the other at the back of the pelvis. The sciatic trunk lies first in the interval between the tuberosity of the ischium and the great trochanter, and then is found nearly in the middle of the back of the thigh, between the biceps and the other flexors of the knee, and rather in front of them. Where it comes out of the pelvis, it is covered by the gluteus maximus; lower down by the long head of the biceps and the semitendinosus. It lies upon the gemini and the obturator internus, upon the quadratus femoris, and the posterior surface of the adductor magnus; it is every where surrounded, but particularly in the thigh, by a large quantity of cellular and adipous substance.

The trunk of the nerve continues in the same course through the ham, where the name of popliteal is given to it. It lies between the tendons of the biceps and semitendinosus, covered externally by the falcia, placed over the popliteal vein, with which it is not in contact, and imbedded in much fat.

The branches of this trunk are numerous, and consist of, 1, several, as it quits the pelvis to the obturator internus, gemini, and quadratus; 2, some, which are not constant, to the gluteus maximus; 3, two or three to the long head of the biceps, one of which extends towards the knee, and is lost on the skin; 4, a branch to the short head of the same muscle; 5, to the semitendinosus and femorobrachialis; 6, to the adductor magnus.

Several of these produce cutaneous filaments, varying in length and distribution, penetrating the falcia, and reaching below...
below to the leg. These, with the branches of the inferior gluteal nerve, cover all the back of the thigh.

The fematic nerve divides into two trunks; a smaller external one, called the peroneal nerve; and a larger internal one, the posteri tibial nerve. This division of this innervation is not always the same: it may take place at the back of the pelvis, or in the middle of the thigh. The two trunks run close together, connected by cellular membrane, but easily separable by diification, and they begin to diverge on the lower third part of the thigh. The outer branch goes towards the head of the fibula, and the inner continues in the direction of the fematic trunk.

External branch, or peroneal nerve. This descends by the side of the lower end of the biceps, goes behind the outer end of the gastrocnemius, the outer condyle and the joint, then turns forwards between the fibula and the peroneus longus, and divides into two branches; but it previously sends off several small nerves: viz., 1, an articular branch, which goes off near its origin, defticient between the femur and the biceps, giving some branches to that muscle, and terminating on the outside of the knee; 2, a considerable cutaneous branch, arising before the nerve has arrived at the condyle (nervus communicans tibiae, or cutaneous longus posteri tibiae), descending over the external end of the gastrocnemius, to which it gives branches, accompanying the ramifications of the lesser saphenous vein, running along the outer edge of the tendon Achilles, and uniting at the bottom of the leg with the external saphenous branch of the posteri tibial nerve; 3, a smaller cutaneous nerve sometimes wanting.

The two branches, into which the peroneal nerve divides at its termination, are the anterior tibial, and the superficial peroneal.

The superficial peroneal (muculo-cutanée of Bichat) descends between the extensor longus digitorum pedis and the peroneus muscles, and then on their surface to about the middle of the leg, when it penetrates the fascia, and passes over it to the foot. It sends branches to the muscles just mentioned, and cutaneous twigs to the lower and outer part of the leg. The trunk divides at the foot into an internal and external superficial branch, which are distributed to the integuments of the back of the foot, and of the toes, communicating on the inside with the nerves saphenous of the anterior crural, and on the outside with the superficial branch of the posteri tibial.

The anterior tibial branch perforates the upper extremity of the peroneus longus and extensor communis, and descends in front of the anterior tibial artery, and in company with it to the back of the foot, where it ends by dividing into an internal and external deepseated branch. The trunk sends off a few muscular branches in its course; the two nerves in which it terminates on the foot are distributed to the extensor brevis and interosseus, and some even reach the toes.

The posteri tibial nerve (nervus tibialis), considerably larger than the peroneal, continues in the same course as the trunk through the hollow of the ham, covered by the fascia of the leg, and separated from the popliteal vessels by much fat. It goes between the two heads of the gastrocnemius, behind the knee joint and the popliteus muscle, then passes between the latter and the edge of the soleus, along the back of the tibia, in company with the posteri tibial artery, between the tibialis posterior and extensor longus digitorum, which are in front of it, and the soleus, which is behind. At the lower part of the leg it becomes nearly superficial, is placed at the inner edge of the tendon Achilles, and behind the malleolus, defends the sole of the foot at the concavity of the os calcis, where it is covered by the abductor pollicis, and terminates by dividing into an external and an internal plantar nerve. It gives origin, in this course, to the following branches.

The external saphenous nerve descends in the interval of the two heads of the gastrocnemius, and then on the outer edge of the tendon Achilles, giving off several twigs principally to the skin, and accompanying the branches of the external saphenous vein. It unites below with the posteri cutaneous branch of the peroneal, and continues to descend, much increased in size, on the outside of the leg, under the fascia; it goes behind the external malleolus, then runs forwards on the outer edge of the back of the foot as far as the faint metaphal bone, where it terminates by dividing into two branches, of which the internal runs over the short extensor and is distributed to the back of the two lateral toes, communicating with the external branch of the anterior tibial nerve, the external continues along the outside of the foot and little toe. Previous to its division, the trunk produces many branches which go under the tendon Achilles, and the skin on the outside of the heel.

Considerable branches to the gastrocnemius, soleus, plantaris, and tibialis. One penetrates the upper opening of the interosseous ligament, and is lost in the front muscles.

Slender and long branches to the lower and front part of the soleus, and to the deepseated muscles at the back of the leg.

Some cutaneous twigs towards the lower part of the leg; the largest of these goes to the sole of the foot, and is distributed between the skin and fascia.

Branches to the abductor pollicis and flexor accessorius just before the division of the trunk.

The two plantar nerves run horizontally forwards in the sole of the foot, supply the different muscles of this part, and terminate on the toes, each of which receives two branches. These run along the sides of the under surface of the toes, in company with the arteries, and have a distribution entirely analogous to that of the digital nerves in the hand.

The internal is the largest of the two plantar nerves; it runs above the abductor pollicis, and by the side of the flexor longus, to the middle of the foot, where it divides into four branches. The first of these, towards the lateral, goes to the inner edge of the great toe; the three succeeding ones, that is, the 2d, 3d, and 4th, go respectively to the intervals between the great toe and the 2d, between the 2d and the 3d, and between the 3d and 4th; each of them divides into two branches, which are distributed to the oppoosed edges of the toes.

The external plantar nerve passes between the flexor brevis and accesorius towards the outside of the sole, and divides into two branches; a superficial one, which gives a branch to the outer edge of the fourth toe, and two branches to the little toe; and a deepseated one, that terminates on the deeper muscles of the foot.

Great sympaletic nerve (sympatheticus, sympathicus, or intercollalis). In conformity with the principle, that the brain is the common origin of all the nerves, the great sympathetic has been derived indirectly from the brain, and immediately from the spinal marrow; and the plexuses of the viscera have been represented as a continuation of the same nerve; but this opinion is irreconcileable with the anatomical facts, that the best anatomists and physiologists have called it in question. Winslow observes concerning the filaments of the 5th and 6th pairs, which have been regarded as the origin of the great sympathetic, that they seem rather to descend from the ganglion to those nerves, and that the nucleus of their union with those pairs is turned forwards. Winslow also regards the twigs, which go from the sympathetic...
Nervous System.

The cervical ganglia are usually two in number; but sometimes three.

The superior, first or great ganglion, is remarkable for its size; it is generally found. It is placed on the side of the front of the vertebral column, immediately under the head. It lies on the rectus major anticus, behind the internal carotid artery, with the par vagum and the hypoglossal nerve on the outside of it, connected to all these parts by cellular sub stance. Its extent and figure are very variable; but it is always largest in the middle, and gradually smaller towards either end. It begins a little below the carotid canal; and it may terminate at the 3d, 4th, 5th, or 6th vertebra of the neck. When short it is broad; when long, narrow. The color is a reddish-grey.

Two branches, or a single one afterwards divided into two, go from its upper end into the carotid canal, where they separate, and include the artery between them. One of these joins the carotid branch of the pterygoid nerve, and sometimes goes on to the abdutor nerve after this union. The other communicates with the last mentioned nerve in the cavernous sinus; and this is the filament commonly regarded as the origin of the great sympathetic nerve. These two branches adhere closely to the internal carotid artery, and give some twigs to the coats of that vessel; the ganglion also produces other slender filaments, which run upon the artery, and follow its ramifications.

There is only one inferior branch, of which the size is various, but never considerable. The boundary between it and the ganglion is not always very clearly marked. It depends on the surface of the rectus major and longus colli, to the inferior cervical ganglion. The carotid artery, jugular vein, and par vagum, lie in front of it; to thevem, as well as to the muscles behind, it is connected by a tolerably close cellular tissue.

The external branches are four in number, arising either separately, or by one or two trunks, and communicating with the three upper cervical nerves.

The internal branches exhibit numerous varieties in number, size, fize, and distribution. They are expanded on the vertebral column, and, after sending numerous filaments to the rectus major and longus colli, terminate on the pharynx and larynx. They are very small. They come either from the ganglion or from its inferior branch, and are distributed on the back of the pharynx, where they communicate with the globo-pharyngeus, and on the larynx and thyroid gland.

The anterior branches are the most important in their distributions; they are the most numerous, and offer the first examples of those intricate inter communications peculiar to the nervous system of the ganglia, which make their distinction very difficult.

The highest and shortest of these communicate with the facial and hypoglossal nerves, and the par vagum.

Next to these come the nerves that form the carotid plexuses, sometimes called, from their soft texture, nervi molles. They have a reddish color and knobbed appearance; arise from the ganglion in one, two, or more trunks, and join the common carotid at its division. Their ramifications descend along the trunk, and ascend with the branches of the external carotid, forming intricate plexuses, which adhere very closely to the arterial coats, and receive twigs from the glorio-pharyngeal, facial, and nervus vagus. These arterial plexuses differ much in their appearance, confuting sometimes of confusing ramifications, while they can hardly be traced at others. From the plexuses formed by the conjuction of these with the pharyngeal and laryngeal nerves, twigs proceed to the two lower constrictor muscles of the pharynx, to the thyroid gland, stylo-pharyngeus, stylo-glossus, sternothyroides, and crico-thyroides.

The superior cervical ganglion produces firstly the superior cardiac nerve, or nervus cordis superficialis; which we shall describe presently with the nerves of the heart.

Middle cervical ganglion (ganglion thyroideum). This is often wanting. When it exists, it is situated between the 5th and 6th cervical vertebra. It varies much in size; sometimes appearing only as a slight swelling of the trunk, that connects the upper and lower cervical ganglia. It lies on the longus colli, and behind the carotid and internal jugular vein. Three or four branches depart from it below, surrouding the vertebral and inferior thyroid arteries, and unite again at the lower cervical ganglion. It communicates with the neighboring cervical nerves, and sends branches to the cardiac plexus, with the inferior thyroid artery to the gland of that name, and to the scalenus. Its branches communicate with those of the recurrent.

The inferior cervical ganglion (cardiacum) exists constantly, but varies greatly in size and figure; sometimes it is even double. It generally lies in the hollow between the transverse processes of the 7th cervical vertebra, and the neck of the first rib; or it may be placed in the hollow of the first rib. It may be either above or below, before or behind, the inferior thyroid artery, and it is partly covered by the vertebral. It extends to the first intercostal space, and sometimes seems confused with the first thoracic ganglion.

This ganglion has one or more superior branches; when it is single it joins the inferior branch of the upper ganglion; when they are more numerous, they surrouund the vertebral or thyroid artery, and join the middle ganglion. Another follows the vertebral artery through the foramina of the transverse processes, gives filaments to the inter-transverse and fascial muscles, and communicates with the cervical nerves.

Two branches come from the ganglion below; one goes behind, and the other in front of the subclavian artery; and they join the first thoracic ganglion.

The external branches communicate with the sixth, seventh, and eighth cervical, and the first dorsal nerves;
Nervous System.

Others are expanded on the coats of the subclavian artery, and some twigs are lost on the anterior scalenus.

The internal branches are few and small; they go to the longitudinal coli, and to the pulmonary plexus, and one analogous with the recurrent nerve. The anterior branches are the inferior cardiac nerves, which unite into one, two, or three trunks.

Nerves of the Heart.—This organ receives its principal supply from the ganglia; but the par vagum and the recurrent communicate with the other cardiac branches.

On the right side there are three cardiac nerves, a superior, a middle, and an inferior. The superior, called by Scarpa the superficial, arises by five or six filaments from the superior cervical ganglion. Thefe unite into a trunk, which descends perpendicularly to the lower part of the neck, along the vertebræ, on the inside of the trunk, which connects the two cervical ganglia. It goes behind the middle cardiac nerve, and divides into several branches, which communicate with the recurrent and the middle cervical ganglion. But sometimes it passes over the common carotid to the arch of the aorta, where it joins the middle cardiac nerve. In its passage along the neck, it communicates with the par vagum, and with the nervous arch formed by the descendens noni; and it sends branches to the oesophagus, and to the muscles covering the trachea.

The middle, called by Scarpa the great or deepseated cardiac nerve, is the largest of the three. It arises from the middle cervical ganglion, passes forwards and downwards by the side of the carotid, and then over the subclavian; it runs along the ateria innominata, and passes between the arch of the aorta and the bronchi to terminate in the cardiac plexus. It communicates with the par vagum and the recurrent, and gives several flender twigs to the aorta.

The inferior, or small cardiac nerve of Scarpa, comes from the lowest cervical ganglion in the form of a plexus, descends behind the subclavian artery, and then by the side of the innominata, to the front of the arch of the aorta, and turns towards the left on that vessel. It receives several twigs in this course from the recurrent and par vagum, and gives many to the aorta.

On the left side there are usually only two cardiac nerves: the superior has the same origin, and nearly the same course as on the right. It descends between the carotid and subclavian arteries, and divides into several twigs, of which some go to the front of the aorta, and the others join the common cardiac plexus behind that vessel.

The great cardiac nerve is formed on the left side by the union of those which come from the two lower ganglia. It goes forwards and downwards to the back of the aorta, and there joins the cardiac plexus. This and the preceding have considerable communications with branches of the par vagum. The nerves of the heart, as they approach the plexus, sometimes form a ganglion (ganglion nervorum cordis), placed near the left cervical vertebra and the subclavian artery, and sometimes wanting.

The cardiac plexus, or the common point of termination of the nerves just described, occupies the posterior part of the arch of the aorta. It corresponds behind to the division of the bronchi, and to the anterior pulmonary plexus of the par vagum; and it extends from the origin of the innominata to the division of the pulmonary artery. The nerves of which it consists are remarkably lost. It receives above the right, middle, and inferior cardiac nerves, several branches from the left superior nerve, and sometimes from the right.

Its anterior branches are inconsiderable; they are distributed to the front of the aorta; the posterior join the anterior pulmonary plexus. The inferior are the largest and most numerous, and belong properly to the heart. These are partly distributed on the large vessels, as the trunk and branches of the pulmonary artery, and the pulmonary veins, and partly compose an anterior and posterior coronary plexus, which extend and surround the anterior and posterior coronary arteries, and follow their ramifications into the surface of the heart. The posterior plexus is much the largest, and, consequently, the flat surface of the heart has more numerous nerves than the convex. The branches of these plexuses adhere closely to the arteries; and it is supposed by some anatomists, that the nerves are entirely distributed on these vessels, without going all to the muscular substance of the heart.

Thoracic Ganglia.—The appearance of the system of the ganglia in the chest is very different from what it presents in the neck: in the latter its parts are so distinct, and so widely separated, that they must be described distinctly. In the chest, on the contrary, the ganglia are so small, and so near to each other, and the unifying branches so large, that the whole looks like a continuous nervous trunk. There are twelve thoracic ganglia, placed on the heads of the ribs, and covered by the pleura; sometimes the lower cervical ganglion extends to the first rib, and takes the place of the first thoracic. Their form is irregular; in most approaching to the triangular; their surfaces are flattened, and their size is inconsiderable, except the first, which is large.

The inferior and inferior branches of these ganglia may be considered together; they unite them into one cord, and are remarkably large, when compared with the corresponding unifying branches in the neck. Two contiguous ganglia are always joined in the chest by a single branch. Careful dissection and examination will always enable us to distinguish the ganglia from the branches that unite them, although in many cases the difference of size is not considerate. The upper ganglion has two superior branches, which we have already described as the inferior of the last cervical ganglion; the inferior branch of the last thoracic ganglion joins the first lumbar ganglion.

The external branches vary from one to three or four for each ganglion; they go obliquely upwards and outwards, and communicate with the anterior branches of the respective dorsal nerves.

Internal Branches.—The superior thoracic ganglion sends branches to the cardiac plexus, to the vertebral and subclavian artery, to the anterior scalenus, and the longus coli.

There are a few small branches sent to the defeding aorta, to the intercostal arteries, and to the plexus formed on the oesophagus by the par vagum. The most important nerves produced by the thoracic ganglia are the splanchnic, two in number, a great and a small one.

The great splanchnic nerve arises by four or five branches, at a considerable distance from each other, from the inner side of the middle thoracic ganglia; from the sixth or seventh, to the ninth or tenth. These pass obliquely forwards and downwards on the vertebral column, covered only by the pleura, and unite into one trunk about the eleventh dorsal vertebra. The trunk continues its course in the same direction, and enters the abdomen by a small slit in the appendix of the diaphragm, being divided, as it passes, into three or four branches, which separate a little from each other, and terminate behind the stomach on one side, and the liver on the other, in ganglia considerably larger than those hitherto described.

A smaller nerve, called splanchnicus minor, or accesorius, aries
NERVOUS SYSTEM.

arises by two branches from the lower thoracic ganglia; these come forwards on the vertebras, and join into one trunk, which passes through the flame opening of the diaphragm with the former, and terminates partly in the celiac ganglia, partly in the renal plexus.

There is a large flattened ganglion, called semi-lunar, on each side of the abdomen, in which the splanchic nerves end. This lies on the surface of the crus of the diaphragm, by the side of the celiac artery, and just below the phrenic. Many other ganglia (from twelve to twenty in number) smaller than this, varying greatly in size and figure, are placed near it. All these are united together, and to those of the opposite side, by numerous short and thick nervous branches, and thus compose an almost inextricable plexus surrounding the root of the celiac artery, and its primary branches, and the sides and front of the aorta. This has been called the foliar plexus, and is named by Soemmering plexus celiacus.

This plexus lies upon the vertebral column, the aorta, and the crura of the diaphragm; the liver, stomach, and pancreas are placed above, in front of, and below it. It has numerous large communications with the nerves of the eighth pair; and it receives branches from the last thoracic ganglion.

From this, secondary plexuses go off with the different arteries to the various organs, and their branches adhere closely to the coats of the vessels. These are formed, like the celiac plexus, of ganglia and nervous chords, and their communications compose quite a fine net-work.

1. The diaphragmatic plexus consists of a few twigs accompanying the arteries, distributed to the concavity of the diaphragm, and communicating with the phrenic nerves.

2. The coronary stomachic plexus surrounds the artery of the same name, turns with it along the lesser curvature of the stomach, and reaches the pylorus, its branches becoming gradually less and less numerous, as it approaches the latter part. This plexus is augmented on the stomach by the par vagum; it joins the hepatic plexus near the pylorus, and it sends branches with the right gastro-epiploic artery.

3. The hepatic is a very considerable plexus, surrounding the hepatic artery and vena portae; and accompanying them to the great fissure on the under surface of the liver. A small plexus parts from this, to accompany the right gastro-epiploic artery, and to feater branches also on the duodenum and pancreas. The ramifications of the hepatic plexus surround the neck of the gall-bladder, and are distributed in considerable number on that organ; many also surround the ductus choledochus. They enter the liver with the hepatic artery and duct, and vena portarum, and follow the ramifications of those vessels in its substance.

4. The splenic plexus is small in proportion to the size of its artery, and does not lie very close upon the vessel. There are two or three small ganglia at its commencement; but afterwards we see only a few branches not communicating very frequently. They enter the substance of the spleen with the arterial branches; give some twigs to the pancreas, and others that follow the left gastro-epiploic artery.

5. The superior mesenteric plexus is a prolongation of the great celiac plexus, in front of the aorta, where it quickly meets with the superior mesenteric artery. It is a very intricate intertissue of nervous branches with numerous ganglia, lying very close on the artery, which it accompanies between the pancreas and duodenum, and then between the two layers of the mesentery. Its branches accompany those of the artery, and are distributed with them to the small intestines, to the caecum, the ascending and the transverse portions of the colon.

6. The inferior mesenteric plexus (mesocolicus, or mesentericus medius) is made up of branches from the preceding, from the lumbar ganglia, from the renal and the spermatic plexuses. It becomes connected with the trunk of the inferior mesenteric artery, and accompanies it to the superior aperture of the pelvis; its branches surround the ramifications of that trunk, and terminate upon the arch, the descending portion, the sigmoid flexure of the colon, and the rectum, and contribute to the formation of the hypogastric plexus.

7. Renal plexuses (plexus nervorum renum gangliiformis, dexter et sinister). These are made up by branches from the celiac and superior mesenteric plexuses, from the smaller splanchic nerves, and from the tenth and eleventh thoracic ganglia; the latter are the posterior renal nerves of Walter. They receive filaments also from the abdominal portion of the sympathetic. According to that anatomist, there are four ganglia on the right, and seven on the left renal nerves; these communicate with each other, and those of the two sides are also joined together. Several nerves proceed from these ganglia, over the artery, nearly parallel to each other, and enter the organ with the arterial branches. Some twigs go to the renal capsule.

8. Spermatic plexuses. These are inconsiderable, and arise chiefly from the renal; two spermatic ganglia are found lower down on each side, communicating with each other, and with the superior and inferior mesenteric, and the hypogastric plexuses. From these sources a small plexus arises, surrounding the spermatic artery, adhering closely to it, and accompanying it to the testis and ovariun. It gives a branch to the ureter.

9. The hypogastric plexus (mesentericus inferior) is produced from the lumbar and spermatic ganglia, and the inferior mesenteric plexus, united with the numerous branches already described of the facral nerves. It consists of numerous small twigs communicating frequently, but not mixed with ganglia, placed at the side and back part of the pelvis, and sending its branches to the rectum, ureter, bladder, vesiculae feminales, vagina, and uterus. The lower part of the aorta, the internal iliac artery and its branches receive numerous twigs from it.

Such are the numerous plexuses which the abdominal viscera receive from the system of the ganglia. The splanchic nerves are usually described as the origin of these; but when we observe that there is no proportion in number between the splanchic nerves and the numerous large ganglia below the diaphragm, and that these ganglia produce nearly all the nerves of the solar plexus, we must regard the sympathetic nerves as the true centres of the abdominal nerves, and the splanchic trunks only as branches of communication.

The abdominal or lumbar ganglia continue the chain from the chest to the junction of the left lumbar vertebra and sacrum, and are described by authors as the continuation of the great sympathetic nerve in the abdomen. They are generally five in number, but there may be only four, three, or even two. Their form and size are subject to great variety; they are usually flattened and angular; larger than the thoracic, and of the ordinary reddish-grey colour. They are more completely distinguished from each other than those in the chest. Their situation is on the anterior lateral part of the vertebral column; either on the bone, or the fibro-cartilage.

They are connected throughout by thinner branches passing from one to the other; sometimes there is a single branch,
branch, sometimes two, or even three. The superior lumbar ganglion is joined to the left thoracic by a branch, which passes through a slit in the fibres of the crus of the diaphragm, rather below the opening which transmits the vagal nerve; the left lumbar is joined to the first sacral ganglion. According to Bichat, the connecting branch between the lumbar and thoracic ganglia is sometimes wanting.

Each ganglion produces two or three branches on the outside, which go obliquely upwards above, transversely in the middle, and downwards below - crofs in front of the lumbar arteries, penetrate the attachments of the psoas, and join the anterior branches of the lumbar nerves. These are much larger than the corresponding communicating nerves in the chest, because the lumbar ganglia are placed far forwards on the spine. Some very small twigs are distributed to the quadratus lumborum.

On the inside, the lumbar ganglia, or the branches which unite them, produce the following nerves: 1, twigs to the aorta and lumbar arteries; 2, a branch to the renal plexus, and another to the psoas; 3, branches uniting together, and with those of the opposite side, to form the arterial ganglia lying on the aorta, giving branches to that vessel, to the lumbar arteries, the inferior mesenteric and hypogastric plexuses; 4, small branches joining those of the opposite side.

The facial ganglia continue the series in the lower part of the vertebral column, and form, with their uniting branches, the pelvic portion of the great sympathetic nerve, according to the common descriptions.

Their usual number, according to Walter, is five on each side; Bichat only mentions three as clearly recognizable. The upper is the largest, and the size decreases downwards; they are flattened, and irregular in figure; indeed they are subject to great variety in all respects. They are placed at the side of the anterior surface of the bone, and covered in front by the peritoneum and rectum.

The first is joined to the left lumbar nerve; they are connected together by one, two, or three branches. Bichat states that the connecting branch between the left lumbar and first sacral ganglion is sometimes wanting.

On the outside the facial ganglia are connected by several branches to the facial nerves; they send also some slender twigs to the pyriformis and levator ani. Branches of irregular number go from side to side to unite the right and left ganglia. Others are sent to the rectum, the hypogastric plexus, and the internal iliac artery: a branch defends to the upper and front part of the coccyx from the last sacral ganglion on each side; they unite on the surface of that bone, and a small swelling marks the point of union; this is called the ganglion coccygeum, but does not exist constantly. A few very small twigs go from it to the end of the rectum, and the surface of the bone.

Besides the works referred to in the article Brain, the reader may consult Sömmering, in De Corporis Humani Fabrica, tom. iv.; Haller, Elementa Physiologiae, tom. iv.; Bichat, Anatomica Generale, tom. i.; and the works of Gall and Spurzheim mentioned in this article. For an account of the ramifications of the nerves, besides the two books here mentioned, see Walter, Tabulae Nervorum Thoracis & Abdominis, folio; Scarpa, Tabulæ Neurologicae, folio; Flich, DeScripto Nervorum Lumbarum et Sacra- lium, folio; Ludwig, Collectio Scriptorum Neurologico- rum Minorum.

NERVUS, in Surgery. In almost every treatise upon surgery, we find a section upon the bad symptoms which originate from wounds of nerves. Now, although it cannot be questioned, that the wound, or division, of a large nerve ought to be regarded as a serious accident, inasmuch as such an injury may even be followed by fatal consequences, and this nearly with certainty when nerves, supplying particular viscera, are intertied, yet it should be understood that, in every accidental cut, numerous nervous filaments are either completely, or partially divided, without any alarming effects being usually produced, and we may therefore conclude, that wounds of ordinary nerves are not attended in common inlines with any remarkable hazard. The complete division of the trunk of a large nerve of course produces paralysis in the parts to which the branches of that nerve tend; and a partial section of it sometimes appears to give rise to violent shooting pains in the same parts, attended with severe nervous irritation throughout the whole constitution. Gunshot injuries, in the track of large nerves, were observed by M. Larrey to be particularly often followed by tetanus in the climate of Egypt. Whether this observation applies to similar accidents in more northern countries, we cannot decide; but, in these, tetanus is well known to be far less frequent.

Mr. Pott, in his lectures, used to mention cases, in which patients had suffered distracting pain after venesection, followed by convulsions, and other symptoms, which could only be ascribed to nervous irritation, originating from the injury of the cutaneous nerves in the operation. Mr. Abernethy has treated this subject with much discrimination; he explains what nerves are exposed to injury; what are the effects likely to be produced by such an accident; and what means are most likely to afford relief.

The two cutaneous nerves are chiefly exposed to the lancet. Most frequently, all their branches pass beneath the veins at the bend of the arm; but sometimes many small filaments are detached from these branches and proceed over the veins. When a nerve is irritated at any point between its origin and termination, a sensation is felt, as if some injury were done to the parts which it supplies. Hence, when the cutaneous nerves are injured, the integuments of the forearm will seem to suffer pain.

It seems highly probable, that some symptoms, con-sequent to venesection, have been, in certain inlines, undeniably imputed to the irritation of a nerve arising from its partial division. As Mr. Abernethy has observed, it would be strange if a partial division of a nerve should not happen in the many operations which are daily performed, and the innervated wounds which are continually occurring; yet no particular symptoms usually ensue.

The practice of completing the division of the nerve, supposing to be partially cut, may therefore from a proceeding, for which the indication is extremely doubtful. The plan, however, has the recommendation of being attended with no particular risk; and, upon the whole, it may be as rational a thing as any which can be purposed, when the symptoms of irritation in the course of the injured nerve are illogical and well marked. A tranverse incision may be made above the orifice in the vein. This wound need not be extensive; for the injured nerve must lie within the limits of the original orifice, and there is no occasion for the cut to extend below the fagia, as all the filaments of the cutaneous nerves lie above this part. See Abernethy's Surgical Works, and Cooper's First Lines of the Practice of Surgery, edit. 3.

Some observations, connected with this subject, will be found in the article Tic Douloureux.

NERVUS, in Botany, the rib or nerve of a leaf. See Costa and Costatum.

NES, in Geography, a river of Denmark, in the island
of Zeeland, which runs into the Baltic; 4 miles S. of Neftved.

NES'A, a town of Persia, in Khurasan, on the borders of Kharaan, serving as a frontier between the two countries. In the year 1221 it was taken, by Jenghiz Khan, after a siege of fifteen days. The Mongols took it by storm, and the next day the inhabitants were drawn out into a plain, and shot with darts and arrows like wild beasts; frighteners, natives, and peacocks without distinction, to the amount of 70,000: 200 miles N. of Herat.

NESBIT, Thomas, in Biography, a Scotch antiquary, the son of the lord presbyterian Neftit, was born at Edinburgh in 1672. He was author of an excellent book on Heraldry, and a Vindication of Scotch Antiquities, which is said to be still in MS. in the advocate's library at Edinburgh. He died in 1725.

NESBIT's Harbour, in Geography, a harbour on the coast of New Britain, in North America, where, in 1753, the Moravians formed a settlement, but being either expelled or killed, a second attempt was made in 1761 under the protection of the British government, favoured by the Equinox, and succeeded.

NESCOPECK River, a river of America, which falls into the Susquehannah river, near the mouth of a creek of the same name, in Northumberland county, Pennsylvania, opposite to the town of Berwick; 160 miles N.W. of Philadelphia. N. lat. 41° 30'.—Alto, an Indian town which formerly stood near the site of Berwick.—Alfo, a mountain of Pennsylvania, near the Susquehannah river.

NESS, a provincial term commonly applied to such animals of the horse or cow kind as are tender or weakly.

NESIGODA, in Geography, a lake of Silefia, in the principality of Oels; 8 miles S. of Miitich.

NESIRBAD, a town of Persia, in Fariflan; 69 miles S.S.E. of Schiras.

NESLE, a town of France, in the department of the Somme, and chief place of a canton, in the district of Peronne; 10 miles S. of it. The place contains 1567, and the canton 8744 inhabitants, on a territory of 117½ kilometres, in 25 communes.

NESLOU, a small island in the Persian gulf; 180 miles W.S.W. ofOrmuz.

NESMIEL, a town of Hungary; 8 miles S.E. of Comorn.

NESPA, a town of Mexico, in the province of Mechucan; at the mouth of a river which runs into the Pacific ocean.

NESPERERA, a town of Spain, in Galicia; 12 miles N. of Tuy.

NESS, a town of Norway, in the diocese of Aggerhus; 36 miles N.N.W. of Christiania.

NESS, Lobe, a lake in the county of Inverness, Scotland, is a most beautiful expanse of water, twenty-two miles long, and from one to two miles and a half broad. Its depth, in the centre, is from fifty to one hundred and thirty fathoms, and even near its sides, excepting at the points of Torr and Foyers, the declivity is such, that a ship of the line might fail in safety within fifty yards of the shore, from end to end, on either side of the lake. Owing to this circumstance the Nefs never freezes, even in the severest winter; a truth which is strongly doubted by Dr. Johnson, though admitting of an explanation as any phenomenon connected with chemical science. Loch Nefi abounds with trout, and a few salmon are also sometimes found to have passed the crives in the river Nefs when the water is high; which in rainy weather takes place to the extent of ten feet perpendicular. This lake is frequently agitated with great violence by the winds; and on some occasions even without any apparent cause. An event of this fort occurred in a most extraordinary manner on the 8th of November 1755; the time of the great earthquake, which nearly destroyed Lisbon. The water rose with the utmost impetuosity from east to west, many of the waves being carried two hundred yards up the Oise, and breaking, on its banks, five feet above the level of the sea. It continued in this state for nearly an hour, when the commotion ceased, by a wave much larger than any that preceded it, overflowing the north shore of the lake. Loch Nefi communicates, by the river Nefs, with the Moray frith, and forms part of the chain of lakes and rivers from that arm of the North sea, to the found of Mull, on the western coast. As the lakes are all navigable, and rise very little above the level of the sea, a canal was lately projected on this line. It is denominated the Caledonian Canal, and is now nearly completed, under the scientific management of Mr. Telford; and as it is designed to admit frigates of 32 guns, there is reason to expect that the singular spectacle will soon be exhibited, of large vessels crossing the British island, from the Atlantic to the German ocean, surrounded by mountains which frequently tower to an enormous height. (See CANAL, Caledonian.) The scenery of this lake is grand and magnificent in the highest degree, as the hills are well covered with wood, and sometimes slope gradually from the shore, and at others rise with the utmost boldness and irregularity. The vale of Foyers, at its eastern extremity, is not inferior in romantic beauty to the celebrated Dovedale of Derbyshire. The river from which it derives its name forms two most beautiful falls, one of them seventy, and the other two hundred and twelve feet in height. The latter is consequently among the loftiest in the world, and, during floods, presents a view, at once grand and imposing. Pennant's Tour in Scotland. Beauties of Scotland, vol v. NESSA, or Nesserland, an island in the N. part of Dollart bay, on the coast of East Friesland, a little to the S.E. of Emden. N. lat. 53° 18'. E. long. 6° 59'. NERSELWANG, a town of Bavaria, in the bishopric of Augsburg; 45 miles S. of Augsburg.

NESSO, NEXUS. See Usus.

NESS, See Nede.

NESTES, in Geography, a small country of France, so called before the revolution, but now a part of the department of the Higher Pyrenees; its chief town was La Barthe.

NESTIER, a town of France, in the department of the Higher Pyrenees, and chief place of a canton, in the district of Bagneres; 4 miles E. of La Barthe. The place contains 503, and the canton 8767 inhabitants, on a territory of 170 kilometres, in 16 communes.

NESTINGS, a name given to Canary birds brought up by hand. See CANARY-BIRD.

NESTON, Great, in Geography, a small market-town in the hundred of Wirral and county palatine of Chester, England, is situated close upon the shore, on the south-western side of a peninsula formed by the curvatures of the Dee and Mersey. It is a place of very little importance, and chiefly supported by the number of perfumes who resort to it as a summer residence. The market day is Friday. The manor here was at an early period in the possession of the family of Montalt, and was bequeathed by Robert de Montalt to queen Isabel in the reign of Edward III. This piece afterwards granted it to William Montacute, earl of Salisbury, but reverting to the crown soon after, by attainer, it was given by Henry IV. to Sir John Stanley, ancestor to the earls of Derby, by one of whom it was sold to
to the Whitmores of Leighton, and from them passed, by
demine heirs, to the Savages and Moflins. The parish is
great extent, and contains the townships of Liddham,
Leyton, Litte Nefton, Nefs, Raby, Thornton, Mayow,
and Willnton, the whole comprising 625 houses, and 1090
inhabitants, as appears from the parliamentary returns of

NESTOR, in Biography, a distinguished Grecian chief
in the time of the Trojan war, was king of Pylos in the
Peloponnesus. He was one of the twelve sons of Neleus,
of whom all but himself were slain in the invasion of
the country by Hercules. Neftor was preferved from death
by his tender age, and by being educated among the
Grecians. He was very successful in battle, while young,
against the Eleans. He was placed by Hercules on the
throne of Pylos, and, as king of that country, and of Neftenia,
he led his subjects to the Trojan war, where he dis-
tinguished himself among the reft of the Grecian chiefs, by
elegance, address, wisdom, justice, and an uncommon pru-
dence in the administration of affairs. His character is re-
prefented by Homer as the most perfect of all his heroes,
and Agamemnon is made to exclaim, that if he had ten
fuch generals as Neftor he should foon fee the walls of Troy
reduced to utter ruin. He is repreffed, by the poets, as of
a great age at the fhe of Troy, and even as having lived three
ages, which has been thought to be about ninety
years. His wisdom, the reft of long expeience, is dis-
payed on several occasions in the councils of the Greeks,
and his honey-like eloquence is employed in conciliating the
diffentions between the leaders. The garrulity of old age,
joined to the qualities of a veteran ffaceman and warrior,
renders him a very natural and interesting perfonage in the
Iliad. After the Trojan war Neftor is supposed to have
returned to Greece, where he enjoyed in the bosom of his
family the peace and tranquillity which were due to his
wisdom and his old age. The manner and time of his
death are unknown: the ancients are all agreed that he
lived three generations of men, and from this circumftance
it was ufual among the Greeks and the Latins, when they
wished a long and happy life to their friends, to with that
they might fee the years of Neftor. He had two daughters
and seven fons, among the latter was Antilochus, a brave
warrior, who perifhed before the walls of Troy. Homer.

NESTOR, of LETOPIS NESTOROVA, a Latin historian,
born in the year 1056 at Bielezero, assumed the monаlithic
habit in the 19th year of his age, and took the name by
which he is known. When he entered the monaftery he
cultivated the Greek language with diligence, though he
is thought to have fladed it rather in the Byzantine his-
torians, than in the older claffes. He is fuppofed to have
died in 1113: the work by which he is chiefly known is a
"Chronicle," containing, after a few introductory account
of the early flate of the world, taken from the Byzantine
writers, a geograPhical defcription of Russia, and the ad-
joining countries; as account of the Scalian nations,
their emigrations, difpersion, and final settlement, and laftly,
a chronological feries of the Russian annals from 858 to
about 1113. This work lay in obscurity, till Peter the
Great ordered a transcript to be made of a copy of it,
found in the library of Konigberg. Professor Molker, in
1722, published a German translation of the first part,
which has been erroneously ascribed to one Theodosius. It
was published at Petersburg in the year 1767, and is va-
ned as the earliest monument of Russian history. The
style of this work is simple and unadorned, fuch as fuits a
mere recorder of facts, but his chronological exactitudes contributes to afferm the era and authenticity of the
events which he relates. We may add further, on the au-
thority of Mr. Coxe, that Neftor was followed firee-firely
by three annalists, the first was Sylvester, abbot of the con-
vent of St. Michael, at Kof, and bishop of Peridif, who
died in 1123; he commences his chronicle from 1115; two
years posterior to that of Neftor, and continues it to the
year 1123, from which period a monk, whose name has not
come down to us, carries the history to 1157, and another,
equally unknown, to 1204. With refpect to these perform-
ances, M. Muller informs us, that the labours of Neftor and
his three continuators have produced a connected feries of
the Russian history fo complete, that no nation can boast of
a fimilar treafure for fo long and unbroken a period. See
Coxe's Travels, vol. iii.

NESTOR, an excellent Roman musician, famous pantomimic,
and a great favourite of Caligula. When he was on the
flage, if any one interrupted him he was infantly scourged, even by the emperor himfelf.

NESTORIANS, in Ecclesiastical History, a feft of an-
cient Christians, flill faid to be fubilating in fome part of the
Levant; who diftinguifhing tenet is, that Mary is not the
mother of God. They take their name from Neftorius, a
Syrian, who, of a monk, became a prieft, and a celebrated
preacher; and was at length, after the death of Sifinnus in
428, raifed by Theodosius to the fee of Conflantinepo.

At firft he fweed a great deal of zeal againft hereby, in
his fennons before the emperor; but at length, taking the
liberty to fay, that he found in Scripture that Mary was the
mother of Jefus, but that he no where found that Mary was
the mother of God; his auditory was fchocked, and a great
part of them retired from his communion.

His writings were foon fpread through Syria, Egypt, and
Perfia, where he made many converts, notwithstanding the
vigorous opposition of St. Cyril.

But nothing tended fo much to propagate with rapidity
the doctrine of Neftorius, as its being received in the famous
school which had for a long time flourifhed at Edesia. For
the doctors of this celebrated academy not only inftructed
the youth in the Neftorian tenets, but translated from the
Greek into the Syriac language the books of Neftorus, of
his fetter Theodorus of Mopfueiis, and the writings also
of Diadorus of Tarfus, and fpread them abroad throughout
Asia and Persia.

One of the chief promoters of the Neftorian caufe was
Barfumas, created bishop of Nifbis A.D. 435: Such were
his zeal and fucces, that the Neftorians, who fll remain in
Chaldrea, Persia, Affyria, and the adjacent countries, confider
him alone as their parent and founder. By him, Pherozes,
the Persian monarch, was perfuaded to expel thofe Chrifti-
ans who adopted the opinions of the Greeks, and to ad-
mift the Neftorians in their place, putting them in position
of the principal feat of ecclefiaftical authority in Perfia,
the fee of Sceleucia, which the patriarch of the Neft-
orians has always filled even down to our time. Barfumas
also erected a school at Nifbis, from which proceeded thofe
Neftorian doctors, who, in the fifth and fourth centuries,
spread abroad their tenets through Egypt, Syria, Arabia,
India, Tartary, and China.

His capital tenet was, that there are two perfons in Jefus
Christ; and that the Virgin was not his mother, as God,
but only as man.

This doctrine was condemned in the council of Ephesus
fummoned by Theodosius the Younger, A.D. 431, at which
above two hundred bishops affifted, and Cyril prelided; and
Neftorius was anathematized, without being heard, and de-
posed from his fee.

Neftorius
Nestorius was not the author of this opinion, but borrowed it at Antioch, where he had studied; and though he was the sufferer and persecuted party from the beginning of the controversy to his death, the flame was first kindled by the presbyter Anastasius. Theodorus Moppeianus, whole discipline he was, had taught the same before him.

The abettors of this doctrine refute the title Nestorians; alleging, that it had been handed down from the earliest times of the Christian church.

In the tenth century the Nestorians in Chaldea, whence they are sometimes called Chaldæans, extended their spiritual conquest beyond Mount Imaus, and introduced the Christian religion into Tartary, properly so called, and especially into that country called Karit, and bordering on the northern part of China. The prince of that country, whom the Nestorians converted to the Christian faith, assumed, according to the vulgar tradition, the name of John, after his baptism, to which he added the surname of Prebyster, from a principle of modesty; whence it is said, his successors were each of them called Prebester John, until the time of Jenghis Khan. But Mosheim observes, that the famous Prebester John did not begin to reign in that part of Asia before the conclusion of the eleventh century. The Nestorians formed so considerable a body of Christians, that the millionaires of Rome were industrious in their endeavours to remove them under the papal yoke. Innocent IV. in 1246, and Nicholas IV. in 1278, used their utmost efforts for this purpose, but without success. Till the time of Pope Julius III., the Nestorians acknowledged but one patriarch who reigned first at Bagdat, and afterwards at Mosul; but a division arising among them, in 1551, the patriarchate became divided, at least for a time, and a new patriarchate was consecrated by that pope, whose successors fixed their residence in the city of Ormus, in the mountainous part of Persia, where they still continue distinguished by the name of Simeon; and so far down as the 17th century, these patriarchs perverted in their communion with the church of Rome, but seem at present to have withdrawn themselves from it. The great Nestorian pontiffs, who form the opposite party, and look with a hostile eye on this little patriarchate, have, since the year 1550, been distinguished by the general denomination of Elas, and reside constantly in the city of Mosul. Their spiritual dominion is very extensive, takes in a great part of Asia, and comprehends also within its circuit the Arabian Néstorians, and also the Christians of St. Thomas, who dwell along the coast of Malabar. It is observed, to the lasting honour of the Nestorians, that of all the Christian societies established in the East, they have been the most careful and successful in avoiding a multitude of superfluous opinions and practices that have infected the Greek and Latin churches.

About the middle of the 17th century the Romish missions gained over to their communion a small number of Néstorians, whom they formed into a congregation or church, the patriarchs or bishops of which reside in the city of Amida, or Diarbekir, and all assume the denomination of Joseph. Nevertheless, the Nestorians in general persevere, to our own times, in their refusal to enter into the communion of the Romish church, notwithstanding the earnest entreaties and alluring offers that have been made by the pope's legate to conquer their inflexible constancy. Mosheim.

Nestosia. L. in Geography, a town of Spain, in the province of Béf cet; 21 miles W.S.W. of Bilboa.

Nestved, a town of Denmark, in the island of Zealand, on the river Nes, near the coast. The river divides the town into two parts, called Great and Little Nestved, and by means of its discharge into the Baltic, furnishes the trade of the town. It has two parish churches; 22 miles E.S.E. of Copenhagen. N. lat. 55° 15'. E. long. 11° 51'.

Nesty, a town of Nepal; 18 miles N.N.E. of Nagcort.

Nesvar, a town of Hindostan, in Allahabad; nine miles W. of Gliazpour.

NET, in Fishng and Fowling, a contrivance by which to catch fish or fowl. See Fishing.

The taking of fowls by nets is the readiest and most advantageous of all others, where numbers are to be taken.

The making of the nets is very easy, and what every true sportsman ought to be able to do for himself. All the tools necessary to it are wooden needles, of which there should be several of different sizes, some round, and others flat; a pair of round-pointed flat scissors, and a wheel to wind off the thread. The packthread is to be of different strength and thickness, according to the sort of birds that are to be taken; and the general size of the meshes, if not for very small birds, is two inches from point to point.

The nets should be made neither too deep nor too long, for they are then difficult to manage; and they must be mended on each side with twilled thread. The natural colour of the thread is too bright and pale, and it therefore to be altered in many cafes, according to the occasion.

The most useful colour is the fafet; this is to be obtained by plunging the net, after it is made, into a tanner's pit, and letting it lie there till it be sufficiently tinged; this is of a double service to the net, preferring the thread very greatly, as well as altering the colour. The green colour is given by chopping some green wheat, and boiling it in water, then soaking the net in this green tincture till it have sufficient colour. The yellow colour is given in the same manner, with the decoction of celandine; this gives a pale and faint yellow colour, which is the colour of fustible in harvest time, and is just what is wanted. The brown nets are intended to be used on ploughed fields; the green on grass grounds, and the yellow on fustible lands.

Great care is necessary in the preferring of nets; and the principal thing to be considered in regard to this is, that all wet rots the threads; whenever they have been used in dew or rain, they must be hung up to dry in the sun; and if there is any rent or breach made, it must be mended as soon as it is discovered. In the drying, they must be hung as far as may be from the walls, that they may be out of the way of mice and rats, which are very apt to destroy them. The utmost depth that should be allowed to a net for fowl, is two fathom, and the utmost length eight fathoms.

The places for using fowling nets to most advantage are the morning and evening haunts, where the birds go to feed. The sportsman is to be at the place at least two hours before the time of their coming, and the nets must immediately be spread flat and even upon the ground, and the two ends fastened down with flakes. At the lower part there is to be a long cord fixed to the upper edge of the net, by means of which it may be immediately raised, and pulled over. The sportsman is to hide himself behind some natural or artificial shelter, at the extremity of this line, and some cut grass must be flayed all over the net, as it lies on the ground, to hide it from the fowl; and some live bird, that has been taken before, should be flaked down before the net, by way of a signal, to draw in the others.

As soon as a sufficient number of birds are within the compass of the net, it is to be pulled swiftly over them, and the fowler having taken those that are under it, may flake.
flake down two or three more live ones, and spread the net, covering it with grass as before. This fort of sport may be continued from as soon as it is light in the morning till an hour after sun-rise; but after that time, the birds have done feeding ravenously, and the sport is over for that day.

Net, Cinque-port, in Fifbery, a name given to a fort of square net, resembling a cage, and having five entrances into it, from whence it has the name. It is a very serviceable net in any pond or river, and is equally good in swift or standing water. In order to make this net, there must be provided four large and straight poles, answerable in length to the depth of the water. The ends of these must be sharpened in the manner of flakes, and there must be notches within a foot of the sharp part to fasten the net to; and at a convenient distance, on the poles, there must be another set of notches, for the fastening the other ends of the net.

The bottom of this net is four-square, without any entrance. A boat must be taken out with this net, to place it properly. The four poles must be fixed in the bottom in such a manner, that each may answer to the other in a direct line; and they must stand at such distances, that the net may be drawn out as stiff as possible between them. If the net is to be fixed in standing water, this method alone will do very well; but if it be a smooth stream, something more is necessary, otherwise the motion of the water will keep the net playing about, and this will frighten away the fish. To prevent this, four strong stakes are in this case to be fastened along the tops of the others, so as to make a fort of frame, to straighten and strengthen the others, and keep all tight.

When the net is perfectly fixed, it represents a cage, and the sides, top, and bottom are kept to form, that the fish do not regard them, but seem to take them for weeds; but going in at the entrances, there is no returning, and in rich places great numbers are taken.

Net, Clap. See Clap-Net, and Dobino. Net, Crow, in Birding, a name given to a fort of net contrived for the catching of wild fowl in the winter season. This net may be used in the day-time, and is to be made of double thread, or of fine packthread, and the meshes are to be two inches wide. The length of the whole should be about ten yards, and the depth about three; it should be, if possible, longer than the meshes. If the nets be very long, it must be opened, and spread at full length and breadth; then its lower end is to be fastened all along the whole length of the ground, so that it can only be moved up and down. The upper end of the net must stand extended on the long cord, the farther end of it being first flaked to the earth by a strong cord, above five yards distant from the net, and standing in an even line with the bottom of the net; the other end of the cord must reach at least five and twenty yards, to some natural or artificial shelter, by means of which the sportsman is to be concealed from his prey. The net must be placed in such exact order, that it will play upon the leaf jerk of the cord, and that must always be given sufficiently, lest the prey escape. This net is principally used for crows and pigeons, on new-fown corn-fields, and it may also be used in fluted-fields, where the flutes will hide the net from the fowl. If the meshes be made smaller, it may be used at barn-doors and the like for small birds, and a bait of chaff will bring them together inside. But the great use of the crow-net, is to spread it in mornings and evenings, where the haunts of wild fowl are, which in hard weather fly in great flocks to and from land, with and against the wind, and then fly close to the ground, in open country and low lands, where there are few hedges. When a whole covert of these are within the reach of the net, it is to be let go over them, and they will be taken in great numbers at one call.

Thus, wine is said to be neat, when not falsified or sophiticated; and coffee, rice, pepper, &c. are neat, when the fibre and impurities are separated from them.

A diamond is said to be neat, when it has no flaws or flaws; a crystal, when transparent throughout.

Net is also used for what remains after the tare has been taken out of the weight of any merchandise; i.e. when it is weighed clear of all package.

Thus we say, a hundred of cochineal weighs 450 pounds, the tare is 70 pounds, and there remains net 480 pounds.

Net-measure, in Buildings, is when no allowance is made for finishing; and in artificers' work, when no allowance is made for waste of materials.

Net-produce, a term used to express what any commodity has yielded, all tare and charges deducted.

The merchants sometimes use the Italian words netto procedure, for net produce.

Net---masonry. See Masonry.

NETE, in the Ancient Greek Music, the fourth string, or highest note of each tetrachord. When the third tetrachord was conjoined with the second, it was the symmenon, and its tene was called nete symmenon. The third tetrachord was called diezengemon, when it was suspended or separated from the second by the interval of a tone, and its tene was then called nete diezeugmenon. And lastly, the fourth tetrachord, called hyperbolen, its nete was always called nete hyperbolen. With respect to the two first tetrachords being both always conjunct, they had no name; the fourth string of the first being also the first of the second, it was called hypotome, and the fourth string of the second, constituting the middle of the fyllem, was called mofe.

NETHER, in Geography, a river of Scotland, which rises near Leithabow, in Lanarkshire, and runs into the Clyde, about 5 miles below Lanark.

NEITHER, river of France, which runs into the Dyke, 6 miles N.W. of Mahnes. A small river of the same name, with the epithet Leffer, unites with the other at Liere.

NEITHER STOWEE. See Stowey Neither.

NEITHER VERTE. See Vert.

NEITHERBY, in Geography, a village of Cumberland, in England, abounding in antiquities, and supposed to have been a Roman station; 12 miles N. of Carlisle.

NETHERLANDS, or SEVENTEEN PROVINCES, a country of Europe, bounded on the N. by the German sea, on the E. by East Friesland, the bishopric of Münster, county of Bentheim, duchy of Cleves, archbishopric of Cologne, and duchy of Juliers, on the S. by the bishopric of Liege and by France, and on the W. by the German sea and part of France. It extended from N. lat. 49° 25' to 53° 30', and from E. long. 2° 30' to 7° 20'. The Netherlands, in general, were anciently known by the name of Belgica Gallica, which fez; by the Spaniards they were called Pays-baxo, and by the French Pays-bas, by the Germans Niederlande, and by the English Netherlands, or Low Countries,
COUNTRIES, in reference to its situation with regard to High Germany. In the time of the Romans, who gained possession of this country with great difficulty, the inhabitants were Pagan, the original population consisting of Celts, who were supplants by the Belgæ; and it is not certain when Christianity was first introduced into this country; towards the end of the third century, the ecclesiastics sent hither by pope Marcellin made many converts, but during the latter end of the fifth century a bishopric was erected at Tournay, and as Christianity began to flourish, churches were built at Cambrai, Arras, Terouane, Meauxfricht, and other towns. In the year 638 St. Amand preached at Ghent, and in the latter end of the seventh century St. Wildebrod, with his companions, preached the gospel in Holland, Zealand, and Utrecht. In the beginning of this century the Vandals committed great enormities in the Netherlands; and in the year 451, Attila, king of the Huns, invaded the country with an army of 600,000 men, and burnt most of its towns. In 443, God AUDRAIN, Pope Gregory the Great, confirmed Tournay, and subdued the country as far as the Meuse. After the irruption of the Franks, this country formed Neustria, or the new kingdom. (The ancient kingdom of the Franks being on the E. of the Rhine,) partly belonging to the province of Flandria, and partly to that of Lotharingia, or Lower Lorraine. Soon after this period it was divided into provinces, forming as many different states, and the number of provinces has been generally reckoned seventeen, viz. the duchies of Brabant, Limburg, Luxemburg, and Gueldres; the marquisate of the empire of Antwerp; the comtés of Flanders, Artois, Hainault, Namur, Zutphen, Holland, and Zealand; and lordships of Malines, Utrecht, Overfkel, Friesland, and Groningen; to which is added Cambra; ho that, in fact, there would be eighteen; but Gueldersland and Zutphen being politically united to the Dutch states, they were called seventeen; and the United States were always called the Seven, although, according to the above statement, they are, in reality, eight. In the middle of the nineteenth century arose the powerful house of the house of Austria; and to the most of the territories, made mention about the same epoch. The dukes of Lower Lorraine and Brabant are little known till the end of the 10th century. These, together with other large inheritances, gradually fell under the power of the dukes of Burgundy, who, in the 15th century, enjoyed dominions worthy of the regal title. During these two last epochs, the Netherlands became the great mart of commerce in the west of Europe, and were distinguished by opulence and the arts. With the heires of Burgundy, the Netherlands passed by marriage to the house of Austria. When the seventeenth provinces were united into one body under Charles V., he ordered their union to be perpetual; and for this purpose he published, in November 1549, with the consent, and at the request of all the states of the provinces, an irrevocable edict or law, providing for the regular succession of the reigning prince. Philip of Austria and his son Charles, being natives of the Netherlands, treated the people with affection, and allowed to the states a kind of share in the supreme authority with themselves. But Philip II., son of Charles V., was born in Spain, and had neither the affection for the Netherlands, nor the generous sentiments which actuated his father's conduct; and therefore, instead of purifying the same mild and moderate measures, he had recourse to violent and cruel proceedings, of which the result was a general intestine. In order to restrain its progress, and the spreading of the reformation, Philip introduced into the country a kind of inquisition, which aggravated the evil, and terminated in a civil war. On this occasion the prince of Orange, retiring into Holland, was enabled, by the assistance of England and France, to preserve Holland and some of the adjacent provinces, which entered into a treaty for their mutual defence at Utrecht, in 1579; and these were afterwards styled the United Provinces; they were seven in number, viz, Holland, Zeeland, Friesland, Groningen, Overfkel, Gueldersland, united with Zutphen and Utrecht. The ten Catholic provinces were Flanders, Brabant, Artois, Hainault, Namur, Luxemburg, Limburg, Upper Gueldersland, the marquisate of Antwerp, and the county of Malines or Mechlin. Several of these were retained by the Spaniards, until the duke of Marlborough gained the victory of Ramillies; after which Bruxelles the capital, and the greater part of these provinces, acknowledged Charles VI., afterwards emperor, as their sovereign; but after his death they were wholly conquered by the French, except part of the province of Luxemburg, and afterwards restored by the peace of Aix-la-Chapelle in 1748; except a few that were retained by the French. Before the revolution in France, the greater part of the fore-mentioned Catholic provinces belonged to the house of Austria; the Dutch, however, occupied some districts of Flanders, Brabant, Upper Gueldersland, and Limburg; the French possessed Artois, with certain portions of Hainault, Namur, Luxemburg, and Flanders; and Upper Gueldersland belonged to the king of Prussia, the emperor, and the Dutch. In consequence of the revolution, Flanders, Austrian Brabant, Hainault, Upper Gueldersland, Limburg, Luxemburg, the bishopric of Liege Antwerp, the circle of the Lower Rhine, the duchy of Julliers, and the territory extending along the left bank of the Rhine, to the influx of the Meuse, were annexed to the French dominions by the treaty of Formio, A.D. 1797. The length of the Austrian Netherlands, computed from the eastern limit of Luxemburg to Olland on the ocean, is about 180 British miles; and about 120 in breadth, from the northern boundary of Austrian Brabant to the most southern limit of Hainault. The extent is computed at 7,520 square miles, with a population of 1,900,000. But if the French territory be extended to the Rhine, and thus to include large portions of the German circles of the Lower Rhine and Westphalia, the territory and population may be increased by at least one-third. The established religion in the Netherlands is the Roman Catholic; but Protestants and other sects are tolerated. According to the new ecclesiastical division of the conquered provinces, the metropolitan see is the archbishops of Mechlin; and the bishoprics aré those of Namur, Tournay, Aix-la-Chapelle, Treves, Gand or Ghent, Liege, and Mentz, all the bishops being appointed by the French emperor. Before the late revolution, the inhabitants were notorious for their bigotry. These provinces boast of early literature from after their conversion to Christianity in the seventh century; but in modern times they have rarely produced any writers of distinguished talents. The Flemish language, which partakes of the German and of the Dutch, remains uncultivated; and the chief authors have used the Latin or the French. Among their writers of any celebrity we may mention Procullar, Philip de Comines, and Lippins. In general the Southern Netherlands are more eminent for artists, and the United Provinces for literary characters. For an account of the engravers of the Flemish school, see Low Country. The most celebrated universities were those of Tournay or Dormack, which have been long subject to the French, those of Douay and St. Omer, much frequented by English Catholics, and that of Louvain, of still greater celebrity, founded

founded in 1425. The manners and customs of the Netherlands partake of those of their neighbours, the Dutch and French, the phlegm of one being tempered by the vivacity of the other. The lower classes have been fond of religious pageantry, and much addicted to the superstitious observances of the Catholic system. The three chief cities of what were called the Austrian Netherlands are, Brussells, Ghent, and Antwerp. The other principal towns are, Mans, Bruges, Namur, Luxemburg, Roermond, and Liiburg. The sea-coast of Flanders (which fee), the maritime province, consists chiefly of sandy hills and downs, and has few inlets, most of the rivers flowing into the Scheldt. The two ports that deserve particular notice are, the Sluys and Oflend; which fee. The Netherlands exceed every country in Europe, if we except the United Provinces, not only in the number, but in the great extent of its cities, towns, and villages. The chief edifices are cathedrals, churches, and monasteries. The canals of this country are very numerous, and some of them ancient. They intersect the provinces in all directions, such are those of Brusse1s, Ghent, Antwerp, Ofland, &c.; but of late years they have been much neglected. The manufactures and commerce of the Netherlands, which were formerly superior to any in the west of Europe, have much declined, partly because other powers entered into competition, and partly because freedom was established in the United Provinces, so that Amsterdam arose upon the ruins of Antwerp. The little commerce that is left is chiefly inland to Germany. The East India company of Ofland was suppressed by the jealousy of England and other powers; and the chief commerce was afterwards carried on by the English established in that city. Some few fragments of the manufactures still remain. Cambrai is renowned for its cambries, and Tournay or Dornick was anciently famous for the finest linens. At Bruges there are still some manufactures of broad fays, baize, and other woollens; considerable fabrics of broad cloth, druggets, halloons, and flockings, were conducted at St. Omers, chiefly with wool smuggled from England. The principal manufactures of tapestry, fine linens, and laces, are at Mechlin, Brusse1s, Ghent, Antwerp, and Louvain; and these still enrich the country, and induce the farmers to cultivate flax, even on the poorest soils. For home consumption, the Netherlands produce abundance of corn and vegetables, and the coal mines, if they were properly conducted, would be important. Tarf for fuel is plentiful, as are also iron, porcelain, clay, and various other commodities.

The climate resembles that of the south of England, and is more moist than warm; nevertheless Luxemburg produces some wine, resembling Rhenish in quality, but destitute of its spirit. The face of the country is generally level; the soil is a rich sandy loam, interspersed occasionally with fields of clay, but more frequently with large intervals of sand. The Netherlands, by the prevalence and boasted excellence of its agriculture, have been long deemed the garden of Europe. The repeated crops of excellent clover, cole, turnips, and clean crops of flax, barley, and oats have attracted the attention of accurate observers; and, indeed, the agriculture of this country has been celebrated for 600 years, ever since their commerce and manufactures became eminent; and it is remarked, that they still possess the essentials of good husbandry in the destruction of weeds, and perpetual crops. Hay, a native and peculiar product, adopted in England in the reign of Henry VIII., is abundant. The Netherlanders never allow an opportunity to be lost of their being poured into the ear as a remedy for deafness; these compositions, by their attenuating qualities, dividing the viscous and thick humours.

The word netopion is also sometimes used to express the

unguentum

E. the Dermer, the Nette, or Nethe, from the N., and the Senne from the S. The Netherlands, although they have no elevations that deserve the name of mountains, have several woods and forests of considerable extent. The plants that are natives of this country may be found in the sandy and marshy districts of the S.E. coast of England, except the Genoviana cruciata. The breed of horses and cattle in this country is esteemed for its size. In various provinces are minerals of different kinds, flate, marble, and alabaster.

Since the union of the Anfirian Netherlands with France, which has extinguished this appellation, or exchanged it for that of the Re-united Country, they have been divided into departments, subjected to the government established in that kingdom. Its condition seems to have been little, if at all, amended by exchanging the opprobrium of the nobles and clergy under its ancient regime for that of French despotism.

NETHE, Two, deriving its appellation from the rivers above-mentioned, one of the thirteen departments of the region of France, called the Re-united Country, formed of the north part of Brabant, 19 French leagues in length, and 13 in breadth, containing 2645 kilometres, or 143 square leagues, 249,376 inhabitants, on the right hand of the Scheldt, in N. lat. 51° 15'. It is divided into 3 districts or circuits, 21 cantons, and 144 communes. According to Haffenrath, it comprehends 1 circuit, 23 cantons, and 153,981 inhabitants. The three circles are Anvers or Antwerp, including 114,507, Turnhout 62,172, and Malines 72,697 inhabitants. Its contributions in the 11th year of the new French era, were 2,667,815 fr., and its annual income 268,236 fr. 53 cents. Its capital is Antwerp. The soil is sandy, and indifferently fertile.

NETHINMS, among the Jews, the politerity of the Gibeonites, who were condemned by Joshua to be hewers of wood and drawers of water for the house of God.

The Nethinims are mentioned 1 Ch. ix. 2. Ezr. ii. 58. Neh. vii. 60. and Ezr. vii. 20. Ezra, in this latter passage, informs us, that they were given by David to the Levites, which is the original of their name; as the Levites were given by God to help the priests; and, therefore, in all places they are mentioned with holy persons. Some have called these persons inferior clergy; but they seem rather to have been servants to them. However mean their original, or low and laborious their employment may have been, the people of Israel were indebted to them for their zeal for the house of God. Many of them readily returned from Babylon to Judea, and performed their part for upholding the worship of God at his temple.

NETHY, in Geography, a river of Scotland, which rises in Inverness-shire, and runs into the Spey, 3 miles S.E. of Grantown.

NETIERS, a town of Bohemia, in the circle of Schlan; 11 miles N.E. of Schlan.

NETO, a river of Naples, which runs into the sea, 7 miles N.N.W. of Cortona.

NETOIDES, acute sounds in the Greek music. See LEPIS.

NETOPTON. NETTOR, a name given by the ancients to a very fragrant and costly ointment, consisting of a great number of the finest spagyric ingredients. Hippocrates, in his Treatise of the Difficulties of Women, frequently prescribes the net pion in discharges of the uterus; and in other places he gives directions to be followed in the case of discharges; these compositions, by their attenuating qualities, dividing the viscous and thick humours.
NETSBUCKTOKE, or Sandwich Bay, in Geography, a bay on the east coast of Labrador. N. lat. 53° 45'. W. long. 57° 30'.

NETSCHIN. a town of Bohemia, in the circle of Pillen; 9 miles S. E. of Teufing.

NETSCHIN, GASPARD, in Biography, one of the most able artists of the Flemish school, was born at Heidelberg. His family afterwards migrating to Ansbach, he was there adopted by a physician, named Pulleken, who placed him first with one Koffee, a painter of dead game; and then with a better master, Gueric Terburgh, who was well qualified to lead the promising talents of Netcher into action.

The subjects he chose, when those talents were matured, were generally of that class called conversation pieces, with figures selected from among the best ranks of his countrymen. Thence, while he touched and finished them with great neatness, he treated with a breadth unknown till then among the Flemish painters. He finished all the parts of his pictures with great perfection, and the most characteristic imitation of nature. The rich silk and satin dresses of his figures, the gold and silver utensils, carpets, &c. &c. with which he introduced in his compositions, are exquisitely wrought, and with uncommon brilliancy and luster. He painted many portraits of a small size, but they exhibit much of the restraint which belongs to portrait painting, and which always prevents the most powerful exertion of an artist's talents; at least, the best effect which those talents are capable of producing.

King Charles II. invited him to London, but was not able to prevail upon him to quit his native country, and the satisfactory enjoyment of labouring in it both honourably and profitably. Although he died at the early age of 45, yet his pictures are not very scarce, but are to be found in most collections of consequence in this country, and throughout Europe.

His principal residence was at the Hague.

NETSCHER, THOMAS, was the son of Gaspard, who taught him the art of painting from his earliest years; so that at the age of nine he was accounted a very extraordinary performer; and when he had attained his eighteenth year, he was solicited by count D'Arvauz to go to Paris, where he was greatly admired and encouraged.

His principal occupation there, where he continued for twenty years, was painting the portraits of the principal personages about the court, which he did with great success, and for which he was highly applauded and handsomely rewarded; but the taille they were executed with is by no means of the highest class. He made the most of the lace cravats and ruffles, the rich velvet robes embroidered with devices, &c., then in use, and relieved them from backgrounds full of bubble. But the principal office of portraiture was lost in this mass of tinsel and flutter; the minds of his subjects seem never to have engaged his thoughts, or are, by accident rather than design, brought forth in a few instances; whilst the idle affectation of flage self-importance reigns predominant in them: as if a nobleman could not have the air of a great man, without (to use a common expression) at the same time "looking big."

He died in 1732, at the age of 71.

NETSCHEP, CONSTANTINE, another son of Gaspard, who was born at the Hague in 1670. He also practised the art of painting under the tuition of his father, but was so unfortunate as to lose that advantage at the early age of fourteen. He nevertheless endeavoured to compensate himself for that loss, by the careful study of his father's works; and though he never was able to equal them, yet he arrived at no mean degree of skill in his profession.

His principal practice was in portraiture, in which he was much encouraged; but being of an infirm habit of constitution, he was much interrupted in his labours, and died at the age of 52.

NETSCHKAU, in Geography, a town of Saxony, in the Vogtland, situated on the Golitz; 12 miles S.W. of Zwickau.

NETTANGER, a town of Sweden, in Helingsland; 6 miles S. of Hudwikfaw.

NETTE, a town of Westphalia, in the bishopric of Osnabruck; 4 miles N.E. of Osnabruck.

NETTER, THOMAS, in Biography, a learned English Carmelite monk, who flourished in the 14th and 15th centuries, was named Walden, probably from the place of his birth, which is supposed to have been Saffron-Walden. He embraced the religious life in a monastery at London, and was afterwards sent to the university of Oxford. Here he pursued his studies with great success, and became public professed, at first of philosophy, and then of divinity. In the last named faculty he obtained the degree of doctor. He zealously contended the opinions of Wickhifl, both in the schools and the pulpit, and was chosen provincial of his order; and by the command of Henry IV. attended, in 1499, the council of Pavia. By Henry V. he was appointed privy councilor, and confessor, and sent to the council of Constance, where he distinguished himself by his speeches against the reformers of that period, the followers of Wickhif and John Hus. He likewise enjoyed the favour of Henry VI., and went to France with the intention of being present at the coronation at Paris; but he died, as he was on his journey, at Rouen, in the year 1450. He was author of Commentaries on many parts of the Scriptures; also of a work, entitled "Discinale Antiquitatum Fidei Ecclefsiae Catholicae," which was published after his death, in 1571, in three volumes folio, and many other works. Morei.

NETTLES, in a Ship, are a fort of grates made with small raper, and feized together with rope-yarn, and are laid in the walle of a ship, sometimes, to serve instead of gratings.

Netting-Sail, in a Ship. See Sail.

NETTLE, the common name of a well-known perennial weed, which may be easily destroyed by cutting the roots, before the plant has perfect its feed.

Nettle, in Botany, &c. See Urtica.

The roots of the common nettle, or urtica dioica, have been much recommended in medicine as powerful diuretics; and great virtues have been ascribed to them in calculous complaints, fevery, gout, jaundice, &c.; and also as hyperuric acid in hemorrhages of all kinds, particularly in spittings of blood, and overflows of the meninges. Authors add to this, that they are specified, by way of antidote, against the poison of henbane and hemlock; but this we are not so well assured of. The account that has been given of its medicinal virtues have now little credit; and the nettle is considered merely as a simple oleaceous plant, and, when young, it is found to be a good substitute for greens, or other pot-herbs. The young shoots of the plant are eaten in the spring, as good against seborrheic complaints.

The sharp hairs upon the fresh leaves of nettles readily enter the skin, and thus produce considerable irritation and inflammation, and therefore have been employed as a rubefacient,
Nettle. See Galeopsis.

Nettle, Sea, in Zoology. See Medusa, Azonia, Animal Flower, and Urtica Marina.

Nettle-Raft, in Medicine, an eruptive disorder, which has been so named, in consequence of the resemblance of the rath to the appearance produced by the flinging of nettles on the skin.

Although this eruption appears to have been well known to medical practitioners from the time of the Arabsians, by whom it was described under the appellation of fara, or offera; yet it is commonly supposed to have been unknown to the Greek and Roman physicians, as well as the contagious eruptive fevers. We have stated, when treating of the history of Measles, that this supposition is probably erroneous; and a perusal of the chapter of Aztins, borrowed from the physician Herodotus, which treats of the eruptions that occur in fevers, leaves no doubt that the nettle-raft, among others, was familiar to the writer. (See Aét. Tetrabb. i. ferm. i. cap. 129.) Subsequent authors, in describing this eruption, have borrowed the Arabian appellation of offera, (see Sennert. Practica, lib. v. i. cap. 27. Heberden Comment. de Morb., and Medical Tran. vol. ii. art. xii.), or have confounded it with erysipelas, (Sydenham, sect. v. cap. 6. De Febri Erysipelo-todia,) with purpura, (Juncker Consect. Med.), or scarlatina. The nofologifits (Vogel and Cullen) have adopted the appellation of urtica, from urtica, a nettle, by which the disorder is now commonly designated. See Frank, de Cerrand. Homin. Morbis, tom. ii. Willan on Cutaneous Difeaes, ord. iii.

The urtica, or nettle-raft, is characterized by the appearance of round, oval, or longitudinal elevations of the cuticle, which are commonly called wheals. These are not very hard, nor permanent, and have no tendency to suppuration; they are usually white at the top, and are often surrounded by a diffuse redness. Although it is in many cases accompanied by fever, the nettle-raft is never contagious. It occurs under several varieties of form, to which Dr. Willan has given distinct specific appellations.

1. The febrile nettle-raft is always attended with considerate disorder of the conftitution. The eruption is preceded for a couple of days by pain and sickfness at the stom-ach, headache, languor, and drowsines, with a quick pulse and white furfed tongue, and by fits of shivering; and when it appears, it is accompanied by a moft troubleome itching or tingling, which is greatly aggravated during the night, so as to prevent sleep for many hours. The eruption occurs on molt parts of the body, but molt copiously on the shoulders, loins, nares, thighs, and about the knees; sometimes, however, extending to the face. The wheals arife irregularly, first on one part and then on another; and they may be excited on any part of the skin, by ftrong frriction or scratching. During the day, the effrowence fades, and the wheals in general subside, but both of them return with a febrile paroxism in the evening. The patches of effrowence often coalesce, so as to produce a confluent rednes; and they are often elevated above the level of the adjoining cuticle, and form dent tumours, with a hard diftinét border. When they are numerous, the face; or the limb chiefly affected, appears tenfe and considerably enlarged. At the latter end of the disorder, the eye-lids are red and tumefied, and there is often a swelling and inflammation on the fides of the feet. On the appearance of the eruption, the pain and sickfness at the stom-ach are generally relieved; but when it disappears, those symptoms return. The whole duration of the febrile nettle-raft is seven or eight days. As the
NETTLE-RASH.

The eruption declines, the tongue becomes clean, the pulse returns to its usual state, and all internal disorders cease: the efflorescence exhibits a light purple or pink colour, and then gradually disappears, being succeeded by slight exfoliations of the cuticle.

This species of nettle-rash, though not in general dangerous, is extremely troublesome from the violent heat of the skin, and the itching and restless fomes with which it is usually attended. It is on some occasions very alarming, especially when the ficksnes and languor, at the beginning of the eruption, bring on repeated fits of fainting. It occurs chiefly in summer, and affects persons of a weak or fanguine habit, especially those who indulge themselves in eating and drinking too freely. It affects even infants, however, under a year old, in confinement of the irritation of teething and of bowel complaints, and renders them hot, fretful, and restless. It is not uncommon, indeed, during the whole period of childhood; and among adults, appears to affect men more frequently than women.

The principal treatment required in the febile nettle-rash is the administration of a laxative, as of rhubarb and magnesia, in the beginning, which may be repeated according to circumstances; and the restriction of the patient to a light and cooling diet, during the continuance of the fever. He should abstain especially from vinous and fermented liquors: he should avoid hot rooms, and all the expedients, both external and internal, which tend to augment the cutaneous circulation, and produce sweating. Sudoeric medicines should be particularly avoided. In the decline of the disease, Peruvian bark, with sulphuric acid, may be taken with great advantage.

2. The urticaia evanida, or tranitory nettle-rash, of Dr. Willan’s classification, is without fever, and without any extensive efflorescence on the skin. The eruption consists sometimes of round wheals, at other times of longitudinal elevations of the skin, resembling those which are produced by the stroke of a whip. They are all white at the top, but in some there is a slight redness at the base. Though often hard and elevated, they do not contain a fluid, nor tend to suppuration. They are occasionally seen on every part of the body, but they are most numerous on parts which are closely covered. The eruption appears and disappears many times in the course of a day and night, according to the temperature of the air, or to the exercise used by the person affected. It may be excited on any part of the body, by strong friction or scratching; but the wheals presently subside again. A violent itching, mixed with a sensation of tingling or flinging, attends the eruption; and these sensations are most troublesome while the patients undress, and for some time after they have lain down in bed, when the eruption is usually most vivid.

This species of nettle-rash continues for various periods, with repeated eruptions, that are more or less extensive in different persons: in some, as Dr. Heberden observes, it lasts but a few days; while in others it goes on for many months, or even for years. It occurs most frequently in persons of the fanguine temperament, especially in those who have a delicate stomach and irritable bowels, and in females more frequently than males. The occasional causes are heat, fatigue, watching, anxiety of mind, and a too stimulant diet. It is remarked by Dr. Willan, that although persons affected with the urticaia evanida may be capable of business and occasional exertion; yet they are often low-spirited, and they seldom remain for twenty-four hours without some bodily uneasiness, as head-ache, languor, pain and ficksnes at the stomach, aching in the limbs, or an oppressive languor.

This form of urticaia is thought to consist in a morbid irritability of the skin, connected with a similar state of the stomach and intestines. It seems attached to particular constitutions, being produced in some individuals by fubstances which make no impression on others. Thus rubbing oatmeal on the hands and wrists has excited the nettle-rash in persons otherwise healthy, which became diffused over the whole body, and proved troublesome for a length of time. The same effect has been produced by a flight application of mercurial ointment. Dr. Winterbottom informed Dr. Willan, that a lady of his acquaintance was affected with an eruption of this kind, whenever her skin is touched with the common wall-flower. And Dr. Heberden has mentioned several fubstances, which produce this disorder through the medium of the stomach; as the wild valerian root, shrumps, honey, and the kernels of fruits. He thinks that it may often be owing to external or mechanical causes, such as the hair of flinging nettles, the down surrounding the pods of cowage, and the epiderm of cantharides. The following observations of Dr. Willan are of great practical importance.

“When the disease continues long,” he says, “without the application of external stimuli, we shall in many cases find it owing to some article in diet, which disturbs digestion. I have deservd several persons affected with chronic urticaia to omit first one and then another accustomed article of food or drink, and have thus frequently been able to trace the cause of the symptoms. This appeared to be very different in different persons. In some it was milt liquor, in others spirit, or spirit and water; in some white wine, in others vinegar; in some fruit, in others fugar; in some fih, in others unprepared vegetables. I must however confess,” he adds, “that several cases have occurred to me, where a total alteration of the diet did not produce the least alleviation of the complaint. In such cases I have employed a variety of medicines, but have found the vortisic and marine acids, with magnesia, rhubarb, or other laxatives, given occasionally, the most successful remedies. Lotions made with brandy, vinegar, saline compounds, &c. cannot be applied extensively enough to produce any considerable effect. Baths, especially warm baths, are necessary for the alleviation of a disease which affects nearly the whole skin. Sea-bathing will be generally found advantageous by those who persevere in the use of it for three or four succesfive months. A bath prepared by dissolving marine salt in water, is not equally efficacious; in some persons it manifestly aggravates the disorder.”

3. In the third species of Dr. Willan, urticaia perfura, the wheals are stationery, and the redness, which at first surrounds them, gradually disappears: but the eruption is still attended with itching, especially when the patient becomes warm in bed or is heated by exercise. It does not, however, extend over the body, but appears chiefly on the arms, breast, and thighs. Pain and ficksnes at the stomach sometimes precede the eruption. Its duration is two or three weeks, and when it is about to terminate the wheals become flat at the top, and then gradually subside, leaving a reddish spot, which is sometimes purdy, and which continues for several days.

This complaint is relieved by the method of treatment recommended in the foregoing species. Moderate doses of the caustic potash, or liquor potash, seems, in some cases, to shorten the period of the eruption.

4. In the fourth species, urticaia conferta, the eruption is full and extensively diffused; and, as the wheals in many places coalesce, or are indented by close contact, they have very irregular forms: when they are singly considered, however,
ever, the size and elevation of them is perhaps less than in any other species of nettle-raft. They are sometimes considerably inflamed at the base, and produce an almost incessant itching and pricking sensation. The eruption often continues many weeks; it appears chiefly in persons who have a dry and fleshy skin, and who are above forty years of age; and is sometimes connected with pain and sickness at the stomach, and sometimes with giddiness and headache. The occasional causes seem to be, too much exercise, exposure to heat, rich or high-feated food, and the inconsiderate use of spirituous liquors; and the cure of the complaint is not easily accomplished, without relinquishing these articles of diet, and abating other causes that are light and cooling. Together with this plan of diet, the use of medicines or tonics is often useful.

5. The subcutaneous nettle-raft occurs at distant intervals, and continues only a few days at each return; but the patient is continually harassed, whether the eruption be present or not, with a violent and almost constant tingling in the skin, with other distressing symptoms. The complaint is at first confined to one spot on the leg or arm, and commences there with a sensation of flitting, which is afterwards felt more and more extensively, along the limb, or perhaps over nearly the whole surface of the body. Sudden changes in the temperature of the air, and agitation of mind, occasion increased uneasiness in the skin, so that pains are sometimes felt, as from a sharp instrument penetrating in different directions, at other times as from needles piercing or pricking the skin upwards. There is usually a stiffness and slight torpor in the muscles of the parts most affected. An appearance of wheels takes place on the arms, chest, or lower extremities, from time to time, especially during the summer, and continues two or three days, but without affecting any change in the sensations above mentioned. Persons affected with these symptoms are liable to frequent pains in the stomach, and to cramps in the muscles of the legs; and usually have a dry and unperifring skin. The complaint is most commonly partial; but is usually tedious and obstinate. It may be relieved, however, by gentle friction and by the repeated use of warm sea-water baths.

6. The only remaining variety is the tuberous nettle-raft, so called by Dr. Frank of Vienna, in which many of the wheels increase to a large size, forming hard tuberous lumps, which seem to extend deeply into the muscular flesh, and occasion a contraction in the fingers, with total inability of motion, and a sensation of pain in the bones. These tumours are usually whitish at their tops; they rise on the arms, thighs, loins, and calf of the leg, and are very hot and painful for several hours. The eruption commonly takes place at night and disappears by the morning, leaving the patient weak, languid, and, as if he had been bruised, or had undergone much fatigue.

This form of nettle-raft is often, like the preceding, tedious and obdurate, and seems to originate from similar causes, and to require similar treatment.

Some persons suffer from a peculiar idiosyncrasy in respect to particular articles of food, inasmuch that a sudden and universal affection of the skin, very nearly allied to the nettle-raft, is produced immediately or within a short time after these articles are swallowed. The most common sources of the affection are shell-fish, as crabs, lobsters, and especially mussels; but in some confections almonds, whether bitter or sweet, the kernels of prune-fruit, rafberries, strawberries, mushrooms, herings, oatmeal, and various other substances produce the same eruption. In these cases the loth of mucus is commonly first affected with pain, a scurf of irritability, and afterwards with sickness and vomiting; diarrhoea also often comes on. Great heat and swelling suddenly take place, commonly about the face and ears, with much itching, and afterwards extend rapidly to other parts of the body, the whole skin becoming tumid, hot, and itchy.

In the course of twenty-four hours or less, these symptoms gradually disappear, and the patient returns to his usual health. For more ample accounts of this singular symptomat cal rash, the reader may refer to Dr. Buchen's dissertation, De Affectione á Mytilorum Efo, annexed to Dr. Werhof's treatise, De Variois et Anthracibus, and to two papers in the Memoirs of the Academy of Brufells, tom. i. p. 243, and tom. ii.

It is affected, in both these dissertations, that vinegar or lemon juice, taken internally and applied externally, soon relieves the persons affected by eating mussels; and the author of the latter, M. du Rondeau, affirms, from experience, that, if the mussels be previously dressed with vinegar, they may be eaten with impunity.

NETTLED. in Geography, a village of England, in Oxfordshire, 18 miles E. of Oxfordshire, and 40 W. of London, remarkable for the elevation of the land on which it is situated.

NETTOLITZ, a town of Bohemia, in the circle of Prachaltz; 6 miles E. of Prachaltz. N. lat. 49° 3'. E. long. 14° 4'.

NETTUNO, a town of Campagna di Roma, on a bay of the Mediterranean, near the ruins of the ancient Antium; 12 miles S.W. of Veletri. N. lat. 41° 31'. E. long. 12° 35'.

NETWORSITZ, a town of Bohemia, in the circle of Beran; 18 miles S.E. of Beran.

NEVA, a river of Russia, which flows from the lake of Ladoga, where it takes its rise, across the government of St. Petersburg for 60 versts in length, and falls in several arms into the Gulf of Cronstadt. It reaches the city under the walls of the Newt mailbox, after having just above it admitted the waters of the rivulet Ohta. The several mouths of the Neva are all within the city, and are called the Neva, the Great Neva, and the Little Neva, which are, from 60 to 100 fathoms broad. The Little Neva goes off from the main river on the right side under the walls of the fortresses and flows W.N.W. to the gulf. It is broader than the Great Neva, but more shallow, and purposely rendered unnavigable by Peter the Great, on account of Sweden and the culls. The Great Neva, having distributed its waters, flows in a S.W. direction, from 150 to upwards of 200 fathoms in breadth, and in some places of great depth, into the Cronstadt gulf. This river and its banks have undergone very great improvements. In the quay, at certain distances, openings are made for defending upon the ice in winter, and slants with spacious landing places and benches, for taking up water, unloading the barks, and the repose and convenience of those who walk here for business or pleasure. Moreover, the face of the wall is furnished with many iron rings for the fastening of gallions, barks, barges, and other vessels. This truly imperial quay, says Mr. Tooke, is, for its length, which, deducting the space before the Admiralty, is 1650 fathoms or 3 versts, for strength, magnificence, and the cost of building it, unequalled in Europe, and the conflagrant subject of admiration to foreigners.

The water of the Neva, and of its several arms and running canals, which, besides the Ligova channel, supplies the whole city, is to be ranked with the lightest, clearest, and purest of river waters; and it thus amply compensates the want of wells and springs in the city. Occasionally, however, it overflows its banks. Some thousands of ships and barges annually pass and repass the Neva, coming from the inland
inland parts of the empire, or from foreign countries across the seas, and bringing commodities and provisions to the amount of several millions of roubles, to St. Petersburg. This river receives in its course the Ijora and the Tofa.

NEVALCOTTY, a town of Thibet; 18 miles W. of Sirinagur.

NEWBENDAM, a town of Persis, in Segeitan; 80 miles N. of Zarong.

NEWBENDAM, a town of Persis, in Chufitian; 60 miles N.W. of Schiras.

NEWBERG, a town of the duchy of Stiria; 20 miles N.E. of Pruck.—Also, a town of the duchy of Carniola; 4 miles N. of Crainburg.

NEUBOURG, a town of France, in the department of the Eure, and chief place of a canton, in the district of Louriers. The place contains 1980, and the canton 14,207 inhabitants, on a territory of 1872½ kilometres, in 26 communes.

NEUBRUN, a town of the duchy of Wurzburg; 4 miles N. of Eilman.—Also, a town of Germany, in the county of Henneberg; 5 miles S.E. of Meiningen.

NEUBURG, a town of Bavaria, in the Upper Palatinate, on the Schwarzw.; 19 miles S.E. of Amberg. N. lat. 40° 15'. E. long. 12° 12'.—Also, a city of Bavaria, and capital of a duchy of the same name. The principalties of Neuburg and Sulzbach, formerly separate, are now united. Neuburg enjoys a government of its own; and the prevailing religion is the Roman Catholic. The capital, which is the seat of government, is well situated on a hill by the Danube, and fortified, having in it a palace; 23 miles N.N.E. of Augsburg. N. lat. 48° 40'. E. long. 11° 38'.—Also, a town of Bavaria, in the county of Feldkirch, on the right bank of the Rhine; 5 miles N.W. of Feldkirch.—Also, a town of Baden, called "Neuenburg," seated on the Rhine, formerly imperial, but much injured by war; 16 miles N. of Bale. N. lat. 47° 49'. E. long. 7° 38'.—Also, a town of Prussia, in Pommeria, on the Ribula; 32 miles S. of Danzig.—Also, a town of Bavaria, on the left side of the Inn; 4 miles S. of Pfaffi.

NEUCHATEL, or NEUCHATEL, County of, a principality of Switzerland, in alliance with the Helvetic confederacy before the French revolution, is bounded on the N.W. by France, on the N.E. by the bishopric of Bale and canton of Berne, on the S.E. by the lake of Neuchatel, and on the S. by the bailiwick of Granon. This principality, long 290, united to the lordship of Vallengin, stretches from the lake to the limits of Franche Comté, and contains in length from north to south about twelve leagues, and about six in its greatest breadth. The district of Neuchatel occupies the whole plain, together with the lower parts of the mountains, while Vallengin is totally enclosed within the Jura. Parallel chains of the Jura run from E. to W., and form, even in the most elevated parts, several valleys. The lower grounds of this chain are arable lands and vineyards; the higher consist of large tracts of forest, in which many parts have been cleared and converted into considerable pastures, intermixed with some fields of barley and oats. The number of inhabitants in the principality of Neuchatel and Vallengin, in 1782, only 28,017 subjects, and 4218 aliens, amounted in 1784, to 31,376 subjects, and 5704 aliens, which gives an increase of near a fourth part within the space of thirty-two years. In the whole principality are four towns, and sixty-four villages. For an account of the general employment of the inhabitants, we refer to the articles CHAUX DE FOND, respecting the reader to Sublime des Sol, and LOCLE. The productions of the principality are wine, both red and white, fruits, corn, hemp, and flax. Most of the inhabitants are Protestants; but in two districts, viz. Lauteron and Courteix, Papists prevail. This country anciently belonged to the last kingdom of Burgundy, with which, in 1533, it devolved to the German empire. In process of time it passed to the house of Chalons, and in 1694 William III. of Great Britain, as heir of that family, transferred to Frederick, elector of Brandenburg, afterwards king of Prussia, his interest in Neuchatel and Vallengin. Several claimants afterwards urged their pretensions to it, and the tribunal of the three colleges of Neuchatel having examined their allegations, decreed, in 1707, in favour of Frederick I., king of Prussia. This sovereign, upon his accession, signed and ratified certain articles, which seemed to establish the prerogative of the prince, and the liberties of the subject; to these others were added in 1768, which terminated the dispute between the sovereign and subject. The prince conferred nobility, nominates to the principal offices of state, both civil and military, and appoints the chancellors and mayors, who preside in the courts of justice. His revenues, scarcely amounting to 2500,250, arise from certain demesnes, a small land-tax, the tributes of wine and corn, and the tenth of the value on the sale of immovables. As to commerce, no subject whatever pays any duties, either of importation or exportation, except for foreign wines imported into the town of Neuchatel. The three colleges, according to the ancient constitution, composed of twelve judges, formed the superior tribunal, and received appeals from the inferior courts of justice. The principality of Neuchatel and Vallengin is divided into a certain number of districts, each of which has its criminal court of justice. But it is needless to enlarge upon the constitution and government of this principality, as it was ceded in 1866 by the king of Prussia to marshal Berthier, one of the generals of France, and the grant confirmed by the emperor Napoleon.

NEUCHATEL, NEU-CHATEL, or NEUZEBURG, anciently Ne- comun or Novum Cajふrum, a small town of Switzerland, capital of the principality above described, lies partly upon a little plain between the lake which here receives the river Sejen, and the Jura, and partly upon the declivity of that mountain, consisting of four principal streets, which contain some elegant edifices, and a castle for its defence, in which the governor resides, and about 3500 inhabitants. The environs are diversified with delightful vineyards, gardens and villas. Between Neuchatel and Yverdon, the country consists of rude or elegant scenery, controllable with well cultivated hills, vineyards, and meadows. At the commencement of the last century, commerce was almost wholly unknown in this town, as the ridiculous pride of its being deemed degrading generally prevailed among the inhabitants; a fanelefs prejudice, which has of late been almost extinguished. The chief article of exportation is wine, produced from the adjacent vineyards, and much esteemed; manufactures also of printed linens and cottons have been established with success; and within some late years, several merchants have raised large fortunes. Several public works and buildings, particularly a town-house, have been lately erected at Neuchatel; and for the embellishment of the town, the burghers have been indebted to the singular munificence of M. David Pury, late banker at the court of Lisbon, who was a citizen of this burgh, born in 1709, and who died in 1785. His benefactions, during his life, and at his decease, amounted to near 200,000l. The citizens have testified their respect for his memory by placing his portrait in one of the apartments in which the government assembles, and a marble built in the new town-house. This town enjoys considerable privileges; it has the care of
the police within its own district, and is governed by its own magistracy, consisting of a great and little council. In the year 1530 this town declared for the Reformation. It is said to have been built by the emperor Conrad, about the year 1034; 30 miles S.S.E. of Bâle. N. lat. 47° 2'. E. long. 6° 43'.

NEUCHATEL. Lake of, or of Yverdon, a lake which separates the county of Neuchatel from the cantons of Bern and Fribourg, and which stretches from N. to S. about twenty miles in length, and in some places about five in breadth. It is well furnished with various kinds of excellent fish, and its shores near Yverdon are covered with country houses.

NEUCLOSTER, a town of Germany, in the duchy of Schwurin; 10 miles E. of Wilmar.—Alfo, a town of the duchy of Bremen; three miles S.W. of Buxtehude.

NEUDOMA, a river of Norway, which runs into the North sea. 20 miles S.W. of Wardhuys.

NEUDORF, a town of Hungary, formerly fortified, inhabited partly by farmers, and partly by miners; 6 miles E.N.E. of Kapfendorf.—Alfo, a town of Antria; 8 miles S. of Vienna.—Alfo, a town of Bohemia, in the circle of Chrudim; 12 miles N.E. of Chrudim.—Alfo, a town of Silesia, in the principality of Oels; 9 miles S.E. of Mifliche.—Alfo, a town of Germany, in the principality of Culmbach; 2 miles S. of Markt Erlbach.

NEUDORFGEN, a town of Prufia, in Oberland; 7 miles S.E. of Marienwerder.

NEUDORFIA, in Botany, a name given by Adanson, Familles des Plantes, v. 2. 219, to the genus now called Nolana, which had been taken for Anropa, or Bella-donna by some, and proving new, was called by Ehret Walkeria, by Hofer Zwingera, and by Schmidel Tegaminus; see Nolana. We find no record of any author or botanist of the name of Neudorf, nor any thing like it.

NEVISLAND, in Geography, a small island of Scotland, on the N.W. coast of Ilay; 4 miles N.E. of Tovmore.

NEVEL, a town of Kufia, in the government of Polotsk; 64 miles N.E. of Polotsk. N. lat. 59° 15'. E. long. 29° 54'.

NEVEL, a town of France, in the department of the Seclent, and chief place of a canton, in the district of Ghent. The place contains 5938, and the canton 15,847 inhabitants, on a territory of 97½ kilometres, in 10 communes.

NEUENBORG, a town of Germany, in the county of Oldenburg; 22 miles N. of Oldenburg.

NEUENBURG, a town of Wurtemburg; 22 miles W. of Stuttgart. Its vicinity are found, among other pits, great quantities of those excellent iron-iron, called glafs-heads, or blood-iron, and from their fize and figure bohn-erze, or bean-ore.—Alfo, a town of the duchy of Courland; 18 miles W.N.W. of Mittaw.

NEUENDAMM, a town of the New Mark of Brandenburg; 9 miles N. of Culbrin. N. lat. 52° 48'. E. long. 14° 52'.

NEUENDORF, a town of Weitphalia, in the Old Mark of Brandenburg; 4 miles E. of Gardelehen.—Alfo, a town of Kufia, in the province of Pomerelia; 10 miles S. of Marnenburg.

NEUENKIRCHEN, a town of Germany, in the county of Verden; 14 miles E.S.E. of Roteburg.—Alfo, a town of Antria; 12 miles S.W. of Ebenfurth.

NEUENPLOSS, a town of Germany, in the principality of Culmbach; six miles N.W. of Bayreuth.

NEUENSTEIN, a town of Germany, in the principality of Holbenloc; 3 miles E. of Ohringen.

NEUERBORG, a town of France, in the department of the Forets, and chief place of a canton, in the district of Bittbourg; 22 miles N.N.E. of Luxembourg. The place contains 1256, and the canton 5226 inhabitants, on a territory of 105 kilometres, in 12 communes.

NEUERDORF, a town of Germany, in the county of Henneberg; 4 miles N. of Smalldalen.

NEVERI, a river of South America, in the government of Caracas, which runs into the Caribbean sea, near Barcelona. N. lat. 10° 7'. W. long. 65° 16'.

NEVERN, a town of Bohemia, in the circle of Pilfen; 10 miles S. of Klattau.

NEVERS, a town of France, and principal place of a district, in the department of the Niévre, formerly capital of the Nivernois, situated on the Loire, at its junction with the Niévre; before the revolution the fee of a bishop, and a place of official importance, containing, besides a cathedral, eleven parih churches, and several religious houses. The principal manufactures of this place are china, glafs, and works of enamel. The town contains 10,150, and the canton 16,087 inhabitants, on a territory of 2234 kilometres, in 15 communes. N. lat. 46° 59'. E. long. 3° 14'.

NEVERZIN, a town of European Turkey, in Dalmatia, on the Narenta; eight miles N.N.W. of Mostar.

NEUFBURG. See NEUBURG.

NEUF-BRISACK, a town of France, in the department of the Upper Rhine, and chief place of a canton, in the district of Colmar. The place contains 1682, and the canton 7925 inhabitants, on a territory of 170 kilometres, in 16 communes.

NEUCHATEAU, a town of France, and principal place of a district, in the department of the Forets, in the Ardennes; before the revolution a strong, but now a mean place; 12 miles N.W. of Arlon. The town contains 648, and the canton 6390 inhabitants, on a territory of 335 kilometres, in 17 communes. Alfo, a town of France, and principal place of a district, in the department of the Voges, seated on the Meuse; 16 miles W. of Mirecourt. The place contains 2700, and the canton 13,568 inhabitants, on a territory of 345 kilometres, in 28 communes. N. lat. 43° 22'. E. long. 5° 48'.

NEUFCHATEL, a town of France, in the department of the Ailne, and chief place of a canton, in the district of Laon; 11 miles E.S.E. of Laon. The place contains 496, and the canton 8175 inhabitants, on a territory of 2324 kilometres, in 28 communes. Alfo, a town of France, and principal place of a district, in the department of the Lower Seine; 18 miles S.E. of Dieppe. The place contains 2838, and the canton 11,350 inhabitants, on a territory of 1824 kilometres, in 27 communes. N. lat. 49° 44'. E. long. 1° 30'.

NEUGEDYN, a town of Bohemia, in the circle of Pilfen; 30 miles S.S.W. of Pilfen. N. lat. 49° 23'. E. long. 12° 51'.

NEUHASEN, a town of Courland; 18 miles S. of Goldingen.

NEUHAUS, or Hradec Gindrichteb, a town of Bohemia, in the circle of Bechin; 27 miles S.S.E. of Bechin. N. lat. 49° 12'. E. long. 14° 53'.

NEUHAUS, or Nienhaus, a town of Weitphalia, in the bishopric of Paderborn, at the conflux of the Ailne and Lippe; a usual residence of the bishop; two miles N.N.E. of Paderborn. N. lat. 51° 42'. E. long. 8° 14'.

NEUHAUS, a town of Germany, in the principality of Heffe Darmitlant; 11 miles S.E. of Worms. Alfo, a town
town of Bavaria, in the Upper Palatinate, on the Naö; 18 miles N. of Straubing.

NEUHAUSZ, a town of the duchy of Bremen, near the mouth of the Oile, with a safe harbour, and formerly the resort of trading ships annually exceeding 100 in number; but the entrance has of late been rendered dangerous by a sand-bank, which has arisen at the conflux of the Oile into the Elbe, so that only few foreign ships can visit it; 19 miles N.W. of Stade. N. lat. 53°25'. E. long. 8°27'.—Allo, a town of Germany, in the principality of Coburg; 10 miles E. of Coburg.

NEUHEUSEL, a town of Hungary, on the Neitra; 32 miles E.S.E. of Pressburg. N. lat. 48°2'. E. long. 18°3'.

NEUHEUSL, a town of the duchy of Carinthia; five miles W.S.W. of Lavamund.

NEUHOF, a town of Germany, in the bishopric of Fulda; six miles S.S.W. of Fulda.—Allo, a town of Bohemia, in the circle of Saatz; 10 miles N. of Egger.—Allo, a town of Germany, in the principality of Bayreuth; 12 miles N. of Anfpaeh.—Allo, a town of Prussia, in the province of Bartenland; three miles W. of Rallenburg.

NEUHOFEN, a town of Austria; 16 miles E. of Steyr.

NEUHORN, a town of France, in the department of Mont-Tonnerre, and chief place of a canton, in the district of Deux-Ponts. The place contains 972, and the canton 3211 inhabitants, in 12 communes.

NEVIL-Holt Waters. See Nevil-Holt Water.

NEVIL'S Bay, in Geography, a bay on the W. shore of Hudson's Bay. N. lat. 61°58'. W. long. 94°.

NEUVILLE-Pont de Pierre, a town of France, in the department of the Indre and Loire, and chief place of a canton, in the district of Tours. The place contains 1750, and the canton 8220 inhabitants, on a territory of 307½ kilometres, in 11 communes.

NEVILLI TESTA. See Testa.

NEULLY, in Geography, a town of France, in the department of the Seine, and chief place of a canton, in the district of St. Denis. The place contains 1500, and the canton 9342 inhabitants, on a territory of 44½ kilometres, in six communes.

NEULLY-en-Thal, a town of France, in the department of the Oise, and chief place of a canton, in the district of Senlis. The place contains 915, and the canton 6614 inhabitants, on a territory of 130 kilometres, in 16 communes.

NEULLY-le-Real, a town of France, in the department of the Allier, and chief place of a canton, in the district of Moulins. The place contains 1156, and the canton 5467 inhabitants, on a territory of 340 kilometres, in 10 communes.

NEULLY-le-Langres, a town of France, in the department of the Upper Marne, and chief place of a canton, in the district of Langres. The place contains 1014, and the canton 6901 inhabitants, on a territory of 175 kilometres, in 17 communes.

NEULLY-St.-Frouard, a town of France, in the department of the Aine, and chief place of a canton, in the district of Chateau-Thierry; nine miles N.W. of it. The place contains 1807, and the canton 11,220 inhabitants, on a territory of 272½ kilometres, in 35 communes.

NEVINS, or NEVIN, a small borough and market-town in the hundred of Dinileyn, and county of Caernarvon, North Wales, is situated on the coast of the Irish sea, and has a small pier, which is found very useful for the herring fishery and coasting vessels. It was constituted a free borough by Edward, the Black Prince, and is at present one of the contributory boroughs with Caernarvon, in returning one member to the British senate. Here Edward I. in 1284, celebrated his triumph over the liberties of Wales, which had for so long defied the utmost exertions of his predecessors for its subjugation. At this time he held a round table, in imitation of the hero Arthur; the concurso was prodigious, for not only the nobility of England, but a vast number of distinguished foreigners graced the festival with their presence. The market day in this town is Saturday, and there are four fairs during the year. According to the population returns of 1811, it contains 280 houses and 1777 inhabitants.

About a mile from Nevin, on the shore, is Porth-y-Llyn, most probably a port of the Romans, as vestiges of a strong entrenchment, apparently the work of that people, are still visible in the vicinity. In the parish of Llanhelty, several miles to the south, many Roman urns have been dug up at different times, and opposite to the extremity of the peninsula of Caernarvon is the small island of Bardsey, once noted for its abbey, and supposed to have been one of the seats of the Coledei or Culdees, the first order of religious recluse in Britain. Beaus of England and Wales, vol. ii. of Carlyle's Topographical Dictionary of Wales, two vols. 4to.

NEVIS, one of the Leeward Caribbean islands in the West Indies, is a beautiful little spot, consisting of a single mountain, rising like a cone in an easy ascent from the sea; the circumference of its base not exceeding eight English leagues. It is supposed to have derived its name from Columbus, its discoverer, who called it "Neives," or "The Snows," from its resemblance to a mountain of the same name in Spain; or, perhaps, a white smoke was seen to issue from the summit, which appeared like snow, and that it derived its name from that circumstance. That it owed its origin to some volcanic explosion, we can have no reason to question; for near the summit there is still visible a hollow, or crater, which contains a hot spring, strongly impregnated with sulphur; and sulphur is frequently found in fublimate, in neighbouring gullies and cavities of the earth. It is well watered, and the land is generally fertile; and even the summit furnishes yams and other excellent vegetables. The soil is flaky; the beds is a lofe black mould, on a clay; and in some places the upper stratum is a stiff clay, the cultivation of which requires labour, that is amply compensated by the produce. Sugar is its only staple production; and in general it yields one hoghead of 16 cwt. per acre from all the canes that are annually cut; and the productive land being about 4000 acres, the produce of sugar amounts to as many hogheads. This small island is divided into five parishes; and it contains a town called "Charles-town," the seat of government and port of entry, besides which there are two other shipping-places, called "Indian-castle" and "New-castle." The principal fortification is at Charles-town, and is called "Charles Fort." The commandant is appointed by the crown, but receives a salary from the island. In the absence of the governor-general, the government is administered by the president of the council, which council consists of six members besides the president. The house of assembly is composed of 15 representatives, three for each parish. The administration of common law is under the direction of a chief justice, and two assistant judges, and there is an office for the registry of deeds. The number of white inhabitants is stated by Mr. Edwards not to exceed 600, while the negroes amount
amount to about 10,000. The former compose a militia, in which there is a troop consisting of 50 horse, well mounted and accoutred.

The English first established themselves in this island in the year 1628, under the protection and encouragement of Sir Thomas Warner. He was succeeded by Mr. Lake, who completed what Mr. Warner had begun, so that under his administration Nevis rose to opulence and importance. N. lat. 17° 14'. W. long. 62° 35'. Edwards's W. Ind. vol. i.

NEUKALDEN, or NEUKALEN, a town of the duchy of Mecklenburg, on a lake; 28 miles S.S.E. of Roßlock. N. lat. 53° 40'. E. long. 12° 46'.

NEUKIRCH, a town of Prussia, in the province of Ermeland; 13 miles N.E. of Elbing.—Alfo, a town of Silecia, in the principality of Oppau; 10 miles E. of Jagernord. N. lat. 50°. E. long. 17° 15'.

NEUKIRCHEN, a town of Switzerland, and capital of a bailiwick, in the canton of Schaffhausen; five miles W. of Schaffhausen.—Alfo, a town of Bavaria; 22 miles N.N.E. of Ratibon.—Alfo, a town of Austria; six miles S.S.E. of Enghartzel.—Alfo, a town of the principality of Hesse; 22 miles N.N.E. of Marburg. N. lat. 50° 40'. E. long. 27° 41'.—Alfo, a town of Bavaria; five miles S.S.E. of Furt.—Alfo, a town of Saxony, in the circle of Erzgebirge; five miles S. of Chemnitz.—Alfo, a town of Saxony, in the Vogtland; 10 miles S.E. of Oelsnitz.

NEUKRUG, a town of Prussia, in the palatinate of Culm; 10 miles E. of Culm.

NEULA, a town of Germany, in the principality of Culmbach, on the Selbitz; three miles S.S.E. of Lichtenberg.

NE ULTRA, or Sir Thomas Roe's Welcome, a narrow strait in New North Wales, between N. lat. 62° and 63°.

NEUMAGEN, a town of France, in the department of the Sarre, on the side of the Meffe; 11 miles E.N.E. of Treves. N. lat. 46° 54'. E. long. 6° 58'.

NEUMANN, JOHN-GEORGE, in Biography, a learned German Lutheran divine, was born in the year 1661 at Mertz, a village of the country of Mersebourg, in the circle of Saxony, of which his father was minister. He commenced his academical studies at Zittau, whence he removed, in 1680, to the university of Wittemberg. He afterwards spent some time at Strassburg, and visited several of the most celebrated German universities. He returned to Wittemburg, and was appointed professor of poetry in 1690, and librarian to the university in 1692. After this he was appointed theological professor, allèfear to the consistory, and provost of the castle-chapel. He died in 1709, in the 49th year of his age. He was author of many learned ' Difcours,' and other tracts on moral, religious, and controversial subjects, of which a list is given in the supplement to the Historical Dictionary, published at Basle. Morel.
NEUME, a term in Canto Ferme. The neume, or neuma, is a kind of short recapitulation of the chant of a mode or ecclesiastical tone, which is made at the end of a chant or antiphon by a simple variety or extemporary division of sounds without words. Roman Catholics authorize this custom by a passage in St. Augustine, which says, that when we are unable to find words worthy of the divinity, we do well to address him with confused sounds of joy and thanksgiving: "For to whom are such exotic sounds due, unless to the Supreme Being? And how can we celebrate his ineffable goodness, when we are equally unable to adore him in silence, and to find any other expressions for our transports than inarticulate sounds?" Amen and Hallelujah are of this kind.

NEUMUNSTER, in Geography, a town of the duchy of Helfeld; 18 miles S.W. of Kiel.

NEUNG-sur-Barrou, a town of France, in the department of the Loire and Cher, and chief place of a canton, in the district of Romorantin. The place contains 11,750, and the canton 45,444 inhabitants, on a territory of 285 square miles in 11 communes.

NEUNKIRCHEN, a town of Germany in the principality of Culmbach; four miles S.E. of Bayreuth. — Alto, a town of Bavaria, in the bishopric of Bamberg; eight miles S. of Forchheim.

NEVONSKA, a town of Russia, in the government of Irkutsk; 92 miles N.N.W. of Irkutsk.

NEUPEURN, a town of Bavaria; 38 miles W. of Salzburg.

NEURACHNE, in Botany, from μυγα, a nereus, and μος, a glume or husk, alluding to the nerves, or ribs, of the calyx-valves. Brown. Prod. Nov. Holl. v. 1. 196.—Clasf and order, Triandria Digynia Nat. Ord. Gramina:

Eff. Ch. Calyx of two ribbed, acute, hifpid, coraceous valves, hardened when in seed; the outer one rather the smaller. Flowers diffusiflora; the outer one neuter, of two valves, of which the outermost nearly resembles the calyx; inner hermaphrodite, of two membranous pellucide valves. Scales two beneath the stamen. Stigma falcate. Seed unconnected, falling out of the membranous corolla.

1. N. alopecuroidea.—Gathered by Mr. Brown on the south coast of New Holland. A perennial graps, with numerous upright fefts, whose knots are beared with filty hairs. Leaves flat and short. Spike solitary, ovate, resembling that of the Fox-tail Graps, Alopecurus, fimple, deftite of any involucrum.

NEURADA, so called, as Linneas himself tells us, Phil. Bot. 153; from μυγα, a nereus, in allusion to the structure of the plant; probably adverting to the strong interbranching ribs or nerves of the feed-velvet. Whether he, or Bernard de Jaffieu, who seems to have given the name, had also in view μυγα of the Greeks; or μοχος, which Dioscorides says is the Ionian appellation of his τριβυς, Aegagrius criticus, Willd. Sp. Pl. v. 3. 1330; a plant supposing its gummy nature, to be useful in confounding nerves or fibres; does not appear. Possibly the long round fefts of our Neuroada, which are clothed with white tenacious cottony down, suggested the idea of a nerve or tendon. It is much to be wished, that the authors of names would, in such obscure cafes, be more explicit.—Linn. Gen. 232. Schreb. 313. Willd. Sp. Pl. v. 2. 821. Mart. Mill. Dict. v. 2. Jull. 336. Lamarck Illust. t. 393. Buxton. t. 32.—Clasf and order, Decandria Deca-gynia Nat. Ord. Succulenta. Linn. Rfofes. Jull.; but this author juftly doubts, whether his uncle and Adanson have not led him into an error; the genus fully belongs to his Ficoidae.

Vol. XXIV.
NEU

Raim: Vieuillens, a physician of Montpellier, has an excellent treatise in Latin, under the title of "Neurographia Universalis," where he shews, that there are more ramifications of the nerves in the skin than in the muscles and all the other parts.

Duncan, another physician of the same place, has also a treatise called "Neurographia Rationalis."

NEUROLOGY, νευρολογία, a discourse of the nerves.

Neurology seems to be of less extent than neurography, inasmuch as the latter may be understood not only of discourses of the nerves, but also of figures and engravings, representing them; whereas the former is confined to discourse alone. Willis has given a fine neurology, in his "Anatomy Cerebrali." See NERVOUS SYST.

NEUROPORA, in Botany, so called by Commerford, from νυσφορα, a nerve, and χορφοεις, a callosity, because there are axillary callosum ulcerations, as it were, at the principal veins underneath, is referred by Jullien to ANTIDÈSMA; see that article.

NEUROPTERA, in Entomology, the name of the fourth order of insects, according to the Linnaean system, so called from the words νυσφορα and χορφοεις, signifying nerve-wound, because the insects of this order are remarkable for the nervous or reticulated appearance of their wings, the fibres running into ramifications and decussations over the whole surface. This order is well exemplified in the Libellulae, or Dragon-flies (which see), in which the characteristic of the order is very conspicuous. The wings are always four in number. This order includes several genera, viz.:—

Ephemera, Hemerobius, Phryganæa, Libellula, Raphidia, Myrmeleon.

The insects of this order are chiefly aquatic; refiding in the waters as caterpillar; and Brying about their surface in the perfect state.

NEUROTROTOS, (from νυσφορα, a nerve, and τρωζεις, to wound,) a person who has received a wound of a nerve.

NEUSALTZ, in Geography, a town of Sileia, in the principality of Glogau, on the Oder; 12 miles N.W. of Glogau. N. lat. 51° 18'. E. long. 15° 15'.

NEUSCHATZ, a town of Hungary, formerly called "Peter Wardein Schanz," separated from the Danube from Peter Wardein in Slavonia, peopled by Rascians, and fortified: the title of a Greek bishop, and made a royal and free town in the year 1751.

NEUSCHLOSS, a town of Bohemia, in the circle of Saaz; six miles E. of Saaz.—Alfo, a town of Bohemia, in the circle of Leitmeritz; three miles S. of Leypa.—Alfo, a town of Bohemia, in the circle of Königgrätz; nine miles W.S.W. of Trautenau.—Alfo, a town of Sileia, giving name to a lordship on the borders of Poland; five miles E. of Militsch.

NEUSE, a river of North Carolina, which rises above Hillborough, and after a course of more than 500 miles, falls into Pamlico Sound; 70 miles below Newbern; 12 miles above which it is navigable for ships.

NEUSIDL, a town of Hungary, on a lake of the same name; 24 miles S.W. of Presburg. The lake is 13 miles long, and three wide.

NEUSLING, a town of Germany, in the margraviate of Anspach; seven miles E. of Weißenburg.

NEUSOL, a town of Hungary, which is royal and free, and the seat of the mine towns, seated on the river Gran. It has six churches and a school, with about 5000 inhab.

NEUSTADT, a town of Germany, in the department of the Roer, and chief place of a canton, in the district of Crevel; the place contains 4423, and the canton 13,853 inhabitants, in 24 communes.

NEUSTADT, a town of France, in the department of Mont Thomas, and chief place of a canton, in the district of Spire, on the Hart; 14 miles W. of Spire. The place contains 2875, and the canton 17,638 inhabitants, in 27 communes. N. lat. 49° 20'. E. long. 7° 10'.—Alfo, a town of the principality of Neuburg; 10 miles N.E. of Neumark.—Alfo, a town of Germany, in the lordship of Stuhlingen; 16 miles N.W. of it.—Alfo, a town of Bavaria, on the N.N.; 45 miles N. of Bamberg.—Alfo, a town of the archbishopric of Salzburg; 12 miles N.E. of Salzburg.—Alfo, a town of Prussia, in the circle of Sambland; 20 miles S. of Memel.—Alfo, a town of Austria, formerly a bishop's see, supprest in 1784. Here are a manufacture of china and a military school; 10 miles S.S.E. of Baden. N. lat. 48° 18'. E. long. 16° 13'.—Alfo, a town of Bohemia, in Königgrätz; 12 miles N. of it. N. lat. 50° 15'. E. long. 15° 57'.—Alfo, a town of Moravia, in the circle of Olmutz; 16 miles N. of Olmutz.—Alfo, a town of Heß; 12 miles E. of Marburg.—Alfo, a town of Sweden, in the province of Finland, near the Gulf of Bothnia; 24 miles N. of Abö.—Alfo, a town of Weitphalia, in the principality of Wolfenbüttel; 24 miles S.E. of Göttingen. Alfo, a town of the Duchy of Holstein, with a spacious harbour on the coast of the Baltic. It has been used for treaty prisoners; 17 miles N.N.E. of Lubeck. N. lat. 54° 7'. E. long. 10° 57'.—Alfo, a town of Bavaria, on the Danube; 16 miles E. of Ingolstadt. N. lat. 48° 44'. E. long. 11° 45'.—Alfo, a town of Weitphalia; 30 miles E. of Göttingen. N. lat. 51° 35'. E. long. 10° 56'.—Alfo, a town of Germany, situated on the foot of a mountain, on which was formerly a citadel. Its trade was formerly considerable in iron; but of late the burghers subsist chiefly by agriculture, and breeding of cattle; 26 miles E.S.E. of Boppa. N. lat. 50° 57'. E. long. 7° 45'.—Alfo, a town of Wurtemberg; six miles N.E. of Heilbronn. N. lat. 49° 18'. E. long. 9° 20'.

NEUSTADT, or Badisch, a town of Sileia, in the principality of Oppeln, inferior only to Oppeln; 25 miles S.W. of it. N. lat. 50° 12'. E. long. 17° 30'.

NEUSTADT am Aisch, a town of Germany, in Cumbach, on the Aisch; 23 miles W.N.W. of Nuremberg.

NEUSTADT am Culmen, a town of Germany, in Cumbach, taking its name from two mountains between which it is situated; 12 miles S.E. of Bayreuth.

NEUSTADT am Duffe, a town of the Middle Mark of Brandenburg, on the Duffe, famous for its manufacture of plate-glass; 36 miles N.W. of Berlin. N. lat. 52° 32'. E. long 12° 30'.

NEUSTADT am Eyfel, a town in the Middle Mark of Brandenburg, on the Finow canal, that forms a communication between the Havel and the Oder; 28 miles N.E. of Berlin. N. lat. 52° 54'. E. long. 13° 50'.

NEUSTADT an der Heyda, a town of Germany, in the principality of Coburg; six miles N.E. of Coburg. N. lat. 50° 20'. E. long. 10° 14'.

NEUSTADT auf dem Mecklenburg, a town of Saxony, in the margraviate of Meclen; 20 miles E. of Dresden. N. lat. 51° 14'. E. long. 14° 16'.

NEUSTADT am Orla, a town of Saxony, and capital of the
the circle of the same name, situated on the Orla. The circle includes nine towns, and more than 220 villages. The town of Neustadt has a citadel, two churches, a court of judgment for the circle, and a mine office; 80 miles W.S.W. of Dresden. N. lat. 50° 39'. E. lon.; 11° 48'.

Neustadt in der Rueinom, a town of Germany, in the county of Wertheim; 18 miles S.S.E. of Francfort on the Main.

Neustadt am Rubenberg, a town of Westphalia, in Catenberg, situated on the Laia; 12 miles W.N.W. of Hanover. N. lat. 52° 33'. E. long. 9° 33'.

Neustadt am Saale, a town of the duchy of Wurzburg, on the Saal; 13 miles N. of Schweinfurt.

Neustadt, or Neustadt pren de Schenben, a town of Saxony, in the circle of Erezgebirg; 17 miles S.S.W. of Chemnitz. N. lat. 50° 20'. E. long. 13° 28'.

Neustadt on the Wiesental, a town of Saxony, in the circle of Erezgebirg, on the borders of Bohemia; 11 miles S.S.E. of Schwartzburg.

Neustadt, a town of Silezia, in the principality of Glogau; 15 miles W. of Gros Glogau. N. lat. 51° 40'. E. long. 15° 45'.

Neustadt, or Neufchatel, a town of Bohemia, in the circle of Pilsen; 32 miles W. of Pilsen. N. lat. 49° 39'. E. long. 13° 15'.

Neustadt, or Nowe-Mentok, a town of Moravia, in the circle of Brunn; fixes miles E. of Saaz.—Also, a town of Bohemia, in the circle of Boleslaw; 14 miles E.N.E. of Krotau.

Neustatt, a town of the principality of Nassau-Dillenburg; fixes miles W.S.W. of Dillenburg. Neustift, a town of the county of Tyrol; 13 miles S.W. of Innsbruck.

Neuter, a person indifferent, who has espoused neither party, and is neither friend nor foe.

Neuter, in Grammar, denotes a sort of gender in nouns which are neither masculine nor feminine. See Gender.

Neuter Verb. See Verb.

Neutral Salts, among Chemists, such as do not abound with an excess of acid or alkali. See Neutralization.

Formerly those only were called neutral salts, which were composed of acids and alkalies united together to the point of saturation, so that they had no acid or alkaline property, and thence they were called neutral. But now this name is commonly extended to combinations of acids with all substances, with which they can coexist, that they lose entirely or modify their acid qualities; as, for instance, when they are united with earthy or metallic substances. See Salt.

Mr. Boyle also gives the appellation neutral to a sort of spirits, differing, in divers qualities, both from vinous, acid, and urinous spirits. These he also calls anammonous and adaphorous spirits.

Neutrality, the state of a person or thing that is neutral.

Neutrality, Armed, Treaty of, in Modern History, a treaty for the protection of the navigation of the North, which was planned by Vergennes, in conformity to the views and wishes of Catharine II., empress of Russia, in the year 1750, and to which almost all the powers of Europe succumbed. This minister, having gained his point in depriving the English of the assistance of the Russian fleet, formed this extensive plan for effecting his political purposes. Well acquainted with the haughty spirit of the empress, Vergennes artfully contrived to interest her in the execution of his project. He wrought upon the ministers of Den-
the latter, her pacific intentions were unavailing; and peace with Holland was the last that was concluded.

The great principle of the armed neutrality was, that free bottoms make free goods; and this was carried to such an extent, that neutral states were entitled to carry on their commerce with the belligerent parties, in a state of war, with the same degree of convenience, ease, and safety, which they might have practiced in time of peace. It was farther laid down, that the neutral bottom has a right to convey, and to render free, all things from any one port of a belligerent state, and even coastwise, to another without let or impediment, saving only such matters as might be deemed contraband in consequence of the fluctuations of former treaties. The courts of France and Spain cordially approved this system, as it suited their own views, till at a future time they might find opportunity to disinfect themselves from the obligation of it. The solitary court of London was obliged to suppress her indignation at an injury which she could not at present resent or remedy. She expostulated with the court of Peterburgh, professed respect for her flag and commerce, and declared a continuance of the same friendly disposition and conduct manifested on former occasions. The principal claims of the confederate powers were thus specified: 1. That all neutral vessels may freely navigate from one port to another on the coasts of the nations at war. 2. That the effects of the belligerent powers shall be safe in all neutral vessels, with the exception of prohibited mercantile goods. 3. That the emperors under-flows, by prohibited mercantile goods, such as are specified in the articles 10 and 11 of her treaty of commerce with Great Britain, extending her obligation in that respect to the other powers at war. 4. That by a port blocked up, is to be understood only a port so strictly watched by the ships of the powers which attack it, that to enter it would be dangerous. 5. That these principles should be admitted as the sole rule whereby to decide the legality of prizes. The emperors added, that in publishing these articles, the declared, that to enforce their execution, and to protect the honour of her flag, the security of her commerce, and the navigation of her subjects, she was about to arm the greater part of her naval forces. That her marine should not in anywise injure the neutrality, which she was disposed to observe as long as she should not be provoked and obliged to exceed the bounds of a just moderation, and the most perfect impartiality. See Tooke's Life of Catharine II. vol. ii.

NEUTRALIZATION, in Chemistry, the act of combining an acid with an alkali, in such proportion that the compound may not exhibit either acid or alkaline qualities, and is, in what is called a neutral state. Under the same circumstances the acid and the alkali are said to be mutually saturated or neutralized. In the old nomenclature, this language, relative to salts, was more appropriate than in the present state of chemistry. Acids used then to be called acid salts, and the alkali's alkaline salts, while these compounds consisted of an acid and an alkali, where neither the acid nor the alkali predominated, were called, for the sake of dilution, neutral salts. The term commonly employed for ascertaining the state of neutrality is a vegetable blue, such as an infusion of violets, or paper stained with almost any vegetable blue. If the colour is not changed, the compound may be deemed neutral. If the colour be changed to red, the acid prevails; but if a green, the alkali predominates.

NEUVIE, in Geography, a town of France, in the department of the Dordogne, and chief place of a canton, in the district of Ribére; 12 miles S.W. of Perigueux. The place contains 1816, and the canton 8566 inhabitants, on a territory of 18244 kilometres, in 16 communes.—Also, a town of France, in the department of the Correze, and chief place of a canton, in the district of Uffel; 10 miles S. of Uffel. The place contains 2037, and the canton 7974 inhabitants, on a territory of 24741 kilometres, in 16 communes.

NEUVILLE, a town of France, in the department of the Lot-et-Garonne, and chief place of a canton, in the district of Bordeaux; 8 miles N.W. of Bordeaux. The place contains 1887, and the canton 9253 inhabitants, on a territory of 325 kilometres, in 16 communes. —Also, a town of France, in the department of the Rhône, and chief place of a canton, in the district of Lyon; six miles from Lyon. The place contains 1950, and the canton 12,147 inhabitants, on a territory of 80 kilometres, in 13 communes. —Also, a town of France, in the department of the Vienne, and chief place of a canton, in the district of Poitiers; seven miles N.N.W. of Poitiers. The place contains 2718, and the canton 9060 inhabitants, on a territory of 1778 kilometres, in 11 communes.—Also, a town of Canada, on the St. Lawrence; 14 miles S.W. of Quebec.

NEUVY-ST.-SEPULCHRE, a town of France, in the department of the Indre, and chief place of a canton, in the district of La Châtre; nine miles W. of La Châtre. The place contains 1672, and the canton 9500 inhabitants, on a territory of 3821 kilometres, in 14 communes.

NEUVALDE, a town of Silesia, in the principality of Neuf; nine miles N.E. of Ziegenthal.

NEWARK, a town of Anterior Pomerania, in a lake communicating with the Frische Haff; 10 miles E. of Ueckermünde. N. lat. 53° 26'. E. long. 14° 15'.

NEWEDEL, a town of Brandenburg, in the New Mark, on the Drage; 30 miles S.E. of Stargard. N. lat. 53° 14'. E. long. 15° 55'.

NEWIED, or New Wied, a town of Germany, in the county of Wied Runkel, on the Rhine. This is a neat town of considerable commercial importance, and its prosperity has been gradually advancing with its trade and manufactures; four miles below Coblenz. N. lat. 50° 29'. E. long. 5° 28'.

NEW, a river of America, in North Carolina, which, after a short course, discharges itself into the ocean, through New River inlet by a wide but shallow mouth. In the winter season it abounds with mullet.

NEW ALBION. See New Albion.

NEW ANDALUSIA. See New Andalusia.

NEW ANDOVER. See East Andover.

NEW ANTICARIA, a town of New Spain; 34 leagues northward of Acapulco.

NEW ANTIGUA, an episcopal city of New Spain, in the province of Guaxaca, erected into a bishopric by Paul III. in 1547. Its noble cathedral is supported by marble pillars.

NEWARK-upon-Trent, a borough and market-town, situated in the south division of the wapentake of Newark, and county of Nottingham, England, is a place of great antiquity, and supposed to have risen on the ruins of the Roman stations of "Ad Pontem" and "Crocolana," which were undoubtedly situated in this vicinity. Stukeley hazards the conjecture that it was the much disputed Sidnacerallis of the Saxons, and Throfly remarks that it was the actual site of "Ad Pontem," but neither of these opinions are generally admitted to be correct. Newark, according to Mr. Dickencon, means New-work, which, he says, evidently implies that there was something older on which it was ingrained, though whether the new erection took place in the time of the Romans, or the Saxons, he thinks cannot be precisely determined. It is certain, however, that this place had acquired its present name.
name before the reign of Edward the Confessor, as it is men-
tioned in his time as the property of Lufne, earl of Mercia,
and given by him to the monastery of Stow, near Lincoln.
What was its condition or extent at this period is un-
known, nor does any circumstance deserving attention oc-
cur respecting it till about the year 1126, when we are in-
formed that Alexander, bishop of Lincoln, built "a large and
magnificent castle here," which was soon afterwards feized
from him by king Stephen, and held for many years in the
possession of the crown. During the troublesome reign of
king John, this fortress was besieged by the rebellious bar-
onors, and resolutely defended till news arrived of the
approach of the monarch, when the assailants thought proper
to retire; the king, in consequence, subjequently entered
the town without opposition; but so fatigued and exhasted
by care, and the difficulties of a long march, that he was
attacked with a dysentery, which, in a few days, put an end
to his life. In the succeeding reign, Newark castle was for-
tified by the barons who had supported the interdicts of prince
Lewis, and were basely defeated by him. The earl of Penbrook marched against them, and having closely invested the
castle, compelled them to surrender at discretion, after a
refusal of eight days. Throughout the time of the grand
rebellion in the seventeenth century, the inhabitants of this
town were conspicuous for their loyalty. By the exertions
made to render the place defensible, and the bravery of the
royalists, it became a most important garrison, and not only
held in subjection the county of Northampton, but laid a
great part of Lincolnshire under contibution. It stood
three very desperate sieges, is all of which much revolution
and gallantry were displayed, nor were the parliamentary
forces able to obtain possession of it till it surrendered to the
Scotch army by order of the king.

Newark, subjequent to the erection of the castle, seems
to have advanced rapidly in extent and population. Edward
VI. constituted it a borough by charter in the third
year of his reign. This deed, has been confirmed, and
many new privileges added, by several of his successors,
and particularly by Charles II., under whose charter the town
is now governed. A mayor, recorder, twelve aldermen,
common council of the principal inhabitants, and a town-
clerk, form the corporation. Two members are returned
from this borough to serve in parliament. The petty se-
fions of two hundred are held here, besides those of the
borough. The market is on Wednesday, and is well sup-
plied with all kinds of provisions. In the market-place,
which is a large square, and laid to have been formerly much
more extensive than at present, stands the town-hall, an elo-
gant stone building, erected in 1805, at an expense of
17,000l., paid out of the funds of the parliamentary citz
left for the advantage of the town. It consists of three flori-
ories, containing the courts and requisite offices and apart-
ments belonging to the corporation, and a large room ap-
propriated to concerts and assemblies. The workhouse of
this town is one of the most commodious and well regulated
in the kingdom. As its prison was, till very lately at least, a
destination to any civilized nation, and still requires consid-
erable amelioration. Here is a grammar-school of ac-
nowledged respectability, founded by Dr. Thomas Magnus
in 1529, as an inscription over the door imports. The
church is a truly superb and capacious edifice of the age of
Henry VI. The tower is finely ornamented with arch-
work and sculpture, and supports a lofty spire, adorned
with statues of the twelve apostles in niches. In the win-
dows appear some paintings on glass, representing the various
events of our Saviour's life, together with a number of
armorial bearings. Close to the river stand the ruins of the
castle, which, notwithstanding the demolition it has under-
gone, still present an august and imposing aspect. The
north front is the most perfect, having a massive square
tower at the north-east angle, and another in the centre of
the elevation. Between these, in the principal story, and
among some large magnificent windows, is an immense pro-
crating window, exhibiting a perfect specimen of those an-
iciently called "bays or bowers." Under the great hall,
which seems to have been of later erection than the rest of
the building, is a most curious arched vault or crypt, sup-
ported by a row of pillars in the centre, and having loopholes
and embrasures towards the river. At the end of this
vault is a subterraneous passage, said to have gone a
great way under ground, but it has never been explored.
The bridge thrown over the Trent here is constructed of
brick, faced with stone, and was the gift of the earl of
Northumberland.

The religious foundations in this town, during the times
of popery, were a house of Austin friars, and another of
Observant friars; besides an hospital dedicated to St. Leo-
nard, built by bishop Alexander, in the latter end of the
reign of Henry I.; and one belonging to the Knights
Templars, founded previous to the year 1185. Near North-
gate was a great house, called the Spittke, which was burnt
down in the civil wars, and suppos'd by some authors, but
without sufficient evidence, to have been the hospital of St.
Leonard. In the church-yard stood an edifice called the
chantry free-school, and a long-school, for an organist and
fix choristers. There was likewise in Newark a second
church, but this was demolished during one of the three last
sieges in the seventeenth century.

The trade and manufactures of Newark are tolerably ex-
tensive. In Northgate is a very large brewery, which was
accustomed to carry on a vast commerce with the north of
Europe, before the development of the continental system.
The manufacture of cotton has been lately introduced, and
affords employment to a considerable number of the poor.
The counties of Nottingham, Lincoln, Derby, Stafford,
Chester, Warwick, and part of York, are chiefly supplied
with malt made in this town and its vicinity. Two large
establishments for the weaving and bleaching of coarse linen
are in a thriving condition, as is likewise an infant manufac-
tory of fail-cloth and facking. Corn and coals form im-
portant articles of traffic in Newark: and there is annually
a very large market, or fair, for chees, held on the Wed-
nesday preceding the second day of October.

According to the parliamentary returns of 1801, this
town contained only 1390 houses, and a population of 6730
persons. By the late returns (1811), however, it appears
that a very material increase has taken place; the houses
being there listed to amount to 1504, and the inhabitants
to 7236 in number. The parish of Newark comprises about
800 acres.

The vicinity of this town has been much cut up by mili-
itary works in the time of the civil wars, many traces of
which remain. Beacon-hill, where are several extensive
quarries of gypsum, was the scene of action between
the royal army under prince Rupert, and the parliament-
ary troops, commanded by sir John Meldrum, who had laid
siege to the castle in 1643. In this engagement the royalists
were completely successful, though much inferior in number
to the republicans. The sfofe-road passes close to this hill.
At Codlington, on the Sleaford road, stands a handsome seat of
S. C. Colclough, esq.; and directly north from hence is the
Bruff or Brough, pointed out by Stukeley as the undoubted
Croclona of the Romans. Balderton, two miles from
Newark, is remarkable for a curious Saxon porch to its
church.
church, wrought with zig-zag mouldings and ozes' heads. Elvaston, or Eliton, situated about four miles south from the town, has acquired just celebrity as the birth-place of the late Dr. Darwin, whose scientific and literary labours, and active benevolence, reflect luster on the human character. Between this village and that of Stoke, or, as some antiquaries affert, of Thorpe, Henry VII. engaged and defeated the army of the earl of Lincoln, who had espoused the cause of the impostor Lambeth Simnel. This action was fought in the month of June, in the year 1577, but much difference of opinion prevails with respect to the exact day: Hall calls it the 6th, Stowe the 16th, and Holinshed the 20th. Tradition affirms that Henry fixed his head quarters, before the battle, in Elton field, close to the village. For an account of some other places in this vicinity, see Southwell. History and Antiquities of the Town of Newark, by William Dickenfon, efq., Newark edit. 1806. 4to. Beauties of England and Wales, vol. xii.

NEWARK, a township of America, in Essex county, Vermont.—Also, a poilt-town of New Jersey, and capital of Essex county, pleasantly situated at a small distance W. of Passack river, near its mouth on Newark bay; nine miles W. of New York city. It is a handfome flourishing town, famous for its excellent cyder, and as being the seat of the largest shoe manufacture in the state. It has also a large and elegant Presbyterian meeting-house, an episcopal church, a court-house, and a gaol. Its academy was established in 1792. This town, which has several tanneries and quarries of flones for building, was originally settled by emigrants from Bradford, in Connecticut, in the year 1662.—Also, a town lately laid out by the British in Upper Canada, on the river which connects lakes Erie and Ontario, directly opposite to Niagara town and fort. The town is handfome, about a mile square, with its streets at right angles, and contains about 150 houses.—Also, a township, comprehending the above town, in the county of Lincoln, Upper Canada, and lying on the W. side of Niagara river, opposite to the fort.

NEWARK Bay, a bay of New Jersey, formed by the confluence of Passack and Hackinack rivers from the N. and separated from that part of North river opposite to New York city, by Bergen neck on the E. This neck forms, with Staten island on the S., a narrow channel from the bay to North river calledway. Newark bay also communicates with Rariton bay, at the mouth of Rariton river, by a channel in a S.W. direction along the W. side of Staten island. The water passage from New York to Elizabeth-town point, 15 miles long, is through this bay.

NEW ASHFORD. See New Ashford.

NEW ATHENS, or Tioga Point, stands on the post-road in America from Cooperstown to Williamburg, in Luzerne county, Pennsylvania, on the point of land formed by the confluence of Tioga river with the E. branch of Susquehannah river, in N. lat. 41° 54', W. long. 76° 32'; 20 miles S.E. by E. of Newtown in New York.

NEW BANK, one of the banks of Newfoundland; six miles S. of Cape Ballard.

NEW BEDFORD. See New Bedford.

NEWBERN, one of the easter maritime districts of North Carolina, comprehending the counties of Carteret, Jones, Craven, Beaufort, Hyde, Pitt, Wayne, Glasgows, Lenoir, and Johnston, and containing 60,453 inhabitants, including 20,114 slaves.—Also, the capital of the above district, which is a poilt-town and port of entry in Craven county, situated on a flat, sandy point of land, formed by the confluence of the rivers Neus on the N. and Trent on the S. This is the largest town in the state, containing about 400 houses and 2,467 inhabitants, of whom 1,258 are slaves. The edifices are all constructed of wood, except the palace, the church, the gaol, and two dwelling houses, which are of brick. The palace was formerly the residence of the governor, but it is now decayed and applied to the use of schools. Newbern carries on a considerable trade to the West Indies and the different states, in tar, pitch, turpentine, lumber, corn, &c. The exports in 1794 amounted to 69,615 dollars; 501 miles S. of Philadelphia. N. lat. 35° 20', W. long. 77° 25'.

NEW BISCAY. See New Biscay.

NEWBLL88, a poilt-town of the county of Monaghan, Ireland; 55 miles N.W. by N. from Dublin.

NEWBROUGH. See Gorey.

NEWBROUGH, a borough, market-town, and parish, in the hundred of Menai, and county of Anglesey, North Wales, is situated on the river Brains, or Brent, about three miles from the shore of Caernarvon bay. The British name of this place is Rhos-Hir, or Vair. Edward I. established it a corporation by charter, and annexed it to the royalties of the prince of Wales; and this deed afterwards received the sanction of parliament, in the reign of Edward III. In the time of Henry VIII. and the first year of Edward VI. Newbrough lent members to parliament, but the latter monarch was pleased to transfer the elective franchise from hence to Beaumaris, in the second year of his sovereignty. The government of the town is now vested in a mayor, two bailiffs, a recorder, and other affiant officers, who continue to hold regular courts. The revenue of the corporation is chiefly derived from about four hundred acres of excellent land, (situated in the vicinity,) which the magistrates have it in contemplation to include. This was an ancient manor of the British princes, who had a lys or palace here; and here was also the seat of justice for the whole comot of Menai, and which continued to long after Wales became subject to England. The chief manufacture carried on by the inhabitants is that of mats, netting, and cordage, made of sea reeds or sea-grass. A few perfons are likewise engaged in fishing, and a considerable number in the labours of agriculture. This town gives title of baron to the family of Wynn. It has a weekly market on Tuesday, and, according to the parliamentary returns of 1811, contains 183 houses, and a population of 750 perfons. The amount of acres in the parish is estimated at 1000.

Adjoining to the town, and near the ruins of a building, which has been generally regarded as the domestic chapel of the ancient palace, may be seen a large upright stone, inscribed "Tilius Ulrici erexit hunc lapidem," and supposed to commemorate some Danish chieftain who had fallen in battle here, as it is well ascertained that the Danes made frequent descents on this coast. At Llanddewyn, a small, narrow peninsula, projecting into the bay of Caernarvon, stood an oratory of St. Dwynwen, the British Venus, or tutelary saint of lovers, who flourished in the fifth century. In after-times a Benedictine abbey was erected upon the same spot, and seems to have been one of the richest in the county. In the time of Owen Glyndwr its wealth gave rise to a very serious deprecatory quarrel, and in the vitiation made by the order of Henry VIII. it is mentioned among the most valuable prebends belonging to the see of Bangor.

Llanddewyn, lying about five miles to the north-east of Newborough, is distinguished as the birth-place of Henry Rowlands, bishop of Bangor, and author of the "Mona Antiqua Reformata," who died in 1723. Almost close to the village is the ferry of Mona-y-Don, by which Agricola crossed over into the island of Anglesey, and where the army of Edward I. sustained a signal defeat in 1282. The field of
Maes-mawr-gad, or the plain of the great army, has been supposed by some to be the scene of the first Saxon battle recorded by Tacitus as fought in this county; and by others to have been an engagement between Gryphyll ap Cyman, king of Gwynedd, and the usurper Trahaern ap Cadrog, which took place in 1082. Plas-Newydd, a feast of the earl of Uxbridge, is situated close to the north bank of the Menai, and occupies a portion of those groves, once so celebrated as embellishing the principal tombs of the ancient Druids. Here, and for several miles round, appear numerous memorials of the religious rites practised during the prevalence of that extraordinary worship. Near the mansion of Plas-Newydd is a large cromlech, with another of smaller dimensions close to it. Particular accounts of these, with an engraving, are contained in King’s “Monumenta Antiqua.” Near a path-way leading into the road from Plas-Newydd to Llandian is a large cernedden, which was opened about seventeen years ago, and found to contain a vault floored with an immense quantity of human bones. This is conjectured to have had a subterraneous connection with the cromlech, and to have formed a place of confinement for the wretched victims destined to be sacrificed. At Tan-bencenn, on the river Briont, are two large embankments of a square form, generally regarded as the works of the chief seat of the Arch-Druid at Tre’r Dryw. The Bryn Gwyn, Braw Gwyn, or royal tribunal of this sovereign priest, still continues distinctly marked. It is a circular hollow, about one hundred and eighty feet in diameter, surrounded by a wall of earth and stones. Near it was one of the Gorsedau’s, now dispersed, but once consisting of a great heap of stones, on which was placed the Druid whose duty it was to harangue and instruct the people when collected on any important occasion. Pennant’s Tour in Wales, vol. iii. Beauties of England and Wales, vol. xvii. by the Rev. J. Evans.

NEW BOSTON. See New Boston.

NEW BRAINTREE, a town of America, in the county of Worcester, between Rutland or Oakham on the E. and Hardwick on the W.; 21 miles N.W. of Worcester. It has 875 inhabitants.

NEW BRUNSWICK. See New Brunswick.

NEWBURGH, a royal borough, market-town, and parish, in the county of Fife, Scotland, is situated on the south bank of the river Tay. This place was very early constituted a borough of regality, by one of the abbots of Lindores, under whom charter it was governed till the secularization of the abbey by James VI. Charles I. granted the charter by which it now enjoys all the privileges and immunities of any royal borough in North Britain, except the right of voting for a representative in the national councils, and of sending a delegate to the convention of branches. The revenue of the community is very considerable, fearlessly exceeding 25 lid. per annum, but the magistracy notwithstanding make a respectable appearance. A court is held weekly, with the usual marks of dignity, and it retains a clerk for recording its public proceedings. The town of Newburgh forms one principal street of considerable length, having small suburbs at each end, and a lane leading towards the shore from its centre. Most of the houses on each side of the lane, and in the suburbs, are of late erection, as well as a great proportion of those in the main street. Hence, in consequence of alterations in such as have not been entirely rebuilt, Newburgh is capable of containing double the amount of inhabitants it could have done formerly, though it probably does not occupy a road more ground now than at the beginning of the last century. At that time the gene-

rality of the houses were low built, and covered with a thatch of straw or of reeds, but for many years a better style of architecture has prevailed, and at present the town has even pretensions to a more than ordinary degree of neatness. The chief street is excellently paved, and kept in repair by means of an assessment from proprietors within the borough. The principal employment of the inhabitants is that of weaving cloth. Acclimated in early life to handle the oar and the plough, as well as to the shuttle, they frequently betake themselves either to the sea, or to agriculture, whenever the price of the kind of cloth they are in the practice of manufacturing suffers any material depreciation in the market. Most of the persons employed in this trade weave their own yarn, and carry their own webs to market, that is to say, dispose of them to a few individuals in the town, or neighbourhood, by whom they are resold to the merchants of Dundee, Cupar, and Glasgow. Close to the borough, but independent of the jurisdiction of the magistrates, is the harbour of Newburgh, consisting of three contiguous piers, projecting into the south deep of the Tay, and of several dwelling-houses, store-houses, and other conveniences for commerce. These piers form very safe stations for the vessels employed in the trade on the river; and though none of the burdens can properly be laid to the town, and few are freighted on it, except with coal or lime, they are seldom devoid of shipping, as the generality of vessels for Perth must wait the flow of the tide here, and not a few of them unload a part of their cargoes, before they can venture up further, even with the tide. Hence arises a great deal of activity at Newburgh; and considerable quantities of grain are annually exported for Edinburgh and London.

The parish of Newburgh is comparatively of inconsiderable extent, and only deserving of notice on account of some vestiges of antiquity which it contains. Of these, the ruins of the ancient abbey of Lindores are the most noted. They are situated at the north-east extremity of the parish, on a gentle eminence, rising from the edge of the river Tay. This monastery was founded in the twelfth century, and filled with monks of the order of St. Benedict. The extent of ground occupied by the buildings of the abbey in former times cannot now be ascertained, as many of them have been completely razed to the very foundations. It was no doubt, however, one of the most superb and magnificent on the northern side of the Forth. The luxury and wealth of its ecclesiastics are strongly marked by the pans they have evidently taken, in the economy of their gardens, to secure all the delicacies of the table. Near the abbey stands the ancient manse of Lindores, once a baronial residence belonging to the family of Leslie.

The other monuments of ancient art, in this vicinity, are two cromles, one called the cros of Mugdrum, and the other Macduff’s cros. The former stands only four yards from the shore, and though much mutilated still displays remains of the figures of horses, but there is no appearance of any inscription. The latter, which is placed in an opening on the Ochil hills, and which, at present, exhibits one large quadrilateral block of free-stone, rudely indented in several places, is traditionally said to have pointed out the limits of the jurisdiction of the powerful Thane of Fife. Concerning Mugdrum cros even tradition is silent. According to the parliamentary reports of 1811, the whole parish contains 283 houses, and a population of 1951 persons. Sinclair’s Statistical Account of Scotland, vol. viii. Beauties of Scotland, vol. iv.

NEWBURGH, a port-town of America, in Orange county, New York, containing 3258 inhabitants, and consisting of between 50 and 60 houses, and a Presbyterian church,
NEW

church, situated on a gentle ascent from the river. The country to the N. is well cultivated, and affords a rich prospect. Vessels of considerable burden may load and unload at the wharfs, and many vessels are annually built, so that the place is encouraging to industry, and thriving.

NEWBURN, a parish of Scotland, in the county of Fife; eight miles S.S.W. of St. Andrew's.

NEWBURY, a large market-town in the hundred of Faircross, Berkshire, England, is situated in a fertile valley on the banks of the river Kennet, 17 miles distant from Reading, and 56 from London. Though its name implies a modern borough, it was a town of considerable importance at the time of the Norman survey, and then known by the name of Vuffels, probably a corruption of Ulwardetone, from Ulward, who pooflewed it in the time of Edward the Confeffor. Newbury was originally the name of a castle which was built by one of the earls of Perch, and this appellation might be transferred to the town instead of its ancient Saxon name. The town was incorporated in 1586 by queen Elizabeth; and is governed by a mayor, high-steward, recorder, six aldermen, and twenty-four capital burgesses. It lent two members to parliament in the 30th year of Edward I., and in the 11th of Edward III. was also represented by three persons in a great council, held on account of trade at Westminister. Extensive manufactories of woollen cloth were established in this town, and furnished the inhabitants with employment for several centuries; but the clothing business has been removed into the more well-endowed parts of the kingdom. It does not appear that the town has suffered by the removal; but on the contrary, from the influx of trade, consequent on the ready communication it now has with London and Bristol, its opulence as well as its population has been on the increase. In the year 1555, when the clothing business was at its greatest height, the number of inhabitants was 1600. The return to parliament in the year 1801 states the houses to be 605, the number of persons 4275: and by the late survey in the year 1811, the houses are returned as 1228; the inhabitants as 4858: these returns do not include the tything of Speenhamland, which is apparently part of the town, but is in the parish of Speen; and contains about 150 houses and upwards of 700 inhabitants. The town confits chiefly of three principal streets, which are spacious and well built. The old market-houfe is an ancient timber building, over which is the gaol and a town-hall: the new market-houfe is a brick edifice of modern date; above it is an assembly-room, sometimes called the new-townhall, where the corporation tranfacted their private business; the public meetings being held at the old hall. The market, which is held on Thursdays by precriptive right, is a great mart for corn, and is under excellent regulations, tending to defeat the artifices of monopolizers: four fairs are kept annually, and a statute for hiring servants.

On the banks of the Kennet, in the vicinity of Newbury, are several mills, which supply the cities of London and Bristol with great quantities of flour. The parish church of Newbury is a plain stone structure, built in the reign of Henry VIII., principally at the charge of John Winchcombe, a wealthy clothier of this town, of which he was a native. He died in the year 1519, and lies buried in the church, by the name of John Smallwood, alias Winchcombe. A brafs plate, with his effigy, was formerly placed over his tomb, but it is now fixed against the wall of the north aisle. The history of this celebrated perfon, who was generally known by the name of Jack of Newbury, is rather of a marvellous cast: he appears to have carried on the clothing business to a great extent; having an hundred looms in constant use, in his own house, for the weaving of broad cloth only. He is recorded to have affiled the king with an hundred of his men, all armed and clothed at his own expense, in the expedition against Scotland, which was terminated by the battle of Flodden Field. The building called his manufactory, is now divided into tenements, respectively occupied as a bookeller’s, a hair dreffer’s, and an inn; the latter bearing the sign of Jack of Newbury. The charitable endowments in this town are numerous; not less than sixty-alms houses being established on different foundations. One of these, called St. Bartholomew’s hospital, is said to have been founded by king John, who granted a fair for its support. It was formerly under the government of a master, warden, or prior: but is now, by charter of queen Elizabeth, vested in the corporation. The original endowment has been increased by various benefactions. In the year 1624, Mr. John Kendrick of Reading bequeathed 4000/ to provide a workhouse and employment for the poor of Newbury. Great part of this gift appears to have been lost: with a portion of it the wharf and other premises were purchased; and the remainder is lent, without interest, in sums of fifty pounds, to weavers, for three years.

In the dreadful contest between Charles I. and his parliament, Newbury became remarkable for being the scene of action in two succeeding years. The first battle was fought September 18, 1643, on a common called the Wafhe; the other in the fields between Newbury, Speen, and Shaw, October 27, 1644. Those who were killed in the first engagement were deposited beneath two tumuli near the field of battle; whilst those who fell in the second contest were interred in a large pit near Newbury church. Many vestiges of these fanguinary conflicts have, at different times, been found in the surrounding country.

About a mile north-west from Newbury is the small village and parish of Speen, a place of considerable antiquity, deriving its name from the Roman Spinæ, which is supposed to have been situated in this vicinity. Speen had formerly a market on Mondays, which was granted, in the year 1218, by William Marshall, earl of Pembroke.

At a small distance from Speen, on the north, but in the parish of Shaw, is Donnington Grove, late the seat of William Brummell, Esq. The house, which is pleasantly situated under a ridge of woody hills, was built by the late James Pettit Andrews, Esq., author of "The History of Great Britain, connected with the Chronology of Europe," and was for some time his residence.

On an eminence north-east of the Grove are the remains of Donnington castle, which was formerly a place of great importance; and by commanding the western road, gave to its possessor a considerable degree of authority. It is said to have been built by Sir Richard Abberbury in the reign of Richard II. About the year 1397 Geoffrey Chaucer, the father of English poetry, became possessor of this castle, and spent the close of his life in retirement here. From the Chaucers the castle descended, by marriage, to the dukes of Suffolk. In the reign of James I. it belonged to the family of the Packers, whose heirress married Dr. Hartley, the ancestor of Mr. Hartley the present possessor. During the civil wars of Charles I. this castle was a poll of great consequence; being fortified as a garrison for the king, and entrusted to the command of Colonel Boys, who bravely defended it during a long siege. Camden, in whose time the castle was entire, describes it as "a small, but very neat place, fronted by the brow of a woody hill, having a fine prospect, and lighted by windows on every side." The walls nearly fronted the cardinal points of the compass, the entrance being at the east end. It was defended by four round towers placed on the
the angles. The length of the east end, including the towers, was 95 feet; the extent from east to west 120 feet. All this part is destroyed; the remains consist of the stone gate-house, with its two towers, and a small part of the east wall. The gateway is in good preservation, and the place for the portcullis is still visible.

To the east of Donnington castle, about a mile distant, stands Shaw house, a large edifice, built in the reign of queen Elizabeth by Mr. Doleman, an eminent clothier, in whose family the estate continued till about the year 1727, when it was purchased by James, duke of Chandos, who sold it, in 1746, to Joseph Andrews, esq. grandfather to Sir Joseph Andrews, bart. who now possesses it.

About a mile southwest of Spen is Benlam place, a villa of lord Craven's. The house, an elegant structure of the Ionic order, was completed in 1775; it was built by Brown, under the direction of lady Craven. The lodges, at the eastern and western extremities of the park, were recently built by the margravine. Lyfons's Magna Britannia, vol. 1. Beauties of England and Wales, vol. 1.

NEWBURY, a district of South Carolina; the court-house being 45 miles from Columbia.—Alfo, a township in York county, Pennsylvania, containing 2041 inhabitants. —Alfo, a town in Lynn county, 40 miles from Northumberland.—Alfo, a poll-town and capital of Orange county, in Vermont, pleasantly situated on the W. side of Connecticut river, opposite to Haverhill, in New Hampshire, and five miles distant from it. It contains a gaol, a court-house, and a handsome church for Congregationalists, and 1304 inhabitants; 130 miles N.E. of Bennington.—Alfo, a township in Essex county, Massachusetts, incorporated in 1635, situated on the S. bank of Merrimack river, and containing 4076 inhabitants. It formerly included Newbury port, and with Merrimack river encircled it. It is divided into five parishes, besides a society of Quakers. The land, particularly on Merrimack river, called "Newbury-Newtown," is of superior quality, and well cultivated. Some few wells are here employed in the filthry. This township is connected with Salisbury by Express Merrimack bridge, about two miles above Newbury port, built in 1792.

NEWBURY Port, a port of entry, and poll-town in Essex county, Massachusetts, pleasantly situated on the S. side of Merrimack river, about three miles from the sea; ranking in a commercial view next to Salem, and containing 5346 inhabitants: incorporated into a township, consisting of 640 acres, in 1764. The churches, which are six in number, are ornamented with steeples; the other public buildings are the court-house, gaol, a bank, and four public school-houses. In this town are ten public schools and three printing-houses. Many of the dwelling-houses are elegant. The harbour is safe and capacious, but difficult of access. The buisiness of ship-building is carried on here; and a considerable trade is conducted between this place and the West Indies, as well as the Southern States. Some vessels are employed in the freighting business, and a few in the filthry. In 1790 there belonged to this port 6 ships, 46 brigantines, 39 schooners, and 28 sloops, amounting in the whole to 11,870 tons. The exports in the year ending September 1794, amounted to $63,380 dollars. A machine for cutting nails has been invented in this town, which will manufacture 200,000 in a day. In this town are a Hamane and Maple Saw-mill. The light-houses are on Plum island, in N. lat. 42° 47'. W. long. 70° 47'. Newbury port is 40 miles N.W. of Boston.

NEW CALEDONIA. See CALIFORNIA.

NEW CANTON, a small poll-town of America, lately established in Buckingham county, Virginia, on the S. side of James's river; 70 miles above Richmond.

NEW CASCO, a poll-town of America, in Cumberland county, Maine; 613 miles N.E. from Washington.

NEWCASTLE, a village of the county of Dublin, Ireland, which before the union returned two members to parliament. It is 10 miles S.W. by W. from Dublin.

NEWCASTLE, a poll-town of the county of Limerick, Ireland, which was originally founded by the Knights Templars, and became a corporation; but has been since reduced, and is now a place of little consequence. It is 114 miles S.W. from Dublin, and 20 S.W. from Limerick. There are some other villages of this name, as one near the river Inny, in the county of Longford, and one in the county of Down, on the Irish sea, but there is no occasion to enlarge.

NEWCASTLE, a town of Upper Canada, situated on the Preque' Ile de Quinte, extending into lake Ontario, from the eastern part of the township of Cramah. —Alfo, the most northern county of Delaware State, about 40 miles in length and 20 broad, containing 25,361 inhabitants, including 13,388 slaves. Here are several mills for different purposes. The chief town is Wilmingtom and Newcastle —Alfo, a poll-town and capital of the above county, situated on the W. side of Delaware river; 32 miles S.W. of Philadelphia. It contains more than 100 houses, a court-house, and gaol; a church for Episcopalians, and another for Presbyterians. This town was settled by the Swedes about the year 1627, and they called it "Stockholm." The Dutch had poiffion of it under the name of "New Amsterdam"; and the English gave it the name of Newcastle. It was incorporated in 1672. N. lat. 39° 38'. —Alfo, a township in Well Chelster county, New York, incorporated in 1791. —Alfo, a town in Rockingham county, New Hampshire, called "Great Island," consisting of about 100 houses and 334 inhabitants in 1790. It is the largest of a number of islands in the mouth of Piscataqua; two miles E. of Portsmouth. It has a meeting-house, and on the N.E. point of the island are the light-house and fort, built in 1795. —Alfo, a poll-town in Lincoln county, Maine, between Damariscote and Skungot rivers; 102 miles N.E. of Boulton. The township contains 19 inhabited. —Alfo, a poll-town in Cheshire county, Virginia; at the mouth of the Allegheny river, on the S.W. side of Panunkey river, containing about 36 houses; 54 miles N.W. of Williamsburgh. —Alfo, a town on the N. coast of the island of Neviss; six miles N.E. of Charletown.

NEWCASTLE Bay, a large open bay of the Pacific ocean, on the N.E. coast of New Holland, in which are some small low islands and shools, S. of York cape.

NEWCASTLE Island, a small island in the Florida stream. N. lat. 24° 48'. W. long. 81° 40'.

NEWCASTLE-upon-Tyne, a borough and market-town, and a distinct county by itself, is seated on the banks of the river Tyne, within the county of Northumberland, England. Julius Agricola, the general of Vespasian, established a Roman poll here about the year 80. Its appellation at this period is uncertain, but in less than half a century afterwards it was called "Pons Eliti," from the bridge built over the river by the emperor Hadrian, when he constructed his celebrated vallum, or wall, which terminated here, and has been traced passing the west door of St. Nicholas church. The rampart formed by Agricola also ran through a part of the town, and not improbably terminated near the seite of the castle, which might have been originally a Roman fort. After the evacuation of Britain by that illustrious people, the history of this place is not well known.
is very little known, though there is no doubt of its having been a town of some importance under the Northumbrian monarchs of the Saxon line. Grey, in his Chronography, says, "the town of Pampedom (now included in Newcastle) is very ancient. I find one of the kings of Northumberland that had a house in it, which we now call Pandon-hall." At the time of the conquest it occurs under the name of Monk-castle, a designation received from a number of religious foundations which had been erected in it during the heptarchy. In 1086, the castle whence the town has since obtained the appellation of Newcastle was built by Robert Curthose, a younger son of William the Conqueror, on his return from an expedition into Scotland against king Malcolm, in revenge for having afforded protection to Edgar Atheling. This structure, with its necessary appurtenances, occupied an extent of three acres, and was a fortres of great strength, having been defended by a deep fosse, and two massive walls. Only fourteen years after its erection, it was seized by the adherents of earl Mowbray, the last of the ancient line of the earls of Northumberland, who had revolted against William Rufus. That prince, laying close siege to it, however, with a strong force, soon compelled the garrison to surrender. In the time of Henry II. the great tower of the castle underwent considerable repairs. At the same period, also, the fortifications were much strengthened and augmented; and the whole fitted up as a royal residence. John Balliol did homage in the great hall to Edward I. for the crown of Scotland; and David Bruce was long detained a prisoner here, under the charge of John Copeland. Twelve of the ancient Northumbrian barons paid castle-guard rents and cornage to this fortres, being the tenures by which they held their lands. These were abolished, together with the tenures by knights’ fees, in the reign of Charles II. From 1603 to 1616, the castle appears to have been in the possession of the worshipful company of tailors, and in 1618 it was granted to Alexander Stevenen, one of the pages of the king, on a lease for fifty years; but this was afterwards purchased by the corporation. Sir John Morley, mayor of the town in 1644, garrisoned this edifice in support of the parliamentary cause, and withstood a very desperate siege against the Scots army, commanded by the earl of Callender and general Levin. Since that time it has gradually fallen to decay. Of the outer wall nothing remains but the principal entrance, called the Black Gate; the inner wall was entirely demolished in 1811. The great tower, a massive square structure, is standing: it is about eighty feet high, and its exterior walls measure near fourteen feet in thickness. There are no fire-places in any part of this edifice, except in a few small rooms, apparently gained out of the walls in later times. The dungeon has been used, for time immemorial, as the county prison during the affizes. A very bold and spacious circular flanary ascends to the summit of the tower, and adjoining, on the east side, is a chapel of most beautiful and curious architecture. The corporation lately purchased this building, and intend to throw an arched roof over it, and to pull down all the old houses built against it.

In ancient times, the town, as well as the castle, was fortified by a strong wall and ditch. In the reign of Edward I., a rich citizen of Newcastle was carried off from that town into Scotland, and being at last ransomed, he began to enclose Newcastle with a very firm wall, and the rest of the inhabitants following his example, he finished the undertaking in the reign of Edward III." This wall had seven massive gates, and seventeen round towers, with smaller watch-towers in each interval between them; but all the gates are now levelled, except two, the "West Gate and New Gate." Leland calls the West Gate "a mighty strong thickness of four wards and an iron gate;" and speaking generally of the wall, he adds, "the strength and magnificence of the mailling of this town from palfeth of all the walls of the cities of England, and most of the towns of Europe." Above the West Gate is the hall of one of the incorporated companies; New Gate is occupied as the town prison.

The rise of Newcastle to eminence as a borough seems to have taken place gradually. William Rufus granted the inhabitants some privileges, which were considerably augmented by Henry I. and John. At this time it was governed by bailiffs only; but in 1251 a mayor was appointed. In 1400 the town was first constituted a county by itself, at which period a sheriff and six aldermen were substituted for the bailiffs. A recorder, eight chamberlains, two coroners, a sword-bearer, a common clerk, and eight sergeants at mace, were added in 1516; and in 1559 the aldermen were increased to ten, and the twenty-four electors constituted a common-council. The powers of justices were conferred on the mayor, the aldermen, and recorder, by queen Elizabeth; and King James I. generally confirmed these, and all the former privileges enjoyed by the corporation. Newcastle lends two members to parliament, who are chosen by the free burgesses resident and not resident, and returned by the sheriff. The number of voters is estimated at 2500.

This town abounded with religious establishments after as well as before the conquest. In 1086 a Benedictine monastery was mentioned as existing here, in which Agas, the mother-in-law of Malcolm, and Christiana her sister, took the veil subsequent to the death of that prince, and his son, at the siege of the castle of Alnwick. Another monastery, dedicated to St. Bartholomew, and said to have been founded by Henry III., stood in the field behind the present Nun-gate. At the dissolution it was exceedingly poor, though originally possessed of large estates. The house of the Black Friars is still standing; as is also the church belonging to it, in which Edward Balioi alienated to Edward I. the five Scottish counties next adjoining to the borders of England. This house was granted to the mayor and burgesses, who afterwards transferred it to nine of the ancient trades of the town, seven of whom hold their public meetings in it to this present day. The priory of Augustinian friars, which stood on the site of the general hospital, owed its origin to William lord Rofs, baron of Wark, about the year 1291. It was of great extent and magnificence, and the usual residence of the kings of England, when passing through Newcastle on their route to Scotland. Here was a priory of Franciscans, or Grey friars, established in 1300 by the family of the Carlisles. In this monastery the celebrated Duns Scotus and friar Martin took the order of St. Francis, and refided during many years. In that part of the town called Confable-Garth was a house of brethren of Penitentia (a Carthusian), subsequently granted by Edward III. to the Carmelites, who had their first house on Wal Knoll, where was also an hospital of Trinitarians, founded by William de Acton in 1361. The grammar-school at Weftgate was formerly the church of an hospital of St. Mary, founded and endowed in the time of Henry II. Near this spot stood another hospital, also dedicated to the Holy Virgin, which at the suppression maintained a master and six brethren. An hospital of St. Mary Magdalen was situated between Vine-lane and Barras-bridge, where many velliges of it are yet visible. It was built and endowed by Henry I. for a master, brethren, and fitters, who were bound to receive persons afflicted with the leprosy. King James incorporated this
this hospital, with the chapel of St. Thomas à Becket, on
Tyne-bridge, and decreed that the revenues of both should
in future be appropriated to the support of a warden, and
three poor, and aged, unmarried burgesses; and that the
mayor and common-council should act in the capacity of pa-
trons. On Sand-hill was an hospital of St. Catharine,
commonly called Thornton's hospital, having been founded
by Roger Thornton, in 1403, for a chaplain, who should
also be master, nine poor men, and four women. This
house is now occupied as a warehouse, and is the property of
the mayor and burgesses. Fordun, and some other
Scottish historians, assert that there was in this town a mo-
nastery of Premonstratensians, founded by David, king of
Scotland. An ancient house in Grindon Chare, traditionally
called the chapel of St. John, is supposed to have been
their convent. On St. Lawrence's quay are the ruins of a
chapel, in honour of St. Lawrence, which was erected
by one of the earls of Northumberland; and near Barras-bridge
are the remains of another, dedicated to St. James. There
was also, before the Reformation, a chapel or oratory in
the town. The present church of Newcastled bridge, and in another part of
it a hermitage tenanted by a recluse. Close to one end of
Tyne-bridge is the chapel of St. Thomas à Becket, the ori-
gin of which is unknown, though certainly built before the
commencement of the thirteenth century. It has lately
been fitted up as a chapel of ease to the church of St. Ni-
cholas.

Newcastle is a town of considerable extent, and con-
tains, according to the popular returns of 1811, 31,46
houses, and 27,587 inhabitants. The larger parts of it,
which are most distant from the river, display a number of wide and re-
spectable streets, but in the lower parts, the streets and alleys are extremely narrow, dirty, and ill built.
The suburbs of Sandgate and the North-shore are chiefly
inhabited by the keelmen, who amount to about seven or
eight thousand in number.

The county of Newcastle includes a district of ten miles
in circuit, and is entirely independent of Northumberland.
Within the town are four parishes, the limits of which were
differently marked out in 1210. All the churches and chap-
els are subject to the mother-church of St. Nicholas. This
edifice is much admired for the elegant architecture of its
tower, which was built in the reign of Henry VI, and
risestothe height of 194 feet. The remainder of the struc-
ture is of more ancient date, having been erected, in 1359,
upon the site of one still older, founded by Osmund, bishop
of Sarum, and burnt to the ground in 1216. In the library
of this church are several curious manuscripts, and among
them a highly illuminated bible, formerly belonging to
Hexham abbey. The other parish-churches in Newcastle are
St. Andrew's, St. John's, and All Saints: the two first were
built in the 13th century, but the last is of modern erection,
and may vie with any church in England in respect of in-
terior decoration. Besides these, there are several chapels
attached to the establishment. Dissenting meeting-houses
are numerous, almost every clafs of religionists known in
the island having one or more places in this town appro-
priated to public worship. The most frequent are those be-
longing to Presbyterian communion with the church of
Scotland. The grammar-school, already noticed as oc-
pupying the premises of St. Mary's hospital, can rank among
its pupils some of the most distinguished characters of this
and the last century, several of whom were likewise natives
of the town. A charity-school is attached to each of the
four churches, and a fifth to the chapel of St. Anne. Sun-
day-schools are scarcely less numerous than the several places
of public worship; and independent of all these, a large
building has been lately erected for the establishment of a
school on the Lancasterian plan, where poor children of every
sect and denomination may be instructed in reading, writing,
and arithmetic. This left is called the Royal Jubilee school,
and was built to commemorate his majesty's entry into the
fiftieth year of his reign. Nor is the health and support of the
poor lefts attended to in Newcastle than their education.
On the west side of the town, and overlooking the river, stands
an infirmary, in which nearly twelve hundred diseased indivi-
duals are annually restored to health; and in Low Friar-
street is a dispensary, established upon the most judicious
and liberal principles. A house of recovery for fever pa-
tients was erected in 1834. All these charities owe their sup-
port to annual subscriptions alone. In an extensive garden,
near Weitgate, a range of very commodious baths was built
by Dr. Hall, some years ago, according to a design ter-
nrnished by William Cranefon, esq. architect. The Lyng-in-
hospital is situated in Kofemary lane; and there is likewise
an institution for the relief of poor women living in at their
own houses. The other hospitals in this town are the
Freemen's hospital, three smaller ones, standing contiguous
to it, and the Keelman's hospital, the funds of which are
managed under the direction of an act of parliament,
passed in 1788. Here is also a spacious asylum for luna-
tics, belonging to the counties of Newcastle, Durham, and
Northumberland.

As the new courts, begun in 1810, are not yet completed,
the exchange and town court-house still constitute one large
structure, which was built in 1658, and is said to have cost
upwards of 10,000l. The lower floor is occupied by the
offices of the town-clerk, the merchant's coffee-house, and a
range of piazzas. On the second floor are the guildhall,
the mayor's chamber, the merchant's court, the archives of
the town, and the revenue-office. In the guildhall are held
the aldermen, quarter-assizes, and all the other courts of
the town and county of Newcastle, except the court of com-
mon council, which is held in the mayor's chamber, where
may be seen an engine called the brackets, formerly employed in
the punishment of scolding women. The manfon-house,
rebuilt in 1691, is a grand and stately edifice, and fitted up
in a handsome style. Here the judges and their attendants
are lodged and entertained during the sessions. The assem-
bley-rooms and theatre-royal are both handsome and com-
modious buildings of modern erection. The old play-house
is now occupied as a concert-room; and the old assembly-rooms
are appropriated to the use of the Literary and Philosophical
Society, which was instituted in 1793; and bids fair to rival
the best establishments of a similar kind in the kingdom.
On the quay-side, at a short distance from the Exchange,
stands the custom-house.

The general appearance of this portion of the town bears
a strong resemblance to the port of London, in the circum-
tances of the river being crowded with a vast fleet of ships
of every fize and description, and having a bridge thrown
over it in a similar position to London-bridge. This struc-
ture was built in 1781, to supply the place of a former
bridge, which was destroyed by a tremendous swell of the
Tyne in 1771, and was found to have been ruined on the
basis of the Pons Ælii, from the number of Roman coins
discovered in the piers. For an account of the borough of
Gateshead, on the Durham side of the river, see the article
GATESHEAD.

The manufactories of this town are various and important,
confiding, however, principally of glass, steel, iron, and
rope-works. Broad and narrow woollen cloths are likewise
manufactured.
history and antiquities of the town and county of the town of newcastle, by john brand, m. a. two vols. 4to.

beauties of england and wales, vol. xii. by the rev. mr. hodgson.

newcastle-under-line, a borough and market-town in the hundred of pyrehill, and county of stafford, england, is situated on a branch of the river trent, and owes its name and origin to a castle built here by edmund, earl of lancaster, in the reign of henry iii. this edifice stood in the centre of a considerable lake, being on the south-west side of the town, but scarcely any vestiges of it now remain. leland says the whole was destroyed by fire in his time, with the exception of one tower, and that it was originally erected to supply the place of the more ancient forfests at cheffield-under-line. hence the appellation newcastle. this town was incorporated, by royal charter, soon after its foundation; and queen elizabeth and charles ii. severally confirmed its privileges. it is now governed by a mayor, two justices, two bailiffs, and twenty-four common-councillors, who have the right of holding courts for the recovery of debts under forty pounds. newcastle sends two members to parliament, and has done so since the twenty-seventh year of the reign of edward iii. the right of election has been much disputed, but was declared, in 1702, to be vested in "the freemen residing in the borough of newcastle-under-line."

the situation of the town is extremely pleasant, and the houses display a superior neatness in their architecture, as well as a more than ordinary degree of uniformity in their arrangement. the principal street in particular is spacious and well paved, but its appearance is somewhat injured by the market-place occupying its centre. it is said there were anciently four churches in this town, though one only now exists, and this is denominated a chapel to stoke. differing meeting-houses, however, are numerous. the almshouses, twenty in number, owe their erection to the marquis of stafford and lord grenville, and are appropriated for the accommodation of twenty poor women, inhabitants of the borough. a manufacture of hats, the coal and clothing trade, and the pottery in the vicinity, form the chief support both of the higher and lower orders of the inhabitants. the market-day is on monday, weekly, for provisions; and every alternate week a great cattle market is held. according to the parliamentary returns of 1811, this town contained 1344 houses, and 6175 inhabitants, showing an increase, since 1801, of 256 houses, and 1771 persons.

as the grand trunk canal, which directly connects the navigation of the trent, the mersey, the severn, and the thames, with, collaterally, almost every trading town in the interior, passes close to newcastle, its position must be regarded as extremely favourable to trade and manufactures. its vicinity, moreover, abounds with coal, and contains an exhaustible store of several kinds of clay, admirably adapted for the manufacture of various sorts of earthen-ware; and accordingly here are situated the most extensive and valuable "potteries" in great britain. the district comprehended under this title is somewhat above eight miles in length, and nearly as many in breadth, including within its compass several thriving market-towns and villages, which owe their rise and prosperity to this branch of industry. (see pottery.) the principal coal mines lie to the north of newcastle, and their produce is conveyed hither by a canal formed by sir niguel greally, under an act of parliament dated in 1755. eturia, the superb manuf. of the celebrated jofas wedgwood, esq. stands about two

manufactured in considerable quantity for home consumption. the chief exports are coals, lead, glases, iron, salt, bacon, butter and tallow, and the imports include almost every article of foreign or british produce, which convenience or luxury can demand. the collieries in this vicinity are perhaps the most valuable and extensive in europe, and afford nearly the whole supply of the metropolis, and of three counties on the eastern coast deficient in coal-tracts. (see the article coal.) most of the glases-houses and potteries belonging to the town stretch along the shore, from the suburbs, for two miles down the river. the chief iron-works are situated at swalwell, three miles above the town, and at new greenwich, on the south bank of the river. the markets here are held on tuesday and saturday weekly, and the annual fairs on the 12th of august, the 29th of october, and the 22d of november. of the fairs, the two first continue for nine days each, and the other for only one. many improvements have lately been effected in the disposition and economy of the markets; which range northwards from the church of st. nicholas towards newgate-street. the new butcher-market was erected at the expense of the corporation in 1809.

besides the historical events already noticed, as connected with the castle, many others of general importance have occurred at this town, some of which may not improperly claim attention, even in an article like the present. a conference for a peace was held here, in 1209, between king john and william king of the scots, but the two monarchs parted without coming to a reconciliation. the meeting, however, in 1244, between henry iii. and alexander, was more fortunate in its result. william wallace, the celebrated champion of scottish liberty, repeatedly attempted to reduce newcastle, and was as often repulsed by the resolution of the townsmen. king david attacked it about the year 1340 with no better success, and in 1346 a dreadful action took place, in which the scots were routed with great slaughter. henry vi. fled hither after the fatal battle of towton. newcastle was the first victim in the grand rebellion, having been besieged by the scottish covenanters, under general lefley, in the year 1640, a few days subsequent to the defeat of lord conway at newburn.

heaton hall, situated about two miles east from newcastle, is the seat of the family of the biddies; and near it are the ruins of an old building, fortified on the north, and said to have been one of the places of king john's retreat from the fury of his rebellious barons. walls-end, the segedunum of the romans, lies still farther to the east; and derives its present appellation from the circumstance of the great stone barrier erected by hadrian terminating close to the village. some remains of the roman fortresses appear in a field called the well or wall-laws. in finding the pits of the colliery here, many curious and valuable relics of roman art were dug up by the workmen. at benwell, two miles west from newcastle, was the condereum of the norttis, and the location of the ala altorum. a hypocaust, a very fine urn (now in durham library), and a variety of inured bones and coins, were discovered here at different periods in the last century. gosforth house, the seat of c. j. brandling, esq., is a splendid mansion, situated about four miles north from the town. the other seats in this neighbourhood are stoke hall, eland hall, their stoke hall is the ancient residence of the ogers, in which david, king of scots, lay the first night of his captivity, is now in ruins. not far from hence, adjoining the village of walton, are the remains of a very remarkable encampment, supposed to be of danish or saxon origin.
two miles north from the town; and nearly at the same distance, but more to the east, in the village of Shelton, the birthplace of Eliah Fenton, a distinguished poet of the last century, Chester-under-Lyne, the site of the ancient fortress, the decay of which gave occasion to the erection of that at Newcastle, is now a trifling village, but there can be no doubt of its having been a place of importance previous to the event we have just mentioned. Scarcely any traces either of the castle or town can now be discovered, but Camden tells us he saw their ruins and shattered walls; and Erdecliffe says, he could perceive the walls had been of wonderful thickness and strength. In the reign of king John, the property of the manor here, and consequently the custody of the castle, were vested by that monarch in Randal, one of the ears of chefter, from whom it most probably took its present name, for we conceive it very likely that it had a different appellation at a more remote period.

At Trentham, three miles and a half from Newcastle, on the south bank of the river, is a magnificent feat, belonging to the marquis of Stafford. The house is a modern erection, as well as the magnificent park of which it forms a part. The grounds of the Garden of St. James's, London, at an extremity of Trentham-park, bordering on the public road, is a family mausoleum, lately erected from the classical designs of J. H. Tatham, esq. architect. Some further particulars of this splendid feat, and of others in the vicinity, will be given in a subsequent account of the town of STONE. In the village of Trentham stood an ancient nunnery, where St. Werburgh, the sister of king Ethelred, was absolved at the time of her death, A.D. 683. This monastery, having fallen to decay, was restored by Randal, second earl of Chester, in the reign of Henry I. and filled with canons of the order of St. Augustine. After its renewal it was dedicated to the Virgin Mary, and All Saints, and at the period of the Reformation St. John's, a collegiate church, had been re-established at Stone, and presented with lands and other properties for the support of its new members, by the earl of Chester, for the amount of 12 l. s. 2d. per annum. The petty feoffcies for the northern division of the hundred of Pyrchill are held here. Beauties of England and Wales, vol. xiii. by the Rev. Joseph Nightingale. See also Carlile's Topographical Dictionary of England, 2 vols. 4to. Tanner's Nottitia, and The Topographer, 4 vols. 8vo.

NEWCASTLE-in-EMLY, a small market-town, is situated partly in the hundred of Elved, and county of Caernarthen, and partly in the hundred of Twedyr-Aur, in the county of Cardigan, South Wales. It is pleasantly situated on the banks of the river Teifi, which meanders along the vale here in a very bold and serpentine course, and adds greatly, by its majestic sweeps, to the charms of the surrounding scenery. The approach to the town lies through an arched gateway, about fourteen feet high, and supported by two octagonal pillars, which contributes also to enhance the romantic and picturesque view beyond it. Here are the ruins of a castle originally founded at a very remote period, and subsequently rebuilt by sir Rhys ap Thomas, who made it one of his principal fefts. Some coins and other relics of a Roman station are said to have been discovered in this vicinity, and the country around exhibits several encampments of different forms and sizes, some of which were doubtless either constructed or altered by the Romans. The market day in this town is Saturday in every week, and there are six fairs during the year. Carlile's Topographical Dictionary of Wales, 2 vols. 4to. See also Evans's Tour in Wales.

NEWCHESTER, a township in America, in Crafon county, New Hampshire, on the W. side of Penmawaff river, incorporated in 1778; 13 miles below Plymouth.

NEWCOME, William, in Biogrophy, a learned Irish prelate, was the second son of the Rev. Joseph Newcome, who enjoyed preferment in England, as well in the county of Bedfordshire as in Berkshire. The subject of this article was born at Barton-le-Clay, in Bedfordshire, on the 10th of April, 1725, O. S. He was educated at the grammar-school at Abingdon, and became greatly distinguished among his contemporaries. In 1745 he was elected to a scholarship of Pembroke college, in the university of Oxford: here he took his degrees with much reputation, and being intended for the clerical profession, he paid every attention in his power to those studîes that would enable him to fulfill the sacred character of a Christian minister with respectability. After this he became fellow and tutor of Hertford college, and among other pupils placed under his care were lord Henry Seymour and the late right hon. Charles James Fox (see his article, vol. xvi.), who always cherished a warm respect for his person and memory. It was at Hertford college that he met with an accident which occasioned the loss of his left arm. In the year 1765 he took his degree of D.D., and was appointed chaplain to the earl of Hertford, then lord lieutenant of Ireland; and in the following year he was nominated to the see of Droome. In this situation he continued about nine years, discharging, with great fidelity, the duties of the episcopal office, and by his affliction, prudence, and moderation, securing the respect of all parties, and of all religious persuasions. Shortly after he had obtained this bishopric he married an English lady, by whom he had a daughter, and on the death of this lady, in a few years, he married a second time, and had several children. In the year 1775, Dr. Newcome was translated from Droome to the bishopric of Oiory, and in this period he began to arrange the papers that he had composed, as the Transactions, the remains of the Transactions, which he afterwards gave to the world. The title of these publications was entitled "An Harmony of the G-sîps, in which the original Text is disjosed after Le Clerc's general manner: with such various Readings as have received Wettin's Sanction, &c." To this work his lordship subjoined observations to settle the time and place of every transaction, to establish the series of facts, and to reconcile seeming inconveniences. The bishop adopts the notion that our Lord's ministry was of more than three years and a half duration, and with this view he divides his Harmony into seven parts. 1. The history before the public ministry of Chrift, including thirty and a half years. 2. The transactions of about six months, from Jesus's baptism till the beginning of the enlisting of the war. 3. The transactions of twelve months, from the beginning of the first war. 4. The transactions of another twelve months, from the beginning of the second war. 5. The transactions of a third twelve months, from the beginning of the third war. 6. The transactions of three years, from the day on which the fourth war was killed, to the end of the month before the resurrection. And 7. The transactions of forty days, from the day of the resurrection to the ascension. See the article PERELEY, in which a different theory and arrangement will be given. Dr.
Dr. Newcome, in the year 1779, was translated to the fee of Waterford, and in the following year he entered into a vindication of the work just spoken of, in a tract entitled "The Duration of our Lord's Ministry particularly considered," which was replied to by Dr. Priestley; and Dr. Newcome published a second tract on the same subject. In the year 1782, he published "Observations on our Lord's Conduct as a Divine Instructor, and on the Excellence of his Moral Character." Three years after this, he rendered an acceptable service to biblical scholars, in a thin quarto, entitled "An Attempt towards an improved Version, a metrical Arrangement, and an Explanation of the Twelve Minor Prophets." "One design," says his lordship, "of engaging in the present aridous province, was to recommend, and, in a small degree, to facilitate, an improved English version of the Scriptures; than which nothing can be more beneficial to the cause of religion, or more honourable to the reign and age in which it was patronized and executed. The reasons for its expediency are, the mistakes, imperfections, and many insidious obscurities of our present version; the accession of various helps since the execution of that work; the advanced state of learning, and our emancipation from slavery to the Maforetic points, and to the Hebrew text as absolutely uncorrupt." His lordship gives a series of fifteen rules for the conduct of such a work, which are allowed by all competent judges to be extremely valuable and important. In the year 1788, the bishop published "An Attempt towards an improved Version, a metrical Arrangement, and an Explanation of the Prophet Ezekiel." In a very admirable preface to this work, and on other occasions, Bishop Newcome recommends most earnestly the cultivation of the Hebrew language, on account of the vast importance of the treasures which it unfolds. "The venerable books written in Hebrew are indeed highly curious and instructive, apart from religious considerations. The historian, the geographer, the chronologer, the antiquarian, the naturalist, the poet, the orator, the legislator, the observer of human nature in its original simplicity, of the sources whence nations sprang, of society in its earliest stage, and of ancient Eastern manners in their only genuine representation; will here find their researches amply rewarded, no less than the divine who raises his eye to the adorable ways of Providence in the religious and civil history of mankind." And the worthy prelate adds, that "Such a vein of Hebrew runs through the writings of the Old Testament, that even these divine oracles cannot be accurately understood, nor the anomalies of their style explained, without some knowledge of Hebrew literature." Another important work given to the public by our learned prelate, was entitled "An historical View of the English biblical Translations; the Expediency of revising, by Authority, our present Translation; and the Means of executing such a Revision." In January 1795, Dr. Newcome was translated to the archiepiscopal see of Armagh; and in this new situation he maintained the same character which had rendered him the object of universal respect and esteem at Dromore, Offory, and Waterford, though he was obliged to assume greater state in his manner of living and appearance, and to mix more in public life, than was agreeable to his wishes, but he conducted himself in those scenes with the same propriety which governed him in all his intercourse with the world, rejoicing when he was enabled to withdraw from them to the enjoyment of domestic happiness and the pursuit of his studies. Shortly after his elevation to the archiepiscopal, he published "A Charge," in which he calls the attention of the clergy to a very important, and at that time much neglected, part of the pastoral care, that of oc- casional and private instruction, pointing out the manner of communicating instruction to different descriptions of persons. This charge was the last publication of Dr. Newcome, who, to the regret of all that knew him, or were acquainted with his works, died at Dublin on the 11th of January, 1820, in the 71st year of his age. Soon after the archbishop's death was published his "Attempt towards revising our English Translation of the Greek Scriptures, or the New Covenant of Jesus Christ, &c." This work, which was printed in 1796, and referred by the author for publication after his death, has been made the basis of an "Improved Version of the New Testament, published by a Society for the Promotion of Christian Knowledge, &c." much to the mortification, as we have heard, of some of the archbishop's relatives. The archbishop had employed a considerable portion of his time on an "Attempt towards revising our English Translation of the Hebrew Scriptures," and he bequeathed his interleaved Bible, in four volumes folio, containing the refult of his labours, to the library at Lambeth-palace. We understand from the article in the General Biography, to which we have been greatly indebted for the foregoing facts, that there exists somewhere in Ms. a memoir of the archbishop drawn up by himself, and in his own hand-writing, in which he gives an interesting account of the progress of his studies, and of the sentiments relative to the characters and opinions which have occasioned much discussion in the theological world.

NEWCOMEN, MATTHEW, a nonconformist divine, who was ejected from the living of Dedham in Essex in 1662, was of St. John's college, Cambridge, where he took his degree of M.A. He was likewise a member of the Welfington assembly of divines, and had some concern in drawing up their catechism. Mr. Newcomen was one of the five persons who wrote "Smeitynnum," which was a treatise against bishop Hall's Vindication of Episcopacy. The title of the work was made up of the initials of the christian and surnames of the several authors, viz. Stephen Marshal, Edmond Calamy, Thomas Young, Matthew Newcomen, and William Spirtlow. After Newcomen was ejected for his adherence to conscience, he went to Leyden, where he died, in 1666.

NEW CORBUDA, in Geography, a town of the province of Tucuman, in South America.

NEW DUBLIN, a township in the county of Lunenburg, Nova Scotia, on Mahone bay, first settled by Irish and afterwards by Germans.

NEW EDINBURGH, a new settlement in Nova Scotia.

NEWEKLOW, a town of Bohemia, in the circle of Beraun; 17 miles S.E. of Beraun.

NEWEL, in Architecture, the upright post which flairs turn about; being that part of the staircase which sustains the flairs.

The newel is, properly, a cylinder of stone, which bears on the ground, and is formed by the ends of the flairs of the winding-stairs.

There are also newels of wood, which are pieces of timber placed perpendicularly, receiving the tenons of the flairs of wooden flairs into their mortises, and wherein are fitted the tahoos and reeds of the staircase, and the flights of each story.

NEWELL, in Geography, a town of Lithuania, in the palatinate of Bresca; 24 miles S.W. of Pinsk.

NEW ENGLAND. See New England.

NEW ENHAM, CAPP, the north point of Brifton bay, on the N.W. coast of North America. N. lat. 58° 42'. W. long. 162° 24'.

NEWEST,
NEWENT, a small market-town in the hundred of Botloe, and county of Gloucester, England, is situated nine miles from the city of Gloucester, and 108 miles from London. Its original appellation, according to Leland, was New Inn, from a building erected for the accommodation of travellers, when the communication was first opened by this road into Wales. The town is irregularly built, and is but of little importance; though formerly it was much larger, and had the privileges of a borough; it was also governed by a bailiff, whose office appears to have fallen into disuse about the end of the 17th century. A house, now dilapidated, still bears the name of the Booth-hall. The church is a spacious structure, of the architecture of various periods; as it appears to have been three times partially rebuilt. Over the porch is a tower, terminating in a lofty spire, erected, with the roof of the nave, about the year 1675: the latter is supported by screws without pillars, in a manner similar to that of the theatre in Oxford. The population returns of the year 1811 state the inhabitants of Newent as amounting to 2538, the number of houses to 511. Four fairs are annually held here, and a weekly market on Fridays. The town and its vicinity were distinguished by many military transactions during the civil wars. The parish, which includes a circumference of nearly twenty-five miles, produces great quantities of coal; two pits have been recently sunk; the thickness of the seam is between four and five feet; the depth to the coal about forty-one yards.

An alien priory was founded in this town, soon after the Norman invasion, by Roger de Montgomery; at whose request it was subjected by the Conqueror to the Benedictine abbey of Cormeille in Normandy. King Henry IV granted its privileges to the collegiate church of Fotheringhay in Northamptonshire, to which they continued annexed till the dissolution. On the site of this priory the court-house was built: an ancient gateway, and some smaller fragments of the monastic building, yet remain. Rudge's History of the County of Gloucester, 2 vols. 8vo. 1803. Beauties of England and Wales, vol. v.

NEWFORD, a small island in the North sea, near the E. coast of Lewis, N. lat. 55°. W. long. 6° 22'.

NEW-FANE, the chief town of Windham county, in Vermont, America, situated on the West river; 12 miles N.W. of Brattleborough, containing 1000 inhabitants.

NEW FOREST. See Forest.

NEWFOUNDLAND, an island in the Atlantic ocean, separated from the continent of America by the straits of Belleisle, about 27 miles wide, and the gulf of St. Lawrence, about 320 miles in length and breadth, approaching to the shape of a triangle, and situated between N. lat. 46° 40' and 51° 30', and W. long. 52° 31' and 59° 40'. This island is rather hilly than mountainous. The soil is rocky and barren. The coals are subject to fogs, supposing by some to be owing to the superior warmth of the gulf stream from the West Indies, and also to snow and frost; and the interior parts, which have not been penetrated above 30 miles, abound with ponds and marshes. It is watered, however, by several rivers, and has many large and good harbours; and it furnishes a supply of birch, malt pine, and fir, which may probably, with due attention, be of service for masts, yards, and lumber of all sorts for the West India trade; but the chief mine of its wealth is the fishery on its banks, which is computed to employ annually 3000 fall of small craft, and 100,000 persons, and to yield about 300,000 lb. a-year, from the cod fish to be caught in Catholic countries. For an account of its fishery, see the article Fishery. The chief towns of this island are, St. John in the S.E., Placentia in the S., and Bonavista in the E.; but not above 1000 families remain here during the winter. In the spring a small squadron is sent to protect the fisheries and settlements, the admiral being also governor of the island, as its sole importance depends upon the fishery; and there are two lieutenant-governors, one at St. John's and another at Placentia.

This island was discovered by John Cabot in 1497; but the French seem to have first availed themselves of the gold mine of the Newfoundland fisheries, in which they were actually engaged in the year 1534. In 1585, Sir Humphrey Gilbert, brother-in-law to Raleigh, made an attempt to settle this important colony; but he was obliged to return without effecting his purpose, and he was swallowed up by the ocean in his voyage homewards, retaining to the last his love of improvement and his piety; for whilst in the midst of danger he was fitting unmoved in the stern of his ship, with a book in his hand, he was frequently heard to say to his companions, "Courage, my lads, we are as near heaven at sea as on land." After several subsequent efforts for making a settlement in this island, and disputes with the French, who had possession of Placentia, and a principa part of the island, it was ceded to England by the treaty of Utrecht in 1713, the French being allowed to dry their nets on the northern shores; and by a treaty in 1763, they were permitted to fish, under certain limitations, in the gulf of St. Lawrence, and the small islands of St. Pierre and Miquelon were ceded to them. For further particulars, see Cod Fishery.

NEW FOUND MILLS, a place of America, with a post-office, in Hanover county, Virginia; 112 miles from Washington.

NEW GARDEN, a post-town of America, in Chester county, Pennsylvania.—Also, a settlement of the Friends, in Guildford county, North Carolina.

NEW GENEVA, a post-town of America, in Fayette county, Pennsylvania, on the S. side of the Monongahela, in which is a manufactory of glass bottles and bucklets. In its vicinity is found plenty of iron ore and coal. Here is a post-office, 230 miles from Washington.

NEW GERMAN TOWN, a post-town of America, in Hunterdon county, New Jersey; 48 miles N.W. of Brunswick.

NEW GLOUCESTER, a small post-town of America, in Cumberland county, Maine; 146 miles N. of Boston; incorporated in 1774, and containing 1553 inhabitants.

NEW GOTTINGEN, a town of America, in Burke county, Georgia, on the W. bank of Savannah river; about 18 miles E. of Waynecoford.

NEW GRANADA. See New Granada.

NEW GRANTHAM, a township of America, in Cheshire county, New Hampshire, incorporated in 1761; about 15 miles S.E. of Dartmouth college.

NEW HAMPSHIRE, one of the United States of America, extending 168 miles in length, 90 in its greatest, and 15 in its least breadth, between 43° 41' and 43° 36' N. lat., and 2° 11' and 4° 29' E. long. from Philadelphia; bounded N. by the province of Lower Canada, E. by the district of Maine and the Atlantic ocean, S. by Massachusetts, W. by the western bank of Connecticut river, and containing 9491 square miles, or 6,074,240 acres, of which at least 100,000 acres are water. This state is divided into 214 townships and townships and locations, most of which are about six miles square. The names of these counties, their chief towns, and number of inhabitants, in 1800, were as follows:

County,
The principal harbour for ships in this state, which has but about 15 miles of sea-coast at its S.E. corner, is the entrance of Piscataqua river. The more remarkable high lands do not appear nearer to the sea than about 20 or 30 miles. The first ridge is denominated the Blue Hills, which pass through Rochefelt, Barrington, and Nottingham, beyond which are several higher detached mountains. The third ridge consists of higher mountains, of which the principal are Chocorua, Offsay, and Kyafarage. Beyond these is the lofty ridge which divides the branches of Connecticut and Merrimack rivers, denominated the height of land. In this ridge is the celebrated Monadnock mountain; and 30 miles N. of this is Sunapee; and 48 miles farther is Mooffehillock mountain. This ridge is then continued northerly, dividing the waters of the river Connecticut from those of Saco and Amificoggins. Here the mountains rise much higher, the most elevated summits of which are the White mountains. The lands west of this ridge, bordering on Connecticut river, are interspersed with extensive meadows or intervals, rich and well watered. Five of the largest streams in New England receive more or less of their waters from this flat; these are Connecticut, Amificoggins, Saco, Merrimack, and Piscataqua rivers. The principal lakes in this flat are, Winnippegus, Umbagog, Squam, Sunapee, Great Offsay, and Maflapecick pond. The soil in New Hampshire is very various; the most valuable is that which lies contiguous to the larger rivers, because it is annually overflowed, and thus enriched; lands of this kind yield wheat, and other kinds of grain, in the greatest perfection; but they are not so good for pasture as the uplands of a proper quality; apples and pears are the most common, and the principal fruits cultivated in this flat. The chief business of the inhabitants is agriculture. Beef, pork, mutton, poultry, wheat, rye, Indian corn, barley, pult, butter, cheese, flax, hemp, hops, eucalptus plants, and roots, may be produced in great abundance in New Hampshire. The principal articles of export from this state are pine-boards, oak-planks, flaxseed, clap-boards, tallow, hoops, barns, rafters, pine and oak timber, masts, spars, hookey, hogheads, sills, dried and pickled, whale-oil, tar, flaxseed, beef, corn, oxen, and cows, horSES, sheep, New England rum, bricks, pot and pearl-ashes, &c. The total value of exportation for the years 1798 and 1799 was 723,342 dollars. The import consists of West India rum, gin, molasses, wine, porter, sugars, tea, coffee, cotton, cheese, nails, cordage, twine, salt, tea-coal, hemp, lead, and grind-flours. The amount of shipping belonging to New Hampshire in 1798 was 49,240 tons. The people in this country generally manufacture their own clothing, and considerable quantities of tow-cloth for exportation. The other manufactures are pot and pearl-ashes, maple sugar, bricks and pottery, and some iron.

By an act of assembly in 1792, a bank, under the style of the "Bank of New Hampshire," was established at Portsmouth, to continue 50 years, under the management of a president and seven directors. The number of inhabitants in the year 1800 was 183,858, and it appears that the number has actually been doubled in less than 19 years; and of these inhabitants several instances occur of remarkable longevity. The people of this state are, in general, hardy, robust, active, and brave; but it is a subject of regret, that the free indulgence of spirituous liquors is one of their greatest faults, particularly in the vicinity of Piscataqua river, and its branches. Since the revolution, the means of information and improvement have been augmented and extended. The only college in this state is in the township of Hanover, called "Dartmouth College," (see College); besides which there are many academies.

The largest town in New Hampshire is Portsmouth, which is; besides which we mention, in their proper places, the towns of Exeter, Concord, Haverhill, Charlestown, Keene, Dover, Amherst, and Plymouth. The principal denominations of Christians in this state are Congregationalists, Presbyterians, Episcopalians, Baptists, and Quakers; here are also a few Sandemansians and Universalists. The constitution of this state is similar to that of Massachusetts. The first discovery of any part of New Hampshire was in 1614; and the first settlement was made in 1623. See Morse's Geog.

NEW HAMPTON, a post-town of America, in New Hampshire, Strafford county, on the W. side of lake Winnipigogee, nine miles S.E. of Plymouth, incorporated in 1777.—Alfo, a post-town in Hunterdon county, New Jersey, 217 miles from Washington.

NEW HANOVER, a maritime county of Wilmington district, North Carolina, extending from cape Fear river N.E. along the Atlantic ocean. The chief town is Wilmington.—Alfo, a township in Burlington county, New Jersey, containing about 20,000 acres of improved land, and a large quantity which is barren and uncultivated. The compact part is called "New-mills," containing about 50 houses; 27 miles from Philadelphia.—Alfo, a township in Morgan county, Pennsylvania.—Alfo, a county of North Carolina, in the district of Wilmington, containing 5371 inhabitants, of whom 2033 are females. See also HANOVER.

NEW HARTFORD, a small post-town in Litchfield county, Connecticut; 14 miles N.E. of Litchfield.

NEW HAVEN, called also Meaching, a town of England, in the county of Suffolk, situated on the English channel, having a small, but convenient, harbour, at the mouth of
of the river Onse; guarded at the entrance by a small fort; seven miles S. of Lewes. N. lat. 50° 47'; E. long. 0° 4.

—Allo, a county of Connecticut, in America, extending along the Sound between Middlesex county on the E. and Fairfield on the W.; about 55 miles long from N. to S. and 28 from E. to W.; divided into 14 townships, and containing, in the year 1800, 31,926 free persons, and 2,768 slaves.

—Allo, a city, the seat of justice in the last-mentioned county, and the semi-metropolis of the State. This city lies round the head of a bay, which makes up about four miles N. from Long Island sound; and covers a large plain, which is enclosed on three sides by high hills or mountains. Two small rivers bound the city E. and W. It was originally laid out in squares, many of which have been divided by crooked streets; four streets run N.W. and S.E., and are crossed by others at right angles; near the centre is the public square, in which are the public buildings, which are a State-house, three college edifices, a chapel and edifice for the library, &c. three churches for Congregationalists, and one for Episcopalians. The public square is encircled with rows of trees, which render it both convenient and delightful. Many of the streets are also ornamented with rows of trees, giving to the city a rural appearance. The city contains between 8 and 100,000 souls, chiefly of wood. Within the limits of the city there were, in 1798, 254 houses, and upwards of 4000 persons, of whom about one in seventy dies annually. As to pleasantness and health, New Haven is hardly exceeded by any city in America. It carries on a considerable trade with New York and the West Indies. The exports for one year, ending Sept. 1794, amounted in value to 171,868 dollars.

Here are manufactures of card-trees, linen, buttons, cotton and paper. For an account of Yale college in this city, see College. This place and Hartford are the seats of the legislature alternately; 40 miles S.W. by S. of Hartford, 132 from Bolton, and 183 N.E. of Philadelphia. N. lat. 41° 18'. W. long. 72° 56'.

—Allo, a post-town in Addison county, Vermont, on Otter creek, between Middlebury and Vergennes.

NEW HEBRIDES. See Hebrides.

NEWHOFF, Theodore Baron, in Biography, commonly entitled King of Corfica, the son of Anthony baron de Newhoff, and de Stein, in Westphalia, was born at Maastricht in the year 1696. His father, by his marriage with the daughter of a merchant, having incurred the hatred of his relations, was obliged to emigrate into France, and died while the son was very young. The duchess of Orleans, to whom the baron had been introduced, took compassion of the destitute state of Theodore, and his fatherless sister, sent for them, and caused them to be brought to court. While a youth. Theodore obtained the appointment of page to the duke regent, and his sufferer, who became maid of honour to her highness, was afterwards married to the count de Trevoux.

The boy manifested at an early period a passionate attachment to military glory; the lives of the illustrious Romans and Greeks, as recorded by Plutarch, were the subjects of his constant study; he read them till his heart was inflamed with an ambition to imitate their heroic deeds. The romantic exploits of Charles XII. of Sweden had filled Europe with the praises of that monarch, and became the principal subject of conversation at this period. Young Newhoff, burning to participate in the glory of this prince, left France, entered into the service of Charles, and soon acquired a considerable share of knowledge in the art of war; and at all times exhibited that indifference for existence which was the characteristic of the hero whom he wished to emulate.

He also distinguished himself by his genius and capacity for public affairs, which introduced him to the notice of baron de Gortz, who directed all the political concerns of the Swedish cabinet. By that minister he was employed in several difficult negociations, and acquitted himself to his entire satisfaction. When that statesman was executed at Stockholm, Theodore Newhoff entered into the Spanish service. Soon after this he married an Irish lady of some rank, who, in consequence of the misfortunes of her family, had taken refuge in a foreign country. This lady married, daughter of lord Kilmarnock, and lady of honour to the queen, by whom he had a son, who was afterwards known in this country by the name of colonel Frederick, who obtained military rank as colonel, from the duke of Wurttemberg, and who, being reduced to great distresses, put an end to his life, in the portals of Westminster abbey, in the year 1796. This gentleman was known in the literary world by "Mémoires pour servir à l'Histoire de Corfica" and by "Description of Corfica, with an Account of its Union to the Crown of England." See Monthly Magazine, vol. iii. But to return to Theodore; he now repaired to France, and became connected with John Law, the famous Scotch adventurer, with whom he embarked in the memorable Missiippi scheme, which was afterwards productive of so much wretchedness to thousands. From thence he passed into Holland and England, and in 1756 we find him at Leghorn. It was during his residence in Florence that his connection with his future subjects commenced. Corfica being, at that time, in a state of insurrection, Theodore went to that island, where the inhabitants chose him for their king. He instigated a new military order, called "The Order of Deliverance," but he was, after a time, obliged to quit the island, having first appointed deputies to manage affairs in his absence. He went to Naples in disguise, but was discovered and made prisoner in the fortresses of Ceuta; at length he escaped to England, where he died. See our article Corfica; also a work entitled "Necrology," published in London in 1800.

NEW HOLLAND, in Geography. See Holland.

New Holland, a post-town of America, in Lancaster county, Pennsylvania, in the midst of a fertile country, containing a German church and about 100 houses; 54 miles W.N.W. of Philadelphia.

NEW JERSEY. See New Jersey.

NEWIN. See Nevin.

NEWINGTON, in Geography, a township of America, formerly part of Portsmouth and Dover, in Rockingham county, New Hampshire, containing 481 inhabitants.

NEWINGTON-Batts, a large village, and a parish, situated in the eastern division of the hundred of Brixton, in county of Surrey, at the distance of somewhat more than a mile to the south of London bridge. The parish is of very small extent, consisting only of about three hundred acres, of which a third is covered with hedges, and the remainder laid out in gardens and purlieus. It is bounded on the west by the parish of Lambeth; on the east and north by that of St. George, Southwark; and on the south by Camberwell. The church, which is a brick building in the modern style, though much enlarged within these few years, is still by far too confined for the population. The living is a rectory in the peculiar jurisdicition of the archbishop of Canterbury. In East-lane, Walworth, are two meeting-houses of the Baptists; and in Well-lane is one belonging to the Independents, who have also another in Lock's Fields. Near the Elephant and Castle stands a conventicle, on the front of which is inscribed, in large letters, "The House of God." The congregation which assemble here only differ from the established church in the circumstance of their entertaining a confident belief that the world is nigh dissolution. In this parish are "The Draper's Alms-houses," founded and endowed by Mr. John Walter in the year 1651. Newington was originally spelt Newton, and afterwards Neweton. It
occurs first as Newington-Butts in a record dated 1558, when there can be no doubt but that "butts" were placed here for archers to shoot at. According to the parliamentary returns of 1811, this parish contains 4994 houses, and 23,853 inhabitants. By the returns of 1801, the former were only estimated at 2940, and the latter at 14,847, so that the population has increased more than a third of its total amount within the last ten years. Lysons's Environs of London, vol. i. 4to. 1795; with "Supplement," published in 1811.

NEWINGTON, Stuke, a parish and village in the hundred of Oufkton, and county of Middlesex, England, is situated at a short distance N.E. of Islington. The parish is bounded by those of Hackney, Islington, Hornsey, and Tottenham, and contains, exclusive of the ground covered with houfes, about 500 acres of land, chiefly laid down in pasture. The manor has, from time immemorial, been attached to a prebend in St. Paul's cathedral. Thomas Sutton, esq. who occasionally resided at the manor-house, which he held on a lease of 99 years, founded the charter-house in this village. The church is a low, ancient edifice, containing a great variety of monuments and inscriptions, but none of them seem entitled to particular notice. Here is a charity school, established before the year 1720, and supported partly by endowments, and partly by voluntary contributions and collections at charity fermons. Twenty boys and fifteen girls are clothed and educated in this school, besides which, there is one belonging to the Diffenters, where fourteen girls receive their clothes and education. Newington poffefles two diftinet meeting-houses of great reputeability, one being at Newington Green. The dilinguifhed and much lamented Dr. Price was long prior of the latter.

In the parliamentary returns of 1801, the number of houfes in this parish were estimated at 221, and the inhabitants at 1462 in number; but by the late returns (1811) it appears to contain 364 houses, and a population of 2199 persons. Lyfons's Environs of London, vol. iii. 4to. edit. 1795, with "Supplement," vol. i. 4to. 1811.

NEW INLET, a channel of the Atlantic, between Cape Fear island and the coast of North Carolina. N. lat. 33° 56'. W. long. 78° 5'.—Alfo, a channel between two small islands on the coast of New Jersey. N. lat. 39° 50'. W. long. 74° 15'.

NEW INVERNESS. See NEW INVERNESS.

NEW IPSWICH. See NEW IPSWICH.

NEW ISLAND, an ifland near the southern extremity of South America; 21 miles N. E. of Event's iflands.

NEW KENT, a county of Virginia, bounded on the S. fide of Pamunkey and York rivers, about 33 miles long, and 12 broad, containing 27,411 free inhabitants, and 3622 slaves; the court-houfe is 30 miles from Richmond, and has a post-office.

NEWLAND, Peter, in Biography, the fon of a carpenter at Dimmermeer, near Amfterdam, was born in 1764. In his childhood he evinced extraordinary proofs of genius, and at the age of ten years produced some excellent pieces of poetry, and was, even then, able to solve problems in mathematics without having had any instruction from a master. The Batavian government appointed him one of the commiffioners of longitude, and he was succeffively professor of mathematics and philosophy at Utrecht and Amfterdam. He died in the year 1794. He was author of several works, among which may be mentioned the following: 1. Poems in the Dutch Language; 2. A Tract on the Manner of enlightening a People; 3. On the general Utility of the Mathematics; 4. Of the System of Lavozier; and 5. A Treatise on Navigation. To these may be added treatises on the form of the globe; on the course of Comets, and the uncertainty of their return; and on the method of ascertaining the latitude at sea.

NEWLAND, in Geography, a small ifland of England, near the N.W. coast of the county of Cornwall, at the mouth of the river Alan; four miles below Padfrow.

NEW LEBANON. See NEW LEBANON.—Afso, a poft-town of Camden county, North Carolina; 279 miles from Washington.

NEWLIN, a township of America, in Chester county, Pennsylvania, on the Brandywine.

NEW LONDON, a maritime county of Connecticut, comprehending the S.E. corner of it, bordering E. on Rhode ifland, and S. on Long ifland found, about 30 miles from E. to W. and 24 from N. to S.; it is divided into 11 townships, of which New London and Norwich are the chief, and contained, in 1800, 34,888 inhabitants, of whom 209 were slaves.—Afso, a city, a port of entry, and poft-town of the above county, and one of the most considerable commercial towns in the flate; situated on the W. fide of the river Thames, about seven miles from its entrance into the Sound, and defended by fort Trumbull and fort Grifwold. Here are two places of public worship, one for Epifcopalians and one for Congregationalists; about 300 dwelling-houses, and 4600 inhabitants. The harbour is large, fafe, and commodious, and has, on the W. fide, a light-houfe. The exports for a year, ending Sept. 1794, amounted in value to 557,453 dollars. In this year 1000 miles were shipped for the Weft Indies; 14 miles S. of Norwich. N. lat. 41° 25'. W. long. 72° 15'. The townhip of New London was laid out in lots in 1648; it was called by the Indians "Namang" or "Toungog," and from being the feat of the Pequot tribe "Pequot." It was the feat of Saffrons, the grand monarch of Long Ifland, and part of Connecticut and Narragangot.—Afso, a small townhip of Hillifboro county, New Hampshire, incorporated in 1776, and containing 617 inhabitants; lying at the head of Blackwater river, and about three miles from the N. E. fide of Sunapee lake.—Afso, a poft-town of Campbell county, Virginia,feated on rising ground, and containing about 130 houfes, a court-houfe, and gaol. It has a magazine of arms, and a flourishing academy, 133 miles W. by S. of Richmond.

NEW MADRID. See MADRID.

NEWMANSTOWN, a town of America, in Dauphin county, Pennsylvania, on the E. fide of Mill creek, containing about 14 houfes; 14 miles E. by N. of Harrifburg.—Afso, a town of North Wales, in the county of Flint; four miles N.E. of St. Afaph.

NEWMARKET, a small market-town and parish in the hundred of Preilatyn and county of Flint, North Wales, is situated at the distance of three miles and a half to the north of the city of St. Afaph. The church here is an ancient edifice, and in the cemetery stands a curious lime crofs. Here are held the petty feftions for the hundred. The market is holden on Saturday; and the fairs, of which there are four annually, on the laft Saturday in April, the third Saturday in July, the fourth Saturday in October, and the second Saturday in December. There is in this town a charity school, founded and endowed by Dr. Daniel Williams, a dilinguifhed Diltinguifhing minifter. According to the parliamentary returns of 1811, the whole parish contained 89 houfes, and 469 inhabitants.

NEWMARKET is a market-town, partly situated in the hundred of Chevely, Cambridgehire, and partly in the hundred of Lackford, in the county of Suffolk, England. It contains two parishes, one being in each county, and is 15 miles diftant from Cambridge, and 61 from London. The houfes are chiefly disposed in one long and wide ftreét, in which are the two parith churches of St. Mary's and All Saints. The town has been twice nearly destroyed by fire; the firft time in 1683, when the king, queen, and duke of York attended
the races; the second conflagration was about the commence-
ment of the last century. According to the population re-
turn in the year 1811, Newmarket contained 332 houses, and
1917 inhabitants. A market is held on Tuesdays; and
two fairs annually. When the town obtained its charter does
not appear; the earliest mention of it on record is in the
year 1227; and it is probable it took its name from a market
then recently established.

Newmarket Heath has long been celebrated in the annals
of horsemanship as one of the finest race-courses in the
kingdom. The diversion of horse-racing, though undoubt-
edly practised in the country in the time of the Romans,
ever made any considerable progress, but rather became ex-
tinct, till the accession of James I., who again introduced it
from Scotland, where it came into repute from the spirit and
fusiveness of the Spanish horses which had been wrecked in
the vessels of the Armada, and thrown ashore on the coasts
of Galloway. From this period it became more fashionable;
and Newmarket had probably a racing establishment as early
as the reign of that monarch, who erected a house here,
which was destroyed in the civil war, but was rebuilt by that
distinguished patron of the turf, Charles II., and is still the
residence of the sovereign, when he visits Newmarket. The
idea of improving the breed of horses has, in a certain de-
gree, induced the legislature to encourage this species of
gambling; and even the throne seems to sanction its con-
tinuance; for in addition to the plates given by the nobility,
the king gives two plates annually. The races are held seven
times in the year; the whole of the race-cours is in Cam-
bridgehire.

At the distance of about one mile and half from Newmarket,
croosing the London road, runs a remarkable excavation,
called the "Devil's ditch," which extends nearly in a straight
line for seven miles, from Wood-Dutton to Reach, in the
parish of Burwell; the most perfect part is for the space
of a mile in the vicinity of Reach; the works here consist of a
deep ditch, with an elevated vault, the slope of which
measures 52 feet on the west side, and 26 feet on the east;
the whole of the works are about 100 feet in width. From
the mode of disposing the excavated earth, it is the opinion
of Dr. Stukeley, and other antiquaries, that the ditch was
made some centuries before the time of Caesar, by the first
inhabitants who settled eastward, in order to secure them-
sewes from the attacks of the inland aborigines. Various
other conjectures have been formed respecting the origin of
this and similar earth-works in this part of the country, which
are unquestionably of very remote antiquity. The Devil's
ditch at present serves for the boundary between the dioceses

Newmarket, a post-town of the county of Kilkenny,
Ireland, 179 miles S.S.W. from Dublin, and about 12 miles
S. by W. from Kilkenny.

Newmarket, a post-town of the county of Clare, Ire-
land, situated upon a river which falls into the Fergus, 108
miles W.W.S.W. from Dublin, 14 W. by N. from Limerick.

Newmarket, a small market town of the county of Cork,
Ireland, in the north-western part. It is situated on the
river Allo, which afterwards unites with the Daha, and is a
considerable thoroughfare to the county of Kerry; 1294
miles S.S.W. from Dublin, about 30 N. by W. from Cork.

Newmarket, a post-town of America, in Rockingham
county, New Hampshire, N. of Exeter; 13 miles W. of
Portsmouth; incorporated in 1727, and containing 1027 in-
habitants. Shells of oysters, mussels, and clams intermixed,
have been found near Lamprey river in this town at the depth
of 17 feet. — Allo, a town of Shenandoah county in Vir-
ginia, containing 100 houses; 20 miles S. of Woodstock;
habited by Germans. — Allo, a post-town in Amherst
county; Virginia, on the N. side of James river, at the mouth
of Tye river; 20 miles above Richmond. — Allo, a post-
town in Rens county, Ohio; 465 miles from Washington.
NEW MARLBOROUGH. See MARLBOROUGH. — Allo, a town in King George's county, Virginia, on the
W. side of Patowmac river; 10 miles E. of Falmouth.
NEW MEXICO. See Mexico.

NEW MILFORD, a post-town of America, in Litch-
field county, Connecticut, on the E. side of Hawatatemc
river, 20 miles S.W. of Litchfield; containing about 500
houses, a church for Episcopalians, one for Congregational-
ists, one for Presbyterians, one for Baptists, and one for
Quakers; also, seven forges, which manufacture 300 tons
of iron, besides hollow ware. — Allo, a post-town at the
head of the tide on Sheepscot river, in Lincoln county, Maine;
10 miles N. of Wiscasset.

NEW MILLS, a place, with a post-office, in Burlington
county, New Jersey.

NEW MILNS, a considerable borough of barony, and
market-town, is situated in the parish of Loudoun and
county of Ayr, North Britain. It is a place of great an-
tiquity, but did not receive its charter of erection till
the reign of James IV.; at which time it appears from the deed
itself to have been a town of no small importance. The
superior lords were the earls of Loudoun, and in their right
the superiority is consecutively now enjoyed by the counteys
of Loudoun and Moira. According to the population re-
turns of 1811, the parish contained 464 houses, and 3170 in-
habitants, of whom about 1500 may occupy the town, which
is not so extensive as formerly.

NEW MOON. See Moon and Neomenia.

NEWNHAM, in Geography, a small market-town in
the hundred of Welbury, and county of Gloucester, England,
is situated on an eminence rising from the western banks of
the river Severn, at the distance of 11 miles from the city of
Gloucester, and 117 miles from London. Its origin is re-
 mote; in the Norman times it appears to have been fortified
to repulse the incursions of the Welsh; and in the records of
St. Bartholomew's hospital in Gloucester, relative to grants
of certain lands in Newham, frequent mention is made of a
castle here; but no remains of it are now to be traced. The
fortifications on the south side of the town are probably of
Norman date; the circumvallation on the back part must be
referred to the time of the civil war, when Newham was
garrisoned for the king by Sir John Wyntour, whose forces
were obliged to surrender to colonel Maffe. Newham was
one of the five boroughs in this county returned on a man-
date from the crown, in the ninth year of Edward I., and
was then governed by a mayor and burgesses; but the au-
thority has long been vested in two constables, though a
formal election of a mayor has, till lately, been kept up.
A sword of plate presented by king John is still preserved
as a memorial of former greatness; it is of polished steel, highly
ornamented, and of exquisite workmanship. The former
importance of the town may be inferred from the names of the
courts and lanes which appear in ancient grants, but
whose situations are now unknown. It was also distinguished
by being appointed for the meeting between king Henry II.,
and earl Strongbow, on the return of the latter from his
conquests in Ireland. The parish church of Newham
stands on a commanding cliff near the river; the arch lead-
ing into the chancel is ornamented with zig-zag mouldings;
and is supposed to have been preferred from the ruins of a
more ancient structure, which stood at a place called Nabb's
Ends. The population of this parish in the year 1811, was
reported to parliament as 952, occupying 150 houses; the
latter are mostly ranged in one long street. The chief em-
ploy of the labouring inhabitants is furnished by a verdigris
manufactory,
but the market conftrufted William th Monmouth, w Toward 1 the is beneath fituated the appears poffeffions. the (lone and is a parliament One huircll Newport the a Beauties borough another of portcullis a Rich different the rfhj

but the market conftrufted William th Monmouth, w Toward 1 the is beneath fituated the appears poffeffions. the (lone and is a parliament One huircll Newport the a Beauties borough another of portcullis a Rich different the rfhj

Newport, a borough and market-town in the hundred of Wentloog, and county of Monmouth, England, is situated 24 miles from Monmouth, and 147 from London. It is called by Gyraldus Novus-Burgo, or New-town, and arose out of the declining greatness of Cardiff, and was by the Welsh denominated Callf-NEWydd, or New-calle. Robert, earl of Gloucester, natural son of Henry 1., erected a caffle here for the defence of his possessions. This fortress defended from the ears of Gloucefer, through several noble families, till on the attainer of Edward, duke of Buckingham, it was, together with the lordship, feized by Henry VIII. The preftent proprietor is William Kemeys, eq. of Maynec. The cell of the caffle, which stands on the bank of the Usk, is a maffive structure, but not of large dimensions, though it appears to have been formerly of greatextent. The building forms nearly a parallelogram, and is confructed with rubble, coigned with hewn flone. The fide towards the town confifs simply of a plain wall, which has led to the conjecture that it was erected solely for defending the passage across the river, but it is evident that formerly the works were much stronger on the southern fide. Toward the north, in the centre, is a square tower, which ferved for the keep or citadel: beneath this is a fally-port, facing the river, with a pointed arch and a groove for a portcullis; and on each fide is a large mafly tower. The centre contains a fpacious apartment called the flate-room, adjoining to this are the remains of the baronial hall. One of the collateral towers, though in a dilapidated flate, is fett up as an habitation.

The town was formerly defended by fortified walls, but no velliges now remain. Leland mentions three gate-houfes as standing in his time: one by the bridge at the eafte end of the town; another at the weft end, near the church; and a third in the centre of the High-street. The fite of the two firft may yet be traced; the central one has been recently taken down.

Newport obtained a charter of privileges from Edward II.; further grants were fowed by fubsequent monarchs; and by a charter, dated in the 21st year of James I., it is now governed by a corporation, fyled "The mayor, aldermen, and burgifles of the borough of Newport in the county of Monmouth." This borough, conjointly with Usk and Monmouth, fends one member to parliament; the elective franchise being vefled in the redifent burgifles. The town confifts principally of one long, narrow flreet, extending from the flat bank of the Usk up to the eminence on which fands the parish church of St. Woolos, which Leland calls St. Guntle Olave, and which is the only place of worship on the eftablifhment. This edifice confifts of a lofty, square tower, a nave with two aifes, a chancel, and a small chapel, now ufed only as a burial place. The church was erected at different periods. Its tower was built by Henry III., as a memorial of his gratitude to the inhabitants of the town for their successful opposition to Simon Montfort, earl of Leiceter. The nave, which is the only part remaining of the original structure, was built, if not in the Saxon, evidently in the earlieft part of the Anglo-Norman period.

Leland flates "ther was a houfe of religion by the key, beneath the bridge." This, Tanner conjectured was a moftery of friars preachers; becaufe, at the dissolution, fuch a one was granted to fir Edward Carn. Some remains are still standing, and confift of feveral detached apartments, and the northern tranfept of the conventual church; the gardens of the moftery are inclofed by the original wall. Newport-bridge, a fome structure of five arches over the Usk; was built at the expence of the county, under the direcHon of the fon of the celebrated Edwards, who erected the famous bridge of one arch, called Pont-y-Pryd.

The inhabitants of the town are principally supported by the commercial relations of the port, which confift of foreign, coaling, and inden trade. The foreign trade has never arrivd at any confiderable eminecy; but the coasting trade is more important: the expotes are chiefly coals, with coal and bar iron from the feventh founderies in the western mountains, brought to the quay by the Monmouthshire canal; the imports are deals, furniture, and all kinds of shop goods. The inland and home trade has been much incrreased since the completion of the canal. The population of Newport, according to the return to parliament in the year 1811, was 2346, occupying 453 haufes. Four fairs are hold annually, and a market weekly on Saturday. Cox's Hiftorical Tour in Monmouthshire, 2 vols. 410.

Newport, a borough in the parift of St. Stephen, in the north division of the hundred of Ealn, in the county of Cornwall, England, is situfed 214 miles distant from London, in the vicinity of Launcelot, to which it appears as a suburb, and was anciently under the fame jurisdiction; but having been granted to the priory of St. Stephen's, it obtained some distinct privileges. After the dissolution, the inhabitants were encouraged to challenge the separate right of returning members to parliament; and the property of the borough being then vefled in the crown, the privilege was awarded without much investigation. The first return was made in the fifth year of Edward VI., and two members have ever since been regularly chosen. The right of election is vefled in two officers, called venners, (who are annually appointed at the court-leet held by the lord of the manor,) and all the inhabitants paying fcot and lot; the whole number fearcely amounting to thirty. The whole borough is the property of the duke of Northumberland, who has a seat in the vicinity. (See Launcelot.) Pol-whole's Hiftory, &c. of Cornwall, two vols. 410.

Newport, a large borough and market-town in the half hundred of West-Medina liberty, in the Isle of Wight, and county of Southampton, England, is situfed near the centre, and may be regarded as the metropolis of the ifland. This place has ri-f-n upon the ruins of Carisbrooke, which was formerly a very confiderable town. Rich de Redvers, fecond earl of Devonshire, granted the firft charter of privileges to Newport in the reign of Henry II., but this contained little more than a grant of liberties in general terms. The next deed was granted by the countefs Isabella de Fortibus, and confirmed by Edward III., and also by severel succeeding monarchs. This grant conferred the privilege of a market and tolls, and many other immunities, but the town was not incorporated till the reign of king James I., whose charter was afterwards confirmed and extended.
tended by Charles II. Under this last deed the government is vested in a mayor, twelve aldermen, a recorder, town clerk, and twelve burgesses, who are chosen from among the principal inhabitants. Two members are sent from this borough to serve in parliament; they are elected by the corporation, and returned by the mayor. The first return was made in the 23d year of Edward I., but the privilege was never again acted upon till the 27th year of Queen Elizabeth, when it was restored through the interist of Sir George Carey, then captain of the island.

The situation of Newport is lofty and extremely agreeable, being watered on its eastern side by the principal branch of the river Medina, (whence it was actually called the borough of Medina,) and on the west by a small rivulet, which rises at Rayner's-Grove, about three miles off, and joins the Medina at the Quay, where it becomes navigable for vessels of large burden. The houses of this town are generally constructed of brick, and are disposed into five parallel streets running east and west, and intersected by three other streets running north and south, and parallel to the original plan. It was intended that there should have been the large squares, at the crozings of the streets, to be appropriated as market-places; but the uniformity of this design has been much impaired by various encroachments. In the larges of these openings stand the town-hall, where meetings of the corporation, and the several courts of the borough, as well as the kniighten court, or curia multum, are held. This court is under the presidency of the governor's steward, or his deputy. It was instituted in the feudal times, as is commonly suppos’d, by William Fitz-Osborne, to whom the Isle of Wight was granted by king William I., soon after the conquest. The original judges were such as held a knight’s fee, or part of a fee in capite, from the proprietor of the lordship. The present judges are freeholders holding of Carisbrooke Castle, who sit in rotation, three or more at a time, and give their decisions without the intervention of a jury. The Monday of every third week is the day on which this court meets for the dispatch of business; when it is empowered to hold “pleas of all actions of debt and trespass, under the value of a mark, and upon replying granted that issue to the party, or his deputy. The proceedings are of the same nature as those in our courts of equity, and are carried on by attorneys admitted by the court. The actions for debt are tried by proof of plaintiff or defendant; and actions of trespass are determined by proof only.”

The church of this town, also standing in one of the squares, is a low, ancient edifice, dedicated to St. Thomas, and hence conjectured to have been originally founded about the time of Henry II. The different styles of its architecture, however, evidently shew it to have undergone very material alterations, at various periods, since its first erection. It is only a chapel of ease to Carisbrooke. On the pulpit, which is of wainscot, is carved a number of figures, representing the cardinal virtues and the liberal arts.

Among the many distinguished persons buried here was the priæces Elizabeth, second daughter of Charles I., who was detained a prisoner in Carisbrooke Castle, and died there of a broken heart, at the age of fifteen. The leading zen, containing her remain, was discovered, some years ago, in a vault under the chancel. The principal monument, in point of grandeur, is that of Sir Edward Horsey, one of the captains of the island in the reign of queen Elizabeth. Besides the church belonging to the establishment, there are meeting-houses in this town for the Roman Catholics, the Methodists, the Arminians, the Baptist, and the Quakers. Here is a free grammar-school for a limited number of boys, which has now almost dwindled to a fine. There is a school-room for having been the place where the negotiations between Charles I. and the parliamentary commissioners were discussed. Another school for clothing and instructing girls has also been instituted, and two Sunday schools, all of them partly supported by endowments, and partly by subscription. The places of public amusement are a theatre, and an amphitheatre, lately erected, and appropriated to assemblies and concerts. A philosophical society was established here about ten years ago.

Newport is a scene of great bustle and activity. The market days are Wednesday and Saturday, when provisions of all kinds are abundant, except fish, which are extremely rare. This was formerly a great mart for grain, but the sale of that article has considerably diminished of late years. According to the returns of 1811, the houses in the town are estimated at 604, and the inhabitants at 3552 in number.

About a mile north from Newport stands the House of Industry for the Isle of Wight, which was erected about the year 1772. It is a large edifice, consisting of several ranges of buildings, capable of accommodating 700 persons. The management of this charity is vested in a corporation, styled “The Guardians of the Poor within the Isle of Wight,” and composed of 24 directors, and 36 sub-committees. At a short distance hence are the Parkhurst barracks and military hospital, which are scarcely inferior to any similar establishments in the kingdom. Carisbrooke Castle lies nearly a mile westward from the borough, and is one of the most ancient fortresses mentioned in the annals of English history. Its origin is by some ascribed to the Britons, and by others to the Romans; but the first authentic notice of it occurs in the Saxons annals, A.D. 530, when it was besieged and taken by Cerdic, the first king of Wessex, whose nephew, Withgar, is said to have rebuilt it. After the Conquest, it was much altered and enlarged, and some fortifications were added by queen Elizabeth. King Charles I. remained a prisoner here, before he was conducted to London for trial; and is supposed to have written his “Suffragio Regabil” during that period. The greater part of this castle is now in ruins, but the tower-gateway and parts of the keep are tolerably perfect. The latter is occasionally occupied by the governor of the island. The whole fortresses occupy an extensive area, and, when in a perfect state, must have been very formidable. In the keep is a very deep well, from which the garrison was supplied with water. The village adjoining retains few marks of its former consequence, except its church, which was built by William Fitz-Osborne, already mentioned, and is a spacious building, with a handsome embattled tower at the west end. Near the church stand the remains of a priory, also founded by Fitz-Osborne, and appropriated by him as a cell to the Benedictine abbey at Lyra, in Normandy. Albin's History, Sc. of the Isle of Wight, 8vo. Worley's History, Antiquities, Sc. of the Isle of Wight, 4to.

Newport, a small market-town in the fourth division of the hundred of Bradford, and county of Salop, England, is situated on the borders of the shire, at the distance of 12 miles from Drayton, and 139 from London. The Woldingham, or great Roman road, passes within two miles of this place, which anciently was the property of the Audleys, and afterwards of a family of its own name, to whom it gave the title of baron. It conveys chiefly of one principal street, of considerable length, and a few narrow lanes diverging from it. The church stands in the main street, and is probably the most incongruous example of ecclesiastical architecture in the kingdom. The body is an ancient stone structure of the 15th century, and retains enough of interior embellishment to evince its former magnificence, while the side aisles are of modern erection, and built with brick, after the model of the Greeks. The abbots and convent of
St. Peter and St. Paul, at Shrewbury, were the original patrons of this church; but it was purchased from them in the reign of Henry VI. by Thomas Draper, a citizen of London, who made it collegiate, and placed in it a college of four fellows. The former was the parochial priest. William Adams, eqq. a native of the town, founded the free-school, which is a flately edifice of brick, and has a library attached to it for the use of the scholars. The lands belonging to this institution are exempted from parliamentary, parochial, or any other kind of taxes, by virtue of a grant from Oliver Cromwell. Pupils are qualified here for the university. Near the school stand two handsome almshouses, erected and endowed by the fame munificent founder, who likewise gave 350l. towards the building of a town-house. Newport sustained very serious damage from fire on the 16th of May, 1655. One hundred and sixty houses, with their contents, were on this occasion consumed by the detroying element. The market-day is Saturday; and here are fix fairs annually. This town contends with Shifnal for the honour of having given birth to the celebrated Thomas, or Tom Brown, who died in 1704, in extreme indigence, and lies buried in the cloisters of Westminister Abbey. His whole works were printed three years after his death in four volumes, comprising dialogues, essays, fatares, letters from the dead to the living, with a number of translations, and other miscellaneous pieces. These writings are perfectly characteristic of the author's mind; they are replete with wit and humour, and display a fund of learning, but are debased by low puns and licentious imagery.

According to the parliamentary returns of 1801, the houses contained in this parish amounted to 323 in number, and the inhabitants to 2307. In that of 1811, the former are estimated at 478, and the latter at 2114, being an increase of 155 houses, and a decrease of 193 males, for the number of women is augmented. This indicates a very great error in one of the reports, and, with many other similar contrarieties, shows how little dependence can be placed on such documents as the basis of statistical or political reasoning.

In the vicinity of the town, on the south, is the village of Lillefhill, noted for its abbey, the ruins of which are situated in a retired and foitary position, and partly enveloped in trees. A large portion of the abbey church remains, but so mutilated, as to render it difficult to form a just idea of its original architecture, except from the structure of its doors and windows. A fine Norman arch, highly reeded, with ribs and running foliage, forms the western entrance, and seems to have also constituted the basis of a tower. The south door, which communicated with the cloister, is one of the most enriched early Norman arches in the kingdom. The east window is of large dimensions, with a beautiful pointed arch of the 14th century, but the windows of the choir are narrow, plain, and round headed. The whole measures 228 feet in length, and 36 in breadth, exclusive of the side aisles. The other buildings are in a much more ruinous condition than the church, though, from what yet exists of them, they appear to have evidently been of very considerable extent. Chetwynd-park, a seat of the noble family of Chetwynd, lies on the north side of Newport, and about two miles beyond this, and close upon the confines of Staffordshire, is a very large encampment, probably of Roman origin. Beauties of England and Wales, vol. xiii. Newport, or Treff Draeth, a borough, market-town, and parish, in the hundred of Cemaes, and county of Pembroke, South Wales, is situated on the river Neven, at the distance of eight miles south-west from the town of Cardiff. This town was incorporated by one of the Martens, lords of Cemaes, who, as barons marchers, enjoyed all the privileges of sovereignty. The castle, or "Caput Baroniæ," stood on a knoll above the town, at the extremity of the principal street, and, though now a complete ruin, still retains marks of former strength and magnificence. The area which it occupied is about 50 paces in diameter, and nearly circular. The grand entrance was by a gateway between two noble ballion-towers, facing the north. At the west end are the remains of another bold baflion, whiwh two others are on the south and east sides. The flat roofs and family apartments appear to have formed the south-east portion of the edifice, which was surrounded by a very broad and deep moat, having a command of water. Under the castle was a gaol for the confinement of felons, who had been apprehended by the lord's tenants; for the proprietor of this castle polieed the power of life and death as absolutely as the monarch himself. Indeed the privileges of the lord of Cemaes were greater than those exercised even by the lord palatine of Pembrokehire. A writ of error ran out of the king's courts into the palatinate; but here the parliament renewed errors. Here the lord marcher had interlits' goods, which the earls palatine had not; and he was sworn to perform contracts like any free and absolute prince, whereas the earls bound themselves by covenant as other subjects were accustomed to do.

The situation of Newport is highly picturesque. Behind the castle, the mountain of Carn-Englyn rises with the utmost boldness; and a view of the bay, which derives its name from the town, opens beautifully in front. From the distribution of the streets, intersecting each other at right angles, this appears to have been once a very considerable place. About two centuries ago, the inhabitants carried on an extensive trade in woollens; but owing to a great mortality, which happened towards the close of the 16th century, the town fell so much to decay, that even its market was discontinued. The market, however, has been revived for many years; and, of late, trade has again begun to flourish, and fill up a few of the chafms in the depopulated streets with new buildings. As the Neven is navigable for nearly two miles above the town, and forms a commodious bay for the anchorage of shipping at its confluence with St. George's Channel, the position of Newport would be extremely favourable for commerce, but for a bar of land at the entrance of the bay. It has, besides, the advantage of having in its immediate vicinity large quarries of slate, capable of being rendered an important article of traffic, as there is a deficiency of that material throughout a great extent of the western coast. The government of this town continues to be vested in a mayor, recorder, two bailiffs, and six constables, in conformity to its original charter. These are empowered to hold courts for the recovery of small debts, and also for the punishment of trivial offences. The petty-feisions for the hundred are held here. The market is weekly, and there is a fair for cattle on the 27th of July annually. Here was anciently a large house of friars, of the order of St. Augustine. In the church, a very old edifice in the shape of a cross, may be seen two monuments, supposed to commemorate Sir William Martin and his lady, the lord Rhys's daughter. The living is a discharged rectory. According to the parliamentary returns of 1811, this parish contains 355 houses, and a population of 1433 persons.

To the east of Newport, on the opposite side of the river, is the village of Neven, once a borough, and the residence of some powerful chiefman, previous to the Norman conquest. The remains of the castle confilt of little more than its foundations, but these are sufficient to prove that there has been a fortress of great extent and strength. The appearance of this village is highly delightful, as it is seated on the margin...
NEW

margin of a beautiful stream, in the midst of rich meadows, gardens, and orchards, and encompassed by swelling hills, profusely girted with wood. In the church-yard there is a number of yew trees, which, under their thick foliage, one of the early stone crosses, consisting of a tall shaft, richly ornamented, and having on the central comparted fome irange characters, not yet deciphered, notwith-standing the exertions of the late Dr. Lort to effect that object. Never had a portreeve, and courts for its government, as well as a council of eighteen burgesses, for many years subsequent to the foundation of Newport, which role upon its ruins. About a mile from the latter town, on the road to Pifgoura, is a cluster of kiltvaens, surrounding a cromlech, long since overturned. All are included by the remains of a circle of large bines. On the peninsula of Dinah-head, formed by the bays of Pifgour and Newport, stands another cromlech, which, Fentos says, is unquestionably the largest Druidical relic in Wales. The impo't rolls upon two columnar bines, gently tapering to a point, with one between, which does not touch, at the south end, and a single upright at the north extremity; there being but three actual supports. The incumbent stones are forty feet long, twelve feet broad, and five feet thick; though another, lying on the ground, ten feet long, and five broad at one end, lies evidently been broken off from it, since it was placed in its present position. Many fallen bines, which probably formed a circle round the cromlech, are scattered over the field where it is fixed. Historical Tour through Pembroke-shire, by Richard Fenton, Esq., F.S.A., vol. 410, 1811. Carlisle's Topographical Dictionary of Wales, 410.

NEWPORT, a poit-town of the county of Tipperary, Ireland, on the river Mulkera, near the foot of the Keeper mountain. It is 86 miles S.W. from Dublin, and 8 N.E. from Limerick.

NEWPORT, a township of Nova Scotia, in Hants county, on the river Avon.—Allo, a township in Cheshire county, New Hampshire, E. of Claremont; incorporated in 1761, and containing 1266 inhabitants.—Allo, a maritime county of Rhode island, comprehending Rhode island, Canoeview, Block, Prudence, and several other small islands. It is divided into seven townships, and contains 14,845 inhabitants. It was named Queen Anne's Hospital. In this town is the metropolis of the state of Rhode island, situated on the S.W. end of Rhode island, five miles from the sea. Its harbour, which extends westward before the town, is one of the finest in the world, having a safe and easy entrance, and so spacious, that a large fleet may anchor in it and ride in perfect security. The town lies N. and S. upon a gradual ascent E. from the water, and exhibits a beautiful view from the harbour and the neighbouring hills. To the W. of the town is Goat island, on which is Fort Washington. Newport contains about 1000 houses, chiefly of wood, and 6730 inhabitants. It has ten houses for public worship, four for Baptists, two for Congregationalists, one for Episcopalians, one for Quakers, one for Moravians, and one for Jews. The other public buildings are a large house, and an edifice for the public library. In this town are an academy, under the direction of a rector and tutors, and a marine society, established in 1752, for the relief of distressed widows and orphans, &c. This city, distinguished by the beauty of its situation and the salubrity of its climate, is abundantly supplied with a great variety of excellent fish; and it has also a confiderable trade. A cotton and check manufactury has been lately established. The exports for a year, ending September 1794, amounted in value to 311,200 dollars. The town was first settled in 1639; 30 miles S. by E. of Providence. N. lat. 41° 29'. W. long. 71° 17'.—Allo, a township in Lower Canada, 20 miles E. of Acot, including about 30 inhabitants.—Allo, a small poit-town in Newcastile county, Delaware, on the N. side of Christiana creek, three miles W. of Wilmington; containing about 200 inhabitants, and carrying on a confiderable trade with Philadelphia in flour; 31 miles S.W. of Philadelphia.—Allo, a township in Luzerne county, Pennsylvania, on the S.E. side of the Susquehannah lake Wilkborough.—Allo, a small poit-town in Chelfer county, Maryland; 94 miles S. by W. of Balti-more.—Allo, a very thriving settlement in Liberty county, Georgia, situated on a navigable creek; 34 miles S. of Savannah. This place, commonly known by the name of "Newport Bridge," is the rival of Sunbury, and commands the principal part of the trade of the whole country.—Allo, a place, with a post-office, in Cooke county, Tennessee; 529 miles from Washington.

NEW PORT-GLASGOW. See Part Glasgow.

NEWPORT-PAGANELL, a market-town in the hundred of the same name, in the county of Buckingham, England, is situated 15 miles distant from the county-town, and 41 miles from London, on the road to Northampton, near the banks of the river Ouse, and is divided into two unequal parts by the small river Lovet. The town has been of considerable consequence from a remote period. The latter term in its name was derived from the Paganells, or Pagnells, to whom the manor descended from William Fitzaynulf, who possessed it at the time of the Norman conquest. The Paganells had a castle at Newport, the site of which is still called the Castle Mead: Leland and Camden both mention this edifice, but there were no remains of the building even in Camden's time. In the early part of the civil war of Charles I's time, Newport was garrisoned by prince Rupert; but soon after the first battle of Newbury it was abandoned by the royalists, and proved a useful station to the parliamentary army during the remainder of the contest. Sir Samuel Luke, the suppos'd Hudibras of Butler, was governor in the year 1645. The parish-town of Newport is an ancient and spacious structure. The vicar is usually master of an ancient hospital, originally founded by John de Somery, in the year 1260, and dedicated to St. John: it was founded by Anne, Queen of James 1, and from her named Queen Anne's Hospital. Two other hospitals were founded here at a very remote period, but the last admitted to them no farther back than 1270. In the church-yard are seven almshouses, founded and endowed, in 1763, by John Revis, citizen of London, for four men and three women, who receive 10l. per annum each, besides clothes and fuel. In addition to these charitable institutions the diffusion of the poor are mitigated by various donations and legacies. In the return made under the population act of the year 1811, this town was stated to contain 556 houses, occupied by 2515 persons. A market was either originally granted, or confirmed by charter, to Roger de Somery, in the year 1270, together with a fair of eight days; the market was again confirmed to John Botetort in 1333. The market-day is Saturday; the principal articles are corn and provisions. Here are now six annual fairs. The labouring class of the people are chiefly supported by lace-making; it is estimated that more lace is manufactured in this town and its vicinity than in all the other parts of England; a special market is held on every Wednesday for its sale; and great quantities are vended at the fairs.

At Tickford, adjoining to this town, a cell for Cluniac monks was founded by Eulk Paganell, in the reign of William Rufus. King Henry VIII suppreessed this monastery in 1525, and gave it, with its lands, to cardinal Wolsey. It afterwards reverted to the crown, and was granted by James
James I. to his physician Dr. Atkins, and was the seat of his descendants. The site of the priory is now occupied by a neat modern house, called Tickford abbey, the property of Mr. Hooton; there are no remains of the conventual buildings. Mr. Hooton's family have a burial place in a retired part of the garden, which is supposed to have been the cemetery of the cell; an obelisk has been erected there to the memory of the late Mrs. Hooton. Tickford park, and the manor of Tickford-end, which were part of the Atkins' estate, are now the property of Mr. Vanhagen. The manor of Caldecot, (a hamlet of this parish,) which belonged to the priory of Tickford, was sold by the Atkins' family, in 1758, to William Backwell, esq. banker of London; he, in 1769, bequeathed it to William Harwood, esq., who had assumed the name of Backwell, and is the present proprietor.

At Tyrningham, about two miles from Newport-Pagnell, is the seat of William Praed, esq. The manor belonged to an ancient family, who took their name from the village so early as the year 1170, and it continued in the family till the year 1685; when the male line became extinct by the death of Sir William Tyringham: from his daughter it has descended to Mr. Praed, who has pulled down the old manor-house, and erected an elegant modern mansion, from the designs of John Soane, esq. professor of architecture to the Royal Academy. The fame profound architect also gave designs for a lodge, and a bridge across the river which runs through the park. In the tea-hall, ball, dining-room, and library, the artist has displayed considerable taste and judgment.

About a mile from Tyringham is Gotherth, in which parish is a fine old manor, the seat of Mifs Wright, one of whose ancestors purchased it in 1704. The house is large, and its chief front appears to have been built in the time of queen Elizabeth. It was pulled down by the Digby family in the time of king James I.; and contains some curious portraits of sir Everard and sir Kenelm Digby, also other branches of that family. Lyfons' Magna Britannia, vol. i.

Newport Pratt, a sea-port and port-town of the county of Mayo, Ireland, near the mouth of a small river, running into the north-eastern part of Clew bay. It is a place of little trade. Newport is 123 miles W.N.W. from Dublin, and 9 from Castletown.

Newrahe Bridge, a village of the county of Wicklow, Ireland, at which there is an inn, where those who visit the intereting scenes of this county often procure lodging. It is about two miles N.W. from Wicklow, and 22 miles S. from Dublin.

New River, a most important artificial canal, or stream of water, passing through parts of the counties of Hertford and Middlesex, England, wascontrived and principally executed by an individual, Sir Hugh Middleton, in order to supply the British metropolis and its environs with fresh water. That of the Thames, though extremely beneficial to London, was so liable to alteration, and subject to foulness, that a copious supply of pure water was extremely desirable. Before, the Thames water must be forced to ascend by machines, even for the lower parts of the city: whereas, a stream on the northern side of London may be made to flow, in a natural decent, to almost any quarter of the widely extended metropolis. From these considerations, in the reign of James I., Hugh Middleton, citizen and goldsmith, projected the plan of bringing water out of Hertfordshire, in a channel to London. Meeting with no cooperation, he, at length, in the year 1608, commenced the undertaking at his own expense; and, after exhausting all his resources, and being refused aid from the corporation of London, he was enabled, by the alacrity of the king, to bring it to completion. On September 29, 1613, the water was let into the New River Head, at Ilfingtont; but the projector was ruined by the expenses, and it was long before the scheme was rendered useful and beneficial to the public. The New River is formed by the collected waters of several springs, which rife at Chadwell, near Ware, Hertfordshire, about 20 miles north-west from London. These springs are collected into a large, open basin of considerable depth, near which a stone is placed, with inscriptions, implying that the stream was opened in 1608, and that from the Chadwell spring the river flows 40 miles. The original supply of water having been found inadequate to the consumption, the mill-stream of the river Lea, which runs near it, was referred to; and after various disputes and litigations between its proprietors and those of the New River, the mill has at length become the property of the latter company, who have now an unrestricted use of the water; so that the river Lea may be considered as one of the sources. On a flume leading from it are flood-gates, with a building, in which a man is placed, whose constant employ is to raise or lower them, according to the fulness of the river below; and that he may not err in the quantity supplied, a gauge is fixed across the flume, consisting of a stone of great bulk, under which all the water paffes; so that the current is regulated, and adjusted with the greatest exactness. To preserve a proper level, the New River takes such a winding course, that the length of the channel is nearly thirty-nine miles. Passing Ware, Amwell, Hoddesdon, and Cheetham, it enters Middlesex near Waltham-Croft; bending towards Enfield-Chafe, it returns to the town of Enfield; and at Bulf-hill was formerly carried across a valley, in a wooden aqueduct, or open trough, 665 feet in length, supported by arches; but the improvement in canal making has suggested a better mode to effect the purpose by means of a mound of earth, over which the river paffes in a new channel, which was completed in the year 1785. Hence the river proceeds with devious bends to Hornsey, between which village and High bury it was formerly conveyed in another wooden aqueduct, now superceded, like the other, by a bank of clay. Still winding, it reaches Stoke-Newington, and paffes on to the east side of Ilfington, where it has a subterraneous channel, for 200 yards beneath the street. Just before this part is a building, whence several mains, or pipes, are fent to supply the eastern side of London. After paffing under the road, the New River emerges and coasts the southern side of Ilfington, till it reaches its termination at the grand reservoir, called the New River Head. The width of the river near Ilfington is fourteen feet and a half, the average depth four feet and a half, but the depth decreases on ascending towards its source. The number of bridges which crosses the river in its whole course is about two hundred: in various places are flumes to let off the waste water; which, with other works, excited admiration in the earlier stage of this branch of mechanics, but are now overlooked in the wonders of canal navigation. Truly admirable are the contrivances for distributing the water through the various parts of London. From a circular basin, now thrice its original size, which first receives it, the water is conveyed by flumes into several large brick cisterns; whence it paffes through large wooden pipes to the several diffietets, and is conveyed into the houses by leaden pipes. At the New River Head is a building, containing two steam-engines and a water-engine for forcing the water to a higher re fieror near Pentonville, and to another near Tottenham-court road, for distribution to the western parts of the town. Near the former reservoir, in a field, a conspicuous object appears, the use of which is little known. It is an iron pipe, twelve feet high, and four feet eight inches in circumference, with a wooden tub placed on its top. It acts in the double capacity of an air and waste water-pipe, and is useful in preventing the buildi.
ing of the pipes, which was formerly very frequent from the force of water, or from compressed air. A new reforrer, communicating with that at Bentonville, has been recently constructed by the side of Tottenham-court-road, for the supply of Maryle-bone and its vicinity; the mains from it are iron pipes of four feet eight inches circumference.

The property of this great concern was originally divided into 72 shares, of which 36 were vested in Sir Hugh Middleton, who was obliged to part with them to various persons; these are termed adventurers' shares. The other thirty-six were vested in the crown for the money advanced by King James towards the undertaking. These were alienated by Charles I., and are called king's shares; but as the crown had no concern in the management, so the holders of these shares are excluded from the direction. The original value of the shares was 100l. each, but so discouraging were the first prospects, that they fell to a very low price. At present they are worth an hundred times their first value: a rule in property scarcely to be paralleled, and demonstrative of the increase of buildings in the capital. The management of the company's affairs is vested, by charter, in twenty-nine holders of adventurers' shares, who form a board. The officers are, a governor, deputy-governor, a treasurer, and a clerk. Few public companies surpass this in property and extent of concerns. The constant repairs and improvements employ a vast number of men and horses; and the whole system of the distribution of the water is so complicated, as to require the utmost skill and attention on the part of the surveyor and other officers.

The New River is a considerable ornament to many seats and pleasure-grounds in its course; though it has too much canal-like regularity to be truly picturesque. It is likewise of great utility in affording a supply of water for cattle, and for various other purposes. Hunter's History of London and its Environs, 4to. 1808. NEW ROSS. See Ross.

NEWRY, a considerable sea-port and post-town of the county of Down, Ireland, situated on the Newry water, which falls into the bay of Carlingford, and which was rendered navigable to this town. It was formerly a pafs and military post of considerable importance, as well as the seat of an abbey, whose head wore a mitre, and the polities of which were very extensive. These were granted by Edward VI. to marhial Bagnell, whose name often occurs in the history of that period, and were formed into the lordship of Newry, which still belongs to the Needham family descended from him. In 1689 it was burned by the duke of Berwick to secure his retreat to Dundalk, when pursued by duke Schomberg. Since that time it has considerably increased, and ranks next to Belfast amongst the towns of Ulster. This increase has been chiefly owing to its canal, by which a communication has been formed between lough Neagh and the bay of Carlingford, by means of which vessels of 50 or 60 tons are enabled to pass through the heart of Ulster. The linen manufacture was carried on very extensively, and large quantities of linen were exported, but this trade has been of late much injured. There is a very considerable export of butter, beef, pork, and grain, especially of the first, which is brought from the counties of Cavan and Monaghan, and even from that of Sligo. The imports consist chiefly of those commodities which are wanted to supply the extensive range of country, with which, by its canal, there is a water communication; and these articles in an opulent manufacturing country are daily increasing. Flax feed and coal are amongst the most considerable. There are also some extensive manufactories and other lucrative establishments. Newry is what is called a post-valling borough, and returns a member to the parliament of the united kingdom. The number of electors is considerable, but the influence of the proprietor generally prevails at an election. In consequence of the grant before noticed, the proprietor, lord victor Kilmorey, not only receives the tithes, and grants marriage licences, but has also great civil authority, though some of his privileges have been purchased by the flate.

Newry is 50 miles N. from Dublin. N. lat. 54° 16'. W. long. 6° 15'. Beaumont, Coote, Wakefield, &c.

News sheet, in Geography, a folio on the N.W. coast of Rio's island, in the Pacific ocean. S. lat. 8° 50'. E. long. 220° 47'.

NEWSPAPERS; for an account of their number in London, see London. By the 44 Geo. III. c. 98. every public newspaper, contained in half a sheet or less double demy, or in one sheet single demy, not exceeding 32 inches in length, and 22 inches in breadth, is chargeable with a duty of 3½d.; and if larger than half a sheet of double demy, or one whole sheet single demy of the same sizes respectively, 3½d. By 37 Geo. III. c. 90. a discount is allowed under certain restrictions, of 16½ per cent. to those who pay at one time 10l. or upwards; but by 49 Geo. III. c. 50. the discount shall be made, provided the price of the newspapers be not advanced more than one halfpenny above the price at which they were entitled to the allowances of such discount under the said act of 37 Geo. III. c. 90. A penalty of 2cl. is imposed on those who do not print the full price on newspapers. On every pamphlet contained in half a sheet of paper, there is a duty of 5d. On every printed copy of a pamphlet larger than half a sheet, and not exceeding a whole sheet, 1½. Above one sheet, and not exceeding six sheets in octavo, or a letter page, not exceeding twelve sheets in quarto, or twenty sheets in folio, for every sheet which shall be contained in one printed copy of it, 2½. (10 Ann. c. 109. Geo. III. c. 93.) These duties admit of certain exemptions. If any person shall write, print, or expose to sale any pamphlet or newspaper, liable to the duties above-mentioned, the said pamphlet exceeding one sheet only excepted, before the paper shall be stamped, he shall forfeit 1cl. with full costs. If any, containing more than one sheet, shall be printed or published, and the duty not paid, and title registred, and one copy stamped deposited where required fo to be, within the time limited of six days after printing, within the bills of mortality, and without the bills at fourteen days, the author, printer, and publisher, and all other persons concerned, shall lose all property in it and in every copy of it, and also forfeit 2cl. with full costs. Nor shall any person expose to sale any such pamphlet, without the name and place of abode of some known person, by or for whom it was printed or published, written or printed thereon, or pain of 2cl. Pamphlets unfold shall be cancelled by the commissioners, and the like number of other sheets stamped gratis shall be allowed for them. (44 Geo. III. c. 98.) Or, instead of these allowances on a cancelling of newspapers remaining unfold, there shall be an abatement made to every person who shall pay at one time for newspaper stamps 10l. or upwards, after the rate of 4l. in the 100. No hawkers
of newspapers, or other persons, shall let out any newspaper for hire to any person, or to different persons, from house to house, on pain of forfeiting 5l. (29 Geo. III. c. 50.) By 16 Geo. II. c. 26. any person convicted of selling, or exposing to sale, any newspaper, or any book, pamphlet, or paper deemed to be a newspaper, unfamped, may be committed to the house of correction for any time not exceeding three months: and any person printing or publishing, and keeping in his custody any newspaper, &c. or paper not duly stamped, shall forfeit for every such paper 5ol. over and above all other penalties. (38 Geo. III. c. 78.) Nor shall any newspaper be printed on paper exceeding 32 inches in length, and 32 in breadth. (44 Geo. III. c. 98.) Any person printing or publishing seditious matter, under colour of its having been printed in a foreign paper, shall, upon conviction, be committed to prison for a term not exceeding twelve, nor less than six months; and be liable to such other punishment as may by law be inflicted in cases of high misdemeanors. (38 Geo. III. c. 78.) For every advertisement in the Gazette, or other printed paper, published weekly, or oftener, or in any periodical paper or pamphlet published at any time exceeding a week, shall be paid by 44 Geo. III. c. 98. 3l. But nothing herein shall extend to any single advertisement printed by itself.

NEWTON, Thomas, in Biography, who flourished in the 16th and 17th centuries, was the eldest son of Edward Newton of Prelbury, in Cheshire, where he was born. He received the first rudiments of grammatical learning under John Brownfwerd, for whom he appears to have retained the most ardent affection. In his excommunication on several illustrious men of England, he applies the following remarkable installation to him:

"Rhethora, grammaticum, polyhifera teque poetam Quis negat?—is Hippus, iucnis, obelus, mers."

So great, indeed, were his respect and attachment for the memory of this gentleman, that he erected a monument to him in the church of Macclesfield, in Cheshire, with a Latin inscription. Newton, the subject of this article, was sent very young to Oxford, from whence, in a short time, he removed to Cambridge, where he entered himself in Queen's college, and became so eminent for his skill in Latin poetry, that he was ranked among the most celebrated modern poets who have written in that language. After this he returned to his native county, and having obtained the warm and zealous patronage of Robert, Earl of Ellifex, he taught school, and at the same time practised phyic with success at Macclesfield. He was likewise in holy orders, and afterwards became beneficed at Little Ilford, in Eiffex, where he also exercised his profication as a schoolmaster, and where he continued till his death, which happened in 1657. He was buried in the church belonging to that village, for the decoration of which he left a considerable legacy. He wrote and translated many books, and among the latter was the tragedy of Seneca, entitled "Thébâis." He undertook also the publication of the other tragedies of this poet, translated by Heywood, Neville, Nuce, &c. Biographic Dram.

NEWTON, John, an English mathematician, and divine of the established church, was born at Oundle, in Northamptonshire, in the year 1642. Having attained a good share of classical knowledge, he was, at the age of fifteen, entered a commoner at St. Edmund's hall, Oxford. In the year 1644, he took his degrees of B.A. and M.A.; the latter in precedence to many students of quality, on account of his distinguished talents in the several branches of literature. He was particularly attached to the study of mathematics and astronomy, and had applied himself so assiduously to them, as to have obtained a high reputation in those departments of learning, of which he reaped considerable advantages during the civil wars, and the government of Cromwell. The sciences, however, properly so called, did not engage so much of his time as to prevent him from becoming great in his profession as a divine, which qualified him for those preferments in the church, to which he was successively appointed. In the year 1661, immediately after the restoration, he was created doctor of divinity at Oxford, and was nominated chaplain to his majesty, and present to the rectory of Roffe, in Herefordshire, which he held till his death on Christmas-day 1678, when he was about 56 years of age. By Anthony Wood he is denominated a capricious and humorous person; but his writings are a proof of his great application to study, of which we may mention the following: "Altronomia Britannica, exhibiting the Doctrine of the Sphere, and Theory of Planets decimally by Trigonometry;" "Help to Calculation, with Tables of Declination, Aization, &c.;" "Trigonometria Britannica, shewing the Construction of the natural and artificial Sines. Tangents, and Secants, &c.;" this consists of two books, one composed by the author, and the other translated from the Latin of Henry Gellibrand; "Chiliadis centum Logarithmorum;" "Geometrical Trigonometry;" "Mathematical Elements;" "Definition and Use of the Carpenter's Rule;" "The Art of Gauging." Besides these, Mr. Newton was author of many popular works for young persons, which were probably extremely useful at that time; though they have long since been superseded by others better adapted to the instruction of youth of both sexes.

NEWTON, Sir Isaac, the most illustrious of philosophers and mathematicians that the world ever produced, and who, on account of his well-earned celebrity, has been denominated the "Prince of Philosophers," was born on Christmas-day 1642, at Woolthorpe, a hamlet in Lincolnshire, about six miles south of Grantham. His father cultivated his own paternal estate, but is represented as being a very weak and unready man, who died three months before the birth of his only son Isaac, the subject of the present article. Mrs. Newton, though the married again, was particularly attentive to the education of her first-born, and had him carefully instructed in the elements of learning. At the grammar-school of Grantham he laid a solid foundation of classical learning, and gave decisive marks of his natural genius. Dr. Stukely, in speaking of him, says, "Every one that knew for Isaac, or have heard speak of him here, recount the pregnancy of his parts when a boy, his fine inventions, and extraordinary inclination for mechanisms; that, instead of playing with other boys, when out of school, he always busied himself in making knicknacks, and models of wood in many kinds; for which purpose he had got little saws, hatchets, and hammers, and a whole shop." The most trifling circumstances, relating to so vast a genius as Isaac Newton exhibited, are deserving of record: hence may be mentioned his very early attention to natural objects and investigation. He had, for instance, when a very little child,
child, a rude method of measuring the force of the wind, by observing how much farther he could leap in the direction of a strong breeze, than he could when he jumped against the wind. When he quit the grammar-school, he was taken home to be inculcated in rural affairs, in order that he might hereafter be capable of managing his own estate with advantage. It was, however, soon discovered that he had higher objects in view than the mere cultivation of land, and attending to domestic concerns: he was perpetually found reading books, which were supposed to be beyond his capacity. He had, previously to this, probably laid it down as a maxim, that what one man could write, that was in itself intelligible, another might, by a certain portion of application, come to understand. Being once sent to Grantham market, he was discovered by his uncle, in a hay-loft, working a mathematical problem; which satisfied this relation that his desire of knowledge was invincible, and that a regard ought to be paid to the turn of his mind: he, therefore, without hesitation, was allowed to enter himself, in the year 1660, of Trinity-college, Cambridge. He was now 18 years of age, and entering upon his course with all the ardour of enthusiasm, much might be expected from him; but, as we shall see, he outran all expectation, and yet at defiance the calculations of his most sagacious friends. The activity of his genius, and excellency of his talents, acquired for him the notice of the most considerable mathematicians in the university, among whom was Mr. (afterwards Dr.) Barrow, at that time a fellow of Trinity-college. The friendship thus begun between these two persons, was continued till the hand of death separated them. Newton began his studies with the “Elements of Euclid”; but these did not detain him long. To him there was no “Pons Aenrorum,” no difficulty that impeded his progress a single moment: he saw the truth of each proposition, it has been laid upon unquestionable authority, as soon as he had read the enunciation, and examined the figure to which it referred. The beautiful and sublime truths of common geometry did not, to Newton, lie deep in a well: they seemed instantly to fasten on his mind, and, as he thought, to urge him on to more difficult steps in the progress of science. Afterwards, however, the ingenuouselffs of his mind led him to regret that he had not flopped longer at the gates of knowledge;—that he had not refled a while in the avenues, to contemplate the beauties and excellencies of the plans and outworks, before he had proceeded into the interior;—that he had not examined with a more minute attention Euclid’s method of demonstration, and the means by which he had contrived to connect every part of his book, so as to make a system or series of truths depending upon one another, and the whole reeling on definitions and axioms; though the axioms themselves will, if closely examined, be found to be only definitions; so that the whole of Euclid’s Elements may be safely said to depend entirely on definitions, which proves how important it is for students in geometry, not endowed with peculiar mathematical facility, to study with the utmost care the definitions, and to proceed from one step to another with the greatest deliberation. Newton, as we have seen, did not fland in need of this precaution; yet he regretted in after life, that “he had committted a mistake in the commencement of his mathematical studies, in applying himself to the works of Des Cartes, and other algebraical writers, before he had considered the Elements of Euclid with that attention which so excellent a writer deserves.” At this period the works of Des Cartes were much in fashion, which of course led our author to study them, attending at the same time to “Kepler’s Optics,” and to the “Arithmetica Infinitorum” of Dr. Wallis, making improvements and marginal notes upon them as he went along, which was his usual method of studying any author. The treatise of “Infinities,” just referred to, set his invention to work, and was probably that which led him to his “New Method of infinite Series and Fluxions,” and which was published in Latin; but which, in 1736, was translated into English by Mr. Colfon, and printed by him, with a perpetual Commentary upon the whole book. In the year 1664 he took his degree of B.A., and about this period he turned his attention to the improvement of telescopes. Des Cartes assuming the commonly received opinion, that light was homogeneous, had, upon this principle, discovered the laws of refraction, and maintained that the perfection of telescopes depended on the discovery of a method of making glasses in elliptic, parabolic, or hyperbolic figures. Newton, therefore, in the year 1666, applied himself to the grinding of optical glasses of divers figures; at that time not supposing that light was other than an homogeneous substance. Not succeeding in various attempts which he made, he procured a glafs prism, for the purpose of examining the phenomena of colours, which had lately been discovered by Grimaldi. The vivid brilliancy of the colours produced by this experiment at first afforded him very great pleasure; but when his surprise was over, and he came to examine them with philosophical accuracy, he was astonished at seeing them in an oblong form, which he thought should be circular. He imputed the irregularity, at first, to some accidental circumstance of which he was not aware; when, however, he found the result uniformly the same in every experiment, he purified the inquiry, till at length he discovered an infallible method of deciding the point, which produced his “New Theory of Light and Colours.” This theory, unexpected and wonderful as it was, did not satisfy him; but urged him on to inquire into the ufe that might be made of it in improving telescopes, which was his first design. Having now ascertained that light was not homogeneous, but a heterogeneous mixture of differently refrangible rays, he computed the errors arising from this different refrangibility; and finding them to exceed some hundreds of times thoé occasioned by the circular figure of the glasses, he began to study the subject of reflection with the utmost care. He was now convinced that optical instruments might be brought to any degree of perfection, provided a sub stance could be found which would bear a polish as finely as glass, and reflect as much light as glasses transmit, and that the art of giving it a parabolic figure could be attained. These desiderata he did not suppose could be realized; but while his mind was intently occupied by the speculation, the breaking out of the plague at Cambridge, in 1665, obliged him suddenly to quit his studies and his books, and retire into the country. From this time, for a space of about two years, Newton lived, in a great degree, secluded from the conversation and the society of those persons, by whom he might have been afflicted in his studies; but the activity of his genius would not permit him to spend this period without engaging in important philosophical inquiries. It was, indeed, in the solitude now referred to, that the hint occurred which gave rise to the System of the World, which is the main subject of his “Principia.” As he was sitting alone in a garden, an apple falling from a tree, led his thoughts to the subject of gravity; and reflecting on the operation of that principle, he began to consider that, as this power is not found sensibly diminished at the remotest distance from the centre of the earth to which we can ride, neither at the tops of the loftiest buildings, nor on the summits of the highest mountains, it was reasonable to conclude that it must extend much farther than was usually imagined. Why not,” said he to himself, “as high as the moon? and if so, her motion must be...
influenced by it. Perhaps he is retained in her orbit by it. Though the power of gravity is not sensibly weakened in the little change of distance at which we can place ourselves from the centre of the earth, yet it is very possible that, as high as the moon, this power may differ in strength much from what it is here." He made the calculation; but having gone upon wrong data, in supposing 60 miles to make a degree, instead of 69', the result did not come out according to his expectations; he therefore concluded, that some other causes must be joined with the action of the power of gravity on the moon; and on this account he laid aside, for that time, any further thoughts upon the subject.

On his return to Cambridge, in 1667, he was elected fellow of his college, and took his degree of M.A. He now was anxious to improve the telescope, and had made preparations for his experiments, when his attention was interrupted by the business connected with the professorship of mathematics, which Dr. Barrow resigned to him in 1669. Having entered upon the office, he made his discoveries in optics the subject of his lectures, for the first three years after his appointment to the mathematical chair: and having brought his theory of light and colours to a considerable degree of perfection, he communicated it to the Royal Society, of which he was a member; and it was afterwards published in their Transactions, for the month of February 1672. The publication gave rise to a controversy that occasioned him much uneasiness, so that he resolved not to publish any thing further, for a time at least, on the subject; and accordingly he laid aside his optical lectures, although they were actually prepared ready for the press. His analysis by infinite series underwent the same fate. He now resumed his telescope, and observing that there was no absolute necessity for the parabolic figure of the glasse, he completed another instrument of this kind. This answered his purpose so well, that, though it was only six inches long, he had seen with it the satelites of Jupiter, and the different phases of Venus. This telescope he lent to the Royal Society, at their request, together with a description of it, published in the Philosophical Transactions for March 1672.

During this year Mr. Newton published at Cambridge "Bernard Vareni Geographia generalis, in qua afferentones generales Tellarum explicatur; aucta et illustrata ap J. Newton." From this time till 1679 our author maintained a correspondence with Mr. Henry Oldenburg, secretary of the Royal Society, Mr. John Collins, Mr. Flamsteed, and Dr. Halley. During this period, at the request of Leibnitz, he explained his invention of infinite series, and shewed how far he had improved it by his method of fluxions, which, however, he still concealed by a transposition of the letters that made up the fundamental propositions of it into an alphabetical order. The letters concerning this are inserted in Collins's "Commercium Epistolicum," printed in 1712. In 1676-7, he discovered the grand proposition, that, by a centripetal force acting reciprocally as the square of the distance, a planet must revolve in an ellipsis, about the centre of force placed in its lowest focus, and, by a radius drawn to that centre, describe areas proportional to the times. About the year 1680 he made many astronomical observations upon the comet that then appeared; which, for some considerable time, he took not to be one and the same, but two different comets, contrary to the opinion of Mr. Flamsteed. He next resumed his enquiries respecting the moon. As Picart had measured a degree of the earth in 1679, by using his measures, Newton was led to the inference that the moon is retained in her orbit solely by the power of gravity, and, consequently, that this power decreases in the duplicate proportion of the distance, as he had formerly conjectured. Hence he found

the line described by a falling body to be an ellipsis, having one focus in the centre of the earth; and ascertaining, by this means, that the primary planets really moved in such orbits as Kepler had supposed, he had the satisfaction to see that the enquiry, which he had undertaken, at first, from motives of mere curiosity, was capable of being applied to the most important purposes. Upon this he drew up, and afterwards demonstrated, about a dozen propositions relating to the motions of the primary planets round the sun, which he communicated to the Royal Society towards the close of the year 1683. Shortly after this he fell down to complete his great work, the "Principia," which was printed under the care of Dr. Halley, and published in the summer of 1687, under the title of "Philosophiae Naturalis Principia Mathematica." This treatise was composed by the illustrious author from scarcely any other materials than the few propositions above-mentioned, and in the space of a year and a half: it has gone through a great number of editions, though it did not at first meet with that fort of applause to which it was justly entitled. One reason of this was, that Des Cartes had then got full posseffion of the world, and his philosophy was supposed to be better adapted to common understandings. The "Principia," on the other hand, is in many places extremely difficult, owing to the number of steps which is left out in the demonstrations, so that the best mathematicians were obliged to study it with care, before they could pretend to become masters of this vast treasure of human learning. And notwithstanding the help that we now have to the right understanding of the "Principia," in Maclaurin’s and Pemberton’s works; in the "Excerpta" of Dr. John Jebb, and in the Commentaries of the Jefuits, published at Rome in four volumes quarto; fill it may be assumed that "none but mathematicians of a high order can completely comprehend the reafonings contained in it. When, however, the true value of this work came to be known, the approbation which had been so slowly gained became universal, and nothing was heard from all quarters, but admiration of what seemed to be the production of a celestial intelligence, rather than of a man." "Does Mr. Newton eat, or drink, or sleep like other men?" said the marquis de l’Hopital, one of the greatest mathematicians of the age, "I repreffent him to myself," he added, "as a celestial genius entirely difengaged from matter."

A short time before this work went to the press, the privileges of the university of Cambridge were attacked by king James I, who sent a mandamus to admit father Francis, an ignorant Benedictine monk, to a degree of M.A. On this occasion Mr. Newton appeared among the most zealous and active defenders of that body, and was appointed one of the delegates to the high-commiffion court, where they maintained their cause with such resolution and firmness that the king did not think it right to press the affair. Newton was, after this, chosen one of the representatives of the university in the convention-parliament of 1688, the feilions of which he attended till its dissolution. In 1696, Mr. Newton was appointed to the office of warden of the mint, and in this situation he rendered very important service to the nation, and was properly rewarded, in a few years, with the appointment of master of the mint, a place worth 12000l. per annum, which he held during the remainder of his life. Upon the promotion he resigned the mathematical chair at Cambridge, and was succeeded in it by Mr. William Whiston. In 1699 he was elected a foreign member of the Royal Academy of Sciences at Paris, and in 1703 he was chosen president of the Royal Society of London, and retained that honourable office till his death. In the following year he published his "Optics; or A Treatise of the Reflections, Refractions,
Newton.

Refractions, Infections, and Colours of Light." This work was the result of his occasional labours for thirty years in bringing the experiments, on which his "New Theory of Light and Colours" is founded, to that degree of certainty and exactness which alone could satisfy himself. This seems to have been his favourite invention: he was the first person who conceived the idea, and engaged in the subtle and delicate study of the anatomy of light; who diffused a ray of light into its primary constituent particles, which then admitted of no further separation; who discovered the different refrangibility of the particles thus separated, and that these constituent rays had each its own colour inherent in it. On this subject we could enlarge would our limits allow. With the approbation of the author, Dr. Samuel Clarke translated the "Optics" into the Latin language, and he did the business so much to the satisfaction of Mr. Newton, that he presented him with 500l. for his labour. It was published in 1706. With the first edition of his Optics, the author published his "Quadratures of Curves," which may be regarded as the earliest appearance, in print, of his Method of Fluxions, which he had invented in the years 1665 and 1666. M. Leibnitz had, since the year 1684, endeavoured to impress the world with the perfections that Newton had borrowed this invention from his "Differential Method," when, therefore, our illustrious countryman laid claim to his own discovery it led to much altercation, but the learned world in general decided in favour of Newton; and Fontenelle, in speaking on the subject, says, "Sir Isaac was, by many years, the first inventor. M. Leibnitz, on the other side, was the first who published this method of calculation; and if he took it from Sir Isaac Newton, he reftumbled Prometheus in the fable, who stole fire from heaven that he might communicate it to men." See our article KILL, John.

In the year 1705, Queen Anne conferred on Mr. Newton the honour of knighthood: two years after this, Mr. Whiston, by our author's permission, published his Algebraical Lectures, under the title of "Arithmetica Universalis, seu de Compositione et Resolutione Arithmetica Liber," which work was translated into English by Mr. Raphson. In 1711, our author's "Analysis per Quantitatum Series, Fluxiones et Differentias, cum Enumeratione Linearum tertii Ordinis," was published by William Jones, Esq. F.R.S., who met with a copy among the papers of Mr. Collins, to whom it had been communicated by Dr. Barrow. It was published in consequence of the dispute relating to the invention of fluxions, which also occasioned the printing, in 1712, by the consent of Sir Isaac, a Collection of Letters, already referred to, by him and others in that controversy, under the title of "Commencium Epistolicum D. Johannis Collins et aulorum, de Analyi promota, jufu Societas Regia in Lucem editum." In the year 1715, M. Leibnitz, with the view of gaining credit to the pretenion that the "Method of Fluxions" had been borrowed from his "Differential Method," attempted to baclle Sir Isaac Newton's mathematical skill by his famous problem of his "Trajectories," which he proposed to the English by way of challenge; but though it was the most difficult proposition which his ingenuity, after much study, was able to devise, the solution of it proved fearcely more than an amusement to Newton. The problem was received by him at four o'clock in the afternoon, as he was returning from the mint, and though he was extremely fatigued with business, he yet finished the solution of it before he retired to bed.

Upon the accession of King George I. to the British throne, Sir Isaac was particularly noticed at court, and was specially introduced to the princes of Wales, afterwards queen Caroline, who took great delight in literary and philosophical enquiries, and in the conversation of men distinguished by their talents and knowledge. With that of our author she was always peculiarly gratified, deriving from it that full satisfaction in every difficulty, which she had in vain sought for elsewhere, and the did not scruple to say that she thought herself happy in coming into the world at a juncture of time which put it in her power to converse with Sir Isaac Newton. At the solicitations of this prince she drew up an abstrac of his "Chronology," and communicated a copy of it to the Abbé Conti, upon the promise of his keeping it secret; instead of which he had it translated and printed at Paris, under the title of "Abregé de Chronologie de M. Le Chevalier Newton, fait par lui-même et traduit fur le Manuscript Anglais:" a copy was sent to Sir Isaac by the bookseller who printed it, under the pretence of asking his consent to the publication; but though he gave a direct and most explicit denial, the work was sent into the world in the course of the year. He accordingly found it necessary to enter into a vindication of himself, which was inserted in the 34th volume of the Philosophical Transactions, under the title of "Remarks upon the Observations made upon a Chronological Index of Sir Isaac Newton, translated into French by the Observator, and published at Paris." Of this paper a translation appeared at Paris in 1726, with a letter of the Abbé Conti in answer to it. In the same year, likewise, some dissertations were published at Paris by Father Sanctier, against the "Chronological Index," a reply to which, by Dr. Halley, was given in the 59th Number of the Phil. Trans.

Our philosopher enjoyed a regular and pretty equal state of health until he attained his eightieth year, when he began to decline: his illness was supposed to be occasioned by a stone in the bladder, which at times was attended with such paroxysms of pain as caused large drops of sweat to roll down his face. During these attacks he was never heard to utter the least complaint, nor to express any impatience, and as soon as he had a moment's ease he would smile and converse with his usual cheerfulness. Till this period he had always read and written for several hours in a day, but he was now rendered incapable of much application.

On the morning of the 18th of March 1726-7, he read the newspaper, and conversed for a considerable time with Dr. Mead, his physician, having then the perfect use of his faculties, of which he was, however, deprived in the course of the following night, and he breathed his last on the 20th of the same month, being in the 85th year of his age. Splendid funeral honours were paid to his remains, in a manner, in every respect, suitable to his extraordinary merit, and that high estimation in which he was deferentially held in every part of Europe. His body lay in state in the Jerusalem chamber, adjoining the house of lords; and at the interment the pall was supported by the lord chancellor, the dukes of Montrose and Roxburghe, and the earls of Pembroke, Suffolk, and Macclesfield.

In contemplating the character and genius of this great man, it is not easy to determine whether sagacity, penetration, strength, or diligence had the greatest share in his composition. He entertained a very modést opinion of his own abilities, saying, when complimented on the extraordinary powers of his mind, if he had done any thing worthy of notice, and of service to the world, it was owing more to his industry and patience of thought, than to any extraordinary sagacity. "I keep the subject constantly before me," said he, "and wait till the first dawning open slowly, by little and little, into a dull and clear light." When engaged in the solution of difficult problems, he was often to completely lost to the world as to forget the common concerns
concerns of life. He has been known to fit for hours on the fide of his bed with his clothes half on and half off, absorbed in thought; at other times he has gone through the day without food, having forgotten the wants of nature, in the contemplation of some mathematical truth. Our author’s temper is said to have been fo mild and equal, that scarcely any accident could disturb it. One insitute in particular is mentioned of this disposition. He had a fa- vertile little dog called Diamond, which being left in his fludy, had overft a lighted candle, among his papers, and burnt the almoft finished labours of many years. This loss was irretrievable, yet the philopher only exclaimed, “O Diamond! Diamond! thou little knoweft the mischief thou haft done.”

It should be noted that Sir Isaac Newton was candied and affable, and always put himself upon a level with his company. He never thought either his own merit or reputation sufficient to exculp him from any of the common offices of social life; and no singularties, either natural or affected, distinguished him from other men. With respect to his religious sentiments, he was unquestionably a firm believer in the truth of divine revelation, and a serious, rational Christian. His discoveries concerning the frame and fystem of the universe, he employed to demonstrate the existence of a God, against Atheifm of all kinds, and to ill- strate his power and wisdom in the creation of the world; and he directed himself with the utmost attention to the study of the sacred writings, and considered the several parts of them with uncommon exactness. He adhered, outwardly, to the communion of the church of England, though he did not believe in all its doctrines: with respect to the perfon of Christ, there seems no doubt that Sir Isaac Newton was inclined to Unitarianifm; for this we have the testimony of his friend and co-operator in the mint, Mr. Hopton Haynes, independently of his own writings. Sir Isaac was never married, and Fontenelle fays he never had time to think of it, taken up as he was, at firft in profound and continual study, and afterwards employed in an important and confiderable poft, which left no vacancy in his life, nor any occasion for domestic society. He died rich, and affeitate. His library has descended to the prezent times, in his own family, and at the moment of writing this article (March 27, 1813.) it is felling by auction in London, by order of the executors of Mrs. Ann Newton. (See Newtonian Philosophy.) For a notice of our author’s works not mentioned in this article the reader is referred to the Biographia Britanica: the moft complete edition of them, collectively, was given to the public by Dr. Horfley in 1785, in 5 vols. royal 4to. See Horsley, Biog. Brit. Pemberton’s and Macauley’s Views, &c.

Newton, Richard, a learned divine of the church of England, the founder of Harfert college, Oxford, was born at Yardley-Chace, in Northamptonshire, in the year 1675. He was educated at Weftminifter school, and at a proper time was elected to a fellowhip of Chriftchurch college, Oxford. Here he took his degrees of M.A. and B.A., but at what particular period is not known: he pro- ceeded doctor in divinity in the year 1710. For some time he filled the office of college tutor, during which he acquired a high reputation, and afterwards became private tutor in the family of lord Pelham, having under his care the two brothers of his lordship, who were afterwards dif- tinguished as statesmen, viz. the duke of Newcastle and Mr. Pelham; and both these illustrious persons ever after entertained for him a very high regard. Dr. Newton had, however, an independent and noble spirit, which prevented him from soliciting a favour, even from his own pupils, when they had the power of ferving him. Mr. Pelham, when prime minister, it has been said, employed him, more than once, to draw up the king’s speeches; and when that statesman was asked why he did not place Dr. Newton in a fation worthy of his merits? he replied, “How could I do it? He never asked me.” Such is the gratitude of prime ministers!! If his labours as a tutor and politician did not obtain for him the debt of justice; his reputation for learning, and the excellence of his character as a clergy- man, were the means of his preferment. Dr. Compton, bishop of London, collated him to the rectory of Sudbury, in Northamptéonshire, and in 1710 he was, through Dr. Aldrich, induced principal of Hart-hall, which he re- tained with the living of Sudbury, where he refided several years. At this time Hart-hall was an appellation to Exeter college: from a state of dependence, Dr. Newton conceived the project of refucing it, and of erecting it into an independent college. In the purfuit of this laudable purpoze he had to encounter much opposition, particularly from Dr. Conynweare (see his article). The struggle between them lafted some years, and it has been faid, that in no con- teft were two abile men more equally matched, and that the papers which paffed between them, like Junius’s letters, de- ferved to be collected, on account of the beauty of their fyle, and the ingenuity of their arguments. Dr. Newton did, however, fucceed in accomplifhing the object which he had in view, and in the year 1740 obtained a charter, converting Hart-hall into Hertford college; of which, at a great expence to himself, and with confiderable aid from his friends, he was the founder and firft head. He was afterwards promoted to a canony of Chriftrinch, and held it with his principalhip of Hertford college till his death, which happened in the year 1753, when he had at- tained to the 76th year of his age. He was as polite a scholar, and as accomplished a gentleman, as almoft any perfon of the age in which he lived. With the modern languages, as well as with the ancient ones of Greece and Rome, he was intimately acquainted. In clofenes of argument, and perfcucity of fyle, he had no superior. “Never,” says his biographer, “was any private perfon employed in more truths, nor were truths ever discharged by any man with more integrity.” Though attached to the church of which he was a member, he lived in habits of friendship with many who difented from that church: he visited and highly efteemed the celebrated Dodridge. He faw, and with pleasure admitted, that they both aimed at the fame great end in fitting young men for the important work of the Christian ministry. On his death-bed, Dr. Newton ordered all his writings to be defteroyed, excepting a fele& number ofermoins which he intended for the press. These, with three or four others that had been published in his lifetime, were published in an octavo volume in 1784: he was author also of “A Scheme of Discipline, &c. for Harfert-hall;” “University Education, or an Explication and Amendment of the Statute which prohibits the Admission of Scholars going from one Society to another, &c.;” “Pluralitys Indefensible &c.;” and after his death, his successor, Dr. Sharp, published from his manuscripts “The Characters of Theophratus, with a strictly literal Translation of the Greek into Latin, &c. with Notes.” Gent. Mag. 1785-4;

Newton, Thomas, a learned English prelate, was born at Lichfield in the year 1704. He received the first part of his education in grammar learning at the free-school of his native town, whence he was removed to Weftminifter school in 1717, and was nominated a king’s scholar. Having continued there six years, he was elected to Trinity college, Cambridge, where he refided eighteen months in every year, affiduously occupied in his studies till he had taken
taken his degree of B.A. after which he obtained a fellowship of his college, and then came to settle in London. He was ordained deacon in December 1729, and priest in the following year by Dr. Gibson, bishop of London. For some time he officiated as curate at St. George's church, Hanover-square. His first preferment was that of reader and afternoon preacher at Grosvener-chapel, in South Audley-street; in which situation he became acquainted with Lord Carpenter, who took him into his family as tutor to his son, who was afterwards created earl of Tyrconnel. In 1738 he was appointed, by Dr. Pearce, morning preacher at the chapel in Spring-gardens, which gave him an opportunity of becoming acquainted with several of the most eminent persons of the day, among whom was that of Mr. Pulteney, and thus opened his way to preferment. When Mr. Pulteney was created earl of Bath, Mr. Newton was appointed his first chaplain, and through his lordship's interest, in 1744, he was preferred to the rectory of St. Mary-le-Bow, in Cheapside. Upon this promotion he quitted the chapel in Spring-gardens; and his fellowship at college became vacant. At the Commencement in 1745 he was admitted to the degree of D.D. During the rebellion of this year, he was distinguished by the zeal with which he defended the cause of his king and country in the pulpit; and he published a sermon which he preached before the house of commons, and other public places. In 1747 he was chosen a lecturer of St. George's, Hanover-square. In 1749, Dr. Newton published, by subscription, his splendid edition of Milton's Paradise Lost, in 2 vols. 4to. accompanied with notes; and he prefixed to it a life of the author, intending to include the substance of all the preceding editions of Milton, with improvements and additions. This was an extremely popular work, and passed through eight impressions during the life of the editor. After this Dr. Newton published the "Paradise Regained," and other poems of the divine Milton, in the same manner, with notes, the result of the communications of persons of the greatest eminence in the republic of letters. From these editions of Milton he gained more in a pecuniary way than the author did from all his works together, but his greatest gain, in his own estimation, was that which he acquired by their introducing him to the friendship and intimacy of two such men as bishop Warburton and Dr. Jortin. In 1751, Dr. Newton preached a sermon at St. George's, Hanover-square, upon the occasion of the death of the prince of Wales, which was the cause of his being appointed one of the chaplains to her royal highness the princess of Wales. In 1754 he lost his father, at the age of 83, and within a few days he met with a still more severe affliction in the death of his wife, at the early age of 38, with whom he had lived most happily about seven years. This, however, was the feverish lass he had ever met with, and it had nearly overwhelmed him. At this time he was fortunately engaged in writing his "Difficulties of the Prophecies," an employment which he found well calculated to draw him from himself, and thus alleviate his forrow. The first volume of this work was published in the following winter, but the others did not appear till about three years afterwards. In the mean time the author was appointed to preach the lecture founded by Mr. Boyle. His "Difficulties" were originally drawn up in the form of sermons, but were afterwards new-modelled, and confirmed by proper authorities. They met with a favourable reception both at home and abroad, having gone through a great number of impressions, and have been translated into several languages. In 1757, Dr. Newton was nominated one of the chaplains in ordinary to his majesty, while he was permitted to retain his situation in the prince's household, and soon afterwards he was made prebendary of Wellminster. This preferment was speedily followed by his appointment to the office of sub-almoner to the king, for which he was indebted to the unfelted favour of Dr. Gilbert, archbishop of York, who also gave him the prebendarship of his church. In 1761 he was nominated bishop of Bristol, and canon-refiduary of St. Paul's, with a permission to hold his city-living in commendam. In 1764 he was thought of by ministers as a proper person to fill the vacant see of London, but the king had given that kind of promise for bishop Terrick, during lord Bute's administration, which he thought himself now obliged to fulfil. In the same year he was prised to accept the premiership of Ireland, but being turned of 60 years of age, he thought it proper to decline the offer, thinking it was too late in life to change his country, and to form an entirely new set of connections, and the more so as his health was very precarious. In 1768 he was made dean of St. Paul's, when his ambition was amply satisfied, and he immediately resigned the rectory of St. Mary-le-Bow. Scarcely had he taken possession of his deanery-house when he was seized with a very serious attack, which had nearly proved fatal, but he recovered so far as to be able, for several years, to go through the duties of his offices with some degree of regularity. In 1776 he retired to a house at Kew-Green, which he purchased for the sake of getting out of the battle of the world. Here his principal exercise was walking in his rooms, which he did repeatedly in the intervals between reading and writing. Company he did not stand in need of; besides, he had resources in himself, and possessed a never-failing fund of employment and entertainment in his books, prints, and pictures. There were the most expensive articles of his life, and in pictures it may be said he indulged in some kind of excels. As a lover of the fine arts, the Royal Academy applied to him, representing that the art of painting would never grow up to maturity and perfection, unless it could be introduced into churches as in foreign countries; that to make a beginning, they offered their services, free of expense, to the dean and chapter to decorate St. Paul's with Scripture histories. The dean was delighted with the offer, and communicated it to his majesty, whose approbation he readily obtained. But the archbishop of Canterbury, and the bishop of London, disapproved of the measure, as likely to excite much clamour and prejudice in the multitude, and to be represented as an artful step towards the introduction of popery. It was also opposed upon the ground of its aptitude to divert the minds of the auditors from the proper subjects of attention in such places. To his regret and mortification, therefore, our worthy prelate was obliged to abandon a scheme into which he had entered with much ardour. He died suddenly on the 4th of February 1783, having long fustained, with regeneration and patience, the infirmities of old age, added to continual fits of fever pain and sickness. He had just risen and dressed, and then enquired the hour; being answered that it was upon the stroke of nine, the bishop made an effort to take out his watch, to set it right, but fusk down in his chair, and expired without a sigh, or the least visible emotion. The life of this excellent prelate was an exemplary pattern of piety and diligence: he was particularly distinguished by a simplicity of mind and manners, but he was much under the dominion of prejudice, and thought very unfavourably of those whose sentiments were different from his own in religion and politics. Nevertheless, he himself did not admit all the doctrines of the church to which he belonged: he was an enemy to the fylent which inculcates the eternity of helltorments, and wrote in defence of the final restitution of all things. The value of the writings of the bishop of Bristol has been thus estimated in the Monthly Review: "They may
may be reckoned among the most useful, if not the most learned and brilliant productions of this or of any other country. They are plain, rational, and instructive. They bear marks of great industry, piety, and a good understanding. If they have nothing to gratify a metaphysical genius, and little to inform the deep scholar; if fancy is not much charmed by their novelty or elegance; if no addition is made by them to the great stores of criticism and erudition, yet they can boast a higher merit, and are likely to produce an effect that will outlive the inventions of genius, and the accumulations of learning." They consist of the "Differtations on the Prophecies," ninety Differtations on various parts of the Old and New Testament, and on various moral and theological subjects; and "Sermons" and "Charges." The whole were collected by the author, and printed in 3 vols. 4to, with his life prefixed to them, drawn by his own hand. They have since their appearance in 6 vols. 8vo. To the life just mentioned, the Brit. Biog., and the 68th volume of the Monthly Review, we refer for other particulars relating to bishop Newton.

NEWTON, in Geography, a pleasant township in Middlesex county, Maffachusets, on Charles river, incorporated in 1691, and containing 1491 inhabitants; 9 miles W. of Boston. Also, a small town in Chelten county, Pennsylvania; 22 miles S. of Philadelphia. —Also, a township in Rockingham county, New Hampshire, on Powow river, adjoining Amherst, in Maffachusets, 10 or 12 miles S. of Exeter; incorporated in 1749, and containing 450 inhabitants.

NEWTON-Buflhel, a market-town in the hundred of Teignbridge, and county of Devon, England, is situated 12 miles distant from Exeter, and 187 miles from London. It consists of two parishes, now united, i.e. Newton-Buflhel and Newton-Abbot. The houses are very indifferently built, and the streets badly paved. The principal street is much obstructed by an old market-house and shambles, said to be erected by Waller, after the civil wars, as a kind of indemnity for his having attempted to deprive the inhabitants of their established market. The parish church stands about a mile to the west of the town; but there are two chapels of ease within it. The population survey of the year 1811, returns this town as containing 193 houses, occupied by 1001 persons. Four annual fairs are held; and a weekly market on Wednesdays.

About a mile south of the town is Ford, a house built in the reign of king James I. by sir Richard Reynell, an eminent lawyer. In 1635 Charles I. took up his abode here. The house, which now belongs to the Courtenay family, stands in a retired lawn, and opposite to it is a small deer-park. Contiguous to it is a charitable institution, called the "Widows Houfe," founded by lady Lucy, wife of sir Richard Reynell, for the reception of four clergyman's widows.

To the west of Newton, about a mile, is Bradley, an ancient mansion, formerly belonging to the Buflhels, or Bufflehs, from whom the town derives its second appellation, and now the property of —— Lane, esq. The house displays some interesting specimens of ancient architecture; and the surrounding scenery is highly picturesque and romantic. Pelawhale's History and Antiquities of Devonshire.

NEWTON-Douglas, a considerable borough of barony in the shire of Wigton, Scotland, is seated on the river Cree, which is navigable within two miles of the town. This place owes its origin to a younger branch of the Stewarts, earls of Galloway, who gave it the name of Newton-Stewart. The superiority of the village, and neighbouring estate, however, having come into the possession of William Douglas, esq., he granted it to a charter, under the chancery seal, constituting it a burgh of barony, by its present appellation. A very flourishing manufacture of cotton is carried on here; and here are a number of tankards, and a carpet manufactory. Over the river is thrown a bridge, which affords a ready communication with the country on the east; and as it is now a flage town on the great road from Edinburgh, in addition to its other advantages, there is every reason to conclude it will shortly become one of the first towns in this portion of Scotland. According to the parliamentary returns of 1811, it contains 524 houses, and a population of 2847 persons. Beauties of Scotland, vol. ii.

NEWTON in the Willows, a borough-town in the parish of Winwick, hundred of West Derby, in the county of Lancashire, England, is situated eight miles distant from Wigan, and 152 miles from London. It formerly had a market, which has long been diffused, though the market-days are still holding. Newton is a borough by prescription, and has returned two members to parliament from the first year of queen Elizabeth. The town consists chiefly of one broad street. Here is an old hall built of wood, with much painted glass still remaining in its windows; it stands on a rocky foundation; and behind it the rock is hollowed out in a very singular manner; appearing to have had subterraneous passages, which, by removing the surface of the rock, are now laid open. Adjoining to this hall is a small riding ground, which was formerly nearly surrounded by a moat, of which here is still a small remnant. The tradition is, that it was, at some remote period, the residence of a king. Newton contained in the year 1811, according to the parliamentary survey, 1589 inhabitants, occupying 269 houses. Four fairs are held annually; and here is a considerable manufactory of fullings and Manchester goods. At a place called the "Red Bank," near Newton, in August 1648, a detachment of Cromwell's army defeated a party of Highlanders on their march from Preston; and the greater part of the prisoners were hanged in a field near the scene of action, which still bears the name of Gallow's Croft. Beauties of England and Wales, vol. ix., by J. Britton, F.S.A.
