It is flated to be the practice in some of the western districts, where the method of paring and burning is much practised, and in high estimation, that old sainfoin lays, and all such fields as are of a sufficient texture, are usually broken up in this way. Turnips are frequently the first crop; and from the freshness of the land, and the good effects of the ashes, a large crop is mostly produced. But as in those cases the time is too short to get the land in proper tilth for the succeeding crops of barley, grasses, and othersimilar crops, it is often adopted as a better method to sow wheat in the first instance on one ploughing; after which, from the ashes being still fresh in the ground, a crop of turnips may be as certainly depended on, and there is a sufficient length of time to get the land into a complete state of tilth. Mr. Young speaks of this as the best method, on account of the danger of grass crops being destroyed by the red worm, which abounds much in such layers. Wheat flubbles, on the more gravelly kinds, which will produce a tolerable quantity of ashes, are also frequently parred and burnt for turnips with a considerable degree of success. In short, when this practice is properly followed up with the turnip and clover husbandry, its good effects cannot, it is conceived, be disputed in any respect. And in other districts, cole-feed is sown on a shallow ploughing, and never harrowed. This is intended either for a crop of feed, or for sheep-food: in the latter case, it sells at some places for a guinea an acre; in the former, for two or three guineas. Oats are then sown; the crop is productive, and the land, if well laid down to grass, becomes good meadow. But the management in this respect is frequently, it is observed, very bad, only clover and ray-grasses being sown, and after
fix or feven years pared and burnt again; instead of which, if proper feeds were fown, the land would be even afer in a state of improvement. On this, Young remarks, that, one peculiar circumstance attending the breaking up of grafs lands, whether old turf or fainfom lays, in this manner, is the bringing them into order for turnips with only one ploughing; and it is a general and very falt observation, both in the north and weft of England, where this husbandry is molt common, that turnips scarcely ever are known to fail on burnt lands: the fly on fuch is nearly unknown. Now any farmer muft be fenfible of the vail impor-tance of thif, and bringing turf lands by only one ploughing to a turnip crop; much tillage is thus faved as well as a great expense, and the turnips are generally a crop that repays the expences of the operation with profit. In a word, this husbandry deferves the warmeft praife.

An able writer states, that where there are poor, wet, cold, hungry pastures and neglected meadows, over-run and filled with all forts of rubbish, and abounding with too few good plants to render their improvement easy without breaking up, that ife should be pared and burnt; not to keep under the plough, to be exhausted and ruined, which is infa-tillable, and the land left in a worse state beyond all com-parifion than it was before, but to be laid immediatly to grafs, that is, as soon as the course of husbandry neceffary will admit. This, it is conceived, ought to be without variation, under any pretence whatever, in this course of crops: 1st. Pare and burn for turnips to be fed on the land with heep: but in moift-bottomed lands, rape will often fucceef better than turnips: and the heep feed better with rape upon fuch lands. 2dly. Oats; and with thefe oats the grafs feeds fhould be fown. The oats and the turnips, it is afcertained, would more than pay all the expence of a previous hollow draining, beould that be neceffary; of the paring and burning, and every other charge; and the change, from a very bad paffure to a very fine one, would all be neceffary profit. The tenant, it is contended, would be greatly ben-efted, and the landlord find his estate improved, if let, as farms ought to be let, with an absolute exclusion of felling a lock of hay under any pretence whatever. And that this method is praified with great success in the fen land in Lin-cinthire, the bufunefs being performed by means of the plough, and coe-feed afterwards fown. In fome cafes, horfes and ploughs are found, and the labour put out, which, including a ploughing in order to turn in the ahes, is done at feven fhillings an acre: the coe is fed with heep, and is worth three pounds an acre; but the felling price forty to fifty fhillings. Then oats, eight quarters an acre, and ten quarteres have been had; then coe and oats again: being laid down with fourteen pounds of white coefer, and one peck of ray grafs, lets at twenty fhillings. It is found to be a great and lafting improvement of the land. This is conceived to be a low elimin, from the land keeping five heep an acre, from Lady-day to Michaelmas, and one and a half on the acre in the winter. Where then, it is inquired, is the suppofed michief of this praife?

And there are other forts of lands, as dry, rough heep-walks, covered with ling, furze, broom, &c which fhould also be broken up in the fame manner, but universally to be laid down again with the graffes suitable to the foil and to heep. On weak, thin, flapled land, two crops of corn, after paring and burning, may often be perrnicous. Per-haps they might be well laid down without a single one, which would be a better method of management. It is also suppofed by fome able agriculturists, that it would be better to take, in fuch cafes, two or three fuceeffive crops of turnips, in order to completely eradicate all the seeds of the ling, furze, and broom, before the land is laid down to grafs, as otherwife thefe plants may appear with redoubled vigour. Thefe observations feem just, and to be founded in good fenfe, reafon, and experiment; they place the ab-furdity of indiscriminately condemning this mode of agricul-tural improvement in the cleareft point of view; as the injury that may take place in fome cafes may be occafioned by an injudicious and improper method of cultivaion. In Kent, Mr. Boys obferves, that, of all the improvements in the cultivation of land that have hitherfo been made use of in that diftrict, this flands foremost; some of the very worth land having been made to produce excellent crops; and poor chalky downs, of scarcely any value in their original flate, are by it made to produce good turnips and clover, and crops of corn often equal in value to double the fee emple of the land. Instead of the land being injured by the ope-rafion, as fome theoretical writers have imagined, provided it be under a proper fystem of management and fairly dealt by, it is put into a progreffive flate of improvement from the time of its surface being burnt. It has frequently hap-pened, that land after burning has been fown with corn four or five years in fucceffion without being folded with heep, or any part of its produce ever returned in manure; even charlock and other weeds have been fuffered to remain, by which it has been annually burtihened with a double crop; hence it has been left in an impoverished flate, and the burning is unjustly condemned for the michief done by the negli-gence and rapacity of the cultivator. Let the land, when better fown, be perfectly cleaned from charlock and other weeds, by growing turnips until the weeds are totally eradicated by hoewing, &c. Let the turnips be fed off the land, by heep lying on the land day and night; then sow it with barley and clover: the latter to be fed off with heep, folding them on the land for wheaf. Laitly, return the itraw pro-duced upon the land in manure, mixed with clay or loam, or any other fresh earth that is near at hand, for a second Norfolk rotation, which may be repeated; or the land may be fown with fainfom, to remain till a turf is formed fit for paring and burning again. This plan being paffured, the praife of burning the foil will not give any caufe of complaint either to landlord or tenant. Theorists exclain that by paring and burning, the flaple of the land is reduced, and the foil is wafted; which may be somewhat true: but all this is very immaterial, if fine crops of corn can be pro-duced where none ever grew before, and the land at the fame time be improved.

Mr. Young, in speaking of cropping repeatedly with white or grafs crops after paring and burning, wrongly remarks, that if a dung-hill were given to a bad farmer, and it was used on similar principles, it would almost equally ex-hauft the foil; yet who has found out that dunging land is bad husbandry? Paring and burning give a dung-hill also; it is bad management alone that converts it into an evil. Make it the preparation for grafs; and all is fafe. It has also been flated, that the praife of paring and burning is fo advantageous in fome cafes, as to render lands, the produce of which was not worth two fhillings and fixpence, in the court of four years capable of producing two valuable crops of corn, and as many turnips, and to be rented at twenty fhillings per acre.

A very intelligent farmer, in the fifteenth volume of the Annals of Agriculture, has given the following flatement of the expences and returns of breaking up frotch land of a fliff loamy quality by means of this prcceed, and cropping it with oats and peas. The flummer in this inftance was left for preparing the ground for a wheat crop. The crops are here charged with rent and taxes for two years.

And from the ameliorating nature of pea crops, and the excellent state in which they leave the land for a crop of wheat, they will, it is supposed, be on the whole more advantageous than the oats.

In Yorkshire, the expenses and profits on cold, moosy, old meadow land, with a north-eaft aspect, cultivated in this manner for turnips, as given in the same work by the writer of the Middlesex Survey, is this:

Thefe expenses of the process of paring and burning are much too low for the present period.

In what respects the kind of gras-feeds that may be proper after this operation, they must probably be different, according to the nature and quality of the soil. In the light stonds of land, thofe kinds of gras-feeds that cover the earth well may be most suitable. On chalky soil, sainfoin may frequently be employed. In the fanny soils of soil, marl-gras with a little meadow fox-tail gras, will often be found beneficial. And a small mixture of the finest ray-gras, or daren, is likewise found to answer well. Marl-gras, though it has some resemblance to red clover, is materially different in its effects; the former being found unfriendly to all natural gras-feeds, while the latter is quite the reverse. This is a fact that has been established by extensive experience. One other very material advantage resulting from the cultivation of marl-gras, is, that neat cattle are not so liable to swell by eating it in moist weather, as they are with red clover. The heavy or clayey soils will in most cases require the largest proportion of gras-feeds to be sown upon them, in laying them down: after being prepared by the process of paring and burning.

In short, it may be concluded, that from the great ease and expedition with which all thofe coarse sorts of land, which have been mentioned as proper for being broken up by this means, are rendered fit for the growth of crops of different kinds, such as thofe of grain, rape, turnips, &c. as well as from the very abundant produce which is generally the cafe after such preparation, that whefe proper attention is paid to the processes, and the method and management afterwards, it must be highly beneficial, and probably the best that can be adopted. It has indeed been remarked, in the able Survey of the North Ridg of Yorkshire, that when the husbandry that succeeds paring and burning is judicious, no mode of improvement can be compared with it; for it is certain to produce great crops of turnips and grain, and these are certain means of future fertility in the hands of a judicious farmer.

**Paring-Ploough**, an implement of great utility in many cafes, where the fylem of paring and burning is praftified. At figs. 1 and 2 in the plates on ploughs, are two fide views of a paring-ploough, recommended by Mr. Young for rough land. It has the flare fix inches in width, by means of the pivot b, which lers into the holes c. It is faid to be capable of performing its work in a good manner, where the ten paring-ploough cannot flir at all. It is faid to have been in use at Sheffiold Place, the seat of lord Sheffield, thirty years ago; having been obtained from Cheshire, where it had been made ufe of on the farm of sir George Warren. See the preceding article.

**Paring-Spade**, a fort of spade which is made ufe of in paring land for burning, being made with a crooked handle, fo as to be pushed forward in ufling by the breath. It is fometimes termed a breath-plough.

**Paring the Hoofs of Horses**, in the Mange, a kind of operation in shoeing, performed on the feet of these animals, with the intention of adapting or suitting them to the shoes. The businefs is executed with a fort of edge tool, which is called a butteris, and is often done to the great injury and prejudice of their feet. As it is unquestionably the object in shoeing horses to preserve the hoof, as well as to defend the fole, it cannot, of course, be necessary to pare away what is wanted to be kept in a flate of perfervation. This is cofquently a practice that should never be submitted to either with farm or other horses, except in cafes where the horay fole is fo very uneven, that the shoes cannot be otherwise made to bear equally upon the feet, which would take off
off from the requisite firmness of them. It may perhaps sometimes be proper in such instances as these, but in other cases it is highly absurd and mischievous, being not unfrequently the occasion of great injury and inconvenience to the animals. See Horse and Shoeling.

PARINo the Sol, in fhowing horses, an improper operation which is too often performed on the hornv parts of the feet of these animals in fixing the shoes upon them, and from which injury not unfrequently arises.

PARINO, in Geography, a town of Mexico, in the province of Culiacan; 42 miles E. of St. Miguel.

PARIBE, a town of Brazil, in the government of Bahia.

PARIPURA, a river of Brazil, which runs into the Atlantic, S. lat. 9'42". W. long. 35'26'.

PARIS, Matthew, in Biography, an early English historian, was a monk of St. Albans, who flourished during the middle of the 13th century. He is described as a man of almost universal accomplishments; he was a mathematician, poet, orator, theologian, painter, and architect. He was employed to visit the monasteries and revive their decayed discipline, and without hesitation he incurred what he found wrong in all orders of people. His principal work is his "Hiftoria Major," which is a history of English affairs from the conquest to the 43d year of Henry III. It was publifhed by archbishop Parker at London in 1571. It is suppos'd originally to have had a firft part commencing with the creation, and coming down to William the Conqueror. It is reckoned a very valuable work, composed with exactness and much candour; and displaying great freedom in expos'ing the uflurpations of the Roman popes, upon the prerogatives of the English kings, on which account it incurs the cenfure of Baronius, who otherwise is inclined to give it great commendation. It was republished with additions, and the author's lives of the abbots of St. Albans, in 1606, by Dr. William Watts. Matthew Paris alfo compofed a "Hiftoria Minor," being an abridgment of the former, with additional circumstances. He wrote other works, which are loft or lie concealed in libraries.

PARIS, Francis, generally known by the name of the abbé Paris, and rendered famous for a time by the impolements and defigns which were praftized at his tomb, was the eldest son of a counsellor to the parliament, and born at Paris in the year 1690. His father wished to bring him up to the law, in order that he might have him for an affi'itant in his business, and that eventually he might become his successor, but he preferred embracing the ecclefialiftical life, and was accordingly admitted to deacon's orders. Upon the death of his father, he renounced all claim to his patrimonial inheritance, in favour of a younger brother, and de-"val'd himself to what he thought was a life of meritorious poverty. Having made trial of different places of folidity, he at length fixed upon a house in the suburb of St. Marcel, at Paris, where he spent his time in prayer, and the moft rigorous acts of penance; hence he acq'ired a character for extraordinary fantity with the superflitious populace, who thought fuch mortifications the very perfection of virtue. He died in 1737, at the age of thirty-seven. His brother erected a tomb to his memory in the cemetery of St. Me-ward, and so highly was his piety esteemed, that many per-sons who had, during his life, been edified by his instructions, went to visit his monument, and some pretended to be cured of their diseases on their approach to the grave. This in-duced others to do the fame, and fo great was the defulion, that government was under the neceffity to order the cemetery to be closed up with lofty walls. Accounts were publifh'd of at least an hundred miracles said to have been wrought on the spot. The abbé Paris was author of a "Commentary on the Gospel of St. Matthew," and "An Explanation of some of St. Paul's Epistles.

PARIS, in Geography, the metropolis of France, is fitu-"ated on a plain, through which the river Seine flows in a moft pleasing and picturesque manner.

History and Extent.—Caesar is the firft historian who makes mention of this city. In the fourth book of his Commen-
taries, that conqueror relates that he sent his lieutenant La-bienus towards Lutetia, which was the name given by the Gauls to the capital of the Parisi. It was then entirely contained within that island on the Seine, which, at the prezent day, is called l'île du Palais; and in comparison with the capitals of the other provinces of Gaul, Lute-
tia was but a fome village; its houses were small, of a round form, built of wood and earth, and covered with straw and reeds. When the Romans had conquered Lu-
tetia, they embelliffhed it with a palace, surrounded it by walls, and erected at the head of each of the two bridges leading to it, a ftrong, one of which stood on the fite of the prifon called "Le Grand Châtelet;" and the other, on that of "Le Petit Châtelet." The Yonne, the Marne, and the Oise, being rivers which join the Seine, fuggelled the idea of establishing a trading company by water, in order to facilitate, by those channels, the circulation of warlike stores, and provisions. The merchants were called "Nautie Paraftacii." The Romans also erected, near the bank of the Seine, a magnificent palace and aedificate. This palace was called Thermes, on account of its tepid baths. Julian, being charged to defend Gaul against the irruptions of the barbarians, took up his residence in these Thermes in the year 360, two years before he was pro-claimed emperor, in the square which was in the front of the palace. "I was," says he, in his work entitled "Mifo-
ponon," or the Enemy of the Bead, which, says Gibbon, "still remains a fingular monument of the refentment, the wit, the humanity, and the indifferetion of Julian," "in winter quarters in my dear Lutetia. Thus is named, in Gaul, the little capital of the Parifii." And by another ancient writer, it is describ'd as an inconsiderable island, surrounded by walls, the foot of which is bathed by the river. The entrance to it, on each fide, is by a wooden bridge. Towards the middle of the fifth century, this city paffed from the d mini'on of the Romans to that of the Franks, and in 508, Clovis declared it the capital of his kingdom, and he contributed very much to the embelliffment of it. Charlemagne founded in it a celebrated school, and in a fhort time after, another was established in the abbey of "St. German-des-Pres." In the course of the ninth century, it was befieged and pillaged three times by the Normans. Philip Augustus surrounded Paris with walls, comprising in the circumference a great number of small towns and hamlets in its vicinity. The undertaking occupied about twenty years, having been begun in 1190, and finished in 1211, and this monarch was the first who cauf'd the fref'ts to be paved. The wars with the English required new fortifications, and in the reigns of John, and Charles V., in the fourteenth century, ditches were dug, and the Baf-tile erected. Francis I., the reforer of literature and of the arts, neglected nothing that might condu'ce to the em-belliffment of this capital. He cauf'd new fref'ts to be made, many Gothic edifices to be pulled down, and was, in France, the firft perfon who revived Greek architecture, the remains of which, buried by the hand of time, or muta-
tated by that of barbarians, being collected, began to im-prove the genius of celebrated artists, and in the fequel led to the production of many fine master-pieces of art. The succéffors of Francis executed a part of his projects, and this
PARIS.

this extensive city imperceptibly lost its irregular and Gothic aspect. Henry IV. was the first of the kings of France who embellished Paris with regular squares, or open spaces, decorated with the different orders of architecture. Having nearly finished the Pont Neuf, he built the Place Royale, and also the Place Dauphinié. During the reign of this king several handsome streets were built and finished in a year. In the reign of Lewis XIV. Paris knew no limits. Its gates were converted into arcs of triumph, and its ditches, being filled up and planted with trees, became public promenades. Paris, however, was not the favoured city of this prince, for he had expended on it a fourth part of the money which he lavished on Versailles, it would have become the most astonishing city in Europe. It must however be admitted, that its great extent and population, magnificent edifices, celebrated national establishments of learning and science, rich libraries, curious cabinets, where legions of knowledge and genius present themselves to those who have a taste for them, together with its theatres, and other places of public entertainment, have long retained Paris deferring of the admiration of enlightened nations. Before the revolution, Paris contained 46 parish churches, and 20 others answering the same purpose, 11 abbeys, and 13 monasteries or convents of men and women, 13 colleges, 15 public seminaries, and 26 hospitals. To these must be added the three royal habitations, the Louvre, the Théâterlaries, and the Luxembourg, also the Hotel des Invalides, the Palais Royal, and the Palais Bourbon. Since the revolution several of these buildings have been destroyed; almost all the monasteries and convents, together with the churches belonging to them, have been sold as national property, and either demolished for the sake of their materials, or converted to different uses.

Population.—The number of houses in Paris, many of which are from five to eight stories in height, has been estimated at upwards of 86,000, and by an official statement a few years since, the number of inhabitants, exclusive of foreigners, was about 630,000. During the last year of the republic, the number of males born at Paris was 926,089; and that of females, 917,643, making the total number of births to be 18,473, of which 54,144 were born out of wedlock, that is, nearly one in five. The number of persons who died in the same period was 10,446 males, and 10,381 females, making together 20,827, causing an annual decrease in the population of 2274. The number of marriages was 3826, and that of divorces 720, nearly two in eleven.

Divisions and Barrières.—Paris is divided into twelve mayoralties, each of which is prefixed over by a central officer of the municipal police. The faubourgs retain their ancient names, but those of many of the streets have been changed since the revolution. In proportion as the limits of the capital became extended, the real gates were removed, but they re-appeared under the name of barrières. These edifices, many of which were very costly, were constructed during the ministry of Calonne, under the direction of Le- doux, the architect, who has taken pleasure in varying their form and character. One represents an observatory; another, a chapel; some have the appearance of rusticated buildings; others of temples. There are about sixty of these barrières, which, during the revolution, were frequently flut to serve the purposes of party, and to favour the arrest of particular persons: they are now occupied by custom-house officers, whose business is to collect duties, and to watch that no contraband goods find their way into the city.

The Seine and Quarries.—The river Seine, to which we have already referred, is justly esteemed one of the most beautiful in France; it is of a light sea-green hue, a singularity which adds to the effect of the noble bridges and quays. This colour is not observable before the junction of the Seine and Marne, where it may be clearly observed to belong to the latter stream, the Seine being of a brown or muddy appearance, while the green hue of the Marne continues unpolluted for a considerable space. Towards the north this plain is bounded by a semicircular range of gentle elevations, mostly composed of gypseum, or alabaster, which by combustion yields the noted plâtre of Paris. This plâtre is much used in the construction of houses. The calcareous free-flone, with which the superior hotels are built, is drawn from quarries on the south of the city. The ancient quarries are without the southern bounds of the original city, in the form of catacombs, or narrow passages of great regularity.

Soil, Climate, and Streets.—The soil on which the city stands is varied. On the south of the river it is calcareous free-flone, frequently covered with shells; while on the north, as far as the streets that rise to the plain of Mont Martre, it consists of alluvial sand to a considerable depth, followed by the gypseum of Mont Martre. “It is,” says Mr. Pinkerton, “a well-known singularity in geology, that the banks of the rivers are often composed of different substances, owing, probably, to some natural incoherence, which afforded an easier course for the water to penetrate.” The fossil bones found at Mont Martre are, by Cuvier, supposed to belong universally to different species and sizes of an animal now extinct but approaching nearest to the tapir of America. And the sea-shells, some of them unknown at present in the Atlantic, discovered at Grignon, to the west of Verailles, in a bed of sand, under a layer of solid lime-flone, indicate changes in the globe which it is impossible to account for. The climate of Paris differs from that of London in the superior heat of the summer, which matures the grape in the open vineyard, a circumstance totally unknown in England. The general warmth of the year is much the same at Paris as at London, the superior cold of the winter being the heat of the summer. In the winter of 1802-3, the river Seine was frozen over during a fortnight, and the cold was intense. Pinkerton says, that he always thought that the environs of Mont Martre were colder than any other part of Paris, not only from the greater height of the situation, but from the proverbially cold nature of the alabaster. In Paris the streets are very narrow and crowded, yet even amidst the inconveniences arising from these circumstances, the superior magnificence of the houses and public buildings is very striking, especially to a person who, after a long residence at Paris, returns to London. While the latter is enveloped in clouds of smoke, none is perceivable at the former, except at the moment of lighting the fires in the morning; and a spectator from a neighbouring eminence is dazzled with the white splendour of the houses and towers. The Parisians have an universal prejudice against the use of coal, which they conceive to be very unhealthy, and hurtful to the lungs. The smoke of wood, though more prejudicial to the furniture, the colour of which it soon changes, is yet far less visible in the open air, while that of coal blackens the surrounding objects, as appears but too certainly from the dark hue of our London churches and other flone buildings. The Parisian edifices, on the contrary, are of such dazzling whiteness, that in the summer the eye is fatigued, and seeks for the repose of some milder colour.

Public Buildings.—It has often been made a question, whether Paris or London is to be reckoned the finer city; ac-
PARIS.

...cording, however, to a well-informed traveller, London is said to be the more imposing to the eye as a whole, but Paris will better bear dissection. The wide streets and broad foot pavements in London give a general impression of grandeur, but the public buildings that can be noticed as really fine ones are few. At Paris, while the city does not give an impression of grandeur as a whole, the objects which, taking it in detail, claim particular attention, are grand and numerous. There is nothing in London which can be compared to the quays at Paris along the Seine, from the Pont Neuf to the end of the town on the west, particularly the quay on the right bank; along which runs a succession, the Louvre, the greensward of which joins it to the Tuileries, the Tuileries itself with the gardens, the Place de la Concorde, and the Champs Élysées. The origin of the Louvre, as well as the etymology of its name, is lost in the darkness of time. It existed under that name in the reign of Philip Augustus, who surrounded it with ditches and towers, and made it a fortress. The great tower of the Louvre, celebrated in history, was infalubilized, and built in the middle of the court. All the principal edifices of the crown derived their tenure from this tower, and came hither to swear allegiance, and pay homage. It was likewise a prison previously prepared for them, if they violated their oaths. The Louvre received also from this enormous tower a melancholy and terrifying aspect, which rendered it not at all adapted to a royal residence. Charles V. endeavoured to enliven it, and made it commodious for those times. Several foreign monarchs succedingly lodged in it, such as Manuel, emperor of Constantinople; Sigismund, emperor of Germany; and the emperor Charles V. The large tower of the Louvre, which, at different periods, had served as a palace to the kings of France, as a prison to the great lords, and as a treasury to the state, was at length taken down in 1528. The part of the palace which at present is denominated the Old Louvre, was begun under Francis I., but was first inhabited by Charles IX., under whom it became the bloody theatre of treacheries and massacres, on the infamous St. Bartholomew's day, which time will never, and ought never, to efface from the memory of mankind, and which, till the merciful reign of Reuben, were unexampled in the history of that country. In after-times this palace became the quiet and happy cradle of the arts and sciences, the school for talents, the arena for genius, and the asylum of artists and literati. The centre pavilion over the principal gate of the Old Louvre, was erected under the reign of Lewis XIII. from the designs of Mercier, as well as the angle of the left part of the building, parallel to that built by Henry II. The eight gigantic cariatides (see the article), which are to be seen there, were sculptured by Sarrain. The several parts of this palace which were constructed under the reigns of Charles IX. and Henry III., partake of the taste of the times, in regard to the multiplicity of the ornaments; but the inspiration, that of the masters of their decorations, the refined taste of Lewis XIV. The part of the Louvre, which, with two sides of the old building, forms the perfect square about 400 feet in extent, called the New Louvre, consists in two double façades, which are still unfinished. The colonnade of the Louvre, which is the master-piece of French architecture, and the admiration of Europe, was built by Perrault. The façade of this colonnade, which is of the Corinthian order, is about 525 feet in length; it is divided into two peristyles, and three avant-corsps. The principal gate is in the centre avant-corsps, which is decorated with eight double columns, crowned by a pediment, whose cornices are composéd of two flores only, each fifty-four feet in length by eight

in breadth, though no more than eighteen inches in thickness. They were taken from the quarries of Mendon, and formed but one single block, which was sawed in two. The other two avant-corsps are ornamented with fixed pilasters, and two columns of the same order, and dipped in the same manner. On the top, instead of a ridged roof, is a terrace, bordered by a stone balustrade, the pedestals of which are intended to bear trophies intermixed with vases. In front of this magnificent colonnade, a multitude of saltemen erect their stalls, and display their various articles. This contrivance still speaks to the eye of the attentive observer. It is the corner of all the rest — grandeur and beggary side by side. The fountain to the river front is terminated, but cannot be compared to the other, and that is unfinished. The other two fronts are so encompasted by houses, that they are seamcely seen at all. The inside of the court, like the rest of the building, will be handsome, and extremely grand, if it be ever finished.

The great Gallery which joins the Louvre to the Tuileries is more than 1200 feet long. The Palais des Tuileries was so called, because a tile-kiln formerly stood on the site where it is erected. At that time, this part of Paris was not comprised within its walls, nothing was to be seen in the vicinity of the tile-kiln, but a few coppices and scattered habitations. The construction of this palace was begun in May 1564. At first, it consisted only of the large square pavilion in the centre of the two piles of building, which have each a terrace towards the garden, and of two pavilions, by which they are terminated. Henry IV. enlarged the original building, and in 1660 began the grand gallery which joins it to the Louvre. Lewis XIII. made some alterations in the palace, and in 1664, Lewis XIV. directed it to be finished by adding the additions and embellishments which have brought it to its present state. These deviations from the first plan have destroyed the proportions required by the strict rules of art; nevertheless the architecture, though variously blended, presents, at first sight, an ensemble which is magnificent and striking. The whole front of the palace consists of five pavilions, connected by four piles of building, standing on the same line, and extending for the space of more than 1000 feet. The first order of the three middle piles is Ionic, with encircled columns. The two adjoining pavilions are also ornamented with Ionic pillars; but fluted, and embellished with friezes from the third of their height to the summit. The second order of these two pavilions is Corinthian. The two piles of building, which come next, as well as the two pavilions of the wings, are of the Composite order, with fluted pillars. An iron balustrade divides the court of the Tuileries from the Carrousel; in this are three gateways, the two end ones of which are ornamented by the four celebrated bronze horses, supposed to have been the work of Le Papus, and which, previously to their occupying their present situation, had successively ornamented the arch of Nero at Rome, the Hippodrome at Constantinople, and the church of St. Mark at Venice. The gardens of the Tuileries are always open to the public, and are the principal promenade of this part of the town. Among the decorations of the gardens are many fine statues, bronze, and cals. The Place de la Concorde, at the end of the gardens of the Tuileries, between them and the Champs Elysées, is one of the finest spots in Paris. The Garde Meuble, which forms one side of the Place, is little inferior in beauty to the grand façade of the Louvre; the design of it seems indeed to have been taken from the latter building, only that in the Garde Meuble there is an arcade below the colonnade which is not the case in the Louvre; a street leading to the Boulevards divides the length
PARIS.

of this building. At the end of this street is seen the church of La Madeleine, begun some years ago upon a very beautiful design, but like many other fine buildings it is only half finished. Four very fine marble groups decorate the gates which lead from the gardens of the Tuilleries, and from the Champs Elysées to the Place de la Concorde. Those on each side of the gates of the Tuilleries are Mercury and Fame; those to the Champs Elysées are wild horses broken by flaves.

Bridges.—Of all the bridges, says Sterne, it must he acknowledged that the grandest, the lightest, the longest, and the broadest, that ever joined land to land, is the Pont Neuf. The first stone of this bridge was laid by Henry III. in 1578, and the foundation of the piers was begun to be surveyed on the 25th of December, 1578, in the presence of the League forces. The architect was then De Cerceau, to withdraw to foreign countries.

The work was not resumed till the reign of Henry IV.; it was finished in 1674. The length of the bridge is 1020 feet and its breadth 72 feet, which is sufficient to admit of five carriages passing abreast. It is formed of twelve arches, seven of which are on the side of the Louvre, and five on the side of the Quai des Augustines, extending over the two channels of the river, which is wider in this place, from their junction. In 1775 the parapets were repaired, and the footway lowered and narrowed.

Soufflot, the architect of the Panthéon, availed himself of the opportunity to build, on the twenty half-moons which stand immediately above each pile, as many rotundas, in honour, to serve as shops. On the outside, above the arches, is a double cornice, which attracts the eye of the connoisseur in architecture, notwithstanding its mouldering flate, on account of the fleurons in the antique style, and the heads of sylvans, dryads, and satyrs, which serve as supports to it, at the distance of two feet from each other. As the mole that forms a projection on this bridge, on the outward and inner faces, is pierced with two bas-reliefs: the one facing the city represents the passage of the Rhine; the other the capture of Maestricht.

On arriving from Calais, you enter Paris by the Porte St. Denis; it was by the Porte St. Denis that kings and queens made their public entry. On these occasions, the houses in all the streets through which they passed were decorated with silk hangings and tapestry, as far as the cathedral of Notre Dame. Scented waters perfumed the air in the form of jets d'eau, while wine and milk actually were made to flow from different public fountains. At a short distance from Porte St. Denis is Porte St. Martin, which was erected in 1764, as a triumphal arch, but it is not at all equal in magnificence to the other. It is pierced with three openings; the central one is eighteen feet wide, and the two others nine. The whole structure, which is fifty-four feet both in height and breadth, is ruffled, and in the four pairs of the arch are four bas-reliefs, which are crowned by an entablature of the Doric order, surmounted by an attic. The Porte St. Martin is the grand entrance into Paris from all parts of France.

Public Libraries.—The most splendid of these collections has had different names according to the nature of the government. Under the kings it was the Royal Library; during the republic it was called the National Library; and it is now the Imperial Library. The building itself is very large, its length being more than 500 feet, and its breadth upwards of 120. The principal floor of the building which surrounds the large court is entirely filled with books, from the bottom to the ceiling. At the window, and in different parts of one of the wings, tables are placed for the accommodation of readers. The library is open every day from ten till two. In a small recess of one of the four sides of the library, is a group of about five feet in height,
Paris.

and fix in breadth, erected in the time of Lewis XIV. It represents Parnassus with Apollo and the Muses. There are likewise in the library some busts of celebrated French literati. This library traces its origin to a very remote era. Charles V. added about 900 volumes to a small collection left by his father John. This collection, placed in a tower of the Louvre, was called "La Tour de la Librairie," and was lighted every night by thirty small chandeliers and a silver lamp, so that students and the learned might be accommodated every hour. The library was after this diffused; for in 1419, when Paris was in the hands of the English, it was in the command of the duke of Bedford, that nobleman bought the 150 volumes, of which it consisted, for 1000 livres. Lewis XI. collected the scattered remnants of this library, and profited by the resources which the invention of printing presented to him. Charles VIII. added to it what the conquests of Italy allowed him to collect. Lewis XII. enriched it with the library of Petrarch: Francis I. with Greek manuscripts; and Henry II. augmented it, in consequence of the decree of 1556, enjoining bookfellers to furnish the royal libraries with a copy on vellum of every book published. Hence it became so large, that many years ago it was allowed to equal, if not to exceed, every other collection extant. It is now much enriched by the spoils of Venice, Florence, and Rome. It consists, fifteen years ago, of more than 300,000 volumes, and is divided into five departments. The first, containing the printed books, is on the first story. The second department comprises manuscripts, to the number of 80,000, of which 25,000 are in learned and foreign languages, and 30,000 on the history of France, chiefly from the reign of Lewis XI. The five great rooms on the second story contain the genealogies, and are filled with 5000 port-folios. The cabinet of medals is decorated with three large pictures, representing Thalia, Calliope, and Terpsichore. There are also three pictures representing Psyche, the inventrix of the flute, led by Hymen, and the three patrons of the Muses. The cabinet of antiques, situated on the third story, contains busts, vases, inscriptions, and instruments of sacrifices collected by the celebrated Caylus. Opposite to the entrance, various Egyptian antiques meet the eye. At one end of the room are warlike instruments of different Indian nations. On the floor stands a large antique marble table. The walls are decorated with the reliefs of Scipio and Hannibal. In the middle of this cabinet of antiques is a long table, covered with Etruscan vases of superior beauty. On the third floor are two apartments, which contain Etruscan vases of extraordinary magnitude, a baulk of porphyry, sacrificing knives, lamps, &c. Two rooms belonging to the library are filled with a collection of 5000 volumes of prints.

The library of the Arsenal is supposed to contain 75,000 volumes and 6000 manuscripts. It formerly belonged to the count d’Artois, now forms part of the library at the Luxembourg, and contains many MSS. beautifully illuminated on vellum. The library of the Pantheon consists of 100,000 printed volumes, and 2000 MSS., and is decorated with different marble busts of French literati. The library of St. Victor was opened in 1652, and among its numerous MSS. is a collection of the proceedings against the celebrated Jeanne d’Arc. Besides these, all the public bodies have their respective libraries, to which access may be readily had by foreigners as well as natives.

Literary Institutions.—The National Institute is the principal of the learned societies of Paris. Its main object is to improve the arts by uninterrupted inquiries; by the examination of literary and scientific labours, and by correspondence with foreign and learned societies. "It is impossible," says an American traveller, "for a foreigner and a student to be a week in the French capital, without having his imagination absolutely overpowered, and his enthusiasm wound up to the highest pitch, by the eclair which he sees attendant on science and literature, and the facilities which it finds open to him for the culture of all the branches of human knowledge. For besides the libraries, and other establishments already mentioned, all of which are innumerable gratuitous lectures read at the expense of government at all hours in the day: a garden of plants, and a museum of natural history, the most perfect in the arrangement, and the most ample in the materials, to be found in the world; and the branches of knowledge to which they relate are daily explained to all visitors, by men illustrious for their skill and their discoveries; public exhibitions to excite literary emulation, and national rewards to give spirit to literary industry." Of the National Institute (see Institute), his imperial majesty himself is a member, and the reputation of this learned body exceeds that of any other learned society in the world. This body is but an incorporation of the old academies of Paris, and is now divided into four distinct classes correspondent to those academies. The first class is that of the physical and mathematical sciences; the second, that of the literature of France, and of the French language; the third, that of history and ancient literature; and the fourth, that of the fine arts. The members, together with the foreign associates, amount to the number of two hundred. When a nomination is to take place, the clafs by which it is to be made selects two candidates, between whom the emperor makes choice. Each clafs has one public sitting annually; at this prizes are distributed, memoirs read, &c. The first clafs has a private sitting every Monday, from three o’clock until fix in the evening, to which strangers are admitted when introduced by a member. The members receive an annuity from government of about fifty pounds. Most of them, however, and particularly those who belong to the first clafs, are invested with public employment, so as to be furnished with an easy subsistence. Upon some of them the highest honours of the flate have been lavished. For some time after his accession to the government, Bonaparte found the Institute the most unmanageable of all the public associations of France. It was filled with men who had taken an active part in the revolution, and some of whom were enthusiastically devoted to the principles of freedom. His efforts to mould them to his purposes, and to render them completely subservient to the consolidation and increase of his power, were for a long time ineffectual. After employing the means of intimidation without success, he had recourse to a system of patronage and corruption, which he has found much more efficacious. The laborious savans, and the indigent literati, were converted into senators, counsellors of state, legislators, inspectors, and even ministers, and the majority of the whole body invested with the crofs of the legion of honour. A complete victory over the Institute was of some importance to the views of Bonaparte, but of a most pernicious tendency with regard to the interests of freedom and found literature. The subordinate classes of this body embrace, with few exceptions, those who are most devotedly eminently throughout the empire for their learning. The first clafs, as a scientific allocation, ranks higher than any other in the world. The public meetings of the National Institute are held in a very extensive and magnificent room. Both its sides are adorned by beautiful colonnades, and the ceiling is finely painted and decorated. Between the columns
lumens are fourteen marble statues, highly finished, of the most celebrated persons whom France ever produced, viz. Condé, Toulouse, Defarges, Bayard, Sully, Turenne, Daugueslet, L'Hopital, Robueil, Duqueyne, Catinat, Vauban, and Fenelon. At the ends are two fitting figures of Pafcal and Rollin. In the antichamber are the statues of Moliere, Racine, Corneille, La Fontaine, and Montesquieu. The hall is extremely well lighted; the floors are covered with carpets, and tables are placed parallel to the four walls of the hall, at which the members of the Institute take their places. The president of the Institute is seated at the upper end of the hall; in the middle, and rather on one side of him, is a tribune, from whom, whatever is proposed is received by the president, who does not leave his chair. The place allotted for members is surrounded by a rail, between which and the walls there is, round the hall, a row of benches, where the spectators take their seats. Each class annually proposes two prize questions; and in these general meetings the answers are made public, and the premiums distributed. The united sections of painting, sculpture, and architecture elect the pupils, who, at the expense of the republic, are to travel to Rome, in order to study the fine arts. Twenty young men are elected by the Institute to travel in France, and in foreign countries, for the purpose of studying rural economy. Six members, also, of the Institute itself, are to travel at the public expense to collect information, and to acquire experience in the different sciences.

In the Museum of French monuments, the several subjects are distributed in different apartments; and by their arrangements they exhibit the state of statuary in France from the earliest periods to the present time. They are arranged according to their respective antiquity, each department containing specimens of a single century, which is numbered at the entrance; and received light through the windows of painted glases, executed during the same period. The Museum of Natural History consists of a botanical garden, an library for natural history, of a menagerie, or collection of foreign animals, and of an amphitheatre, or lecture room. Professors deliver public lectures in rotation during the summer months.

Public Instruction.—After the suppression of the colleges and universities existing under the monarchy, the National Convention, by a decree of the 14th of January 1795, established Normal schools throughout the republic. Professors and teachers were appointed to them, and it was intended, that in these nurseries youth should be prepared for the higher schools, according to the new plan of instruction. However, in the course of a few months, these Normal schools were shut up, and primary, secondary, and central schools, were ordered to be established in every department. In the primary schools, reading, writing, and arithmetic formed the chief part of the instruction. Owing to various causes, the secondary schools were not established. In the central schools, the whole of the instruction was divided into three classes or sections. In the first are taught reading, natural history, and grammar. In the second, mathematics, physics, and chemistry. In the third, universal grammar, the fine arts, history, and legislation. In the first class, the pupils were to be received at the age of twelve; in the second, at fourteen; and in the third at fifteen. To each central school are attached a library, a botanic garden, and an apparatus for chemistry and experimental philosophy. The professors are examined and chosen by a jury of instruction, and that choice confirmed by the administration of the department. Besides these, there are special schools, in which are taught the useful sciences, jurisprudence, medicine, and natural history. There are likewise schools appropriated to different professions, solely devoted to the public service, and which require particular knowledge in the arts and sciences. Hence they bear the name of "Schools for public Services." In order to be admitted into any of these schools, the candidates must prove themselves qualified by the preliminary instruction required in the examinations at the competition prescribed for each of them. The pupils of these schools receive a salary from the nation. At the head of them is the Polytechnic School, which is the grand nursery whence the pupils, after they have attained a sufficient degree of perfection, are transplanted into the other schools for public services. Next come the Schools of Artillery, of which there are eight in the places where the regiments of artillery are garrisoned. The pupils who are sent thither as officers, after having been examined, apply their knowledge to the art; to the construction of works; and to the manoeuvres of war dependent on artillery. Each school, in which the pupils must remain two years longer, is under the superintendence of a general of brigade of the corps. The school of military engineers, united to that of miners, is established at Metz. Its labourers relate to the application of the theoretical knowledge of the pupils which has imbibed at the Polytechnic school. The object of these labours is the construction of all sorts of works of fortification, mines and countermines, mock representations of sieges, attack and defence, the drawing of plans and military surveys, and all the details of the duty of engineers in fortified places, and in the field. The number of pupils is limited to twenty: they have the rank and pay of second lieutenants. They undergo a strict examination respecting the objects of instruction, which examination is entrusted to a jury, composed of the commander-in-chief of the school, a general or field officer of the corps, appointed every year by the minister at war, and one of the permanent examiners of the Polytechnic school. This jury forms the list of merit which regulates the order of promotion. The school of Sully, which was founded, in 1787, by Trudaute, and continued under the direction of Perronet, chief engineer of the corps, till his death, in 1794. By his will be bequeathed to this school, for the instruction of the pupils, his library, his models, his manuscripts, and his portrait, bust. This school unites the deposit, or repository of plans and models, canals and harbours, for trade. The number of pupils is fifty. They are taken from the Polytechnic school, and retain the salary which they received there. The instruction given to them chiefly consists in the application of the principles of physics and mathematics to the art of planning, and constructing works relative to roads, canals, and sea-ports, and the buildings belonging thereto; the means of execution; and the mode of forming plans and estimates of the works to be executed, and the order to be observed in keeping the accounts. The practical schools of mines are established, one at Geilhautern, in the department of La Serre, and the other at Pay, in the department of Mont Blanc. The director and professors form a committee for the working of the mines, in order, as well as for the profit of the pupils. In consequence of the report of this committee, the council of mines, established at Paris, proposes to the government the measures necessary to be adopted. Twenty pupils, who have passed their examination at the Polytechnic school, are attached to the practical schools for the purpose of applying the theoretical part of their instruction. The school of Naval Engineers is for pupils who have been students, at least two years, in the Polytechnic school. The examination of the candidates takes place every year,
and the preference is given to those who excel in descriptive geometry, mechanics, and the other branches of knowledge appropriated to the first year's study at school. When the pupils have proved, in the repeated examinations which they must undergo, that they are sufficiently qualified, they are then sent to Brest, in order to apply the theory they have acquired to the different works carried on in that port, where they find both the example and the precept, and are taught every thing relative to the construction of ships of war and merchant vessels. The pupils admitted into it receive a salary of 1800 francs, or about 75l. per annum.

The schools of mathematics and hydrography, established for the navy of the late, and the schools of hydrography defined for the merchant-service, bear the name of School of Navigation. Every year there is a competition for the admission of candidates for naval employment. The hydrographical examiner makes a general tour to the different ports, where he interrogates the pupils in arithmetic, algebra, geometry, statics, and navigation. According as they prove themselves worthy by their examinations, they are admitted to the rank of aspirans de marine, or midshipmen; captains of merchant-ships for long voyages; masters of coasting vessels; pilots, &c. Besides these, there are special schools of painting and sculpture; of architecture, music, &c.

Hospitals and other charitable Institutions.—The civil hospitals in Paris form two distinct classes: the one comprehends the hospitals of the sick; the other, those for the indigent: the former are devoted to the relief of the afflicted, the latter serve as an asylum to children, to the infirm, and to the aged indigent. All persons who are not ill enough to be admitted of necessity into the hospital nearest to their residence, are obliged to present themselves to the Bureau Central d'Admissions. Here they are examined, and if there be occasion, they receive a ticket of admission for the hospital where their particular disorder is treated. At the head of the hospitals for the sick stands the Hôtel-Dieu. Formerly this was rather a charnel-house than a hospital. It was founded, as far back as the year 660, for the reception of the sick and maimed of both sexes, without any exception of persons. All of every country, and of every religion, were admitted without form or recommendation. Though it contained but 1200 beds, the number of patients very often exceeded 5000, and on the average it was never less than 2500. Till the year 1780, no Reps were taken for enlarging the hospital, or providing elsewhere for those who could not be conveniently accommodated in it. The air of the neighbourhood was contaminated by the noisome exhalations continually arising from this abode of pestilence, and that which was breathed within the walls of the hospital was so contagious, as to turn a trifling complaint into a dangerous disorder, and a fimple wound into a mortification. In 1785, the attention of the government being called to this furious evil by various memoirs, the Academy of Sciences was directed to investigate the truth of the bold affirmations made in different publications. A report was made, and the hospital enlarged, so as to contain 2000 beds. Since the revolution, the improvements introduced into the interior government of the Hôtel-Dieu have been great and rapid. Each patient now has a bed to himself. Those attacked by contagious disorders are transferred to the Hôpice St. Louis. Insane persons are no longer admitted; men, thus afflicted, are sent to a special hospital established at Charenton, and the women to Salpêtrière. At the Hôtel-Dieu every method has been put in practice to promote the circulation of air, and expel the noxious miasma. In all the French hospitals, one ward, at least, is now always kept empty. The moment it becomes so by the removal of the patients into another, the walls are fime-whitened, and the air is purified by the fumigation with some of the mineral acids, according to the plan first proposed by Guyton-Morveau. This operation is thus alternately performed in each ward in succession; that which has been the longest occupied being purified the first, and left empty till it is wanted. The number of hospitals in Paris has of late years been considerably augmented. They are all supported by government, and not, like those in England, by private benefactions. Sick children of both sexes are no longer admitted promiscuously into different hospitals; but are received into a special hospital, established for the purpose, in a line airy situation beyond the Barrière des Sevres.

Two institutions have been formed for the aged, infirm, and indigent, who pay on entrance a moderate sum. An hospital for gratuitous vaccination is open for the continual treatment of the cow-pox, and the distribution of the matter to all parts of France. In general, the charitable institutions in Paris have, within the last twenty years, undergone very considerable improvements. The male orphans admitted, to the number of two thousand, into the asylum formerly called La Pitie, are to remain idle, or employed only to follow in funeral precedions, but are now kept at work, and are instructed in some useful trade. A new institution for female orphans has also been established. The palace of the Hospital des Enfans-Trouves is supplied by an establishment on a large scale, called the Hôpice de la Maternité, which is divided into two branches, each of which occupies a separate house. The one for foundlings, in the rue de la Bourbe, is intended for the reception of children abandoned by their parents. Here they are reared, if not sent into the country to be fucked. The other, in the rue d'Enfer, which may be regarded as the General Lying-in Hospital of Paris, is destined for the reception of pregnant women. From 1500 to 2000 are here delivered every year. No formality is required for the admission of new-born infants.

Marriages and Funerals.—The civil act of marriage is entered into at the office of the municipality. But this is not to be confounded with the contract drawn up by the notary, and containing the stipulations, clauses, and conditions. The former signifies merely that such a man and such a woman take each other for man and wife. There are but few, if any persons married, who do not repair from the municipality to the parish church, or go thither the next morning; the civil act being considered by individuals only as the ceremony of the betrothing; and till the priest has given the nuptial benediction, the relations take care, that the intended bride and bridegroom shall have no opportunity of anticipating the duties of marriage. At the church mails is said in a low voice, during which the priest, or rector, receives the promise of the wedded pair. To give little exception the ceremony is the fame for all. The families are well and married at the high altar; the act was made, the words were well and married at the high altar; the act was made, the words were...
somewhat like those of our hearths. An officer of the police, clothed in black, and holding a cane with an ivory head, walks before the cobbillard or hearth. Each corps has its particular coffin furnished by the municipality. The relations follow on foot, or in carriages: few of them are in mourning, and still fewer wear a cloak. Before the revolution, the church-yards in Paris were not numerous, the burials being often in the churches themselves. That of the Innocents was the largest and most remarkable, a pre-dilection for its preformed holiness having been adopted by the devout. Since the law ordaining that the dead should not be buried in churches, not even in the city, only two church-yards are open for this populous capital. One serves for the southern half of the city, including Hôtel Dieu; the other, for the northern half, is in a small irregular vale, on the southern declivity of Mont Martre. The latter repository is not only in a picturesque situation, but variegated by the unevenness of the ground; it is furnished with a wall of moulded clay, capped with flat tiles, to protect it from the weather, and supported by so many buttresses, that a stone wall would probably have been cheaper. On entering this place you see to the left a fancy elevation of the natural soil, declining towards the west. The coffin is let down on the edge of this declivity to a shelf at a small depth, and covered with a few shovels full of sand. If the body come from an hospital, it is only enclosed in a sack, and borne by two men on a hand-bier, over which two half hoops support a linen cloth. The rapidity with which burials are hallowed deferves the severe reprobation, the bodies being kept at no time 24 hours, so that the death can scarcely be ascertained: the bodies are, however, exposed in the gateway of the hotel, with tapers and holy water, which is sprinkled over the coffin by devout visitants. Towards the right, or eastern part of Mont Martre, there is a little vale, planted with weeping willows and shrubs interpered with tombs of stone. This part is referred for those of a superior class: the epitaphs are elegant and concise.

Government and Police. — Of the fewest, officers at the head of the government in Paris, etc. is denominated the minister of justice, who is charged with the printing and distribution of the laws, proclamations, and orders of the government; he corresponds with the various tribunals, and their commissaries; he submits to the councils of state the new questions which may arise relating to the administration of justice, and superintends its administration. The minister of the home department corresponds with the prefects of the departments. All acts relative to prisons, hospitals, roads, bridges, public works, canals, commerce, industry, agriculture, manufactures, arts, inventions, public schools, museums, and national festivals, are under his immediate direction. What particularly regards the government of the city of Paris is the department of the police, of which the minister or director, for it matters not the name he is called by, has a most arduous task. "He has not," says a close observer, "a moment that he can call his own; he is every day obliged to punish; he is afraid to give way to indulgence, because he does not know that he may not one day have to reproach him. He is the minister of the severest, and of acting contrary to the inclination of his heart. Not a crime is committed, but he receives an exaggerated account of it. Not an accident happens but he must prescribe the remedy; he has but a moment to deliberate and act, and he must be equally fearful to abate the power intrusted to him, and not to use it opportunely. Popular rumours, flights conversations, theatrical factions, false alarms, every thing concerns him. He must be answerable for every thing; he must trace the robber, and the assassin, for the magistrate appears blameable, if he has not found means to deliver him up quickly to justice. The time that his agents have employed in this capture will be calculated, and his honour requires that the interval between the crime and the imprisonment should be the shortest possible. What dreadful duties! What a laborious life! He must daily make up for the imperfection and tardiness of the civil laws, but he must, at the same time, use this rare privilege with extreme circumspection. The chief of the police is become a minister of importance; he has a secret and prodigious influence; he knows to many things, that he can do much good, or create a deal of mischief, because he has in his hand a multitude of threads, which he can entangle or difentangle at his pleasure; he strikes or he saves, he spreads darknings or light; his authority is as delicate as it is extensive. He exercises a despotic sway over the mouchards, or spies, who are found disobedient, or who make false reports; as for these wretches, they are of a class to hate, that the authority to which they have sold themselves, has necessarily an absolute right over their persons. This is not the case with those who are apprehended in the name of the police; they may have committed trifling faults, but are frequently detained without the sanction of any law. A few real advantages compensate for the irregular forms to which every one is subjected, and, as an excuse for the arbitrary imprisonment of individuals, it is said there are an infinite number of irregularities which the slow and grave proceed of the tribunals can neither take cognizance of, nor put a stop to, nor foresee, nor punish. The audacious or subtle delinquent would triumph in the winding labyrinth of our civil laws. The laws of the police, more direct, watch him, and surround him more closely. The abuse is contigious to the people, I admit, but great many private acts of violence, base and shameful crimes, are repelled by this vigilant and active force, which ought, nevertheless, to publish its code, and submit it to the inspection of enlightened citizens. Could the minister of police communicate to the philosophy of all, he knows, all these to the world, and like wife impart to him certain secret things, of which he alone is well informed, there could be nothing so curious, and so instructive, under the pen of the philosopher. But this magistrate is like the great penitentiary; he hears every thing, relates nothing, and is not astonished at certain delinquencies in the fame degree as another man. He is in a perpetual state of milrict; and in the main he ought to oppose such a character; for he ought to think nothing impossible, after the extraordinary lenity which he receives from men and things. The spies of the police are a regiment of inquisitive fellows, with this difference, that each individual belonging to it has a distinct dress, which he changes frequently every day, and nothing so quick, or so alarming as these forts of metamorphoses. The same spy who figures as a private gentleman in the morning, in the evening represents a priest; at one time he is a peaceable limb of the law; at another a swaggering bully. The next day, with a gold-headed cane in his hand, he will assume the deportment of a married man buried in calculations: the most singular disguises are familiar to him. In the course of twenty-four hours he is an officer of instruction, and a journeyman hair-dresser; a sham apostle and a fausse. He visits the dace-ball, and the lowest sink of vice. At one time with a diamond ring on his finger, at another with the most filthy wig on his head; he almost changes his countenance as he does his apparel; he is all eyes, all ears, all legs; for he trots over the pavement of every quarter of the town. Sometimes, in the corner of a coffee-room, you would take him for a dull, stupid, tiresome fellow, snoring till supper
is ready; he has, however, seen and heard all that has passed. At another time he is an orator, and the first to make a bold speech; he courts you to open your mind; he interprets even your silence; and whether you speak to him or not, he knows what you think on any particular proceeding. Such was the universal instrument employed in the reign of Lewis XVI. for divining secrets; and such uninquenionably is the system now carried on for the same purpose. There may be variations in the manner, as there must be different characters to perform their parts, but the police is, at least, as strict as it ever was in the reigns of the most arbitrary monarchs, and the means pursued for the purpose as hostile to the rights and liberty of the subject."

Paris, Department of, one of the new divisions of France, including the city of Paris and its immediate environs.

Paris, a town of Prussia, in the province of Bartenland; eight miles N.N.E. of Raftenburg.

Paris, a thriving post-town of America, in the state of New York, and county of Oneida, incorporated in 1792, and containing, in 1800, 4,721 inhabitants. Iron ore is found in its vicinity, and the land is excellent. It has an academy and a parish church, and its progressive improvements are rapid.—Also, the county town of Bourbon county, in Kentucky; 18 miles N.E. of Lexington. It has a court-house and gaol, a Presbyterian church, and several mills in its vicinity. Its houses are principally constructed of brick and stone. The town is pleasant and thriving, and contains 377 inhabitants.—Also, a town of London county, Virginia; 39 miles from Washington.—Also, a town in Cumberland county, and state of Maine; containing 844 inhabitants.—Also, an island on the coast of South Carolina.

Gen. Ch. Cal. Perianth inferior, permanent, of four lanceolate, acute, spreading leaves, the length of the corolla. Cor. Petals four, spreading, awl-shaped, equal, permanent, similar to the calyx but narrower, and alternate with the corolla. Stam. Filaments eight, awl-shaped, short below the anthers, which are long, united to the middle part of the filaments. Pjfl. German superior, roundish, with four blunt angles; styles four, spreading, shorter than the filaments; stigma downy. Peric. Berry nearly globule, with four blunt angles, somewhat depressed, of four cells. Seeds several, globule, inserted in two rows, upon a central receptacle.

Eff. Ch. Calyx of four leaves. Petals four, narrower than the calyx. Berry superior, of four cells. Anthers united to the middle of the filaments.

feoty simple, round, smooth, naked, except at the very summit, where it bears a whorl of four spreading, nearly equal, ovate, broad, acute, entire, three-ribbed, velvty, smooth leaves, tapering at the base, of a dull green hue, and plant texture, each of them about three inches long, increasing in size as the fruit ripens, after which the whole plant loom turns of a pale yellow and withers. Flower solitary, terminal, central, on an upright angular stalk, about half as long as the leaves. Calyx leaves, of a lighter green than the foliage, each an inch long. Petals of the same colour and length, but much narrower. Stamens half the length of the calyx, ascending, green, with yellow anthers. Styles pale, downy. Berry purple. The leaves occasionally vary in number to three or five. Haller mentions five. Linnaeus says the roots are emetic, but only half as powerful as Ipecacuana.

2. P. polyphylla. Many-leaved Herb Paris.—Leaves lanceolate, eight or ten. Discovered by Dr. F. Buchanan, growing in woods near rivulets, in Upper Napan, where it is known by the name of Dai Suwa. The root is creeping, but much thicker and more tuberous than the former. Stem a foot or more in height, brownish, thrice the thickness of the first species, crowned like that with a whorl of leaves, in a similar spreading position, but about twice as numerous, and much narrower, being elliptic-lanceolate, taper-pointed, triple-ribbed; each supported on a short purplish stalk. Flower stalk much shorter than the former, but the flower is, of the same green colour. Its calyx leaves and petals are usually five, with ten flaments, but sometimes only four, with eight flaments, or even three with six. The styles, as well as the cells of the pericarp, always agree in number with the petals, but the former are combined by a thick columnar bafe, which character, added to his not having seen the ripe fruit, caufed Dr. Buchanan to doubt of the genus. The habit, and efl of the characters, however, leave no scruple in our mind; but it is very probable that what Linnaeus, in the European species, calls styles, may be almost wholly filaments, for they are downy all along their upper side, and the Napan plant will then be found to differ merely in having the style more elongated.

PARIS, Herb, of Canada. See TRILLIUM.

PARISCATY, in Geography, a town of Hindooflan, in Oude; 25 miles E. of Goorachpore.

PARISH, the precinct, or territory, of a parochial church; or the circuit of ground within which the people belonging to any church, or under the care of one parson or vicar, do inhabit.

The word comes from the Latin parochia, of the Greek παροιχία, habitation; compounded of παρά, near, and οιχία, house. Accordingly, Du Cange observes, that the name παροιχία was anciently given to the whole territory of a bishop, and derives it from neighbourhood; because the primitive Christians, not daring to assemble openly in cities, were forced to meet secretly in neighbouring houses.

In the ancient church, there was one large edifice in each city, for the people to meet in; and this they called parochia, parish. But the signification of the word was afterwards enlarged, and by parish was meant a diocefe, or the extent of the jurisdiction of a bishop, consisting of several churches; unlefs we will suppose, as some do, that these bishoprics were only pastors of single churches.

Du Pin observes, that country parishes had not their origin before the fourth century; but that those of cities are more ancient. The city of Alexandria is said to have been the first that was divided into parishes. Barnum says, that in the time of pope Cornelius there were forty-fix parishes in Rome.

How
How ancient the division of parishes is it is not easy to ascertain; for in the early ages of Christianity in this island parishes were unknown, or at least signified the same that a dioecese does now. There was then no appropriation of ecclesiastical dues to any particular church; but every man was at liberty to contribute his tithes to whatever priest or church he pleased, provided only that he did it to some; or if he made no special appropriation thereof, they were paid into the hands of the bishop, whose duty it was to distribute them among the clergy, and for other pious purposes, according to his own discretion. (Sedl of Tithes, 9. 4. 2 Init. 646. Hob. 296.) Camden says England was divided into parishes by archbishop Honorius, about the year 650 or 656. Sir Henry Hobart maintains that parishes were first erected by the council of Lateran, held A.D. 1179. But Mr. Selden has shown, that the clergy lived in common without any division of parishes, long after the time mentioned by Camden; and it appears from the Saxan laws, that parishes were in being long before the council of Lateran, in 1179. The division of parishes occurs in the laws of king Edgar, about the year 970. It seems pretty clear and certain, says judge Blackstone, (Com. vol. i. 113.) that the boundaries of parishes were originally ascertained by those of a manor or manors; because it very seldom happens, that a manor extends itself over more parishes than one, though there are often many manors in one parish. The lords, he adds, as Christianity spread itself, began to build churches upon their own demesnes or wales, to accommodate their tenants in one or two adjoining lordships; and in order to have divine service regularly performed therein, obliged all their tenants to appropriate their tithes to the maintenance of the one officiating minister, instead of leaving them at liberty to distribute them among the clergy of the diocese in general; and this tract of land, the tithes of which were so appropriated, formed a distinct parish; and this will account for the frequent intermixture of parishes one with another. For if a lord had a parcel of land detached from the main of his estate, but not sufficient to form a parish of itself, it was natural for him to endow his newly-erected church with the tithes of such lands.

Extra-parochial wales and marsh lands, when improved and drained, are by 17 Geo. II. cap. 37, to be sold to all parochial rates in the parish next adjoining. For settling the bounds of parishes, see PERAMBULATION.

Camden reckons 9284 parishes in England. In a book made out by cardinal Wolsey in 1520 are reckoned 9407 parish churches. And Chamberlayne makes at present, 9913, and the number of parishes is now reckoned to be about 10,000. See CHURCH OF ENGLAND.

Parish-Priest, the parson or minister who holds a parish as a benefice.

If the medial tithes be appropriated, the parson is called rector. If they be improperly, he is called vicar.

Parish-Clerk. In every parish the parson, vicar, &c. hath a parish-clerk under him, who is the lowest officer of the church. These were formerly clerks in orders, and their business at first was to officiate at the altar; for which they had a competent maintenance by offerings; but now they are laymen, and have certain fees with the parson on christenings, marriages, burials, &c. besides wages for their maintenance.

The law looks upon them as officers for life; and they are chosen by the minister of the parish, unless there is a custom for the parishioners or churchwardens to chuse them; in which case the canon cannot abrogate such custom; and when chosen it is to be signified, and they are to be sworn into their office by the archdeacon, for which the court of king's bench will grant a mandamus.

Parish clerks, after having been duly chosen and appointed, are usually licenced by the ordinary, and when they are licenced, they are sworn to obey the minister. The parish-clerk ought to be deprived by him that placed him in his office; and if he is unjustly deprived, a mandamus will lie to the church-wardens to restore him: for the law looks upon him as an officer for life, and one that hath a freehold in his place, and not as a servant: and therefore will not suffer the ecclesiastical court to deprive him, but only to correct him, for any misdemeanor, by ecclesiastical censures.

Parish-Clerks, Company of. See Company.

Parisi, in Ancient Geography, inhabitants of Britain, feated to the north of the Cortani, and occupying that district which is called Holmefeld, or as Mr. Camden imagines, the whole cell riding of Yorkshire. The Parisi are supposed to have derived their name from the two British words "Pair tua," which signify low pasture, and which are descriptive of the situation and use of their country. However this may be, it is evident that our Parish never attained to any great degree of power or consequence, but were always subject to the authority, and followed the fate of their more powerful neighbours, the Britanes. Their only town was "Pitaria," probably Patrington in Holderness.

Parisan Island, in Geography, an island in lake Superior, near the S.E. coast. N. lat. 46° 30'. W. long. 85°.

Parisis, a French money of account, formerly a real coin struck at Paris, at the same time with the Tournois, struck at Tours.

The Parisi exceeded the Tournois by one-fourth; so that the livre, or pound Parisi, was twenty-five ios; and the livre Tournois twenty. The fols and deniers Parisi, &c. were in proportion. See Coin.

Parisot, in Geography, a town of France, in the department of the Aveiron; 10 miles S.W. of Villefranche.

Paristemiotamus, from παρικηθαμος, the tonsil, and πυμος, to cut, in Surgery, an instrument anciently employed for faring the tonsils.

Parita, in Geography, a town of South America; in the province of Panama; 5 miles N. of Santos.

Paritee-Hotun, a town of Chincan Tartary. N. lat. 42° 28'. E. long 125° 16'.

Parium, in Ancient Geography, Camar, a town situated in the Propontis, between Lamphacus and Priapus. Its territory was fertile, and produced excellent wines, and it had a good port. This town was founded by the Mileans, the Erythrazans, and the inhabitants of the Isle of Paros, from which it took its name. Augustus established a colony in this place, and, like many others, it was governed by a senate or council composed of decurions. The worship of Apollo and Diana was transported from Aegiria to Parium, where a large and splendid altar was erected, the work of the celebrated Hermocreon. Strabo. Pliny also mentions a statue of Cupidon, belonging to this city, the production of Praxiteles, and not inferior in beauty to the Venus of Cnidus. Parium was ravaged in the year 267 by the Heruli, a German nation; but these barbarians were defeated and driven into their own country by the emperor Gallienus, in consequence of which a triumphal arch was erected; which arch consisted of three arcades, upon which the emperor appeared in a car drawn by two elephants, between two victories, which presented to him a crown of
of laurel. When the government of proconsular Asia was divided into several provinces, Parium was comprised in the new province of the Hellepont, of which Cyzicus was the metropolis.

PARIVOA, in Botany, a name in Aublet, t. 2, 756, for one of those genera on which Schott founded his Dimorphia; see that article, as well as Panzera. As we have, after Willdenow's example, separated the latter, the Pariva must remain under the denomination of Dimorpha, which, however, by this diffusion, loses its original meaning.

PARIYATTEKA, is the Sanscrit name of a species of ayxanthae, and in the mythological legends of the Hindoos a golden tree, yielding in its fruit whatever the heart can desire. It is said to have arisen from the ocean when charmed by the gods and demons, as described under the article Kurmahatara, and to have fallen to the lot of the demigod Indra, regent of the firmament, who, hence, and from similar poffeibions, is called the lord of wealth. (See Indra.) The name is commonly pronounced cariot, and it is often alluded to in the holy tales and fables of the Hindoos. Sometimes it is called Lakshimi-vriksha, the tree of Lakshmi, or wealth. This is a treatise on Hindoo music in the Persian language, probably a translation from the Sanscrit, named after this all-yielding tree Parivatetaka.

PARK, Parsus, a large inclosure, privileged for wild beasts of chase, either by the king's grant, or by prescription. Co. Litt. 235. 21 Rep. 36.

The word is originally Celtic; where it signifies an inclosure, or place shut up with walls.

Manwood defines a park a place of privilege for beaufs of venery, or hunt, and other wild beasts of the forest, and of chase; vita sequi, quem comedisse. A park differs from a forest, in that, as Compton observes, a subject may hold a park by prescription, or the king's grant; which he cannot with respect to a forest.

A park differs from a chase also; because a park must be inclosed; if it lie open, it is a good cause of seizing it into the king's hand, as a free chase may be, if it be inclosed.

Nor can the owner have any action against such as hunt in his park if it lie open. See CHASE.

Du-Cange refers the invention of parks to king Henry 1. of England, and the first park in England is said to have been that of Woodstock in Oxfordshire, made by him, which was walled round with stone, and seven miles in circumference: the royal example was first followed by Henry, earl of Warwick, to preserve his deer and other animals for hunting; after which the practice of park-making became general among persons of opulence. But Spelman shews it is much more ancient; and was in use among the Anglo-Saxons. Zophimus affuies us also; that the ancient kings of Phisia had parks.

The clergy of rank, at all times, had the privilege of hunting in their own parks and inclosures; and therefore, that they might not be prevented from following this favourite pastime, they took care to have such receptacles for game belonging to their parks. Accordingly, at the time of the Reformation, the see of Norwich, only, was in the possession of not less than thirteen parks, well stocked with deer and other animals for the chase.

No man can now erect a park without a license under the broad seal; for the common law does not encourage matters of pleasure, which bring no profit to the commonwealth. Wood's Inft. 207.

But there may be a park in reputation, erected without lawful warrant; and the owner of such park may bring his action against persons killing his deer. Ibid.

To a park three things are required. 1. A grant thereof.

2. Inclosures by pale, wall, or hedge. 3. Beasts of a park, such as buck, doe, &c. and where all the deer are destroyed, it shall no more be accounted a park, for a park consists of vert, venison, and inclosure; and if it is determined in any of them, it is a total dispairing; and the king may by letters patent dispose of his park. Cro. Car. 59. 66.

Offenders pulling down park-walls or pales, shall be liable to the same penalty as for killing deer, &c. by statute. See DEER-STEALERS.

A park ought to have three sorts of ground in it: 1. Mountainous and barren. 2. Hilly and yet fertile. And 3. Plains that are sufficiently fruitful. The mountainous part should be well covered with high woods over at least a third part of it. The downs and hilly part should have one-third part coppices and low woods; and the plains should be at least one-third part pasture ground, with some arable or corn land. There should be a river contrived to run through some part of it, and a spring or brook to go through a great part, and at length fall into the river.

These are the natural advantages to be wished in a park; but when they are wanting, they are to be supplied as far as may be by art, as by ponds to preserve rain water, to supply the place of rivers and springs, and proper plantations and exposures for the rent; only the person who is to make a park should know what the natural advantages are, that he may take in as many as he can. When ponds are to be made to supply the place of natural brooks and rivers, they should be made large enough; the extraordinary expense in this will be easily repaid, by breeding fish in them, and fowl may also be kept in plenty on them. The park should also be well stored with trees; oaks should not be wanting in it, but beech and chestnut are the quickest of growth, and are easy to be had: these, therefore, should be planted in considerable numbers. Apple-trees and plum-trees also should be planted, as generally thriving very well, and affording good food to the deer, &c.

The best inclosure for a park is a brick or stone wall; but as the expense of this is very great, it may be done by palings; the pales must in this case, be of found heart of oak; and so close planted, that no animal of prey can make its way in between them; and for a farther defence, a good quick-felt hedge is very proper, and should be kept in good order. Some part of the mountain and high wood may conveniently be made a heronry, and some part of the middle may be a warren for hares and rabbits. Cots and hovses may be bred at large in the park, and in the summer season it will be proper to have cows in the pasture-ground on the plains.

There should be at least five or six inclosures in the park, that the deer may be shut out or let in as occasion requires. In the colder seasons, they should always be kept altogether in the high woods, where they have good shelter, and are to be fed conjointly with provender by the keepers. In the summer such a number as are intended to be used may also be kept on the belt-ground, that they may thrive quicker than those intended only for forest. Some artificial holes and caverns should also be made for the deer to retire into in the hot weather, as well as in the cold.

Park, in Gardening, an inclosed piece or portion of ground, of a larger or smaller extent, which surrounds a mansion or residence, and which has commonly some sort of forest or other trees, planted or growing on it, for the purpose of beauty or ornament. Large parks mostly contain deer or other similar animals, and the more they have of this wild
PAR

wild or forest scenery, the more natural and proper they appear.

It is supposed by Mr. London, in his "Treatise on Country Residences," that parks should be of two kinds; those belonging to small houses, where regard should principally be had to the value of the pature, and where the pasturing animals are horses, cattle, sheep, &c.; and those where grandeur of character is the main object.

In the former, the surface of the ground should be unbroken, but clothed and varied, or characterized chiefly by trees, unless a few shrubs of the lower growths be admitted near the stems of trees, or shrubs, or the pleasure of the pleasure grounds. The apparent extent of this kind of parks depends more upon the variety of the woods, and the manner in which the trees and shrubs are planted, than upon the number of acres. A level or uniform surface, spotted by circular, oval, or even angular clumps, and surrounded by a compact ferny belt, as at Duddington, and some other places, can never, it is supposed, appear extensive; but a very few acres of varied ground, sprinkled over with light groups, thorns, and hollies, appear boundless. In such a park, every leap presents a new composition, arising from the varied herds of cattle intermingling with the trees, &c., and changing their position: and as there is no permanent mark by which one scene can be distinguished from another, so as to know it again; a person might wander up and down the extent of a few acres for several days, without being able to say whether he was not traversing a park of several square miles. And this is the case in natural forests, as depending on the same principles.

In the latter kind of parks, nothing, it is believed, can contribute so highly to the necessary grandeur of effect, as the wild, forest style, of breaking the ground, and planting trees, shrubs, low growths of plants, furze, bramble, ferns, &c.; and spreading roots, decayed trunks, rocks, or flones, when they may appear with propriety, and as it were fortuitously. The grazing animals in this effect should be principally deer, a few wild cattle, and horses. It is suggested, that as parks are the prominent features of all extensive residences, were this appearance of wildness and forest scenery given to them, words could not convey an adequate idea of the beauty and grandeur that would be communicated to them, and at the same time to the country at large. The materials by which this is chiefly to be effected are, as has been seen, the proper arrangement of low shrubby growths, wild plants, and forest trees. Nothing can however give an idea of what these effects might be, except looking at the finest ranges of forest scenery, the few of which now exist in the country. In the New Forest, as well as that of Needwood, it is however supposed, that there are still feek ranges or tracts, which the true admirers of nature will view with rapture or enthusiastic delight, and by the imitation of which, some ornamental advantages might be made to the already beautiful parks of Donnington, Blenheim, and Croom, as well as all those esteemed the finest in the kingdom.

Some may suppose the utility of such parks thus to be injurious. And so it would in some degree; but it is asked, is not beauty or grandeur of character one of the chief objects of such scenes? if not, why change the common character of the country, why make the interlarding variety of corn-fields, farms, cottages, hedges, coppices, &c. give way to one dull rapid monotonous surface of green, as insipidly varied by trees; where one might wander an age without seeing any thing else than their naked trunks and lump-like heads? Nothing, it is believed, can be grand or sublime, but as it soars above the common appearances of the like things. Now, says the writer, in a fertile and cultivated country, what can be more truly uncommon with regard to the surface, than making it assume the wild irregularity and excellencies of nature, leaving flocks and herds to roam at pleasure, and defying the seeming abundance of cultivation, and the greater ideas of mere profit or use?

It is not, however, meant by this to affirm, that there would be much real difference in the annual profit of a park so laid out, when compared with one in the modern taste. What would not be occupied with pastures would be covered with wood; which, whether as undergrowth, or timber produce, would be highly valuable, and often produces as much profit as either pasture or aration, and in many places is highly suitable for parks: besides the abundance of every kind of game which thus would produce, as well as the encouragement it would give to different classes of beautiful singing-birds. It is added, that this being the case, and it being taken into view that deer are not grazed for pecuniary advantage, it cannot be seen that there would be any real disadvantage in point of profit by adopting the mode; and hence it is wished that it should in some degree be attended to, even in parks of the smallest size, where cattle and sheep are grazed. And it is farther suggested, that in this age of refinement and universal cultivation, wildness and native simplicity have charms which are highly interesting to all, except those engaged in the vortex of fashion.

Park is also used for a moveable pallisade, set up in the fields to inclose sheep in to feed, and rest in, during the night.

The shepherds shift their park from time to time, to dung the ground, one part after another.

Park is also used for a very large net, disposed on the brink of the sea, with only one hole, which looks towards the shore: and which becomes dry after the flood is gone off; so that the fish once got in have no way left to escape.

Park, in War. Park of Artillery. A post in a camp, out of cannon-shot of the enemy, and fortified to incamp the train of artillery, and to secure the magazines and ammunition, as well as the battalions of artillery, appointed for its service and defence. See Artillery Park.

The figure of the park of artillery is commonly a parallelogram, unless the situation of the ground renders another necessary. The artillery is generally placed in the centre of the second line of encampment, and sometimes in the rear line, or corps of reserve. In both places the muzzles of the guns are in a line with the fronts of the serjeants' tents of the regiments of artillery and infantry. Some generals place the park about three hundred paces before the centre of the front line of the army: some place all the cannon and mortars in the front, together with their spare carriages; others are for dividing the equipage in brigades, and place the first in the front line, the second in the next, &c. But the most approved method, says Mr. Muller, Artill. p. 281, is to divide the artillery into brigades; and to place the guns of the first, to the right of the front line, and their ammunition behind them; then those of the second brigade next to the first in the front, leaving five paces between them, and their ammunition behind them; and all the rest in the same order; the pontoons forming the last line. The artillery companies and miners are half encamped to the right; and the other half to the left of the park, with some of the lieutenants in the rear. At about twelve paces in the rear of the park, are encamped the civil lift in one line; behind them, at the distance of thirty paces, is a line of the remaining lieutenants, and behind these the captains and commissaries. Opposite to the centre, and thirty paces behind the captain's line, is the major's tent; and behind this, at twenty paces,
the colonel's to the right, and the comptroller's to the left. Opposite to the centre, and fifty paces before the park, is placed the army guard; and opposite to the right wing, the artillery guard at the same distance. In the middle of the front, two light pieces are advanced at a distance of twenty paces, loaded with powder for the alarm guns, which are ready to be fired when required. To the right of the park are placed the officers with their tools, materials, and baggage, in a line from the front to the rear. To the left of the park, the commissaries and their baggage; to the right of the artillery, with their baggage and officers behind them; and to the left of the commissaries the second battalion in the same manner. The horses are placed behind the first battalion, except those of the piquet in the rear of the park.

Every attack, at a siege, has its park of artillery.

Park of Provisioun, is a place in the camp, on the rear of every regiment, which is taken up by the fustiers, who follow the army with all forts of provisions, and fell them to the soldiers.

Park Butts, in our old Writers, signifies to be quit of including a park or any part thereof. 4 Init. 508.

PARKANY, in Geography, a town of Hungary, at the confluence of the rivers Gran and Danube; 2 miles N. of Gran.

PARKEI, a town of Hindoostan, in Golconda; 32 miles S.S.W. of Hyderabad.

PARKER, Matthew, in Biography, archbishop of Canterbury, was born at Norwich in 1504. He had the misfortune to lose his father when he was only twelve years of age; but his mother took care to place him under good masters, by whom he was well grounded in grammar-learning. In the year 1520 he was sent to Cambridge, and was entered of Corpus Christi college, of which house he was chosen a bible-clerk, or scholar, in the following year. Here he applied with great assiduity to his studies, and in 1523 was admitted to the degree of B.A. In 1527 he was ordained deacon, and afterwards priest; and in the same year he commenced M.A., and was chosen fellow of his college. When he was about 29 years of age, he preached his first sermon before the university; and almost immediately became a popular preacher in the neighbourhood of Cambridge. He had by this time imbibed the principles of the Reformation, and shewed so much zeal for them, that archbishop Cranmer granted him a licence to preach throughout his province. About this time he was sent for to court, and was made chaplain to queen Anne Boleyn, who appointed him, a short time before her death, to the particular charge of her daughter Elizabeth. About the year 1534 he was presented by the queen to the deanery of the college of Stoke, near Clare, in Suffolk, a preferment of small value in a pecuniary view, but affording him a pleasing place of retirement, when he chose to withdraw from the court, from which it was about 20 miles distance. Here he laboured to reform the Popish superstitions, and founded a grammar-school, for the instruction of youth in found learning, and in the principles of the Christian religion. In 1537, after the death of queen Anne Boleyn, he was appointed one of Henry VIII.'s own chaplains; and in the following year he was created doctor of divinity. In 1541 he was installed prebendary in the cathedral church of Ely; and in 1542 he was presented by the chapter of Stoke to the rectory of Aitchen, in Effex. He obtained other preferments in the church; and in 1544, on account of his high character and great learning, he was chosen master of Corpus Christi college, to which he afterwards became a liberal benefactor, and compiled for it a new body of statutes. In 1545 he was elected vice-chancellor of the university of Cambridge; and in the same year he was presented by his college to the rectory of Landbeach, in Cambridgeshire. After the accension of king Edward VI. he married; and in 1549, being accidentally in Norfolk, during the time of Kett's rebellion, Dr. Parker had the resolution to go to the rebels' camp, where he preached to them under the oak of Reformation, exhorting them most earnestly to temperance, moderation, and submission to the king. In so doing, he ran great risk of his life; but he fortunately escaped out of their hands. In 1551 Dr. Parker was included in a commission for correcting and punishing the Anabaptists; and about this time he preached a funeral sermon for Martin Bucer, regius professor of divinity, with whom he had been on terms of great intimacy. In 1552 Dr. Parker was presented by Edward VI. to a prebendary in the cathedral church of Lincoln, and also to the deanery of the fame church. He had been nominated, previously to this, a chaplain to his majesty. Thus he lived in great reputation and influence, during the reigns of Henry VIII. and Edward VI., and happy in the acquaintance and esteem of all the principal men of his time.

After the accension of queen Mary, Dr. Parker was deprived of all his preferments, and gladly withdrew into privacy. Great pains were taken to find out his retreat; but he eluded the machinations of his enemies; and on the death of the cruel and bigoted sovereign, he was by her successor preferred to the archbishopric of Canterbury, and was duly and regularly consecrated at Bow church; though the Papists, some years afterwards, propagated a report, that Parker had been consecrated at a tavern in Cheapside, which was proved most fallaciously to be a calumny. Being thus constituted primate and metropolitan of the church of England, Dr. Parker endeavoured to fill the vacant fees with men of learning and distinguished piety, who were zealous for promoting the Reformation; and very soon after his own consecration, he consecrated, at Lambeth, Grindall, bishop of London, Cox, bishop of Ely, Sandys, bishop of Worcester, Jewel, bishop of Salisbury, and several others. He also extended his influence and his anxious concern for the Protestant interest to the kingdom of Ireland, sending over proper instructions to the archbishop of Dublin, for completing the work of reformation in the church of Ireland.

About this time archbishop Parker received a letter from Calvin, exhorting him to prevail with the queen to summon a general assembly of all the Protestant clergy, wherever soever dispersed, for the purpose of agreeing upon one common form of worship and of church government to be established, not only within her dominions, but also among the reformed and evangelical churches abroad. This letter was taken into consideration by the queen's council, who requested his grace to return thanks to Calvin for his proposals, but, at the same time to signify to him, that the church of England would still retain her episcopacy. It is not in our power, in this article, to notice all the attempts made by Elizabeth, in which the archbishop seems to have concurred, to introduce a uniformity of faith. In consequence of those proceedings against the Puritans, many churches in London, and in every part of the kingdom, were shut up for want of preachers. The sufferers under these persecutions, having been refused a hearing by the archbishop, and the other commissioners appointed by the queen, appealed to the public, and circulated various books and pamphlets in defence of their nonconformity. To some of these, answers were written, on the part of the bishops, either by themselves, or their chaplains; which were followed by replies from Puritans, whose tracts were eagerly sought after. In consequence
sequence of this, a decree was obtained from the star-chamber, prohibiting all books and pamphlets, in which any thing should be advanced against the queen's injunctions, and empowering the wardens of the stationers' company to search all suspected places for such books, and to bring the offenders before the ecclesiastical commissioners. This scandalous stretch of tyranny took place in the month of June, 1566. In the following year the archbishop founded three grammar-scholarships in Bennet-college; and two years afterwards, seven further scholarships, and two fellowships, in the same house. In 1568, a new folio edition of the English bible was published, chiefly under the inspection of archbishop Parker, with a preface written by him. It was commonly denominated the bishop's bible, on account of its having been revised and corrected principally by the bishops, from the two editions published by the predecessors; and it was made use of in the churches, till the last translation took place in the reign of James I. One of the last acts in which the archbishop was employed was a metropolitan visitation of the diocefe of Winchester, and in particular of the Isle of Wight, in 1575, in which he exercised such severities as exposed him to universal odium, and even induced the court to interfere and revere his proceedings. He died in the month of May, 1575, when he was in the 71st year of his age, and was buried, with great magnificence and solemnity, in his own private chapel at Lambeth, under a tomb erected by himself, which remained there till 1648, when the tomb was pulled down, and the ashes of the prelate exposed to much insult. Some time after the restoration, they were recently re-interred in the place where the monument formerly stood, and another was now erected to his memory. Archbishop Parker has the honour to rank among the principal agents in exposing the superfluities of Popery, and in placing the Protestant religion on a permanent footing in England: he, however, fulfilled his reputation, by introducing the English version of the Bible, and by perfecting the church from which he separated. He was naturally of a warm temper, but, till his head was turned by his exaltation, he exhibited no infinences of haughty-ness or ill nature. He was to the last hospitable and charitable, and did many kind and benevolent things for private people, as well as for the public benefit. The regulation of his family was extremely laudable: he assigned all his domesticks some particular employment, and suffered none to be idle. Those who were not occupied in learned pursuits, about the management of his revenues, or the affairs of his household, were variously employed; some in binding books, others in engraving, painting, transcribing manuscripts in fine hand-writing, drawing, or illuminating.

The archbishop was much attached to the study of Britifh and Saxon antiquities, and he spared neither labour nor expense in collecting and preferring whatever manuscripts of this kind could be met with, of which a fatal havoc and destruction had been made at the time of the diffolution of the monasteries. In 1563 he was the instrument of preferring two monums of calligraphy to his folio, in which the archbishop Cranmer, whatever he was able to collect, he deposited in a library that he built for Corpus Christi college, in Cambridge. He published editions of four of our ancient English historians, viz. Matthew of Westminster, Matthew Paris, Thomas Walthingham, and Ather's Life of King Alfred. He also published "A Teftimony of Antiquity, showing the ancient Faith of the Church of England, touching the Sacrament of the Body and Blood of the Lord, here publicly preached, and also received, in the Saxons' Time, about seven hundred years ago, being a Sermon translated out of Latin into Saxon by Ælfric, Abbot of St. Albans, about the year 996, and appointed to be delivered to the People at Easter, before they should receive the Communion." Another considerable work of the archbishop contains the lives of his predecessors in the see of Canterbury, and is entitled "De Antiquitate Britannicae Ecclesiae, et Privilegiis Ecclesiae Cantuariensis, cum Archi-episcopis ejusdem LXIII, 1572." The materials for this performance were collected from ancient historians, by John Jofeline, secretary or chaplain to the prelate, who was himself the digester and compiler of it. The first edition of this work is that of 1729, illustrated with fine engravings. Biog. Brit. Neal's Hift. of Puritans.

PARKER, Samuel, an English bishop, son of John Parker, a ferjeant at law under the protectorate of Oliver, vis. de Robertis, the reformation, Cantorborn at Walthamstow in 1640. He was educated in grammar-learning among the Puritans, at his native place; after which he was sent, in 1656, to the university of Oxford, where he was entered of Wadham college. Here he is said to have led a very retired and religious life. In 1659 or 1660 he was admitted to the degree of B.A. Although now a zealous Puritan, he became, at the restoration of Charles II., violently attached to the court, obtained preferment, and was, in 1667, appointed chaplain to Dr. Sheldon, archbishop of Canterbury. In 1670 he was nominated to the archdeaconry of Canterbury, and obtained several other benefices. In the reign of James II. he was made, for his servility to the king's arbitrary measures, bishop of Oxford and privy counsellor. He was also conftituted, by mandamus, president of Magdalen college, in violation of the privileges of that society. He was a man of numbers; and he left behind him, in manuscript, "A Hiftory of his own Times," in Latin, which was published in 1726, under the title of "Reverendi admodum in Chrifto Patris Samuæ Parkeri, Juræ novi Canterburiae vicarii, vicarii, vicariorum," of which two English versions afterwards appeared. He died in March, 1687-8, at the age of 48, unlaunted and defpised by good men. Bishop Burnet says, "he was a man of no judgment, and of as little virtue; and as to religion, rather impious. He was covetous and ambitious; and seemed to have no other fene of religion but as a political interest, and a subject of party and faction." Biog. Brit. Burnet's Hift.

PARKER's Bay, in Geography, a bay on the south coast of Jamaica, south of Palmetto point.

PARKER'S Creek, a river of Maryland, which runs into the Cheapeake, N. lat. 38° 30'. W. long. 76° 59'.

PARKER'S Iland, an ifland in the Cheapeake, near the coast of Maryland; 15 miles S. of Annapolis. N. lat. 38° 55'. W. long. 76° 41'.—Allo, an ifland called Rythobegan, in Lincoln county, and state of Maine, formed by the waters of Kennebec river well, by the sea fouth, by Jeremyfuch bay, and by a small ifland which divides it from Arothe of island north; so called from John Parker, who purchased it from the natives in 1650, part of it still remains to his poffeffors. It is in the township of Georgetown.

PARKER Riuer, a river which takes its rife in Boxford, in the Mafachuaffetts, and pursuaffing a variable courfe, at length wanders through the marshes, and enters Plum ifland found by a mouth about a quarter of a mile wide. It is richly firoed with fish, and is navigable for coating veifels to the head of the tide, but obtruded by two bridges.

PARKGATE, or the New Quay, a fea-port and ham-let in the parish of Great Newton, hundred of Wirral, and county-palatine of Chelfter, England, is situated on the north-eastern bank of the estuary of the river Dee, at the distance
distance of twelve miles from the county-town, and one hundred and ninety-three from London. This place has of late years become a convenient and fashionable bathing place, and is also celebrated as a station for the Irish packets, which fail from Dublin four times a week. The houses here are chiefly built in one long street stretching itself parallel with the river, and are mostly neat modern buildings of brick. The chief support of Parkgate arises from the custom of the passengers to and from Ireland, and from its celebrity as a bathing- quarter. Beautiful Beaux of England and Wales, by E. W. Hawkins and John Britton, F.S.A.

PARKHURST, John, in Biography, second son of John Parkhurst, esq. of Cateby in Northamptonshire, was born in June 1728. He was educated in grammar learning at Rugby school, in Warwickshire. Being intended for the church, he was entered of Clare-hall, in the university of Cambridge. Here he took his degrees of B. A. and M. A. in 1752, and was many years fellow of his college. Soon after he had entered into holy orders, by the death of his eldest brother he became heir to a very considerable estate, but neither then, nor at the death of his father, when he came into possession, did his accession of fortune produce any change in his manners or pursuits. He still continued to cultivate the studies becoming the clerical profession, paying particular attention to that of the original languages of the Jewish and Chritian scriptures. He never obtained any preferment in the church, yet he took pleasure in the exercise of the clerical duty, and for a long time officiated in the capacity of curate, with exemplary zeal and diligence, but without any falary, in his own chapel at Cateby, which afterwards served as a parith church. When he became possessed of the right of presentation to a living, he confered church-patronage as a truth, rather than property, and instead of taking it himself, he bestowed it on a gentleman, known to him only by character, from no motive but a persuasion that he would faithfully discharge the duties of his office. In 1754 Mr. Parkhurst married a lady, by whom he had a daughter and two sons, and after her death he married a second time, by whom he had one daughter, who had a passion for classical learning, and who arrived at a degree of perfection in it, which is seldom met with among females. He was first known as an author in 1755, by publishing a "Friendly Address to the Rev. John Wesley;" his next work was "An Hebrew and English Lexicon, to which is added a Methodical Grammar, adapted to the use of Learners." This performance reflects much credit on his learning and patient enquiry, and may be recommended as affording valuable assistance to the biblical student in forming an acquaintance with the Hebrew scriptures. In 1758 a second edition of it was published with corrections and improvements, and a third was given to the public in 1792. The author had, however, in the mean time, published a "Greek and English Lexicon to the New Testament," to which was prefixed a plain and easy Greek grammar. A second edition of this work was published in 1794, and it was the intention of the author to give new editions of them in octavo, but he died before he could complete the business, and the task of editing them devolved on his younger daughter, the wife of the Rev. Joseph Thoms. Mr. Parkhurst departed this life, after a long and painful illness, in February 1797. Through his whole life he had been a most affiduous student; for many years it was his usual practice to rise at five o'clock, and in winter to light his own fire. He was attached to the works of Hutchinon, but was well acquainted with their defects as well as their excellencies. He was an ardent lover of the truth, and was not afraid to avow his sentiments. In forming his religious principles, he followed no guide but the scriptures, the study of which was the business and the pleasure of his life. Mr. Parkhurst at one period of his life engaged in a controversy with Dr. Priestley respecting the divinity and pre-existence of Christ. He was naturally irritable, warm, and earnew in his resentments, but he effectually subdued this temper by an attention to the injunctions of religion, and passed through a long life in peace and harmony with all around him, respected by men of learning, beloved by his friends, and honoured by his family. PARKHURST, in Geography, a town of Bengal; 32 miles N. of Ramgur.

PARKINSON, John, in Biography, a celebrated old herbalist, of the latter part of the 17th century, and the first half of the 17th, was born in 1657, and bred up as a London apothecary. He is mentioned by his contemporaries as a man of eminence in his profession, and was at length appointed apothecary to King James I. King Charles I. afterwards conferred upon him the title of Botanicus Regius Primarius. A great share of his attention, during a long life, was devoted to the study of plants. He had a garden well flored with rarities, and he bestowed equal notice upon the curiosities of the flower-garden, in all their luxuriant Proteus-like varieties, and on the native productions of his own and other countries, embrazing their literal history, as well as their practical investigation.

His first publication was his Paradisus in Sole Paradisi terricri, or a Choice Garden of all sorts of Rare Flowers, &c.; to which is annexed a Kitchen Garden, &c. This was printed at London, anno 1692, in a folio of 612 pages. A second edition, "much corrected and enlarged," appeared in 1696, after the decease of the author. Both editions are dedicated "to the Queen's most excellent Majesty," which could hardly have been, as Dr. Pulteney supposed, Queen Elizabeth; but rather the Queen of Charles I.; and it is to the honour of those who edited the new impression, in 1696, that this dedication was not then suppressed. About a thousand plants, either species or varieties, are described in this book, of which 750 are figured, in wood cuts, partly copied from Clusius and Lobel, partly original, but all of them coarse and stiff, though sometimes expressive. Numerous remarks are interposed, respecting the botanical history or medical virtues of the plants, as well as their culture; but the latter subject is, for the most part, given in the introductory chapters, which display no small degree of intelligence and experience. This book affords a very correct and a very respectable idea of the gardens of the ancients, at the time it was written, and has been considered, by the learned authors of the Hortus Kewensis, unequivocal authority as to the time when any particular species was introduced or cultivated among us. The florist and the kitchen gardener will find some productions recorded which have since disappeared, and though our kitchen gardens had not arrived at such luxuriant perfection or variety as they afterwards attained, in King William's days, and have since preferred, there is reason to think the science of horticulture declined considerably after the time of Parkinson, previous to its restoration at the end of the 17th century. As to the botanical garden, Dr. Pulteney remarks, from an investigation of the Paradisus terricri, that "inter-tropical productions had, at this period, been but sparingly imported. The strow plants are very rare throughout the book. There are some American species, and particularly from Virginia, as being a part of that continent with which England had the most frequent intercourse. But the principal productions of the English gardens were exotic European, and Greecian plants, some African, and a few from the northern coasts of Africa."—It is no small praze to the work before us, that
the late Mr. Curtis held it in particular estimation. He always cites it in his Magazine with peculiar pleasure and respect, giving many a specimen of the old writer's amusing quaintness, whilst he enriches us with his information.

In 1640 our author published his principal work, the "Theatr um Botanicum, or Theatre of Plants, or an Herbal of large extent; &c." This is a ponderous folio of 1746 pages, with innumerous wooden cuts. This work and the Herbal of Gerard were the two main pillars of Botany in England till the time of Ray, who indeed gave them fresh importance by his continual reference to their contents. These volumes were dispersed throughout the country, one or other, or both, being the inexhaustible resource of all who had any love for plants, or any interest in enquiring into their qualities. The benevolent country divine, the lady of the manor, the village doctor, and the humble herb gatherer employed in the service of all the rest, consulted Gerard or Parkinson, as they would have consulted their bibles, and with little less importance, which were indeed two authors. It is truly observed that Parkinson was by far the most original and the most copious, but his cuts being of very inferior merit to those admirable ones, prepared for Conrad Gesner, with which Gerard had the means of adorning his publication, the latter has greatly prevailed in popularity, as a book of reference. It is indeed chiefly for the figures that we now cite these works. Nice distinctions of species, or any discrimination between species and varieties, are not to be expected; still less, any ideas of classification or scientific arrangement, worthy a moment's consideration or comparison. Parkinson is much more original than Gerard in his descriptions, and more particular in his indications of the places of growth; he is also very learned and critical in his synonymy, and, above all, in the medical part of his subject. Gerard, though intelligent and industrious, was fundamentally a compiler, without always taking the pains to accommodate his text to the country in which he published, as we have already sufficiently noted; see Gerard. It is not to be wondered at if these great works contain some hundreds of repetitions, when we consider the obscurely many plants had been described, or even figured, by previous authors; infomuch that it was, in many cases, next to impossible to discover whether a given plant had been described before. Parkinson however is entitled to superior praise on this head, having taken all possible pains to avoid such mistakes, by his deep study of synonymy. Some papers of Lobel are laid to have fallen into the hands of Parkinson, after the death of the former, which proved of use to his undertaking, but it does not appear that he implicitly confided in such, any more than in previously printed authorities, without a due investigation, and therefore they became in some measure his own.

The time of Parkinson's decease is not known, but he appears to have been living when his Herbal was published, in 1639, at which period he was, if Dr. Pulteney's date of his birth be correct, 73 years old. Nothing is recorded of his family. Some copies of his Paraphrase have an engraved portrait of the author, done in his 62d year, and there is a small oval one in the title-page of his Herbar, or Theatr um Botanicum. Pulteney's Sketch of the progress of Botany in England is Haller Bibl. Bot. Parkinson's Works. S.

Gen. Ch. Cal. Perianth inferior, of one leaf; its base bell-shaped, shallow, persistent; border in five deep, ovate, acute, coloured, spreading, nearly equal, deciduous figures. Car. Petals five, with claws, widely spreading, varying, nearly equal; four of them ovate; the lowermost kidney-shaped, with a longer claw. Stam. Filaments ten, awl-shaped, rather declining, shorter than the corolla, villous in their lower part; anthers oblong, incumbent. Fls. Ger- man superior, long, cylindrical, declining; style thread-shaped, curved upwards, the length of the flaments; stigma oblong. Peric. Legume very long, roundish, with numerous headlike swellings, pointed. Seeds several, in each one tumid part of the legume, obvate, roundish, obtuse.

Eff. Ch. Calyx five-cleft; its segments deciduous. Petals four of them ovate; the fifth kidney-shaped. Style awl-shaped. Legume beaded, with many roundish seeds.

1. P. aculeata. Prickly Parkinsonia. Linn. Sp. Pl. 536. Hort. Clif. 157. t. 13. Jacq. Amer. 121. t. 80. Walt. Hort. 36. t. 13. — Native of South America and the West Indies. Miller appears to have cultivated this plant in 1739, and it is often to be seen in floves, but we never heard of its flowering in England. Jacquin describes it as a very elegant tree, about twelve feet high, with a green shining bark, turning brown and frizzled on the trunks of older individuals only. Wood white. Prickles solitary, awl-shaped, somewhat recurved, under the infection of each leaf, about four lines long; on the older branches they are often three together, which case the midrib of the leaf becomes much larger and stronger. Leaves alternate, with an equal tuft of three, four, or five beides, pinnate, shining; the midrib about a foot long, flattened and linear; leaflets extremely numerous, minute, obvate, entire. Clusters axillary and terminal. lax, simple, smooth, each consisting of about ten sweet-smelling yellow flowers, about an inch or rather more in diameter, their kidney-shaped petal besprinkled with scarlet dots at the base. Leaves yellowish. Seeds variable in number, tumid, polished.

Jacquin says this shrub grows very quickly, flowering the first year after it is sown, and combining with the Poinciana, or Barbadoes Flower- fence, to make the most beautiful of all hedges. Dr. Swartz has it not in his Prodrumus or Flora, so that it seems not to be a general West Indian plant.

PARKINSONIA, in Gardening, contains a plant of the exotic flowering tree kind, of which the species is the prickly Parkinsonia (P. aculeata). In Jamaica it is called the Jerusalem thorn. These trees perfume the air to a considerable distance; for which reason the inhabitants of the West Indies plant them about their houses.

Method of Culture. — It is capable of being increased here by sowing the seeds in pots filled with light rich mould, early in the spring season, plunging them in a hot-bed. When the plants have attained a few inches in growth, they should be carefully removed into other small pots, separately re-plunging them into the hot-bed, shading them till fresh rooted, when fresh air should be admitted according to the warmth of the seafon. The only method by which these plants have been kept with success through the winter, in this climate, has been by hardening them in July and August to bear the open air; and in September placing them on shelves in the dry stove, at the greatest distance from the fire, so that they may be in a very temperate state of warmth.

These plants afford ornament among other potted plants of the stove kind.
PAR

PARKON, in Geography, a town of Austrian Poland, in Galicia; 30 miles N.N.W. of Chelm.

PARKSTÈIN, a town of Bavaria, in the principality of Sulzbach; 17 miles N.E. of Sulzbach.

PARLAGOW, a town of Hindoostan, in Candeih; five miles E. of Barawany.

PARLASCA, a town of Italy, in the department of the Lario; five miles N. of Como.

PARLEY, formed of the French parler, to speak, talk, a conference with an enemy, &c.

Hence to beat or found a parley, is to give a signal for the holding such a conference, by beat of drum, or found of trumpet. See CHAMADE.

PARLIAMENT, Parlamentum, in England, a grand assembly, or convention, of the three elates of the kingdom, viz. lords spiritual, lords temporal, and commons, summoned to meet the king, to consult of matters relating to the commonweal; and particularly to enact, and repeal, laws.

The word parliament, parlement, or colloquium, as some of our historians translate it, is comparatively of modern date, derived from the French, and signifying the place where they met and conferred together. It was first applied to general assemblies of the state under Louis VII. of France, about the middle of the twelfth century. The first mention of it in our statute law is in the preamble to the statute of Welf. 3 Edw. I. A.D. 1272. But long before the introduction of the Norman language into England, all matters of importance were debated and settled in the great councils of the realm; a practice which seems to have been universal among the northern nations, particularly the Germans; and carried by them into all the countries of Europe, which they overran at the dissolution of the Roman empire.

The two houses of parliament are the king's grand council.

Till the conquest, the great council, consisting only of the great men of the kingdom, was called magnatum conventus, and prelatorum procuramque concilium, aoffis generalis, and sometimes communis regni Anglia. The Saxons, in their own tongue, called it wittenagemote, i.e. assembly of the wise; and it hath subsisted immemorially under these appellations and others, as michel-synnoth, or great council; and michel-gemote, or great meeting.

We have instances of its assembling to order the affairs of the kingdom, to make new laws, and to amend the old, so early as the reign of Ina, king of the West Saxons, Offa, king of the Mercians, and Ethelbert, king of Kent, in the several realms of the heptarchy. And after their union, the Mirror informs us, that king Alfred ordained for a perpetual usage, that these councils should meet twice in the year, or oftener, if need be, to treat of the government of God's people: how they should keep themselves from sin, live in quiet, and receive right. Our succeeding Saxons and Danes imitated this, and held frequent councils of this sort, as appears from their respective codes of laws; the titles of which speak them to be enacted either by the king, with the advice of his wittenagemote or wise men, or by those fages with the advice of the king, or by them both together. These great councils were also, without doubt, held regularly under the first princes of the Norman line. Gnanvil, who wrote in the reign of Henry II. speaking of the particular amount of an amercement in the sheriff's court, says, it had never yet been ascertained by the general affize, or assembly, but was left to the custom of particular countries. In Edward III.'s time, an act of parliament, made in the reign of William the Conqueror, was pleaded in the chancery of the abbey of St. Edmund's-bury, and judicially allowed by the court. Hence it appears, that parliaments or general councils are coeval with the kingdom itself. Though the high antiquity of parliaments in this kingdom must be universally allowed, it does not so clearly appear how they were composed; and particularly whether the commons were summoned at all, or, if summoned, at what period they began to form a distinct assembly. Nevertheless it is generally agreed, that in the main the constitution of parliament, as it now stands, was marked out before long as at the eleventh year of king John, A.D. 1215, in the great charter granted by that prince, in which he promises to summon all archbishops, bishops, abbots, and the greater barons, all the faithful, and all other tenants in chief under the crown, by the sheriff and bailiffs; to meet at a certain place, with forty days' notice, to afeids aids and scutages when necessary. And this constitution has subsisted in fact at least from the year 1266 (49 Hen. III.), there being still extant writs of that date, to summon knights, citizens, and burgesses to parliament.

Sir Walter Raleigh, in his Prerogative of Parliament, thinks the commons were first called in the eleventh year of Hen. I. and Dr. Heylin fixes the time of their first admission to the reign of Henry II.

Indeed, sir Edward Coke, Dodderidge, Prynn, and others, have shown, that the commons of England had always a share in the legislature, and a place in the great assemblies; though not on the present footing, as making a distinct house, and as composed of knights, citizens, and burgesses.

Parliaments are to be summoned, prorogued, and dissolved by the king alone: nor can a parliament begin without the king's presence, or that of his commissioners.

At first, great parliaments were called every year; by degrees their term grew longer. In the time of king Charles II. they were held a long time with great interruptions between them. Both which methods were found of such ill consequences, that in the beginning of the reign of king William an act was passed, whereby the term of all parliaments was restrained to three sessions, or three years; this was hence called the Triennial act. Since that, from other views, the period of parliaments is lengthened to seven years.

A parliament is called by the king's writ, or letter directed to each lord, commanding him to appear; and by other writs directed to the sheriffs of each county, to summon the people to elect two knights for each county, and one or two burgesses for each borough, &c.

This writ is issued out of chancery by advice of the privy council, at least forty days before it begins to sit. This right of summons is a branch of the royal prerogative; so that no parliament can be convened by its own authority, or by the authority of any, except the king alone. Nor is it an exception to this rule, that, by some modern statutes, on the demise of a king or queen, if there be then no parliament in being, the last parliament revives, and is to sit again for six months, unless dissolved by the successor; for this revived parliament must have been originally summoned by the crown. Indeed, by statute 16 Car. 1. c. 1. it was enacted, that if the king neglected to call a parliament for three years, the peers might assemble and issue out writs for choosing one; and, in case of neglect of the peers, the constituents might meet and elect one themselves. This act, however, was deemed injurious to the royal prerogative, and repealed by statute 16 Car. II. c. 1.

There are, it must be acknowledged, two capital exceptions to this rule, which were justifiable on a principle of necessity, that superseded all law. The convention parliament, that reared king Charles II. met above a month before his return; the lords by their own authority, and the commons in
PARLIAMENT.

in pursuance of writs issued in the name of the keepers of the liberty of England by the authority of parliament; and this parliament sat full seven months after the restoration, and enacted many laws still in force. But the first thing done after the king's return, was to pass an act declaring this to be a good parliament, notwithstanding the defects of the king's writs. And it was thought further necessary to confirm its acts in the next parliament, by 13 Car. II. cap. 7 and cap. 14. The other exception occurs at the time of the revolution, A. D. 1688, when the lords and commons by their own authority, and upon the summons of the prince of Orange (afterwards king William), met in a convention, and disfranchised the crown and kingdom. The throne at this time was vacant by the abdication of king James II. and it was declared by W. & M. flat. 1. cap. 1, that this convention was really the two houses of parliament, notwithstanding the want of writs, and other defects of form.

As the king only can convene a parliament, he is bound to do this every year, or oftener, if need be. And by 16 Car. II. cap. 1. it is enacted, that the sitting and holding of parliaments shall not be intermitted above three years at the most; by 8 W. & M. flat. 2. cap. 2. it is declared to be one of the rights of the people, that for redress of all grievances, and for the amending, strengthening, and preserving the laws, parliaments ought to be held frequently; and this indefinite frequency is reduced to a certainty by 6 W. & M. cap. 2 which enacted, that a new parliament shall be called within three years, after the determination of the former.

As to the constituent parts of a parliament, these are the king, who sits there in his royal political capacity, and the three estates of the realm; the lords spiritual, the lords temporal, who sit together with the king in one house; and the commons, who sit by themselves in another. And the king, and these three estates together, form the great corporation or body politic of the kingdom, (4 Obt. 1. 2. flat. 1. Eliz. c. 3. Hale of Parl. 1.) of which the king is said to be caput, princeps, and finis. (See King.) For upon their coming together the king meets them, either in person, or by representation, without which there can be no beginning of a parliament; and he also alone has the power of dissolving them. 4 Obt. 6.

The spiritual lords consist of two archbishops and twenty-four bishops, who are supposed to hold certain ancient baronies under the king, in right of which they obtain their seats in the house of lords; where they intervene in their votes with the temporal lords, so that in every effectual senate they form one estate. (See Archbishop and Bishop.) The lords temporal consist of all the peers of the realm, as dukes, marquises, earls, viscounts, and barons. Some of these sit by decsent, as do all ancient peers; some by creation, as do all new made ones; others, since the union with Scotland, by election, which is the case of the sixteen peers, who represent the body of the Scotch nobility: and twenty-eight peers for Ireland, besides one archbishop and three bishops. Their number is indefinite, and may be increased at will by the power of the crown. (See Peer.)

The commons consist of all such men of any property in the kingdom as have not seats in the house of lords; every one of whom has a voice in parliament, either personally, or by his representative. (See Commons.)

The number of English representatives is five hundred and thirteen (sixty-nine-two knights of the shire, fifty-six cities, thirty-four counties, and sixty-four boroughs), two each; five for five boroughs, one each; and twelve for twelve boroughs in Wales, Pembroke and Merioneth; four for the two universities, and sixteen for the eight counties); of Scots forty-five, and of Irish one hundred; so that the representatives of the united kingdom amount to 658. The consent of all these three parts is required to make any new law that shall bind the subject. Whatever is enacted for law by one, or by two only, of the three, is no statute, and no regard is due to it, except in matters relating to their own privileges. It is particularly enacted by statute 13 Car. II. c. 1. that if any person shall maliciously or advisedly afirm, that both, or either of the houses of parliament have any legislative authority without the king, such person shall incur all the penalties of a "præmunire." (See Præmunire.)

The jurisdiction of parliament thus composed and considered as an aggregate body, is to transcend, says sir Edward Coke (4 Obt. 35.), that it makes, enforces, enlarges, redeems, abrogates, repeals, revives, and expounds laws and statutes, concerning matters ecclesiastical, civil, criminal, maritime, &c. And for making of laws, and in proceeding by bill, this supreme court is not confined either for cauæs or persons within any bounds; nor is it tied down to any certain rules or forms of law, in proceedings and determinations: the court of parliament hath power to judge in matters of law; and redresses mischiefs and grievances that happen, especially such as have no ordinary remedy; to examine into the corruption of judges and magistrates, and illegal proceedings of other courts; to redress errors, and determine on petitions and appeals, &c. and from this high court there lies no appeal.

It can regulate or new model the succession to the crown; as in the reign of Henry VIII. and William III. It can alter the established religion of the land, as was done in the reigns of kings Henry VIII. and his three children. It can change and create any even the constitution of the kingdom, and even of parliaments themselves, as was done by the act of union, and the several statutes for triennial and septennial elections. And, therefore, some have not scrupled to call its power, by too bold a figure, the omnipotence of parliament. It is therefore, as judge Blackstone observes, a matter most essential to the liberties of the kingdom, that such members be delegated to this important trust, as are most eminent for their probity, their fortitude, and their knowledge; for it was a known apothegm of the great lord treasurer Burleigh, "that England could never be ruined but by a parliament;" and as Sir Matthew Hale observes, this being the highest and greatest court, over which none other can have jurisdiction in this kingdom, if by any means a misgovernment should any way fall upon it, the subject of this kingdom are left without all manner of remedy. To the same purpose the president Montefiquieu (we trust too hastily,) prefages; that as Rome, Sparts, and Carthage, have lost their liberty and perished, fo the constitution of England will in time lose its liberty and peril; it will perish, whenever the legislative power shall become more corrupt than the executive.

Affairs of parliament are to be determined by parliament; and though the parliament err, it is not reversible in any other court; and not only what is done in the house of commons, but what relates to the commons during the parliament, and sitting of the parliament, is no where else to be punished but by themselves, or a succeeding parliament. Every court of justice having laws and usages for its direction, the highest court of parliament hath its own proper laws and usages, called the laws and customs of parliament; inasmuch that no judges ought to give any opinion of matters done in parliament, because they are not to be decided by the
the common law: but the parliament, in their judicial capacity, are governed by the common and statute laws, as well as the courts in Westminster-hall.

The lords and commons in their respective houses have power of judicature, and so have both houses together: and in former times, both lords and commons sat together in one house of parliament. The king cannot take notice of any thing laid to be done in the house of commons but by the report of the house; and every member of the house of parliament has a judicial place, and can be no witnesses.

The house of lords is a distinct court of judicature from the commons, to several purposes; they try criminal causes or impeachments of the commons, and have an original jurisdiction for the trial of peers upon indictments found by a grand jury: they also try causes upon appeals from the court of chancery, or upon writs of error to reverse judgments in the king's bench, &c. Also the house of commons is a distinct court to many purposes; they examine the right of elections, expel their own members, and commit them to prison, and sometimes other persons, &c. And the book of the clerk of the house of commons is a record.

In order to prevent the mischief that might arise from reposing such extensive authority with incompetent persons, it is provided by the custom and law of parliament, that no one shall sit or vote in either house, unless he be twenty-one years of age, (7 & 8 W. III. cap. 25.) No member shall sit or vote in either house, till he hath, in the presence of the house, taken the oaths of allegiance, supremacy, and abjuration, and subscribed and repeated the declaration against transubstantiation, and invocation of saints, and the sacrifice of the mass. (30 Car. II. flat. 2. 1 Geo. I. c. 13.) No alien, even though he be naturalized, shall be capable of being a member of either house of parliament. (12 & 13 W. III. c. 2.) As to the qualifications of members of the house of commons, besides the above qualifications, it is declared and required by the law of parliament or special statutes, that they must not be any of the twelve judges, because they fit in the lords house, nor of the clergy, because they sit in convocation, nor persons attainted of treason or felony, because they are unfit to sit in any place: that sheriffs of counties, and mayors, and bailiffs of boroughs, are not eligible in their respective jurisdictions, as being returning officers: that no persons concerned in the management of any duties or taxes created since 1692, except the commissioners of the treasury, nor any of the officers following, viz. commissioners of prizes, transports, fick and wounded, wine licences, navy and victualling; secretaries or receivers of prizes, comptrollers of the army accounts, agents for regiments, governors of plantations and their deputies, officers of Minorca or Gibraltar, officers of the exchequer and customs, clerks or deputies in the several offices of the treasury, exchequer, navy, victualling, admiralty, pay of the army or navy, secretaries of state, falt, flamps, appeals, wine licences, hackney-coaches, hawkers, and pedlars; nor any persons that hold any new office under the crown, created since 1705, are capable of being elected members: that no person having a pension under the crown during pleasure, or for any term of years, is capable of being elected: that if any member accepts an office under the crown, except an officer in the army or navy accepting a new commission, he vacates his seat, but is capable of being re-elected: and moreover, per sons in particular circumstances have forfeited the right of choice, and have been declared ineligible for that reason by a vote of the house of commons, or for ever, by an act of the legislature. By 22 Geo. III. c. 45, contractors are ineligible. It has been also required, in strictness, that all members should be inhabitants of the places for which they are chosen, but this is altogether disregarded and repealed by 14 Geo. III. c. 53. For other qualifications, and for the qualifications of electors, see BURGESS AND KNIGHTS OF THE SHIRE.

As for the method of proceeding in elections, when the parliament is summoned, the lord chancellor (or if a vacancy happens during parliament, the speaker, by order of the house) sends his warrant to the clerk of the crown in chancery; who useth out writs to the sheriff of every county, for the election of all the members to serve in that county, and every city and borough in it. Within three days after the receipt of this writ, the sheriff is to send his precept, under his seal, to the proper returning officers of the cities and boroughs, commanding them to elect their members: and the said returning officers are to proceed to election within eight days from the receipt of the precept, giving four days notice of the same and to return the persons chosen, together with the precept, to the sheriff. But elections of knights of the shire must be proceeded to by the sheriffs themselves in person, at the next county court, that shall happen after the delivery of the writ. If this court falls upon the day of delivering the writ, or within six days after the sheriff may adjourn the court and election to some other time, not longer than sixteen days, nor shorter than ten; but he cannot alter the usual place without consent of the candidates: and in all such cases, ten days public notice must be given of the time and place of election. In order to prevent all undue influence, as soon as the time and place of election, in counties or boroughs, are fixed, all soldiers quartered in the place are to remove at least one day before the election, to the distance of two miles or more; and not to return till one day after the poll is ended. By vote of the house of commons, no lord of parliament, or lord lieutenant of a county, hath any right to interfere in the election of commoners; and by statute, the lord warden of the cinque ports shall not recommend any members there. If any officer of the excise, customs, flamps, or other branches of the revenue prelimes to meddle in elections, by pernading or disuading any voter, he forfeits 100l. and is disabled to hold any office.

For the provisions against bribery, see BRIBERY.

On the day of election, the returning officer first takes an oath against bribery, and for the due execution of his office; the candidates, also, if required, must swear to their qualifications; and the electors, both in counties and boroughs, are compelled to take the oath of abjuration, and that against bribery and corruption. When the election is closed, the returning officer in boroughs returns his precept to the sheriff with the persons elected by the majority: and the sheriff returns the whole, together with the writ for the county, and the knights elected, to the clerk of the crown in chancery, before the day of meeting, if it be a new parliament; or within fourteen days after the election, if it be an occasional vacancy; under penalty of 500l. If the sheriff does not return such knights only as are duly elected, he forfeits, by the old statutes of Henry VI. 100l.; and the returning officer in boroughs, for a like false return, 40l.; and they are besides liable to an action, in which double damages shall be recovered, by the later statutes of King William; and any person bribing the returning officer shall also forfeit 500l. But the members returned by him are the sitting members, until the house of commons, upon petition, shall adjudge the return to be false and illegal.

The privileges of parliament are very large and indefinite: the chief of these are privilege of speech, of person, of their domiciles, and of their lands and goods. Privilege of speech is declared to be one of the liberties of the people, and
PARLIAMENT.

and it is declared by statute 1 W. & M. 2. & 3. Ann. c. 18. that the freedom of speech and debates, and proceedings in parliament, ought not to be impeached or questioned, in any court or place out of parliament. And this freedom of speech is particularly demanded of the king in person, by the speaker of the house of commons, at the opening of every new parliament. So likewise are the other privileges, which are immunities as ancient as Edward the Confessor, and the old Gothic constitution. To assault by violence a member of either house, or his menial servants, is a high contempt of parliament, and there punished with the utmost severity; and there are also penalties annexed to it in the courts of law, by the statutes 5 Hen. IV. cap. 6. and 11 Hen. VI. cap. 11. Neither can any member of either house be arrested and taken into custody, unless for some indictable offence, without a breach of the privilege of parliament. But all other privileges, which derogate from the common law, in matters of civil right, are now at an end, save only as to the freedom of the member’s person; which in a peer (by the privilege of peerage) is always inviolable, and in a commoner for forty days after every prorogation, and forty days before the next meeting; and this is commonly as long as the parliament sitteth, it seldom being prorogued for more than four more days at a time.

As to all other privileges, which obstruct the ordinary course of justice, they were restrained by the statutes 12 W. III. 2. & 3. Ann. c. 18. and 1 Geo. II. c. 24. and are now totally abolished by the statute 10 Geo. III. c. 50, which enacts, that any suit may at any time be brought against any peer or member of parliament, their servants, or any other person entitled to privilege of parliament, which shall not be impeached or delayed by pretence of any such privilege; except that the person of a member of the house of commons shall not thereby be subjected to any arrest or imprisonment. Likewise, for the benefit of commerce, it is provided by statute 4 Geo. III. c. 33, that any trader, having privilege of parliament, may be heard with legal process for any just debt to the amount of 100l.; and unless he makes satisfaction within two months, it shall be deemed an act of bankruptcy; so that comminutions of bankruptcy may be inflicted against such privileged traders, in like manner as against any other. See farther, on this subject, under the article Commons.

As to the special privileges and claims of peers, we may observe, that, by the charter of the forest, confirmed in parliament 9 Hen. III. every lord, spiritual or temporal, summoned to parliament, and passing through the king’s forests, may, both in going and returning, kill one or two of the king’s deer without warrant. They have also a right to be attended by the judges of the court of king’s bench and common pleas, and such of the barons of the exchequer as are of the degree of the coif, or have been made serjeants at law, and likewise by the masters of the court of chancery, for their advice in point of law, &c. The secretaries of state, the attorney and solicitor-general, and the reas of the king’s learned counsel, being serjeants, were also used to attend the house of peers, and have, to this day, their regular warrants of summons issued out at the beginning of every parliament: but as many of them have of late years been members of the house of commons, their attendance here is fallen into disuse. Every peer, by licence obtained from the king, may make another lord of parliament his proxy, to vote for him in his absence; which no member of the house of commons can do, because he is himself but a proxy for a multitude of other people. Each peer has also a right, by leave of the house, when a vote palles contrary to his sentiments, to enter his differ on the journals of the house, with the reasons for such differ, which is usually styled his protest. All bills, likewise, that may in their conseqvences affect the rights of the peerage, are by custom of parliament to have their commencement in the house of peers, and to suffer no amendments or changes in the house of commons. Moreover, the statute 6 Ann. cap. 23. which regulates the election of the fifteen representative peers of North Britain, peculiarly relates to the house of lords.

The special privilege and right of the house of commons comprehend all grants of subsidies or parliamentary aids, which begin with them, and are first belowed in their house. See Money Bills.

The place where the parliament meets is wherever the king pleases; of late it has been in the palace of Westminster, the lords and commons each in a distinct apartment. In the lords house the princes of the blood are placed in distinct seats; the great officers of state, dukes, marqueses, and bishops, on benches, and the viscountes and barons on others across the house; all according to their order of creation, place, &c.

The commons sit promiscuously, forty members constituting a house; only the speaker has a chair at the upper end; and the clerk and his affairant at a table near him. See Speaker.

As to the Manner of debating and passing Bills in Parliament.—To bring a bill into the house, if relief sought by it is of a private nature, it is first necessary to prefer a petition; which must be presented by a member, and usually sets forth the grievance defird to be remedied. This petition, (when founded on facts that may be in their nature disputed) is referred to a committee of members, who examine the matter alleged, and accordingly report it to the house; and then (or otherwise upon the mere petition) leave is given to bring in the bill. In private matters the bill is brought in upon motion made to the house, without any petition at all. Formerly all bills were drawn in the form of petitions, which were entered upon the Parliament Rolls, with the king’s answer thereunto subjoined; not in any settled form of words, but as the circumstances of the case required: and at the end of each parliament the judges drew them into the form of a statute, which was entered on the Statute Rolls. In the reign of Henry V., to prevent mistakes and abuses, the statutes were drawn up by the judges before the end of the parliament; and, in the reign of Henry VI., bills in the form of acts, according to the modern custom, were first introduced.

The persons directed to bring in the bill, present it in a competent time to the house, drawn out on paper, with a multitude of blanks, or void spaces, where any thing occurs that is dubious, or necessary to be settled by the parliament itself (such, especially, as the precise date of times, the nature and quantity of penalties, or of any sums of money to be raised); being indeed only the skeleton of the bill. In the house of lords, if the bill begins there, it is (when of a private nature) referred to two of the judges, to examine and report the state of the facts alleged, to see that all necery parties consent, and to settle all points of technical propriety. This is read a first time, and at a convenient distance a second time; and after each reading the speaker opposes to the house the substance of the bill, and puts the question, whether it shall proceed any farther.

The introduction of the bill may be originally opposed, as the bill itself may at either of the readings; and, if the opposition succeeds, the bill must be dropped for that session; as it must also, if opposed with success in any of the subequent stages.

After the second reading it is committed, that is, referred
to a committee; which is either selected by the house in matters of small importance, or else, upon a bill of consequence, the house resolves itself into a committee of the whole house. A committee of the whole house is composed of every member; and, to form it, the speaker quits the chair (another member being appointed chairman), and may sit and debate as a private member. In these committees the bill is debated clause by clause, amendments made, the blanks filled up, and sometimes the bill entirely new modelled. After it has gone through the committee, the chairman reports it to the house with such amendments as the committee have made; and then the house reconsider the whole bill again, and the question is repeatedly put upon every clause and amendment. When the house have agreed or disagreed to the amendments of the committee, and sometimes added new amendments of their own, the bill is then ordered to be engrossed, or written in a strong good hand, in one or more long rolls (or preffes) of parchment sewed together. When this is finisht, it is read a third time, and amendments are sometimes then made to it; and, if a new clause be added, it is done by tacking a separate piece of parchment to the bill, which is called a rider. The speaker then again opens the contents; and, holding it up in his hands, puts the question whether the bill shall pass. If this is agreed to, the tide to it is then fetted; which used to be a general one for all the acts passed in the session, till, in the fifth year of Henry VIII. different titles were introduced for each chapter. After this, one of the members is directed to carry it to the lords, and define their concurrence; who, attended by several more, carries it to the bar of the house of peers, and there delivers it to their speaker, who comes down from his woolfack to receive it.

It there passes through the same forms as in the other house (except engrolling, which is already done), and if rejected, no more notice is taken, but it passes sub silentio, to prevent unbecoming alterations. But, if it is agreed to, the lords send a message, by two maders in chancery, (or sometimes two of the judges,) that they have agreed to the same; and the bill remains with the lords, if they have made no amendment to it. But if any amendments are made, such amendments are sent down with the bill to receive the concurrence of the commons. If the commons disapprove to the amendments; a conference usually follows between members deputed from each house; who for the most part settle and adjout the difference; but, if both houses remain inflexible, the bill is dropped. If the commons agree to the amendments, the bill is sent back to the lords by one of the members, with a message to acquaint them therewith. The same forms are observed, mutatis mutandis, when the bill begins in the house of lords. But, when an act of grace or pardon is passed, it is first signed by his majesty, and then read once only in each of the houses, without any new engrolling or amendment. And when both houses have done with any bill, it always is deposited in the house of peers, to wait the royal assent; except in the case of a money-bill, which, after receiving the concurrence of the lords, is sent back to the house of commons.

The royal assent may be given two ways. 1. In parson; when the king comes to the house of peers, in his crown and royal robes, and sending for the commons to the bar, the titles of all the bills that have passed both houses are read; and the king's answer is declcared by the clerk of the parliament in Norman-French. If the king confents to a public bill, the clerk usually declares, "le roy me veut; the king wills it fo to be!" if to a private bill, "fais faict comme il est defire; be it as it is defir'd." If the king refuses his assent, it is in the gentle language of "le roy t'avisera; the king will advise upon it." When a money-bill, or bill of supply, is passed, it is carried up and presented to the king by the speaker of the house of commons; and the royal assent is thus expressed, "le roy remercie ses loyal sujets, accepte leur benevolence, et auffi le veut; the king thanks his loyal subjects, accepts their benevolence, and wills it so to be."

In case of an act of grace, which originally proceeds from the crown, and has the royal assent in the first stage of it, the clerk of the parliament thus pronounces the gratitude of the subject: "les prelates, sieurs et commons, en ce present parlement assemblees, au nom de tous vos autres sujets, remercient humblement votre majesté, et prient a Dieu vous donner en fante bone vie et longe; the prelates, lords, and commons, in this present parliament assembled, in the name of all your other subjects, most humbly thank your majesty, and pray to God to grant you in health and wealth long to live."

2. By the statute 33 Hen. VIII. cap. 21. the king may give his assent, by letters patent, under his great seal, signed with his hand, and notified, in his absence to both houses, assembled together in the high house. And when the bill has received the royal assent, in either of these ways, it is then, and not before, a statute or act of parliament: a copy of which is usually printed at the king's press, for information of the whole land. See, on this article, Blackit. Com. book i. chap. 2.

Parliament, Adjournment of, is a continuance of the session from one day to another, as the word signifies, which is done by the authority of each house separately, every day, and sometimes for a fortnight or a month together; but the adjournment of one house is no adjournment of the other.

Parliament, Debates of, is the civil death of the parliament, which may be effected either by the king's will, expressed in perfon, or by representation, or by the demise of the crown; in which case it is enacted, by 7 & 8 Will. III. cap. 15. and 6 Anne. cap. 7. that the parliament in being shall continue for six months after the death of any king or queen, unless sooner prorogued or dissolved by the luccedor; and that if, at the time of the king's death, it stands adjourned or prorogued, it shall assemble immediately; and that, if no parliament is then in being, the members of the last parliament shall assemble, and he again a parliament; or, lastly, by length of time, which by 6 W. & M. cap. 2. was three years; but, by 1 Geo. I. cap. 38. is now seven years; so that the parliament must expire or die a natural death at the end of every seventh year.

Parliament, Prorogation of, is the continuance of it from one session to another. This is done by the royal authority, expressed either by the lord chancellor, in his majesty's presence, or by commision from the crown, or frequently by proclamation. Both houses are necessarily prorogued at the same time; it not being a prorogation of the house of lords or commons, but of the parliament. The difference between a prorogation and an adjournment is obvious; the former puts an end to the session, and then such bills as are only begun, and not perfected, must be resumed de novo (if at all) in a subsequent session; whereas, after an adjournment, all things continue in the same frame, and may be proceeded on without any fresh commencement.

Parliament, Rolls of. See Rolls.
Parliament is sometimes also used for other assemblies beside those of the states of the realm. Thus we read, that the abbot of Croyland was used to call parliaments of his monks, to consult of the affairs of the monastery. And, at this day, an assembly of the two temples, called to consult of their common affairs, is called a parliament.
PARLIAMENTS of France, according to the old constitution, were courts, or assemblies, established by the king to judge of the differences between particular persons, and to pronounce on appeals from sentences given by inferior judges.

There were twelve of these parliaments in France; that of Tholune, established in 1302; that of Dijon, in 1476; that of Grenoble, in 1453; that of Rouen, in 1499; that of Nantes, in Bretagne, in 1553; that of Bourdeaux, according to Du-Cange, in 1460; that of Aix, in 1501; that of Metz, in 1633; that of Pau, in Bearne, in 1519; that of Bégaüon, in 1422; that of Doway, in 1668; and that of Paris, about 1254.

The parliament of Paris was the principal, and that whose jurisdicti was of the greatest extent. This was the chief court of justice throughout the realm. It consisted of eight chambers; the grand chamber, where causes of audience were pleaded; the chamber of written law; the chamber of counsel; the Tournelle criminel, for judging criminal affairs; the Tournelle civil, in aid of the grand chamber; and three chambers of inquests, where proceses were adjudged in writing; besides these, there was also the chamber of vacations, and those of requests.

In 1771, the king thought fit to branch the parliament of Paris into six different parliaments, under the denomination of superior courts, each parliament having similar jurisdiction.

Under their second race of kings, this parliament, like that of England, was the king's council; it gave audience to ambassadors, and consulted the affairs of war and government.

The king, like our's, at that time presided in them, without being at all matter of their resolutions. But, in aftertimes, their authority was abridged; the kings having reserved the decision of the grand affairs of the public to their own councils; leaving none but private ones to the parlements.

PARLIAMENT-Heel, in Sea Language, the situation of a ship, when she is made to loop a little to one side, so as to clean the upper part of her bottom on the other side, and to cover it with a new composition; and afterwards to perform the same office on that part of the bottom which was first immersed. See Boot-Topping.

PARLIAMENTARIAN is a term used to denote those, who, in the time of the civil war, were attached to the parliament, in opposition to the royalists, devoted to the king.

PARLIAMENTUM Indoctorum, a denomination given to a parliament, held at Coventry, 6 Henry VI. whereunto, by special precept to the sheriffs of the several counties, no lawyer, or person skilled in the law, was to be called.

PARLIAMENTUM Infaenum, was a parliament held at Oxford, anno 41 Henry III. thus called, says our chronicles, because the lords came with great retinues of armed men to it; and many things were violently transacted therein against the king's prerogative.

PARLIAMENTUM Diabolicum, was a parliament held at Coventry, 38 Henry VI. wherein Edward, earl of March (afterwards king,) and several others, were attainted. The acts passed herein were annulled by the succeeding parliament.

PARLIAMENTUM de la Bande, was a parliament in Edward I. 's time, whereunto the barons came armed against the two Spencers, with coloured bands on their sleeves, for distinction.

PARLIE, in Geography, a town of Hindooftan, in Guzerat; six miles S. of Pernalla.

PARLOUR. Parlour, from the French parler, to talk, in nunneries, a little room or closet, where people talk, the nuns, through a kind of grated window.

Anciently there were also parlours in the convents of monks, where the novices used to converse together at the hours of recreation; but there were listening-places over, from whence the superiors could hear every thing they said. Such a one there still subsists in the abbey St. German de Prez.

In the order of Feuillans, the parlour is a little room open on all sides, placed at each end of the dormitory, where the monks talk together, it not being allowed them to speak in the dormitory.

PARMA, among Antiquaries, a kind of ancient buckler. Polybius describes the parma as very strong, round, three feet in diameter, and big enough to cover the whole body; yet Servius on the Æneid, and even Virgil himself, mention it as a light piece of armour, in comparison of the clypeus, though bigger than the pelta.

PARMA, or "The Parmesan," in Geography, a duchy of Italy, to which are united the territories of Placentia or Piemio, and Guazzalla; which see respectively. This country is bounded on the N. by the river Po, separating it from the Cremonese and the Lodefan, on the E. by the duchy of Modena, on the S. by Tuscany and Genoa, and on the W. by Genoa and the Pave; about 40 miles from N. to S., and from 30 to 48 from E. to W. These conjoined territories were contested by the Lombards, and by the exarchs of Ravenna; and after many revolutions, became subject to the papal see; from the dominion of which they were transferred by pope Paul III. in the year 1545, to his natural son Pietro Aloyfius, or Farnefe, from whom that family sprung. This family becoming extinct in 1771, the dukedoms of Parma and Placentia, after some contt, were finally aligned to the Bourbon family in Spain. By the treaty of Luneville in 1801, the dukedoms of Parma was nominated by the emperor and the French republic, to the throne of Tuscany, with the title of king of Etruria, of which he soon after took possession. The population of these dukedoms is computed at 350,000, and the revenue at 375,000l. Parma and Placentia have each of them an university. The soil of these territories is a rich sandy or gravelly loam, producing corn, olives, chefsants, and various kinds of fruit. The pastures are excellent, and the cheese, called "Parmesan," has been long held in high estimation. The farms are small, and agriculture has been ill conducted, irrigation being little practised. The sheep are bad, yielding a wool like hair. The Bourbon family very much neglected the improvement of the country.

PARMA, the capital of the above dukedoms, is divided by the river of the same name, which rives in the south part of the duky, and runs into the Po near Viadana, into three parts, that communicate with each other by two bridges. This city was founded by the Etrurians, taken by a tribe of Gauls, called the Boi, and, at length, colonized by the Romans. It is said to have suffered much from the licentious cruelty of Antony; and its sufferings on this occasion are pathetically deplored and immortalized by Cicero, in his 14th Philippic, the last tribute which he paid to Rome and to liberty. During the disarts period that occurred between the reigns of Theodosius and Charlemagne, it was taken and retaken by the Goths and Romans, the Lombards and Greek exarchs, till it was given by Charlemagne to the holy see; and after a succession of ages and changes, it was at length bequeathed by Paul III. on his son, Ottavio Farnefe.
Farnese. In this family it remained till its extinction, in the middle of the last century, when it passed to a prince of Spain; and on the death of the last duke, was taken possession of by the French, and is now pinning away under the influence of their domination. The city is large, populous, airy and clean, though it cannot boast of any very striking or regular building. It is surrounded by walls, flanked with bastions, and a ditch filled with water. On the fourth is the citadel, which is a regular pentagon, and reckoned the belt in Italy. The roads that lead to Parma are in a line, and the streets are straight and broad, formed by well-built and painted houses, and meet in the centre, constituting a handsome square. The new palace was erected on the ruins of the old, and forms an irregular and huge mass of building. The theatre is represented as one of the most beautiful in Italy, and is said to contain upwards of 12,000 spectators, who, by the structure of the place, are capable of hearing the actor on the stage, without any elevation of voice. Here is also a smaller theatre, for the accommodation of the inhabitants. This city is the see of a bishop, suffragan of Bologna. Its university was founded in 1599, and its academy of sciences was instituted in 1601. It has five collegiate and 50 parish churches, besides the cathedral, many of which contain pictures by Correggio, and other eminent masters, and 40 convents. The cathedral is Saxon, but lined in the interior with Roman architecture; its dome is much admired, on account of Correggio’s paintings. The baptistery is an octagon, in the same style with the cathedral, cased with marble, and ornamented with various arches and galleries. The Steccata is the most regular church in Parma, in the form of a Greek cross. The church of the Capuchins is only remarkable for being the burial-place of the celebrated Alexander Farnese. The arts and sciences have by no means been neglected in Parma. An university, two academies, schools of painting, &c. announce the application; and a long catalogue of great names might be produced, to prove the success of the Parma in every literary pursuit. The dukes have for many years affirmed the character of Mecenas, and, by their judicious encouragement, attracted men of talents, from other countries, to their territories. The public walks on the ramparts are very pleasing. The country round is well wooded, and the town and territory of Parma, on the whole, seems to have been in a flourishing state till the entrance of the French army. Since that fatal period, its prosperity has been on the decline, its government unsettled, and its inhabitants impoverished and discontented. The contributions raised by the French amounted to five millions of French livres; a sum enormous for so small a territory, and equalling two years of its regular income. The chief trade of the place consists in stockings, and some other articles of silk manufacture. The printing press, established by Bodoni in 1765, has been distinguished for beautiful publications. The number of its inhabitants is not accurately ascertained; some reckoning them at 45,000, and others at 37,000; 32 miles S.W. of Mantua. N. lat. 44° 47’. E. long. 27° 52’.

Ach. Acharius’s proper name was Levetius, and he was the author of the name and of the genus, tells us, from a species of Lichenes. (See that article, sect. 3. n. 16.) The learned writer, whose distribution of this tribe we have explained in that place, has judged it best to exclude the name of Lichen, as a generic appellation retaining it for the whole natural order, which is perhaps the most commodious plan; otherwise, it should have remained with the genus before us, as being the most extensive in species, and the most comprehensive in character, of the whole. It is indeed so miscellaneous in habit, that we cannot but feel favourably disposed to any attempt at dividing it; and yet we can hardly accede to the very great multiplication of genera in Acharius’s most recent work, the Lichenographia universalis; a book indeed so very scarce in this kingdom at present, that we have not been able to acquire or to study it. Collema however is so naturally distinct in habit and appearance, that no doubt can remain of the propriety of its separation. (See its character in the place above cited.) That of Parmelia, see Ach. Meth. 155; should therefore stand as follows.

Shields orbicular, horizontal, superficial, somewhat elevated, with a cartilaginous accedent border. The dis is sometimes concave, often nearly flat, or indeed convex and hemispherical when far advanced in age, of a different fulbance and colour from the border, and without any border, or separate edge, of its own substance, in which last respect it differs from the Acharian genus Leucidea. The texture of the dis is tolerably firm, though occupied with innumerable vertical parallel cells, each containing about eight minute fece, placed one above the other. Its external colour is different in different species, most generally brown or reddish, but always totally unlike that of the border; internally it is paler. By age the dis in many species becomes loosened, falling out, and leaving its border in the shape of a small cup, or rather faucer, as may be seen in P. confervus, Ach. Meth. 205. In P. jubifera, 167, see Engl. Bot. L. 2109. a very extraordinary prolixous appearance is occasionally seen in the dis. The writer of this has fixed its well in jubifera especially, when impregnation fails, the dis does not acquire its proper colour.

The border is of the same colour and substance with the frond, from which it proceeds, being elevated more or less above the level of that part, and very generally, at least in the more leafy species, attached merely by a central stalk, though its circumference is flat, and clapped, often very closely, to the surface. In the crustaceous kinds the union of the parts is more considerable; in the more filamentous or branched ones it is merely central, by an elongated and obvious stalk. The extreme part of the border is more or less tumid and thick, either smooth or powdery, entire or crenate, rarely fringed or leafy, while the very edge itself is inflexed and even.

The frond is various and of many different shapes and appearances. When crustaceous, leprous, or tartaceous, it is either uniform, and limited by a well-marked border, usually blackish; or it is loosely dispersed, without any distinct limitation, frequently in small portions or patches, and then, in many instances, finally disappears by age, leaving the bare and scattered shields, as if growing independently out of the stone or bark. In other cases the frond consists of lobed fragments, assuming a leafy imbricated aspect, and a cartilaginous texture; from which there is an insensible gradation to a truly leafy configuration, which is either membranous or coriaceous, dilated and lobed, or narrow and repeatedly branched, round or comprised, erect, horizontal, or pendulous; in all cases it readily imbibes moisture, and by that means becomes instantly soft, flexible, and
and vegetative, however dry, contracted and brittle before. The colour of the frond is commonly very different in its moist and flourishing state, to what it is when dry; being, in the latter condition usually pale and greyish, but assuming a beautiful green when moistened. Yet there are some species always of the same grey hue, whether wet or dry, by which that very circumstance are well distinguished from others. See P. Jellaris and aiophila. Ach. Meth. 209.

The male fructification of Parmelia is suppos'd, rather than known, to consist of scattered powdery warts, mostly of a lighter colour than the frond, on whose surface or segments they are situated, burling, as it were, from under the cuticle. They are conspicuous in P. cespit, see Engl. Bot. t. 1052, and phylodes t. 126. There is perhaps much reason to suppose such effluences to be of the nature of buds, or gemmae, by which the species may be increased. The great Hedwig however speaks of them, in the example last cited, as clearly anthers. (See his Theoria, 124. p. 31, and Withering, v. 371. t. 16. f. 86, 87.) In that they are commonly found on a separate plant from the thalls, a rare occurrence in this tribe. They are also in the species in question, as well as most others, by far most abundant when the thalls, which are unquestionably the female parts of fructification, are sparingly produced; which is rather in favour of the opinion of their being buds. The fame opinion is strengthened by a consideration of the plants constituting a suppos'd genus called Leparia, which are propagated very copiously by such powdery granulations only; and yet a few of its species are known to bear sometimes, though very rarely indeed, proper thalls, with the character either of a Parmelia or a Lepraria; and we are much inclined to presume they may all be capable, in favourable circumstances, of doing so. The parts of the thall, at the period when imregnation, in whatever mode, must take place, are fo minute, homogeneous and obscure, that if we still remain in total ignorance of the flowers of Fenn, no wonder we are equally in the dark respecting Lichens.

PARMENALORE, in Geography, a town of Hindoo, a town of Hindoo, in Coimbertore; 15 miles S.W. of Errood.

PARMENIDES, in Biography, a celebrated Greek philosopher of the Eleatic sect, who flourished about 450 years before Christ, was a native of Elea, possefled a large patrimony, and lived in much splendour in his earliest years. He was distingished in civil affairs, and is said to have drawn up for his fellow-citizens some excellent laws, to which their magistrates obliged them annually to swear obedience. He at length withdrew from the concerns of public life to the silence and leisure of the schools. He became the disciple and successor of Xenophanes, and is said to have attended upon the initiations of Anaximander. According to the testimon of Cebes, in his allegorical table, our philosopher was distinguished as an eminent pattern of virtue. He wrote the doctrine of his school in verses, of which only a few fragments remain. Plato, in the dialogue which he denominated Parmenides, professed to reproduce his tenets, but confounded them with his own. He maintained that philosophy was twofold; that which follows the report of the senses, and that which is according to reason and truth. The former treats of the appearances of sensible objects; the latter considers the abstract nature of things, and inquires into the constitution of the universe. He maintained that the universe is one, incorruptible, eternal, and of a spherical form; that the earth is spherical, and placed in the centre, being exactly balanced by its distance from the heavens, so that there is no cause why it should move one way rather than another. Parmenides adhered more closely to the Pythagorean doctrine than Xenophanes, the founder of the Eleatic sect; for while the latter considered the universe as possefled within itself a divine force, the former suppos'd the deity to be an informing principle, or intellectual fire diffused throughout the universe, but more especially residing in the extreme sphere of the world; on which account, he is metaphorically represented by this philosopher as a crown of light, inclining within its circumference the celestial orb. Enfield's Hist. Phil. Parmenides' Philosophy. See Eleatic.

PARNENIO, in Biography, a distinguished Macedonian commander, who rose to great reputation under king Philip. That monarch is said to have pronounced him the only general he had ever met with. When Alexander invaded Asia, he was accompanied by Parmenio, who, after the victory of Granicus, gave the advice of venturing upon a naval engagement, and offered himself to serve on board the fleet. Alexander, however, regarding the sea as the proper element of the Persians and their allies, would not consent to the hazard. At the battle of Issus, Parmenio had the command of the left wing; and after that important victory, he was dispatched to Damascus, to take possession of the treasures of Darius, left in that city. In the decisive action of Arbela, Parmenio again commanded the left wing of the Macedonian army; while his two sons, Philotas and Nicander, had separate commands on the right. During the battle he had to fulfill the charge of the whole Persian cavalry, and was, at one time, reduced to such danger, that he sent for succour to Alexander, who was victorious in the centre. The prince arrived in time to rescue Parmenio, who thereupon took possession of the enemy's camp, while Alexander continued the pursuit of Darius in person. He next endeavored, but in vain, to divert Alexander from the frantic design of burning the royal palace of Persepolis. The ruin of Parmenio was occasioned by the indiscretion of his own son Philotas, who, elated by his prince's favour, affected a pomp and splendour which might render him suspected of ambitious views. The discontents of the army, at the Persian manners assumed by Alexander, after the death of Darius, having produced a conspiracy against his life, Philetas, on its detection, was involved in the guilt, or at least in the accusation, and was put to the rack to force a confession. Unable to endure the torture, he named many accomplices, and among the rest his father. His criminality being suppos'd to be proved, he was put to death; but the life of Parmenio was at last taken away in a base and treacherous manner. The perfons employed in this infamous business, approaching the general as he was walking in his pleasure-grounds, presented him with a letter from the king, and another in which the hand of Philetas was counterfeited; and while he was intent upon reading them, they flabb'd him with repeated wounds. His head was then cut off, and sent to Alexander, while his affectionate followers mournfully interred his body. Univer. Hist.

PARMENTIER, John, a scientific French navigator, a native of Dieppe, was born in the year 1494. He was intended and educated for mercantile pursuits, but possefled a love of science, and spirit of enterprize, he acquired celebrity among his contemporaries. He was also esteemed as a poet, and wrote verses on different subjects, of which a collection was published in 1531, under the title of 'Description nouvelle des Dignités de ce Monde, et de la Dignité de l'Homme, composée en Rhime Français, et en Manière d'Exhortation.' This work is now extremely scarce, and very highly prized by collectors of curious and rare books; but it is chiefly valuable, as containing particulars concerning

PAR
PAR

concerning the author prefixed to it, from which the following is extracted. *From the year 1522 he had applied himself to the science of cosmography, and the study of the wonderful fluctuations of the sea. On these subjects he became profoundly skilled, as he was likewise in the science of astrology.* He drew several maps and charts, both spherical and planar, which were of great service to navigators. He was worthy of the esteem of all men of learning, and capable, had his life been prolonged, of reflecting honour on his country, by his great enterprises. He was the first pilot who conducted ships to the coast of Brazil, the first Frenchman who discovered the Indies as far as the island of Sumatra, called Taprobane by the ancient cosmographers. It had been his intention to have proceeded as far as the Moluccas; and he frequently told me, says the editor, Pierre Crignon, that he was determined, after he should have returned to France, to seek a northern passage, and from thence to pursue his discoveries towards the south.* This design was frustrated by his death, which took place in 1530, at the island of Sumatra, when he was only 36 years of age.

**PARMESAN, Ths, in Geography.** See PARMA.

**PARMESAN** is a name given to a cheese, much esteemed among the Italians, and made at Parmetan, whence it is conveyed to various parts of Europe.

The excellent pasture-grounds of this country are watered by the Po; and the cows, from whose milk this cheese is made, yield a great quantity of it. Of this cheese there are three sorts, the *formaggio di forma*, about two palms in diameter, and seven or eight inches thick; and the *formaggio di rabiele and di ribolini*, which are not so large. This cheese is of a fair brown colour, and the belt is kept three or four years. See LODESAN.

**PARMIGIANO, It, in Biography,** was the cognomen of Francesco Mazzuolo, a painter of great and deserved renown, born at Parma in 1504. He was the pupil of his uncles Michele and Filippo, and at the early age of nineteen had attained very considerable celebrity; having made Correggio, who was then living, the object of his imitation. He then went to Rome, and taking with him some of his productions, was introduced by their renown to pope Clement VII. who highly honoured and esteemed him. In Rome he attached himself to the study of Michael Angelo and Raphael; and exhibited the loftiness of his mind, by composing a style for himself from the high qualities of those two great men, in conjunction with what he had learned of Correggio. In Rome, and under the immediate influence of this newly acquired guile, he painted several pictures, and among them one which was bought by the marquis of Abercorn, of Mr. Dumo in Italy, for 1500L, and refold by him in 1809 to Mr. Davis of Bristol, for 3000 guineas. It represents the Virgin feated in glory with a book in her hand, and the infant standing on the clouds, and leaning against her knee; in front is a figure of St. John kneeling upon one knee, pointing with one hand to the Virgin, and turning his face to the observer; and in the background, asleep, is a figure of St. Jerome, who is supposed to have been this vision, and from which the picture takes its name. Vafari makes especial mention of it; and says, Parmigiano painted it for Donna Maria Bufalina of Citta di Castello, who intended to place it in the church of St. Salvatore del Lario; in a chapel near the door. In the execution of it, Parmigiano had nearly lost his life; for notwithstanding the siege of Rome by the Colones, he continued painting upon it, and some Germans, intent upon plunder, entered his room while he was so engaged. The splendour of the work, however, fortunately so astonished and delighted them, that though they spared in no excess, but robbed the palaces and churches of every thing they thought worth having; yet they protected the painter and honoured his abilities. He did not quite complete the picture, and soon after left the city; but not till the folders had obliged him to make for them a number of drawings in pen and ink. He was afterwards, in going to see some friends, made a prisoner by other folders, from whom he eluded himself by paying money; and then his uncle, alarmed for his safety, removed him from Rome and sent him back to Parme. This grand picture was safely lodged in the convent of the Trati della Pace, where it remained in the refictory many years, and was there carried by Giulio Bafilino to its original dedication, the church of Santa di Castello.

In his return to his native place, Parmigiano stopped at Bologna; and there for a while he engaged himself in making those free and elegant etchings, with which the cognoscenti are so enamoured. He also painted several pictures there, and made a great number of drawings, and two portraits of Bonifacio Gozzadino and his wife. Among the pictures was a large one for the monks of St. Margaret, of the Virgin, with several saints, which was very highly esteemed by the Caracci, and by Guido was preferred to the St. Cecilia of Raphael. He there also painted a portrait of Charles V. with a figure of fame crowning him with laurel, which he effected after seeing the emperor dining in public several times; and it so gratified his majesty that he wished to have it, but Parmigiano flattering that it was not finished, it remained with him, and afterwards passed to the possession of the duke of Mantua.

He at length returned to his native city, and was immediately engaged to paint, in fresco, the vaulted ceiling of the church of Sta. Maria della Steccato; and in the lower part executed fix figures, a Moors, three Sybils, and an Adam and Eve. Of which Mr. Barry, in a letter to Mr. Burke, says, "that they exhibit powers which, if fully displayed, might have exceeded either Raphael or M. Angelo."

Unfortunately at this time, when Parmigiano ought to have pursued this great work, and have established his fame upon it, he turned aside to the alluring study of alchemy, and waited his time and his fortune in vain attempts at transformations; which only prevented him from exercising his abilities in a more certain mode of obtaining not only gold, but also glory. He died at the age of 36 or 7, in 1540-1.

"The ruling features of his style are elegance of form, grace of countenance, contrivance in attitude, enchanting chiaro-furore, and blandishments of colour. When these are pure, he is inimitable; but his elegance is often stretched to excessive flinerness, and his grace deformed to affectation."

He was a learned designer: to his depth in design, we must ascribe that freedom of execution, those decided strokes of his pencil, which Albano calls divine, and which add grace to the finish of his pictures: they have not indeed all equal impatience of colour, nor equal effect, though some, for the ame with which they are conducted, have been ascribed to Correggio: such is the Cupid fcooping his bow, with the two infants at his feet, one laughing, the other crying, of which, beides that in the Imperial gallery, there are several repetitions. Such was the delight found in the study of the pictures of Parmigiano, that copies, and excellent ones too, are found all over Italy; and are not unfrequently fold here as originals. The one upon which we have dwelt minutely above, the dream of St. Jerome, is of so high a class, that it may rank with the Peter Martyr of Titian, the Transfiguration of Raphael, and the St. Jerome of Dominichino.

His cousin, Girolamo Mazzuolo, was his friend and pupil, and possessed so much skill in execution, that it is not impossible
possible that many pictures ascribed to Parmigiano are executed by this artist." He was more attached to the style of Correggio than Francisco; and feized its character with great felicity in the Nuptials of St. Catherine, in the church of the Carmine. He excelled in perspective; and in the Last Supper in the refectory of S. Giovanni, placed and pointed a colonnade with all the illusion of Pozzo. To the most harmonious chiaro-furo, he added grandeur, variety, vivacity, in ffeo. None of his fellow artists equalled him in com-positions, fertility, and execution; and to these perhaps we may ascribe the inequality perceptible in his works.

PAMMILLIEU, in Geography, a town of France, in the department of the Ière; 24 miles E. N. E. of Lyons.

PARNONCA, a town of Peru, in the audience of Lima, near the sea; 35 miles N. N. W. of Gauora.

PARNAPICABA, a river of Brazil, which runs into the Atlantic, S. lat. 24° 14'.

PARNASSA, a town of Hindostan; 15 miles S. S. E. of Allahabad.

PARNASSIA, in Botany, well altered by Tournefort from the old name of Gramen Parnassii, which has been appropriated to this most curious and elegant plant, because it appears really to be what Dioscorides terms the Grafs of Parnassius, μπαρνασσίαν. Not that it has any thing to do with the grasses, properly so called; but he describes it as "having ivy-like leaves, a white and pleasantly-scented flower, with small not ineffective seed, five or fix roots as thick as the finger, white and soft." This description sufficiently answers to our Parnassia, except that we know of no small in the flowers. Some have taken Convallaria bifolia for what Dioscorides intended.—Linn. Gen. 151. Schreb. 204. Willd. Sp. Pl. t. 151. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 359. Prodr. Fl. Græc. Sibth. v. 1. 719. Ait. Hort. Kew. ed. 2. v. 2. 177. Jul. 245. Tourn. t. 127. Lamarck Illntr. t. 216. Gærtn. t. 62.—Clafs and order. Pentandria Tetragynia. Nat. Ord. Campanaceae. Linn. MSS. Caparidies, Jaff.

Gen. Ch. Cal. Perianth inferior, in five, deep, elliptic-oblong, spreading, permanent segments. Cor. Petals five, roundish, frilled, concave, spreading. Nectaries five, opposite to the petals, each a roundish or oblong felty scale, fringed with from three to thirteen marginal flasks, bearing every one a small globule, shorter than the petals. Stam. Filaments five, awl-shaped, the length of the nectaries, separately flexed for a time over the germen; anthers incumbent, depresso. Pist. Germin superior, ovate, large, felty; style none, but an aperture in its place; stigmas four, obtuse, permanent, enlarged in the fruit. Fr. Cap. Capiate ovate, somewhat quadrangular, of one cell and four valves, the partitions from the centre of each valve, each bearing a furrowed parallel receptacle. Seeds several, oblong, aciculiform.

F. Ch. Calyx in five deep segments. Petals five. Nectaries five, fringed with flaked globules. Capule of four valves, with many seeds.

i. P. palustris. Common Grafs of Parnassus. Linn. Sp. Pl. 391. Engl. Bot. t. 82. Fl. Dan. t. 684. Mill. Illntr. t. 15. Sm. Intr. t. 13. f. 175. Dickf. H. Sicc. fæse. 7. 10. Ehrh. Pl. Off. 133. (Gramen Parnassii; Ger. en. 840) Leaves heart-shaped. Petals felty, emarginate. Nectaries with numerous segments.—Native of boggy pastures throughout Europe, flowering in autumn. Dr. Sibthorpe gathered it on the Bithynian Olympus, and there is every reason to believe it may grow on Parnassus, and other Greek hills; whereas Convallaria bifolia, which some botanists suppose to be what Dioscorides meant, is not known to be a Greek plant, but is rather confined to the northern parts of

Europe. The root of P. palustris is perennial, cylindrical and feely, throwing out many long fibres. Stems erect, near a span high, simple, angular, twilled, smooth, bearing one felty leaf, and one flower. Leavés heart-shaped, entire, ribbed, felty; the radical ones numerous, on flasks three times their own length. Petals terminal, above an inch wide, white, and singularly elegant. Petals marked with many parallel pellucid lines. Nectaries wedge-shaped, each bearing about thirteen globletipped bristles; the globes, like the anthers, pale yellow. The stigmas are bent succefeivel over the stigmas to impregnate them, retaining subfequently, as in Sarifraga and Ruta. Afterwards the stigmas are brought nearer together, closing the aperture of the germen; but the inference of the seeds proves that the impregnation must take place through the usual parts, and not by the aperture.

2. P. caroliniana. Carolina Grafs of Parnassus. Michaux Boreal. Amer. v. 1. 184. Ait. n. 2. Sims in Curt. Mag. t. 1459.—Leaves almost orbicular. Petals nearly fefile. Nectaries deeply three-clift.—Discovered by M. Bofé on boggy in North Carolina. It was sent to Kew garden in 1802 (not 1782) by the late Mr. Maffon, and is hardy in our climate, flowering in autumn. This has altogether the habit of the preceding, but is somewhat larger. The leaves are more orbicular. Petals more elliptical, not emarginate, the lines green and very numerous, the whole of the petals of a greenish falt. Nectaries remarkably different, being deeply divided into three oval-shaped segments only, with a yellow ball upon each point. Mr. Aiton mentions this species as flowering in May and June; Dr. Sims from July to September.

3. P. afarifolia. Kidney-leaved Grafs of Parnassus. Venten. Jard. de la Malmaison. t. 39.—Leaves kidney-shaped. Petals with claws. Nectaries oblong, with three terminal segments.—Native of bogs in North America, flowering in the latter part of summer. M. Ventenat described it from the collection at Malmaison. This differs from both the foregoing in having shorter or kidney-shaped leaves; petals furnished with considerable claws; nectaries of an elongated and linear form, divided at the upper part only, into three bristle-like segments, tipped with darker-coloured globules. The petals moreover seem to be smaller, and more rounded, than in the caroliniana; entire, and not, as in the palustris, emarginate. We have not heard of this, any more than the following, in the English gardens.

4. P. simbriata. Fringe-flowered Grafs of Parnassus. König in Ann. of Bot. v. 1. 301.—Leaves kidney-shaped. Petals fringed at the lower part, with entire claws. Nectaries palmate, with numerous segments.—Gathered by Mr. Archibald Menzies on mountains on the north-west coast of America. We are indebted to him for fine specimens, by which this species appears to agree with the last in habit, but the flowers are essentially different. The claws of the petals are smooth and entire, but the base of each petal islpsi is copiously fringed with fine long capillary segments. The nectaries are palmate, mostly resembling those of the first species, which they seem to approach in their number of segments, but those segments are of a much shorter proportion. The stem leaf is much nearer the flower than the root; the radical ones are remarkably hollowed out at their base, close to the lateral ribs, which are connected with one another by a common base, like the divisions of a pedate leaf, and have a very elegant appearance. The same thing is seen, though less remarkably, in Arthrostichina Clematis.

PARNASSUS, in Ancient Geography and Mythology, a mountain of Greece, in the Phocidea, consecrated by the poets to the Muses, hence called Parnassides, to Apollo and Bacchus. It was situated to the S.E. of the Crif-

U
Sean gulf, and N.W. of the river Cephinus. On this hill, though for the most part sterile, there were groves and small villages adapted to excite and inflame the poetic genius. It is described as having two summits, one called Hyampela, the other Phitorea, between which arises the Callatian fountain. The Greeks call this mountain Licoura.

Parnassus was also a town of Asia, in Galatia, upon the route from Cysaren to Ancyra, between Apcona and Nyfia, according to the Itinerary of Antonine.

Parnell, in Geography, a town of Hindoostan, in Dowlatabad; 15 miles S.W. of Amednagur.

Parnell, Thomas, in Biography, an English poet, defended from an ancient family in Cheflere, was born at Dublin in the year 1679, and received his school education in that city, after which he was transferred to the college. He was admitted to the degree of M.A. in 1700, took deacon's orders in the same year, and was ordained priest three years afterwards. In 1705 he was prefented to the archdeaconry of Clogher, and about the same time was married to a lady of great beauty and merit. From this period he began to make frequent excursions to England, in which the pleasing part of his life was spent. He connected himself with the whigs, who were at that time in power, and was familiar with their most distinguished men of letters, as Addison, Congreve, and Steele. Towards the close of queen Anne's reign, Parnell, influenced, it was thought, by Swift, deserted his former friends, and joined in clove union with that celebrated wit, and his associates, Pope, Gay, and Arbuthnot. Swift introduced him to lord-treasurer Harley, and with a dictatorial air intituted upon the treasurer going with his staff in his hand into the anti-chamber, where Parnell was waiting to welcome him. Parnell, however, never had any claim to a high rank in literature, nor was it possible he could render his friends much political service. He was a pleasanl good tempered man, attached to his particular associates, and so much addicted to society, that he preferred what was indifferent to solitude. He was, at one period, an affidious preacher in the London pulpits, hoping to rise into notice by the popularity of his talents, but the complete change in the administration by the death of queen Anne entirely destroyed his brilliant prospects in the church. By means of Swift's recommendation of him to the notice of archbishop King, he obtained a prebend and a valuable living. In 1712 he received a mob levee shock, by the death of his beloved wife, from whom he never recovered. The loss is said to have had such an effect upon his spirits, as to lead him into those habits of intemperance in wine which shortened his life, and his biographer, Dr. Goldsmith, represents him, in some measure, a martyr to conjugal fidelity. He died at Chelfer, on his way to Ireland, in July 1717, in the 35th year of his age, and was buried, without any monumental record, in Trinity-church in that city. He was author of several pieces both in prose and verse. He wrote the Life of Homer, prefixed to Pope's Iliad, which, however, on account of the stiffness in the style, cost that poet much labour in the correction. It is as a poet that he is now exclusively known and valued. After his death, Pope made a collection of such of his pieces as he thought worth preserving, and published them in one volume octavo. They have since been a part of the body of approved English poetry. They are remarkable for cale, sprightlines, fancy, clearness of language, and melody of variation. Though not ranking among the noblest and most finifhed productions of the British muse, they claim a place among the moss pleasing. Their sentiments are elegant, and their morality very pure. A volume of posthumous pieces was printed at Dublin in 1758, the contents of which have been since added to the former in the collections of English poets. Dr. Johnson has thought it unnecessary to enquire into their authenticity, or canvass their merits; he expressly limits his commendations to the pieces published by Pope.

Parnes, in Ancient Geography, a mountain of Greece, in Attica, on which were a statue of Jupiter Parnesian in bronze, another of Jupiter and Seraph, and another altar on which the adjacent inhabitants sacrificed to Jupiter, under the apppellations of beneficent and rainy, or pluvius. This mountain abounded with bears and wild boars.

Parnipa, in Geography, a river of Brail, which runs into the Atlantic, S.lat. 10°.

Parnon, in Ancient Geography, a lofty mountain of the Argolides, on which were the Hermene statues of Mercury, which, in the time of Pausanias, indicated the limits of Laconia, and of the territory of the Taygetes, a people of Arcadia.

Parnops, in Natural History, the name of a species of wap, found very frequently in vineyards, and among the wine fields, especially in hot countries. It is distinguished from all the other waps by the roundness of its body, which is not slender or flattened in the common way, but round and tumid.

Paro, or Paragon, or Kinnijo, in Geography, a town, castle, and palace, as well as valley of Bootan. The castle stands near the base of a very high mountain, in the form of an oblong square, fenced by walls and parapets, having one entrance over a bridge, that may be easily removed, and guarded by stone buildings, placed as a kind of out-post, in a triangular position upon the side of the mountain. This is the residence of the governor, and famous for the manufacture of idol deities and forging of arms, particularly of swords and daggers, and the bars of arrows. Paro boils the only market in Bootan, and appears to be much frequented. The valley exceeds that of Tellifun on by almost a mile in width; it has nearly N.W. and S.E., and the river intersects it irregularly, as it pursues its winding course. Paro lies 12 miles S.W. of Tellifun. N.lat. 27° 43'. E.long. 89° 32'. Turner's Tibet.

Paro, a small island near the coast of Nicergia, in Salinas bay. N.lat. 10° 5'. W.long 85° 56'.

Pato House, a town of Chineie Tartary; 288 miles N.N.E. of Peking. N.lat. 44° 21'. E.long. 118° 47'.

Parochieus, from oikos and oikognomon, a term used by Hippocrates; this expresses a derivation of the humours from one part, in order to the evacuating them by another not far distant. This is often a very happy turn for the cure of a disease.

Parochial, something belonging to a parish.

Every church is either cathedral, collegiate, or parochial. Cathedral is where there is a bishop's seat, or feast, called cathedra. Collegiate consists either of regular clerks, professing some religious order; or of a dean and chapter. Parochial church is that instituted for the performing of divine service to the people who dwell within a certain compass of ground. See Parish and Extra-parochial.

Parochus, among the Romans, one who provided mules, tents, and carriages, with all other necessaries, for the provincial magistrates in their journeys, as also for ambassadours. For, in the early times of the republic, they had their charges borne by the public, that the allies or provincials might not be burthened.

Parodial Degrees, in an equation, the several regular terms in the quadratic, cubic, biquadratic, or other equation, the indices of whose powers added or subtracted in an arithmetical progression.

Thus
Thus $Z + Z^2 + Z^3 + Z^4 + Z^5 + Z^6 = S$ is a cubic equation where no term is wanting, but having all its parodic degrees, the indices of the terms regularly descending thus, $3, 2, 1, 0$. Harris.

**PARODY, Parodia**, formed from παρώδες, and oμεγα, oμοιον, way, as being trice, or passing among the people, a popular maxim, adage, or proverb.

**Parody, παρωδία** is also a poetical pleasantery, confining in applying the verses written on one subject, by way of ridicule, to another; or in turning a serious work into burlesque, by affecting to observe, as nearly as possible, the same rhymes, words, or cadences.

The parody was in full foot on foot by the Greeks; from whom we borrow the name. It comes near to what some of our late writers call travesty.

Others have more accurately distinguished between a parody and burlesque: and they observe, that the change of a single word may parody a verse; or of a single letter a word. Thus, in the last cato. Cato exposed the inconstant disposition of Marcus Fulvius Nobilior, by changing Nobilior into Nobilis.

Another kind of parody consists in the mere application of some known verse, or part of a verse, of a writer, without making any change in it, with a view to expose it.

A fourth instance is that of writing verses in the taste and style of authors, little approved.

The rules of parody regard the choice of a subject, and the manner of treating it. The subject should be a known and celebrated work: as to the manner, it should be by an exact imitation, and an intermixture of good-natured pleasantry. Mem. de l'Acad. Belles Lettres. tom. viii. p. 39. &c.

The French term it parodying an instrumental air when it is made vocal, by writing or adding words to it. In good compositions, the melody is made for the words; but in parodying an air, the words are set to the melody. In ballads, and songs of many flantas to the same air, Rouille observes, that all but the first are parodies, which are easily discovered by the liberties taken with the rhythm by the fingers, and the want of musical knowledge in the poet.

**PARÖMIA, παροιμία, from παροιμιος and ομεγα, oμοιον, way; quaæ, παροιμιον, junta viam; i.e. tritam, a proverb; which see.**

**PAROL, Parole, in Law**, is sometimes used in ancient writers for a plea in court.

**Parol, Conveyances**, are such as were formerly, in many instances, made by parol, or word of mouth only, without writing; but this occasioning a variety of frauds, the statute 39 Car. II. c. 3, enacted, that no lease estate or interest in lands, tenements, or hereditaments, made by livery of seisin, or by parol only (except leases, not exceeding three years from the making, and wherein the referred rent is at least two-thirds of the real value,) shall be looked upon as of greater force than a lease or estate at will: nor shall any assignment, grant, or surrender of any interest in any freehold hereditaments be valid: unless in both cases the same be put in writing, and signed by the party granting, or his agent lawfully authorized, in writing.

**PAROL Demurrer, is a privilege allowed to an infant who is sued concerning lands, which came to him by descent: and the court thereupon will give judgment, *Quod legula prædicta remaneat quaæque*, the infant comes to the age of twenty-one years. And where the age is granted on parol demurrer, the writ doth not abate, but the plea is put *fine dis*, until the infant is of full age; and then there shall be a remonstrance.

The granting of a parol demurrer is in favour of an infant, and for his benefit, that he may not be prejudiced in his right, for want of well knowing his estate, &c. In many real actions, brought by or against an infant, under the age of twenty-one years, and also in actions of debt brought against him, as heir to any deceased ancestor, either party may suggest the nonage of the infant, and pray that the proceedings may be deferred till his full age: or (in our legal phrase,) that the infant may have his age, and that the *parol may demur*, that is, that the pleadings may be laid; and then they shall not proceed till his full age, unless it be apparent that he cannot be prejudiced thereby. (Fitch. I. 360.) But by the statutes of Westminster I. c. 46. and of Glocester 6 Edw. I. c. 2. in writs of entry *par dixit* in some particular cafes, and in actions auncelltrel brought by an infant, the parol shall not demur; otherwise he might be deforced of his whole property, and even want a maintenance till he came of age. So likewise in a writ of dower the heir shall not have his age; for it is necessary that the widow's claim be immediately determined, else she may want a present subsistence. (1 Roll. Abr. 137.) Nor shall an infant patron have it in a *quære impedito* (ibid. 138.), since the law holds it necessary and expedient, that the church be immediately filled.

**PAROL Evidence. See Evidence.**

**PAROL Leave, or per Parol, is a lease by word of mouth; thus called to distinguish it from one in writing. See LEASE.**

**PAROL Pleadings. See Pleading.**

**PAROLE, in War, &c. When a prisoner of war is allowed to go into his own country, or to his own party, upon his word and promise to return at a time appointed, if not exchanged, he is said to be upon parole, i.e. upon his word.**

**PAROLE, Pafs. See Pass-Parole.**

**PAROLI, in Gaming, the double of what was laid at stake, before. Hence to offer the parole, &c.**

**PAROLLES, Fr. the words of a song, an opera scene, or a cantata.**

**PARONE, in Geography, a town of Hindoostan, in the country of Nayäs; 32 miles S. of Calcutta.**

**PARONOMASIA, παρονομασία, from παρονομασίαι, name, and παρά, name, q. d. proximity or resemblance of two names, in Rhetoric, a pun, or figure, whereby words nearly alike in sound, but of very different senses, are affected or defiledly used.**

As, not friends but fiends were here. So Tully to Antony, *cum in gremio minarum mentem & mentum deponeris*: and to Atticus, *confulse ipse parvo animal & pravo, facie magis quam factitis ridiculus*. And that of P. Chryseologus, *monochorum cellette jam neremticus* fed aromiticus. And, in another place, *hoc agent in cellis quod angelis in cæulis.*

Among the Greeks the paronomasia was very familiar. Thus Herodotus, παρόνομα, παρανομα, quæ novel, docent. And thus that inscription of Apollodorus, a celebrated painter, on one of his pieces.

*Мοιρισθή τις μαλλιν, ε μωρισθή.*

"It will be easier to deride, than to imitate."**

**PARONYCHIA, in Botany, a name that has been applied to several plants, according as commentators were pleased to conjecture one or other of them to be the *pars pro toto* of Dioscorides, a point which nobody could ascertain. He describes it as "a diminutive shrub, growing in vile places, and resembling purslane, but of more humble growth, though U a 2 the
the leaves are larger. The whole plant bruised is a remedy for whistles and scald-heads." Matthiolus supposed the Wall-rue, Aphantium Ruta-muraria, to be what Dioscorides intended; but he cites other botanists who have thought Molugo tetrapterylla to be the plant in question; see Matt. in Gr. v. 2. 388, 389. Dodonaeus, Lobel, and Gerarde took Saviagra iridiflavia to be the true Paronychia. Clusius has called a species of Illecebrum by the name of Paronychia hispanica, and hence, rather by accident than for any particular reason, Linnaeus has denominated that plant Illecebrum Paronychia. The most prevalent opinion has been, that some plant of the class Tetradynamia was intended by Dioscorides; though it is difficult to guess why this idea was adopted. Hence however the name of Whitlow-gras has remained with our Draba vera, which is reckoned, by several authors, one sort of Paronychia at least; and hence that English name has been extended to all the British species of Draba.

Tournefort has a genus under the name of Paronychia, of which the above-mentioned Illecebrum is its first species; see his t. 388. Gaertner follows him v. 2. 218. t. 128, saying that amongst all the species of Illecebrum which he has met with, the verticillatum only answers to the Linnaean character, the root belonging to Achyranthes, Cefalof, or this genus Paronychia, either by reason of its flamine being united at the base, or the capsule delitute of valves, or splitting into two hemispheres. See Illecebrum.

Paronychia, from τεσευς and αινεις, the nail, an abcess towards the extremity of the finger, more commonly known by the name of whitlow. See Whitlow.

Paronyma, in Grammar, are words which have some affinity in their etymology.

Paropamisus, in Ancient Geography, a province of India, the eastern limit of which, in Alexander's arrangement of boundaries, was the river Cophenes. According to the ideas of Ptolemy, it lay between the countries which the moderns name Khorasan and Cabul; and answers to the tract between Herat and Cabul. Alexandria was regarded as the capital. This province was separated from Babiria by the chain of mountains called "Paropamisus." See Gaur.

Parorchidium, from τεσευς and αινεις, the nail, the cafe in which the tefticles do not descend into the scrotum, but remain within the ring of the external oblique muscle, or pass no farther than the groin. A little before birth, these bodies usually descend into the scrotum; but it sometimes happens that this occurrence is retarded by causes, with which we are not satisfiedly acquainted, and, in particular individuals, the testicles even continue within the abdomen during life. Mr. Pott remarks, that he knows not of any particular inconvenience arising from the detention of a testicle within the cavity of the belly; but its lodging in the groin exposes it to be hurt by accidents. When hurt, it may be mistaken for a different disease, and occasion very improper treatment. Besides these confiderations, he adds, that there is no kind of disease to which the testicle is liable in its natural situation; but what may also affect it in any, or all its unnatural ones. In the first cafe, related by Mr. Pott, a testicle being detained in the groin of a young healthy man, who hurt the part by lifting it against a piece of timber, the tumour became extremely painful, and was mistaken for a bubonoele, from which it might have been more readily distinguished by the following circumstances, had not the extreme tenderness of the injured testicle prevented any examination by the touch; and the very hard swelling of the scrotum precluded any certainty of a testicle being there, or not. Mr. Pott observes, that the tumour in the groin did not, like the bubonoele, point obliquely from the ilium to-
tholes have fled; and the Greeks who remain, idle and wretched, find themselves exposed every year to the oppression of the officers of the captain-pacha's squadron, to the sword of the sailors, and to the rapacity of all. Although its extent is not to be considered as that of Naxos, it has in proportion a much greater quantity of lands fit for culture. Its mountains are less elevated, its rising grounds less arid, and its plains would be as fertile, if they were as well watered. A small town called "Parčeha" has replaced the ancient city of Paros, on the W. coast of the island, facing Antiparos; it presents no idea of it, except it be by the beautiful ruins, which are employed, without taste, in its construction. Similar fragments of magnificent monuments cover, in an ufeles manner, almost the whole territory of the island, and in those deserted remains, art would ill discover objects worthy of its admiration. Off "Parčeha" the sea forms a bight, and a harbour whose entrance is difficult, on account of the shoals that obstruct it on the opposite coast. The harbour of Nauffa, situated to the north, is one of the finest and most picturesque in the archipelago. Here are still visible the batteries which the Ruffians had erected for defending its entrance, when masters of the archipelago in their war before the last with the Turks, they had made Paros the depot of their forces. In autumn this harbour is infalubrious, and also towards the end of the summer, on account of some marshes which are situated at the head of it. The Ruffian army suffered from them to such a degree, that it was obliged to quit the place, after having loit a great number of soldiers and sailors. There are three harbours on the E. side of the island; the first, called Port Santa Maria, towards the N. point, is sheltered by some islands from winds from the N. and S.; but it is open to the N.E., which prevents ships from frequenting it in winter. The harbour of Marmora lies in the middle. Near it is seen Fort San Antonio, in which Veniero, prince of the island, sustained for a long time all the efforts of Barbarossa. He gave up this important post only because the garrison were in want of every thing, and perishing with thirst and hunger. The harbour of Trío lies lower down, and it is, like the first, sheltered by some islands, but open to fetideryr winds. Here the captain-pacha remains at anchor every year upwards of a month, till the return of the galleys and small vessels which he dispatches to the neighbouring islands, in order to collect the import to which they are subject. There is only one harbour to the westward, at the head of which the principal town, now a wretched village, is built. Vessels of burden without, under shelter of some islets, as well as in the narrow channel that separates Paros from Antiparos,月经, situated to the westward of the harbour of Marmora, is the most lofty mountain in the island; and it is this that furnished more particularly the marble for which Paros was so celebrated. Near an ancient quarry, about four miles from Parčeha, is still to be seen a bafso-relievo, mentioned by Tournefort, cut in the rock, and containing 29 figures of nymphs and satyrs, dancing a kind of carol. The most valuable monuments of antiquity now extant, called the Oxford or Arundelian marbles, were constructed by a native of this island, whose name is unknown, but who, according to Uher, lived in the third century before the Christian era. (See Parian Marble.) The inhabitants of Paros and Antiparos supply themselves from the produce of the islands with wheat, barley, wine, oleum, and some legumes. Cotton is the most considerable production, and the only one that enables the inhabitants to pay their impost, and to procure for themselves such commodities as they need. These two islands pay an impost somewhat more than 8000 piastras. Archi-

ochus the fatirid, was born at Paros, about 720 years B.C. (N. lat. 37° 4'. E. long. 25° 18'.

PAROTID GLANDS. Parotis, in Anatomy, from παροτίς, near, and ως, the ear, the largest of the salivary glands, situated in front of the ear. See DEGLUTITION.

PAROTID DULL, Wounds and Fistula of. See Wounds of the Face, and Salivary Fistula.

PAROTIDES, in Medicine, signifies the inflamed and tumid state of the parotid glands. An inflammation of these glands often occurs in persons of scrofulous constitution, without any very obvious exciting cause; but more commonly they are inflamed in consequence of irritation from the absorption of acid matter, as in the case of excoriations about the face and ears, of scald head, &c.; or from sympathy with inflamed gums, or tooth-ache, especially in the lower jaw; or, lastly, from an extension of inflammation of the throat to them, as in the case of Mumps, or Cynanche parotidea; which see. In scrofulous or debilitated habits, inflammation and suppuration of the parotids, as well as of other glands, are liable to occur at the close of acute fevers, of which they appear to be sometimes critical; but in other instances, especially when they follow severe attacks of measles, or small-pox, they are often extremely tedious in their progress, and difficult of cure, and seem to be indicative of a cachectic condition, left by these fevers. See SCROFULA.

PAROTIS, from παροτίς and ως, the ear, in Surgery, the parotid gland: also an inflammation, or abscess, of this part.

PAROXYSM, παροξυς, in Medicine, is the fit, attack, or exacerbation of a disease, that occurs at intervals, or has decided remissions or intermissions. It is applicable to all febrile, inflammatory, convulsive, painful, or otherwise violent diseases, whether the periods of remission be regular or irregular. Thus we speak of a paroxysm of ague, of gout, of colic, of epilepsy, of infancy, &c.

PARAJAH, in Geography, a town on the N.E. coast of the island of Sumatra, on the river Camfer. N. lat. 6° 15'. W. long. 102° 45'.

PARARSARAT, an island in the straits of Malacca, near the coast of Sumatra, about 50 miles in circumference. N. lat. 1° 21'. E. long. 102° 15'.

PARPOOY, a town of Hindooistan, in Concan; 28 miles N.N.E. of Goa.

PARPOUR, a town of Bengal; 70 miles N.W. of Middnapur.—Also, a town of Bengal; 8 miles N. of Currockpour.

PARR, Thomas, in Biography, mentioned in this work on account of the great age to which he attained, a husbandman in Shropshire, was born about the year 1483. At the age of 120 he married a second wife, by whom he had a child. In the year 1535, he was brought to London by lord Arundel, and introduced at court to king Charles I. as a prodigy; but the change of air, and the new mode of living to which he was necessarily subject, occasioned his death in the same year.

PARRA, in Geography, a town of Peru, in the province of Segeitan; 60 miles N. of Zarang.

PARRA, the Jacana, in Ornithology, a genus of birds of the order Grallae. The generic character is; bill tapering somewhat obtuse; nostrils oval, in the middle of the bill; front covered with lobate caruncles; the wings are spinous. Sixteen species are enumerated by Gmelin, which are as follow.

Species.
Dominica; or St. Domingo Jacana; so called from its being found in that island, as also in the island whence it derives its specific name, and in almost all the warm parts of America. It is characterized by yellow and moderate claws. The bill is yellow; the caruncle lax, and of a pale yel-low colour; the head and body above are of a pale yellow, beneath it is ochre, inclining to rosy.

Ludovicana; Louisiana Jacana. The bill and caruncle are tawny; the crown is black; body above is grey-brown, beneath of the colour of ochre. It is about eleven inches long; and is found in the country whence it takes its name. The quill-feathers are black, mixed with a little grey; the tail is of a pale yellow, tip with black; the legs are red; claws are black.

Cayennensis; Cayenne Jacana. Legs reddish; hind-head brown, with a blackish crest. It inhabits Cayenne, feeds on insects, and is about eight inches and a half in length. The bill is red, tip with black; front and chin black; middle of the crown cinereous; breast with a broad black band; belly and vent white; back greenish-purple; wings white without; tail from the base to the middle white, the rest black, the tip edged with white.

Goensis; Goa Jacana. Caruncle red; legs yellow; head, neck, wings, and middle of the tail black; body beneath white. It is found in or near Goa; and is about thirteen inches long. The bill is dusky; from the hind part of the eye a black streak runs through the sides of the neck as far as the breast; the back and wing-coverts reddish-brown, the greater ones white; the tail is white at the base, and tip with brown.

Senegalensis; Senegal Jacana. Claws moderately long, and the legs are red. It is found, as its name imports, near Senegal, and is twelve inches long. The bill is of a yellowish-green, tip with black; the front is white; caruncle lax, and of a pale yellow; chin and throat black; lower part of the belly, tail-coverts, and greater wing-coverts, white; quill-feathers black, t ipt with white. At the bend of the wings is a black spur; the tail, from the base to the middle, is white, the rest black, tip with reddish; the rest of the body and head is of a grey-brown.

Chilenensis; Chilet Jacana. Claws moderately long; legs brown; hind-head sub-crested. It inhabits Chili, and is the fize of a jack, but with longer legs. It feeds on worms and insects, is noisy, and defends itself by the spurs on its wings; it builds in the graves, and lays four tawny eggs, which are speckled with black. The bill is conical, and about two inches long, a little curved at the tip; the irides are yellowish, caruncle two-lobed and red; the neck, back, and fore-part of the wings are violet; throat and breast black; wings and a short tail brown; spurs on the wings yellowish, conical, bony, and about half an inch long.

Jacana; Chefnut Jacana. In this species the hind claws are very long; the legs are greenish. It inhabits the watery places in South America, and is ten inches long. The bill is about an inch and a quarter long, and is of an orange-colour; and on the forehead is a membranous flap, half an inch long, and nearly as broad. On each side of the head also is another of the same kind, about a quarter of an inch broad, and both together they surmount the base of the bill. The head, throat, neck, breast, and under parts, are black; and sometimes mixed with white. The birds of this species are chiefly found in Brazil, Guiana, and Surinam; but they are not at all uncommon at St. Domingo, where they frequent the marshy places, the lides of ponds and streams, and wander up to the thighs in water. They are also generally seen in pairs, and, when separated, call each other continually till they join again. They are very shy, and most common in the rainy seasons in May and November. They are at all times very noisy; their cry is sharp and shrill, and they may be heard a great way off. The flesh of this bird is accounted very good.

Nigra; Black Jacana. Hind-claws very long; legs cinereous; head, neck, tail, and body above black. It inhabits Brazil, and is of about the same size as the last. The bill is of a fai rron colour; the front is rufous; the breast, belly, and vent brown; quill-feathers green, tip with brown; the wing-spurs are yellow.

Brasilensis; Brazilian Jacana. The hind-claws are very long; the body of a greenish black. It inhabits Brazil and Guiana. The size and manners very much resemble those of the chefnut Jacana; it is gregarious, and feeds on fish and insects; the wing-spurs are yellow.

Viri dis; Green Jacana. Hind-claws long, yellow; legs yellowish-green; body blackish-green. It inhabits Brazil, and is of the size of a pigeon. The bill is partly red, and partly yellow; the front is red; the head, neck, and breast are of a glossy-violet; the toes are very long.

Variabilis; Variable Jacana. Hind-claws long; legs blueish. This is also denominated the spur-winged waterhen, and is about nine inches long. The colour of the bill is of an orange-yellow. On the forehead is a flap of red skin; the crown of the head is brown, marked with spots of a darker colour; the hind part of the neck is much the same, but of a deeper dye. On the fore part of the wing is a yellow spur. The legs are furnished with long toes, as in all the others; the colour of which is of a blueish-sih.

This species inhabits Brazil, and is said to be pretty common about Carthagena, and in other parts of South America.

Luzoniensis; Luzonian Jacana. Beneath white; toes long; legs black. This species is found in the marshy and maritime parts of the Manilla islands.

Africana; African Jacana. This species is of a pale cinnamon; the toes are long; the legs greenish-black. It inhabits Africa, and is about nine inches and a half long.

Sinensis; China Jacana. The toes of this are long; legs greenish; body of a claret colour. It is found in China, and is about twenty-one inches long.

Chavaria; Faithful Jacana. Toes long; legs tawny; hind-head crested. This is the most remarkable of all the species. The bill is of a dirty-white; upper mandible like that of the dung-hill cock; on both fides, at the base of the bill, is a red membrane extending to the temples, in the middle of which are the eyes; irides brown; hind-head with about twelve blackish feathers, three inches long, forming a pendent crest; the rest of the neck is covered with thick black down; the body is brown; the wings and tail blackish; it has two, and sometimes three wing-spurs, half an inch long; the belly is of a light black; the thighs are half bare; the toes so long as to entangle each other in walking. This species inhabits the rivers and inundated places near Carthagena in America; it feeds on herds; its gait is slow; and it cannot run unless affrighted by the wings, but flies easily and swiftly. When the skin is touched, a crackling is felt; the voice is clear and loud. The natives keep one of these tame to wander with the poultry, and defend them against birds of prey, which it does by means of the spurs on its wings. It never defers the charge committed to its care, but brings them home at night. It will readily
PARRAL, in Geography, a town of Mexico, in the province of New Bisoy, on a river which runs into the Couchos; 230 miles N. of Durango. N. lat. 28° 10'. W. long. 105° 12'.
PARRAMATTA, a settlement founded in New South Wales, near Port Jackson; 16 miles W. of Sydney Cove.
PARKAMPOR, one of the small islands in the Atlantic ocean, which line the E. coast of Northampton county, Virginia.
PARRAN, Pere, in Biography, published, in 1646, a treatise on theoretical and practical music, containing the rules and precepts of composition.
PARRAS, in Geography, a town of Mexico, in the province of Zacatecas; 60 miles N. of Zacatecas.
PARRIS, in Geography, a town of Mexico, in the province of Zacatecas; 60 miles N. of Zacatecas.
PARRISIUS, in Biography, a.distinguished Jesuit missionary, was born in 1665; and in 1682 we find him entered among the Jesuits at Aix-en-Provence, with the view of engaging in their missions. In 1698 he was sent to China. The reigning emperor was at that time favourable to the Christian missionaries, on account of the scientific improvements which they introduced into his dominions, and Parriss had matters affixed to him for instructing him in the languages of the country, in which he acquired a proficiency beyond that of any preceding European. The emperor, who was a thoughtful and learned man, frequently conversed with him on the history, manners, and politics of Europe, and on different sciences, with which he was desirous of becoming acquainted. The missionary was obliged to study hard, to satisfy the curiosity of the Chinese monarch, and he translated into the Tartar language every thing which he found new and curious in geometry, astronomy, and anatomy, in the memoirs of the French Academy of Sciences, and in other works. During the space of twenty years he followed this emperor in his progresses through the different provinces of the empire, and for a full longer time he acted as interpreter for all European missionaries and ambassadors, who came into China, and as mediator in the disputes between the courts of Moscow and Pekin. He drew up many books in the Chinese and Tartar languages, as well for the information of the emperor, as the instruction of the profelytes. He wrote a vast number of letters to correspondents in Europe, relative to the bufkins of his mission, and to the manners, customs, sciences, and occurrences of China, which were printed in Du Halde's collection. Of these the most valuable are his letters to De Mairan.
PARRETA, a river of England, which rises on the borders of Dorsetshire, passes by Langport, Bridgewater, &c., and runs into the Brithol channel, about ten miles below the last town.
PARRHASIA, in Ancient Geography, a town of the Peloponnesus, in Arcadia: it is mentioned by Homer and Pliny; but not noticed by Pausanias nor Strabo, though they speak of a mountain and people under this appellation.
PARRHASII, a people of India, beyond the Ganges, mentioned by Quintus Curtius.—Alfo, a people who inhabited the S.W. part of Arcadia.
PARRHASIUS, Aulus Janus, in Biography, the assumed name of Giampaolo Parissio, was born in 1470. His father, Tommaso Parissio, a counsellor in the Neapolitan senate, would gladly have brought up the son to the fame professions; but the young man had imbibed so decided a taste for literature, as to refuse to settle to bufkins. The wars in the kingdom of Naples occasioned his removal to Rome, where his life was brought into danger by his attachment to two cardinals, who had incurred the displeasure of pope Alexander VI. He escaped to Milan, where he married a daughter of Demetrius Chalcondylas, and was appointed professor of eloquence in the university. This was about the year 1500, when he first appeared as an author, by publishing his commentaries upon Claudian's Rape of Proserpine. He soon obtained a very high reputation as a lecturer, and had the most distinguished people in the country as his auditors. His fame excited against him many enemies; he was charged with citing books that never had any existence, and he was accused of crimes of an infamous nature, which were frequent to have had no other foundation than the envy of his rivals. He retired to Vicenza, where he was elected to the chair of eloquence with a liberal salary. The wars excited by the league of Cambrai obliged him to quit that country, and he returned to his native place, where he...
he laid the foundation of the Cofentine academy, which afterwards became very famous. He after this accepted of an invitation from Leo X. to occupy the chair of eloquence at Rome; scarcely, however, had he entered upon the duties of this office, when ill health obliged him to resign; he returned to Cofenza, where after passing many years in continual sufferings, he died in the year 1534. His works were published, collectively, by Henry Stephens in 1567, of which the principal is entitled "Liber de Rebus per Epitomam Quæstis." This consists of a number of letters written to different learned men, containing explanations of passages in the ancient writers, and elucidation of points of antiquity, which display much erudition. There are also illustrations of Ovid's Heroic Epistles; of Horace's Art of Poetry; of Cicero's Oration for Milo, and various other tracts on classical subjects. The whole collection was reprinted in the first volume of Gruter's "Thesaurus Criticus." A new edition of the book "De Quæstis," with additions from the author's manuscript, was given at Naples in 1771. Moretti.

PARRHESIA, in *Rhetoric*, a figure in which a person admonishes or reproves another with art and address, and in such circumstances as render it difficult to displeas.e. See Revelation, chap. ii. 2—5.

PARRIAH, in *Geography*, a town of Hindooftan, in Bahar; 35 miles N. of Durbungah. N. lat. 26° 40'. E. long. 82° 52'.

PARRICIDE, Parricida, or Patricida, in *Iliad*, denotes the murder of a father; as matricide does of a mother. Though the word parricide is also ordinarily extended to both.

The Romans, for a long time, had no law against parricides; which was also the law at Athens; from an opinion, that nobody could be so wicked as to kill his parents. The Persians, according to Herodotus, entertained the same notion, when they adjudged all persons who had killed their reputed parents to be halarthos. L. Otilius was the first who killed his father, five hundred years after Numa's death; and then the Pompeian law was made, which ordained, that the person convicted of this crime, after he had been first scourged till the blood came, should then be tied up in a leather jacket, together with a dog, an ape, a cock, and a viper, and so thrown into the sea, or the next river. By the English laws, this crime is treated no otherwise than as simple murder, unless the child was also the servant of his parent. 1 Hal. P. C. 380.

Parricide is also extended to the murder of any near relation, as a husband, wife, brother, sister, child, grandchild, uncle, &c. and even to that of great or sacred persons, though no way allied in blood, as a king, &c.

PARRIER, in *Geography*, a town of Hindooftan, in Oude; 35 miles S.W. of Lucknow.

PARRIDA, a small island in the Pacific ocean, near the coast of Veragua. N. lat. 7° 10'.

PARROAH, a town of the island of Ceylon; 50 miles W.S.W. of Trincomaly. N. lat. 8° 17'. E. long. 80° 34'.

PARROCEL, Joseph, in *Biography*, was born in Provence in 1645, and was the pupil of Bourgonneau, whose subjects and style he imitated, though not with so much fire and freedom of touch. He endeavoured to improve himself by a residence at Venice for some time, and did acquire somewhat of the tones of that school. His colouring is rich, deep, and fresh; and there is great beauty and animation in his designs; which were not always warlike, but sometimes of fancy, of history, and of portrait. He died in 1704, leaving a son, Charles Parrocel, who successfully imitated the compositions and manner of his father, and who died in 1729, at the age of 52.

There was also a nephew of the name of Ignatius, who also painted battle-pieces in the same style, and who died in 1722.

PARROQUET, of Parrakeet, in *Ornithology*. See Psittacus.

PARROT. See Psittacus.

PARROT, in *Geography*, a cluster of islands in Dolly bay, New Zealand; 3 miles S.W. of Taele harbour.

PARROT'S KEY, a small island in the Spanish main, near the Mosquito shore. N. lat. 10° 57'. W. long. 82° 50'.

PARR'S POINT, a cape on the N.E. coast of the island of St. Christopher.

PARRY, Richard, in *Biography*, a learned divinity, was educated at Oxford, and in 1604, was made bishop of St. Afaph. He revised the first edition of the Welsh bible, which was published in 1620. Before his elevation to the episcopal dignity, he was master of Ruthin school, Denbighshire.

PARRY, John, generally known by the appellation of the celebrated blind harper. He was the first among his contemporaries, who played either a lefion or a concerto on the treble Welsh harp, an instrument which had been long lost to the world, and owed its revival to the genius and diligence of this great performer. He died at Rhubeson, in Denbighshire, in 1782, about whose time the harp had very supererogated all other harps on the continent, as well as in our island, so that it appears as if its resurrection was for a very short period. Evans played on that truly British instrument at the oratorio in 1772, on which he accompanied "O had I Jubal's lyre."

PARRYING, in *Fencing*, the action of defending a man's self, or of felling off the thralls, strokes, &c. offered him by another. See FENCING.

Good fencers push and parry at the same time.

The Spaniards parry with the poniard. The ancients parried with their bucklers.

PARKS, in *Geography*, a town of Bavaria, in the principality of Neuburg; 18 miles N.W. of Ratibn.

PARCHINA, a town of Ruffia, in the government of Tobalk, on the Niznei Tunguska. N. lat. 60° 40'. E. long. 106° 54'.

PARKHEPATN.AM, a town of Hindooftan, in Madaraw, on the coast; 6 miles N. of Tondy.

PARKSLEY, in *Botany*, *Gardening*, and the *Materia Medica*. See Apium.

PARKSLEY, in *Agriculture*, a well known tap-rooted biennial plant. It is observed, in the twenty-second volume of the *Annals of Agriculture*, that Mr. Fleet of Hampshire, famous for curing the root of sheep, cultivates it largely with succelf; he lows half a buffer to the acre, with a buffer of rye-grafs, with spring corn; and he finds that it lasts in the ground till it is permitted to feed. He feeds it constantly, being excellent for sheep, and when fed with grass to get a head, pigs feed wonderfully upon it in the autumn. After September, it will not run to seed. When it was ploughed up, he obtained good oats. The land was poor, and the next round of the course, the clover was much the better for the pasture having been low, or the clover omitted; for in a field of half parsley, half clover, when the clover came again to be ploughed, it was excellent on the parsley half, but bad on the clover part. In laying down land to grass, Mr. Hoyte, in the fourth volume of *Communications to the Board*, advises the fowing with twelve pounds of white clover, two pounds
of red clover, two pecks of rye-grafs, and two pounds of parsely to the acre, as the parsely stands two years, and by its nature makes the prevents the sheep from dying of the red-water, which too luxuriant seeds are apt to produce.

And the following trial with this vegetable, is related in the fifth volume of the Farmer's Magazine, printed at Edinburgh. A friend of mine, says the writer, having occasion to observe the partiality of black cattle for the garden parsley, and their preference of it, when growing, to all other green food, took it in his head to try how it would succeed in a field that he was going to sow down for pasture. He accordingly sowed two or three ridges with parsley-feed, and the rest of the field with clover and rye-graft. As soon as the field was ready for pasture, he led his cattle into it, and it was perfectly evident that they preferred that part which was sown with the parsley to any other part of the field, infomuch that they never touched the rest while there was a single blade of parsley to be had. Horsetails were equally fond of it. He had not an opportunity to try sheep upon it; but the probability is, that they would, if possible, have been even more inclined towards it than the cattle.

This, therefore, seems worthy of a farther trial. We know that black cattle, sheep, horesets, and indeed every other animal, always prefer that food (when they have it in their power to make a choice) that is most agreeable to them, and most conducive to their health. We know also that parsley is a most wholesome vegetable for the human species. It is a powerful antiseptic. If we were to reason from analogy, we should suppose that its beneficial properties should extend to the animal creation in general. As it is a biennial plant, it will answer well for fields that are to be laid down for pasture for a considerable while. Sheep in particular, being of a tender and delicate constitution, and especially subject to bowel complaints, its antiseptic quality may be of great use to correct these. The difficulty may be at first to get the feed in any considerable quantity; but that may soon be remedied, if the experiment be thought worth while. He would suppose that the ground upon which it is sown mull be good, in condition and clean, otherwise it will not have a fair trial. It should of the land thrown by in more than any of the other two. This, therefore, seems worthy of a farther trial. We know that black cattle, sheep, horesets, and indeed every other animal, always prefer that food (when they have it in their power to make a choice) that is most agreeable to them, and most conducive to their health. We know also that parsley is a most wholesome vegetable for the human species. It is a powerful antiseptic. If we were to reason from analogy, we should suppose that its beneficial properties should extend to the animal creation in general. As it is a biennial plant, it will answer well for fields that are to be laid down for pasture for a considerable while. Sheep in particular, being of a tender and delicate constitution, and especially subject to bowel complaints, its antiseptic quality may be of great use to correct these. The difficulty may be at first to get the feed in any considerable quantity; but that may soon be remedied, if the experiment be thought worth while. He would suppose that the ground upon which it is sown mull be good, in condition and clean, otherwise it will not have a fair trial. It should of the land thrown by in more than any of the other two.

More experiments are wanting to fully ascertain the value of this vegetable in field culture; but it has been found very beneficial as a rabbit-food, and would constantly be raised as one of the most proper crops where these kinds of animals are kept. Se RABBIT.

PARSNOX, in Agriculture, the name of a tap-rooted plant, cultivated for the sake of the root. This sort of crop requires a rich, mellow, and deep soil, in order that the roots may have full room to thicken and run downwards. It is the garden parsnip that is made ufe of in the field culture, which has a long fibrous root much larger than the carrot, and equally sweet, nutritious, and juicy. And it has been suggested, that from its being more hardy, it is probably better suited to the northern parts of the island than the other varieties. Its early culture, and the large produce which it is capable of affording, should render it more an object of the farmer.

Soil.—The soils most suited to this sort of crop, are those of the rich, deep, friable, loamy or sandy kinds, in which the roots can get down to a great depth, and become large. It is observed by Mr. Young, that of all the roots which a farmer can cultivate, this is the most valuable; but it demands a better soil than any other crop he can put into the ground. If he has not land of an extraordinary quality, he had better not venture on the attempt. It loves a very rich, dry, patrid, sandy loam, worth 40s. or 50s. an acre, which should be ploughed as deep as possible about the end of the autumn, and left for the roots to exert their influence upon. This fine deep pulverization of the land is effected in different ways in different districts. In some it is given by ploughing the ground with a light plough, which is regulated in the fore part by two wheels being fixed to it, one of which runs in the furrow, and the other on the un-ploughed land, the former being fourteen or fifteen inches higher than the latter, and which opens down and turns the mould to the depth of about five inches; and which, the furrow is dug down with a spade, so as to form a trench of about sixteen inches in depth, proceeding in the same way till the whole of the field is prepared; but the latter, which is by means of two ploughs of different kinds, one following in the same track after the other, is by much the most expeditious and economical.

But the light plough just described, answers very well in performing the first part of the operation; and in the second, one of the trench kind must be made use of, by which the mould is railed from the bottom of the furrow made by the first, and applied over the site it had turned up. In this way the soil is not only broken up to a great depth, but the surface left in a fine flate of mould. Where this fort of tillage is practised, the work is generally performed in the more dry forts of land about the middle of February; and in those that are retentive of moisture, towards the latter end of March. The ground, after being thus exposed to the action of the atmosphere for a week or a fortnight, is harrowed lightly over in order to render it fit for the feed. In some cases, however, a flight ploughing is given to the lands intended for this crop in September, the use of the other ploughs being had recourse to in January in the succeeding year. The principal object in this business is, that of loosening and rendering the soil mellow to as great a depth as can possibly be done.

But though the use of manure is not in general so necessary for this crop as some others, where the land is not in tolerably good heart, it should constantly be employed in such proportions as may be sufficient to render it rich. Well-rotted farm-yard dung is the best adapted to this crop, being turned into the soil by a light plough immediately before the time of putting the feed into the ground.

Seed.—In the cultivating of this sort of crop, great care should be taken to have good perfectly ripened feed, and which should always be made ufe of while perfectly fresh, old feed frequently either wholly failing, or coming up with great irregularity, or in a fraggling manner.

In respect to the proportion of feed that may be employed, it must be different according to the nature of the soil and other circumstances; but in general about five pounds to the acre may be sufficient for the purpose.

As to the time of sowing, the most usual period is the early part of the spring, as soon as the frosts will admit of it; as
about the beginning or middle of February, or in the following month. It is, however, sometimes sown in the autumn of the preceding year, immediately after it has been ripened and collected from the plants, as about the beginning of September. And it is contended by some, that in this way the plants will appear more early in the following spring, and of course become large and strong before any weeds rise to injure them; and that as the plants are in little or no danger from the severity of the winter season, this is, on the whole, the most eligible period. Where the soil is, however, in a proper state of preparation, as there can be no apprehensions of their being inconvenienced by the growth of weeds, the former must be the most safe and convenient season for the purpose.

The most usual method of sowing the parsnip seed is in broadcast over the land, being afterwards covered in by means of a light harrow. It is probable that this sort of crop might be sown in rows, either by means of the drill machine, or by having small furrows made in the land, and sowing the seed over it in the broadcast method, afterwards lightly harrowing it into them. In this mode, by having the rows at sufficient distances, the crops might be kept more clean and at les expensive than in the simple broadcast method. But in this way they have not been found to answer so well.

The author of Practical Agriculture states, that in drill plots where parsnips are much cultivated as a field crop, it is the common practice to have beans at the same time with them, either planted in single rows, at the distance of four feet and a half, and about eight or ten inches from each other, or double ones at the distance of twelve feet, and eighteen inches in the rows. In this manner two crops are obtained from the same piece of ground; but unless care be taken to remove the beans in good time, great injury may be done to the parsnips. As though there may have been much leaf and item before the roots of the beans, begin to swell out and acquire their size towards August, the beans ought never to be suffered to remain longer than that period upon the ground.

After-culture.—The management of these crops, after they have been put into the ground, is, that they require to be kept perfectly clean and free from weeds during the early parts of their growth; frequent hoeing and weeding are, therefore, to be practised. Where cultivated in rows at sufficient distances, the intervals may be cleaned by the plough or horse-hoe. It is sometimes usual, where this sort of crop forms a part of field husbandry, to have recourse to the harrow before the process of hoeing or weeding is begun. This must be performed about the time the seeds first begin to germinate; as by harrowing too soon the weeds will not have rifen, and if deferred too long, there may be danger of destroying the buds of the parsnips. This is supposed more necessary on the flatter forts of soil, as it renders them more easily weeded. The first weeding may be performed about the beginning or middle of May, according to the forwardness of the plants, being at this operation only partially thinned out where they appear to fland much too close together. The same operation is to be again performed about the beginning of July; when the plants must be carefully thinned out to the distance of six inches. This sort of work is executed either by means of a small fork with two prongs, or a kind of very small spade having a short handle; the labourer, in making use of it, kneels on one knee, and, holding it in his right hand, digs and turns the mould, while with his left he pulls up and removes the weeds. After this second weeding, nothing further is found requisite in the parsnip culture.

As this sort of root strikes downwards to a great depth, and of course draws much of its nourishment from below, it may with propriety be introduced after most sorts of fibrous-rooted crops. And there is little hazard in the cultivation of parsnip crops, except from the falling of too much rain immediately after sowing, by which the seed may be in danger of being washed away; or when dry weather succeeds, from the baking of the land rendering the plants incapable of putting their roots sufficiently down. They are seldom injured by frosts or other causes during the winter season, or liable to be destroyed by any kind of insects or other vermin.

It is stated, that the produce of this sort of crop, when cultivated on a proper soil, and in a suitable manner, will, from the great size of the roots, be equal to, if not greater than, that of the carrots, and is valued as follows, per acre:—

- With regard to the methods of application of this root, they are much the same as that of the carrot. In the fattening of cattle it is found equal if not superior, performing the business with as much expedition, and affording meat of exquisite flavour, and a highly juicy quality. The animals eat it with much greediness. It is reckoned that thirty perches, where the crop is good, will be sufficient to fatten an ox of three or four years old when perfectly lean, in the course of three months. They are given in the proportion of about thirty pounds weight, morning, noon, and night; the large ones being fit in three or four pieces, and a little hay supplied in the intervals of these periods. And when given to milch-cows with a little hay in the winter season, the butter is found to be of as fine a colour, and as excellent a flavour as when feeding in the belt pastures. Indeed the result of experiments has been, that not only in neat cattle, but in the fattening of hogs and poultry, the animals became fat much sooner, and are more bulky, than when fed with any other root or vegetable. And that, besides, the methods of application, in the trials of an experienced farmer in Surry, the results were the same; he in the first place put up sixteen hogs to fatten upon them. The method he took in giving them to the hogs, was throwing the parsnips upon the ground whole. This he continued for about a month, when finding his hogs grow heavy, he observed that they did not go on so well with them as at first. Upon this he boiled the parsnips, and made wash of them; thickening the wash with half a bushel of barley-meal every day. He gave it them in a trough, and continued this for two months, when he killed them, and found them to be very good meat; weighing from 28 to 33 lb. per hog. One of them, being very large, weighed 58 lb. The next value of his hogs, when killed, amounted to 52l. 17s. 4d. The whole expense of his barley-meal with which he thickened the wash, amounted to 5l. 18s. 9d.; of the hiring to boil them, at 5d. per day, 1l. 10s.; of a boy to look after them for three months, at 6d. per day, 2l. 5s.; and sums added to the expenses attending the parsnips, prime cost of the hogs, &c. amount in the whole to 5l. 7s. So that the profit upon this article only is 17l. 16s. 8d. which remains to be carried to the account of the parsnips. After his hogs were killed, he kept four dairy cows upon the remainder of the parsnips for three months, which at 1l. 6s. per week, amounted to 5l. 12s.; and this sum added to the 17l. 16s. 8d. before mentioned, makes the net profit on the one acre of parsnips to be 21l. 8s. 7d. But he says, he must observe, that giving his dairy cows the parsnips, answered his purpose greatly, by increasing their milk, and making the butter much richer and finer than turnips or carrots, which he had given them long before; the manner in which he gave the parsnips was,
cutting them in pieces. On finding the parsnips agree with his hogs and cows to well last year, he now determined to give them to his horses; and having five that were making up for sale, he began with giving them a very few the first week. He observed then that they agreed with them extremely well, and he therefore gave them a larger quantity, which made them thrive very fast, and determined him to continue giving them the parsnips, which faved him a great deal of hay, as he found they had occasion for very little of it. He kept them in this manner for ten weeks, when he sent them to Mr. Dever's repository, where they were sold for forty guineas each horse. The manner in which he gave them the parsnips was, cutting them in small pieces, and throwing them into the manger. He calculates the expense half a guinea per week, for the parsnips for each horse, which amounts to 26l. 5s. to be carried to the account of the parsnips for this year. And he adds, that at the same time he began fattening an ox, which cost him 4l. 10s. from the plough. He was fattening thirteen weeks in fattening, and ate nothing but parsnips the whole time. He then sold him to Job Spratley, a butcher at Guildford, for 22l. 6d. per stone, weighing 152 stone 6lb., which amounted to 13l. 4s. 4d.; exclusive of the above, he had within him 22 stone 6lb. of loofe fat, which was more than ever was known to be taken out of a bullock of that weight in the town of Guildford, and it was remarked by many, that finer beef never was eaten. He mentions these particular, in order to shew the great use of parsnips, as he is convinced by experience, they are preferable to carrots or turnips. But to proceed on in his account; the profit upon this bullock amounted to 6l. 4s. 4d. which he also carries to the account of the parsnips. And, the remainder of his parsnips he gave to seven dairy cows eleven weeks, at 12s. 6d. per week each, which amounts to 5l. 5s. 6d. So that the net profit (after deducting 6l. 12s. per acre for the necessary expenses attending the parsnips, as per the calculation for last year) amounts to 28l. 10s., besides a great many of the parsnips that he gave occasionally to his other hogs and cattle, which he valued at 3l. 10s. This statement fully shews the vast advantage of cultivating this sort of crop, where the farmer has a fair proper for their being grown upon.

It has been stated, that when chopped and used with dry cut meat, hores eat them freely, and are kept in good condition with them. Parsnips are also found an excellent, wholesome, and very nourishing food for cattle in other countries.

And in France they have been used to great advantage to fatten cattle. Hogs have no other food in winter, and bullocks and oxen thrive well upon it. Cows fed with parsnips give more milk than with any other winter fodder, and it yields better butter than the milk of cows nourished with any other subsistance. Horses fatten with this food; though some pretend that it renders them less mattefome, and hurts their legs and eyes.

And cattle eat these roots raw at first, sliced lengthwise; and when they begin not to relish them, they are cut in pieces, put in a large copper, preffed down there, and boiled with only fo much water as fills up the chimns between them. They then eat them very greedily, and continue to like them.

And in addition to their advantages in these ways, the tops afford a large portion of green food for these sorts of live stock, either by having them cut off when taken up, or by being confumed in the field. In the latter method, the moit proper period of having them eaten is at the period when they begin to shrink and get dry.

In respect to their being taken up and preserved, they may be dug up with three-pronged forks in the beginning of the autumn. Feason, as potatoes, and be packed up in dry sheds in the same manner.

On this plant it has been remarked by Mr. Young, that when the soils are suitable, the inducement to the cultivation is very strong, as they fatten bullocks, as well as oxen, and are of great use with hogs. They have also the valuable property of preparing the land in an excellent manner for grain crops.

To save the seeds of this plant in the most advantageous way, some of the longest, straightest, and largest roots should be fented out and planted about two feet afunder, in a place where they will be defended from the strong fourth and well winds; for the stems of the parsnips generally grow to a great height, and are very apt to be broken by strong gulls of wind, if they are exposed thereto. The ground should also be kept clear from weeds; and if the leaven should prove dry, watering the plants moderately twice a-week will increafe the quantity, and improve the quality of their seeds, which will be ripe about the end of August, or the beginning of September, when the heads should be carefully cut off, and spread upon a coarse cloth for two or three days to dry. The seeds should then be beaten off, and put up for sale. But neither the leaven nor carrot seeds should be depended on after they are above a year old, as they seldom grow well.

Parson. Clarkly. See Echinophora.
Parson, Water, the name of a species of Sium; which see.

Parson, in Geography, a town of Hindoostan, in Baglana; 17 miles S.W. of Naderbar.
Parson, Persoon eccleple, the rector or incumbent of a parish-church; who has full poftsession of all its rights.

He is paid, by fome, to be thus called by way of eminence; the revenues of a church being defined to maintain magnum personam; or, as fome will have it, because he is bound by virtue of his office, in propria persona servire Deo; whereas imperfonare, in old charters, is to put in poftsession of a parsonage, &c. Or, according to others, because the original parsons, perfona, were, in reality, only dignitaries, and poftfessed benefices, which gave them some peronal prerogatives in the church or chapter, but no power. Or, fally, according to others, becaufe the parfon, for his time, reprefents his church, being in himfelf a body corporate, and fuff acclaim the perfon thereof, as well in faying, as being fayed, in any action touching the fame.

Some diftinguifh between a rector and parfon; the rector, fay they, is where the vicarage is endowed: and the parfon, perfona, where the parfonage is without a vicarage: the diftinction fems new and fubtle. But fon apparently fers rector and parfon as fynonymous terms.

For the difference between a parfon and vicar, fee Vicar. The method of becoming a parfon or vicar is much the fame. To both the following four requifites are indifpenfible: viz. holy orders, presentation, infitution, and induction; which fee repercutively. There are many ways by which a parfon or vicar may ceafe to be fo: viz. by death, by feflion in taking another benefice, by defecration, by renunciation, and by depriuation. See Ceccum, Confederation, Regeneration, and Depriuation.

Formerly, he who had a church by infitution and induction, only for his own life, was called parson mortal: but any collegiate or conventual body, to whom the church was for ever appropriated, was called parson immortal.

Some, again, make a diftinction between parfon simply, and parfon impofition, or imperfonated.
Parson is the rector or incumbent in possession of a parish church, whether presented or proprietary, and with whom the church is full: or a parson in possession is a clerk presented, instituted, and inducted into a rectory, or, and therefore, in complete possession.

Parson simply, they contend, is properly the patron, or he that has the right of a presentation: called parson, because, before the Lateran council, he had a right to the tythes, in respect of his liberality in erecting or endowing the church, quad suffinetur perfomam ecclesiae.

It is certain, in the register of writs, persona imperfomata is used for the rector of a benefice presentative: and, in Dyer, a dean and chapter are said to be personas imperfomata of a benefice appropriated to them. So that forma imperfomata seems only chanced into imperfomata, in respect of the possession of the benefice. See Coke on Litt. fol. 300.

Parson's Island, in Geography, a small island near the coast of Maine. N. lat. 44° 36' W. long. 67° 25'.

Parson's Town, a town of the state of North Carolina; 60 miles W. of Salisbury.—Also, a post-town of the King's county, Ireland, formerly called Bier; under which name an account of it has been already given in this work.

Parsoneage, a rector, or parish-church, endowed ordinarily with house, glebe, and tythes, for the maintenance of a minister, with care of souls, within such parish.

There may also be a rectory or parsonage without any glebe land, except the church and church-yard; and without any tythes, or other fixed income, except an annual payment, or pound rate.

Parsoneage, in its original, and, at this day, in other countries, is a benefice, which gives some prerogative, or pre-eminence in a church or chapter, but without any jurisdiction.

The ancient parsonages gave a little honour and dignity as to the person, but they gave no power; whence, apparently, the name, intimating the effect of the dignity to be referred to the person, persona parson.

Such are still the chantries in several churches, and the subchantries in others.

Some, as Oldtrae, &c., extend the word parsonage to dignitary, and comprehend under it the archdeacons, deans, &c., in cathedrals; but this seems to be straining the sense of the word.

In effect, the canonists use the term very differently; some applying it to all who have any prerogative in the choir or chapter, over the other canons, either in options, suffrages, elections, or barely in place and procession; thus confounding it with dignity; while others apply it to simple rectors, &c.

Parson, James, in Biography, a physician, anatomist, and antiquary, was born at Barnstable in 1705. His father being appointed a barrack-master in Ireland, he was taken over to that country while an infant, and received his early education at Dublin. Choosing medicine for his profession, he went to Paris for the purpose of cultivating that science, and attended the courses of all the eminent teachers of that metropolis. He afterwards visited some other continental schools, and received the degree of doctor of physic at Rhenus, in 1736. He settled in London, and was employed by Dr. James Douglas as his anatomical assistant. His practice was directed principally in the oblique line, and his residence was in Red-Lion-square. In 1740, he was elected a fellow of the Royal Society, and he maintained an intimate connection with the most distinguished of its members. He was also a fellow of the Society of Antiquaries; and he corresponded with several of the most learned and scientific men abroad. He was every where respected for his useful and extensive acquirements, and the goodness of his heart, and died much regretted in 1770.

Dr. Parson left the following works. 1. "A Mechanical and Critical Enquiry into the Nature of Hermaphrodites," Svo. 1741, which was principally a compilation. 2. "A Description of the Urinary Human Bladder, and the Parts belonging to it, with Figures," 1742, which was intended to disprove the reported utility of Mrs. Stephens' medicines for the stone. 3. "Philosophical Observations, on the Anatomy between the Propagation of Animals and that of Vegetables," Svo. 1752. As an antiquary, Dr. Parsons distinguished himself by an elaborate publication, entitled "Remains of Japhet; being Historical enquiries into the affinity and origin of the European Languages," 4to. 1767. This is a performance of great erudition and research; but the author, like most of the speculators upon these topics, is induced, by his zeal for establishing a fylum, to place too much confidence in fabulous traditions and dubious remains. He finds, in the inhabitants of the Britis Isles, the lineal descendants of Gomer and Magog, with the velliges of their primitive language. Besides these separate publications, Dr. Parsons was the author of several papers, printed in the Philosophical Transactions; &c. "Cromonian Lectures on Muscular Motion," 1745, in which he considers the muscular fibres as tubes; "Human Physiology explained," in the Appendix to the Philos. Trans. for 1746; and several other papers on anatomical and physiological subjects, especially an account of the dikection of a rhinoceros, which is valuable, and illustrated by good figures. Gen. Biog.

Parson, Robert, a musician of the 16th century, born at Exeter, admitted early into the chapel royal, and afterwards appointed organist at Welminister Abbey. He was extremely dexterous in writing upon a plain long, moving in flow notes of equal value; but the building harmonies upon an ancient or gallican chant, was no more than written deficient, which is still an exercise for young contrapuntists in the conservatories of Naples, and practised in Italy by all writers for the church. During the 16th century, many of our great harmonists displayed wonderful science and abilities in these laborious undertakings, and like some of the proud sovereigns, that were led in triumph by the ancient Romans, preferred an appearance at least of dignity and independence, even in choirs. There are some excellent compositions by Parsons in the MSS. of Christ-church college, Oxford, particularly an "Ave Maria," and an "In Nomine."

Parsonsfild, in Geography, a small town in America, in York county, in the province of Maine; 36 miles N.W. of Portland; incorporated in 1755, and containing 1350 inhabitants.

Eff. Ch. Corolla funnel-shaped, naked and pervious at the mouth; limb in five deep, recurved, equilateral segments. Stamens prominent. Filaments thread-shaped, inserted into the lower part of the tube. Anthers arrow-shaped, adhering to the middle of the stigma, their hinder lobes destitute of pollen. Germs two, sometimes but one, of two cells. Style one. Stigma dilated. Scales at the base of the germen five, either separate or united.

A genus of twining shrubs, with opposite leaves. Their flowers cymose, sometimes racemose, and either situated between the footstalks, or terminal. Mr. Brown proposes to divide them thus.

2. *P. floribunda*. Many-flowered Parfonia. (Echites floribunda; Swartz. Ind. Occ. v. 1. 534. Willd. Sp. Pl. v. 1. 1239.)—Clusters corymbose, axillary. Leaves ovate, pointed with parallel ribs. Branches straightish. Native of bushy places on the hills of Jamaica. The branches of this are, according to Swartz, nearly erect, flexible, tough, and somewhat climbing among the surrounding bushes, but not twining; they are smooth, furrowed in the upper part, often red. Leaves alternate, opposite, ovate, with a short point, entire, furnished with numerous, parallel, but not prominent, nerves, which are wanting in the foregoing species; their substance is coriaceous and laurel-like; their surface smooth and shining, paler beneath. *Folilices* axillary, compound, corymbose, shorter than the leaves. *Fowers* small, white.

3. *P. spicata*. Spiked Parfonia. (Echites spicata; Jacq. Amer. 34. t. 20. Linn. Sylf. Nat. ed. 12. v. 2. 190. Willd. Sp. Pl. v. 1. 1240.)—Spikes axillary, opposite, denfo, much shorter than the leaves. Leaves ovate-oblong. Gathered by Jacquin near Cartagena, in clove woods, where it twines round the loftiest trees, to the height of more than sixty feet. The *flnem* are an inch in diameter, ornamented, here and there, with alternate, leafy branches, about eighteen inches long. Leaves six inches long, veiny, nearly smooth. Spikes an inch and a half long, denfo, rarely divided, composed of numerous small white flowers, with scarcely any scent. Jacquin could never meet with the fruit, the flowers being all, as far as he could discover, in the course of many months, abortive. They are chiefly produced in July and August.

4. *P. capulifera*. New Zealand Parfonia. (Periplocosa capulifera; Forst. Prod. 30. Willd. Sp. Pl. v. 1. 1241.)—Chillers cymose, downy, many-flowered. Leaves ovate, emarginate, smooth. Gathered by Forster in New Zealand. His specimen before we does not answer to his specific character, the leaves being by no means lanceolate, but ovate, emarginate, an inch or inch and half long, entire, smooth on both sides, paler beneath. The *flnem* is twining.

Young branches downy. Flowers numerous, in repeatedly branched, downy-tubed, lax, cymose clusters, or panicles, which terminate the short lateral leafy shoots. In size and general appearance the flowers resemble those of *P. corymbosa*, but of their colour we know nothing. The *calyx* is downy, as well as the outside of the corolla. We know not to what the specific name alludes.

7. *P. lanceolata*. Smooth-lanceolate-leaved Parfonia. Br. p. 3.—"Cymes divided. Leaves lanceolate, pointed, smooth."—Gathered, like the two last, in the tropical part of New Holland, by Mr. R. Brown, whose specific characters are all we know of the history of these three species. This genus is entirely a stranger at present in the gardens of England; and is, as its author remarks, but too nearly related to *Lyonia,* see that article, from which it differs only in having distinct *folilices,* or at least merely cohering in some species, whereas in *Lyonia* they are perfectly united into a cylindrical capsule, divided into two cells by a parallel distinct partition.

**PART, PARIS**, a portion of some whole, considered as divided, or as divisible.

**PART, Logical,** is that referring to some universal as its whole; in which fene, the species are parts of a genus; and individuals, or singulars, are parts of the species.

**PART, Physical,** is that which, though it enter the composition of a whole, may yet be considered apart, and under its own distinct idea; in which fene, a continuum is said to consist of parts.

Physical parts, again, are of two kinds, homogeneous and heterogeneous; the first are those of the same denomination with some other; the second of a different one. See HOMOGENEOUS, &c.

Parts, again, are distinguished into subjective, essential, and integrant.

**PART, Subjective or Potential,** is the same with logical part; viz. that contained in some universal whole, not in act, but only in power. As, man and horse are in animal: Peter and Paul are in man.

**PART, Essential,** is that whereby, with the concurrence of some other, an essential whole is constituted. Thus, the body and soul are essential parts of men.

**PART, Integrant, or Integral,** is that which is necessary to the integrity of the whole. As, a head is of a man, &c.

Anatomists divide the parts of a human body into containing and contained; similar and dissimilar; and the similar, again, into spermatic and fanguineous, &c.

**Parts, Noble, or Essential,** are those absolutely necessary to life. As, the heart, lungs, liver, brain, &c.

**Parts, Natural, or Genuin,** popularly called *privy parts,* are those ministering to generation.

The finest writings of physicians are those which treat of the use of the parts. Galen's works, "De Uhu Partium," afford infinite arguments of the being and wisdom of God.

Nature,
Nature, we say, always discharges itself on the weak part, the diseased part, the part affected, &c.

Parts, Quant of. See Consent.

In chemistry, bodies are said to be resolved into their minute parts, their component parts, &c.

That art is said to separate the homogeneous parts from the heterogeneous; and the volatile, subtile, sulphureous, mercurial, &c. parts from the fixed, refr. earthy, vitreous, &c. parts.

Part, in Geometry and Astronomy, is applied to the divi-
sion of lines and circles.

The semidiameter of the circle, called also the radius, and the circumference, is divided into a hundred thousand parts; and the circumference of the circle into three hundred and sixty parts or degrees, in which two divisions all the celestial computations are made.

Parts, Aliquot and Aliquot. See the adjectives.

Part, Proportional, is a part or number agreeable and analogous to some other part or number: or a medium to find some number or part unknown by proportion and equality of reason.

Parts, Similar, are those which are to one another as their wholes are to one another.

Part, Organical. See Organical.

Part, in Music, denotes a piece of the fonce or partition written by itself. for the convenience of the musician; or it is one or more of the fucceflions of sounds which make the harmony, written apart.

Or, the parts are the sounds made by several persons singing or playing in a concert.

Music in parts was unknown to the ancients; they had but one part: all their harmony consisted in the succession of notes, none in the composition.

There are four principal parts; the treble, bass, tenor, and counter-tenor.

Some compare the four parts in music, to the four ele-
ments: the bass, they say, represents the earth; the tenor, water; counter-tenor, air; and the treble, fire.

Part, in Trigonometry. In a rectangular spherical tri-
angle, A B C, (Plate I. Trigonometry, fig. 3.) that part lying between two others, considered as extremes, is called, by some authors, the middle part. Thus, if A B and B C be the extreme parts, the angle B will be the middle part.

If the parts, considered as extremes, be contiguous to the middle part, and one of the extremes; those are called conjunct parts. Thus, if B be in the middle part, A B and B C will be in the conjunct parts.

If, between the extremes and the middle part, there lie another, besides a right angle; then the parts are said to be disjoint or separate; e.g. if B be the middle term, A C and C will be disjoint parts; because, between the middle part B, and the extreme C, there lies the hypotheneus B C, and between the middle part B, and the other extreme A C, besides the right angle, there lies the leg A B.

Thofe parts either joined to the middle part, or separated from it, are called lateral parts. See Circular Parts. Triangle, and Trigonometry.

Parts of Speech, in Grammar, are all the sorts of words which enter the composition of discourse.

The grammarians usually admit of eight parts of speech; viz. noun, pronoun, verb, participle, adverb, conjunction, preposition, and interjection. See each in its proper place. Noun, Pronoun, &c.

Part of Fortune, in Jurisdiction, is the lunar hor-
scope; or the point wherein the moon is, at the time when the fun is in the ascendant point of the call.

The fun in the ascendant is supposed, according to this
however, lose their effect. But works of this kind are now
almost wholly in disuse in this country: however, for the
fack of variety, they may, on some occasions, still be admitted,
though not immediately in the front of the house, but in
some convenient place.

Parterres, therefore, vary in their forms, extents, and
kinds from those of the common flower gardens to be met
with in many parts of the country, or the remains of those
old French parterres, which contained the shapes of family
arms, animals, &c. cut in the trees, and shell-works of dif-
ferent forms. Nuneham and Beaumont-hall have gardens
of the firl kind; and Wentworth-cause, and Leven's-park,
 furnish examples of the latter description.

It is noticed by Mr. Loudon, that in ornamental gardens
and parterres of every kind, the soil should be manured,
and much attended to; both the situation and ex-
posure should be good, and the surface of the ground beau-
tifully varied. The extent of them must be in proportion
to the nature of the place to which they belong. In gen-
eral they need not be large. In almoft every kind, a few
trees and shrubs should be introduced, to remove from the
general view the appearance of uniformity, and to break it
into separate fenes; one of which alone should be seen at a
time, that the extent of vision being circumcibed, the spe-
cator may thus be induced to examine or admire the
minute beauties of fingle objects, or small compositions.
And it is observed, that where parterres are intermingled
with lawns, those digutting lines of separation at the edges
of walks, or round groups and dug patches of flowers or
shrubs, which abound everywhere, shoid not be intro-
duced; the gravel of the walk, and the earth at the edges
of the dug patches or groups, ought to be kept nearly on
a level with the grafts on the lawn. Where much culture is
required in the groups, the line of feparation should be
delicate and graceful; and where this is not necessary, or
not much attended to, both the lives of the walk, and the
lines of the dug group, or patch, should blend and har-
monize, and, in a natural easy manner, glide insensibly into
each other. The most remarkable varieties of parterres are
thefe.

18. The general flower garden parterre, that should con-
tain only a variety of beautiful trees, shrubs, and flowers,
&c. as that a number of each will be in perfection every
month of the year, particularly in the summer season. They
should be placed in irregular groups and thickets, of dif-
ferent fizes, gliding into one another on smooth lawn, beau-
tifully varied, and broken into small confined fenes by
trees and shrubs of the molt elegant forms. And throughout
the whole, smooth gravel walks should wind in a graceful
and easy manner. In this kind of garden parterre, a green-
houfe and fioves for exotic plants and trees may be placed.
In the summer season, these plants which are reared in the
green-houfe may be dispersed throughout the garden; and
the pots being sunk in the earth, the plants will appear
as natives; or they may be arranged in a fitation by them-
theselves, and retain their own character: and, during this
season, the houfe may be filled with balls, coxcombs,
amaranths, and other tender annuals. And few elegant feats,
both covered and uncovered, may also be introduced; but
no grottos, urns, bufs, or temples, which have all their
proper places in ornamental feneery, but which, as has been
formerly remarked, are unuitable to this kind of fenee.

2dly. The winter garden parterre, which should contain
principally such trees, shrubs, plants, and other kinds of
growing vegetables, as are in perfection, or retain their ver-
dure, during this severe fenea; as most of the evergreen
tribe; and several flowering plants, as aconite, Chriftmas-
rofe, &c. and they should be grouped and arranged in the
natural manner, a dry gravel walk being carried and con-
ducted throughout the whole. In regard to situation, this
fort of parterre should conflantly be placed near to the man-
zon or residence, in order that it may be conveniently and
comfortably approached in the winter months, and the con-
servatory should be occasionally placed in it.

3dly. The spring garden parterre, which should compre-
hend all those deciduous thubs and trees which bloom or
put forth leaves the molt early in the spring, such as the
amorion, the mezecoon, the fringe tree, and several others
which puffles the fame qualities. Also all the early-blowing
flowers, as well thole of the bulbous, as the fibrous-rooted
kinds, as the narcissus, crocus, iris, cowslip, auricula, hep-
tica, and many others. Here the walks should likewise be
gravelled, and but very little, or no lawn at all, appear to the
eye.

And it is proper that this fort of garden parterre should
contain a houfe or other erection for heaths, auriculas,
and other early-flowering plants. It should also be placed near
to the former, and be connected with it and the manfon or re-
dence by a comfortable gravel walk, that they may be ap-
proached at any feason. The foils of both should be light
and dry, the situations well exposed to the sun, and sheltered
from the north and eafterly blasts or fiores.

4thly. The autumn garden parterre, which ought to com-
prize such a collection of ornamental plants and trees as may
be in full perfection at this season of the year, as most forts
of annual flowers when late fown; many kinds of herbaceous
plants, as the afper, foldago, and feveral others, as well as
various trees and thubs that continue a long time in per-
feclion, as the honey-fuckle, the rofe, acacia, and some
others.

5thly. The bulbous root parterre, which requires to be
somewhat different in form and design from any of thefe.
The general form in this fort should be as regular as possible.
It may be a square, a circle, or an oval, divided into compart-
ments, and each of thefe laid out into beds of three or four
feet broad. In this fort may be grown the different varieties
of tulips, hyacinth, ranunculuses, anemones, and other
fimilar root plants, each being cultivated in its proper
fort of foil or earth, and such a parterre may contain a fiove
or hot-houfe for the ixia and amaryllis tribe of plants, as
well as for other fimilar bulbous exotics, and have near it the
auricula and carnation fhed.

6thly. The parterre garden may also be formed solely for
the purpose of cultivating any particular family, genus, or
fpecies of thubs or plants. In this way there may be a
parterre garden of roxes, of annual flowers, of pinks and
carnations, of double flowering plants and trees, of va-
riegated kinds only, and several others; also parterres of
ferns, of grafts, and of the vegetables, natives of any par-
ticular country, as thoie of the Cape America, Siberia,
the Alps, or of any other part of the world.

Parterres may likewise exist in the forms of the ancient
British flower gardens, the Chinese gardens, the Grecian,
Roman, Italian, French, and Dutch gardens, as well as
in thoie of the modern British flower gardens.

And they are not only pleasing and amusing in themselves,
but when introduced in a pleasure ground, by their contrast
with other fenes, and with one another, may add to the va-
nety and interest of that kind of ornamental feneery.

PARTESTI, in Geography, a town of Bukovina; 18
miles W. of Suceva.

PARTHA, a river of Saxony, which runs into the
Pleis, near Leipzig.

PARTHA, in Mythology, a name of the Phallic emblem,
worshiped
worshipped by certain sects of Hindoos, and called by them Līnga; see that article. The Par'tha is, we believe, a domes-
tic idol, made of the usual conical form, with clay, and
without any thing indecent in its appearance, for females to
pay their daily adoration to. It is sometimes placed under a
tree, and circumambulated a certain number of times daily, es-
pecially by barren females, in the hope of offspring. This
ceremony is called pradaṇā, and is described under that word.

PARTHENAY, Catherine, in Biography, hereinafter to
the lordship of Soubise, was married, in 1568, to the baron
de Pons, and afterwards, in 1575, to Renatus, vicomte Ro-
han. The celebrated duke de Rohan, who so courageously
defended the Rohan banner in France during the civil wars
of Louis XIII., was her eldest son. Catherine, one of her
daughters, has rendered her name illustrious by the following
answer which she made to Henry IV., who solicited her fa-
vours: "I am too poor, fire, to be your wife, and too proud
to be your mistref."

She afterwards married the duke de

Deux-Ponts. Catherine, the subject of this article, was at
Rochelle at the time of its memorable siege, and when
the place surrendered, she and her daughters were sent to
the castle of Niort. She died in 1651, at the age of seventy-
seven. She published poems in 1572, and likewise a tra-
gedy, entitled "Holofernes," which was performed at Ro-
chelle. She translated the precepts of Iocrates to Demo-

PARTHENAY, in Geography, a town of France, and
principal place of a district, in the department of the
Two Sevres, near the river Thone. The place contains 3215,
and the canton 6319 inhabitants, on a territory of 362 ½
kilometres, in 11 communes. The trade of the town, which is
considerable, consists in cattle and corn; 21 miles N.N.E.
of Niort. N. lat. 46° 58'. W. long. 1° 10'.

PARTHENIA, the title of a thin folio book of
leffons for the Virginal, that was engraved on copper, and
published in the reign of King James I., under the follow-
ing title: "Parthenia, or the Maidenhead of the first Musicke
that ever was printed for the Virginalles. Composed by three
famous masters: William Byrd, Dr. John Bull, and Or-
lando Gibbons, Gentlemen of his Majesties most illustrious
Chappell." Bird being here called "Gentilman of his Ma-
jesties chapel," seems to imply, that he was still living when
it was published. King James died in 1525, and Bird in 1523.

The three first movements in this collection, consisting of a
Preludium; Pavana; or William Peder; and a Gallardo;
are in G minor, and may be called a Suite of leffons.
The fourth and fifth movements, Preludium; and Gallardo;
Mrs. Mary Brownle, in C; and the sixth, seventh, and eighth,
Pavana, the earle of Salisbury; Gallardo primo; and Ga-
llardo secundo, Mrs. Mary Brownle, in A minor; con-
stitute what may likewise be regarded as two other Suites de
Pieces, or sets of leffons.

PAR

PAR

THENIA, or Parthenia, in Mythology, an epitaph given
to Eurydike, because she is said to have preserved her virginity.
When the Rhodians neglected the worship of that goddess,
and their care in improving the fine arts, the Athenians began
to distinguish themselves in this respect, and took her for
their patroness. Accordingly they dedicated to her a mag-
nificent temple under the name of Parthenos, the virgin.
Phidias adorned it with a statue of gold and ivory, which was
a master-piece; and the Athenians also celebrated to her hon-
our a festival, which was afterward called "Panathenaea."
Parthenos was also a name given to Juno, from a notion that
this goddess, by bathing herself every year in the fountain
called Canathos, which was at Nauplia, recovered her vir-
}
heart-shaped, compound, naked. *Recept.* very small, convex. There are scales separating the florets, in such a manner that each female has two perfect ones at its back.

1. *P. Hyllerus.* — Cut-leaved Ballard Feverfew. *Linn. Sp. Pl.* 1452. — Ait. Hort. Kew. ed. i. v. 3. 345. — Argyrocheta bipinnatifida; Cavan. Is. v. 4. 54. t. 378. Matricaria Achaoven disca ffinus, &c ; Pink. Phyt. t. 45. f. 3. — Leaves pinnatifid, many-eleft.—Native of Jamaica, and other parts of the West Indies, as well as Mexico. The root is annual. Stem much branched, two feet high. Leaves alternate, doubly pinnatifid, with rounded sinuses, nearly smooth. *Panicula* terminal, compound, spreading, of numerous small white *flowers*, which have little beauty to recommend them, so that although the plant is raised every now and then in gardens, from foreign seed, it is seldom preferred. Cavanilles was not aware of its being already described, when he saw it flowering at Madrid in July 1797, and therefore considered it as a new genus. He describes the *flavens* as four only, the *antlers* forming a tube. The Linnaean specific name alludes to the generic appellation given by Vaillant, founded on an obscure anatomical comparison.

2. *P. integrifolium.* — Entire-leaved Ballard Feverfew. *Linn. Sp. Pl.* 1402. Mill. Illustr. t. 80. Wild. Hort. Berol. t. 4. t. 4. (Parthenitrum heleni folio ; Dill. Eth. 302. t. 225.) — Leaves undivided, oblong, toothed.—Native of North America; Michaux says Virginia and the hilly parts of Carolina. It has been 150 years, or more, in our gardens, flowering from June to the end of autumn. Root perennial. Herb much floucer and taller than the former, rough and barb. Leaves ovate-oblong, acute, rigid, rough, coarsely crenate or toothed, with one rib and many transverse veins; the upper ones clasping the stem; the lower larger, and somewhat flaked. *Flowers* in dense, terminal, corymbose panicles, white, said to droop on the approach of night, which we have had no opportunity of observing.

*Parthenium,* in *Gardening,* contains plants of the annual and perennial kinds, of which the species are the cut-leaved parthenium, or Ballard feverfew (P. hyllerus) ; and the entire-leaved parthenium (P. integrifolium). Method of Culture.—The first fort may be increased by fowing the seeds on a hot-bed early in the spring; and when the plants come up, transplanting them upon another hot-bed, about five or six inches distant, giving them water and shade until they have taken new root; after which, they must have a pretty large share of fresh air in warm weather, by raising the glazed of the hot-bed every day, and be duly watered every other day at leaf. When the plants have grown so as to meet each other, they should be carefully taken up, preferring a ball of earth to their roots, and each planted into a separate pot filled with light rich earth; and be plunged into a moderate hot-bed till fresh-rooted; after which they may be exposed, with other hardy annual plants, in a warm situation, where they will flower in July; but if the season should prove cold and wet, it will be proper to have a plant or two in shelter, either in the close, or under tall frames, in order to have good feeds, if those plants which are exposed should fail.

The second fort may be increased by sowing the roots in autumn, and being planted in the fall ground, where it will abide the cold of our ordinary winters. They afford ornament in the borders, and among potted plants.

*Parthenium,* in *Ancient Geography,* a river of the isle of Samos.—Allo, a river of Alia Minor, which ran into the Vol. XXVI.
to settle in this barren and inhospitable region. They called themselves, on their first settling here, Parthians; that is, in the old Scythian language, *Xaita*; and hence, it is said, originated the name of Parthia.

The Parthians were a courageous and warlike people, not undervalued esteemed the best horsemen and archers in the world. They were accustomed, from their infancy, says Dionysius (in *Poem de Situ Orb.*), to the warlike and manly exercises of managing a horse and handling a bow; and in both excelled all other nations. They had the art, peculiar to themselves, of discharging their arrows with incredible dexterity, whilst they were retiring at full speed, so that their retreat was more formidable than their attack. To these exercises of horsemanship and archery, the air and country very much contributed; for the dry air, as Dio observes, seafomed their bows, and their extensive plains afforded them room for training their horses. From the age of 20 to 50, they were all, without exception, obliged to serve in war, to attend the masters, learn the military exercises, and be ready, at a very short warning, to take the field. Persons of any rank or distinction among them never appeared in public on foot, but always on horseback, armed with scimitars. In war they did not use trumpets like other nations, but large hollow vessels of brass, covered with skins, such as our kettle-drums, which, being beat with hammers, yielded a very warlike sound. The Roman poets often refer to the military character and evolutions of the Parthians. Thus Virgil says in his "Georgics," l. iii.

"Fidentemque fuga Parthum verfique Sagittis."

Horace, "lib. i. Carm. Od. 19," says:

"Et verus animosum equis
Parthum dicer."  

And Ovid, "lib. iii. de Art. Am." observes,

"Ut color avercis utere Parthes equis."

In his "Fasti, lib. v." we have the following couplet:

"Quid tibi nunc mittis folitae pote terga sagittae? 
Quid loca, quid rapidi profugit ufer equi?"

Seneca, the tragedian, in his "Thyestes," says,

"Nil opus eft equis
Nil armis et inertibus
Telis, quae pruocul ingenit
Parthis, cum simulat fugas."  

Some have said that they had recourse to the aid of lions in their combats, and that at the commencement of a battle, they let them loose against the enemy: to this purpose Lucretius (l. v.) says

"Et validos Parthi pra fe miferne leones
Cum daedalibus armatis, fervifque magifrius."

Their religion was much the same with that of the Persians, and they worshipped the sun under the name of "Mithras." They believed that those who fell in battle enjoyed perpetual happiness: a doctrine suited to the genius of a warlike nation. They were religious observers of their promises, thinking it highly dishonourable not to perform their engagements, or to deceive those who repose their confidence in them.

As to their government, it was monarchical, and in the highest degree absolute. The kings treated their subjects as the meanest of slaves, and scarcely as men, whilst they put themselves on a level with the immortal gods. Their usual titles were "the king of kings, the great monarch, the brother of the sun and moon." These haughty titles they not only assumed in all the laws and edicts which they enacted, but in their letters to other princes. Their conduct corresponded to the lofty titles which they assumed; for they obliged all whom they vouchsafed to see, to kiss the threshold on their first entrance into the royal palace; to prostrate themselves before them on the ground, and to acknowledge their majesty with some offering.

The history of the Parthians is involved in great obscurity before the time of Araxes I. They were first subject to the Medes, afterwards to the Persians, and lastly to Alexander the Great, upon whose death Parthia fell to the share of Seleucus Nicator, whose successor held it till the reign of Antiochus Theus, when Araxes, shaking off the Macedonian yoke, founded a new kingdom, which became much the most powerful in the East. Araxes I. was properly the founder of the Parthian monarchy. Having induced the Parthians to revolt from Antiochus Theus, and having defeated and taken prisoner his son and successor, Seleucus Callinicus, he assumed the title of king, and established an empire in the East, which counterbalanced the overgrown power of the Romans in the west. He reduced Hyrcania, and some other neighbouring provinces; and was at last killed in a battle against Ariarathes IV. king of Cappadocia. From him all his successors of the same race took the name of Araxes; so that the empire of the Parthians was sometimes denominated the empire of the Araxesides. Araxes II. succeeded his father, and made himself master of Media, whence he was driven by Antiochus the Great. Retiring into Hyrcania, he assembled a formidable army, and compelled the king of Syria to make a disadvantageous peace; for he abandoned Parthia and Hyrcania to Araxes. After two reigns, the Parthians became very powerful under Mithridates I. The reign of this prince is regarded by authors as the epoch of the Parthian grandeur; for, under him, that empire was by far the most extensive, as well as powerful, in the East: all the countries that lie between the Euphrates and Mount Caucausus receiving law from him, and most of the princes of Asia being either subdued, or obliged to enter into an alliance with him, upon his own terms. Phraates II., who succeeded him, was overcome in three successive battles by Antiochus Sidetes, king of Syria; and having been deprived of Mecopotamia, Babylonia, and the other countries which his father had reduced, was confined within the narrow limits of the first Parthian kingdom. However, the Scythians, and Greek mercenaries, came to the assistance of Antiochus, and falling upon the Parthians, cut their army to pieces, killed their king, and laid waste his dominions. On the departure of the Greeks and Scythians to their own countries, Arshomenes I. took possession of the crown, and after a short reign, he was succeeded by his son Pacorus I., who, hearing of the great exploits of the Romans, sent ambassadors to Sylla, who was then in Cappadocia, soliciting the friendship and alliance of so powerful a people. In consequence of this alliance, peace was maintained for some time within the two empires, till at length M. Licinius Crassus, having been created consul at Rome with Pompey, and having, by the Trebonian law, obtained the dominion of Syria, and the neighbouring provinces, was prompt to his infulable avarice to make war with the Parthians, whose army was entrusted to the command of Surenas. The preemption and ardour of the son of Crassus brought on a battle between the two armies, the event of which proved fatal, not only to the father and son, but to a great number of the Romans. Although the victory was chiefly owing to the skill and valour of Surenas, Orodes, the Parthian monarch,  

jealous
jealous of his fame, perfidiously ordered him to be put to death. After this contest, the Romans and Parthians continued for some time in a state of mutual hostilities; the latter having often the advantage, and pursuing their conquests in Syria, Phcenicia, and Acha Minor, &c. At length Ventidius re-established the honour of the Roman arms; and having surprised the Parthians, attacked them at an unfavourable moment, and defeated them; Pacorus, the son of the Parthian king, being killed, while he was fighting with incredible bravery at the head of the Parthian horde. Some time after, the Parthians took ample revenge; and Statianus, the lieutenant of Sylla, was cut off with 10,000 Romans. Orodes was assassinated by his son Phraates, who exercised the same cruelty over the nobility, and all the rest of the royal family, not sparing his eldest son, left the discontented Parthians to found him on the throne. This monster prolonged his reign under the character of a warlike prince, and prosecuted a prosperous war against Antony. In process of time he made peace with Augustus, and restored all the captives and enclaves which the Parthians had taken in their wars with Caius and Antony. He also sent four of his sons, with their wives and children, as hortages to Rome. His son Phraates remained with him; and it is said that he was poisoned by his wife Thermofa, in order to place the son upon the throne. The Parthians, however, disdaining to be governed by so wicked a prince, rose up in arms, and drove him into banishment, where he perished some years after. The succeeding reigns were of short duration; and Artabanus, one of the race of the Arsacides, who reigned in Media, was called to the Parthian throne. His cruelty rendered him detestable, and afforded to Tiberius an opportunity of placing on the throne Tiridates, who was likely to be more devoted to the will of the Roman emperor. Artabanus was ultimately restored to the kingdom by the influence of Izates, king of the Adiabenians; and from this time he governed the kingdom with great equity and moderation; so that, after a reign of 30 years, he died, greatly lamented by all his subjects, leaving behind him seven sons, one of whom succeeded him. Under the reign of Nero, Vologeles, the Parthian king, sent ambassadors to the emperor, soliciting the kingdom of Armenia, and offering to renew the alliance made by his ancestors with the Roman people. Nero refused to renounce all pretensions to the crown of Armenia. Vologeles was incensed, but dreading the consequence of a war with the Romans, he at last consented that his brother Tiridates should go in person to Rome, and there receive the crown of Armenia, as a gift from Nero, who accordingly bestowed it upon him. Thus the ancient alliance between the two empires was renewed, and the affairs of the East were settled in peace. However, under the reign of Trajan, Armenia became a subject of difference between the two empires. Cofores, for some reason that is not known, invaded Armenia, and expelled Exadorus, who had been appointed king of that country by the emperor Trajan, and placed his eldest son upon the throne. But Trajan, thus incensed, determined to humble the Parthians, and for this purpose hastened into the East. His journey was so sudden and unexpected, that he reduced the whole country without opposition, and took the Armenian king prisoner. He then entered Mesopotamia, and made himself master of that opulent kingdom, never before subjected to Rome, and reduced it to a Roman province. After several contests of various illoge, Cofores was defeated by Lucius, a commander detached for this service by Trajan. The emperor having gained possession of all the best and most fruitful provinces of the Parthian empire, and perceiving that he could not maintain his con-

PARTHIA.
hat with the Romans, was alarmed by a revolt of the Per-
fines; and prepared, by the whole strength of his kingdom, to supptress it. A bloody battle ensued, and the Parthians, after the most valiant exertions, were forced to yield to the Per- fians, who were commanded by Artaxerxes, who, though of man decent, possessed great military experience. The Parthian king was taken prisoner, and soon after put to death by the order of Artaxerxes. The Parthians, having lost their king and their army, were forced to submit to the conqueror, and became vassals to a nation which had been subject to them for the space of 475 years. Thus was this gallant and warlike nation subdued at last, and the empire once more transferred to the Perfians. However, the royal family of Arfaces did not end in Artabanus, but continued to reign in Armenia, till the time of the emperor Julianian, holding that kingdom of the Perian monarchs, to whom the Aracades of Armenia were tributaries. See ARSACIDE. Anc. Un. Hist. vol. ix.

To this historical account of the Parthians we shall addjoin a concise statement of the geography of their country, more especially as very erroneous ideas concerning the local situation of this country have generally prevailed. Thence, whose knowledge of it has been chiefly derived from its wars with the Romans, have conceived Parthia to be only the country bordering on the Euphrates and Tigris; whereas Parthia proper was a small province very near to the S.E. extreme of the Caspian sea, which territory, as we have already historically detailed, after the division of Alexander's empire, fell to the choice of the Seleucidæ, kings of Syria, and of the east, about 300 years before our era. About 50 years after, Parthia rebelled; and together with Hycania, and other adjoining provinces, became an independent state under Arfaces. As the empire of the Seleucidæ grew weaker, the Parthians extended their country westward; and the fine province of Media fell to them; and within a century after the foundation of their state, it had swallowed up all the countries from the Indus to the Eu-
phrates, Bactria included: and this province had thrown off the yoke of the Seleucidæ, long before Parthia. The Parthian conquests in Armenia, about 70 years B.C., brought them acquainted with the Romans; while conquerors met theirs both in that country and in Syria. The Parthians, together with their conquests, had advanced their capital westwards, and had established it on the Tigris at Seleucia, or rather Ctesiphon (near the present Bagdad) before their wars with the Romans commenced. The expe-
ditions of Pompey and Antony, and the defeat of Crassus, need not be again recited. On occasion of the last event, the Parthians extended their conquests farther westward, but afterwards were compelled to retire; and they generally lost ground in Armenia and Mesopotamia, during the time of the Roman emperors. Trajan penetrated to their capital; and satisfied his curiosity by embarking on the Indian sea. The moderation of Adrian restored the ancient boundary of the Euphrates. In A.D. 245, Peris, or Peria proper, which had for some ages ranked as a province of Parthia, gained the ascendency; and, under Artaxerxes, put an end to the dynasty of the Arfaridae, and restored the ancient name of Peria to the empire, after that of Parthia had perished about 480 years: so that, in fact, the Parthian em-

der was considered generally, was the Perian, under another name. Rennell's Memoir.

PARTIS, name of a town of Afia Minor, in Caria.

PARTI, PARTY, or PARTED, in Heraldry, is applied to a shield or escutcheon, denoting it divided, or marked out into partitions.

The French heralds, from whom we borrow the word,
PATTERN. DIFFERENCE.

Clairaut also discovered the same theorem, of which he availed himself, in two memoirs on the Integral Calculus, printed amongst those of the Academy of Sciences, for the years 1739 and 1740. These memoirs are far more elegant and periphecal than those of Fontaine, in which this notion is first adopted, and the latter in particular is very interesting: here we find the equations drawn from the consideration of curve surfaces, and some forms of facts, in this paper, first suggested by Fontaine, Lagrange employed as the base of his elegant theory of Partial Integrals, published by him in the Memoirs of Berlin for 1774, and afterwards in his Leçons des Fonctions. But all those who preceded d'Alembert in the theory of partial differences, Euler has perhaps the greatest claim to priority of invention, having completely integrated an equation of this description in 1734, in vol. vii. of the Acta Petrop., but afterwards forgot or neglected his new calculus, not being aware probably of its extensive application to physical problems. This application we owe entirely to d'Alembert, and the great ingenuity and talice displayed in the integration of his equations, cannot fail of placing him among the first of modern mathematicians. D'Alembert was first led to this integration on attempting the solution of certain problems relating to the vibration of musical chords, and afterwards employed it with great success in his theory of the winds, the refraction of fluids, and other very difficult and delicate investigations.

Theory of Partial Differences.—Having given a slight sketch of the progress of this interesting branch of analysis, let us now endeavour to explain more particularly the nature of the calculus, and its application in one or two particular cases.

When we have any function $z$ of two variables $x$ and $y$, or of a greater number, we know that in differencing at first with $x$ as variable and $y$ as constant, and again with $y$ as variable and $x$ as constant, we obtain $d z = p dx + q dy$, $p$ and $q$ being the co-efficients that affect $dx$ and $dy$ respectively. Hence the complete differential of $dz$ is $p dx + q dy$; and $p dx$ and $q dy$ the partial differences. This definition is sufficient for our present purpose, which will be farther illustrated in the sequel.

These co-efficients above denoted by $p$ and $q$, are more commonly denoted by $d z/d x$ and $d z/d y$, which are in fact the same; for, if we differenciate first with $x$ variable and $y$ constant, and divide by $dx$, we have $d z/d x$, which represents what the function becomes on this supposition, and in the same way $dz/d y$ will represent its value, supposing $y$ variable and $x$ constant; so that the complete value of $dz$ is expressed by $dz = d z/d x dx + d z/d y dy$, and it is commonly under this form that equations of partial differences arise.

Hence every equation between the quantities

$$ z, x, y, d z/d x, d z/d y, \&c. $$

is called an equation of partial differences, and which may be compounded or not with known quantities: thus,

$$ a d z/d x + b d z/d y - xy = 0, $$

is an equation of this kind, the solution and integration of which requires, that we should find such a function of $x$ and $y$, that the co-efficient of the differential $dx$ plus the co-efficient of the differential $dy$; the first multiplied by $a$ and the second by $b$, may produce $xy$; and the method of performing this is what is called the integral calculus of partial differences.

Again,

$$ d z/d x + d z/d y - x^2 - 4xy - y^2 = 0, $$

is also an equation of partial differences, the integral of which is $z = x^2 + y^2 x$.

For differentiating this first with $x$ variable and $y$ constant, we have

$$ d z/d x = 2xy + y^2; $$

and again, with $y$ variable and $x$ constant,

$$ d z/d y = x^2 + 2xy; $$

whence

$$ d z/d x + d z/d y = x^2 + 4xy + y $$

or

$$ d z/d x - d z/d y = -x^2 - 4xy - y^2 = 0. $$

These equations, in which only the first differentials of the variables enter, are the most simple, and are called partial differential equations of the first degree. If the second differentials enter, the equation is said to be of the second degree; if the third enter, of the third degree; and so on for others:

$$ \text{thus, } d^1 z/d x^1 + d^1 z/d y^1 + P = 0, $$

is an equation of the second degree; and

$$ d^1 z/d x^2 + d^1 z/d y^2 + P = 0, $$

is an equation of the third degree, and so on of superior orders; but the first and second are those only that can be employed to any advantage, the integration of the higher orders being too complex to admit of a solution except in a few particular cases; indeed, the complete integrations of equations of the first and second degrees, is at present a difficult art of modern analysts.

In the preceding part of this article, we have only mentioned functions of two variables, but it is needless to apprise the reader that the same may have place in those of three or more variable quantities; we have merely limited our observation to those of two, for the sake of greater simplicity.

In the limits to which we are under necessity of confining this article, we cannot enter at any great length upon the method of integrating equations of this kind; but in order to give some idea of it, let us take one of the most simple cases; viz. $d z/d y = P$, $P$ being any function of $x$ and $y$, with or without constant or known quantities.

Here, then, our object is to find a function $z$, of $x$ and $y$, which being differenced with $y$ as variable, and divided by $dy$, shall be equal to the given function $P$. In order to this, let us multiply the whole by $dy$, and we shall have

$$ d z/d y = Pdy, $$

from which it follows that $P dy$ is only a part of the differential of $z$, viz. that part which arises by considering $y$ as variable; so that the integral of $d z/d y$, which is $z$, (since the expression above results from its differentiation)
PARTIAL DIFFERENCE.

Making only \( y \) variable, will be equal to \( f' = \frac{d}{dx} P \), plus a function which contains only \( x \), and which may be found after the same manner as the correction of any
other integral to render it complete from the conditions of the problem.

Let us represent this function of \( x \) by \( F (x) \), and we shall have
\[ \frac{dz}{dy} = F (x) \] and in the same manner, if we
\[ \frac{dx}{dy} = P \] we should have a solution \( f = \int P \, dx + F (y) \).

Suppose, for example, the integration of the equation
\[ \frac{dz}{dy} = axy + y^2 \]
were required. Here we should have
\[ \frac{dz}{dy} = axy \, dy + y^2 \, dy = P \, dy, \]
and
\[ \int P \, dy = \frac{axy^2}{2} + \frac{y^4}{4} \]
and as in this expression of \( P \), we have only \( y \) variable, we have, as above,
\[ z = \frac{axy^2}{2} + \frac{y^4}{4} + F (x) \]
For differencing this with \( y \) variable, we obtain again
\[ \frac{dz}{dy} = (axy + y^2) \, dy = P \, dy \]
\( F (x) \) having no differential, from the nature of the equation
being considered as constant with regard to \( y \), and as to the particular value of \( F (x) \), this must be determined from the nature of the problem from which the equation has been obtained, in the same manner as is found the correction
of an integral or Fluent.

The next equation to the preceding in the order of difficulty is,
\[ M \frac{dz}{dy} + N \frac{dz}{dx} = 0 \]
then again
\[ M \frac{dz}{dy} + N \frac{dz}{dx} + P \, z = 0 \]
and, finally, the most general of all,
\[ M \frac{dz}{dy} + N \frac{dz}{dx} + P \, z + Q = 0 \]
in which \( M, N, P, \) are any functions of \( x, y \), and constant quantities, and consequently these will be more or less complex,
according to the degree of composition of \( M, \&c. \) But the limits of this article will not allow of our entering more at length upon
the integrations of equations of the first order; we can, therefore, only refer the reader for farther information to the "Traité du Calcul Integral" of Courand and Bofut, and to the "Traité du Calcul Differenciel et du Calcul Integral" by La Croix, and the other works above referred to.

It will be proper, however, before we dismiss this article, to say a few words with regard to partial differential equations of the second degree; all that has been said above being with reference to the first degree only.

We have before observed, that every equation between a function \( z \), of two variables \( x \) and \( y \), and its partial
differences
\[ \frac{dz}{dx} \quad \frac{dz}{dy} \]
is an equation of partial differences of the second order, and
from which an idea may be formed of those of a higher degree,
as the third, fourth, or even of the indefinite order \( n \); as also of those comprehending a greater number of variables,
as \( x, y, u \); \( x, y, z \); \&c. We shall here, however, as in
the preceding case, limit our remarks to those only of two
variables. And of these we shall propose, first, the equation
\[ x \, y - \frac{d \, z}{d \, x} = 0 \]
this being the simplest partial differential
equation of the second degree.
Let it be then proposed to integrate the equation
\[ x \, y - \frac{d \, z}{d \, x} = 0 \]
In order to this, make \( \frac{dz}{dx} = u \), and we shall thus have
\[ \frac{d \, u}{dx} = \frac{dz}{dx} \]
considering \( dx \) as constant, and thus the proposed equation becomes \( x \, y = \frac{du}{dx} \), or \( y \, x \, dx = du \). Integrating
now only with regard to \( x \), we shall have \( u = \frac{x^2}{2} \, y + F (y) \).

But now instead of \( u \) put its value \( \frac{dz}{dx} \), and we obtain
\[ \frac{dz}{dx} = \frac{x^2}{2} \, y + F (y) \]
which, multiplying by \( dx \), becomes \( dx = \frac{y \, x^2 \, dx}{2} + d \, x \, F (y) \), and finally integrating with regard to \( x \) only, we have
\[ z = \frac{y \, x^3}{6} + x \, F (y) + f (y) \]
and that this is the integral sought, will appear by differencing
again this expression, observing that \( y, F (y), \) and \( f (y) \),
being each considered constant with regard to \( x \), will have no
difference; thus
\[ d \, z = \frac{y \, x^3 \, dx}{2} + d \, x \, F (y) \]
\[ \frac{dz}{dx} = \frac{x^2}{2} \, y + F (y) \]
And differencing again, and making \( dx \) constant, we have
\[ \frac{d^2 \, z}{dx^2} = \frac{2 \, y \, x \, dx}{2} \]
as first proposed.

Whence it appears, that in equations of the second degree,
in order to render the integral complete, we must connect
with it two different arbitrary functions of the variable, of
which the differential enters not into the given equation, and
the particular form of which must be found from the nature
of the problem whence the equation is deduced.

If the equation were of the third order, as \( x \, y = \frac{d^3 \, z}{dx^3} \) the steps of the operation would be nearly the same. Thus in
supposing at first \( \frac{d^3 \, z}{dx^3} = u \), we deduce \( \frac{d^2 \, z}{dx^2} = \frac{d \, u}{dx^2} \) and substituting \( \frac{d \, u}{dx^2} \) in the place of \( \frac{d^3 \, z}{dx^3} \), we shall have \( x \, y = \frac{d \, u}{dx^2} \) or
or \( d^2 z = y x \, dx \, d; \) integrating again; \( u = \frac{y x^3}{2} + F(y) \); that is \( \frac{d^2 z}{dx^2} = \frac{y x^3}{2} + F(y) \), by which the equation is reduced to the second degree; and in like manner it may now be transformed into one of the first, as
\[
\frac{d z}{dx} = \frac{y x^3}{2} + x F(y) + f(x),
\]
from which the final integral is obtained as above, viz.
\[
z = \frac{y x^4}{24} + x^2 F(y) + x f(x) + \phi(y),
\]
which may be verified the same as before by taking the successive differences.

If the proposed equation of the second order were
\[
\frac{d^2 z}{dx \, dy} = x y \; \text{we must suppose} \; \frac{d z}{dy} = u, \; \text{and then proceeding as above, we shall find} \; u \frac{d z}{dy} = \frac{y x^4}{2} + F(y), \; \text{and consequently}
\frac{d z}{dx} = \frac{y x^4}{2} + F(y) \; \frac{d y}{y} \; \frac{d x}{x}, \; \text{and integrating this again,}
\frac{z}{y} = \frac{y x^4}{4} + F(y) \; y \; f(x) \; \phi(x).
\]

Lastly, if \( z \) was a function, these variables \( x, y, \) and \( u, \) and the proposed equation for integration, was
\[
z \; y \; u = \frac{d^2 z}{dx \, dy \, du} = c,
\]
we should find by similar substitutions,
\[
z = \frac{y x^4}{2} + x^2 F(y, u) + x(\phi(x), u) + \phi(x, u),
\]
where the three arbitrary functions, necessary for completing the integral, are those formed from the different combinations of the three variables \( x, y, \) and \( u, \) taken two and two at a time.

And in a similar manner, the integral of a function consisting of any greater number of variables may be obtained, the number of arbitrary functions being equal to the exponent of the order of the equation.

The integral calculus of partial difference is sometimes considered under a different point of view, which is by finding a function of many variables, when we know the relation of the differential co-efficients of the total differential. The notation employed is also given by some authors, rather different from that given above, but our limits will not admit of entering, in this place, into any farther explanation; we shall, therefore, conclude this article with an enumeration of the principal memoirs and works on this interesting subject, not mentioned in the preceding part of this article, and to which the reader is referred for more complete information, viz. Lagrange Memoirs of Berlin, 1774, 1775; Leçons sur le Calcul des Fonctions by the same au hor; Legendre Memoires de l'Académie de Paris 1787; La Place Memoires de l'Académie 1773, and in various parts of his Mécanique Celeste. Condorcet Memoires de l'Académie des Sciences for the years 1770, 1771, and 1772; Monge Memoires presented to the Academy of Sciences, vols. vii. and ix. and in vol. iv. of the Memoirs of the Academy of Turin; Boffut, Traité du Calcul Integral; Cousin, Traité Calcul Integral; La Croix Traité du Calcul Differenciel, et du Calcul Integral; Paoli Elemen't d'Algebra, and the article Integral Calcul des Differenciel Particuliers, Encyclopédie Methodique. We cannot but regret, that in this enumeration, we are under the necessity of confining our references to foreign works only; an English author, to the best of our knowledge, having any where attempted an investigation or illustration of this difficult branch of analysis.

Partial Eclipse. See Eclipse.

PARTICIPATION, Participatio, that which gives us a part or share in any thing, either by right or grace.

In Italy, they distinguish participating officers, as prothonotaries, &c. which have a real function; from honorary ones, which have only a title, without any duty or employ.

Participation, in Music, in the tuning of keyed instruments, implies equal harmony: that is, dividing the imperfections of the scale equally among all the sounds of the system. By this means the 3d is better, and the sharp 3d worse, than in common tuning, when there is a wolf. (See Wolf.) This manner of tuning seems necessary now, and to be generally received; as modulation is so licentious, that in a long movement it is impossible, by relative founds, for the performer to guess where he shall be carried, as every key, and every chord on the instrument, are sure to be called into use before the final close in the original key. In making all the 5ths perfect, there is a redundance of a half tone. Now, if that is divided into twelve parts among all the semitones, it should seem as if no one key would suffer much; yet an ear not accustomed to such harsh major 3d's is at first much offended.

PARTICIPATIONIS MEDIUM. See Medium.

PARTICIPATO, Ital. see Temperament. Participation is likewise a mixture of the diatonic and chromatic genera in the music of the ancients, according to Padre Martini. We may, indeed, say that all modulation in modern music is brought about by the mixture or participation of the diatonic and chromatic genera. The rising or falling by minor semitones is chromatic. So that in the key of C natural, an F# which modulates into G is chromatic.

PARTICLE, Particulum, in Grammar, an adjective formed of a verb; so called because it still participates of some of the properties of the verb; retaining the regimen and signification of it: whence most authors confound it with the verb.

Mr. Harris observes, that, as a complete verb is expressive of an attribute, of time, and of an action, if we take away the action, there will remain the attribute and the time, which make the essence of a participle. There are two kinds of participles, the one called active, because expressing the subject which makes the action of the verb; as legens, audientes, reading, hearing. The other called passive, because expressing the subject which receives the action of the verb; as lectum, audiendum, read, heard.

As our adjectives are not declined, the participles, being real adjectives, are also not declined: in the Latin, &c. where the adjectives are declined, the participles active are declined likewise. Thus they say audientes, audientis, audienti, &c. and in the French the participles passive are declined like their adjectives, as j'ai lu, elle a lu, nous avons lu, &c.

In our language, the participles and gerunds are not at all distinguishable.

The English grammar lays down a good rule with respect to its participle of the part, that they all terminate in \( d, t, \) or \( n \); which analogy is liable to as few exceptions as any.

PARTICLE, Particula, in Physics, the minute part of
of a body, or an assemblage or coalition of several of the atoms of which natural bodies are composed.

Particle, in Physics and Chemistry. Those minute parts of matter, by which bodies are constituted, are called atoms or particles of simple bodies. The particles of simple bodies are unchangeable under all circumstances, so far as regards their weight and figure. The changes which bodies undergo by heat and chemical attraction, are to be ascribed only to a change of distance and arrangement of their unalterable atoms. Mathematicians may prove the infinite divisibility of matter, but nature has evidently given limits to this division. Without such limitation there would be no definite point for the commencement of compoundability, and the number and variety of compounds would be infinite. Nothing, however, is more clearly proved, than that the number and proportions of compounds are limited. This alone is sufficient to establish the following facts, that simple bodies are constituted by literally similar atoms, which are unalterable in figure, size, and weight; that compound bodies are constituted by compound particles, which are equally unchangeable by heat or mechanical action, so long as they remain combined; and that their decomposition confiits in the operation of their simple atoms. When chemists have ascertained the relative weights of the simple atoms, which is no difficult task, the proportions of all compounds will be known without the aid of experiment, and chemistry will stand on as firm a basis as mechanical science. Although we are indebted to Dalton for this beautiful system of chemical philosophy, the principles on which it is founded did not escape the penetrating eye of Newton. We find the following observations at the latter end of his 31st query.

"All these things being considered, it seems probable to me, that God in the beginning formed matter in solid, malleable, hard, impenetrable, moveable particles, of such sizes and figures, and with such other properties, and in such proportions to space, as might conduct to the end for which he formed them; and these primitive particles being solids, are incomparably harder than any porous bodies compounded of them, even so very hard as never to wear or break in pieces: no ordinary power being able to divide what God himself made one in the first creation. While the particles continue entire, they may compose bodies of one and the same nature and texture in all ages: but should they wear away, or break to pieces, the nature of things depending upon them would be changed. Water and earth, composed of old worn particles, and fragments of particles, would not be of the same nature and texture now with water and earth composed of entire particles in the beginning: and, therefore, that nature may be lasting, the changes of corporeal things are to be placed only in the various separations and new associations, and motions of these permanent particles, compound bodies being apt to break, not in the midst of solid particles, but where those particles are laid together, and only touch in a few points." He farther supposes that these primitive particles may act upon each other by laws similar to gravity, which determines the motions of malleable matter. We may, perhaps, at some period find, that chemical affinity, or that power by which the particles of simple matter act upon each other, may be no more than the force of gravity, acting upon each other at such small distances, as to make their attractions equal to greater mallees at greater distances. The primitive particles, even when their weights are the same, may attract other matter with very different forces, by being of different degrees of density. The attraction of one particle for another would be as their weights, and as the squares of their diameters inversely. For instance, the atom of copper appears to be nearly of the same weight with an atom of zinc, but their attraction for oxygen are very different. If, then, chemical affinity be of the same force with gravity, we must suppose the atom of zinc to be denser than the atom of copper in the ratio of their affinity for oxygen. If the relative affinities of bodies can be known, and can be proved of the same force with gravity; the relative density, as well as the relative weight of the atoms of bodies, may be known. A view of the Daltonian theory, with more particulars on this interesting subject, will be given under the article Proportions definite of chemical compounds.

The cohesion of the particles of matter, the Epicureans imagined, was effected by means of hooked atoms; the Aristotelians by heat, that is, by nothing at all. But for Isaac Newton it is done by means of a certain power by which the particles mutually attract, or tend towards each other. By this attraction of the particles he shews that most of the phenomena of the lesser bodies are effected; as those of the heavenly bodies are by the attraction of gravity.

Particles, for the laws of this attraction of. See Attraction and Cohesion.

All bodies, the same great author shews, consist of the same solid, perfectly hard particles or corpuscles.

Particle, in Grammar, denotes a little indeclinable word, consisting of one or two syllables at the most.

Those are properly particles which are neither declined nor conjugated.

Brightland calls particles, manners of words, because they rather serve to express the circumstances and manners of other ideas and objects of the mind, than to represent any distinct objects of their own.

Particles may be reduced under three heads: the first shew the manners or qualities of words, by being added to them; called adverbs. The second denote some circumstances of actions, and join words to words, sentence to sentence, &c. See Conjunction. The third express the emotions of the soul. See Interjection.

It is in the right use of particles, Mr. Locke observes, that more particularly confit the clearness and beauty of a good stile. To express the dependence of his thoughts and reasonings one upon another, a man must have words to shew what connection, reduction, distinction, opposition, emphais, &c. he gives to each respective part of his discourse. This cannot be rightly understood without a clear view of the pollutes, flands, turns, limitations, exceptions, and severall other thoughts of the mind. Of these there is a great variety, much exceeding the number of particles that most languages have to express them by; for which reason it happens that most of these particles have divers, and sometimes almost opposite significations. Thus the particle but, in English, has several very different significations: as in, but to say no more, where it intimates a flrop of mind in the course it was going, before it came to the end of it. I saw but two planets; here it shews, that the mind limits the sense to what is expressed with a negation of all other. You pray, but it is not that God would bring you to the true religion, but that he would confirm you in your own: the former of these intimates a supposition in the mind, of something otherwise than it should; the latter shews, that the mind makes a direct opposition between that and what goes before. All animals have senfe, but a dog is an animal: here it signifies the connection of the latter proposition with the former.

Particles is also a term in Theology, used in the Latin church for the crumbs or little pieces of consecrated bread, called pepsis; in the Greek church.
In the Greek church they have a particular ceremony, called τας μνημεια, of the particles, wherein certain crumbs of bread, not consecrated, are offered up in honour of the Virgin, St. John Baptist, and several other saints. They also give the name πολταίς, oblation, to these particles.

Gabriel, archbishop of Philadelphia, has a little treatise expressly in τας μνημεια, wherein he endeavours to shew the antiquity of this ceremony, in that it is mentioned in the liturgies of St. Chrysolom and Basil.

There has been a considerable dispute on this head, between the Reformed and the Catholic divines. Aubertin and Blondel explain a passage in the theory of Germanus, patriarch of Constantinople, where he mentions the ceremony of the particles as in use in his time; in favour of the former; Mejfiers de Port Royal contest the explanation: but M. Simon, in his notes on Gabriel of Philadelphia, endeavours to shew, that the passage itself is an interpolation; not being found in the ancient copies of Germanus; and consequently that the dispute is very ill grounded.

*Particule out of Share,* in Astronomy. See *Particula Exors.*

**Particotty,** in Geography, a town of Hindostan, in the Carnatic; 7 miles N.E. of Timevelly.

**Particula Exors,** in Astronomy, the difference between the equatorial triangle L A C (Plate XVIII. Of Sciences, fig. 16.) and its fellow B L Z.

To find the particula exors, the menial eccentricity A C, and the annual argument of the longitude H A D, being given; from the data in the triangle B C A, find the hypotenuse A B to the angle C, and to the angle C A B, find the subtense C B. Multiply C B into half the menial eccentricity A C; the product is the area of the triangle A C B. Find likewise the area of a circle described by the radius of the eccentric B L. Then as the area of the circle is to 360° or 129600; so is the area of the triangle A C B to its value in those seconds: which value is the particula exors.

**PARTICULAR, PARTICULARIS,** a relative term referring to species, or individual; and opposed to general, or universal. See General, &c.

In the schools, particular is defined to be something included under an universal; as man under animal.

Though sometimes it is also taken for an individual, as Peter.

There is a difference between particular and singular, that particular denotes a thing taken as a part; as Peter in respect of mankind: whereas singular denotes the part taken after the manner of a whole; as Peter considered in himself.

**Particular averment,** character, geography, gravity, maps, nature, proportion, quality, rheumatism, tenant, theorem, and winds. See the several subjunctives.

**Particular Epitome,** in Law. See Remainder.

**Particular Integral,** in the Integral Calculus, is that which arises in the integration of a given differential equation, by giving a particular value to the arbitrary quantity or quantities that enter into the general integral.

Thus, for example, in the equation

\[ y = \frac{2 x y}{d x} - \frac{y d y}{d x} \]

the general integral is

\[ y = 4 m (x - m) \]

and by taking \( m = 1 \), we have

\[ y = 4 (x - 1) \]

which is a particular integral.

**Vol. XXVI.**

We call also a particular integral, that which is obtained by means of an equation of inferior dimensions; thus in the above, if we make \( x = y \), we shall have

\[ y = \frac{2 y d y}{d x} - \frac{y d y}{d y} = 2 y - y, \]

which obviously answers the conditions of the equation.

So likewise in the equation

\[ x d x + y d y = d y \sqrt{(x^2 + y^2 - a^2)} \]

we see immediately, that \( x^2 + y^2 = a^2 \), will answer the conditions, and is therefore called by some authors a particular integral.

But neither this equation \( x^2 + y^2 = a^2 \), nor that obtained above, \( a^2 x = y \), is deducible from the general integration of their respective equations, and they therefore thus far differ from those integrals defined above, which arise out of the general integration, by giving to the arbitrary quantity some particular and definite value.

The term particular integral, then, though sufficiently expressive for either of these cases, ought not to be employed for both, and accordingly some authors distinguish the two cases as follows; they call a complete integral that which is drawn from the general integration; an incomplete integral, that which is found, as in the latter of the above equations, by means of an equation of inferior dimensions; and lastly, a particular integral, that which arises by giving to the indefinite quantity in the general integral some particular determinate value. But Lagrange, in his Leçons, as also in his *Théorie des Fonctions Analytiques,* instead of incomplete integrals, used the term *valeurs singulieres.*

One of the most remarkable cases of these incomplete integrals was first noticed by Clairaut. He observed there are some differential equations of the first degree, of which the integration is attended with considerable difficulty by proceeding in the usual manner, which may sometimes be found by a second differentiation, instead of leading us farther from it, as in the usual case. Such is the differential equation

\[ y d x - x d y = a \sqrt{(d x^2 + d y^2)} \]

to which we are led in the solution of the following geometrical problem. A point being given to find a curve line such, that drawing to this line a tangent, and from the given point on the tangent a normal, it shall be always of the same length. We may arrive at the solution of this problem, by supposing \( y = u \sqrt{(a^2 - x^2)} \), and separating the variables \( u \) and \( x \), which ultimately produces the equation

\[ \frac{d u}{\sqrt{(u^2 - 1)}} = \frac{d x}{\sqrt{(a^2 - x^2)}}. \]

But by differencing we are led to the solution in a much more simple manner: for if, in order to simplify the differentiation, we make \( d x = \rho \ d y \), the above equation,

\[ y d x - x d y = a \sqrt{(d x^2 + d y^2)} \]

becomes

\[ y = \rho x + a \sqrt{\left(1 + \rho^2 \right)} \]

which, although in appearance an equation in finite terms, is still a differential equation, because \( \rho = \frac{d x}{d y} \). If now we difference this equation again, we shall have

\[ d y = \rho d x + x d \rho + \frac{a \rho d \rho}{\sqrt{\left(1 + \rho^2 \right)}} \]

which, because \( d y = \rho d x \), gives

\[ \phi = x d \rho + \frac{a \rho d \rho}{\sqrt{\left(1 + \rho^2 \right)}} \]
and dividing by $dp$, we have

$$o = x + \frac{ap}{\sqrt{(1 + p')}} \quad \text{or} \quad x = -\frac{p}{\sqrt{(1 + p')}};$$

and lastly, if in the above equation

$$y = p x + a \sqrt{(1 + p')}$$

we put instead of $p x$ its proper value, as before determined,

we find

$$y = \frac{a}{\sqrt{(1 + p')}}.$$

Now, if by means of these two values of $x$ and $y$, we eliminate $p$, we shall find ultimately

$$x^2 + y^2 = a^2,$$

which is the equation to the circle the curve required, as is obvious, on the slightest consideration of the nature of the problem. It is to be observed, however, that this question admits of another solution, which arises also out of the equation

$$x \frac{dp}{y} + \frac{a \sqrt{dp}}{(1 + p')} = 0,$$

it follows that $p$ is any constant quantity $= n$, that is $\frac{dx}{y} = \frac{d}{n}.$

A constant quantity, which flew it to be a right line; and because of the indeterminate $n$, an infinite number of right lines will equally answer the conditions of the equation; and this last is one of those cases of particular integrals, as above defined.

Euler has proposed many equations of this kind, which he was led to in the solution of certain geometrical problems, which he had proposed to himself; as also many others, which belong more directly to the cases of incomplete integrals, or fngular values mentioned in the second case above; such are

$$x \frac{d}{y} + y \frac{d}{y} = \frac{a}{\sqrt{(x^2 + y^2 - a^2)}},$$

in which the fngular value is $x = x' = y = a$, an equation to the circle; but in the complete integral, viz. $y + c = \sqrt{(x^2 + y^2 - a^2)}$, we can by no means arrive at the first equation.

This and some other cases mentioned by Euler were considered by that celebrated analyst as indolable paradoxes; but Lagrange, in the Memoirs of Berlin for 1774, has explained this apparent anomaly nearly as follows.

The integral of a differential equation between two variables, contains one constant arbitrary quantity. If we regard these variables as the rectangular co-ordinates of a curve line, referred to some determined axis, it is obvious that we may imagine as many different curves to be described, all particular integrals of the proposed equation, as we can give different values to the constant arbitrary quantity, that is, we may have an infinite number. How if it happens that these curves have one constant quantity common to them all, the equation of this common tangent ought to satisfy the differential equation proposed; because some one element of this tangent is confounded with some of the elements of the curves; fill this tangent forms no part of the curves, and therefore ought not to be contained in the complete integral, but in an incomplete integral, as above defined; See Memoirs of Berlin for 1774; the Théorie des Fonctions Analytiques, and the Reçuons des Fonctions, by Lagrange; the article Integrales Particulieres, Encyclopédie Méthodique, and Montucla Histoire des Mathematique, tome iii. p.180.

PARTICULARIST, among Polémical Divines, a person who maintains particular grace, i.e. who teaches or believes, that Christ died for the elect only; and not for mankind in general. See Grace.

PARTIDO, in Geography, a small island, under the hill of St. Martin, in the S.W. part of Campeachy gulf—Alfo, a river of Mexico, which runs into the Pacific ocean, S. lat. 16° 20'.

PARTIE, Fr. Part, in English implies the melody or notes allotted to a single voice, or instrument, many of which parts constitute a chorus, symphony, or concerto. Three founds, at least, are necessary to form a chord; but a complete chord built on the generator or fundamental base with its 3d, 5th, and 8th; and each of these founds distributed into different parts, would furnish a first treble, second treble, tenor, and base. The high notes in most instruments played with a bow have no bounds, as the perfected audience can tell; but below there is a ne plus ultra. Violins can go no lower than G in the fourth space in the base, the tenor to C, unison with the second space in the base, and the violoncello to double C.

PARTIES, in Law, are those who are named in a deed, or fine, as parties to it; i.e. those who levy the fine, and to whom the fine is levied.

So they who make any deed, and they to whom it is made, are both called parties to the deed.

PARTILE Aspect, in Astrology. See Aspect.

PARTING, in the art of refining metals, is a process by which gold is separated from silver. When those metals which are oxydable in the cupel have been separated from gold, the silver not undergoing that change remains alloyed with it. This is always the case in refining jewelers' gold. In order to separate the silver, the alloy is first rolled into very thin plates, the thinner the better; these plates are to be boiled with pure nitric acid. By this means, the silver is dissolved by the nitric acid, giving to the plates a corroded appearance, as if perforated with a small instrument. When the silver ceases to be dissolved, the plates are to be melted. If the gold is required of greater purity, it may be rolled in plates, and exposed to the acid a second time. If the nitric acid contains any muriatic acid, which is generally the case with the acid of commerce, some of the gold will always be dissolved. Should this be the case, the silver should first be precipitated in the form of muriat, with common salt, and the gold afterwards thrown down with green sulphat of iron.

The most effectual method of separating gold from silver is to diffuse the whole of the thin plates in nitro-muriatic acid. The silver will be found at the bottom of the vessel in the form of muriat, while the gold remains in solution, and may be precipitated with sulphat of iron. The silver may be obtained by heating the muriat with soda in a crucible. The muriat of scd sublimes, while the silver is left pure. See Assaying.

PARTING, Dry, or parting by fusion, is performed by sulphur, which has the property of uniting easily with silver, while it does not attack gold. The most advantageous method, says Dr. Lewis, of separating a small portion of gold from a large one of silver, appears to be by means of sulphur, which unites with and corrodes the silver without affecting the gold: but as sulphurated silver does not flow thin enough to suffer the small particles of gold diffused through it to re-unite and settle at the bottom, some addition is necessary for collecting and carrying them down.

In order to the commixture with the sulphur, fifty or sixty pounds of the mixed metal, or as much as a large crucible will receive, are melted at once, and reduced into grains by lading out the fluid matter, with a small crucible made red-hot, and pouring it into cold water firred with
with a rapid circular motion. From an eighth to a fifth
of the granulated metal, according as it is richer or poorer
in gold, is reserved; and the rest well mingled with an eighth
of powdered sulphur. The grains enveloped with the ful-
phur are again put into the crucible, and the fire kept gentle
for some time, that the silver, before it melts, may be thor-
oughly penetrated by the sulphur; if the fire was hastily
urged, great part of the sulphur would be diffused with-
out acting upon the metal.

If to sulphurated silver in fusion pure silver be added,
the latter falls to the bottom, and forms there a dundr
fluid, not miscible with the former. The particles of gold,
having been enveloped with the sulphurated silver, join them-
selves to the pure silver, wherever they come in contact
with it, and are thus transferred from the former into the latter,
more or less perfectly according as the pure silver was more
or less thoroughly diffused through the mixed. It is for
this use that a part of the granulated metal was reserved.
The sulphurated mafs being brought into perfect fusion,
and kept melted for near an hour in a close covered cru-
clide, one-third of the reserved grains is thrown in; and as
soon as this is melted, the whole is well flitred, that the
fresh silver may be distributed through the mixed, to collect
the gold from it. The stirring is performed with a wooden
rod; an iron one would be corroded by the sulphur, so as
to deprive the mixed of its due quantity of sulphur, and
likewise render the subsequent purification of the silver more
troublesome. The fusion being continued an hour longer,
another third of the unflitured grains is added, and an
hour after this the remainder; after which the fusion is
farther continued for some time, the matter being flitred at
least every half hour from the beginning to the end, and the
crucible kept closely covered in the intervals.

The sulphurated silver appears in fusion of a dark brown
colour: after it has been kept melted for a certain time,
a part of the silver having escaped from the top, the
surface becomes white, and some bright drops of silver,
about the fize of peas, are perceived on it. When this
happens, which is commonly in about three hours after
the last addition of the reserved grains, sooner or later, ac-
cording as the crucible has been more or less closely covered,
and the matter more or less flitred, the fire must be im-
dimately discontinued; for otherwise more and more of the
silver, thus losing its sulphur, would subside and mingle
with the part at the bottom in which the gold is collected.
The whole is poured out into an iron mortar greased and
duly heated; or if the quantity is too large to be safely
lifted at once, a part is first laid out from the top with
a small crucible, and the rest poured into the mortar.
The gold, diffused at first through the whole mafs, is now found
collected into a part of it at the bottom, amounting only
to about as much as was reserved unflitured. This
part may be separated from the sulphurated silver above it
by a chaffed and barrier; or if more perfectly, the surface of
the lower mafs being generally rugged and unequal, by
placing the whole mafs with its bottom upwards in a cru-
clide: the sulphurated part quickly melts, leaving unflitred
that which contains the gold, which may thus be completely
separated from the other. The sulphurated silver is effayed,
by keeping a portion of it in fusion in an open crucible,
till the sulphur is diffused; and then disflaving it in aqua
fortis. If it should still be found to contain any gold, it is
to be melted again; as much more unflitured silver is
to be added as was employed in each of the former in-
jections, and the fusion continued about an hour and a half.

The gold thus collected into a part of the silver may be
further concentrated into a smaller part, by granulating the
mafs and separating the whole process. The operation may
be again and again repeated, till so much of the silver is se-
parated, that the remainder may be parted by aqua fortis
without too much expense.

The foregoing process, according to Mr. Schlutter, is
practised at Rammelberg, in the Lower Hartz. The pre-
vailing metal in the ore of Rammelberg is lead: the quan-
tity of lead is at most forty pounds in a quintal or hundred
pounds of the ore. Thelead worked off on a teft or con-
crete hearth yields about a hundred and ten grains of silver,
and the flilver contains only a three hundred and eighty-
fourth part of gold; yet this little quantity of gold, amon-
ging scarcely to a third of a grain in a hundred weight of
the ore, is thus collected with profit. The author above
mentioned confines this method of separation to such silver
as is poor in gold, and reckons parting with aqua fortis
more advantageous where the gold amounts to above a sixty-
fourth of the silver: he advises also not to attempt con-
centrating the gold too far, as a portion of it will always
be taken up again by the silver. Mr. Scheffer, however,
relates (in the Swedish Memoirs for the year 1752), that he
has by this method brought the gold to perfect finenesses
and that he has likewise collected all the gold which the
silver contained; the silver of the last operations, which had
taken up a portion of the gold, being referred to be
worked over again with a fresh quantity of gold-holding
silver. The sulphurated silver is purified by continuing it
in fusion for some time with a large surface exposed to the
air; the sulphur gradually exuoles, and leaves the silver en-
tire.

Lewis's Comp. Phil. Techn. p. 161, &c. See Gold
and Revining.

PARTING-Glases are used in the operation of parting;
they have the form of truncated cones, the bottom being
commonly about seven inches wide, the aperture about one
or two inches wide, and the height about twelve inches.
These glases vessels ought to have been well annealed,
and chosen free from flaws; as one of the chief inconveniences
attending the operation is, that the glases are apt to
break by exposure to cold, and even when touched by the
hand. Some operators secure their glases by a coating.
For this purpose they spread a mixture of quick lime flaked
with beer and whites of eggs upon linen cloth, which they
wrap round the lower part of the veffel, leaving the upper
part uncovered, that they may see the progress of the op-
eration; and over this cloth they apply a composition of clay
and hair. Schlutter advises to put the parting-glases in
copper vessels containing some water, and supported by
treves, with fire under them. When the heat communi-
cated by the water is too great, it may be diminished by
adding cold water, which mus be done very carefully by
pouring against the sides of the pan, to prevent too sud-
den an application of cold to the parting-glase. The in-
tention of this contrivance is, that the contents of the
glases, if these should break, may be received by the
copper veffel. Into a glase fifteen inches high, and ten or
twelve inches wide at bottom, placed in a copper pan
twenty inches wide at bottom, fifteen inches wide at top,
and ten inches high, he usually put about eighty ounces of
metal, with twice as much aqua fortis.

PARTING Roots in Gardening, the practice of dividing
the roots of some sorts of plants in order to their being
set out; which is an expeditious mode of increasing a great
number of fibrous-rooted perennial plants. A great num-
ber of herbaceous, fibrous, and tuberous-rooted perennial
plants often increase by the root into large clusters of
bunches, composed of numerous small slips or offsets, par-
ricularly
particularly many of the flowery tribe, such as the campanula, perennial sun-flower, golden-rod, perennial aster, polyanthus, and daisy, balm, mint, burnet, ives, and pennyroyal, with innumerable other sorts; which from one small flip or offset of the root, often in a season or two multiply into a large cluster of such offsets; and these clusters of roots being parted into several separate slips, with root-fibres at their bottom, and one or more buds at top, each commences a distinct plant; so that, by parting the roots in this way, one plant may infinitely be multiplied into many, each of which becomes alike in growth and general habit to the original, and all flower in the ensuing season in their due course; and in their turns detach from their sides all around, a due supply of offsets for further propagation.

Commonly the better general seafon for parting roots is in the latter end of summer or autumn, after they have done flowering, and the flaks are decayed; which is in August, and the two following months; in which, when the detached offsets are planted directly, they will take good root before winter. But in many hardy sorts it may be performed almost any time, in open weather, from September till March; and some of the tender kinds succeed best in spring. In these cases it should, however, be done before they begin to shoot forth their flaks or advance considerably in their spring shoots.

In performing the busines, when any plant designed to be increased has multiplied by its roots into a cluster of offsets, the whole may be either taken up entirely, and the root parted into as many slips as are furnished with fibres, &c., or a quantity of slips may be detached from the sies all around as the parent plant stands in the ground: in either method, the work may in many sorts be effected easily with the hand; and in others by the assistance of a knife, &c. And when it is wanted to make as great an increase as possible, the root may be parted into as many slips as may be convenient, provided each is furnished with some fibre or root-part, and crowned with one or more buds or eyes for forming shoots at top. But in the flowery tribe, when the detached offsets are wanted for flowering as strong as possible the ensuing seafon, they should not be parted too small, but into middling-sized slips, where practicable; which being planted in the proper places will flower in tolerable perfection in the following season. The slips should generally be planted directly by dibble; the very small ones in nursery-beds to stand till next autumn, to acquire strength; then transplanted with balls into the places where they are to remain; but the larger ones at once where they are to grow.

This method may be practised in many sorts annually, as numbers of the herbaceous perennials multiply in one seafon into large bunches.

PARTING, in Sea Language, denotes the state of being driven from the anchor, when the ship has broke her cable by the violence of the wind, waves, or current, or all of them together.

PARTISAN, in the Military Art, the commander of a partizan-party.

PARTISAN-Party, a small body of infantry, light horse, and hussars, given to a partizan, to make an incursion upon the enemy, to lurk about their camp, to disturb their foragers, to intercept their convoys, and to procure intelligence.

PARTISAN has been also applied to a halberd or pike, and to a marshal’s staff.

PARTITI, Ital. in Music, the score of a composition separated or drawn out in fipple parts.

PARTITION, the act of parting, dividing, or distributing, a thing.

The denomination partitiones oratoriae is also given to a dialogue of Cicero’s, between him and his son; in regard the discourse is, as it were, parted or divided between them.

PARTITION, in Architecture, that which divides or separates one room or apartment from another.

PARTITION, in Heraldry. See Quartering.

PARTITION, in Husbandry. The partitions in land foun with wheat by the drill, for the horse-hoeing husbandry, are different according as the wheat is foxt, in double, treble, or quadruple rows. The double row has but one partition, and this is to be used in cases where the land is suspected to be full of the seed of weeds, which might be taken out with the hand-hoe. This partition should be twelve or fourteen inches wide. Whole fields drilled in these rows might formerly have been hand-hoed at the expense of four shillings an acre; and when there is but one foot in fix, the price of that work ought to be proportionable.

The common width of the two partitions, when the wheat is foun in treble rows, is six or eight inches. Care is to be taken in this particular; for if they are planted clover, they will flarte one another before the intervals are hoed to give them a fresh supply of nourishment; and, if they are planted too far alender, the two outer rows will thrive well, but the middle row will be flarted, and look worse and weaker, because of its being at so great a distance from the hoed intervals.

In quadruple rows, the partitions are set to be seven inches wide each; at this distance the plants will thrive sufficiently, and if they are set nearer, the whole will be worse; and, if farther off the two outer rows will thrive, but the two inner ones will be flarted, by reason of their distance from the ploughed intervals. See ALEY, and Hus-

PARTITION, in Land, a dividing of lands defended by common law, or custom, among coheirs, where there are two at least.

The partition is made several ways; whereof four are by agreement, and one by compulsion.

The first partition by agreement is, when the parencers divide the land equally themselves into so many parts as there are coheirs; and each has a determinate part.

The second is, when they agree to choose some of their friends to make the division for them; and each takes a part according to seniority of age, or otherwise, as shall be agreed. In this case seniority is personal; so that if the eldest fireter be dead, the next filter, and not the issue of the firft, choosers. However, with respect to an adowson it is otherwise: the eldest and her issue, and even her husband, or her affigures, shall present alone, before the younger.

The third method of partition is, when the eldest divides, but choosers left.

The fourth is by drawing lots, thus: having first divided the land into as many parts as there are perfons, they write every part severally in a distinct scroll, and, wrapping it up, throw each into a hat, or such a thing; out of which each one draws according to superiority; and to the land is severally allotted.

The other partition, which is by compulsion, is, when one or more of the heirs, by reason of the refusal of some other, sues out a writ of partitione facienda, upon which the sheriff shall go to the lands, and make partition thereof by a verdict of the jury there impannelled; and assign to each of the parencers her part in severyality. In Kent, where land is of gravel-kind nature, they call their partition shifting.
Partition also may be made by joint-tenants, and tenants in common, by affent, by deed, or by writ. By the 8 & 9 W. c. 31, it is enacted, that if the high sheriff cannot conveniently be present at the execution of any judgment in partition, in such case the under sheriff, in presence of two justices, may proceed to execution of the writ of partition.

Partition, in Mufic, is the disposition of the several parts of a song, set on the same leaf; so as upon the uppermost ranges of lines are found the treble; in another the bass; in another the tenor, &c. that they may be sung or played either jointly or separately.

Partition, Partitis, in Rhetoric, otherwise called enumeration, is that part in which the orator acquaints his hearers with the several parts of his discourse upon which he designs to treat. Some also comprehend under this head separation, in which the orator shews in what he agrees with his adversary, and wherein he differs from him. The requisites of a good partition are the following: it must be short, so that each proposition contains in it nothing more than what is necessary; it ought to be complete, no necessary part being omitted in the enumeration; and it should consist of as few members as is consistent with the nature of the subject. The ancient rhetoricians prescribe three or four at the most; and Cicero never exceeds that number. It may be afterwards convenient to divide these general heads of a discourse, or at least some of them, into several parts or members: and this is best done as the speaker comes to each of them, in the order at first laid down. Instances of this kind occur in Cicero's oration for the Marian law.

A good partition is attended with considerable advantages; it gives light and ornament to a discourse, and affords great relief and assistance to the hearers. However, some orations, particularly of the demonstrative kind, do not require any particular proposition, being little more than a continued narrative or illustration of the subject. Ward's Orat. vol. i. p. 210, &c.

PARTITONE FACienda, in Law, a writ which lies for those who hold lands or tenements pro indivisa, and would fever to every one his part, against them that refuse to join in partition, as copartners, &c. F. N. B. 61. 31 H. VIII. cap. 1. Cowel.

PARTITURA, Itat., Partition, Fr., in Musie, implies a score, or the several parts of a composition arranged over each other, and separated into equal portions of time by bars, or perpendicular lines drawn through all the parts; whence the word score.

PARTIUM PIECE. See PIECE.

PARTNER, and PARTNERSHIP. See COMPANY, CO-PARTNER, and FELLOWSHIP.

Partners, in a Ship, are strong pieces of timber nailed round the several scuttles, or holes, in a ship's deck, wherein are contained the masts and capsterns. They are used to strengthen the deck, where it is weakened by such breaches, but particularly to support it when the mast leans against it, as impriessed by a weight of sail, or when the capster bears forcibly upon it, whilst charged with a great effort.

Some ships do not fail well unless their masts are loose, and have leave to play in the partners; but in a storm, this is dangerous, lest the partners should be weakened (as they say), i.e. forced out of their places; for then there is no help but to cut the mast by the board.

Partners is also a name given occasionally to the scuttles themselves, wherein the masts and capsterns are fixed.

PAR-TOUT. See PASS-PAR-TOUT.

PARTRIDGE, PERDIX, the tetrao perdix of Linnaeus, in Ornithology, a bird well known and esteemed at table. See Tetrao Perdix.

The partridge is a timorous and simple bird, and yet so valuable at the table, that there are a great many ways of taking it invented by sportsmen, all of which succeed from the folly and fear of the animal.

The places which partridges most delight in are corn-fields, especially while the corn grows; for that is a safe retreat, where they remain undisturbed, and under which they usually breed. They frequent the same fields after the corn is cut down, and that with another intent; for they then feed on the corn that has fallen from the ears, and find a sufficient shelter for them under cover of the stalks, especially those of wheat and flubble. When the wheat flubble is much trodden by men or beasts, they retire to the barley flubble, and will there hide themselves in coveys of twenty or thirty. When the winter comes on, and the flubble fields are trodden down or ploughed up, they can retire to the upland meadows, where they lodge in the high grass, and among the rushes; sometimes they resort to the low coppice woods, especially if there be corn lands near them.

In the harvest-time, when the corn-fields are full of men, they are found in the fallow fields next to the corn-fields, where they lie lurking among the woods till evening, and then they get over into the corn, and feed late and early on the corn in the heavens. When the proper haunts are known, the next thing is to find the birds in them: this is done variously; some will do it by the eye only; and this art can never be taught, but can be had only from long observation: the colour of the birds being so like that of the earth at a distance, that no eye but a very conserver one could distinguish them. When they are once seen, the bufinesses is to keep an eye upon them, and then to keep in continual motion. They are a very lazy bird, and by this means will let a person almost tread upon them; though, if the perfon stands still to ey it, they will rise immediately, though they are at a considerable distance.

Another method of observing them is by going to their haunts very early in the morning, or at the close of the evening, which is called jucking-time. The noise of the cock partridge is to be attended to at this time, and is very loud and ear-nell. The hen will soon come up to the cock after her making the noise, which she does by way of answer; and when they are got together, their chattering will discover them. Thus they may always be found at these times: but there is a yet better method of finding this bird, which is by the call. The bufinesses, in order to have success in this way, is carefully to learn the notes of the partridge, and be able to imitate all the several sounds. When perfect in this, the person is to go to the haunts morning and evening, and, placing himself in some situation where he can see the birds without being seen by them, he is to listen to their calling; and, when they are heard, he is to answer in the same notes, doubling again as they do: by continuing this, they may be brought to near, that the per-son, lying down on his back, may count their whole number. Having in this manner found where the birds are, the next care is to catch them.

They are so foolish, that it is extremely easy to take them in nets. In order to this, there needs no more than the going out, provided with two or three nets, with lines somewhat smaller than those of the pheasant nets, and walking round about the covey, a net is to be fixed so as to draw over them, on pulling a line at a distance. All this may be easily done; for so long as the sportsman continues moving about, and does not fix his eyes too intently upon them, they will let him come near enough to fix the nets, without moving.
moving. If they lie so straggling, that one net will not cover them, then two or three must be fixed in the same manner. The sportsman may then draw the nets over them; and they will often lie still with the nets upon them till he comes up to fright them, then they will rise, and be entangled in the net.

A second method of taking them is with bird-line: this is done by means of wheat-straws. These must be large, and cut off between knot and knot; they must be well limed with the bole and strongest bird-line, and the sportsman must carry a great number of them out with him. Having found a field where there are partridges, he is to call; and, if they answer, lie is then to tick up the limed straw in rows across two or three lands, and, going backward, call again to them, leading them on in the road where the straw is: they will follow one another like a flock of chickens, and come out to the call; and will in their way run upon the straws, and liming themselves, they will daub one another by crowding together, so that very few of them will be able to escape.

But there is yet a pleasanter way of taking them than this, that is, by driving of them: in order to this, an engine is to be made of canvas fluttered with straw, to represent a horse: this horse and nets are to be taken to the haunts of the partridges, and the nets being placed flapping or floating in the lower part of the field, the sportsman is to take the wind in his back, and get above them, driving them downwards; his face is to be covered with something green or blue; and, placing the horse before him, he is to go towards them slowly and gently; and by this means they will be raised on their legs, but not on their wings, and will run before the horse into the nets. If in the way they go into a wrong path, the horse is to be moved to face them; and they will be thus turned back again, and driven every way the sportsman pleases. See Game.

Partridges are often found very troublesome and destructive to the grain produce of the farmer. These sorts of birds principally delight to lie and bask in the corn-fields, especially while the grain is upon the land in its growing state, as it then affords them a safe and pleasant retreat, where they can remain without being in any way disturbed, and in which they can the more conveniently breed and rear their young. In this way they, however, frequently commit much injury upon the different crops, by feeding and trampling upon them, and therefore require to be destroyed. When the corn is cut, they also frequently continue in the stubble of the same fields, feeding upon the grain which has fallen out of the ears, and find in these a sufficient cover for concealing them, especially in those of the wheat kind. Afterwards, when these become thin, and much trodden down, they betake themselves to the barley and oat stubbles, or the clovers, where they collect together in large coves, and conceal themselves. In the winter part of the year they are not so often met with in these places, but retire to the low woods and uplands, or pastures, where they lie in the bushes, and among the high coarse plants. The low cop- pices very frequently supply a covering for them at this season, particularly where there are corn lands at no great distance, where they can get food that is suitable for them. They likewise confine the grain at the time of putting it into the earth, in which way they are also mischievous to the farmer.

Partridge, Indian, Coturnix Indica, the name given by the Spaniards to a bird of the West Indies, of which there are three or four species: all of which Nieremberg says, are properly of the partridge kind. See Tetrao (Coturnix). See also Colin, and Quauntzonecolin.

Partridge, Red-legged, a very delicate and valuable bird, called cotsmus by the Italians. It is distinguished from the common partridge by the redness of its beak and legs; it is of a greyish-ash colour on the back; its throat is white near the head, but has a small black spot on each side at the angle of the bill, and this white space is surrounded by a black line; its breast is of a yellowish-brown, and its wings are variegated with black, yellowish, and white. It is not found in England, but is sometimes shot in the islands of Guernsey and Jersey. See Tetrao Rufus.

Partridge, White, Perdix Albus, a name given by many to the lagopus, a rough-footed bird of the gallinaceous kind, common on the snowy mountains, and by some called the robolane. See Ptarmigan. See also Tetrao Lagopus and Albus.

Partridge, Sea, Perdix Marinia, in Ichthyology, a name given by some authors to the foal-fish, from the firmness and delicacy of its flesh.

Partridge Bay, in Geography, a bay on the south coast of Labrador. N' lat. 50° 16'. W. long. 63° 20'.

Partridge Island, an island of the South Pacific ocean, in the vicinity of Van Diemen's land, and discovered in the voyage for search of La Peroue, May 1790, and so called by some of the crew who first observed it, from an apprehension that it abounded with partridges, which were probably mistaken for quails. This small island is upwards of 150 toises in length, and situated in S. lat. 43° 23' 20". On the shore was found the low species of parsley, called "aspin prostratum," in great abundance. Many species of the "caesarina" grow here, and, among the plants, seen for the first time, was a remarkable species of the "limodorum." Numerous kinds of ferns were also collected, and a beautiful species of the "glycine," remarkable for its scarlet flower. No fresh water was found upon this island; though several forfaken huts were observed that it had been frequented by the savages. Labillardiere's Voyage in Search of La Peroue, vol. 1.

Partridgefield, a township of America, in Berkshire county, Massachusetts; 26 miles W.N.W. of Northampton; containing 1561 inhabitants.

Partunda, in Mythology, a goddes among the Romans, who presided over women at their delivery.

Parturition, in Midwifery, the act of bringing a child into the world, from parturio, to be in labour. See Labour.

Partus, Labour, the birth of a child, from partio, to bring forth. It is also used to denote the fruit, or thing produced. "Ferox diligent partus fuos." Cicero. Beasts love their offspring. See Labour.

Partus Cesareus, the delivery of a child through an opening made through the integuments of the abdomen, and into the uterus. See Cesarean Section.

Party or Partie, a faction, interest, or power, considered as opposite to another. England was, for upwards of a century, divided into two parties. See Whig and Tory.

Party, in Law. See Parties and Charter-Party. Party, in the Military Sense, is used for a small body of men, whether cavalry, infantry, or both, commanded out on any expedition, such as pillaging the country of an enemy, taking prisoners, and obliging the country to make contribution. Parties are also sent out to view the roads and ways, get intelligence, seek force, reconnoitre, or amuse the enemy upon a march; they are also frequently sent upon the flanks of an army, or regiment, to discover the enemy, or
near, and prevent surprize or ambuscade. The following allowances are granted to parties escorting defectors, in consideration of the unavoidable extraordinary wear of their clothing and necessaries on that duty; viz.

In the like proportion allowances are to be made for parties of four, five, and six men, but no higher. This, however, is to be understood as a regulation of allowance merely; it not being the intention of government thereby to restrain any commanding officer from employing larger parties on the escort duty, if he should think proper, but that whatever may be the actual number of the parties, the allowances are to be in the proportion of

Three men for an escort of from 5 to 8 defectors.

Four - - - - - - - - - - - 9 - 12

Five - - - - - - - - - - - 13 - 16

Six - - - - - - - - - - - 17 - 20

Exact returns of the said duty, as performed by each corps, are to be made up, according to a prescribed form, as soon as possible after every 24th of June and 24th of December, for the half years immediately preceding, and are to be transmitted to the office of the secretary at war, in order that the allowance may be settled. James Mill. Dict.

Parvati, Fire, denotes those who are selected to fire over the grave of any one interred with military honours, if below the rank of brigadier-general. The specific number of which the party is to consist, depends upon the rank of the officer interred.

Parvati, Worker, consists of small detachments of men under the immediate command and superintendence of officers who are employed on fatigue, which are not purely of a military nature. They are generally called fatigue duties, being different from those of parade, or of exercise in the field. They principally consist in digging canals, repairing roads, working on fortifications, except such as may be constructed in one field, or upon actual service. An addition is made to their pay, as a reward for their labour, and a compensation for their extraordinary wear of necessaries; half of which should always be paid into the hands of the captains and commanding officers of companies, for this latter purpose. James.

Parvati, Arches in buildings, are arches built between separate tenures, where the property is intermixed, and apartments over each other do not belong to the same estate.

Parvati, Blue, in the Military Art, a name formerly given to a party of robbers, who infested the roads in the Netherlands. They belonged to neither army, but robbed both sides, without any regard to paffies. Hence the term has been more generally applied to a band of military robbers.

Parvati, China, a name given by the English merchants, and others, to a sort of porcelain or china-ware, which is elegantly painted on the outside with some bright colour, and blotted or variegated with round or square spots of a different tinge. The manner in which the Chinese do this is a very simple and easy one, and may be imitated in our potteries with great ease.

They prepare as many pieces of paper as they intend to have spots on the vessel, and cut them exactly into the shape of those spots; they wet these, and then spread them smoothly on the places where the spots are to be. When this is done, they cover the vessel with the brown and gold, or any other varnish, and then take off the papers; in the places which they covered no varnish has come; so that they are so many regular white spaces. They then cover with some other colour, laying it on carefully with a pencil: when this is done, they varnish over the whole vessel with the common varnish, and bake it. In some vessels they lay on only plain blue, or plain black, in the spaces defined for spots; and after the first baking, they cover these with gold, and make them so many figures of squares, triangles, or globes, pure gold.

Parvati, Walls, in buildings, are partitions of brick made between buildings in separate occupations, for preventing the spread of fire. For the regulations prescribed by an act of 14 Geo. III. see Building, subtituting for 42d 14th.

Parvati, Jury, in Law. See Medecias Lingua, and Jury.

Parvati, in Heraldry. See Parv, Pale, and Sesse.

Parvati, in Geography, a fort of Brazil, in the jurisdiction of Paru, on the N. side of the river Amazon. N. lat. 1° 50'. W. long. 54° 10'.

Parvati, Ginepape, a river of Brazil, which runs into the Amazon, near Paru.

Parvati, in Ichthyology, the name of a very singular American fish. See Stromateus Paru, and Chetodon Paru.

Parvati, in Geography, a river of Brazil, which runs into the Atlantic, S. lat. 13° 20'.

Parvati, in Mythology, the name of the Hindoo deity Siva, the personification of the destructive, or rather renovating or changing power in their triad. (See Siva.)

The conforts of the Hindoo male divinities are termed their Sakhi, which means their energy, or active power. (See Sakti.) The females are thus coequal to their spouses, and are endowed with the same attributes, and differ, in effect, excepted, very little from them. (See Math.) A hillary of the goddess Parvati, under her various forms and names, might be extended to volumes, and many volumes, we may say scores of volumes, have, in fact, been written thereon.

The sacred romances called Puranas abound in legends relating to the origin and proceedings, the amours, quarrels, incarnations, battles, &c. adventures of this all-producing, all-pervading personification of nature. She is said, like her lord, to have a thousand names; they are figuring metricaly together, and are recited by her votaries in their propitiatory adorations. Parvati means mountain-born, the having, in one of her many terrestrial defences, sprung from such a parentage, as is noticed under the article Meru. In her name and character of Parvati, many magnificent temples are erected to her honour in different parts of India, especially on mountains and elevated situations. All mountains, as bearing a conical form, a form naturally assumed by fire, are typical of this goddess or her lord; he being a personification of that destructive, and in its form of heat, renovating, element. Throughout India, from Nepal to Ceylon, and from Siam to Surat, temples are reared to this extensively worshipped couple, and their feftaries, under various names, still offer adoration in them. At Poona the principal temple is on a hill called Parvati, or Parbatty, which gives a name to the quarter of the city in its neighbourhood. Durga is another of her names, and this name, meaning difficult of access, is appropriately given to hill forts, provincially corrupted into Dooag or Durgam. Chitteldroog, for instance, is corrupted from Sita, and Durga, names of this goddess, which, in composition, and with a grammatical copulative, mean the hill, or inaccessible place of Sita. See Chittel-droog;
of the slaughter, which gave great offence to the Hindoo followers of milder tenets and practice, the Brahmins inculcate a belief, that the poor victims rife in the heaven of Indra (see Indra), and become the musicians of his band. Under the article Kali of this work, a minute description is given of Hindoo images of this black goddes. A cap, called by both Romans and Hindoos patera (see Patra), a whip, or cord (see Pasli), a sceptre, a child, a car drawn by peacocks, and by lions, a turceted crown, a drum (called dyinside both in Greek and Sanscrit), a sphere, a torch, a lily or lotus, a serpent; a spear, a bow, with other common attributes, might be noticed as identifying the multiform, myrmimous goddes of quillon. A consideration of what is given in this work under the articles Astarte, Cybele, Diana, Juno, Proserpine, Venus, and other names of the same goddes, compared with that under this, and the various articles hence referred to, is more than sufficient to convince us of their identity.

That the names just noted, as well as Urania, Iris, and many others, are in fact of the same goddes Nature, under different forms, there can be no doubt. The Pantamorphia Mater; Dea Jana, or Diva Jana, was easily made by the Romans into Diana. Devi-jenni, the teeming goddes; Vifwa-jenni, the all-producing, are Sanscrit terms, applicable to Parvati in her character of Prakriti or Nature. Juno may be derived from Yoni; Ceres from Siri, or in one case Sris; Anna Perenna, from Ana-purna, a name of Parvati, meaning, in Sanscrit, abundance of food, or one who fills with food. In this character she holds a ladle. Astarte, as well as Either, Ahtaroth, and the Persian Sitara, meaning a star, or something sidereal, may be traced to Ahtar, another name of the Hindoo goddes, derived from a legend in which she was seated among eight points, and hence applied to the radii of a star. The learned antiquary Spon (Mif. Erd. Ant.) gives a print of a monument where Diana is called Citara; her attributes are those of Parvati, one of whose names is Kalratri, the goddes of darkness, the origin possibly of its unmeaning synonyme. Under the articles Linga and Siva, is shown that the first in the shape of a cone, mostly a black conical stone, is the phallic emblem of the latter, and of course of his comfort Parvati. Western mythologists tell us of a black conical stone that fell from heaven; it was placed in a temple of Astarte, or the moon, and itself adored as a type of the sun. See Astarte.

The Paphian goddes was also anciently symbolified by a cone. When Dr. Clarke, in his recently published "Travels," describes some antiquities of the holy land, we might almost imagine that he was in the country of the Hindoos. He describes "a subterraneous conical temple, having no resemblance to any Christian temple, its situation under the pinnacle of a mountain, one probably of the three points of the Mount of Olives, (see Muru,) the highest of which was set apart for the worship of Ahtaroth," &c. (vol. ii. p. 578.) denoting strongly the Hindoo superlation having been anciently prevalent there. The pyramids of Egypt, Stonehenge in England, and many other antiquities now remote from its scene, are referred, and with plausible arguments, to the same polytheitic source.

It is curious to see in Dr. Clarke's plate delineating the sacred pictures in ufe among the Cumbuck tribes," exact representations of Hindoo deities. In the figure that he properly styles "Diva Triformis, Luna, Diana, and Hecate," we recognize, unequivocally, the Hindoo Parvati, in one of those many forms in which she is generally termed Devi, or the goddes. Devi Tri Sakti, or with three forms, or powers, is one of her names. In Dr. Clarke's plate, the
PARVATI.

has her own mystical hieroglyphic, a type of the Yoni, on the forehead; collars, of skulls perhaps, round and pendant on her neck and belly; a glory, or nimbus round her head; fix-handed, holding a bow and arrow, the trishula or trident of Siva (see Trisula), a cone or linga, the chakra, or discus of Vishnu, his club, and lotos (see Vishnī), and the cord, or paña of Devi, before referred to; and the Kalmuck divinity sits in one of Devi's commonest postions on a throne. Such a subject we should have expected to find in the Hindoo Pantheon, rather than in Russian travels. A representation is likewise given of "Oliris or Bacchus of the Czarks." This is also a Hindoo subject, but being only two-handed there is not much scope for attributes; it has the distinguishing forehead-mark, attitude, countenance, and character of the Hindoo school. The next, "Hyperion or Phereus of the Czarks," is a barbarous representation of Krithna, with the serpent Kaliya, and other Hindoo attributes. (See Kaliya.) The "Terphichore of the Calmucks playing on the Balalaikas," is Sarrafwati with her Vina. Dr. Clarke does not say where he obtained these subjects, nor in what degree they are honoured; but we see no reason to doubt their genuineness. They have found their way into Asiatic Tartary, through China probably; and would lead us to infer that the Calmucks have, or have had, some Hindoo superstitions among them. Their name is easily traceable to the same source. Kal-mu-ki is pure Sanscrit, and means black-faced, or with the countenance of Kak; a name that is applicable to Parvati in some of her characters; although we do not recollect any specific authority for giving her that appellation.

But it would be tiresome and almost endless to follow this female Proteus through her varied changes, and the many legends detailing them in the Puranas. We will proceed to offer a lift of some of her names; and for beauty's sake, such of them as have furnished articles for this work are put in capitals, to which articles the reader desirous of farther information is thus generally refereed. Amba (see Uma). Annapurna. Amnasa. Anjanabha. Anumati. Antaragati: under this name she is invoked as a martial goddess, for strength of heart and courage. Aparajita: this has been thought the same word as the Greek Aphrodite (see Matri). Aranya-Davi, or the goddes of the forest. Ardha Nari, or half women: in this character she is represented conjoined to her spouse; one side being Siva with his attributes, the other side her own. The celebrated one-atrailed gigantic figure in the cavern temple at Elphanta, is of this subject. Aftara. Afta. Avini, meaning a mare; in this form the sun approached her as a horse, and on their nothris touching he conceived twins, who are called Avini-Kumari, represented like Caesar and Pollux, and each has the character of Eucalus among the gods. It will be recollected, that he is said to have defended from a nymaph, who in the form of a mare was impregnated with fun-beams. His name is traceable to the Sanfur, in which language Afts-Kalama means mare-defended. Bhdra. Kali (see Kali). Bhagis, as the comfort of Bhaga, a name of Siva, and of the sun. Bhavani, as comfort of Bava, a name of Siva, the author of existence. Bhavani is the general power of fecundity. Venus generatrix. Bhudevi, goddes of the earth. (See Patala-devi) Cawiski, or Kawiski. Chamunda. Chandika. Charchika. Devi, the goddes, the queen, pre-eminently so called by her sectaries, and by others. This title is, however, sometimes given to other femal divinities. Devi-jenni, the prolific goddes, or the mother of gods. Durga, or difficult of access, as noticed in an earlier part of this article. Feringahi. Ganga, the river Ganges: in this character she sprung from the head of Siva, and bore a son to him, named Karlikya, which fee, and Men and Meia. Gauri, meaning fair or young. When seen together, in pictures or statues, or conjoined as noticed before of Ardha Nari, the goddes and her spouse are frequently called Har-gauri; Hara being a name of Siva, and Hari of his confort. Indra. Iltita. Isani. Iswari (see Iswara). Iva, or of one letter, derived from I, and pronounced as a diffilable exactly like Eve. Kalratri. Kirti. Kaumari. Kali. Kattavari. Kwificki. Lilefvari (see Lileswara.) Ma. Mahakali. Mahamati. Maheshwari. Malabara. Matar. Mekara. Nila. Paleanghi. Para. Parmeswari. Pataladevi. Pedmadevi. Pikeshwari. Prabha. Prakrishi. Rajarajeswari. Rami. Raudri. Rudri. Rudrani. Sani. Samidevi. Samirami. Saraswati. Saryajaya. Sarvamangala. Satarupa. Satii. Satwii. Shashit. Shyamula. Srd. Sudurga. Sukali. Swadevi. Syama. Tamasi. Trikaledevis. Trisakidevi. Trividhia. Uma. Vageswari. Vajreswari. Viswajenni. Vyagaraya. Yoni.

In her character of Parvati, she is usually seen in pictures in company with her spouse, and is represented as of perfect beauty, splendidly drest and decorated; sometimes sitting on his knee, or on a carpet beside him, or on a tiger's or elephant's skin, presenting him amrita (ambrosia) in a golden goblet. Sometimes she is mounted with him on a white bull (fee Nandi), with their reputed sons Karlikya and Pollear; fee those articles.

Under her various forms and characters she is variously arrayed and arrayed; fee, for inancues, under Kali and Matri. Sometimes she has four, eight, twelve, sixteen, and as far as thirty-two arms. In the plates of the Hindoo Pantheon, she is represented upwards of four thousand times, in varied form and character; and legends are said to be found in the theogonical and mythological writings of the Hindoos, detailing her origin and achievements in each. In some plates of the work just alluded to, she is represented, from original subject, pre-eminent placed as the supreme object of adoration; the chief of the gods, even the three pertons of the Hindoo triad, being among her votaries. See of the Hindoo triad, under Trimurti. Such pictures and sculptures may be ascribed to the sects who adore her exclusively as Nature. Such sects are called Lingi-Lingaja, and Sakta. See those articles, and Linga.

Like their copies, the Jupiter and Juno of the Greeks, the Hindoo Mahadeva and Parvati, have, in the Puranic legends, many quarrels and reconciliations. These are, in fact, the phenomena of nature, hidden from the vulgar eye in a veil of allegory, and in such a veil sometimes, as not to be altogether decent to the taste of people less groths than the Greeks and Hindoos. The language of Parvati is occasionally as free as Juno's in the page of Homer. In illustration of this allegorical style, the following verse may be aptly introduced from fir W. Jones' spirited hymn to Ganga, a perfomation of the river Ganges. It exhibits the popular notion of a solar eclipse, for Siva's frontal or central is, like himself, the moon, obscured by the intervention of the hand of Parvati, or the moon. We see too, (for the idea of the hymn accordin strictly with the legends of Hinduftan,) the means confidently resorted to by a priest-ridden people for rerolling the equilibrium of nature's elements; and that Ganga springs, like Pallas, from the forehead of the Indian Jove.

"Above the stretch of mortal ken,\nOn blest Kailafla's top, where everyItem\n
A Glow'd
PAR

Glow'd with a vegetable gem,
Mahesa, fate, the dread and joy of men;
While Parvatl, to gain a boon,
Fixed on his locks a beamy moon,
And hid his frontal eye, in jocund play,
With reluctant sweet delay.
All nature 'lght was lock'd in dim eclipse,
Till Brahman's pure, with hallowed lips
And warbled prayers restored the day;
When Ganga from his brow, by heavenly fingers prefet,
Sprang radiant, and descending, grace'd the caverns of the wel's.'

Parvati and Saraswati are sometimes seen to correspond in character. It may, perhaps, be thus accounted for; Siva is the changing, or renovating, rather than the destroying power; he re-produces; for destruction, say the philosophers, is but reproduction in another form. This is so similar to making or creating, the province of Brahma, that the terms and powers almost coalesce. Brahma, indeed, is merely a periodical reorganizer of chaotic matter. (See Kalpa.) Parvati and Saraswati are the energies of the perfonification of those changing powers, and we may hence discern why their characters and attributes are sometimes made to accord. The confort of Brahma is occasionally, though but rarely, called Prakriti, and the helpmate of Siva, Sarasvati; here changing names and characters, as it were. Bhavani is also occasionally invoked as the goddes of speech, or eloquence, a character more especially of Sarasvatii. (See that article.) In like manner this pantomorphic goddes is found now and then to correspond in name and attributes with Lakshmi. She is occasionally seen with the chank or shell of the latter power: and with the lotos, more especially her emblem, and hence Padma-devi is a name common to both, meaning the goddes of the lotos, that plant being the emblem of female beauty, and being aquatic, also of humidity; and both these goddesse assume the character of the Venus of the Greeks. (See Lakshmi and Rhemba.) Sri, or the blessed or fortunate, is likewise a name given to them both.

The fectaries of this goddes, who under different names, and adoring her under different forms, are numerous, have various symbolical marks by which they are distinguished. Generally speaking, horizontal lines on the forehead distinguish the Sivas from the Visnus, (see those articles,) the latter having them perpendicular. On the subject of such fectarian marks and distinctions, a plate exhibiting a great many, with copious remarks, is given in the Hindu Pantheon, to which we refer those discriminative of farther information hereon.

It has been noticed that to this goddes, in her character of Kali, it was that human victims were formerly offered. The rites and ceremonies to be observed on these litorid occasions, are minutely laid down in the Kalika Purana, extracts from which are given under the article NARAYANA of this work. See also Kali and Purana.

Parvati, in Geography, a chain of mountains debouched by Prolevy, corresponding to the heights of Sihamanroec, lying S.E. of Candilir, and being the southern boundary of the province of Paro-pamissus.

Parwich, in Geography, a small island in the Adriatic, near the coast of Dalmatia, fertile in grapes, olives, and mulberries.

Parvise. See Parvise.

Parulis, from pox, and which, the gums, in Surgery, an inflammation, or abeeches of the gums; a gumboil. See Gums, Dissease of.

Parur, in Geography, a town of Hindoostan, in Cochin; 10 miles S.S.E. of Crranganore.

Parus, the titmouse, in Ornithology, a genus of birds of the order Passeres. The generic character is; bill very entire, narrow, subcompressed, strong, hard, pointed and covered at the base with bristles; the tongue is truncate, bristly at the end; the toes are divided to the origin, the hind one large and strong. These birds are found in almost every part of the old continent, from the north of Europe to the south of India. They are highly prolific, laying eighteen or twenty eggs, which they hatch with unwearied patience. They build their nests with particular neatness and skill, and very often on the extremity of some branch suspended over water, by which they secure it from the attacks of various animals, to which it might otherwise fall a prey. They are wonderfully active and alert, rapid and adroit in their search for insects, on which they principally subsist, under the bark, and in the crevices of trees, which they clear of the immense multitudes of caterpillars covering them in spring, and which would totally blight their vegetation. They are not migratory, though they occasionally change their residence for short distances. They are irritable and irascible to a great degree, and when angry, will display the ardent eye and ruffled plumage, which indicate the paroxysm of agitation. They possess a very extraordinary degree of courage, and will sometimes attack birds three times their fize. The owl is not secure from their rage; and whatever bird they pursue, their first attempts are levelled at the head, and particularly at the eyes and bristis, the latter of which they devour with particular avidity and relish. According to Gmelin, there are thirty-one species, though Linnaeus describes twenty-four only.

Beak: Touquet Titmousse. Head crested, on the forepart black; body cumerous; beneath white rufous. It inhabits the woods of North America, and is five inches long. The bill is black; crest pointed, grey; orbits pale rufous; quill and tail-feathers edged with grey rufous; the tail is slightly forked, the legs are of a lead colour. The female has a white belly.

Crissatus: Crested Titmousse. Head crested; collar black; belly white. Inhabits Europe, chiefly in fir-woods; is five inches long, solitary, and not easily tamed.

Major: Great Titmousse. Head black; temples white, nape yellow. The bill, chin, and tail are black; the back and wings are olive; rump blue-grey; belly greenish-yellow, divided in the middle by a band of black, extending to the vent; the quill-feathers are of a dusky colour, edged partly with blue and partly with white; exterior fides of the outmost tail-feathers white, of the others blueish; inner fides dusky, legs lead-coloured. This species weighs little more than an ounce, and is almost six inches in length. It is found in Europe, Asia, and Africa, and is very common in this country, frequenting gardens and orchards, where it does a deal of mischief, by picking off the tender buds of trees. The nest is made of moss, lined with hair, and placed in the hole of a wall, or of a tree. The female lays six or eight or ten eggs, which are white, spotted with a rusty kind of colour, and so exactly like those of a nut-hatch, as not to be distinguished from them. The common note of the great titmousse is a sort of chatter, but in the spring it affumes a greater variety, a thrill whistle, and a very singular noise, something like the whetting of a saw, but the ceaee with incubation. There is a variety of this species, called the crook-billed titmousse, which is olive-brown, beneath dirty-yellowish; the head is black, the temples cumeous; the bill forked. This bird was killed once near Feverham in Kent; it had its bill croffed, as in the Locxia curvirostra.
PARUS.

IGNOTUS; Stremlian Titmouse. Yellow-green; breast yellow, spotted with rufous; belly blue; vent yellowish. It inhabits Norway, and very much resembles the Major.

CAUSUS; Azure Titmouse. Pale blue, beneath snow; rump and crown whitish-hoary; neck above white, with a broad blue band; shoulders and tail-coverts blue. It is found in divers parts of Russia and Siberia, and is about five inches long.

AMERICANUS; Creeping Titmouse. Blueish; temple, breast, and back yellowish; flanks of a purple colour. It inhabits Carolina and Canada, is nearly five inches long; continually runs up and down trees in search after insects.

* C. MARUS; Blue Titmouse. Quill-feathers blueish, the primaries white on the outer edge; front white; crown blue. The bill is blackish; line from the bill to the eyes, and one surrounding the temple, black; the back is of a yellowish-green; wing-coverts blue; quill-feathers black, with dusky edge; tail blue, the middle feathers longer, body whitish-yellow beneath; legs and claws black. It is about four inches and half long, and weighs less than half an ounce. This species would, probably, be much admired for its beauty, if it were less common. In winter it frequents houses, and will devour flesh very greedily. It is also a constant attendant where horse-fleath is kept for hounds, and in the farm-yard, being very fond of oats; which it plucks out, and retiring to a neighbouring bush, fixes the grain between its claws, and hammers it with the bill, to break the husk. In summer it feeds chiefly on insects, in search of which it plucks off a number of young buds from the trees. The nest is made very like that of the Major, and the female is so tenacious of her nest, that the will often suffer herself to be taken rather than quit it. She menaces every intruder in a singular manner, hailing like a snake, erecting all its feathers, and uttering a noise like the fretting of a cat, biting, at the same time, cleverly, if handled.

ATRICAPILLUS; Canada Titmouse. Cap and chin black; body cinereous, beneath it white. It inhabits North America, is four inches and a half long; feeds on worms and insects, and is very patient of cold.

* A. CALEO; Creole Titmouse. Head and back cinereous; hind head and breast white; the bill and chin are black; a broad black stripe beneath the eyes, from the bill to the neck; belly and vent redbrown; wing-coverts grey, t ipt with white; quill and tail-feathers brownish ash, edged with grey; legs and claws lead-coloured. It does not weigh much more than a quarter of an ounce, and is four inches in length. It has frequently been confounded with the next, the Palustris, but is not so common; it keeps more to the woods, seems to live entirely on insects, and has also a different note.

* PALUSTRIS; Marsh Titmouse. Head black; back cinereous; temples white. There are three varieties. 1. Wings without the white bands. 2. Body beneath and band on the hind-head white. 3. Crown black; nape yellowish. This species inhabits different parts of Europe; it is fond of flesh and also of oats, like the blue titmouse. It is partial to low wet ground; in the holes of which it frequently nests.

VIRGINIANUS; Virginian Titmouse. Rump yellow; body cinereous. It inhabits Virginia and Carolina, and is five inches long. The bill is black, body above olive brown, beneath grey; legs and claws brown.

PEREGRINUS; Crimmon-rumped Titmouse. Rump scarlet; body cinereous, beneath white. It is of the size of the P. major. The quill-feathers are brown; tail-feathers black, except the four middle ones, which are obliquely yellow on the hind part.

GRISEUS; Crimmon-crowned Titmouse. This is of a grey colour; the crown is red. It inhabits Greenland.

AFR; Black-brested Titmouse. Blackish; cheeks, nape, and belly white; neck beneath, and breast black. It is found at the Cape of Good Hope, and is six inches long.

CAUDATUS; Long-tailed Titmouse. Crown white; tail longer than the body; it weighs about a quarter of an ounce, and measures five inches and a quarter in length. This is a very elegant and singular species, and is chiefly confined to the woods and thickets of Europe and Siberia, where it makes a curious oval nest of lichens, firmly woven together with wool, and having only a small hole on the side, placed in the fork of some bush, or branch of a tree. The female lays from nine to seventeen eggs, which are white, and sparingly marked with small dull-coloured spots towards the larger end.

CAPENSIS; Cape Titmouse. Greyish; quill-feathers black, edged with white; tail above black, beneath white. The bill and legs are black. It inhabits the Cape of Good Hope. It constructs a luxurious nest of the down of a species of afeleniae; near the upper end projects a small tube, about an inch in length, with an orifice about three-fourths of an inch in diameter. Immediately under the tube is a small hole in the side, that has no communication with the interior of the nest. In this hole the male sits at night, and thus both male and female are screened from the weather.

BIARMICUS; Bearded Titmouse. Rufous; crown hoary; tail longer than the body; head bearded; vent black. It inhabits the marshy places in many parts of Europe, is about six inches long, feeds its nest between three reeds; the eggs are reddish-white, with small red spots.

SINENSIS; Chinese Titmouse. Rutty-brown; head and neck paler; quill-feathers and long tail brown, edged with black. It inhabits China; is not quite four inches long. The bill is black; the legs are red.

MALABARICUS; Malabar Titmouse. Grey; chin, wings, and middle tail-feathers black; body beneath, rump, spot on the wings, and base of the lateral tail-feathers, tawny. It inhabits Malabar, is nearly six inches long. The bill is black; the irides red. The under part of the female is rufous yellow.

ALPINUS; Alpine Titmouse. Black, beneath pale rufous, spotted with black; from the base of the bill to the neck there is a white line; hind-claw very long. It inhabits the alpine parts of Perula, and is about the size of the P. caudatus.

SIBIRICUS; Siberian Titmouse. Grey-brown, beneath whitish; belly rufous-grey; lower part of the neck black in the middle; fides pale rufous. A variety of this species has the belly and vent white. It is found in Siberia, and is about five inches long.

KSIASIK; White; beneath, ocular line, and collar livid. It is found among the oak forests of Siberia.

HUDSONIUS; Hudson's Bay Titmouse. Reddish-brown; back cinereous; throat black; band under the eyes and breast white; the fides are rufous. It inhabits Hudson's Bay, and is about five inches and a half long.

MACROCEPHALUS; Great-headed Titmouse. Black; breast orange; belly whitish; head tumid; spot on the front and wings, and two outmost tail-feathers, white. A variety of this species has the breast scarlet. It is found in New Zealand, and is about four inches and a half long.

NOYA SEELANDIX; New Zealand Titmouse. Red-ash, beneath
beneath rufous-grey; eye-brows white; two middle tail-feathers black; the lateral ones in the middle with a square black spot. It inhabits New Zealand, and is five inches long. The bill is brown, tipt with black; legs dusky-black.

**Pendulinar**; Penduline Titmouse. Head ferruginous; ocular band black; quill and tail-feathers brown, and edged on each side ferruginous. It is about four inches and a half long. It inhabits Europe and Siberia, frequenting watering-places for the sake of aquatic insects, on which it feeds. These birds display great art in the construction of their nests. They employ the light down found on the buds of the willows, the poplar, on thistles, and the dandelion. With their bill they entwine this filamentous substance, and form a thick close web, almost like cloth. They fortify externally with fibres and small roots, which penetrate into the texture, and, in some measure, compose the basis of the nest. They line the inside with the same down, but not woven, that their young may lie soft; they flit it above to contain the warmth, and they suspend it with hemp, nettles, &c., from the chief of a small plant branch over some stream, so that it may rock more gently, afflicted by the spring of the branch. In this situation, the brood are well supplied with insects, which constitute their chief food, and, after the same time, they are protected from their enemies. The nest sometimes resembles a bag, and sometimes a short purse. The aperture is made in the side, and is almost always turned towards the water. It is nearly round, and only an inch and a half in diameter, and is frequently surrounded by a brim. These nests are found in the fens of Bologna, Tuscany, Lithuania, Poland, and Germany. The peasants regard them with superstitious veneration, one of them being usually suspended near the door of each cottage, as a charm against lightning.

**Narponensis**; Langedoc Titmouse. Rufous-grey; crown hoary; wings and tail blackish, edged with rufous, primary quill-feathers edged with white; four inches long. It inhabits France, and builds a strong pendulous nest on the forked branch of a tree. The bill is black; the upper mandible edged yellow-brown; the legs are of a lead colour.

**Cela**; Guiana Titmouse. Black; bill white; spot on the wings and base of the tail yellow. It inhabits Guiana.

**Amatorius**; Amorous Titmouse. Blackish-blue; longitudinal spot on the middle of the wings half yellow, and rufous; five inches and a half long. It inhabits Northern Asia, and is remarkable for the mutual affection of the two sexes. The bill is black at the base, and tipp with orange.

**Coccineus**; Scarlet Titmouse. Cinerous; breast, spot on the wings, rump, and lateral tail-feathers on the hind part, scarlet. The bill and legs black, the vent is yellowish.

**Indicus**; Indian Titmouse. Above cinereous, beneath ferruginous; chin and throat of a dirty white; the limbs are black-brown. It inhabits India.

**Parusa**, in *Mythology*, is a name applied by the Hindoos to several of their deities. The word seems to mean the primeval person or man; and in some fables it is related that he was produced by the Creator at the formation of the world, with Prakriti, a personification of Nature. (See Prakriti.) The allegorical union of these two powers, male and female, have furnished endless fancies for Hindoo metaphysicians, who, among such fancies, describe an allegorical immolation of this primeval being; sometimes making Paruha, or Puruha, the victim; sometimes Brahma, or Narayana. In the Veda, called Yajur, or Yajñ, the necessary ceremonies for the sacrifices called Āñamadha and Puruñamadha, are laid down; "but they are not," as the words imply, "really sacrifices of horses and men." In the first mentioned, fix hundred and nine animals of various kinds, domestic and wild, including birds, fish, and reptiles, are made fat; the same ones to twenty-one pots, and the wild ones in the intervals between them; and after certain prayers, the victims are let loose without injury. In the other a hundred and eighty-five men of various specified tribes, charactér, and professions, are bound to eleven pots, and after a certain hymn concerning the allegorical immolation of Narayana, these human victims are liberated unhurt; and oblations of butter are made on the sacrificial fire. This mode of performing the Āñamadha and Puruñamadha as emblematical ceremonies, not as real sacrifices, is taught in this Veda; and the interpretation is fully confirmed by several rituals, and by commentators, one of whom affirms as a reason, "because the flesh of victims, which have been actually sacrificed, must be eaten by the persons who offer the sacrifice: but a man cannot be allowed, much less required, to eat human flesh." This passage is cited by Mr. Colebrooke from memory; he adds, "It may be hence inferred, or conjectured at least, that human sacrifices were not authorized by the Veda itself; but were either then abrogated, and an emblematical ceremony substituted in its place, as they must have been introduced in later times on the authority of certain Puranas and Tantras, fabricated by persons, who in this, as in other matters, established many unjustifiable practices on the foundation of allegories and emblems which they misunderstood." (A.F. Ref. voL viii.) A human sacrifice is called Narāmadha, and, as described under that article, was formerly a usage among the Hindoos. For the significations of the words Narayanay, Purana, Tantra, and Veda, that occur above, the inquirer is referred to those articles.

**Paruša-Medha**, among Hindoos, is an allegorical sacrifice of a man, as noticed under the preceding article.

**Paruta.** Paolo, in *Biography*, a noble Venetian, was born in 1540. He succeeded Contarini as historiographer of the republic in 1579, and afterwards filled various offices in the state. He was employed in several embassies, was made governor of Brescia, and finally was elected a procurator of St. Mark. With a high character for wisdom, integrity, and zeal for the public welfare, he died in 1598, at the age of 58. The following is an enumeration of his principal works, "A funeral Oration to the Prince of those who fell in the Battle of Curzolari in 1571;" "Della Perfezione della vita Politica;" "Difcori Politici," published by his sons in 1599; "A History of Venice, from 1513 to 1551, with the Addition of an Account of the War of Cyprus!" This work is written in Italian, and is annotated one of the best works of that class in the language. He had begun to write it in Latin, in imitation of the style of Sallust, and had finished four books in that language. A new edition of this history was given by Apollonio Zeno in 1703.

**Paruta, Filippo**, a learned antiquarian, was a noble of Palermo, and secretary to the senate of that city, where he died in 1639. He was author of several works, but is principally known by his "Sicilia defcripttta con Medaglie," published at Palermo in 1612. This work was afterwards enlarged by Leonardo Agostiri, and printed at Rome in 1649; and at Lyons in 1697. Havercamp published a Latin edition of it in three volumes folio, 1723, which
which makes part of the Italian antiquities of Gravius and Burmann.

PARVUM CAPR. See Cape.

PARWAN, in Geography, a town of Candahar; 60 miles N.W. of Cabul.

PARWIDA, a town of Sweden, in Tavastland; 45 miles N.N.E. of Jamfio.

PARWIS, a town of the Tyrol; 18 miles W.N.W. of Innsbruck.

PAR-YARD, in Agriculture, a term provincially applied to the flraw, or fold-yard.

PARYPATE, in the Ancient Music, was the name of that note or chord of a tetrachord which lay next to the hypate.

As the hypate was the principal, the first, or principal found, according to Martianus Capellus's translation; so the parypate was, according to him, the sub-principal. See Tetrachord.

The name parypate was given to this second note when a tetrachord was considered separately from others; but, when combined, this chord sometimes took the name trite. See Diagram, and Trite.

PARYPATE Hypaton, in the Ancient Greek Scale of Muses, was the second note of the hypaton tetrachord, and answers to the C-fa-un of Guido's scale. See Diagram, and Parypate.

PARYPATE Mefon, in the Greek Music, was the second note of the menor tetrachord, and answers to the F-fa-un of the Guidonian scale. See Diagram.

PARYS, in Geography, a mountain of North Wales, in the island of Anglesea, about nine miles in length, and half as much in breadth; apparently waffle and barren in the extreme, but abounding in the richest mines of copper and lead ore, with a mixture of silver in the latter: the bed of copper ore is supposed to be the largest that is known on the globe; 2 miles S.E. of Amlawch.

PARZANEGA, a town of Italy, in the department of the Serio; 15 miles S.E. of Bergamo.

PAS, MAXENSES DE, Marquis de Pesquières, in Biography, was the posthumous son of Francis de Pas, who was slain at the battle of Ivry. He was born at Saumur in 1550, and distinguished himself as an able general and negociator. At the siege of Rochelle he was taken prisoner, was continued in confinement nine months, and was ransomed in exchange for general Ekenfort, two colonels, and 10,000 crowns. The reduction of the city of Rochelle has been attributed chiefly to him. He was afterwards ambassador to the court of Sweden and Germany, where he displayed great talents. In 1635 he commanded the army in conjunction with the duke of Saxe-Weimar. He died in 1640. His negotiations in Germany were printed in 1753, in 3 vols. 12mo. Moreri.

PAS, ANTHONY DE, Marquis de Pesquières, grandson of the above, was one of the greatest generals of his time. He signalized himself at the battle of Stafarde, at the taking of Sutza, and other strong places in Italy, but he was so severe a disciplinarian, that it was a common saying, that De Pas must be the bravest man in the world, since he slept every night in the midit of a hundred thousand enemies. He was governor of Verdun, and in 1689 he was made, on account of his great talents, a field-marshall. He died in January 1711, aged 63. His memoirs were printed in 4 vols. 12mo. Moreri.

PAS, in Geography, a town of Prussia, in Bartenland; 10 miles N.E. of Ralnenburg.

PAS, a town of France, in the department of the Straits of Calais; 13 miles S.W. of Arras.

PAS de Calais. See STRAITS of Calais.

PAS de Souris, in the Military Art, the same with lizzire.

PASA, or Fasa, in Geography, a town of Persia, in the province of Farhlan; 68 miles S.E. of Schiraz. N. lat. 29° 10'. E. long. 53° 40'.

PASAGINIANIS, or Circumcised, in Ecclesiastical History, a singular sect, which sprang up in Lombardy towards the close of the 12th century. Like several other sects that subsisted about the same time, this sect had the utmost aversion to the dominion and discipline of the church of Rome; but it was distinguished, at the same time, by two religious tenets that were peculiar to itself. The first was a notion, that the observance of the law of Moses, in every thing except the offering of sacrifices, was obligatory upon Christians; in consequence of which, its followers were circumcised, abstained from those meats, the use of which was prohibited under the Mosaic economy, and celebrated the Jewish Sabbath. The second point that distinguished this sect was a denial of baptism, to the purpose of opposition to the doctrine of three persons in the divine nature; for the Pasaginians maintained that Christ was no more than the "first and purest creature of God." Nor will their adoption of this opinion seem very surprising, if we consider the prodigious number of Arians that were scattered throughout Italy long before that period. Mosheim.

PASA, or Buxadedwar, in Geography, a town of Bootan; 60 miles S.S.E. of Taffasudon. N. lat. 26° 48'. E. long. 89° 30'.

PASAK, or Buxadedwar, in Geography, a town of Bootan; 60 miles S.S.E. of Taffasudon. N. lat. 26° 48'. E. long. 89° 30'.

PASAKAMENITZ, a town of Bohemia, in the circle of Chrudim; 8 miles W.N.W. of Politzkza.

PASAI, a town of Africa, in the kingdom of Fonia. N. lat. 14° 40'. W. long. 15° 30'.

PASAN, Antilepe Orys, in Zoology, a species of antelope, with a straight, slender, distinctly annulated horns, which taper to a point; the body and sides are of a reddish ash colour, having a raised duny line along the back, the hairs of which at the posterior end are reversed. This is the Gazella Indica, or Indian antelope of Ray; the capra gazella, or goat antelope of Syri, Nat. ed. 12: 1. the oryx of Pliny, and other ancient writers; the Egyptian antelope of Pennant; and the pafan of Buffon. It inhabits Syria, Arabia, Perse, India, Egypt, Ethiopia, and near the Cape of Good Hope. It is about the size of a fahow deer; the horns are near three feet long, the points sharp, and about 14 inches asunder; the face is white, with a black spot at the base of the horns, another on the middle of the face, and one on each side reaching from the eye to the throat, joining that on the face by a transverse band of the same colour; the belly, rump, and legs are white; the white colour of the belly is divided, on the sides, from the reddish ash-coloured upper parts, by a broad longitudinal duny band, which reaches to the breast; each leg is marked with a duny spot below the knee; the tail is near two feet and a half long, and is covered with longish black hairs. This species is named gems bock, or chamois, at the Cape, and is supposed by Gmelin to be the zibi of the facred writers.

PASANGA, in Geography, a small island in the East Indian sea, near the coast of Sumatra. S. lat. 5° 10'.

PASAR, a town of Hindoostan, in the Carnatic; 21 miles W. of Tiagar.

PASARGADA, or PASARGADE, in Ancient Geography, a town of Asia, in the Periade. The name signifies the camp of the Persians, and the town had been founded in the place where Cyrus had vanquished Assyges or Cyaxares in a pitched battle. According to Plutarch, there was in this
this town a temple of the gods of war, who was supposed to have been Pallas.

PASARNA, a town of Asia, in Lesser Armenia, at some distance from the Euphrates, in the Lavinian prefecture. Ptolemy.

PASCA-GOULA, in Geography, a river of America, in the Missiappi territory, which, after pursuing a S. by E. course through West Florida, and part of Louisiana, discharges itself into the gulf of Mexico by several mouthes, occupying a space of three or four miles, which is a continued bed of oyster-shells, with very shallow water. This river is said to be navigable more than 150 miles. The adjacent soil improves as you advance towards its source. The bay formed by it lies in N. lat. 36° 23'. W. long. 88° 35'.

PASCAL, Blaise, in Biography, a celebrated mathematician and philosopher of the 17th century, was born at Clermont, in Auvergne, in the year 1623. His father was a man of great consideration in his province, was president of the court of aids, and was illustrious as a general scholar, as well as an able mathematician. To promote the studies of his only son Blaise, he relinquished his official situation, settled at Paris, and undertook the employment of being his tutor. The pupil was, from a very early period, remarkably inquisitive, and dextrous in knowing the principles of things; and when good reasons were not given to him, he would search for better, nor would he rest contented with any that did not appear to his mind well founded. His father soon discovered that the bent of his genius was decidedly to mathematics, from which he was determined, if possible, to keep him, lest he should, by this pursuit, be prevented from learning the languages. He accordingly locked up all the books that treated of geometry, and the sciences properly called, and refrained even from speaking of them in his presence. On one occasion, however, the youth asked, with an importunity not to be put off, what was geometry? to which the father replied, "Geometry is a science which teaches the way of making exact figures, and of finding out the proportions between them; but at the same time, he forbade him to speak or think of the subject any more, which was perhaps the very readiest way to excite in him an earnest desire to become acquainted with it. Accordingly the science soon occupied all his thoughts; and though but twelve years of age, he was found, in the hours of recreation, making figures on the chamber-floor with charcoal, the proportions of which he sought out by means of a regular, though perhaps uncounted, series of definitions, axioms, and demonstrations. It is said, apparently upon unquestionable authority, that he had proceeded with his inquiries so far as to have come to what was just the fame with the thirty-second proposition of the first book of Euclid, and that without any assistance either from living instructors, or the works of the illustrious dead. From this time, young Pascal had full liberty to indulge his genius in mathematical pursuits, and was furnished by his father with Euclid's Elements, of which he made himself master in a very short time. So great was his proficiency in the sciences, that, at the age of sixteen, he wrote a "Treatise on Comic Sections," which, in the judgment of the most learned men of the time, was considered as a great effort of genius. At the age of nineteen he contrived his admirable arithmetical machine, furnishing an easy and expeditious method of making arithmetical calculations, in the fundamental rules, without any other aid than that of the eye and the hand. About this time, owing to ill health, he was obliged to suspend his studies, which he was unable to renew for four years; when having been witness to the famous Torricellian experiment respecting the weight of air, he instantly directed his attention to discoveries in the science of pneumatics. He made a vast number of experiments, of which he circulated a printed account through the whole of Europe. He soon ascertained the fact of the general pressure of the atmosphere, and composed a large treatise, in which he fully explained the subject, and answered the objections which were advanced against his theory: afterwards, thinking it too prolix, he divided it into two small treatises, one of which he entitled "A Differtation on the Equilibrium of Fluids;" and the other, "An Essay on the Weight of the Atmosphere." These treatises were not published till after the author's death.

The high reputation which M. Pascal had acquired, caused him to be looked up to by the most considerable mathematicians and philosophers of the age, who applied for his assistance in the resolution of various difficult questions and problems. Among other subjects on which his ingenuity was employed, was the solution of a problem suggested by Torricelli, which had baffled the thoughts of all who had attempted it: this was to determine the curve described in the air by the nail of a coach-wheel, while the machine is in motion; which curve was at that time known by the name of the roulette, but is now designated the cycloid; to which article we refer our readers for a farther account of the matter.

Before this time he had drawn up a table of numbers, which, from the form in which the figures were dispensed, he called his "Arithmetical Triangle." He might perhaps have been an inventor of it, but it is certain that it had been treated of, a century before Pascal's time, by Cardan, and other arithmetical writers. See Triangle.

When M. Pascal was in the 24th year of his age, and the highest expectations were formed of the advantages to be attained in science from his labours, he on a sudden renounced the study of mathematics, and all human learning; devoted himself wholly to a life of mortification and prayer; and he now became as great a devotee as almost any age has produced. From this period he renounced all kinds of pleasures, and not only denied himself the most common gratifications, but was in the habit of daily entrenching some part of his dress, food, &c. which he did not consider as necessary. He carried the matter much farther, and endeavoured to diminish his attachment to his dearest friends, because ardent affection was due to God alone. He occasionally wore an iron girdle, full of blunted points, to increase his mortification and pain, and to remind him of his duty to God. During the latter years of his life, his principal relaxation from the rigorous system which he preferred to himself, consisted in visits which he paid to churches, where some relics were exposed, or some solemnity observed; and for that purpose he had a spiritual almanack, or ephemeresis, which informed him of the places where particular services were performed. He was not, however, so completely abstracted from the world, as to be wholly indifferent to what was passing in it; and in the disputes between the Jesuits and Jansenists, he became a partisan of the latter, and wrote his celebrated "Provincial Letters," published in 1656, under the name of Lewis de Montale, in which he only employed his talents of wit and humour in ridiculing the former. These letters have been translated into almost all the European languages, and probably nothing did more injury to the cause of the Jesuits. They attempted various answers, but with little effect; they then obtained a decree of condemnation against them, but they still maintained their ground, intrenching the more serious readers by their solemnity, and those of a lighter turn of mind by their wit. After the publication
publication of the "Provincial Letters," he became entirely a recluse, spending his whole time in meditation and prayer. He made his own bed, and performed almost all other menial offices; employing a servant only to dress his food, and to go on unavoidable errands. He allowed himself nothing in his apartment but a table, a bed, and two or three chairs. This course of life proved unfavourable to his health of body and mind. His reason became in some measure affected, and, with his circumstances, produced not an impression which could not be effaced.

In 1654, while he was crossing the Seine in a coach and four, the two leading horses became unmanageable at a part of the bridge where the parapet was partly down, and plunged over the side into the river. Their weight fortunately broke the traces, by which means the other horses and the carriage were extricated on the brink of the precipice.

From this fright it was difficult to excite the feeble Pascal, and he never afterwards had the poise of his mental faculties. He always imagined that he was on the edge of a vast abyss on the left side of him, and he would at no time sit down till a chair was placed there, to assure him there was no real danger. After languishing some years in this miserable state, he died at Paris in 1662, at the age of 39. He intended to have written a work against atheists and unbelievers in Christianity, and had collected a mass of materials for that purpose, which he did not live long enough to digest. These consisted of reflections upon devout, moral, and subject connected with the evidences of the Christian religion, which were written down by him at different times, on the first piece of paper which he could find. After his decease, these pieces of paper were found filed, but without any order or connection; and being exactly copied, were arranged and published in 32 chapters, under the title of "Pensées de M. Pascal fur la Religion et fur quelques autres Sujets." They have been translated in our own and other languages, and have been greatly admired as the precious remains of a great and good man, though certainly a misguided, man. They exhibit, in the original language, striking traits of his sublimity of genius, beautiful turn of sentiment, as well as force and true elegance of expression. Many of the ideas do not reflect honour on the wisdom and benevolence of the deity; and on some of them Voltaire has written able animadversions, in his "Lettres Philosophiques."

The works of M. Pascal were collected and published in five volumes, octavo, in 1779, at the Hague, and also at Paris. This collection, which consisted in part of posthumous pieces, was given to the public by the abbé Boffi, who thus describes the author: "This extraordinary man inherited from nature all the powers of genius. He was a geometer of the first rank, a profound reasoner, and a sublime and elegant writer. If we reflect that, in a very short life, oppressed with continual infirmities, he invented a curious arithmetical machine, the elements of the doctrine of chances, and the method of resolving various problems respecting the cycloid; that he fixed, in an irreproachable manner, the wavering opinions of the learned concerning the weight of the air; that he wrote one of the most perfect works existing in the French language; and that in his own "Pensées," there are passages, the depth and beauty of which are incomparable; we can hardly believe that a greater genius ever existed in any age or nation." Bayle pronounces M. Pascal to have been one of the sublimest geniuses whom the world ever produced; and says, if he might make use of the expression, he would call him "a paradoxical individual of the human species." Voltaire, also, who did not spare the posthumous works of Pascal, says, in his "Sicile de Louis XIV.," that the "Lettres Provinciales may be considered as a model of eloquence and humour. The bête comedies of Molieres have not more wit than the first part of them; and the sublimity of the latter part is equal to any thing in Boffuet." In another place, speaking of this same work, he says, "that examples of all the various kinds of eloquence are to be found in it. Though it has been written almost an hundred years, yet not a single word occurs in it favouring of that vacillitude to which living languages are so subject. Here then we are to fix the epoch, when our language may be said to have assumed a settled form." In a moral point of view, as well as an adept in science and literature, Pascal has been most highly applauded. "His heart," says his biographer, "was the seat of the purest benevolence; and his exertions in alleviating the miseries, and contributing to the happiness of the unfortunate and indigent, were limited only by the extent of his means. Though his abilities entitled him to assume an air of superiority, he never displayed that haughty and imperious tone which is commonly observable in men of shining talents, but was distinguished by uncommon modesty and humility." Moreri. Bayle.

PASCALANK, in Geography, a river of North Carolina, which runs into Albemarle sound, N. lat. 36° 6'. W. long. 76° 53'.

PASCALIA, in Botany, so named by Professor Ortega, whose work we have not at present an opportunity of consulting, but we presume the genus is designed to commemorate some botanist. Ort. Dec. 4. 39. Wild. Sp. Pl. v. 3. 1228.—Clas and order, Syngenes Polygium superfibius. Nat. Ord. Compositae oppositifolia. Linn. Corymbifera, Juss.

1. P. glauca. Ort. Dec. 4. 39. 14.—Native of Chilli. Root perennial. Stem erect, eighteen inches high, finely branched in the upper part only. leaves opposite, filiform, smooth, glaucous; the lower ones ovate, with angle-like teeth, three-ribbed, venous; the upper ones lanceolate, narrow, three-ribbed, obscurely toothed towards the base. flowers yellow, solitary at the summits of the stem and branches. The pulpy or dryaceous seeds appear to render this genus, as Willdenow observes, very distinct.

PASCATAQUA, in Geography. See Piscataqua.

PASCHAL I., pope, in Biography, a Roman by birth, who flourished in the ninth century, became a prepriest of the church, and abbot of the monastery of St. Stephen. In the year 817, upon the death of pope Stephen V., he was elected his successor, by the unanimous suffrages of the fenate, the clergy, and people. Immediately after his elevation to the pontifical throne, he sent his nomenclator Theodore into France, to carry the tidings of his elevation to the emperor Lewis, who sent him assurances of his protection, and conferred the grants which had been made by his father and grand-father to the holy see. No sooner was his election known in the East, than letters were sent to him from the mark Theodore Studita, and the other defenders of image worship, containing grievous but very exaggerated complaints of the persecution which they suffered from the Iconoclasts (see the article); and exhorting him to assemble a council for the purpose of anathematizing those heretics. This measure he refused to adopt, but sent letters to the complainants, confirming them in their adherence to their usual practice; and to comfort them under their sufferings, he assured them that to be martyrs on account of Images, was in fact to be martyrs on account of Christ; and that the same reward was referred in heaven for those who suffered under the Image-breaking
Upon escaping to Germany, his adherents were cruelly murdered at Rome. Lewis instantly sent commissioners to examine if the pope were at all implicated in the transaction, but after the strictest inquiry no certain information could be obtained as to the guilt or innocence of Paschal. They, therefore, acquiesced in an offer which the pope made of declaring his innocence upon oath. He could not be persuaded to deliver the affاins, alleging that they were his fervants, and, in fact, guilty of no crime, since the persons who had been put to death had long and richly deserved that punishment by their treasonable practices. The pope died in February 824, and firmly it was believed that he was privy to the affаination which his fervants had perpetrated, that the people would not allow him to be interred with his predeceffors in the Vatican, and he remained unburied till his successor caused his remains to be deposited in one of the churches that he had rebuilt. Three letters that have been attributed to him are inserted in the seventh volume of the "Collectio Conciliorum;" but very considerable doubts are entertained of their genuinenefs. Moreri, Bower.

Paschal II. pope, originally called Rainerius, or Ragin- nerus, was a Tuscan by nation, and was educated in the monastery of Chany, where he embraced the monastic life while he was very young. At the age of 20, he was sent by his abbot to Rome on business relating to the monastery, when Gregory VII., who was then on the pontifical throne, struck with his talents and behaviour, retained him at his court, and, in a short time, he was ordained priest, and soon after was promoted to the dignity of cardinal, with the title of St. Clement. In 1099, upon the death of pope Urban II., the cardinals, bishops, and clergy of Rome, having assembled in the church of St. Clement, determined to elect cardinal Rainerius; he wished to escape, and withdrew himself, but being discovered, he was brought back, and unanimously placed on the pontifical throne. On the following day his consecration took place, when he assumed the name of Paschal II. His first object was effectually to crush his rival Guibert, who had maintained the name of pope for nearly 20 years, and had given considerable trouble to three of his predeceffors. In this the new pope soon succeeded; attempts were made to introduce other rivals, but the interest of Paschal completely prevailed, and having featured possession of the apostolical chair, he began the exercise of his pontifical office by sending legates to France to remonstrate with King Philip on account of his living in open adultery with Bertrada, the countess of Anjou, and to cut him off from the body of the church, should not admonition bring him to a sense of his duty. The legates were unable to convince the adulterers of the errors of their conduct, and accordingly excommunicated them. In the year 1101 the pope, through the interest of Anselm, archbishop of Canterbury, attempted to introduce his own unlimited power into England, and sent over Guido, archbishop of Vienne, with the character of his legate a latere; but when king Henry and the nation understood that he was commissioned to exercise in this kingdom the same uncontrolled power over all persons which had been displayed in other countries, they would not acknowledge him, nor was he allowed to exercise any function of his office. (See Anselm and Henry I.) In the following year Paschal assembled a council at Rome, in which the decrees of his predeceffors against infultures were confirmed, and the pope himself, with great solemnity, in the presence of an immense multitude, pronounced the sentence of excommunication against the emperor Henry IV. This prince was afterwards glad to abdicate his throne in favour of his son Henry V. Upon the death of the former the pope held a council, in which decrees were passed which re-united the whole of Lombardy to the apostolical fee, from which all that country, excepting the places held by the countesses Matilda, had been separated ever since the year 828, when it declared in favour of the antipope Guibert. By this time the pope had the mortification to find, that the new emperor was determined, equally with his predeceffors, to maintain his right to infultures; the pope, therefore, to strengthen his own hands, fought an alliance with Philip of France, whom he had, some time previously to this, abdolved from the sentence of excommunication. An attempt was made by Henry to terminate all differences with Paschal, but as he would not recede in the least from his claims, the object was not accomplished. In 1107 the pope prefided in a council at Troyes, confiling of the bishops from many places, who proved themselves to be wholly subfervient to the ambition of the court of Rome, by confirming all the decrees relating to the pretended papal right to infultures. In 1110 a compromise took place, and in the following year Henry fet out for Rome, at the head of a numerous army, to be crowned. He was received with every mark of respect, but when the conditions of the treaty were to be mutually fulfilled, the German and Italian bishops pretendprotected unanimously against partitioning with their estates, which they said the pope had no right to dispose of. This produced a warm altercation between the king and the pope, Paschal declaring that he would not proceed with the coronation unless the monarch immediately ratified his part of the treaty. Henry, in reply, ordered his guards to arrest the pope and all his cardinals, thinking that, by this measure, he should compel Paschal to crown him. Two of the cardinals contrived to escape in disguise, and they animated the citizens of Rome to fly to arms, to rescue their pontiff. A civil contention took place, in which the friends of the pope were repelled with great slaughter. After Paschal had been prisoner about two months, the monarch swore, in the presence of his army, that if he did not fulfill the articles of agreement, he would put him, and all his adherents, to death. The pope was still unmoved, till the cardinals, and other prisoners, begged him to yield for their sakes, and to prevent the calamities which must otherwise fall upon the church. The articles of agreement were accordingly signed, and the monarch received a papal bull, confirming to him the right of infulture. Things being thus settled, the pope and Henry proceeded to the church of St. Peter, where the king was crowned emperor of the Romans by the pope, with the usual solemnity; soon after which that prince took his leave of his holiness and returned to Germany. Paschal's reception at Rome was highly mortifying, he was accused of having sacrificed the rights of the church, and the dignity of his liation, to his own safety. He affected great contrition, and functioned the excommunication of the emperor. Hostilities were carried on by both parties till 1117, when Henry resolved to bring matters to a crisis, and set out a second time for Italy, at the head of a numerous army. The contests were carried on with great violence, till the beginning of the following year, when the pope died, after a reign of about eighteen years and a half, which he
spent in infantile efforts for extending the power, and promoting the aggrandisement of the papal see. More than 100 of his letters, and some fragments of his decrees, are inferred in the 16th vol. of the Collect. Concil. Morei. Bower.

Paschal III. pope, or antipope, originally known by the name of Guy de Crema, was probably a native of the city whence he derived his surname. He was promoted to the sacred college by pope Adrian IV. who sent him into Germany as legate to appease the resentment of the emperor Frederic Barbarossa, which he had provoked by his exorbitant and arrogant claims to the temporal power and authority. He was not successful in the object of his mission; on the death of Adrian, in 1159, the cardinals were divided into two parties, the greater number of whom declared the election to have fallen upon Alexander III., while the minority, in which Guy was one, gave votes for cardinal Ocebari, who had long aspired to the pontificate, and was even prepared to support his pretensions by an armed force. A double election took place, and the two rivals were consecrated by their respective partizans, on which occasion Ocebari assumed the name of Victor. Supported by the emperor, he retained the pontifical dignity till his death in 1164, when cardinal Guy was chosen his successor, and took the name of Paschal III. This election was confirmed by the emperor, and in 1166, Paschal was acknowledged in the character of sovereign pontiff by the bishops and princes of the empire at the diet of Wurtzburg. The Romans, however, declared for Alexander, and received him with the same honours which had been paid to his predecessors. A furious contest was excited, but at length the greater part of the Romans submitted, and acknowledged Paschal as lawful pope. He died in 1168, after he had held the title about four years. One of the chief acts by which he performed in this character was the canonization of Charlemagne, in the year 1166, but as the Roman church claffed Paschal among the antipopes, it does not agree to the honours of saintship which are paid to that prince.

There was another antipope of the name of Paschal, who created a schism in the Roman church in the seventh century. He held the office of archdeacon, and upon the death of Conon, in 687, aimed at the papacy, and was elected by his friends to the high dignity, but in the end he was deposed even from the more humble office of archdeacon, and shut up in a monastery, where he died in about five years.

Paschal. Paschalis, something belonging to the Jewifh paffover, or to the Christian Easter.

The paschal lamb was a lamb which the Jews eat with great ceremony, in memory of their having been brought out of slavery in Egypt. It should be eaten flading, their loins git, the flaff in hand.

Paschal Canon. See Canon.

Paschal Tapers. See Tailer.

Paschal Rents, are rents or annual duties paid by the inferior clergy to the bishop, or archdeacon, at their Easter visitations.

They are also called synodal.

Paschal Letter, in Church History, a circular letter, which the patriarch of Alexandria first, and afterwards the pope, anciently wrote to all the metropolitans; to inform them of the day whereon the feast of Easter was to be celebrated.

Paschaisius-Radbert, in Biography, a celebrated French monk, who flourished in the ninth century, to whose writings Protestant controverticallists trace the origin of the doctrine of tranffubfiantiation, was a native of Soifons, and being deftered in his infancy by his relations, he was brought up by the charity of the nuns in an out-house dependent on their convent. When he had attained manhood, he embraced the monastic life among the Benedictines of the abbey of Corbie, where he applied, with great diligence, to his studies; became distinguished in polemic conferences, and wrote several books. In 844, when he was only in deacon's orders, he was, on account of his high reputation, elected abbot, which he soon after resigned, and returned to the simple condition of monk, spending the remainder of his life in the exercises of the cloister, close study, and the composition of various books. The first work which he gave to the public was a treatise "Concerning the Sacrament of the Body and Blood of Christ," composed by him in the year 851. In this he pretends to explain the doctrine of the church on this head, maintaining that after the consecration of the bread and wine in the Lord's supper, nothing remained of these symbols, but the outward figure, under which the body and blood of Christ were really and locally present, and that the body of Christ thus present in the eucharist, was the same body that was born of the virgin, that suffered on the cross, and was raised from the dead. That this doctrine was then new, may be concluded from the great astonishment which it excited, and the general opposition which it met with from the learned men of the age. Mosheim has given an abstract of the controversy to which this publication gave rise. In the year 846, Paschatus published a treatise entitled "De Partu Virginis," intended to support an opinion propagated at that time by certain German doctors, that Jesus was born in a manner entirely different from those general laws of nature that regulate the birth of the human species. He was author of many other pieces, all which were collected and published by father Sirmond in 1618, in one volume folio. They are also to be found in the fourteenth vol. of the Biblia Pata Morei. Prieley, Hist. of the Christian Church. Mosheim.

Paschius, George, a learned German Lutheran divine, was the son of a tradesman at Dantzic, where he was born in the year 1661. When he had completed his studies, he travelled for further improvement in Germany, France, and England. In 1701 he obtained the appointment of professor of moral philosophy at Kiel in Holstein, and in 1706 he was nominated professor extraordinary of divinity in the same university. He died in the following year at the age of forty-six. He was author of various publications, abounding in curious and highly useful learning. His first and principal work was published in 1695, entitled "Tractatus de novis inventis, quorum accuratiori Cultui Facem praebuit Antiquitas," which afterwards appeared in a new and enlarged form in 1700, under the title of "Inventorum novantiquorum." It is a work replete with profound enquiries, and calculated to exalt former times at the expense of the present. The author attempts to prove, that the knowledge of the ancients has been imperceptibly borrowed from the rich stores of ancient wisdom, and that our boasted inventions are only improvements on the discoveries of the ancients. In endeavouring to establish his point, he brought forward a number of interesting facts relating to the history and progres of the arts and sciences. One of the other works of this author was entitled "De fictis Rebus publicis," being a treatise on the imaginary republics of Plato, for Thomas More, and Campanella. The titles of his other pieces may be found in the General Biography, to which we refer the readers.

Pascomayo, in Geographia, a sea-port of Peru, in the bithopric of Truxillo, and jurifdiction of Lima, at the mouth of a river of the same name.

Pasewalt, a town of Anterior Pomerania, situated on
on the Ucker, by means of which the inhabitants transport their goods to the great Haff. In its vicinity are some iron works; 24 miles W. of Old Stettin. N. lat. 55° 30'. E. long. 13° 57'.

PASH, or PASHA, in Mythology, is an attribute or implement of several of the deities of the Hindoos. It seems to be an implement of punishment, a whip or lamp to chastise, or cord to strangle, sinners. A doubled cord is often seen in the hand of Parvati, in any of her terrific or avenging characters, and it is such characters that the pasha is chiefly confined. (See KALI.) In Hindoo books the pasha is frequently mentioned, and it is generally distinguished by the name of the deity to whom it is attributed. Thus the Varuna-pasha is the cord of Varuna, the Hindoo Neptune. "Varuna," says Menu, "mole affuredly binds the guilty in fatal cords," ch. xi. v. 308. "The Dharma-pasha, the dreadful Kalapasha, and the highly valued Varuna-pasha," are mentioned in the Ramayana, as part of the "weapons, missile and maul," with which the gods armed Rama for the war of Lanka. They severally mean the cords of Justice, of Death, and of Varuna.

PASHA. See BASHAW.

PASHAUNA BEADY, in Natural History, a name given by the people of the East Indies to a kind of fibrose tale, found in the sides of the mountains, and used in medicine with them. They calcine it, and then powder and boil it in milk, and give half a dram for a dose mixed in milk, for the gravel and stone.

PASI, Antonio, of Bologna, in Biography, a disciple of Piofocche, highly extolled by the greatest masters of his time. Mancini, in his "Treatise on Singing," says that he was gifted with a taste and intelligence in the art of singing which were wonderful. To a very simple method, and a clear and dignified portamento, or carriage of his voice, he was the first who united those little licences which produce the greatest effects. By this art his style became extremely singular and piquant. But he had then and since many bad imitators, who abused the art of which he was the original, and by a redundancy of ornaments fo disfigured and disfigured the melody, that it became wholly unforcible. Yet, from the ambition of fining by variations and heterogeneous ornaments, they lost the true expression of that melody which was thought so essential to music, which was the boast of the end of the 17th century, and the beginning of the next; but it is to be feared that it has not since been found.

PASICANA, in Ancient Geography, a town of India, on this side of the Ganges. Ptolemy.

PASIDIUM, a town of Asia, in Syria, situated on the sea-coast, W. of mount C斐us.

PASIGA, in Geography, a river which rises in the province of Darien, and runs into the bay of Panama.

PASIGRAPHY, in Literary History, the art of universal writing. This art was suggested by lord Bacon in his "Institution of Discourse;" where he says, "it is possible to invent such figures for the communication of our thoughts, that people of different languages may, by this means, understand each other; and that each may read immediately, in his own language, a book which shall be written in another." Lord Bacon did not think, however, of confining this, as citizen Memmius has lately proposed to do, to 12 characters, which may be learned in 12 hours; on the contrary, he requires a greater number, at least as many as the number of radical words, on which head he quotes the example of the Chinese; "and although," he adds, "our alphabet may appear more commodious than this method of writing, the thing itself is nevertheless well deserving of attention. The problem relates to the figures by which thoughts may be rendered current; and as money may be struck of other materials as well as of gold and silver, it is possible likewise to discover other signs of things as well as letters and words." Des Cartes, in his third letter to father Merremus, discusses the invention of a Frenchman, whom he does not name, but who, by means of a certain language and an artificial writing, pretended to understand all the different idioms. He remarks on this subject, that it would be very possible to compose a short and convenient grammar, with general signs, which should render all foreign languages intelligible. In the year 1661, John Joacim Becher published a Latin folio, entitled "Characters for the Universal Knowledge of Languages; a Steganographic Invention hitherto unheard of." This was in effect paligraphy, or a method of making one's self understood by all foreigners by writing in one's own language, and also of comprehending what they write in theirs. Becher, being the first who gave a complete treatise on this art, may be considered as the inventor. He begins his work by a set of very delicate and highly interlacing observations upon general grammar, and the fundamental relations of all languages with regard to each other. He gives a learned comparative table of the relations and harmony of the Latin, the Greek, the Hebrew, the Arabian, the Scelovian, the French, and the German. This work cannot be too highly esteemed, and affuredly was not unknown to the author of the work "Du Monde Primitif." A Latin dictionary then follows, in which every word corresponds with one or more Arabic numeral figures arbitrarily taken. Every number is assumed as distinctive, or denoting the same word in all languages; and consequently nothing more is required than to compose a dictionary for each, similar to that which he has given for the Latin. There is likewise a table of declensions and conjugations, which presents certain determinate numbers for all the cafes, moods, tenses, or persons. By means of this general disposition, when a Frenchman is anxious of writing to a German the following phrase, La guerre est un grand mal (war is a great evil), he seeks in his index, guerre, cite, grand, mal; and he writes the correspondent numbers,

13; 33; 67; 68.

The sentence might be understood by these four characteristic numbers; but to leave no room for ambiguity, he says, Guerre is the nominative case, and finds, as the characteristic of the nominative, the Arabic figure 1. Eft is the third person singular of the indicative mode, present tense, of which the characteristic is 15. To grand, and to mal, belong likewise the figure 1, for the nominative case; he will therefore write

13.1 | 33.15 | 67.1 | 68.1

where the numbers are separated by small vertical bars to prevent confusion. It may easily be conceived how, by the inverse method, the German will find in his tables the words denoted by the cyphers, which will form Der krieg ist ein großer nobel.

This invention of Becher, which is the same thing nearly with regard to language, as algebra is to arithmetic, could not have cdit him any great effort of the imagination; and it evidently reduces itself, as is the case with regard to all paligraphy, to the learning a new language, or having a dictionary at hand for use. It is besides made of an inconsiderable simplicity, and even a few hours practice will render it easy. If any reader should be curious to see more applications of this kind, he may have recourse to the Latin work of Sturmian, "Essais d'Expériences curieuses," probably the "Collegium experimentale, five curiosum, &c. Ioannis Christophori Sturmian," 410. Norimberg, 1701.
In the same year George Dalgarnie, an Englishman, published at London, a work of which the prolix title is sufficiently to shew its object. It is "The Art of Signs, or an Universal Character and Philosophical Language, by means of which, Men of the most different Idoms may, in the Space of two Weeks, learn to communicate, whether by Word of Mouth or Writing, all their Thoughts, as clearly as in their Mother Tongue. Besides which, young Persons may therein learn the Principles of Philosophy, and the Practices of true Logic, more speedily and more readily than in the ordinary philosophic Writings." The book of Dalgarnie is written in Latin. Beckmann accuses him of extreme pedantry. His characters likewise were cyphers.

Joachim Frischerus, professor at the Gymnasion at Riga, was employed on a similiar attempt, namely, to introduce a natural, rational, and universal language, of which some sheets printed at Thorn in 1681 may give an idea. The death of the author interrupted his labours. He purposed to call his new language Ludovican, in honour of Louis XIV. under whose patronage he purposed his labours; a prince who extended his generosity to the learned of all countries.

The curious in researches of this nature may also find a project of this kind in a folio volume published at Rome in 1665, by the celebrated mathematician Athanasius Kircher, the title of which is, "A New and Universal Polygraphy deduced from the Art of Combination;" and by means of which, says Marhoff (Polyhier. l. ii. c. 5.), he who understands one single language only may correspond in writing with all the nations of the earth.

It would be perhaps unjust to fail in silence the little-known work of father Befnier, Jesuit, who, in a book entitled "La Réunion des Langues, ou l'Art de les apprendre toutes par une seule," that is, The Union of Languages, or Art of learning all Languages by one alone, printed at Paris in 1674, has given several intimations which lead directly to 

The most remarkable work of all which has been written on this subject is, perhaps, that for which we are indebted to bishop Wilkins, the brother-in-law of Cromwell. It is entitled "An Essay towards a Real Character and a Philosophical Language," London 1668. It is divided into four parts. I. Considerations on the various languages, their defects and imperfections, from which a philosophical language ought to be exempt. II. Philosophical enquiries respecting all the things and notions to which proper names ought to be affixed. III. The science of natural History considered as the necessary means of representing simple ideas in discourse. IV. The application of the general rules to every character and language. Examples, &c. This concise outline sufficiently shews the importance of the work.

In his appendix, the author explains the utility of a method of writing without alphabetic characters, by means of signs, which are to be used to denote all the principal ideas, the relative attributes being digested by small strokes added at right, acute, or obtuse angles, to the right or left, &c. Of principal or chief ideas he admits but forty, under which he ranges all the others, by that means forming a kind of categories. His new language is calculated to afford great facility of comprehension, and new openings to the unfolding processes of science. A learner might make more progress in it in a month, than in the Latin in several years. The Chinefe writing, which is a very complicated polygraphy, has given two learned men the idea of forming one upon a more simple plan. The Œuf is Caramel, in his "Apparat Philosophique," p. 128; and the other Andrew Müller Grienfench, in his "Cie Chiinoife." The latter promised to teach to women and children, in the course of a few days, a kind of writing by which all the several languages should be rendered intelligible to them.

After so many attempts more or less philosophical, and of different degrees of perfection, with others probably of which we know nothing, we must not overlook the efforts of the celebrated Leibnitz for the introduction of a polygraphy. His history and development of a characteristic universal language is in every library. Leibnitz exhibited, and with reason, his universal characteristic as the art of inventing and judging. He was convinced that an alphabet might be formed, and of this alphabet such words as would afford a language capable of giving mathematical precision to all the sciences. "Men may thus acquire," says he, "as it were a new organ, which would add energy to their moral faculties, as the microscopic lens increases the power of the eye. The compass is not more highly valuable to the navigator, than this philosophical language would be to him who embarks on the sea of reason and experiment, which is now at full of danger."

We must not forget the ingenious method of the abbé de l'Épée, who, by means of the same identical gestures, dictated to his deaf and dumb pupils certain discourses, which they wrote with equal readiness in four languages. Nothing can more effectually resemble a true polygraphy than these gestures.

The abbé de Condillac, a humble metaphysician, particularly with regard to human language, has not neglected signs and characters. In his "Art of Thinking" (Art de Penser), in his "Art of Writing" (Art d'Écrire), and more particularly in his "Logic," he has shewn the advantages of a philosophical language, which should proceed perfectly in the order of the ideas, and of which the signs should be the most simple and analytically. He expressly reduces the study of all the sciences to that of a well constructed language, and quotes, as an example, algebra in the mathematical sciences. Nicholson's Journal, vol. ii. or Anderfon, on an Universal Character. Dr. Brown's Hints on the Establishment of an universal written character. See Characters, Language, and Writing.

PASIN, in Geography. See BAKDIS.

PASIPEDA, in Ancient Geography, a town of India, on the bank of the Ganges, and on this side of it, between Pifca and Sulicana. Ptolemy.

PASIRIS, a town of European Sarmatia, on the bank of the river Carcinite, between Torreco and Herceabum. Ptolemy.

PASITIGRIS, a name given to the junction of the Euphrates and Tigris, at the mouth of the Persian gulf.

PASKA, in Geography, a town of Africa, in the kingdom of Fonia, in which the king keeps a garrison of 100 men. The town is surrounded with palisades, and contains about 100 inhabitants.

PASKARETT, a town of Mingredia; 20 miles N.N.E. of Anargia.

PASKATAQUES, a large branch of Penobscot river, on its W. side, which waters more than 50 miles, and receives 10 tributary streams.

PASKAU, a town of Moravia, in the circle of Prerau; eight miles E. of New Titchfein.

PASKEN, a town of Prussia, in Bartetzland; 10 miles S.E. of Bartzenlein.

PASMANT, an island of the Adriatic, near the coast of Dalmatia, 15 miles long, and two broad, which contains seven villages, and produces wine and oil in abundance. N. lat. 44° 8'. E. long. 15° 56'.
PASO FERREIRA, a town of South America, in the government of Buenos Ayres; 340 miles N.N.W. of Buenos Ayres.

Paso de Pefcado, a town of South America, in the province of Tucuman; 50 miles N. of St. Miguel de Tucuman.

PASOLATO, a river of Sicily, which runs into the sea, on the fourth coast, N. lat. 36° 49'. E. long. 13° 32'.

PASOMDSO, a lake of Tibet, about 50 miles in circumference. N. lat. 29° 42'. E. long. 84° 24'.

Gen. Ch. Cal. Glume of two membranous, equal, almost orbicular, slightly concave valves, containing one floret; the inner one flatlet, turned from the dilated unilateral receptacle. Cor. of two roundish, cartilaginous valves, the size of the calyx, externally convex, inflating at the base. Nectary of two membranous scales at the base of the germen. Stam. Filaments three, capillary, the length of the calyx; anthers ovate. Pfl. German. superior, roundish; styles two, capillary, the length of the corolla; stigmas pencilled, hairy, coloured. Peric. none, except the permanent closed glumes. Seed solitary, roundish, compressed, convex at one side, coated by the permanent cartilaginous corolla.

Eff Ch Calyx of two valves, nearly orbicular, fingle-flowered. Corolla of the same fife and shape, compressed. Stigmas pencil-shaped. Seed coated with the hardened corolla. Common receptacle unilateral.

Obf. Mr. Brown remarks, that this genus is very closely related to Panicum, inomuch that if, in those species of the latter which have an unilateral spike, the outer valve of the calyx be supprimed, it makes a real Paspalum. Such a defect does, according to this botanist, actually take place in some few, in which, however, either the nectariferous scales, as Linnaeus thought them, or a very minute valve within the inner valve of the calyx, do indeed sometimes occur; but for the most part, and on the outside of the lentic convex valve of the corolla, sometimes observable, says Mr. Brown, in Paspalum orbiculare. There is a peculiar aspect of neatness, arising from the more or less perfectly orbicular form, and regular arrangement, of the flowers, which characterizes the genus before us.

Linnaeus at first referred such of its species as he knew, to Panicum, but in Syll. Nat. ed. 10. v. 2. 1359, he gives the generic character of Paspalum at length, for the first time, enumerating four species in p. 855 of the same volume, which were all he then knew. He subsequently, as we shall find, confused the history of the first of them, dimidiatum, in such a manner, that it could not be developed, but by investigation of his specimens and manuscripts. He erred at first in confounding the genus as andreus, but this is corrected in his Species Plantarum. The history of the species has hitherto been so imperfectly detailed, that we shall attempt a more ample, if not a complete one.

constante; Pluk. Mant. 9. Phyt. t. 350. f. 2.)—Spike alternate, sessile, from a leafy, broad, rough-edged receptacle. Flowers smooth, slightly elliptical, three-ribbed. Leaves smooth. Stipula membranous, bearded.—Native of North America. Sent to Linnaeus by Kalm. Stem leafy, bent at the joints. Leaves linear-lanceolate, smooth, finely serrated, a little rough at the edges, with long, rather rigid, smooth, slender, thread-like filaments. Stipula membranous, jagged, unaccompanied by any hairs or bristles. Spikes three or four on the upper part of the stem, which closely rises above the leaves, each rather more than an inch long. Common and, or receptacle, of each spike much dilated, linear, exactly even, leafy, serrated, rough-edged, one-eighth of an inch, or more, in breadth, having at its inner side a small, angular, longitudinal rib, bearing numerous, alternate flowers, in two rows, on short filaments. The calyx-glumes are exactly but broadly elliptical, rather rigid, pale, with three fine green ribs, perfectly smooth and naked. Perhaps this may be P. menziesii of Walter, Pl. Carolin. 75.

2. P. fitaceum. Michaux Boreal.-Amer. v. 1. 43.—Spike one or two, on long, straight filaments, with a narrow wavy receptacle. Flowers mostly in pairs, on short, winged, divided capitula, fairly obovate, smooth, finely serrated. Leaves downy above. Stipula hairy. Sent from Lancaster, Pennsylvania, by the Rev. Dr. Muhlenberg. We at first confounded it with the former, but on examination it proves abundantly distinct, and answers well to the character in Michaux. The stem is erect, slender and smooth, terminated by one spike, two inches long, on a slender, stiff, naked flake, many inches in length, whose base is enclosed by the very long flake of the upper leaf, from which often proceeds another similar, but shorter-stalked, spike. The upper leaf, at least, is much shorter than its sheath, lanceolate, clothed above with soft hairs. Michaux says his plant grows in dry situations in South Carolina.

3. P. debile. Michaux ibid. 44.—Stem weak, brittle, like at the top. Leaves hairy. Spike mollly solitary, slender. Flowers solitary, alternate, slightly downy, slightly obovate.—Native of maritime situations, in Carolina and Georgia. This feems by Michaux's character, which is all we know of it, to be akin to the last.

4. P. conjungatum. Bergius in Act. Helvet. v. 7. 120. t. 8. Willd. s. 12. Swartz Ind. Occ. v. 1. 133. (P. dif-rectum; Linn. Syll. Nat. ed. 12. v. 2. 86.)—Spike two, terminal, unequal, nearly smooth. Receptacle broad, even, with a wavy rib. Flowers solitary, very numerous, alternate, imbricated, ovate, acute, ribs, fringed with long soft hairs. Common in the West Indies, in moist pastures. Linnaeus obtained a specimen from Browne's herbarium, which he confounded with the first species, though nothing can be more distinct. Hence the specific character of P. dif-fectum became corrupted in his Syll. Veg. which Willdenow has copied. The description however in the late-named author, copied from Sp. Pl. ed. 2, is right, except the downy nature of the leaves. P. conjungatum is a larger species than any of the foregoing, with broad, taper-pointed, often downy leaves. Stipula hairy. Spikes two, on a level at the top of the stem, nearly sessile, slender, a little divaricased, each nearly four inches long, of innumerable, crowded, alternate, small, yellowish, ovate, acute flowers, each on a short flake; their calyx ribs, remarkably fringed with long, lax, white hairs. One of our specimens bears a third spike, an inch below the others. Swartz says this is called, in the West Indies, Sour Lump, and is now eaten by cattle.

5. P. citralsorum. Michaux Boreal.-Amer. v. 1. 43.—Leaves dilated, downy, finely serrated, fringed. Spikes one or two, terminal, elongated. Flowers in pairs, somewhat obo-
vate, very obtuse, smooth, forming three rows.—Native of Carolina. Michaux. This seems akin to the last.

7. P. level. Mich. ibid. 44—"Erect, very smooth. Leaves shortish; with compressed sheaths. Spikes several, alternate. Flowers in two ranks, ovate, somewhat orbicular, even and smooth."—Native of Georgia. Michaux. We have adopted these three species from Michaux, that they might be recorded in a general view of the genus, though we are not acquainted with them. It seems the North American \textit{Paspalum} are but incompletely known; nor can we, by the above short, and far from scientific definitions, refer these to any in Linnaeus or Willdenow. Two others, in the same predicament, will be noticed hereafter, among the species to which they may be presumed most nearly to belong.

8. P. soro-bulatum. Linn. Mant. 29. Willd. n. 2; Ait. n. 7. Houtt. Nat. Hist. v. 13. 165. t. 89. f. 3. Dryand. —Spikes alternate, with a leafy, broad, rough-edged receptacle. Flowers alternate, orbicular, on simple dilated flanks, many-rilled, bordered, imbricated, ovate at the base externally.—Native of the East Indies, in wet places. Root perennial, of many long, blackish, branched fibres. Stem one or near two feet high, clothed with ribbed, smooth leaves; having long purplish sheaths, hairy at the bottom. Spikes few and distant; their receptacle flat, near a quarter of an inch wide, minutely fringed. Flowers not unlike hemp seed in size and aspect, very numerous, alternate, imbricated in two rows, each on a short, dilated, close-preted partial flalk, and very nearly unapparent, tubid, smooth and naked, with numerous ribs near the margin, remote from the central one, the flatter valve of the calyx marked with a pair of depressions at the base.

9. P. polyphaydum. Brown n. 1—"Spikes numerous, crowded. Flowers smooth, orbicular. Outer valve of the calyx five-ribbed. Leaves flat, smooth, with a thin finely-toothed margin."—Gathered by Mr. Brown, in the tropical part of New Holland. This species is described by him as too nearly related to the last, except that the dimples in the base of the calyx are wanting. We have perceived that character to be doubtful or variable in various specimens of \textit{P. serobiculatum}.

10. P. wilflum. Thunb. Jap. 45. t. 8. Willd. n. 2—Spikes alternate, with a hairy receptacle. Flowers alternate, elliptical, three-ribbed, villous.—Found by Thunberg, near Nagasaki in Japan, flowering in July. Stem three feet high, smooth. Leaves roughish at the touch, fringed, naked. Spikes about three or four, inclining all one way. Flowers crowded, in two rows only, about the size of \textit{P. serobiculatum}, but more oblong, and hairy. The receptacle is narrow, very hairy like the top of the stem. We have seen no specimen.

11. P. virgatum. Linn. Sp. Pl. 81. Willd. n. 4 (Gramen daefylon majus, paniculis longâ, episcis pluribus nudis craulis; Sloane Jam. v. 1. 111. t. 69. f. 1.)—Spikes rather numerous, alternate, hairy at the base. Flowers in pairs, somewhat obvate. The tunid valve of the calyx fringed. Native of meadows in Jamaica. Perennial. About the size of \textit{P. serobiculatum}, but differing in having smaller, obvate, fringed flowers, which being disposed in pairs along the narrow wavy receptacle, make four rows instead of two; each glume has a central rib, with a marginal one at each side, and the concave one is finely fringed in the upper part.

12. P. floridanum. Mich. Boreal-Am. v. 1. 44—"Erect. Lower leaves hairy; upper ones smooth, with long sheaths, upright. Spikes few, erect. Flowers in two rows, nearly orbicular, smooth, naked."—Native of Florida and Georgia. This, says Michaux, is akin to \textit{P. virgatum} of Linnaeus. We know nothing of it but from the above character, which is essentially different in all most every point from the \textit{virgatum}. Michaux adds that the flowers are rather large. We subjoin the only remaining species of that author, not knowing where else to place it.

14. P. paniculatum. —Spikes very numerous, crowded, hairy at the base. Flowers in four rows, orbicular, even and naked.—Gathered in Jamaica by W. Wright, M.D.—A very fine and handsome species, whose dense and very numerous spikes, crowded together into one common spike, a foot long, give, with their close little round flowers and seeds, some idea of \textit{Panicum italicum}, except that the whole is erect and unilateral. The leaves are long, near two inches broad in some parts, tapering to a rough-edged point, but otherwise very smooth to the touch, and finely ribbed. Each partial spike is two inches, or more, in length, with a flat rather narrow receptacle, bearing a few feathery hairs throughout, and very hairy at its base. Flowers disposed in four rows, on short capillary flanks, about the size of \textit{Panicum italicum}, almost perfectly orbicular, of a light tawny hue, the calyx-valves even and smooth, each with a central rib, but no others, except at the very edge. This grass was formerly known in the Bankian herbarium, by the expressive name of \textit{Paspalum polyphyllum}; now appropriated by Mr. Brown to our 9th species, which, from his description, must be very unlike the present.

15. P. paniculatum. Linn. Sp. Pl. 81. Willd. n. 5. Ait. n. 2. (Gramen millicum, panicula viridi vel purpurea; Sloane Jam. v. 1. 115. t. 72. f. 2.)—Spikes numerous, crowded, somewhat whored, spreading every way, hairy at the base. Flowers in alternate pairs, orbicular, even, slightly hairy. —Receptacle very narrow. —Sloane says this grows in several plantations in Jamaica, on a moist clay soil. The leaves are an inch wide, hairy on their upper side, as well as about the lipula on both sides; their sheaths long, smooth, ribbed. Common spike a span long, composed of numerous narrow spikes, two inches or more in length, partly scattered, partly whored, spreading every way, each with an extremely narrow, though slightly winged, receptacle. Flowers numerous, small, rather loosely disposed in alternate pairs, on twine or combined flanks; their glumes very nearly orbicular, obtuse, somewhat hairy, single-ribbed.—Such is the genuine plant of Sloane and Linnaeus; though the latter describes his herbarium another specimen, from which the particular description in \textit{Sp. Pl.} was taken, but which is a very distinct species; see the following.

16. P. repens. Bergius in A. H. Helvet. v. 7. 129. t. 7. Willd. n. 7. (P. paniculatum; Linn. Sp. Pl. 81, as to the description only.)—Spikes numerous, crowded, somewhat whored, spreading every way, naked at the base. Flowers alternate, elliptical, acute. Leaves and receptacle rough.—Native of Surinam, according to Bergius, who describes the stem a foot or more in length, fringed, smooth, jointed, leafy, creeping by means of fibrous roots thrown out at the joints. Leaves linear-lanceolate, acute, scarcely a finger's length, fringed, downy, dark green, with a feathing bafe, which
which in his figure and description is represented as flying off from the stem, probably in consequence of drying or pressure; the upper leaves are smooth, the lower roughish, with minute points. Stipula oblong, membranous, lacerated, abrupt. Spikes numerous, slender, drooping, an inch or two long, the upper ones whorled, the lower opposite. Receptacle linear, broad, taper-pointed, leafy, roughish, dark green. Flowers ranged alternately, but solitarily and not in pairs, each on a short stalk. Their form is ovate, or rather elliptical, pointed, by no means orbicular; the larger valve convex, and in our specimen downy; the smaller concave and smooth, with a pair of minute, parallel, close-pressed, reddish, lanceolate scales at its base, which perhaps invalidate the generic character, even more than the shape of the glumes. (See Panicum.) Whether they are the rudiments of abortive flowers we presume not to determine. Our specimen, to which no place of growth is attached, is much more luxuriant than what Bergius has drawn, but has only an upper leaf. The spikes are for the most part above two inches long, half-whorled, spreading in every direction. There are none of the brilliantly hairy spikes of the *Poa*, seen in *P. paniculatum*, nor are there any such hairs below the spikes, except a very few minute ones to the lowermost of all. The *Poa sylvestris* is externally downy.

17. *Poa sylvestris*. Bosc. Tr. of Linn. Soc. v. 2. 83. t. 16. Willd. n. 6. Ait. n. 3. (P. racemofum; Jacq. Ic. Rar. t. 302.)—Spikes very numerous, crowded, racemose. Flowers alternate, elliptical, pointed, tranverse and corrogated, overlapping the lanceolate pointlets receptacle.—Native of Peru, where it is commonly known by the name of *Alcalillo*. We received seeds from Mr. Bosc in 1791, from which plants were raised by Mr. Hoy, in Sion gardens. Sir Joseph Banks sent this species to Kew in 1794, where it is kept in the *Poa*, flowering in July and August. This is a very handsome perennial grass, whole stem is branched, two feet high, leafy, smooth, prismatic at the base, and throwing out roots from the joints. Leaves broad, almost ovate at the base, from four to six inches long, acute, smooth, many-ribbed, rough-edged; their sheaths close, long, and smooth. Stipula short, membranous, without hairs. Common *spike* near a span long, elegantly variegated with purple, green and white; partial ones numerous, crowded, feathered or partly whorled, each scarcely an inch long, supported by a short downy stalk. Receptacle lanceolate, bristly, ovate, rough-edged, green and leafy, without any taper point. Flowers from eight to ten to twenty in each spike, alternate, imbricated in two rows, elliptical with a small point; the margins, of the flatter calyx-valve more especially, corrugated and crenate.

18. *P. cynosbium*.—Spikes several, alternate, cynosbode; the lower ones longest. Flowers alternate, nearly orbicular, smooth, almost sessile. Receptacle wavy. Leaves and sheaths hairy.—Gathered by Dr. Aifelius at Sierra Leone. The lower part of the leaf is decumbent, and bent at the joints; the leaf erect, leafy, about 18 inches high. Leaves rather narrow, sharp-pointed, clothed on both sides with soft hairs. The *Poa* are hairy likewise, especially at the upper part. Stipula chiefly composed of long hairs. Spikes about five, crowded near together at the top of the *Poa*, alternate, spreading every way; the lowest two inches and a half long, the rest gradually shorter, so that all are about level at the summit. Receptacle linear, but rather narrow, wavy, smooth, except at the edge. Flowers very numerous, imbricated in two rows, nearly orbicular, smooth, fimbriated, fo gibbous as to be almost hemispherical, on short smooth stalks.

19. *P. gramineum*. Forl. Prodr. 7. Brown n. 2.—Spikes alternate, distinct, bristly at the base. Flowers alternate, nearly orbicular, smooth; their outer glume three-ribbed. Leaves flat; thickened and toothed at the margin.—Gathered by Forlter in the Society island, by Mr. Brown in the tropical part of New Holland, as well as near Port Jackson. We have seen no specimen of this or the next.

20. *P. pubescens*. Brown n. 3.—Spikes alternate, distinct, sessile. Flowers ovate, downy; their outer glume three-ribbed. Leaves flat, hairy, and rough above, thickened and toothed at their margins.—Gathered by Mr. Brown, in the tropical part of New Holland.

21. *P. littoralis*. Brown n. 4.—Spikes two or three, alternate, downy at the base. Flowers ovate, acute, smooth. Leaves involute, naked. Stem compressed.—Found by Mr. Brown in the tropical regions of New Holland, as well as near Port Jackson. We have specimens, gathered by Dr. White at the latif-mentioned place, which answer to Mr. Brown's definition, except that though in some of them the spikes are only two, one elevated above the other, in others they are three, ranged alternately along the angular top of the stem. Each flake on a very short downy stalk. The receptacle is leafy, wavy, rather narrow, one inch and a half to two inches long, smooth, except the edges. Flowers large, imbricated in two rows, projecting much more beyond the receptacle, on short, smooth, compressed stalks.

22. *P. hispidum*. Retz. Obs. fasc. 2. 7. Willd. n. 8.—Spikes about two, alternate. Flowers many-nerved, smooth. Leaves, sheaths, stem, and partial flower-flakes hairy.—Sent from China by Bladh. The *Poa* are erect, leafy, hairy in their upper part. Leaves flat, ribbed, hairy all over, as well as their sheaths, which are bearded at the top. Spikes nearly erect, alternate, two only in Retzius's specimen, their receptacle leafy, narrower than in *P. ceratobum*. Flowers in two rows, alternate, smooth, with three or five ribs, on hairy stalks. Retz. Willdenow by mitrace copies from Retzius's *Spica zubiniani* (placed in pairs) for *fzbiniani*; an important difference.

23. *P. Kora*. Willd. n. 9, excluding Forlter's *Syn.*—Spikes two or three, alternate, hairy at the base. Flowers orbicular, smooth, five-ribbed. Stem and leaves smooth. Stipula hairy.—Native of the East Indies. Sent from Tranquebar, by the Rev. Dr. Rottler. The *Poa* is branched, decumbent in the lower part, smooth, as are the leaves and their sheaths. Stipula membranous, short, accompanied by a few long hairs. Spikes two or three, alternate, one and a half to two inches long, of numerous, alternate, crowded, nearly orbicular flowers, half as large as *P. ceratobum*, on very short partial flacks. Receptacle leafy, narrow, straight and even, scarcely zigzag, except its midrib.

24. *P. efioleatum*. Linn. Sp. Pl. 82. Willd. n. 11. Ait. n. 4. Swartz. Obs. 39. t. 2. f. 1. (Gramen dactylion Rame repens, foliis latis breviusi; Sloane Jam. v. 1. 112.)—Spikes two or three, alternate. Flowers ovate, acute, smooth, three-ribbed. Receptacle straight. Leaves smooth, as well as the stem. Stipula hairy.—Native of rather moitiy grassy pastures in the West Indies. The *Poa* is simple, near two feet high, decumbent at the base, very smooth. Leaves flat, according to Swartz; involute when dry, taper-pointed, smooth; with long smooth sheaths, crowned with a hairy *spike*, and not (as Swartz says) hairy at the base. Spikes usually two, one above the other, sometimes three, approximated, but really alternate, one inch and a half long, with a linear, even, straight, flat, smooth, rather glaucous receptacle. Flowers twenty or thirty, alternate, crowded, nearly sessile, ovate, acute, pale, conical on the outside, with three ribs. Anthers dark purple. Stigmas blue.

25. *P. longiflorum*. Retz. Obs. fasc. 4. 15. Willd. n. 10.—Spikes two, terminal, equal, on short flacks. Flowers
Flowers ovate, pointed, smooth, three-ribbed. Receptacle zigzag. Root creeping. Stems erect. Leaves smooth. Stipula hairy. Native of the East Indies. Sent from Tranquebar, by the Rev. Dr. Rottler. This has a long creeping root, like Carex arenaria, throwing up, like that, many stems, hardly a span high, slender, smooth, leafy, rarely branched. Leaves smooth, narrow, acute, spreading, with long smooth sheaths, crowned with a short stipula befitting with bristly hairs. Spikes two, an inch long, on a level at the top of the stem, first erect, then diverged, each on a smooth, short, tapering flake. Receptacle zigzag, smooth, with a zigzag furrow. Flowers ten or twenty, situated and shaped nearly as in the last, but rather more elongated and more pointed, slightly convex rather than concave at the base. Willemow says it has sometimes three spikes, but he neglects to inform us how they are, in that cafe, situated. We have never seen more than two, always on flanks of equal length, springing from one point, which is not the cafe with the diffichum.—The habit and aspect of this grass resemble Panicum Dactylon; and it appears defined, like that, to grow in loose blowing sand, which the many-branched fibres of its roots are calculated to bind together and to fix, thus performing a very important service in the economy of agriculture.

26. P. sagittatum. Swartz Ind. Occ. v. i. 155. Willd. n. 13.—Spikes two, terminal, equal, on short flanks. Flowers ovate, pointed, smooth. Receptacle somewhat zigzag. Stem creeping, bent at the joints, branched. Stipula hairy.—Native of pastures, on a clay soil, in Jamaica. Swartz. By his description, which is our only source of information concerning this species, it comes very near the Iaf in technical characters, except that it does not seem to have the same long creeping roots, and numerous, more simple, stems. He describes the roots as numerous and thread-shaped. Stem a foot high, creeping, bent at the joints, and subdivided. Leaves nearly linear, acute, spreading, with broad, compressed, two-ranked, falcate, smooth sheaths, crowned with hairs. Spikes an inch long, spreading. The rest of his description we have compared with the last, in order to compose a specific character. Had we specimens of both, more differences might appear.

27. P. filiforme. Swartz. ibid. 136. Willd. n. 14.—Spike mostly solitary, linear, very slender. Flowers very numerous, on short flanks, elliptical, three-ribbed. Leaves bristle-shaped, channelled. Common in dry open fields in the West Indies. Communicated by Dr. Swartz. This species is known from all the rest by its extremely slender habit. It is two feet high, and grows in tufts. The stem is quite smooth, almoft capillary, but rigid and erect. Leaves long, straight, almost equally slender; convex and smooth beneath; channelled above; with long close sheaths, hairy at the top. Spike two or three inches long, with a very narrow, slightly zigzag receptacle, covered on one side with a double row of closely imbricated, small, smooth, elliptical flowers. Anthers yellow. Stigmas blueish.

28. P. decumbens. Swartz. ibid. 138. Willd. n. 13.—Spike solitary, on long, capillary, solitary or aggregate flanks. Flowers nearly orbicular, pointed. Leaves ovato-lanceolate, hairy.—Gathered in dry sandy mountainous situations, on the west side of Jamaica, by Dr. Swartz, to whom we are obliged for specimens. The stems are procumbent, about a foot long, branched, leafy, slender, smooth, bent at the joints, apparently compressed, though described as cylindrical. Leaves rather broad, lanceolate, acute, ovate at the base, clothed, more or less, on both sides, with soft scabrous hairs; with thinly tumid sheaths, about their own length, whole edges are thickly fringed. Stipula short, membranous, jagged, hairy. Flowers from one to five, from the sheaths of some of the upper leaves, rather shorter than the leaf, capillary, loosely spreading, simple, angular, downy. Spikes solitary, hardly an inch long, drooping. Flowers from fifteen to twenty, loosely imbricated, in two rows, on short flaks, slightly obtulate, or very nearly orbicular, quite smooth; convex and almost hemispherical, with short furrows, on one side; quite flat, even, and riliefs on the other. This flat side is accompanied at the base with a small abrupt seale, or imperfect glume, like what Mr. Brown mentions in P. orbiculare; see observations after the generic character; which appears to us to bring the present species very near indeed to Panicum. The receptacle is narrow and convex, smooth, except at the base, by no means of the leafy dilated form usual in Papahum.

We have thus added thirteen species to the fifteen in Willemow, nor are we without fulpicion of some more, which we have not sufficient materials to determine. There can be no doubt, that the greater part of the described species conftitute a natural genus, which ought to be kept distinct from Panicum, whatever may be some ambiguous ones; especially as Panicum itself is so overloaded with species already, and so difficult, in many cafes, to define.

It is remarkable that no Papahum has been found in Europe, though the species of Panicum are scattered all over the world. S.

PASPARDO, in Geography, a town of Italy, in the department of the Adda and Oglio; 4 miles N. of Breno.
PASAYA, a town of South America, in the vice-royalty of Buenos Ayres; 60 miles S. of La Plata.
PASQUA, a town of Mexico, in the province of Xalifico, situated at the mouth of a river, which runs into the Pacific ocean; 45 miles W.N.W. of La Purification. N. lat. 20° 5'.
PASQUALI, Signor, in Biography, an excellent performer on the violin, and a good musician, who came to England about the year 1743, went to Edinburgh in 1752, where he had an establishment, and lived much respected as a professor, and beloved as a man by all who knew him, till the time of his death in 1757. The following is extracted from the Edinburgh Caledonian Mercury of Saturday, Oct. 16th, 1757.

Thursday, October 13th, 1757. Died at Edinburgh Signor Pasquali, master of music in this city, a person eminent in his profession as a composer, performer, and teacher. He joined to a singular probity of manners, good sense, and knowledge of mankind, free from the smallest tincture of caprice. One qualification most remarkable in him was, that although he did the greatest justice as a teacher, yet he acted in his profession more from a real delight in music, and regard to fame, than profit or gain. Under his conduct, the spirit of this branch of the fine arts has diffused itself through all ranks, and is now carried to a degree never before known in this kingdom. Signor Pasquali's death is a public loss to this city, that will not soon be supplied.

PASQUILINI, Signor, an Italian performer on the violoncello, who arrived in England about the year 1747, and remained here till the time of his death, about 1756. He had great knowledge of the finger-board, and his execution was very neat; but his tone was thin, crude, and uninteresting. After the death of Caposale, he was the principal performer on the violoncello at the opera, at Ranelagh, and at all the great concerts. He was a good musician, and performed correctly the part assigned him; but without effect. In Dublin, when he had played half his solo, the Seward
PASQUARO, or UTZIUS PASQUARO, in Geography, a town of Mexico, and present capital of Mexico, on the S. side of a large lake abounding in fish. The population consists of 522 families of Spaniards and Mulattoes, and 2000 families of Indians, chiefly employed in sugar-mills, and neighbouring copper-mines; 120 miles W. of Mexico. N. lat. 19° 50'.

PASQUE-FLOWER, in Gardening, the common name of a well-known flower. See Anemone.

PASQUETANK, in Geography, a county of North Carolina, in the district of Edenton, N. of Albemarle found, containing 5237 inhabitants, including 1593 whites.—Also, a small river of North Carolina, which rises in the Great Dismal Swamp, and, passing by Hertford, falls into Albemarle found.

PASQUIER, Stephen, in Biography, a celebrated lawyer, and man of letters, was born at Paris in 1528. Having been educated for the bar, he was, at a proper time, admitted an advocate in the parliament of Paris, and became distinguished as one of the most eloquent pleaders of his time, as he really was one of the most learned men of his age. He found, particularly in the causes which he pleaded against the Jesuits, who, he contended, ought not only to be excluded from the university, but banished wholly from the kingdom. He was at all times a zealous friend to the royal authority, and was rewarded by Henry III. with the post of advocate-general of the chamber of accounts, which he exercised with great credit, and transmitted to his eldest son. He died in 1615, at the great age of 87. He had been thrice married, the first time, as he says, in a Latin epigram, for enjoyment, the second for the sake of money, and the third for help. He was a considerable writer in verse and prose. His poems are in Latin and French; the former are reckoned by much the best. The most important of Pasquier's works is entitled "Recherches fur la France," of which he published seven books, and three more were given from his papers after his decease. The first edition of it is that of 1605. His letters, in five volumes, are full of curious anecdotes and remarks. His "Catechisme des Jesuites" is a very severe attack upon the founders and principles of that order. His second son Nicholas, a dever of requets, left a requert of letters abounding with historical anecdotes. Moreri.

PASQUIN, a mutilated statue, seen at Rome, in a corner of the palace of the Ufoni. It takes its name from a cober of that city, called Pasquin, famous for his fineers and gibes; and whose hop was the resort of a number of idle people, who diverted themselves with bantering folks as they passed by.

After Pasquin's death, as they were digging up the pavement before his shop, they found a statue of an ancient gladiator, well cut, but maimed, and half spoiled. They set up, in the place where it was found, at the corner of the deceased Pasquin's shop; and, by common consent, called it by the name of the defunct.

From that time all statues and lampoons are ascribed to this figure, and are put in its mouth, or pasted against it; as if they came from Pasquin redivivus. Pasquin usually addressed himself to Marforio, another statue in Rome; or Marforio to Pasquin, whom they then make reply.

The answers are usually very short, poignant, and unlucky. When Marforio is attacked, Pasquin comes to his affilliance; and Pasquin is asliffed by Marforio in turn; i.e. the people make the statues speak just what they please.

PASQUINADE, or PASQUIL, is properly a satirical libel, fastened to the statue of Pasquin.

Hence, by extension, the term becomes used for any satire, lampoon, or sneer upon the public, or upon the ruling powers.

There is this difference between a pasquinade and a satire; that the end of the latter is to correct and reform; whereas that of the former is only to scoff and expose.

The Italians have published several books which they call Pasquino in Zoffa, Pasquino in an effay.

PASQUINO, Marforio, in Biography, a great organ-player at Rome, began to flourish about the year 1620, and his son, Bernardo Pasquino, the master of Gaspardini, about 1672. This last was contemporary with Corelli, and frequently played in the same orchestra with him at the opera in Rome. See Paral. des Fran. et des Ital.

PASS, in Military Language, a straight, narrow and difficult passage, which shuts up the entrance into a country.—Also, a voucher for the absence of a non-commissioned officer or soldier.

Pass, To, is to march by open order of columns, for the purpose of saluting a reviewing general. Each division or company, on its march, will open its ranks at the distance of 50 paces from the general, and again close them, after it has passed thirty paces. The whole march in ordinary time, till the leading division arrives at the spot where the left of the battalion originally stood. The commanding officer then halts the regiment, the music ceases to play, and the different divisions which supported arms march in quick time until they have completed the third wheel from the ground of original formation, when arms are ordered to be carried, the music plays, and as each division completes the third wheel, the officers shift to the right, and the whole pass the general.

Pass, All's well, a term used by a Britifh fentry, after he has challenged a perfon that comes near his post, and has given him the proper parole, watchword, or counter-sign.

Pass-Parole, a command or word, which is given out at the head of an army, and from thence paffed from mouth to mouth, till it reach the rear.

Pass. See Passport.

Pass, picturesque, in Fencing, a leap, or advance upon the enemy.

Of these are several kinds; as voluntary paff, commencing from the left foot out, of measure of the firm foot; as when the enemy is not expected.

Others, necessary, made after a pufh, from the right foot; where, being to pufh by the enemy as not to have time to retire, you endeavour to seize the guard of his fword.

The measure of the paff is, when the two smalls of the fwords are fo near, that they may touch one another.

There are paffes within, above, beneath, to the right, the left; and paffes under the fword, over the lign, &c.

Pass, among Miners, a frame of boards confifting of two or three bottom boards, and two side ones, fit flopewife; through which the ore slides down into the cofler of the flaping-mill.

Pass of Arms, in Chivalry, a place which the ancient knights undertook to defend, e. gr. a bridge, road, &c. which was not to be paffed without pufhing the perfon who kept it.

The knights who held the pafs, hung up their arms on trees, pales, columns, &c. erected for the purpofe; and such as were difposed to difpute the pafs, touched one of the
PAS

thee armories with his sword, which was a challenge the other was obliged to accept. The vanquished gave the victor such prize as was before agreed on.

PASS-GUARDS, in Ancient Tilting Armour, were plate fixed on each shoulder, declining from the face like wings, which were intended to protect the eyes from the point of the lance: the left side of the face, the left shoulder and breast were covered by a plate called grand-guard.

PASPA, Uso Paffa, in Pharmacy, a term applied to those dried grapes, which we call raisins.

Uso PASSE is sometimes also used, with less propriety, for figs.

PASSACAGLIO, a slow dance, resembling the chaconne; the only difference is, that it is generally somewhat slower, and more pathetic: on this account, the passacaglii are almost always composed in the minor keys. Broffard.

PASSACAILLE, Fr. Rouffeau gives nearly the same definition; adding, that the passacaille of "Arma" and "d'Eff" are famous in the operas of Lulli and Mondonville.

PASSADE, or PASSADO, in Fencing, a thrust or pas.

Passade is also a benevolence or alms given to poor passengers.

Passade, in the Manege, signifies a turn or course of a horse backwards or forwards on the same plot of ground, passing or repassing from one end to the other.

This cannot be performed without changing the hand, or turning and making a demi-tour at each of the extremities of the ground. Hence it is, that there are several sorts of passades, according to the different ways of turning, in order to part or put again, and return upon the same piste, or tread; which we call closing the passade.

The passades are the truest proofs a horse can give of his goodnes. By his going off, you judge of his stnfts; by his stops, you discover the goodnes or imperfection of his mouth; and by the readiness with which he turns, you are enabled to decide upon his address or grace.

A passade of free times, or a demi-volte of five times, is a demi-tour made at the end of the straight line, one hop in, in five times of a gallop upon the haunches; and, at the fifth time, he ought to have closed the demi-volte, and to present upon the passade line straight and ready to return. The demi-voltes of five times or periods are the most common airs of changing the hand, or turning, that are now practiced.

A perfect passade is made in this manner: your horse standing straight and true upon all his feet, you go off with him at once, you flop him upon his haunches, and in the same time or cadence in which he made his flop, being exactly obedient to the hand and heels, he ought to make the demi-volte, balancing himself upon his haunches, and so waiting, till you give him the aid to set off again. In this case it is necessary, that the least motion or hint of the rider should be an absolute command to the horse. If you would have him go off at full speed, yield your hand, and close the calves of your legs upon him; if he does not answer to this aid, give him the spurs, in such a manner as not to remove them from the place where they were; without opening or advancing your legs before you strike.

Raised, or high passades, are those which a horse makes, when, being at the end of his line, he makes his demi-volte in any air he has been taught, either in the mezoir, or in curves. In high passades, let your horse go off at full speed; let your flop be followed by three curves; let the demi-volte consist of the same number, and demand of him three more before he sets off again. It is usual to make nine curves, when you work a horse alone.

Vol. XXVI.

PAS

Furious, or violent passades, are when a horse gallops at his utmost speed straight forward, and makes his half stop, bending, and playing his haunches two or three times before he begins his demi-volte, which is made upon one line in three times; for at the third time he should finish the demi-volte, and be straight upon the line of the passade, in order to go off again and continue it. This kind of passade was formerly used in private duels.

Passade of one time, is a demi-volte or turn, made by the horse, in one time, of his shoulders and haunches.

In all passades the horse should, in making the demi-volte, gather and bring in his body, making his haunches accompany his shoulders, without falling back, or not going forward enough each time; and he should go in a straight line, without traversing or turning his croupe out of the line. Berenger's Horsemanship, vol. ii. chap. 15.

PASSADUNKEAG, in Geography, a considerable branch of Penobscot river, meandering through four townships, and affording a route by which the Indians have an inland communication with the Schooduck lakes, and other waters which flow into Paffamaquoddy bay by a short portage.

PASSAGE, in Sea Language, denotes a voyage from one place to another by sea; an outward or homeward bound voyage.

Passage Boat, a boat to carry passengers and luggage from one place to another by water.

Passage, in Commerce, or Right of Passage, is an imposition, which some princes exact by their officers or farmers, in certain narrow close places of their territories, either by land or sea, on all vessels, and carriages of all kinds; and even sometimes on persons as passengers coming in or going out of ports, &c.

The passade of the Sound (that famous strait, which carries us out of the German into the Baltic sea,) is the most celebrated passade in Europe. The does thereof belong to the king of Denmark, and are paid at Ellinore or Cronenbourg.

Passage, in the Manege, an action, in which the horse raises two legs together, a hind and a fore-leg, in form of St. Andrew's cross; when setting these two on the ground again, he raises the other two; and thus alternately, never gaining above a foot of ground at a time.

The beauty of the passage consists in keeping the legs a good while in the air: setting that aside, the motion of the legs in the passade is the same as in pacing and trotting.

As the passade is the key which opens to us all the juf- tnesses of the art of riding, and is the only means of adjudging and regulating horses in all sorts of airs, it is necessary to observe, that there are many kinds of it. In that which is derived from the trot, the action of the horse's legs is the same as in the trot; and this passade is distinguished from the trot, merely by the extreme union of the horse, and by his keeping his legs longer in the air, and lifting them both equally high and being neither so quick nor violent as in the action of the trot. In the passade which is founded on the walk, the action of the horse is the same as in the trot, with this difference, that he lifts his fore-feet a good deal higher than his hinder; that he makes a certain time or interval sufficiently long between the motion of each leg; his action being much more together and shortened, more distinct and flow than the ordinary walk, and not so extended as in the trot, so that he is, as it were, kept together and supported upon himself. There is another sort of passade, to which the trot likewise gives birth, and in which the action is so quick, so diligent, and so supported, that the horse seems not
not to advance, but to work upon the fame spot of ground. No horse should be put to passage till he has been well trotted out, is supple, and has acquired some knowledge of the _union_, which see. Berenger's Horseman, vol. ii. chap. 10.

To passage a horse upon his own length, see LENGTH. 

**Passage.** *Paffio_, Ital. in _Music_, is a fugue, or sentence, selected for praise, censure, or illustration. But in France, according to Roufcau, it is a flourish, or division in gracing a particular bar, or trait of melody. But in Italy, fingers are obliged to know how to invent passages extemporaneously upon any given notes; whereas in France, and, we fear, in England, young fingers dare not hazard a single passage that has not previously been written down and practiced.

**Passage.** _Birds of_, in _Ornithology_ are such as only come to us at certain seashore, and then disappear again; being supposed to pass the sea to some other climate.

Among the birds of passage are the skylark, swallow, nightingale, martin, woodcock, quail, hooded crow, cuckoo, wry-neck, several species of the pigeon and thrush. Snipe, curlew, several species of land-piper, long-legged plover, land-rail, several species of grebe, divers, terns, merganers, many species of ducks, &c.

Mr. Pennant remarks, that every species of the genera of curlews, woodcocks, land-pipers, and plovers, that forfakes us in the spring, retire to Sweden, Poland, Prussia, Norway, and Lapland, to breed; and as soon as the young can fly, they return to us again; because the frosts which fet in early in those countries, deprive them of the means of subsistence; and the dryness and hardness of the ground, in general, during our summer, prevent them from penetrating the earth with their bills in search of worms, which are the natural food of these birds. Of the numerous species of migrating fowl, there are scarcely any that may not be traced to Lapland, a country of lakes, rivers, swamps, and alps, covered with thick and gloomy forests, that afford shelter during summer to these fowls, which in winter differ over the greatest part of Europe. In those northern regions, by reason of the thickness of the woods, the ground remains moist and penetrable by the woodcocks, and other slender-billed fowl; and for the web-footed birds, the waters afford larvae with numbers of the gnat. The days are long, and the light nights are favourable to their collecting this food; to which we may add, that mankind are very sparingly scattered over that vast northern waste. British *Zoology_, vol. ii. Appendix. See Migration.

Befide the migratory birds, which live in different countries a whole winter, or a whole summer, there are some others which annually appear in particular places, at the time of the ripening of particular kinds of grain which their own country is deficient of; and these depart after a short stay, and are no more seen till that time the following year. Of this kind are the rice-bird, and blue-wing of Carolina. Birds, like men, pursue their searches after food, or whatever else is necessary and agreeable, through distant climates; and, when they discover some new grain, or pleasing food, they return and acquaint their community of the good fortune; and them, joining in numerous flights, make annual excursions to fetch themselves on this exotic food.

Since the discovery of America, there have been introduced from Europe several kinds of grain which were before unknown there, and which, not before some length of time, were found out, and coveted by birds of this migratory kind. Of this fort there is a very beautiful species, which has very lately made its first appearance in Virginia; these arrive annually at the time that the wheat is ripe, or nearly 10; and constantly, since they found it out, have appeared in great droves every year, at the season of its ripening: the inhabitants call them, for this reason, wheat-birds. _Phil. Trans_. N° 483.

There are also fishes of passage, as herrings, mackerel, &c. See Fishery.

**Passage.** *Passage_, in _Geography_, a town of South America, in the government of Tucuman, on a river of the same name; 116 miles N. of St. Miguel de Tucuman

**Passage Canal,** an inlet in Prince William's sound. N. lat. 66° 48'. E. long. 212° 15'.

**Passage Fort,** a small town of Jamaica, in the road between Port Royal and Spanish Town; 7 miles S.E. of the latter, and at the mouth of the river Cobre, where it has a fort, with ten or twelve guns. Its trade is brisk, and it contains about 400 houses, most of them being houses of entertainment.

**Passage Island,** a small island at the entrance of a channel from the North Pacific ocean, among the Philippine islands, about 20 miles E. from the island of Leyta. N. lat. 10° 44'. E. long. 125° 27'.—Also, a small low island in the gulf of Georgia, at the entrance into Howe's sound. N. lat. 49° 21'. E. long. 237° 3'.

**Passage Islands,** two small islands among the Virgin islands in the West Indies, near the coast of Porto Rico.

**Passage, Great,** one of the Virgin islands in the West Indies, about seven miles long and two wide; 12 miles E. of Porto Rico.

**Passage, Little,** one of the Virgin islands, near the former.

**Passages, Las,** a sea-port town of Spain, in Guinea, with a good harbour, sheltered by mountains, with depth of water sufficient for a 50-gun ship. This is one of the largest and safest harbours in Europe; 3 miles E. of St. Sebastian. N. lat. 45° 10'. W. long. 2°.

**Passage Point,** a cape on the coast of Patagonia, in the straits of Magellan. S. lat. 53° 15'. W. long. 75° 40'.

**Passage Rocks,** two rocks in Prince William's sound, one north, about 25 miles N.N.W. from the north point of the entrance into port Chalmers, Montague's island, and the other south, half a mile W. from the same point.

**Passagers.** See _Aliens_.

**Passagio,** in the _Italian Music_. See Passage.

**Passago,** in the _Glas and Trade_, the instrument with which the workman makes the bowl of the drinking-glasses, or other like vesseis.

**Passaic,** in _Geography_, a river of America, which rises in a large swamp, in Morris county, New Jersey, and pursues its course from W.N.W. to E.S.E. until it unites with the Hackinoc at the head of Newark bay, N. lat. 40° 43'. W. long. 74° 5'. The cataract, or Great Falls, in this river, is one of the principal natural curiosities in the state. The river is about 40 yards wide, and moves with a gentle current till it approaches a deep cleft in a rock which crosses the channel, and then falls above 70 feet perpendicularly, presenting a most beautiful, though tremendous, scene. The new manufacturing town of Paterson is erected on the Great Falls of this river, and its banks are adorned with many elegant country seats. It abounds with various kinds of fish. A bridge, 500 feet in length, crosses this river on the post-road from Philadelphia to New York.

**Passa.** A town of France, in the department of the Orne, and chief place of a canton, in the district of Domfront; 6 miles S.W. from Domfront. The place contains 2224, and the canton 14,556 inhabitants, on a territory of 170 kilometres, in 9 communes.
PASSALORHYNCHITES, PASSALORHYNCHITE, in Ecclesiastical History, a sect of Montanists in the second century, who made profession of perpetual silence, and, the better to maintain it, kept the thumb continually upon the lips; founding their practice on that of the Psalms, Set a guard, O Lord, on my mouth.

St. Jerom mentions his having met with some of them in his time.

PASSAMAN, in Geography, a town on the W. coast of the island of Sumatra, near the equator.

PASSAMAQUODDIIES, a tribe of Indians, who inhabited the vicinity of Paffamaquoddy bay.

PASSAMAQUODDY, a town and river of America, near which is the division line between the British province of New Brunswick and the United States. The island of Camo Bello in the North Atlantic ocean, is at the middle or W. passage of the bay, in N. lat. 44° 50', and W. long. 66° 46'. The distance from Crof's Isle, Machias, to W. Paffamaquoddy head, is nine leagues N.E. by E.; and from the head over the bar to Allen's Isle N.N.W. two leagues. Three rivers fall into the bay; the largest of which is called by the Indians the Scoodich, but by De Moms and Champlaine, Etchemina. Its main source is near Penobscot river, and the carrying place between the two rivers is only three miles.

PASSAMEZZO, from pafer, to walk, and mezzo, the middle, in Mufic, is a slow dance, differing little from the action of walking. As a galliard consists of five paces, or bars, in the first strain, and is, therefore, called a cince pace, the paffamezzo, which is a diminutive of the galliard, has just half that number, and from that peculiarity takes its name.

PASSANGAN, in Geography, a town on the N. coast of the island of Sumatra. N. lat. 4° 45'. E. long. 97° 2'.

PASSANT, in Heraldry, a term applied to an animal in a shield, appearing to walk leisurely; or, to the ordinary posture of terrestrial animals.

Thus we say, he bears gules two lions passant, pale. For mall beait, except lions, they frequently use the word triping instead of passant.

PASSARA, in Geography, a town on the W. coast of the island of Bornco; 83 miles S.W. of Bornco.

PASSARADO, or Passaree, in a Ship, is a rope whereby all the sheet-blocks of the main and fore-rips are hauled down; the clew of the main-rip to the cubbridge-head of the main-mast, and the clew of the fore-rip to the cat-head. This is to be done when the ship goes large; and they are also kept firm down, and hindered from flying up, by this passaredo rope.

PASSARCA, in Geography, a river of Prusia, which runs into the Frisch Hall, N. lat. 54° 23'. E. long. 19° 44'.

PASSARGOS, Log, a small island in the Grecian Archipelago, between the coast of Natolia and the island of Scio. N. lat. 38° 17'. E. long. 26° 14'.

PASSARO, a town of Sicily, in the valley of Noto; 30 miles S. of Syracuse.

PASSARON, a town of the Morea; 18 miles S. of Argos.

PASSAROWITZ, a town of European Turkey, in Servia, near the river Morava; 33 miles E.S.E. of Belgrade.

PASSARUAN, PASSAROWAN, Passorouang, or Pas- fouroang, a town of the island of Java, and capital of a kingdom, situated on the N. coast; the chief trade of which consists in cotton. The hones are neatly built, and the country appears to be well cultivated. The product of this settlement is rice, of which they export large quantities. The Dutch here are few; the Javanese are numerous, and their chief lives with considerable splendour. They have good roads, and posts are established along the coast; and it appears to be a busy and well-regulated settlement. S. lat. 7° 36'. Stavornov's Voyage, vol. ii.

PASSAU, a city of Germany, in the circle of Bavaria, and capital of a bishopric and principality of the same name, situated on the Danube, where it receives the Inn and the Ilz. It consists of three towns, viz. Passau properly so called, betwixt the Danube and the Inn, Innaufzdt, and Ilzauftdt. The city, where it is surrounded by water, is without the walls, but towards the land side of Bavaria is fortified with ramparts and ditches. Passau is well situated for trade. It remained under the power of the Romans till it was taken by the Alamanni in the year 475. After its fall under the dominion of the Franks, it continued subject to the dukes of Bavaria. In 990, it was made subject to the bishop by the emperor Otho III. In 1552, the religious peace, usually denominated "The treaty of Passau," was concluded here. In 1802, part of the bishopric beyond the Ilz and the Inn, towards Austria, was given to the grand duke of Tucfany; 82 miles E.N.E. of Munich. N. lat. 48° 34'. E. long. 13°.

The famous treaty of " pacification" with the Protestants was concluded at Passau, soon after the advantage gained by Maurice of Saxony against the emperor Charles in the year 1552: the emperor also promising to assemble, within six months, a diet, in which all the tumults and diversions that had been occasioned by a diversity of sentiments in religious matters should be removed. (See Augsburg.) As this treaty is considered by the German Protestants as the basis of their liberty, it may not be improper to insert here some of its principal articles.

By the three first articles it was stipulated that Maurice and the confederates should lay down their arms, and should lend their troops to Ferdinand to defend Germany against the Turks, and that the landgrave of Helft should be freed at liberty. By the fourth, it was agreed that the role of faith, called "Interim," should be considered as null and void; that the contending parties should enjoy the free and undisturbed exercise of their religion, and a diet should be assembled to determine amicably the present disputes; and that this religious liberty should continue always, if it should be found impossible to come to an uniformity in doctrine and worship. It was also resolved, that all those who had suffered banishment, or any other calamity, on account of their having been concerned in the league or war of Smalcald, should be reinstated in their privileges, possessions, and employments; that the imperial chamber of Spire shall be open to the Protestants as well as to the Catholics; and that there should be always a certain number of the Lutheran persuasion in that high court.

PASSAWAY, a town of Hindooftan, in the circar of Jynagur; 30 miles E. of Parasooll.

PASSE-BLEU, in Ornithology. See Tanagra Caerulea.

PASSE-HENDAELE, in Geography, a town of France, in the department of the Lys, and chief place of a canton, in the district of Ypres. The place contains 2604, and the canton 14117 inhabitants, on a territory of 110 kilometres, in 5 communes.

PASSEMANT, Claude Simeon, in Biography, an able French optician and mathematical instrument-maker, was born at Paris in the year 1702. He had little more than his industry to depend on, and for some time he wrote in an attorney's office; after this he entered himself as a clerk.
clerk or shopman to a woollen-draper, and then carried on the busines of a haberdasher on his own account. Being married, he committed the care of his shop to his wife, and directed his own attention to the study of natural philosophy, optics, and astronomy, which he had cultivated from his youth at leisure hours. He devoted likewise much of his time to the construction and improvement of mathematical instruments, for which he seems to have had a decided mechanical turn. In 1738, he published "A Treatise on the Construction of Reflecting Telescopes." Some time after this, he published "The Description and Use of Telescopes, Microscopes, &c." of his own invention. He constructed an astronomical pendulum, crowned with a moving sphere, which was made to represent the revolutions of the planets, in a manner that exactly corresponded with the astronomical tables. He presented this machine to Lewis XIV, and it was formerly to be seen in the royal apartments at Versailles. He made a similar instrument for the Turkish emperor, which showed the rising and setting of the sun and moon. He furnished the king and other great men in France with sets of instruments for making experiments in optics, and other branches of science. He died suddenly in 1769, respected as well for his integrity and amiable character, as for his talents and acquirements.

PASSENHEIM, in Geography, a town of Pruflia, in the province of Oberland; 70 miles S. of Konigberg.

PASSEZ-PIED, a dance, though of the same measure as the minuet, except that it admits of no binding-notes, and begins with an odd quaver. Indeed it more resembles the courant than the minuet.

PASSEZ, in Geography, a river of the Tyrolese, which runs into the Adige, near Meran.

the study of antiquities, which he pursued with affinity during a four years' residence at Rome. Returning thence to Todi, he collected the monuments of antiquity in that place and its vicinity. In 1726, he turned his attention to Etruscan antiquities, and collected a great number of lamps, and other things, which he arranged in cabinets. In 1738, having lost his wife, he entered into the ecclesiastical order, and obtained the office of vicar-general of Pefaro. This he exercised many years with zeal and fidelity. He was killed by a fall from his carriage in the year 1780, as he was returning from his country house. He was author of a great number of works, among which are the following: 

When he died, the first volume of an extensive work of his was printing at Rome, entitled, "Thesaurus Germannum Selecffimærum."

PASSERINA, in Botany, from paffer, a sparrow, a name which has been applied to some plants, on account of the resemblance of their leaves to the tongue of a small bird. Such at least is its application with reftpect to *Lyfimachia* Linnæus, *Linum-fiflatum, Linum fritium*, and *Stellera Pafferia*. But Linnaeus, who has chosen this appellation for the genus that now bears it, cites Pukcnat for saying it is so called because the fruit represents the head of a little bike with its beak; see Linn. Hort. Cliff. 146. The resemblance is not very striking, but the name is preferable to that given by Chibus to the same genus, *Sanamunda*, supposed to be derived from fano, to heal, and mundus, clean; though he adopted it from the Moors of Græcia, who were accustomed to use some of this tribe as a poultice. Linn. Gen. 153.

Gen. Ch. Cal. Përr. of one leaf wrihing, externaly rude, internally coloured; tube cylindrical, slender, tumid below the middle; limb spreading, in four deep, concave, ovate, obtuse segments. Cor. none. Stam. Filaments eight, britle-shaped, the length of the limb, inserted into the top of the tube; anthers nearly ovate, erect. Pçft. Germin ovate, within the tube of the calyx; style thread-shaped, springing from the fide of the summit of the germen, as long as the tube; stigma capitatis, rough all over with brilly hairs. Peric. leafy, ovate, of one cell. Seed foliary, ovate, obliquely pointed at each end.

Eff. Ch. Calyx coloured, four-clft, withering; Corolla none. Stamens prominent. Style lateral. Seed follicular, coated.

Oh! The analogy of *Daphne* renders it indisputable to consider this flower likewise as having a coloured calyx, not a corolla, especially as others of the same natural order have petals, or séctaries, besides; see Corolla and Daphne. Linnaeus has observed that, in *P. capitata*, there are eight interior abortive flaminæ; and in *uniflora*, the rudiments of eight supernumerary anthers, in the bottom of the flower. These influences keben the value of the reputed petals, séctaries, or glands, which diluting from other genera from this and Daphne. Accordingly, of the eight *Pafferia* in Linn. Sp. Pl. ed. 2. *fœtæ*, *dodcedandra* and *levigata* are now removed from hence; though recent discoveries have, on the other hand, enlarged the genus to fifteen species. How far any of the new ones may be liable to exception in the generic character, we have no infallible means of detemining, but we shall briefly enumerate the whole. All, except *hirfata*, *orientalis*, and *canicentis*, are natives of the Cape of Good Hope; five are cultivated in Britain.

1. *P. filiformis*. Filiform Sparrow-wort. Linn. Sp. Pl. 513. Ait. Hort. Kew. v. 1. (P. foils linearius; Linn. Hort. Cliff. 246. t. 11.) —Leaves linear, convex, imbricated in four rows. Branches downy.—This is often seen in green-houses, flowering in summer. The *flæm* is shrubby, repeatedly branched; the younger branches downy, covered with imnimmere smooth narrow leaves, about half an inch long. *Flowers* solitarie, small, yellowish, from the bôfoms of many leaves together towards the tops of the branches, such leaves having at their base, on each fide, a broad, membranous, rounded, furrowed dilatation.—The synonym of Bremynus, still retained by Williamow, belongs to *Gnidia simplex*, under which he repeats it. Linnaeus in Hort. Cliff. has several faulty synonyms besides, as he there confounds not various African, but even European, plants.

3. *P. cricoides*. Heath-like Sparrow-wort. Linn. Mant. 236.—Leaves oblong, obtusé, polished, bluntly keeled; with a woolly furrow above. Tube of the calyx globoul and hairy; limb smooth. From the Cape.—This has much the aœst of an *Erca*, and is yet closely allied to both the foregoing, as if intermediate between them, yet perfectly distinct. The branches are downy or woolly. *Leaves* not a quarter of an inch long, of a short, oblong, prismatic shape; green and polished, except a narrow hairy furrow along their upper or inner surface. *Flowers* axillary, selfifile, the accompanying leaves being dilated and ovate. The globule hairy tube of the *flœur* is filled by the germen, and finally forced off by the ripe *fruits*, which appears to be pupy, and if so, the plant becomes perhaps more properly a Daphne. The *seed* is black and shining.

4. *P. neroida*. Ribbed Sparrow-wort. Thum. Prodr. 75. Wild. n. 4.—*Leaves lanceolate, three-ribbed, smooth. Flowers capitata.*—Of this and the following we have been no specimen.

6. *P. capitata*. Smaller-headed Sparrow-wort. Linn. Sp. Pl. 513. Ait. n. 3. (Thymelæa folis linearius alternis, flor. bus ex unro petiolo copiosis; Burm. Afric. 133. t. 48 f. 3.)—Leaves linear awl-shaped, smooth on both sides. Heads of flowers downy, or downy, clav-ribbed, terminal *flalks.*—Sent from the Cape in 1789, by Mr. F. Maffon. It flowers at Kew from June to September, being kept, like all the rest, in the green-house. Burman describes this as of very lotty growth, with red or purplish branches two feet long, which are repeatedly subdivide; the younger *flœhs*
flattens only slightly hairy. **Leaves** scattered, linear, acute, keeled, smooth, convex above; rather more than half an inch long. **Flowers** white, about ten or more in each dense, hairy terminal tuft, whose stalk is thickened upwards, downy, crowned with a hairy ring or border around the flower. Burmann by mistake uses the word petiolo for pedunculo in his definition above.

7. **P. orientalis**. Oriental Sparrow-wort. Willd. n. 7. (P. folis lanceolatis; Gronov. Orient. 48; Sanamanda prima; Clus. Herb. v. 128; R. R. Willd. Ro. R. 885.) Leaves lanceolate, somewhat flabby, blunt, slightly hairy. Flowers axillary. Native of Spain and the Levant, in open sunny spots, flowering in March and April. A bushy shrub, about two feet high, with a dark-coloured bark. Leaves compared by Clusius to those of *Cenorum tricoccum*, but smaller, shorter, and flabby, somewhat hairy, ranged in a regular manner along the branches. **Flowers** among the leaves, oblong, resembling those of the Olive, but yellow. **Fruit** like that of *Thymelea* (Daphne Gnidium), but blackish. This is all we can gather from Clusius, whose synonymy was originally cited by Linneus under *Pafflerina ciauta*, but afterwards struck out, in his own copy of Sp. Pl. Willdenow has established the present species, on the authority of the authors quoted; but if Clusius be right, the fruit should make it a Daphe. We have a specimen gathered by the Abbé Durand in Barbary, which answers well to the description and figure of Clusius except that the **flowers** are terminal, in little heads on the short lateral branches, and by no means as he represents them.

8. **P. citatum**. Fringed Sparrow-wort. Linn. Sp. Pl. 514. Willd. n. 8. Thunb. Prod. 75. (Thymelea folis oblongo-acutis, ad oras fimbriatis, floribus ex foliorum alis spicatis; Burm. Afric. 139 t. 47 f. 2.)—Leaves opposite, lanceolate, acute, many-rubbed, fringed. Flowers axillary; their tube capillary, twice as long as the leaves. Native of the Cape of Good Hope, not of Europe. The history of this species is extremely confused, as the late Mr. Dryander has shewn, in Tr. of Linn. Soc. v. 2. 234, that excellent botanist and critic having been able to prove rather what it was not, than what it was. The plant described in Hort. Cliff. is merely *Struthiola sirrata*, with which it seems three others are confounded in the Cliffortian collection. The Herbarium of Linnaeus has no specimen. We can, therefore, only depend on Burmann’s synonym, which Linneus uniformly cited, and which he has marked in his copy of Burmann’s hook. Of this the young branches are fquare and purplish. We cannot learn why Willdenow defines the flem as villous. The leaves are foffile, opposite, crossing each other in pairs, ovato-lanceolate, acute, entire, many-rubbed, half an inch, or more, in length, fowly, except a dense fiky marginal fringle. **Flowers** solitary, with a flender tube, about twice the length of the leaf. Burmann’s figure has all the appearance of a Gnidium. We know nothing of the colour of the flowers, for what Willdenow has on that subject is taken from Bergius, whose *P. ciauta* is evidently a different thing. What the Spanish botanists fend under this name is either *P. orientalis*, or *Daphne villosa*. Thus we must still leave the matter in uncertainty, till the genus of Burmann’s plant be ascertained.

9. **P. uniflora**. One-flowered Sparrow-wort. Linn. Sp. Pl. 514. Ait. n. 4. (Thymelea ramosa, linearibus foliis angustis, flore foliario; Burm. Afric. 131 t. 48 f. 1.)—Leaves opposite, triangular-awhaped, smooth and even. Flowers terminal, solitary; their segments acute.—From the Cape. Miller cultivated it in 1759. This is a humble, bushy, smooth *forb*, whose flender branches are clothed with opposite awl-shaped leaves, cropping each other in pairs, and keeled at the back. **Flowers** solitary at the top of each branch, erect, pale purple; their tubes hairy, as long as the leaves; limb of the same length, in four ovate, acute, spreading segments, hairy at the back. Burmann’s fig. 2 is a doubtful variety. See the next species.

10. **P. grandiflora**. Great-flowered Sparrow-wort. Linn. Suppl. 226. Ait. n. 5. Curt. Mag. t. 292 (?; P. linoides; Thunb. Prod. 75?) Thymelea folis imbricatis oblongis, floribus fereis, ramosa; Brum. Afric. 123 t. 46 f. 1.)—Leaves opposite, elliptical, smooth; concave above; convex below; somewhat ribbed beneath. Flowers terminal, solitary; their segments obtuse.—Such are the characters of the original specimen of this plant, gathered at the Cape by Sparrmann. It seems to be of much loftier growth than the last, with thicker branches, downy when young. **Leaves** short and elliptical; very concave above; and no leaves convex at the under side, which prefers itself to the spectator, and which is smooth and shining, furnished with an obscure midrib, but by no means keeled: in a dry flat there is some appearance of lateral ribs at the base, and many corrugations all over the surface, but these latter seem the effect of drying. **Flowers** terminal, solitary, twice the size of the last, apparently pale red, very silky externally, and downy within; their segments broadly elliptical and obtuse. *Stamens* and *style* rising above the tube, but shorter than the limb. By this description it will appear that the plant of the Botanical Magazine answers but imperfectly to ours. Its leaves are much narrower and longer, flowers white, smaller, with acute segments. We are rather inclined to think this latter may be what is represented in Burmann’s t. 48 f. 2, which Linneaus, and the editors of Hort. Kew. have cited as *P. uniflora*; and possibly both are the real *linoides* of Thunberg; but this we have no materials to determine. This author has nothing under the name of *grandiflora* in his Prodromus, nor any single-flowered species, except *uniflora* and *linoides*. Burmann’s t. 46 f. 1 is evidently our *grandiflora*; his f. 2, may be that of the Bot. Mag. See fp. 17, at the end of the genus.

13. **P. laxa**. Slender-branchied Sparrow-wort. Linn. Suppl. 226. Willd. n. 13. Thunb. Prod. 75 (?) Werd. Obl. 20 t. 2 f. 20. *Wild.*—Leaves scattered, lanceolate, keeled, smooth. Branches hairy, divaricated. Flowers cipitate, terminal, bristly.—Gathered by Sparrmann at the Cape. If the younger Linneaus has not decribed from the collection of Thunberg, whom he quotes, a different plant from the marked specimen in his herbarium, given to his father by Sparrmann, nothing can be worse than his description. The branches indeed are flender, and loosely spreading, clothed when young with upright hairs. But the leaves are of a narrow elliptic-lanceolate form, not ovate, nor are they hairy, as Thunberg describes them, except when young. Nevertheless, the allusion in the Suppl. to *P. ericoides*, convinces us that the specimen in the herbarium is correct. The flowers grow feveral together, in terminal leafy heads, and are flender, clothed
clothed externally with long, creé, filkly hairs, the segments of the limb scarcely half the length of the tube.

15. P. anthyliódit. Harry-headed Sparrow-wort. Linn. Suppl. 225. Thunb. Prodr. 76. Willd. n. 15. (Thymelœna folius imbricatis floribus subtornatis, ac subtus incanis; Burm. Afric. 126. t. 46. f. 3.)—Leaves scattered, ovate, hairy. Flowers capitata, terminal, externally bristly.—Gathered by Thunberg, at the Cape. A very handsome species, well described, though not very well figured, by Burmann, whose synonymy is unnoticed by Linnaeus and his followers. The branches are stout, creé, repeatedly subdivided in a falcinate or determinate manner, hairy and most leafy while young. Leaves scattered, imbricated, about three-fourths of an inch long, elliptic-ovate, nearly flat, ribbed, hairy beneath, especially when young. Flowers in large terminal heads, encompassed with numerous large hairy leaves; their outside covered with long, dense, creé, white, silvery hairs; the inside smooth, yellow when fresh, black when dry. Burmann, who saw them in the latter state only, supposed them to be purple. Fruit ovate, of a shining brown, clothed with upright bristles. Seed minutely dotted.

16. P. pentandra. Pentandrous Sparrow-wort. Thunb. Prodr. 76. Willd. n. 16.—"Leaves ovate, hairy. Spikes ovate, terminal." Thunb.—Known only by this description of Thunberg. If the flowers have precisely five flaminæ, it cannot but excite some doubts as to the genus.

Linnaeus admitted into Pafserina, in the Supplementum, three diandrous species, which formed the genus Bankia of Porter. These are now, with many others, established as a separate genus, by the name of Timeæa; see that article. Meanwhile the name of Bankia has been applied to a fifth genus of the Proteaceæ order, with which it remaitly while young.

Having under P. grandifloræ, p. 10, suggested some doubts respecting the linoïdes of Thunberg, we shall here venture to propose that, with what appear to be its synonyms, as a supplemenary species, for future consideration.

17. P. linoidæ. Flax-like Sparrow-wort. Thunb. Prodr. 75. (P. grandifloræ; Curt. Mag. t. 292. Ait. n. 5.) Thymelœna folius imbricati angustiflori, floribus fereciscis, epi- cata; Burm. Afric. 125. t. 46. f. 2. T. scaphodæ, monomotapênus, five folioli glabris triquetris cauis cymbaforibus, floribus foliatissimis fructu caulis villosis; Pluk. Mant. 180. t. 445. f. 8.)—Leaves opposite, elliptic-lanceolate, smooth, concave above; convex, even and three-ribbed beneath. Flowers terminal, foliary; their segments acute. Native of the Cape, from whence it was first by Mr. Maffin in 1789. If we are right in this species, it differs from P. uni- flora in being a much taller herb, with elliptical (though narro-) concave leaves, not awl-shaped keeled ones, and the flowers are white, not purple or blue. From grandifloræ, to which it is most allied, it differs chiefly in having much narrower leaves, even, not ro.065, at the back, and flowers but half as large, whose segments are ovate and acute, not obtuse. Pluknet is inaccurately quoted by Burmann, which the confused plan of his work renders it difficult to avoid.

This species is said by Mr. Curtis to be a hardy greenhouse plant, flowering in May and June, and increased without difficulty by cuttings. It is still, if we mistake not, cultivated by Meffrs. Lee and Kennedy, at Hammer- smith. S.

PASERINA, in Gardening, contains plants of the shrubby, exotic, evergreen kind, of which the species cultivated are, the filiform sparrow-wort (P. filiformis); the flaggy sparrow-wort (P. hirifusa); the headed sparrow-wort (P. capitata); the ciliated sparrow-wort (P. ciliata); and the one-flowered sparrow-wort (P. uniflora).

Method of Culture.—All the sorts may be increased by cuttings planted in a bed of loamy earth, during the summer months, and closely covered with a bell or hand-glass, to exclude the air, steadying them from the sun, and refreshing them now and then with water. When well rooted they may be planted out, each into a small pot filled with loamy earth; placing them in the shade till they have taken new root; then be removed into a sheltered situation, to remain till the beginning of autumn, when they must be placed in the green-house, and treated as the myrtles. They may likewise be increased by layers.

The second sort may also be raised by sowing the seeds in autumn, soon after they are ripe, in small pots filled with light earth, plunging them into an old bark-bed under a common frame in winter: the plants ride in the spring, and must be treated like the cuttings. The feeding plants grow the most creé, and make the handiwork appearance.

This sort is capable of living abroad in common winters, in a dry foil and warm situation; but in hard frosts the plants are frequently destroyed; one or two should therefore be kept in pots, and sheltered during that season.

They afford variety among other potted greenhouse plants.

PASERON ISLANDS, in Geography, a cluster of small islands in the Indian sea, near the coast of Africa. S. lat. 11° 12'.

PASEROTTI, Bartolomeo, of Bologna, in Biography, was a pupil of Zuccari, and a very ingenious painter, one of whose works, (a picture of Titius,) was mistaken by the connoisseurs of Bologna for the painting of Michael Angelo, and whose portraits were thought by Guido to have nearly approached those of Titian. He was a skilful draftsman, and aided in forming the Carracci, particularly Agolino; who made his lines in his pened drawings the guide of his graver. He composed a book on anatomy and symmetry; but was not always guided by his own directions. The debauchery of true taste, begun by the freedom of his master, he aided in its progress; and allowed his better talents to bend to facility of execution, and lose the manner of Passe-Vert, in Ornithology. See Tanagra Cayana.

PASSIDAGPOUR, in Geography, a town of Hindoo- flan, in Oude; 24 miles N. of Manickpour.

PASSIFLORA, in Botany, a name altered by Linnaeus, from the Paeoniae of preceding authors. This was applied to the beautiful genus in question, known universally at present by the appellation of Pafion Flowers, because the instruments of Chiril's passion were thought to be represented in the parts of fructification. The five flaminæ were compared to his five wounds; the three stiles, more aptly, to the nails by which he was fixed to the cross; the column, which elevates the germen, to the cross itself; and to the pillar which he was bound; and the rays of the nothary, to his crown of thorns. There are cuts to be found in some old books, apparently drawn from description, like the hog in armour upon our figures to represent the rhinoceros, in which the flower is made up of the very things themselves. Linn. Gen. 466. Amon. Acad. v. 1. 211. Schreb. 199. Willd. Sp. Pl. v. 3. 606. Ait. Hort. Kew. ed. 1. v. 3. 360. Mart. Mill. Dict. v. 3. Cavan. Diff. 442. Swartz. Ind. Occ. v. 2. 1135. Jull. 397. Lamarck Dict. v. 3. 32. Ilustr. t. 732. (Granadilla; Tour. t. 123. 124. Geizn. t. 60. Muracua; Tour. t. 125. Jull. 308. Taconia; Jull. 358).—Clas and order, Gynandria Pentandria. Linn. Monadelphia Pentandria, Cavan. Willd. Pentandria Trigynia, Schreb.
PASSIFLORA.

Gen. Ch. Col. Perianth of one leaf, in five deep, oblong, equal segments, much resembling the petals, but pointed below the top; its base concave or tubular. Cor. Petals five, oblong, flat, obtuse, usually the size and shape of the calyx, and alternate with its segments; sometimes wanting. Nectary a manifold radiating crown, rarely simple, within the base of the petals; the outer rows longer, the inner of more or less simple, separate or combined, rays or membranes. Stam. Filaments five, awl-shaped, spreading, inferted at the base of the pericarp, upon the column which elevates it; anthers incumbent, pendulous, versatile, oblong, deprected, obtuse. Pif. Gyno-carp roundish, elevated upon the top of a straight cylindrical column, generally shorter than the petals; styles three, spreading, swelling upwards; stigmas capitate, broad. Peric. Berry fleshy, nearly ovate, falked, of one cell. Seeds numerous, ovate, with a pulpy tunic. Receptacles of the seeds three, attached lengthwise to the bottom of the pericarp.

Obf. In the Murucuia of Tournefort, of which two or three species are now known, the nectary is a conical abrupt membrane, disjunct into rays. *P. fabora, minima,* and some allied to them, have no petals. We gladly, at the fuggeration of Wildenow, reduce the Linnean ideas of the calyx and corolla of this genus, which some new-discovered species, the base of whose calyx is elongated into a cylindrical tube, had formerly induced us, like Cavanilles, to give up. Thence the name Tacsonia of Jussieu, Tacso of the Peruvians; a name no less exceptional than the genus. Wildenow errs, nevertheless greatly, in still terming the bracteas an involucrum.

This is one of the most natural genera that can possibly be. Its root is perennial. Stem climbing to a great extent, branched; more or less shrubby below. Leaves alternate, either undivided or lobed, scarcely ever compound, falked, with glands, for the most part, upon their falked, and accompanied by a pair of stipulas, as well as by solitary, fimple, spirally tendrils. Flowers on axillary undivided falks, solitary or in pairs. Bracteas very various in form, usually three, a little remote from the flower, and deciduous; in the long-tubed species often combined into a three-cliff tube, and persistent. Hence when the petals and calyx, both together, came to be considered as a monopetalous corolla, in ten segments, the bracteas were taken for a calyx. See Plant. Jc. ex Herb. Linn. f. 1. t. 24. 25.

The species of this genus are numerous. Linneus in his differtation, de Passif, published in 1745, and reprinted in the first vol. of his Amant, describes 22, with imperfect indications of 18 more. The leaves of those 22, on which only the specific differences chiefly depend, are there very neatly engraved. Twenty-six species are given in Sp. Pl. ed. 2, and 28 only in the 14th edition of Syll. Veg. Lamarck in his Dictionary, v. 3. (Grenadille) has 35. Cavanilles in his tenth differtation describes 44, of which 31 are there figured. Wildenow in his Sp. Pl. has 46. We add five to the list, from the fifth volume of Cavanilles' Icones, and four new ones.

The two last-mentioned authors refer the genus to Monadelphus, and even Schreber has added a note, in his second vol. 426, that the filaments are combined at their base. This union appears to us no flight, and indeed to often wanting, that we much prefer continuing Passiflora in Pentandria, where Schreber first placed it. The Linnean idea, of its being gynandrous, is totally exploded; for there is no infertion of the filaments upon, or above, the germen; the organs of fructification are merely elevated, all together, on a columnar receptacle.

It is remarkable that every described species is exclusively of South American or Well Indian origin, except two found in Virginia and Florida, one in the remote counties of New Caledonia and Norfolk Island, and one in Cochinchina: see n. 2.

The whole are disposed in four artificial sections, by the forms of their leaves. Being such general favourite, we must briefly notice every species, especially as Wildenow is, in some point, very imperfect. Since we follow his arrangement, it is needless to cite him throughout, and we shall confine ourselves in the synonyms to what is absolutely essential, or to what he has omitted.

Section I. Leaves undivided. Thirteen species.

1. *P. ferratiphila.* Note-leaved Passion-flower. Linn. Sp. Pl. 1355. Jacq. Hort. Vind. v. t. t. 10. Curt. Mag. t. 651.—Leaves ovate, finely serrated, downy beneath.—Native of Surinam. A flower plant in England, flowering copiously all summer long. Houfton introduced it to Chelsea garden in 1731. The branches are very long and slender. Leaves green on both sides, smooth above, very soft beneath. Flowers peculiarly delicate, distinguished by the very long, very narrow, curling rays of their nectaries, which are purple at the base, pale blue upwards. The scent of the flower is aromatic, but not unpleasant, partaking of rhubarb-root. Curtis commends it.

2. *P. pallida.* Pale Passion-flower. Linn. Sp. Pl. 1355. (Clematis indica alia, flore minore pallido; Plum. Amer. t. 89.)—Leaves ovate, entire. Footstalks with two glands. Petals none. Fruit elliptical. Gathered in Hifpaniola by Plummer, by whose figure and short description only have we any knowledge of this species. He represents the flowers as scarcely above an inch broad, and delittate of petals, so that it cannot be, as he thinks, the Murucuia-miri of Pifo 248, which is described with very evident red ones. In other respects the figures are not diffimilir. Plummer's has no bracteas, which may be an accidental omission. The fruit is the size and shape of an elve. Pifo's cut expresses nothing as to the bracteas or fruit, but he says the latter is pear-shaped. His plant is greatly commended as a debiffuent, even superior in virtues to Sarpaparilla. Loureiro gives *P. pallida* as a native of Cochinchina; how correctly we now know not at all, it is at least a somewhat hybrid plant.

4. *P. cuprea.* Copper-coloured Passion-flower. Linn. Sp. Pl. 1355. Jacq. t. 1. t. 606. —Leaves ovate, entire, three-rubbed, obtuse. Footstalks without glands. Bracteas minute, deciduous. Fruit elliptical. Native of the Bahama islands, from whence the seeds were brought by Cateley to England, in 1744. It is a tender flower plant, scarcely, if at all, to be seen here at present. The three-rubbed ovate leaves, glaucous at the back, with several dots between the ribs, and the almost linear petals, and segments of the calyx, both

Scriban and Preston.

New Series. Volume I.
both of a dull red on the upper side, mark the species. The
glands of the *foottalks* are perhaps entirely wanting, but
not the *bracteas*, though the latter are minute, and fall off
early, as Jacquin's plate, and even that of Dillenius, ex-
presses.

Sp. Pl. 1355. Cavan. Diff. t. 285.—Leaves heart-shaped,
entire. Foot-talks without glands. Bracteas ovate, shorter
than the calyx. Native of the neighbourhood of Limburg,
where it is cultivated in gardens, but seems never to have
been brought to Europe. Cavannille's plate seems to be
fabricated from Feuille's, at least it does not appear that
the former had seen a specimen, any more than Linnaeus.
The broad heart-shaped *leaves*, reticulated with copious
veins at the back, differing this from all the foregoing.
For the want of glands on their stalks we must rely on
Feuille's figure. The *rays* are crimson, divided by a white
line. Fruit globular, two inches and a half in diameter,
variegated with crimson and yellow, full of sweet Watery
pulp.

Repor. t. 207.—Leaves ovate, pointed, entire. Foot-talks
with two glands. Bracteas ovate, downy, longer than the
calyx. Native of the West Indies, and known in Jamaica
by the name of Sweet Calabash. Our specimens in flower
came from the Hon. Mrs. Barrington's *flower* at Mongewell,
in 1705, where the fruit was also ripened, which seems to
be much like the last. The *leaves* however are narrower,
ovate, very slightly cordate, four inches long. Bracteas
large, pale, soft and downy, extending beyond the flower.
Petals lanceolate, much narrower than the segments of the
calyx, pale fleshy-coloured. Raya variegated with red and
white in their lower part, with purple and white towards the
ends.

plate.—Leaves ovate, with numerous transverse nerves,
extinct. Flower-talk triangular. Stipulas ovate. Stem
with four membranous angles.—Native of the West Indies.
It has long been in our gardens, but to flower and fruit in
perfection, requires a whole spacious flowe itself; along
whole horizontal windows it must be trained, being cut
down every year to the main trunk, which soon acquires
the fize of a small cherry-tree. Thus we have seen it at
lord Harewood's in Yorkshire, laden with huge flowers,
magnificently variegated with violet-purple and crimson,
and with abundance of green oval fruit, the fize of a large melon.
The cavity however is very small in proportion, filled with
sweet pulp, most esteemed perhaps for its rarity. The
stem has very four sharp, thin, prominent angles, or wings.
Leaves near a foot long, broad-ovate, entire, smooth, with
four or fix cup-like glands, full of honey, on their foot-
talks; ten or twelve transverse ribs spring from the main
one at each side. The *petals* are ovate, broad, and entire.
The triangular *flower-talk* is well indicated by Mr. Sowerby,
in Tr. of Linn. Soc. v. 2. 21. t. 5, as the most certain
distinction of this from the next.

Kew. ed. 1. v. 3. 306. Curt. Mag. t. 66.—Leaves ovate,
with few transverse nerves, entire. Flower-talk cylindrical.
Stipula lanceolate. Stem with four membranous angles.
Native of the West Indies, from whence it is said to have
been introduced at Kew in 1772. This is smaller in every
part than the last, generally with four, glands only on the
foot-talks; not more than five or fix curved transverse ribs,
on each side of the principal one; lanceolate *stipulas*, which
are now and then slightly serrated, and much smaller
Bracteas. The flowers are very agreeably and powerfully
fragrant; the upper sides of the petals and *calyx* of a pecu-
lar deep scarlet red, the rays creft, as long as the petals,
variegated with purple, white and crimson, incurved at the
points. No *fruit* has ever been produced in England. The
plant is propagated by cuttings, and is a great ornament to
a flowe. We have a *specimen* gathered by Commerson in
the isle of Bourbon, to which country this species was pro-
bably brought originally from the West Indies. We must
observe that the *flower-talks*, cylindrical when fresh, become
triangular in drying.

elliptical, with a small point, entire, veiny, smooth. Foot-
talks with two glands at their summit. Bracteas elliptical,
concave, toothed, as long as the calyx.—Native of Surinam
and Martinico. Known in the West Indies by the name of
War Lemon, its yellow ovate fruit being extremely grate-
ful for its sweetens and fragrance. The *leaves* are oval, co-
riceous, smooth and shining, reticulated with small veins.
*Stipulas* linear-lanceolate, toothed. Flowers remarkably
handome, though less vivid in colour than the last; their
petals and *calyx* reflexed, pale, dotted with red; their
rays creft, thick, richly speckled with blue and white.
This easily cultivated in a flowe, and has been known in England
since 1690, when the first earl of Portland introduced it.
The two doubtful *Passiflore*, Pl. Surinam. n. 152 and 74,
Linn. Am. Acad. v. 8. 262, appear to belong to this.

285. t. 324.—Leaves ovate, somewhat heart-shaped, sharply
serrated, nearly smooth. Foot-talks with four or fix glands.
Bracteas elliptical, concave, obtuse, as long as the calyx.
Observed by Aubet in Guiana, flowering in August, when
also he gathered the *fruit*, which he describes as divided into
three cells, full of a pleasant eatable pulp. The brown rough
*petals* of the *leaves* distinguish this from all the rest of the
present collection. Cavanilles, who saw specimens in Juffieu's
collection, says they are downy beneath when young; and he
also represents the large inflated *bracteas* serrated through-
out; *Aubet* figures them entire. The *flowers* are of a
brilliant red, with orange rays.

11. *P. muerata*. Pointed Passion-flower. Lamarck
Dict. v. 3. 33. Cavan. Diff. t. 282.—Leaves heart-shaped,
obtuse, reticulated, smooth, entire. Foot-talks with two
glands. *Stipulas* and *bracteas* broad-ovate, pointed, entire,
flat. Stem cylindrical. Gathered by Commerson at Rio
Janeiro. The texture of the *leaves* is like *laurifolia*, but
their form is ovate, heart-shaped at the base. *Stipulas* and
bracteas remarkably pointed; the latter are flat, and hardly above
half the length of the *calyx*. The *petals* are narrow, and, as
far as we can judge by the dried flower, pale. The young
*leaves* feem elegantly speckled.

Diff. 453. t. 281.—Leaves ovate, acute, reticulated, smooth,
entire, foot-talks with two glands. Bracteas much shorter
than the tube of the *calyx*, with two glands at their base.
Nectary extremely short.—Gathered by Mr. Stoupny in
Cayenne. Cavanilles. This appears to be one of the *Toc-
fonie* of Juffieu, having a tubular *calyx*, though not of any
great length; and a very short fringe to the *nectary*, as in our
third species. The *leaves* however are smooth, of the na-
ture of *P. laurifolia* and *muerata*. Bracteas very small;
usually awl-shaped; sometimes oblong; always furnished with
a pair of glands at their base. Fruit the size and shape of a
hen's egg.

PASSIFLORA.

Linn. Sp. Pl. 1356. Cavan. Diff. t. 272. — Leaves ovate-oblong, entire, downy on both sides. Flower-flanks aggregate, hairy. Petals none.—Native of the West Indies. Our specimem is from Santa Cruz. This is much smaller, in all its parts, than any of the foregoing, and clothed all over, even the outside of the calyx, with soft pubescence. Several small greenish flowers, without petals, grow together from the bosomes of the leaves. Plummer says they are very fragrant.

See n. 20. P. auglysfolia, as apparently belonging to this section.

Section 1. Leaves two-lobed. Ten species.

14. P. perfoliata. Stem-clapping Passion-flower. Linn. Sp. Pl. 1356. Jacq. Hort. Schoenbr. t. 182. Andr.-Repos. t. 547. — Leaves smooth, with two oblong, obtuse, spreading lobes, dotted beneath; their base heart-shaped, clasping the stem. Calyx bell-shaped; its segments awl-shaped, much narrower than the petals. — Native of dry and very rocky places, near the sea, in the south part of Jamaica. It flowered at Meffrs. Lee and Kennedy's in 1706, and since in the Comtefe de Vanders' fine collection. The leaves consist of two oblong, almost linear, obtuse, divaricated, entire lobes, connected with a heart-shaped base, with some traces of an intermediate lobe; altogether varying greatly in breadth, and, though supported by short footstalks, often clasping the stem; they are smooth on both sides, reticulated with veins, glaucous, and furnished with a variable row of glandular dots, beneath. Stipulas small, awl-shaped. Flowers on long footstalks, with minute, capillary, remote, deciduous bractces. Calyx with a bell-shaped tube, closed by the plaited nectary, and with awl-shaped crinum segments. Petals of the same colour, elliptical, an inch long, rather exceeding the calyx. Willdenow remarks that the flowers are open from their very first budding.

P. normalis is purely but a narrow-leaved variety of this; see n. 16.

16. P. normalis. Compafls-leaved Passion-flower. Linn. Sp. Pl. 1357. — Leaves smooth, with two limbs, obtuse, rectangular lobes, and a small pointed intermediate one; their base emarginate.— Native of Jamaica. Linneas had it from Browne. This seems to us merely a variety of perfoliata, with narrow linear leaves. The synonym of Hernandez does not belong to it, though a part of his figure, with the longell leaf, is like our plant. See P. Contraincara, n. 23.

18. P. Margarita. Tubular-crowned Passion-flower. Linn. Sp. Pl. 1357. Cavan. Diff. t. 287. — Leaves smooth, somewhat wedge-shaped, with two obtuse spreading lobes, dotted beneath. Nectary tubular, abrupt, undivided.— Native of the West Indies. We have never seen it alive. The leaves are shorter than in the last, and not heart-shaped at the base. Flowers deep red, distinguished by the undivided crown of their nectary. Bracteas like the last. The column of the germen is remarkably long, and the aspect of the whole flower is much like that of perfoliata, whose nectary indeed appears likewise tubular, the rays being all brought together round the column, but they are not combined.

19. P. Vesperillo. Bat-winged Passion-flower. Linn. Sp. Pl. 1357. Granadilla bicornia, (&c.; Dill. Elth. t. 137.) — Leaves wedge-shaped, smooth, with two, rather pointed, spreading lobes, and two glands at the base. Rays capillary, twisted, longer than the petals. — Native of Surinam and the West Indies. Sherard cultivated it at Eltham in 1723, having received it from Amsterdam. The leaves appear to vary much in shape, and in the dots more or less scattered over their upper surface; indeed we are inclined to doubt whether some Surinam specimens, in the Linnean herbarium, may not be more than a variety. Yet their flower agrees with the true P. Vesperillo, whose rays are remarkably long and slender, variously bent and twisted. The calyx is horizontal and shallow, totally unlike that of perfoliata and Margarita, and most agreeing with rubra and lunata, the whole flower being about the size and shape of rubra. The berry on one of the Surinam specimens, N. 767, of the Pl. Surinamensce, Linn. Am. Acad. v. 8. 262, is globular, the size of a large gooseberry; its seeds transversely furrowed.

20. P. clypeata. Petalate Bat Passion-flower. — Leaves smooth, peltate, five-ribbed, with two rounded, pointed, widely-spread ing lobes. Of this we have an incomplete specimen in the herbarium of the younger Linneas, marked as from the West Indies, and a single leaf, sent by Mutis from New Granada, and called in his letter to P. Wallis, folium magnum." This leaf expands six inches; the former are smaller and younger. The stem is slender, angular. Footstalks an inch or more in length, with two cup-like glands near the base, and in one instance two at the top. Leaves truly peltate, the flake being inserted above a quarter of an inch from the base. Live long radiating ribs springing from its infusion; with two much smaller, directed towards the base. Both sides are smooth, reticulated with innumerable veins; lobes very broad, rounded, with short points; in the leaf from Mutis only there is a shallow, minutely pointed, intermediate lobe; but that character is sometimes found to be variable in this tribe. A few large glandular dots are scattered towards the margin of the lobes. The Ripula are minute and awl-shaped. No traces of flowers are to be seen. This seems a most distinct species, though mentioned hitherto by no author that we have met with. Its habit comes very near hecatonis of Cavanilles, fe n. 33, but if there be any reliance on the outline of the leaves, they must be different.

21. P. oblongata. Oblong-leaved Passion-flower. Wild. n. 20. Swartz. Ind. Occ. v. 2. 1135. — "Leaves oblong; dotted beneath; rounded at the base; with two crenate, lobate, very short terminal lobes, and a minute intermediate bristle." — Gathered by Swartz. on shrubby hills in Jamaica. The stem is rough and rigid, climbing by its tendrils to a great height. Leaves flaked, two or three inches long, entire, three-ribbed, vein, thin, smooth; pater beneath, with a double row of remote dots. Footstalks without glands. Stipulas linear-awl-shaped, rigid. Flowers solitary, rather large;
PASSIFLORE.

22. P. capsularis. Capsular Passiflora. Linn. Sp. Pl. 1357. (Grandiflora rubens, folio bicornut; Plum. Ic. 129. t. 135. Clematis indica, flore clavato, &c.; Plum. Amer. 68, the first species, with a triangular form.) — Leaves smooth, somewhat heart-shaped, with two acute slightly spreading lobes. Fluctuates without bractae. Stem triangular. — Found by Plumer in Hispaniola only. The late Hon. Mrs. Barrington received a plant from Jamaica, which flowered in Oct. 1793, at Melfia. Lee and Kennedy's, and answers well to this species, which Linnaeus never saw, nor has any succeeding author been able to verify. It is in many points allied to P. rubra, n. 15, along with which Plumer describes it; but is distinguished by the triangular branches; the frownethoots of the leaves, which in our specimen are scarcely cordate at the base. This last character, and the flowers being in pairs, not solitary, are the only circumstances in which our Jamaica plant does not correctly agree with Plumer's figure and description. The fruit is laid to be longer, and more pointed, than that of rubra, apparently with less pulp. The rays are shorter than the petals, somewhat club-shaped. Calyx shallowed and broad. German smooth. There are two glands at the base of the leaf, at least in our specimen. — In the herbarium of the younger Linnaeus are specimens, without flowers, gathered by Smeathman in the West Indies, which agree very nearly with what we have just described, except that the leaves have much narrower, more deeply separated, lobes, elegantly variegated, with a white central frirpe on the upper side. We procured a similar leaf in 1791, from the house of Mrs. Barrington, who had the plant from Jamaica. This may be a distinct and very curious species, which the flowers, when known, may serve to distinguish hereafter.

23. P. Contraayeru. Horto-flor Passiflora. (Con- ranepilli feu Contrayeru; Hernand. Mex. 361.) — Leaves smooth, without glands, somewhat heart-shaped, with two obtuse, oblong, pointed, slightly spreading lobes. Footstalks without glands, or filipulas. Stem angular. Calyx spreading. — This appears to us a very interesting species, hitherto totally unknown. We have unmarked specimens in the two Linnaean herbariums, answering precisely to the figure and description of Hernandez, whose synonym was certainly very ill applied by Linnaeus to normals; see n. 16. Hernandez says his plant is found in various parts of the country of Mexico, and the root is famous for its medicinal virtues, being sweetish, with some pungency and fragrance, and considered as a powerful counter-poison, defibruant, cordial, &c.; three ounces of the bruised root being a dose. Hence the appellation of Contraayeru, which it poises in common with Dorfleia, and some other reputed counter-poisons. Hernandez well describes the leaves as shaped like a crecent, or a horse-shoe. They are about an inch long, his figure being scarcely half the natural size. He represents three dots, like nails, on their side, which he says are yellow, but which our specimens do not show. The flowers are slender, angular, tawny, and climbing by tendrils. We have no flowers. He describes them as shaped like a carnation, but much smaller, and of many colours; the berries globular, dark chef-nut-coloured. His figure well expresses one of the flatish, spreading, or shallow-flowered kinds, with thick horizontal rays, and a moderately elevated column. Root as thick as the little finger, long and twisted.

Section 3. Leaves three-lobed. Twenty-seven species.

24. P. rotundifolia. Round-leaved Passiflora. Linn. Sp. Pl. 1357. Cavan. Diff. t. 290. Wild. n. 22. — Leaves roundish, with three very shallow equal lobes; dotted beneath and at the base. Footstalks without glands. Calyx oblong, nearly with spreading rays. — Native of South America and the West Indies; sent to Kew in 1756, by Baron Hake, but we have never heard of its flowering in any garden. The leaves are about two inches in length and breadth, quite smooth on both sides in our specimen; as is also the ripe fruit, though authors attribute some downy to both. The flowers we have not seen. Cavanilles and Plumer represent them of the size and general form of rubra and capsularis, with thickish rays.

25. P. orbicularis. Orbicular Tubular-crowned Passiflora. Cavan. Diff. 456. t. 286. Wild. n. 23. — Leaves roundish, with three very shallow obtuse lobes; dotted beneath, but not at the base. Footstalks without glands. Petals none. Necktary tubular, abrupt, undivided. — Native of Hispaniola. Given by Thouin to the younger Linnaeus. The flowers of this rare species much resemble the last, but the lobes are very obtuse, the middle one broadest; in a young state the under side of the flower, and always very much reticulated with prominent veins. Stipulas and bracteas oval-shaped. Tendril short. Flowers in pairs, crimson, the size of Muruca, n. 18, and with the same undivided necktary, but no petals. The base of the calyx is globule; when young downy, like the flower-stalks. Column very long and flender, extending far beyond the calyx.

26. P. puntata. Dotted Passiflora. Linn. Sp. Pl. 1358. Cavan. Diff. t. 269. (Granadilla folio tricuspis, obfuto ct oculto; Feuill. Peruv. 718. t. 11.) — Leaves roundish, slightly heart-shaped, with three shallow obtuse lobes, and many rows of dots at the back, but not at the base. Footstalks without glands. Calyx flat. Rays spreading half the length of the petals. — Gathered by Feuillée in a garden at Malambo, a suburb on the north of Lima. He never met with this plant elsewhere. Cavanilles saw it in flower at Paris. We have never seen a specimen, nor did Linnaeus; his description in the Mant. and Syll. Veg. copied by Willdenow, being taken from our lunata, which is the puntata of Ait. Hort. Kew. ed. 1. (See Sm. Ic. Pitt. t. 1.) The leaves are broader and shorter than in the two last described, and more copiously dotted at the back. Flowers solitary, with a flatish expanded calyx, whitish ovate petals, and violet rays, tipped with bright yellow, which are much shorter than the petals, and somewhat club-shaped. Fruit rather oval, with a sweet pulp.

27. P. lutea. Small Yellow Passiflora. Linn. Sp. Pl. 1358. Jacq. Ic. Rar. t. 607. Michaux Boreal-Amer. v. 2. 37. — Leaves heart-shaped, three-lobed, obtuse, smooth. Footstalks downy, without glands. Flowers in pairs. Petals half the breadth of the calyx. — Native of North America, from Virginia to Florida, as well as of Jamaica. It has long been in our gardens, but is little valued, the flowers being small and pale. The leaves somewhat resemble, in shape and size, those of Annona reticata. They are smooth, glaucous beneath, without dots or glands. Footstalks and flower-stalks hairy, without glands, or branched. Flowers horizontal, flatish, with narrow pale-yellow petals, and spreading rays of the same length and colour.

28. P. pannosa. Cloth-leaved Passiflora. — Leaves heart-shaped, unequally three-lobed, bluntish, downy on both sides, as well as the stalks, tendrils, and branches. Petals none. German brilhly. — Native of the West Indies. We obtained a specimen from Kew garden, in November, 1791, but have never elsewhere seen or heard of this species, which from its fordid habit, and minute, greenish, inconspicuous flowers, is likely to have generally escaped notice.
PASSIFLORA.

The form and size of the leaves are like rubra, n. 15, and some of them have actually but two lobes, as in that; but most have a broad central lobe, as long as the others. Every part is pubescent like rubra, and the genera brilhly, but the flowers are otherwise totally unlike that species, scarcely a quarter so large, definite of petals, and with a very small nectar; though their petals bear conspicuous finely three-cleft bracteas, which rubra wants. However deficient in splendour, this plant is worthy the attention of a curious botanist, on account of its various refemblances and affinities. See fadta and bolyferica hereafter.

29. P. angustifolia. Narrow-leaved Passion-flower. Willd. n. 26. Swartz Ind. Occ. v. 2. 1133. (P. heterophylla; Ait. n. 13. Jacq. Hort. Schoenbr. v. 2. 28. t. 181. P. longifolia; Cavan. Diff. t. 270.)—Leaves smooth; the lower ones three-lobed; the rest undivided, lanceolate, elongated, pointed. Footstalks with two glands. Petals none.—Native of thickets in Jamaica; said to have been brought to England about the year 1773. It flowers in the robe most part of the summer. Those who should observe the upper leaves only, which are quite undivided, long, ovato-lanceolate, and taper-pointed, would refer this species to the freckled lobe; but as more or less of the lower leaves are furnished with one or two lateral lobes, it obtains a place here, among species to which it is most naturally allied. Some indeed have thought it is a variety of the next. The footstalks bear a pair of minute, globular, flabellate glands, near the leaf. Stipulas bristle-shaped. Flowers in pairs, small, about half an inch wide, yellowish, on flender italks without bracteas. Calyx spreading or recurved, slightly concave at the base. Petals none. Rays erect, recurved, yellow, rather shorter than the calyx, purple at the base. Berry roundish, deep violet, sweet, the fize of a black currant.

30. P. minima. Dwarf Passion-flower. Linn. Sp. Pl. 1359. Jacq. Hort. Vind. v. 1. t. 20. Cavan. Diff. t. 266.—Leaves deeply three-lobed, entire, rather downy; the middle lobe longest. Footstalks with two glands. Petals none.—Native of Curassao; not uncommon in fives, flowering in July. Every part of the herbage, in all our specimens, is finely downy, but not at all bumpy. Leaves rather paler at the back, but not glaucous; the side lobes are the shortest; all of an ovate, or rounded shape, sometimes more oblong, and in that case more deeply separated. The glands, as well as the flowers, nearly accord with the lobe. The calyx however is downy at the back, and the sepals are downy, and rather broader. P. bifurcata, n. 38, seems to be a hairy variety of this.

31. P. fruticosa. Cork-barked Passion-flower. Linn. Sp. Pl. 1358. Jacq. Hort. Vind. v. 2. 77. t. 163. Sm. Exot. Bot. t. 28.—Leaves three-lobed, entire, smooth; the lateral lobes very short. Footstalks with two glands. Petals none. Fruit ovate. Stem with corky angles.—Native of the Wett Indies; easily cultivated in a fove, where it bears greenish flowers, and ovate black fruits, both twice the fize of the two lobe species, throughout the summer and autumn. The leaves are of a dark shining green above, paler beneath, of a brown ovate figured, with two small, acute, lateral lobes. Rays of a much shorter proportion than the lobe, recurved at the points. Germaeospermate with white. The bark of the old leaves is white, and very corky; sometimeth of which indeed is observable in angustifolia and minima.

32. P. petiata. Peltate Spreading-lobed Passion-flower. Cavan. Diff. 447. t. 274. Willd. n. 29. (Clematis indica, folio angustu trinido, frutu olivasiformi; Plum. Amer. 70. t. 85.—Leaves peltate, smooth, three-ribbed, with three deep, equal, oblong, spreading lobes. Footstalks with two glands. Flowers solitary, without petals.—Found in hedges in the Antilles, according to Plumier; few other botanists have seen it. The peltate inflorescence of the foot-stalks, and the large, deeply three-lobed leaves, mark this species. Its flowers are twice the fize of P. fruticosa, with longer and brighter rays. Fruit much the same.

33. P. hederaea. Peltate Ivy Passion-flower. Cavan. Diff. 448. Willd. n. 30. (Clematis indica, folio hederacea, major, frutu olivasiformi; Plum. Amer. 70. t. 84.—Leaves peltate, ovate, smooth, five-ribbed, three-lobed. Footstalks with two glands. Flowers solitary, without petals.—From the same country as the lobe, where Plumier only appears to have seen it. The leaves are peltate and five-ribbed exactly as in our ceytrata, n. 20, but of a very different outline, rounded at the base, and terminating in three rather spreading but not deep lobes. Their fize and appearance, except having but three lobes, is like our broadest variety of Hedera helix, called Irish Ivy. Flowers like the lobe.

34. P. variifolia. Tubular Green Passion-flower. Cavan. l.c. v. 5. 15. t. 424.—Leaves peltate, smooth, with three deep ovate lobes. Tube of the calyx as long as its segments. Petals and bracteas wanting.—Gathered by Louis Née, near Acadulco, flowering in February. The leaves have seven radiating ribs, and three deep lobes, of which the middle one specially is greatly contracted at the base; each two or three inches long. The footstalks have two sepals towards their origin. Stipulas lanceolate. Bracteas and petals wanting. Calyx green; its tube an inch long; segments spreading, linear-oblong, of about the same length. Rays short, combined by an entire base. Column very flender. A curious species, known only from the work of Cavanilles. We have however a West Indian specimen from the late Mr. Smeathman, which answers to it nearly in every respect, except being hairy all over.

35. P. reflexa. Reflexed Passion-flower. (P. reflexiflora; Cavan. l.c. v. 5. 15. t. 425.—Leaves peltate, smooth, with three deep, spreading, obtuse lobes; their inflexed and flalk glands glandular. Tube of the calyx as long as its segments. Bracteas ovate, veiny.—Gathered by Louis Née near Panama. About the fize of the lobe. The leaves are somewhat haffled, entire, five-ribbed, with five flalked glands on their footstalks, and as many sepal ones in each sinus, between the lobes. Stipulas large, half-ovate, wavy. Bracteas large, veiny. Tube of the calyx an inch long, the thicknecks of a goofy-quill, its segments, as well as the petals, oblong, of the same length, reflexed, scarlet. Nectar a double fringe, of minute upright rays. Column very flender.

36. P. glauca. Glaucescent-leaved Passion-flower. Ait. n. 11. Willd. n. 31. (P. flickata; Aubl. Guan. t. 325. Balfamara altera, indica, &c.; Anbroph. Phy. 92.)—Leaves slightly peltate, heart-shaped, smooth, with three broad, spreading lobes; glaucous beneath. Footstalks glandular. Baf of the calyx hemispherical. Bracteas minute.—Native of Cayenne, Introduced by Meffrs. Lee and Kennedy in 1770. It flowers in the fove in August and September, and is very ornamental as well as fragrant. The flowers somewhat resemble those of P. ferratifolia, and are remarkable for the innumerable dense tufted filaments of their nectar, the outermost nearly equal to the petals, the reil gradually shorter and more erect. Every part of the plant is somewhat glaucous, and very smooth. Leaves di-vided about half way down. Stipulas large, half heart-shaped. Bracteas a quarter of an inch long, at some distance from the convex glaucous bafe of the calyx. Nobody before us has noticed the old figure of Ambrofinus, though
PASSIFLORA.

though it cannot be mistaken, and is the only one with flowers.

37. P. holosericea. Velvet-leaved Passion-flower. Linn. Sp. Pl. 1359. Curt. Diff. t. 291. (Granadilla folio halato holosericeo, &c.; Mart. Decad. t. 51.)—Leaves ovate, three-lobed, downy on both surfaces, with a recurved tooth on each side at the base.—Native of Vera Cruz, from whence it was originally sent by Houltoun. The leaves are remarkable for their exquisite velvet-like softness, and for the two recurved teeth at their base; their side-lobes are small. Flowers flat, one inch and a half broad. Petals white, often minutely dotted with red, as well as the segments of the calyx, which they resemble in size and shape. Rays spreading, straight, parti-coloured with red and yellow.

38. P. bifurca. Hairy Passion-flower. Linn. Sp. Pl. 1359. Curt. n. 16. Cavan. Diff. 443. (Clematis indica, folio minimo pallido, folis hirtifus; Plum. Amer. 74. t. 88. f. A.)—Leaves hairy, with three oblong entire lobes, the middlemost longest; the lower leaves smooth on the upper side. Footstalks with two glands. Sander in Act. Hort. Kew.—Native of the West Indies. Sent to Kew in 1778, where it is said to flower in the flower in September. This is a doubtful species. What the younger Linnaeus collected for it in England, if we mistake not, is certainly only a hairy specimen of minima, n. 30, and has no petals. Plukkenet's t. 212. f. 1. and the figure in Hermann's Parad., p. 176, appear to belong to some species unknown to us, with jagged leaves, and flowers with petals. Linnaeus, having no specimen, evidently adopted the species from Plumer, whose plant we believe to be no other than minima, and whose solitary leaf is copied in Am. Acad. f. 16.

39. P. fistulosa. Stinking Passion-flower. Linn. Sp. Pl. 1359. "Giseke Ic. t. 29." Wild. n. 34. Cavan. Diff. t. 289.—Leaves hairy, heart-shaped, somewhat three-lobed. Bracteas repeatedly pinnaflit, in capillary glandular segments, like the stipulas.—Native of the West Indies; not rare in our flowers, where it blossoms in summer, and ripens fruit, which resembles a gooseberry in size, and somewhat in flavour. The whole plant is hairy, wufcid, and fistulid, of a pale green. Flowers white, distinguished from all the foregoing, by large finely divided bracteas, encompassing them in the bud, as well as the fruit, like the involucrum of Nigella damascena. The root is said to be annual or biennial, but we doubt whether it be so in a state of nature.

40. P. citata. Fringe-leaved Passion-flower. Curt. n. 18. Wild. n. 35. Curt. Mag. t. 258.—Leaves smooth, with three wavy, somewhat serrated, fringed lobes; the middlemost longest. Bracteas repeatedly pinnaflit, in capillary glandular segments, like the stipulas.—Mrs. Norman, a lady long celebrated for the cultivation of botanical rarities, received this plant from Jamaica in 1785, or earlier. Linnaeus knew it not. The bracteas resemble the lal, but are not so much divided. Petals and calyx pink. Rays spreading, variegated with purple and white. The leaves are coriaceous, veiny, quite smooth except their margin. It is not impossible that Hermann's t. 176 may be a diminished and very imperfect representation of this; see n. 38.

41. P. ferruginea. Finely-serrated Passion-flower. Curt. Obs. falc. 2. 26. t. 46. f. 2. Wild. n. 36.—Leaves three-lobed, very minutely serrated; the middle lobe longest. Footstalks with two glands. Bracteas distinct, entire.—Gathered by Jacquin at Carlhagena. He compares it with incurvata, n. 44, from which he says it is very certainly distinguished by the leaves not being cut away close to the side ribs at the base, and by the minutenee of their

42. P. aspera. Norfolk-Island Passion-flower. Forst. Prodr. 63. Wild. n. 37. Andr. Repol. t. 205.—Leaves smooth, dotted beneath, with three spreading bluish lobes; rounded at the base. Calyx somewhats tubular, longer than the petals. Nectary tubular, abrupt, lobed, surrounded with upright rays.—Native of New Caledonia and of Norfolk Island. It flowers copiously in a flower in summer, requiring a light dry foil. The leaves are sometimes slightly five-lobed. Flowers orange, the tube of their nectary green, longer than the purple upright rays which surround it. This is akin to n. 24 and 25 of our list, near which Willdenow ought to have placed it. The nectary is very peculiar, being, like the whole flower, shaped much as in P. Macarujla, n. 18, but nevertheless accompanied with rays; its orifice moreover is lobed or jagged.

43. P. cristafoila. Wedge-leaved Passion-flower. Cavan. Diff. 460. t. 292. Wild. n. 38.—Leaves deeply three-lobed, serrated, acute; three-ribbed, with two glands, at the base. Bracteas distinct, elliptical, acute. Calyx flat. Rays not half so long as the petals.—Native of America. Seen by Cavanilles in Thouin's herbarium. We have it not. The specific characters distinguish it from the next, which it greatly resembles.

44. P. incarnata. Flesh-coloured Passion-flower. Maccoo, or May-cock. Linn. Sp. Pl. 1360. Sm. Insectis de Georgia, t. 12. Jacq. Ic. Rar. t. 187. (Clematis trifolia, five folios passionis; Ger. em. 1592.)—Leaves deeply three-lobed, serrated, acute; three-ribbed, with two glands, at the base. Bracteas distinct, lanceolate, with glandular teeth. Calyx flat. Rays as long as the petals.—Native of North America. One of the first species introduced to the knowledge of European botanists, and cultivated here in the days of Gerarde and Parkinson, though now seldom met with, as it will fearlessly ever survive the English winter, or rather spring. It however merits a place in the conservatory. The leaves are very deeply three-lobed, three-ribbed, serrated, finely downy on both sides; paler beneath. Flowers rather large, flesh-coloured or pale purple, the long slender spreading rays elegantly speckled with crimson and white. Jacquin's figure is too blue.

45. P. f. fanginux. Blood-coloured Passion-flower.—Leaves deeply three-lobed, serrated, acute, without glands. Bracteas distinct, lanceolate, with glandular teeth. Calyx downy, its tube half as long as the segments. Rays half the length of the petals. Stamens linear, flat.—Gathered by Smeathman in the West Indies. A very fine species, of which we can find no description nor figure. The branches, and all the bracts, are downy; tendrils smooth. Footstalks, and base of the leaves, deltitate of glands; fronds rather coarse; upper surface smooth; lower downy, with prominent ribs and veins. The stipulas seem fallen. Flowers near three inches broad; as far as can be judged from the dried speci- men, they appear of a rich deep red. Tube of the calyx above half an inch, or twice its diameter, in length, clothed with fine ruly down; limb horizontal, its segments linear lanceolate, with the awl-shaped tips longer than usual; pe- tals rather smaller than the calyx, but of the same shape and colour. Rays reddish, slender, much curved in a dry state, but apparently half the length of the petals, the inner row erect about the column, which is tall and slender. Filaments remarkably broad and flat, somewhat combined at the base, with large anthers. Gemen finely downy.

its tube nearly equal to the segments. Rays very minute. Stem square.—Gathered by Louis Née, in several places in Peru, flowering in March. The square stem, which is slightly downy, and the branchlets united into an ovate, oblong, slightly notched, and three-cleft tube, full half as long as the tube of the calyx, is characteristic of this species, which is one of Jussieu’s genus Tafsonia, like the four following. The leaves of this are rather broader than long, their lobes broad and rounded, equally serrate; glaucous, and in some degree downy, at the back. Footstalks with four sejunct glands. Stipulas squarish, toothed. Flowers almost near the end of the segments. Stipulas with four sejunct glands. Stipulas squarish, toothed. Flowers on stalks near four inches long, being twice the length of the leaves. Flowers rose-coloured, large, horse-like, externally and internally smooth; their petals elliptical, an inch long, a little shorter than the calyx. Nectarary crowned with minute teeth rather than rays, as in aedulera, n. 3. Filaments flattened. Fruit globose, rather downy, one inch and a half in diameter.

47. P. trifolata. Three-leaved Passion-flower. Cavan. t. 16. t. 427.—Leaves ternate, elliptical, downy, entire. Branchlets distinct, toothed. Tube of the calyx as long as the segments, tumid at the base. Rays very minute.—Native of Peru and Chili, where it was found by Louis Née, flowering in March and April.—Remarkable for its truly ternate leaves. The stipulas are half heart-shaped, with heart-shaped teeth. Feet stalks downy, without glands. Branchlets large, ovate, downy, with broad, blunt, tooth-like leaves, three inch an inch below the calyx. Flowers rose-coloured, large, horse-like, the like, but with a longer calyx-tube, whose base is inflated and umbilicated.

48. P. pennitifer. Wing-footed Passion-flower. (P. pen- nutiflora; Cavan. t. 16. t. 428.)—Leaves three-leaved, lobed, downy, acute; woolly beneath. Branchlets distinct, serrate. Tube of the calyx as long as the segments. Rays half as long as the petals. Stipulas deeply pinnatifid.—Found by Louis Née in various parts of Chili, from whence he has a specimen, gathered by Mr. Menzies. The leaves are three-cleft more than half way, reticulated, serrate, two or three inches long; very smooth, and bright green, above; their backs, like the branchlets and flowers, clothed with dense, white, woolly fine. Stipulas finely and deeply pinnatifid, smooth. Branchlets ovate, sharply serrate, deciduous, rather downy externally only. Flowers much larger than in the last, of a pale rose-colour, very finely downy externally, as is also the stem. Rays capillary, spreading on the petals, and full half as long. Column remarkably angular, smooth. With great reluctance we have been obliged to alter the uncorrected name given by our lamented correspondent Cavanilles, but has retained his idea. The singularly divided stipulas are like a pair of wings to the footstalk.

49. P. totmentea. Downy Long-tubed Passion-flower. Cavan. Difl. t. 275. t. 276. Wild. n. 40.—Leaves three-leaved, serrate; downy on both sides. Branchlets combined, tubular. Tube of the calyx thrice as long as the segments.—Gathered long ago, by Jofeph de Jussieu, in Peru. His specimems were seen in his celebrated nephew’s herbarium at Paris, by Lamark and Cavanilles, from whose publications only our knowledge concerning this magnificent plant is derived. The respective proportions of the flower, and its minute rays, agree with our third species; but the whole flower appears to be larger, and the branchlets are combined into a sharply three-cleft downy tube. The leaves have three broad, moderately deep, lobes, and, like the rest of the plant, are clothed with fine short down. The footstalks bear numerous stalked glands. The stipulas are half-ovate, pointed, and downy. The flower expands three inches, and is laid to be rose-coloured; its tube is five inches long, whether smooth, or downy as in the next, is not mentioned; nectary a row of very small, roundish, finely filged glands, or obtuse rays, crowning the tube. Fruit ovate-oblong, soft, full of yellow etable pulp. The Peruvians know this plant by the name of Tacca.

50. P. mixta. Smooth-leaved Long-tubed Passion-flower. Linn. Suppl. 408. Sm. Plant. t. 25. Wild. n. 41. (P. longiflora; Lamarck. n. 28. P. Tacca; Cavan Difl. t. 277.)—Leaves with three or five lobes, serrate, acute; smooth on both sides. Branchlets combined, tubular. Tube of the calyx thrice as long as the segments.—Sent by Muttis from New Granada to Linneaus, along with drawings, in Indian ink, of this and our third species. The present differs from the last in having smooth, more deeply lobed leaves, whole side-lobes are occasionally slightly divided; but that such a circumstance is accidental, may be presumed, not only from the coincidence of every other part, but because there are always five ribs, more or less apparent; see the plates quoted. The footstalks bear about five glands, and are rather downy. Flowers, tubular branchlets, and especially the outside of the calyx, are finely and densely pubescent. Flowers, rose-coloured, or purplish, a little smaller than those of P. tomentea, with much the same form of nectary. Fruit oblong, with a long terminal furrow.—Linneus roundly affirms that this species is produced between incarnata and aedulera, for which there is no authority, except the affinity of its fructification to the latter, and some resemblance in the shape of its leaves to the former. Nothing could be greater acquisitions to our conservatories than these tubular Passion-flowers, whose seeds the Spaniards surely might obtain with great ease, and which would probably prove almost hardy in our climate, like the elegant Fuchsia, Coba, and other late discoveries, from the same country.

Section 4.—Leaves with many segments. Five species.

51. P. cerulea. Common Blue Passion-flower. Linn. Sp. Pl. 1566. Wild. n. 42. Cavan. Difl. t. 295. Mill. Illust. t. 74. Cort. Mag. t. 28.—Leaves deep blue, and are rather downy. Flowers, tubular branchlets, and especially the outside of the calyx, are finely and densely pubescent. Flowers, rose-coloured, or purplish, a little smaller than those of P. tomentea, with much the same form of nectary. Fruit oblong, with a long terminal furrow.—Linneus roundly affirms that this species is produced between incarnata and aedulera, for which there is no authority, except the affinity of its fructification to the latter, and some resemblance in the shape of its leaves to the former. Nothing could be greater acquisitions to our conservatories than these tubular Passion-flowers, whose seeds the Spaniards surely might obtain with great ease, and which would probably prove almost hardy in our climate, like the elegant Fuchsia, Coba, and other late discoveries, from the same country.

52. P. tomentea. Downy Long-tubed Blue Passion-flower. Cavan. Difl. t. 294. Wild. n. 43.—Leaves palmate,
PASSIFLORA.

in five acute serrated segments. Footstalks with two sessile glands. Bracteas distinct, serrated. Rays longer than the corolla. —Native of America. Cavanilles described it from the garden of the late Duke del Infantado, to whose family he was preceptor. We had, at the first view of his figure, for we have seen no specimen, a suspicion that this might be a variety of some three-lobed species. The glands of the footstalks agree with those of *ferrulata*, n. 41, but the shape of the leaves, and their coarser serratures, as well as the serrated bracteas, materially differ. From *incarnata*, n. 44, and *cuneifolia*, n. 43, the only species hitherto with which it can be compared, it is distinguished by the leaves not being cut away close to the ribs at the base, as well as by the situation of the glands on their stalks, and the presence of other glands in the finques. The *fipulas* moreover are half-pinnatifid, not awl-shaped and entire; and the *bracteas* differ in size from *incarnata*, and in their serratures from *cuneifolia*. The *leaves* we understand to be smooth; their five-lobes much smaller than the others. Flower coloured somewhat like the *bracteae*; furnished with five rows of rays, of which the outermost extend beyond the *calyx* and *petals*. Fruit globose, with white vifcid pulp.

53. *P. ferrata.* Many-lobed Serrated Passion-flower. Linn. Syot. ed. 10. v. 2. 208. Syot. Veg. ed. 14. 823. Willd. n. 44. Cavan. Diff. 449. t. 296. (P. ferrato-digita*) Linn. Sp. Pl. ed. 1. 662. P. digita*; ed. 2. 1360. Clematis indica polyphylla major, flore clavato, fructu colorochnidis; Plum. Amer. 62. t. 79. —Leaves palmate, in five or seven very deep serrated segments. Footstalks with several glands. Bracteas combined, entire. —Gathered by Plummer in Martinico, in one place only, near St. Mary's river. Cavanilles saw a specimen in Jafficus's collection, and there is one without flowers, in that of the younger Linnaeus; but this very magnificent species is unknown in our gardens. The *flowers* equal even those of the *quadrangularis*, n. 7, in magnitude and splendour, and the broad many-lobed *leaves*, whole under side is somewhat downy, are much more handsome. Plummer says the *flowers* are as large, hard, and knotty as those of a vine, spreading widely over the trees and bushes, which they decorate with verdant foliage. The flower-bud, invested with its large, ovate, pale, purpl' veneined *bracteas*, combined at their base, and entire at their margin, is as big as a hen's egg. The *calyx* has a broad funnel-shaped base; its segments are of a violet colour, like the *petals*, but much broader, each about one inch and a half long. *Rays* about the same length, very numerous, thick, and somewhat angular, in a double row, the outermost shorter, each ray whitish at the point, violet in the middle, paler from thence to the base, with five violet bands. The tube of the *calyx* is internally lined with short, red-headed, glandular rays. *Fruit* as big as an orange, with a thick coat. Plummer did not meet with it ripe, but it seems much like that of the *quadrangularis* in colour and structure. The *flowers* are fragrant. —The synonyms differ remarkably in the specific name, made by Linnaeus himself. We should have preferred *digita*, not only as given in his most classical work, but as the most expressive, had it been strictly correct; the *leaves* however are not truly digitate, but merely divided in a fingered manner, and not more so than in *coriacea*, n. 58. The young ones have sometimes but three lobes, though five or seven ribs. The *fipulas* are small, half-pinnatifid, as in *flamentosif*., n. 52.

54. *P. pedata.* Curled Passion-flower. Linn. Sp. Pl. 1360. Art. n. 21. Cavan. Diff. 462. (Clematis indica ala polyphilla, flore crispatis; Plum. Amer. 66. t. 81.) —Leaves pedate, of seven serrated acute leaflets. *Bracteas* distinct, serrated. *Rays* twisted. —Found by Plumier, by the road side near Miragoan in Hispaniola, and no where else. The *flowers* are somewhat angular. *Leaves* remarkable for being pedate, as in *Helloborus niger*, confiding of seven, almost entirely distinct, elliptic-lanceolate, acute, single-ribbed, sharply serrated *leaflets*, of a fine shining-green, the central one three or four inches long. *Footstalks* rather long, with a pair of glands in the middle. *Stipulas* not represented. *Flowers* furrowing all the reft, according to Plumier, in size, fragrance, and brilliancy of colours. *Bracteas* large, ovate, acute, concave, very sharply jagged and serrated at the edge. *Calyx* pale green, dotted on the inside with red. *Petals* blue. *Rays* in one principal row, spreading, longer than the petals, deep red, with two or three white bands, their extremities of a fine violet, tapering, zigzag, and twisted. *Column*, *flaments* and *filyses* white, speckled with red. *Stigma* divided. *Fruit* globose, like a small gourd, the size of a moderate apple, speckled with shades of green. —Mr. Millon is recorded as having sent this noble plant to Kew in 1781, from the West Indies, but there is no account of its flowering, and we fear it is now lost.

55. *P. heterophylla.* Various-leaved Passion-flower. Lamark, n. 32. Willd. n. 46. Cavan. Diff. 462. (Gra
dadilla heterophylla, flore albo; Plum. Ic. 129. t. 139. f. 1.) —Leaves pedate, of five, nearly entire, abrupt leaflets; the lower ones linear, ternate or simple. *Rays* straight. —Gathered by Plummer, near a rivulet in the fourth part of Hispaniola, flowering and fruiting in September. Lamark. This is the most remarkable of all, for the difference between the lower *leaves*, which are long, very narrow, undivided, and entire, either simple or ternate, and the upper ones, which are pedate, of five broad, short, abrupt, entire, sometimes slightly lobed *leaflets*, an inch or two long. *Flowers* yellowish-white, fearcey above an inch wide, their *calyx* horizontal and flat, twice as long as the *rays*, the *petals* being of an intermediate length between both. *Fruit* oval, rather bigger than an olive, deep violet. full of violet juice. Nothing is known of the *bracteas*. —This singular species approaches in foliage to the last, in *flower* to *lunata*, n. 17, and in fruit to *suberofa* and its allies. No other botanist, than Plummer seems to have met with it, nor is it known in the European collections.

The scientific botanist who contemplates the above view of this interesting genus, will perceive that it has many claims to be considered as a natural order, requiring subdivision into several genera. This talk will at first appear ca
y, as nothing can be more striking than the difference of structure in the *naturae* of several species, nor are the tubular *calices* of others less remarkable. On a further inspection, however, more and more difficulties will arise. The *calyx* is tubular in various species, otherwise very un
differentiated, and flat in others, nor is there any particular among themselves. The minutest of the rays in some of the *Tacsonia* of Jafficus, loses its importance when we consider the several new species in the fifth volume of Cavanilles' *Icones*. The *bracteas*, which Cavanilles reckons a *calyx*, and on the absence or presence of which, as well as their union or separation, he forms his subdivisions of the genus, are of all things most improper, even for that purpose, and lead to a lea natural arrangement than the *leaves* themselves, which will we have followed, from necessity rather than choice, after the example of Linnaeus, Lamark, and Willdenow. The want of *petals* collects several species into a molt natural afflambage, but others, as *orbiculata* and *petalata*, for instance, totally overet the authority of that character. A minute and regular investigation of all their *naturae*, facti
such as Mr. Sowerby has bestowed upon six species, in the second volume of the Transactions of the Linnean Society, might throw considerable light upon the subject, but is not to be undertaken without a great variety of specimens, either fresh, or preferred in spirits. It is much to be regretted that these fine plants have received so little attention from our periodical authors, to whose pages many of them, easily to be procured, would prove a great accession.

Passiflora, in Gardening, contains plants of the herbaceous and shrubby flowering kinds, of which the species cultivated are: the common or blue passion-flower (P. caerulea); the rose-coloured passion-flower (P. incarnata); the yellow passion-flower (P. lutea); the notch-leaved passion-flower (P. ferratifoila); the apple-fruited passion-flower (P. maliformis); the square-leafed passion-flower (P. quadrangularis); the wing-flaked passion-flower (P. alata); the laurel-leaved passion-flower; or water lemon (P. laurifolia); the many-flowered passion-flower (P. multi flora); the red-fruited passion-flower (P. rubra); the moon-shaped-leaved passion-flower (P. murucuja); the bar-winged passion-flower (P. vespertilio); the round-leaved passion-flower (P. rotundifolia); the ciliated passion-flower (P. ciliata); the cork-barked passion-flower (P. tuberoa); the silky-leaved passion-flower (P. holofericea); the glaucous-leaved passion-flower (P. glauca); and the dwarf-leaved passion-flower (P. minima).

Of the first fort there is a variety with much narrower lobes, divided almost to the bottom; the flowers come later in the summer; the petals are narrower, and of a purer white colour.

It is observed, that if the feverth fort does not equal the first in elegance, it exceeds it in magnificence, in brilliancy of colour, and in fragrance, the flowers being highly odoriferous.

**Method of Culture.**—In all the forts it is either by seeds, layers, or cuttings, according to the kinds.

The first or hardy fort is capable of being raised either by seeds, layers, or cuttings; the seed should be sown in the early spring, as March, in large pots, half an inch deep, either ploughing them in a warm border, and as the weather becomes warm planting them to the shade; or in a hot-bed, which will forward the germination of the seed more fully, and the plants will rise sooner; which should afterwards be hardened gradually to the open air till the autumn, and then placed under a garden frame for the winter, to have shelter from frosts, and in the spring planted out in pots, or some in the nursery; and in a year or two they may be transplanted where they are to remain, against some warm south wall.

The layers should be laid down from some of the branches in the common way in the spring, when they will readily emit roots, and make proper plants by autumn; when, or rather in the spring following, they should be taken off and transplanted either into pots in nursery rows, or where they are to remain. The cuttings should be made in February or March, from the strong young shoots, in length from about eight to ten or twelve inches, planting them in any bed or border of common earth, giving frequent watering in dry weather, and when funny and hot, if in a situation exposed to them, a moderate shade of mats will be of much advantage. They will emit roots at bottom, and shoots at top, and become good plants by autumn, allowing them the occasional shelter of mats, &c. during the winter’s frost; and in the spring let them be planted out. If a quantity of these cuttings be planted close, and covered down with hand-glass, it will forward their rooting; observing, however, when they begin to shoot at top, to remove the glass, in order to admit fresh air.

The second and third, or green-house kinds, may be increased by feed, layers, and parting the roots; the feed, obtained from America, should be sown in pots in March or April, plunging them in a hot-bed to raise the plants, which afterwards inure to the open air in summer, giving them the shelter of a green-house or frame in winter; and in the spring following plant some out in pots, placing them among the green-house plants; and others may be planted in the full ground, under a warm fence, to take their chance.

The layers should be made in the summer from young shoots, which will readily grow, and become good plants for potting off in autumn. The packing the roots should be done in spring, before they begin to shoot. The second fort multiplies exceedingly by its creeping roots; which should be divided into slips, and planted in a bed of rich earth till autumn, when some should be transplanted into pots for occasional shelter in winter.

All the more tender flower kinds are capable of being increased by feed, layers, and cuttings; the feeds are procured chiefly from abroad; and should be sown in spring in pots, plunging them in a hot-bed, or in a stove bark-bed; the plants soon appear, which, when three inches high, should be pricked out in separate small pots, giving water, and re-plunging them in the hot-bed, occasionally shading them till rooted; as they advance in growth, they should be shifted into larger pots, and be retained constantly in the stove.

The layers should be made from the young branches in the spring or beginning of summer, which will readily grow, and be fit to pot off separately in autumn.

The cuttings should be made in the spring or summer, from the young shoots, planting them in pots, plunging them in the bark-bed, and giving water frequently; when most of them will take root, and be fit to pot off singly in autumn.

In respect to their general culture; as in severer winters, in the first fort, the branches, if not duly protected, are sometimes killed, it is advisable at such times, whilst the plants are young in particular, to give them the shelter of mats during the inclement season, and protect their roots with dry litter laid over the ground; carefully uncovering their branches as soon as the frost breaks; this covering, however, is only necessary in very severe frosts.

The green-house sorts should generally be potted, to move to shelter in winter, either in a green-house, or deep garden-frame; some plants of each fort may also be planted in the full ground, in a warm border, to take their chance; covering the ground over their roots in severe weather; and in the different orders of planting, placing flasks for the support of their climbing growth in the summer. And all the flower kinds must constantly be kept in pots, placed in the stove, and for the most part plunged in the bark-bed; placing strong flasks for the purpose of training the branches to, and managing them as other flower plants of a similar growth. See STOVE Plants.

The first fort is highly ornamental in the open ground, when trained against southern walls, &c.; and those of the green-house, and flower kinds, among other plants in these collections.

**PASSIANANO, in Geography, a town of Italy, in the Perugiano, on the N. side of the Lake; 22 miles N.W. of Perugia.**

**PASSING Notes, in Music.** This is a subject to well treated by Dr. Pepusch, in his Treatise on Harmony, that we shall do little more than transcribe his rules.
After giving instructions for preparing and relieving regular disorders, he says, we will now shew how disorders may be cured without being prepared, particularly by foppotions; but then they are no longer to be called disorders, but passing or transient notes.

In diminutions or divisions, all the notes that are not to be found in the chord upon which the passage is built, are called passing notes. Passing notes must be used in a regular accent or defect, not by leaps, or wide intervals. See in Music Plates examples of passing notes selected from Pepusch.

**Passing-Places.** are wider places than the ordinary breadth of some canals, for boats to lie in, while others pass, and to turn in, &c.

**Passing-Tickets, or Permits, are notes or checks which the toll-clerks on some canals give to the boatmen, specifying the lading which they are found to have on board.**

**Passion, Passion, Pasion, or Pasion,** is applied to the different motions and agitations of the soul, according to the different objects that present themselves to the senses. In propriety, all those motions, whereby the soul is carried towards any thing; as love, ambition, revenge, &c. are rather passions than passions.

Those motions, by which the soul finds itself interrupted in its actions, as grief, &c. are the only real passions.

We find various modifications and impressions of pleasure and pain inseparably annexed by an established law of nature, to the several judgments we form concerning good and evil: these judgments, with their respective modifications of pleasure or pain annexed, according to the various appearances and relations of the object considered, either as good or evil, present or absent, certain or uncertain, probable or improbable, possible or impossible, and affecting the machine in a certain manner peculiar to such modifications, make what we call the passions.

How, or by what means, this mutual action and communication between soul and body are effectuated, we, are, in a great measure, ignorant: we have but very obscure and faint notions of any thing prior, or more simple, to resolve it into, except the immediate will and agency of the first cause itself.

Malebranche defines the passions to be all those emotions naturally arising in the soul, on occasion of extraordinary motions of the animal spirits, and the blood: in opposition to those motions of the soul, which are common to us with pure intelligences, and which he calls natural inclinations.

Though the passions be inseparable from inclinations; and though a man be only capable of sensible love or hatred, because he is capable of spiritual ones; yet does it appear just in that author to distinguish between them? Passions are much stronger and warmer than inclinations; their objects also are different, and so are their causes: in truth, passions and inclinations differ just as much as sense and imagination.

In effect, the passions of the soul are the impressions of the author of nature, which incline us to our bodies, and all things that may be of use to their preservation: natural inclinations are the impressions of the Author of nature, which determine us primarily to love him, as our supreme good.

An ingenious writer has accurately distinguished between our affections and our passions; the former, which we apply indifferently to all reasonable beings, may most properly signify the desires and inclinations, founded in the reasonable nature itself and essential to it; such as self-love, benevolence, and the love of truth. Thefe, when aided and strengthened by additional, instinctive determinations, are, properly, passions. Those tendencies within us, that are merely arbitrary and instinctive, such as hunger and thirst, and the desires between the sexes, we commonly call appetites or passions, indifferently, but seldom or never affections. Price's Rev. of Morals, p. 125, &c. For the difference between appetites and passions, see **Appetite**.

Passion, says another excellent writer, is a kind of medium between a simple affection of the mind, and the appetites and sensations of the body. Passion is an affection of the mind, which distinguishes it from the appetites of the body, hunger and thirst, and from bodily sensations; and it is attended with a peculiar and extraordinary emotion of the animal spirits, by which it is distinguished from pure affection, and from the several sensations; in all which, though there be some motion of the blood and spirits, yet that motion is natural and regular; whereas in the agitation, occasioned by the passions, the spirits are moved after a more vehement and tumultuous manner. Grove's System of Moral Philosophy, vol. 1. chap. 7.

Dr. Cogan, who merits a place among other approved authors on this subject, in his "Philosophical Treatise of the Passions," that one or other of the three terms, passion, emotion, affection, is always employed to express the sensible effects which objects, or ideas concerning them, have upon the mind; but these terms are so frequently employed in a vague and indiscriminate manner, that some difficulty attends the attempt to reduce them to their precise and differentiating signification. Accordingly the word *passion* is rendered subject to several peculiarities in the application of it. Sometimes it is used, in a generic sense, as expressive of every impression made upon the mind, whether they be weaker or stronger. In one instance the word is emphatically employed to express "suffering," as "our Saviour's passion;" in another it indicates "anger" exclusively. Sometimes the term "passion," and also its adverb "passionately," expresses a very strong predilection for any pursuit, or object of taste; a kind of enthusiastic fondness for any thing. In a sense familiar to this the word is also applied to every propensity, which operates strongly and permanently upon the mind; as the selfish passions, the general passions. Yet when we mean to particularize any of these, a different phraseology is used. The word "passion" is appropriated to the evil propensities which are uniformly operative. Thus, we do not lay the "affection" of pride, or of avarice, but the "passion." The term "affection," on the other hand, is appropriated to the virtuous propensities; as the social, friendly, parental, vital affections, &c.; though, philosophically considered, the relation they bear to the state and workings of the mind is perfectly analogous. This latitude of expression is not confined to the language of the vulgar, but it is obvious even among philosophers, who are not agreed in their ideas of the terms they employ. The controversy between the ancient Peripatetics and the Stoics, with regard to the passions, was probably owing to their affixing different meanings to the word. The one feele maintained, that the passions are good, and useful parts of the constitution, while they are held under the government of reason. The other feele, conceiving that nothing is to be called passion, which does not, in some degree, becloud and darken the understandings, considered all passions as hostile to reason, and therefore maintained, that, in the wise man, passion should have no existence, but be utterly exterminated. One feele considered passion only as the cause of those bad effects which it often produces. And the other considered it as fitted by nature to produce good effects, while it is under subjection to reason; but both allowed, that no dialect
of passion ought to be followed in opposition to reason. Their difference therefore was verbal more than real, and was owing to their giving different meanings to the same word. The precise meaning of this word seems not to be more clearly ascertained among modern philosophers. Mr. Hume gives the name of "passion" to every principle of action in the human mind; and consequently maintains, that every man is and ought to be led by his passions, and that the use of reason ought to be subservient to the passions.

Dr. Hutcheson, considering all the principles of action as to many determinations or motions of the will, divides them into the calm and the turbulent. The turbulent, he says, are our appetites and our passions. Of the passions, as well as of the calm determinations, he says, that some are beneficial, whereas the feline; that anger, envy, indignation, and some others, may be either feline or benevolent, according as they arise from some opposition to our own interests, or to those of our friends, or persons beloved or esteemed. It appears, therefore, that this excellent author gives the name of passions, not to every principle of action, but to some; and to those only when they are turbulent and vehement, not when they are calm and deliberate. This view of the subject coincides with Cicero's translation of the Greek word παθήματα, which he renders by perturbatio. It is evident, says Dr. Reid, that this meaning of the word "passion" accords much better with its common use in language, than that which Mr. Hume gives it.

When he says, that men ought to be governed by their passions only, and that the use of reason is to be subservient to the passions, this, at first hearing, appears a focking paradox, repugnant to good morals and to common sense; but, like most other paradoxes, when explained according to his meaning, it is nothing but an assemblage of words. For if we give the name of "passion" to every principle of action, and of every degree, and give the name of "reason" only to the power of discovering the fitness of means to ends, it will be true, that the use of reason is to be subservient to the passions.

Dr. Reid, advertling to the use of words in common language, means by the word "passion," not every principle of action distinct from those desires and affections which he had previously explained (see the terms Desire and Affection), but such a degree of vehemence in them, or in any of them, as is apt to produce those effects upon the body or upon the mind of which we have already taken some notice, and which will be further considered in the sequel of this article.

According to the statement of Dr. Cogan, the primary idea annexed to the word "passion" is that of passionis, or being impulsively acted upon. In this sense the term properly signifies the tenible effect, the feeling to which the mind is become subjected, when an object of importance suddenly and impetuously demands its attention; and for several of our passions are of a disagreeable and powerful nature, and as this agree or helps flate is so frequently connected with suffering, the transition from one specification to the other is not only natural but unavoidable; and a passion will often be considered as synonomous with suffering. Upon the whole, the mind is equally passive in every effect suddenly and unexpectedly produced upon it, whether its influence be of a pleasant, or unpleasant nature. Accordingly this writer observes, that the term "passion" may, with strict propriety, be used, and used exclusively, to represent the self feeling, the persuasion as it were, of which the mind is conscious from some impulsive cause, by which it is wholly acted upon without any efforts of its own, either to solicit or escape the impression. For the difference between passion and emotion, see Emotion; and between passion, emotion, and affection, see Affection.

Writers on this subject have differed very much in their arrangement or classification of the passions. The ordinary distribution is into passions of the conceivible appieite, which are pleasure and pain, desire and aversion, love and hatred; and those of the irceivible appetite, which are anger, courage, fear, hope, and despair. See the authors on the subject of the passions; Des Cartes, who considers them physically; Coëfèau, who gives us the table, or picture of the passions; La Chambre, the characters of the passions; Sevall, the uses of the passions; and Hutcheson, Watts, and others, who consider them in a moral and religious view.

Some authors have placed the passions in contrast to each other, as hope and fear, joy and sorrow: some have considered them, as they are personal, relative, facial: some, according to their influence at different periods of life: others, according as they relate to past, present, or future time; as sorrow refers principally to things past, joy and anger to present occurrences, hope and fear to future events. The academicians advanced that the principal passions were fear, hope, joy, and grief. Thus Virgil:

"Hine metuunt, cupiant, gaudentque, dolentique."

They included aversion and despair under the fourth; and hope, fortitude, and anger, under desire. But this arrangement is in some respects too general, and in others defective.

Dr. Hartley has arranged the passions under five grateful and five ungrateful ones. The former are love, desire, hope, joy, and pleasing recollection; the latter are hatred, averse, fear, grief, displeasing recollection. To this classification it has been objected, that all these cannot be considered as cardinal passions; nor do the distinctions themselves appear sufficiently accurate; hope is certainly a species of desire; pleasing recollection is a modification of love; aversion is only a particular manner of testifying hatred; and displeasing recollections are sometimes the renewal of grief, sometimes of anger.

Dr. Watts has distinguished the passions into two classes, viz. primitive and derivative. The primitive passions he subdivides into two ranks: 1. Admiration, love, and hatred. 2. The diverse kinds of love and hatred, as esteem, contempt, benevolence, malevolence, complacency, displacency. The derivative passions are desire, aversion, hope, fear, gratitude, anger, &c. Thus, if an object be rare or uncommon, either in its kind or qualities, it excites our admiration or wonder; if such an object is presented to us in a sudden and unexpected manner, the passion is called surprise; and when our wonder rises to a high degree, it is called astonishment. Moreover, admiration, according to the different character of its object, is denominated esteem or contempt; though some writers make esteem and contempt to be particular species of love and hatred. Esteem is the admiration of an object, on account of its excellence, contempt, for its insignificance or worthlesness; whence proceed veneration, and slight or scorn.

If we look on any object as good, or in any respect agreeable to us, it may engage our love; but if it be evil or disagreeable, it excites our hatred, or an endeavour of the soul to disseise itself from the apprehended evil. When the evil is present, it produces grief, and a desire of its removal; this desire of escaping an evil may be considered as solitary, without desiring it may befall another person, in which case it is called aversion; but when accompanied with such a desire, it is denominated malevolence. The ancient phi-
philosophers meant much the fame by their ἡ τινὶς καὶ
ὁμοιὸς, the concupiscible and the irrefrangible part.

To this arrangement, it has been objected, that admiration
has not an equal title to be considered as a primitive
passion with love and hatred. Besides, a subdivision of
the primitive into two ranks creates a confusion, if it do not
fully indicate, that they cannot all be equally primitive;
and the influences under the second rank may justly be
considered as different modifications of the two grand prin-
ciples, and not as primitives of a distinct character. More-
over, this plan makes no distinction between the passions and
affections, which the nature of the subject not only admits,
but requires.

Mr. Grove, adopting in part the arrangement of Dr.
Watts, reduces all the passions to the three heads of admiration,
love, and hatred, which he styles accordingly the primitive passions: the others he denominates mixed passions,
of which some have admiration blended with them, and
others are compounded only of the passions which fall under
love and hatred. Those passions, in which admiration is a
principal ingredient, are ambition, glory (made up of joy,
self-love, and esteem), shame (of an followed, self-
love, and contempt), emulation, horror, and conformation.
The other passions, compounded of love and hatred, may be
distributed into such as more immediately regard ourselves,
and such as have others for their objects: of these which
concern ourselves, the principal are the following, viz. fluc-
tuation, conflicting of desire and grief; resolution, hope,
and fear; security, which is hope advanced beyond the fear of
a disappointment; despair, which is fear without any mix-
ture of hope; jealousy, and difficulty. Of these which
express our dispositions towards others, the chief are the fol-
lowing, viz. irritation, or that mirth which is excited in us
by the sight of another's absurdities or misfortunes; com-
miseration, which is the compound of love and sorrow;
congratulation, or that joy which our love to another makes us
receive from the gifts of nature or Providence bellowed upon
him; envy, anger, gratitude, and that which the Latins
call defiderium, or longings for the memory of persons and
things, which have been greatly beloved by us, springing from
the reflection on a past good, which we depair of enjoying
again.

Dr. Cheyne confides the passions as either spiritual or
animal. Spiritual passions he defines to be those sentiments
produced in the soul by external objects, either spiritual
ones, immediately; or material ones, by the mediation of
the organs of the body.

Animal passions he defines to be those effects produced by
spirits, or bodies, immediately on the body.

Hence, as outward objects may be considered either as
goods or evils, the most natural division of the passions,
whether spiritual or natural, as they regard those objects, is
into pleasurable and painful.

And, in this sense, all passions may be reduced to love
and hatred; of which joy and sorrow, hope and fear, are
only so many modifications or complexions, according to the
various appearances, positions, &c. of the object.

In fact, all the passions may not only be reduced to two,
viz. love and hatred; but, perhaps, to one, love; and even
that may be all resolved into self-love; and this into a prin-
ciple of self-preference, or necessary invincible desire of
pleasure and happiness. The rest are only rivulets from this
source, or special applications of this principle to particular
occasions.

Thus, the desire of any thing, under the appearance of
its goodness, suitableness, or necessity to our happiness,
constitutes the passion of love; the desire of avoiding or
avoiding any thing apprehended to be mischievous, hurtful,
or destructive, constitutes hatred or aversion; the desire of a
good, which appears at the same time probable, and in our
power, constitutes hope; but, if the good appear impro-
bable, difficult, or impossible, it constitutes fear or despair;
the unexpected gratification of desire is joy; the desire of
happiness to another under pain, or suffering, is compas-
sion; and the desire of another's punishment, is revenge or
malice, &c.

The single desire of happiness, then, is the spring or mo-
tive of all our passions, as those are of all our actions.
Some wise and reasonable motive, or end of action, says
Dr. Morgan, is certainly necessary to all wise and reasonable
action: to act without a motive, would be the same thing
as not to act at all, that is, such an action could answer to
further or better end than not acting; and consequently the
action, as well as the agent, would be so far insignificant
and valueless. He, who should have no object at all of his
love, or aversion, hope or fear, joy our grief, might be
simply and purely indifferent to all action; and, consequently,
he must either be in a state of perfect rest and inaction, or
in a state equivalent thereto; wherein the action of such a
being could be of no more significance than the uncertain
fluctuation of an atom, or the quivering of a feather in
the air.

But we can by no means approve the opinion of those
who will allow no ultimate object of desire, or motive to ac-
tion, besides private good. It is justly observed by a writer
already cited, that this opinion springs from not carefully
distinguishing between desire, and the pleasure implied in
the gratification of it. The latter is subsequent to the former,
and founded in it; that is, an object such as fame, know-
ledge, or the welfare of a friend, is desired, not because we
foresee, that, when obtained, it will give us pleasure, but
vice versa; the obtaining it gives us pleasure, because we
previously desired it, or had an affection carrying us im-
mediately to it, and refting in it. And if there were no
such affection, the foundation of private enjoyments and
happiness would be destroyed. Of our views, or appetites, some are subordinate to self-love, and given with a
view to the preservation and welfare of individuals; others
are subordinate to benevolence, and given in order to secure
and promote the happiness of the species; and both the one
and the other are essentially distinct parts of our intelligent

Dr. Cogan, in the Treatise already cited, having ex-
pressed his dissatisfaction with any of the arrangements of
the passions which he has had occasion to consider, proposes
another classification, which he conceives to be less liable to
objections. Of this he has given an ample detail, in which our
limits will not allow us to follow him. We shall, however,
give as concise, and at the same time as satisfactory, an ac-
count of it as possible. He begins with stating, that it is
essential to the nature of every sentient and intelligent being
to be gratified with, or delight in, "well-being." This
well-being is an essential good, and its opposite an essential
evil. Whatever is productive of this desirable state, we
call good; and we characterize as evil, whatever is inti-
mical to it. Under the imputation of this sentiment we indulge a prediction for the one, and feel an abhorrence
of the other. Upon that which we deem to be a good, or con-
ductive to happiness, we look with a plegant lenstion; we
deem it defirable, and it inspires the affection of "love." Whatever occasions or threatens a privation of happiness, or
inflicts positive misery, we view with chilpleasure, and regard
as injurious, or as an absolute evil; and it inspires the affec-

3 E 2
tation of "hatred." "Love" and "hatred" are entitled to the denomination of primary or cardinal affections.

"Love" may be considered either as a principle or as an affection. As a principle, it may be defined "an invariable preference of good; an universal and permanent attachment to well-being or happiness;"" When this principle is directed to any particular good, it becomes an affection; and whenever love is more violent in its effects upon the system, it is even deemed a passion. When the affection of love immediately relates to surfices personally, it is called "self-love." When our love or desire of good goes forth to others, it is termed "good-will," or "benevolence." When love extends to the whole human race, it is termed "philanthropy." And when the love of benevolence embraces all beings capable of enjoying any portion of good, it becomes universal benevolence. When the dispositions springing from this source are acting principally towards every thing capable of enjoyment, they are called the benevolent affections; and as these become, in those who indulge them, operative rules of conduct, or principles of action, we speak of the benevolent principle.

"Hatred" expresses the disposition we entertain concerning, or the manner in which we are affected by, the contemplation of whatever we suppose to be evil. Hatred of misery, and its causes, is a natural and necessary consequence of our solicitude to preserve good. Personal hatred, or malevolence towards an individual, commences with some circumstance, quality, or disposition, which is displeasing to us, or with some species of injury committed or intended. These are its professed objects. But notwithstanding the excesses and exaggerations of hatred and malevolence, yet they cannot possibly be so extensive in their operations as the principle of love; because the affection of hatred has for its objects only particular and partial evils, while the principle of love may embrace the universe.

With the affections of love and hatred are intimately connected those of desire and aversion. As love and hatred may be resolved into that one principle, "the love of well-being," the affections of desire and aversion may be resolved into "de sire." After these preliminary remarks, and others on those introductory emotions which produce surprise, wonder, and astonishment, the author proceeds to develop his plan of the arrangement of the passions.

"Class I." comprehends the passions and affections which owe their origin to the principle of "self-love."

This class includes two distinct orders, viz. that in which "love," and the "idea of good," that is, something either beneficial or pleasant, are more immediately present to the will, and that in which "hatred," and the "idea of evil," are most imperative. The first order comprehends two kinds; the one relating to good in itself, the other to that in expectation. The first kind inspires joy, gladness, which is an inferior degree of joy, ibericfulness, or an emotion of still gentler influence, mirth, or a higher degree of cheerfulness, contentment, satisfaction, and complacency. The latter affection of complacency has its counterfeits; and false conceptions of our own talents, a queriment, and conduct, may inspire pride, vanity, haughtiness, and arrogance. The second division under this order comprehends desire and hope. A wish is an inexact desire. As the above passions and affections are inspired by the contemplation of evils, they are most of them of a pleasurable nature.

The second order comprehends those passions and affections operating upon the principle of "self-love," in which the idea of evil is present to the mind. Of these there are three kinds, the first relates to actual losses and disappointments; the second to evils of which we are apprehensive; and the third, to the conduct which seems to deserve reprehenlion. These insipre the passions of sorrow, fear, and anger, with their different modifications and combinations. Sorrow sometimes allumes the appearance of discontent and dissatisfaction. Impatience is a mixture of sorrow and anger: repining is sorrow united with a degree of resentment against some superior agent, where the mind cannot be brought forth to strong emotions of anger; and sympathetic sorrow is that which we participate with others, in consequence of our social connections, or the general benevolence of our nature. (See sympathy.) Of the virtuous affections inspired by sorrow, which are personal, the most conspicuous are patience, resignation, and humility. Fear is a painful sensation produced by the immediate apprehension of some impending evil. The modifications of this passion are confusion, effort, and terror. The affections, that is, the more permanent imprefions of fear, unaccompanied with external signs to characterise emotions, are dread, despair, remorse, cowardice, pusillanimity, timidity, doubt, irresolution, fear, modesty. The affections and dispositions opposed to fear, are fortitude, which expresses that firmness of mind that refists dangers and sufferings; courage, which is active fortitude; and intrepidity, expressing a courage perfectly undaunted, or a superiority to the veryفة of fear. The third strong effect produced by the immediate perception of evil, is anger. Anger, in the excess of its violence, is termed rage; sorath is violent and permanent anger, and such as may be denominated an affection: repiniment is a lesser degree of wrath; indignation is resentment against a conduct that appears peculiarly unworthy. Although anger, and its principal ramifications, are generally directed against the conduct of others, they are sometimes directed against ourselves, when our conduct has been either negligent or criminal. In repentance, contrition, and remorse, self-reproach, and even indignation, are largely intermixed with the affection of sorrow. Exultation, Toad, and impatience, do not relate to persons so much as to particular circumstances of a pleasing nature. Pecuniou3 may be considered as a lighter degree of anger perpetually recurring to irritable persons from trifling causes. Fortitude, courage, and intrepidity, which have been referred to fear, might, without impropriety, have been placed under the passion of anger.

"Class II." comprehends the passions and affections derived from the "social principle." The social principle extends its regards to the state, the conduct, and the character of others. No one general term is adapted to all those passions and affections which belong to this principle. Dr. Hartley, however, has comprehended them all under the name and character of sympathy, which he divides into four classes; rejoicing at another's happiness; grieving at his misery; grieving at his happiness, and rejoicing at his misery. But the word sympathy, whether we advert to its genuine import or common usage, is ill adapted to the two last divisions. The usual idea of sympathy is that of suffering with another, which is the most opposite possible to grieving at his happiness, or rejoicing at his misery. These two opposite dispositions are usually expressed by the opposite terms benevolence and malevolence. The first referring to kindly dispositions towards its objects, and the other to the reverse; yet these terms are not wholly unexampleable, as they do not always convey ideas perfectly correspondent with the various differences comprised under these general heads. Instead of malevolence, Dr. Cogan substitutes displeasure as a generic term. The second class is divided into two orders. The first includes passions and affections excited by benevolence, in
in which good is the predominant idea. Of these there are the following kinds. 1. Those which respect benevolent dispositions and dispositions. Of these which respect dispositions, the principal are compassion, mercy, which is the most exalted branch of compassion, commiseration, confidence, pity, generosity, liberality, charity, and confidence. Another important branch of benevolence consists in partaking of the good fortune of others; in the participation of their joy, upon the accession of good, or liberation from evil. The immediate expressions of our joy are denominated "congratulations." 2. The affections derived from good opinion. Of these the most conspicuous are gratitude, admiration, esteem, respect, reverence, awe, and reverence. As self-complacency has its counterfeit in pride and vanity, the concomitant affections are liable to abuse, and give rise to the following imperfections, viz. fondness and partiality.

The second order comprises passions and affections excited by disapprobation, in which evil is the predominant idea. Of this order there are two kinds. 1. The disapprobation which is indicated by malevolent dispositions and dispositions. The first species of malevolence relates to those occasional and more transient fits of ill-will, which are excited by particular provocations, and which are not totally regnant to the benevolent affections. These are indicated by anger, and its various modifications. Such are rage, revenge, wrath, resentment, suspicion, and jealousy. 2. The disapprobation, which is indicated by unfavourable opinion of conduct and disposition; and this gives rise to the following emotions and affections, viz. horror, indignation, contempt, disdain, and irifion.

The natural or occasional cause of all the passions, Malebranche makes to be the motion of the animal spirits, which are diffused through the body, to produce and preserve a disposition therein suitable to the object perceived; to the end that the body and mind may mutually affect each other on this occasion, it being the order of the Creator, that our wills be followed by motions of the body proper to execute them; and that the motions of the body, mechanically excited in us by the view of external objects, be accompanied with a passion of the soul, which inclines to will or nil what appears serviceable or noxious to the body.

It is a continual impression of the will of the Creator, that unites us thus intimately to a piece of matter, and occasions this reciprocation of motions and emotions; were this impression of the Creator's will suspended a moment, we should be delivered from all depend-ence, all passions, &c. For what people usually imagine of a necessary connection between the motions of the spirits and blood, and the emotions of the soul, is wholly inconceivable.

Certain little parts of the bile, say they, move with some violence among the fibres of the brain; therefore, the soul must necessarily be agitated by some passion, and this passion must be anger rather than love. What relation can we conceive between the faults of an enemy, a passion of contempt or hatred, and a bodily motion of the parts of the blood striving against certain parts of the brain? How can the union or alliance of two things so different as spirit or matter be effected, but solely by the omnipotent will of the Author of nature?

Dr. Cogan observes, that the essential and characteristic difference between a passion and an affection depends upon the super-addition of surmise to the natural effect produced by the real or suppos'd quality of an object, and that this emotion, conjointly with the specific nature of its exciting cause, is virtually the efficient cause of a passion; the perpiration of surmise rendering the affection visible by characteristic signs, correspondent with its specific nature. This obervation is exemplified in the passions of joy and anger.

There has been much controversy about the seat of the passions; whether it be in the spiritual, or in the animated material part of man. Some philosophers place the passions solely in the corporeal system; among these was the celebrated Descartes; but when we consider, says Mr. Grove, that passion signifies a sensation of the soul, it must be lodged there, and not in any part of the body. As this sensation is joined with a tumult or agitation of the spirits, the passion must go along with the spirits moved. Thote in admiration, which seems to be a more speculative passion, on being employed chiefly about the novelty or grandeur of objects, are in the brain, the great instrument or condition rather of thought and contemplation. In other passions, which respect the good or evil of objects, proceed from a principle of self-preservation, the spirits agitated are in the heart, the fountain of life, and itself residence of those motions of the animal spirits, which are intended for the benefit and preservation of life.

Others again ascribe some of the affections to the animal principle, and some to the rational. Dr. Reid doubts whether the principle of esteem, as well as that of gratitude, ought to be reckoned in the order of animal principles, or if they ought not rather to be placed in a higher order. He has, however, finally placed the esteem of the wise and good in the order of animal principles, though the same affection is sometimes placed by this philosopher under the animal, and sometimes under the rational principle. Speaking of resentment he observes, that sudden or instinctive resentment is an animal principle, common to us with brute animals; but that resentment, which some authors call deliberate, must fall under the class of rational principles. He also excludes parental affections from the rational principle, because it is not grounded on an opinion of merit in the object. (See his Essays on the Active Powers of Man, &c. in chap. 4.) This embarrassment of Dr. Reid seems to arise from the expectation that the rational principle must always act rationally, which leads him to infer that whenever the passions and affections do not receive the function of reason, they cannot be assigned over to the animal principles. But the hypothesis would tempt us to doubt of the very existence of the rational principle in the number of our species; it leads us to conclude that the two natures, deemed so diametrically opposite to each other, possess powers so perfectly similar, that it is difficult for the keenest discernment to distinguish between their operations; and it compels us to infer, that whenever some of our affections become conformable to reason, they have changed their seat from the animal to the rational principle.

Philosophers and divines, who distinguish man into the three constituent parts of body, soul, and spirit, which, notwithstanding the intimacy of their union, they suppose to be different in their natures, ascribe the appetites to the body, the passions and affections to the soul, and to the spirit these intellectual powers which seem remote from passions or emotions of any kind. But if the affections pertain to the soul exclusively, that alone is capable of enjoying; the spirit is deprived of every motive for speculation; and since it sometimes happens that speculations of the most abstruse kind excite pleading fomentations, the spirit must certainly perceive, though it has no faculties to lament its hard lot, as often as it is conscious, that these delightful fomentations, which are its own work, are transferred to the soul. After all, it
PASSION.

it must be admitted, that every passion, emotion, and affection, proceeds from certain impressions or ideas excited concerning the nature, or state, or agency of the exciting object. These ideas have undoubtedly their seat in that part of man which we distinguish by the appellation of mind. The exciting cause, therefore, changes the state of the mind respecting the particular object. From total indifference it becomes some way or other interfused. This impression, if it be poissified of a certain degree of strength, produces a correspondent change upon the body. Universal observation, and universal phænomena, which is doubtless founded upon this observation, unite to evince that a very perceptible influence of every strong emotion is directed towards the heart. The heart experiences various kinds of sensation, pleasant or unpleasant, over which it has no control; and from thence the influence of asituated spirits seems to be diffused over the body. This state of mind is styled an affection, and it appears to be totally mental; but stronger influences produce such changes, that the inward disposition becomes obvious to the spectator, through the medium of the corporeal frame. It is now called an emotion, and this may increase in strength, until the whole system becomes agitated and convulsed. From this statement it appears incontrovertible, that the affections and passions have their origin in the mind, while emotions are corporeal indications of what passes within, according to the conjecture of Mr. Grove above mentioned.

It is a point, about which the divines and philosophers can never agree, whether this relation and connection of thoughts of the mind, and motions of the body, be the gift of nature, or the punishment of the first sin; and whether the passions be the institution of nature, or its corruption. Indeed, considering the good and wise purpo'se the passions serve, with regard to knowledge, virtue, and happiness, and their absolute necessity, it is surprising it should ever be doubted that they are essential to human nature.

This union or relation is found in all men, but in different degrees, and of different extent, according to the different temperaments, conditions, ages, sexes, occasions, objects, &c.

In every passion there may be several things to be distinguished: the first, the judgment the mind makes of an object, or the view of the relation which the object bears to us. This is the determining of the will towards that object, supposing it to appear as good or evil. The third, the peculiar sensation of modification, which accompanies them; as the affection of love, hatred, desire, or joy, which sensations are always different in the different passions, and are, at it were, the characteristics of them. The fourth, a new determination of the course of the blood and spirits towards the several parts of the body: before the sight of the object of the passion, the animal spirits were pretty equally diffused throughout the body; but the presence of the new object disturbs the whole economy; and the greatest part of the spirits is sent into the muscles of the arms, legs, face, &c. The fifth is, the sensible emotion of the soul, which finds itself shaken by this sudden overflowing of spirits. The sixth is, the different sensations of love, hatred, &c. caused, not by the intellectual view of good or evil, but by the different states or movements the animal spirits occasion in the brain. The last is, a certain sensation of joy, or an inward satisfaction, which detains the soul in its passion, and retains its being in the state it ought to be in with regard to the object.

The influence of the affections and passions has been the subject of copious discourses; and it may be considered in three different points of view: as, to the physical, or medical influence of the passions, (for which see the next article,) their metaphorical, or influence upon the train of our ideas, correspondent language, &c., and their moral, or influence upon the character and happiness.

The influence of the passions on thoughts and language is a matter of universal experience and observation. When any subject presents itself to the mind, with sufficient force to excite a passion, or very strong affections. all the powers of the imagination become immediately active, the whole soul is engaged upon its object, and the whole train of ideas is turned into a channel correspondent with the view we entertain of them. This state of mind not only manifests itself by gestures, looks, and tones correspondent with the nature of the passion, but it has a characteristic influence upon the language and expressions employed to give vent to the passion, as it is emphatically termed. Upon the first impulse, the thoughts are tumultuous and confused; but as the passion approaches somewhat nearer to an affection, the mind recovers in some degree its power over itself; though still, as it continues to feel strongly, it is eager to do justice to its feelings, by the strength, pertinency, and impetuosity of its language. Impetuosity equally defines peculiarities of detail. It enhances the accuracy of figures and details the most concise, and the most fitted to its new conceptions. When passions and emotions give place to more permanent affections, language becomes less vehement and more diffuse. Nature has accommodated the mode of utterance to the character of the passion; thus it has rendered joy loud and vociferous, producing strong exclamations mixed with triumphant laughter. Sorrow communicates a plaintiveness to the voice, belted adapted to wailings and lamentations. Anger is loud and turbulent; the voice rises with the passion in order to strike terror and silence opposition. Fear is oppressed and breathless, or screams aloud for help. Love is soft, soothing, infuriating, and gentle; sometimes assuming the plaintiveness of sorrow, sometimes the vivacity of hope, and the transports of joy.

The nature of the passions and affections indulged, and of the objects by which they are excited, and the degree of influence and permanency which they are allowed to exert upon us, constitute the moral characters of men; pointing out their innocence, their excellencies, or their defects. By character is generally understood the kind of reputation acquired by the prevalent disposition or temper, which suggests almost every motive, and takes the lead in almost every action; and moral character refers to that prevalent temper which relates to moral obligation, respecting either ourselves or others. The cardinal affections of love and hatred, in themselves, possess neither merit nor demerit. It is neither a duty, nor a possibility to dwell ourselves of them. The passions, emotions, and affections which are immediately consequent upon these, or may be deemed simple modifications of them, are also inseparable from our nature, and are both unavoidable and innocent: such as joy, satisfaction, contentment, hope, desire, fear, sorrow, anger, repentance, &c. Virtue, however, directs, restrains, and controls their influence.

There is another distinction of the passions and affections, as they relate to the moral character, indicating a scale of comparative merit and demerit. Some are innocent simply, as hope, joy, moderate grief. Some are laudable, as contentment, satisfaction, complacency. Others are deemed peculiarly noble: thus the virtue of benevolence is much more dignified than any of the affections that originate and terminate in self. And in the different branches of this virtue there are also degrees of excellence. But sentiments of
of this kind are familiar and obvious to the reader, and it is needless to enlarge. Upon the whole it appears, that character depends upon the prevalent use or abuse of certain propensities or affections of our natures. Those who select and cultivate the most beneficial, are the best of characters; those who are habituated to the most injurious, are the worst.

With regard to the influence of the passions and affections on happiness, we may observe, that although the desire of good is in reality the cause of every passion, emotion, and affection, yet the immediate effects of each on our faculties are correspondent to its own specific nature. The influence of one is productive of temporary well-being; while others are comfortless, irksome, or productive of a great degree of wretchedness. Love, placed upon a deifying object, and recompensed with a reciprocal affection, joy, emulation, complacency, satisfaction, contentment, lively hope, are decidedly sources of personal enjoyment. The social affections of benevolence, sympathy, compassion, and mercy, are also other ingredients of happiness, from a less selfish and more refined source than the preceding. Every species of benevolence poiseless the quality our great dramatic poet has ascribed to a merciful disposition.

"The quality of mercy's not strain'd:
It dropeth as the gentle rain from heaven
Upon the land beneath. It is twice blest;
It blest him that gives, and him that takes."

Emotions and affections of another class are of the unquiet and irritating class: as the whole family of anger. The emotions and affections of fear, dread, horror, despair, are of the most horrid and tremendous class. Excessive jealousy, envy, remorse, despair, shame, arising from the detection of guilt, are misery unmixed. Surprize, wonder, astonishment, and mortification, principally receive their complexion from the subjects that inspire them: and they are introductory to happiness or misery according to the nature of the cause that excites them. For a farther detail, see Cogan's Treatise already cited.

Passions, in a Medical View, constitute one of the fix non-naturels, as they have been called, and are of great importance, whether considered as a cause of disease, or as exerting a remedial influence when certain diseases exist.

The theoretical discussions of the metaphysicians about the essential distinctions of the mind and the body, have confused, rather than elucidated, the subject, and have led to erroneous views of the operations of the animal economy. All that we can know upon the subject, from experience, is, that the living body prefers two classes of phenomena, one of which comprehends the functions of thought, sensation, volition, and various emotions, which we refer to the mind, and call mental power, and the other includes the more mechanical or chemical functions, which reflect the operations produced by inorganized machines, such as digestion, respiration, the circulation of the blood, and the secretions from it, which we deem more chiefly corporeal functions. Nevertheless we have no actual knowledge of these functions, of either class, except in conjunction, and in that organized form, which constitutes the living body. If the subject be viewed in this light, independently of speculative opinions, it is at once obvious, that these two classes of functions constitute but one whole, and that they are, as far as the physician is concerned, inextricably connected, and mutually dependent upon each other. How extensive this reciprocal influence is, and how powerfully the corporeal functions are modified by those which are called mental, we have taken pains to demonstrate, at great length, in a preceding article. (See Imagination, Influence of, on the Corporeal Frame.) In common language, we are apt to separate the intellectual faculties from the passions and emotions, and, in compliance with that custom, we ascribed to the imagination simply, the numerous phenomena detailed in the article referred to. But, in truth, the passions were more or less concerned in the production of these phenomena; since the imaginary powers of the agents (as in the case of animal magnetism, &c.) necessarily excited the hopes and fears and anxieties of the persons on whom they operated. Having detailed many proofs, in the article just referred to, of the effects of these emotions, when excited by imaginary agents, upon the corporeal frame; we have now to point out the influence of these emotions, when excited by real and common causes.

The passions have been commonly considered by physicians as of two kinds, in respect to their influence on the state of the body, namely, as exciting and depressing agents. They are exercised, and consequently as producing analogous effects on the functions, to those which arise from the operation of stimulant and sedative agents of a material nature. Among the exciting passions, are anger, terror, joy, cheerfulness, hope, desire, love, admiration, and the emotions of taste; the depressing passions are grief, fear, shame, and anxiety.

It is matter of observation, that the agency of these exciting and depressing emotions in the animal economy, follows the same laws, as that of the material stimulants and sedatives just alluded to. The moderate excitement of the former contributes to the free and perfect performance of all of the functions, and therefore to the support of the general health; and debility equally ensues from the immoderate influence of the exciting, and from the direct operation of the depressing causes, which uniformity of effect affords an additional proof of the identity of the living system. The operation of the passions and emotions, both as a cause of health and disease, and also as a remedy in many morbid conditions, is illustrated by the observations of many physiologists and pathologists, and by numerous cases, which have been recorded, as may be seen by consulting the comprehensive and indefatigable Haller. Elements Physiologie, tom. v. lib. xvii. p. 380 et seq.

The exciting passions have been observed to produce the following effects in the corporeal frame. Cheerfulness and moderate joy are found to give vigour to the circulation, and to increase the action of the heart and arteries, and consequently to support the vital functions connected with it; they render the respiration easy and free, increase the heat and perspiration, and affix the operations of digestion and secretion in the various organs of the body; whence the healthy condition of the system is universally pronounced. Nevertheless, when the excitement of joy has been excessive and sudden, it has sometimes brought on an acute fever, not unfrequently it has occasioned syncope or fainting, and in a few instances even sudden death. Examples of death thus produced, from an unexpected restoration from imprisonment, from the return of a beloved son, who was supposed to have been dead, or from extraordinary and unexpected accession of wealth, have been recorded. (See Thorpey, Nat. Hist. of Leeds, p. 625. Robinon the Spleen, p. 91. Nichols, de Anim. Med. p. 16.) It was superfluous to repeat the various hypotheses, which different writers have framed to account for these phenomena; as they are altogether gratuitous, or merely statements of the fact, with a change of words. Haller considered the affection as a kind of apoplexy, occasioned by the increased action of the vessels of the brain; but Dr. Cullen appears to have been nearer to the truth, in deeming it the mere result of over-excitement of the nervous system; which is generalizing it to that.
that universal law of the animal economy, by which extreme exhaustion invariably follows excessive stimulation. See Excitability.

The passion of love, being a pleasurable emotion, produces effects similar to those of joy. It excites the powers of the mind, as well as those of the body, causes a glow of heat, and an acceleration of the pulse; and, when it is vehement, it excites palpitation of the heart, and a tenor of burning heat, through the circulation. The acceleration of the pulse, however, is mostly accompanied with some irregularity, occasioned perhaps by fear and apprehension of the want of success. The love of Antæus for his step-mother Stratonica, is recorded to have been discovered from the pulse.

The ardor of fire accompanying ambition, or other strong passions, especially when attended with the prospect of success, produces nearly similar effects. So powerful its excitement has been, in some instances, as to have even cured paralytic affections, and roufed the body to exertions, far above those to which the strength seemed adequate, and has even protracted death. Muley Moluc, emperor of Morocco, who was wearing away under an incurable disease, when the Portuguese invaded his territories, did not expect to live out the day when his last decisive battle took place. Before the battle began, he was carried along the ranks in an open litter, to encourage his troops; but finding afterwards the battle to go against him, though very near his last agonies, he threw himself out of his litter, rallied his army, and led them on to the charge, which ended in a complete victory to his party. He had no sooner brought his men to the engagement, than finding himself utterly spent, he was again replaced in his litter, where, laying his finger on his mouth, to enjoin secrecy to his officers, who stood around him, he died a few moments after in that posture. See Spectator, No. 349.

Anger is another active stimulant passion. It roufed the powers of the body and mind, and impelled them into action, accelerated the pulse, and produces redness and heat of the skin. These exertions are often so violent as to exhaust the vigour of the nervous system, as appears from the tremor of the limbs, and the faltering voice with which they are accompanied. When this passion has been still more vehement, various diseases have sometimes been the result, such as ecchymoses, hemorrhages, apoplexies. great dilation of the heart, ruptured cicatrices of wounds, local inflammations, profuse perspiration, vomiting, and diarrheea. Indeed the increase of the bilious secretion by this passion is very remarkable, and has been well attested both by ancient and modern observation; insomuch that bile and choler are deemed synonymous with anger. On the other hand, these stimulant effects have, under certain circumstances, proved remedial. Thus gout, palsy, dumbness, have all been removed by purges of rage, and life itself evidently prolonged for several days. See Haller, loc. cit. and Falconer's Diff. on the Influence of the Passions on the Disorders of the Body, p. 13.

The genial and salutary influence of hope, in supporting the health against the impending evils of disease, by maintaining a steady excitement both of body and mind, has been strikingly illustrated on various occasions; and in no instance more remarkably, than in that of the siege of Breda, as described by Vander Mye, which we have detailed under the article Imagination, before referred to. The distributions of an ignominious medicine among the garrisons, said to be sent from their prince, and to poisons infallible powers of curing the scurvy, effectually prevented the progress of that fatal malady. After mentioning this fact, the celebrated Dr. Lind, (in his Treatise on Scurvy,) observes, "an important lesson is hence to be learned, the wonderful and powerful influence of the passions of the mind on the states and disorders of the body. This is too often overlooked in the cure of disorders, many of which are sometimes attempted to be cured by the sole mechanical operation of drugs, without calling in to our aid the strong powers of the imagination, or the concurring influences of the soul. Hence it is, that the same remedy will not always produce the same effect, even in the same person, and that common remedies often prove wonderfully efficacious in the hands of bold quacks, but do not answer the purpose in a timorous and diffident patient."

The depressing or debilitating passions produce an opposite effect; they rob the body of its vigour, diminish and interrupt the secretions, weaken the digestive powers, and, if continued, wear out the energies of life; while some of them, like a sudden and violent narcotic poison, infatuation, or deprive the brain and nervous system of its powers, and occasion immediate death. Fear and grief are the most injurious, perhaps, of the depressing passions. Under the influence of fear, the force of the heart is diminished, and the pulse is rendered weak, variable, and intermittent; whence paleness, shivering, tremor, faintness, and even actual syncope, are attendant symptoms on the operation of this passion; whence also hemorrhages of every kind have ceased under its influence, the natural secretions, as of the milk and perpiration, have been suppressed, and discharges from the body have stopped, and even the blood has not flowed from an opened vein. Or, on the other hand, from the general relaxation of the vesicles, a cold and clammy sweat has been poured out by the exhalants, like that which attends syncope and great weakness; or a collicative diarrhoea has occurred from the relaxed exhalants of the intestines. The effects of fear, very much resemble those of fatigue, watch, and other sources of debility, in rendering persons much weaker; and even the more violent hepatic and mental diseases; whence the panic, which often accompanies an epidemic, tends greatly to increase the number of its victims. (See many references upon this point in Haller, loc. cit. p. 584.)

It greatly debilitates the organs of digestion; whence flatulence, eructations, acidity, cramp at the stomach, and various other symptoms of want of power in the stomach and bowels are produced by it. When its impressions have been more violent, many severe examples of its directly sedative and paralyzing effects on the nervous system have occurred. Some persons have instantaneously lost the power of muscular exertion, remaining equally unable to fly or to defend themselves from the universal treach which feizd them. Van Swieten has recorded an instance, in which the tremor, so produced, continued during the remainder of life, namely, for twenty years. In other cases, palsy, amours, loss of voice, mental imbecility, permanent melancholy, epilepsy, and even sudden death, have resulted from the violent impressions of fear.

Yet it is justly remarked by Haller, that terror and alarm have often a stimulant effect, like that of anger, and have produced violent exertions both of mental and corporeal power, and strong muscular action, even in the heart. Whence those who have lost the use of speech, have recovered it suddenly, and paralytic limbs have been roufed to action, by a sudden alarm. Van Swieten relates from Hildanus, that a man, disfigured to represent a ghtl or spectre, took another, labouring under a paroxysm of gout, out of his bed, and carried him upon his back down the stairs, dragging his feet and legs, which were the seat of his pain, down the stairs, and placed him at last on the ground. The man thus treated immediately recovered the use of his limbs, and ran up
up the stairs again with great swiftness, and under the strongest impressions of terror. After this incident, he lived many years free from any symptoms of the gout. In a similar way, the gout has been suddenly cured by a fit of anger.

A sudden impression of fear, when accompanied by despair and despair, has sometimes occasioned a singular disorder of the cutaneous exhalations; we once witnessed an universal anaesthesia, or superficial dropy, which was produced in the course of one night, in a poor woman, who had lost her pocket, containing a few pounds, which were her all, and the savings of many years. And fear combined with anxiety have, in many cases, which have fallen under our observation, produced extensive diffuse effusions of the fluid of the skin, and febrile heat. See Bateman's Pract. Synop. of Cutan. Diff. p. 149, note. Alfo Edin. Med. and Surg. Journ. vol. v. p. 127.

Grief is another depressing passion, the effects of which resemble in several respects those of fear, but differ in consequence of the longer duration of this passion. Grief diminishes the bodily strength in general, and particularly the force of the heart and circulation, as is obvious from the frequent sighs and deep respirations which attend it, and which seem to be necessary exertions, in order to promote the passage of the blood through the lungs. It diminishes perpiration, obstructs the mensural discharge, produces paleness of the skin, and anaesthesia, and febrile obstructions in the glandular parts. It aggravates the fever, and the malignity of febrile and contagious disempers, and also renders people more apt to receive the infection of them. When it comes on suddenly and in a great degree, it excites palpitation of the heart, and renders the pulse irregular, and unequal in the two arms. Blindness, gangrene, and sudden death, have followed excessive grief; and its effects in changing the colour of the hair are well known.

One of the most remarkable effects of the passions on the body is exemplified in the nostalgia, or that vehement desire of revisiting one's native country, which occurs in persons abroad. This is much allied to grief, and hope is its cure; for the moment that allowance of the opportunity of returning is given, the diseaše, which would otherwise terminate in atrophy and death, begins to disappear. See Nostalgia.

From this sketch of the effects of the passions on the operations of the animal economy, it must be obvious that they are important agents in the modifications of health, and the regulation of them becomes a matter of interesting inquiry to the physician, and affords him a source of considerable influence over the corporeal functions. Many difficulties, however, must occur in the management of these nice and precarious inquirums, and the direction of them will be most successfully undertaken by those who possess the greatest discernment in estimating individual character and constitution, and who are possess'd of what is called a knowledge of mankind and the world. A considerable influence towards the cure and alleviation of disea's, may, however, be easily exerted by the inspiration of hope and confidence, and by diffusing the groundlefs fears and apprehensions: and even fictitious means, or such as a great philosopher might despife, are not to be neglected, where a depressing passion is thwarting the operations of medicine, and the natural efforts of the constitution. The powers of the tractors, and of animal magnetism, although purely imaginary, were nevertheless capable of producing substantial effects; and where the efficacy of our instruments can be thus augmented, by employing such mental aid, it is neither unphilosophical nor unfeasible to resort to it. See Imagination, Influence of.

We shall here subjoin some of those inferences to which we have referred in the preceding article, and with which ancient history presents us, of fatal effects from the excess of joy; but it plainly appears from their narration, that the subjects were, at the instant preceding, under the pleasure of extreme anguish of mind. Pliny informs us (lib. vii. § 7.) that Chilo, the Lacedemonian, died upon hearing that his son had gained a prize in the Olympic games. Valerius Maximus tells us (lib. ix. cap. 12.) that Sophocles, the tragic writer, in a context of honour, died in consequence of a decision being pronounced in his favour. Aulus Gellius (Noet. Attic. lib. iii. cap. 15.) mentions a remarkable instance of the effects of what may be termed accumulated joy, in Diogoras, who expired at the instant, when his three sons were crowned in the same day as victors; the one as a pugilist, the other as a wrestler, and the third in both capacities. Livy also (lib. xxii. cap. 7.) mentions the instance of an aged matron, who, while she was in the depth of distress, from the tidings of her son's having been slain in battle, died in his arms from the excess of joy upon his safe return. We are also told by the Italian historian Guicciardini, that Leo X. died of a fever, occasioned by the agitation of his spirits, on his receiving the joyful news of the capture of Milan, concerning which he had entertained much anxiety. In all these instances the previous state of mind, with its pathological effects upon the body, made the impulse of joy the stronger, and contributed to render it fatal.

Passion, Calm. See Celiaa.
Passion, Hypochondria. See Hypochondriasis.
Passion, Hysteria. See Hysteria.
Passion, Ilae. See Enteitis.
Passions, in Poetry. denote the passionate sentiments, gestures, actions, &c. which the poet gives his persons.
The passions are, as it were, the life and spirit of the longer poems. Their necessity is tragical and comedy is obvious; nor can the epopeia subsist without them.

It is not enough that the epic narration be surprising; it must likewise be moving and passionate, hurried away the reader's mind, and filling it with anxiety, joy, terror, or some other violent passion; and this for subjects which it knows are feigned. Though passions be always necessary, yet all are not equally necessary, or suitable to all. Comedy has joy, and agreeable surprises, for its part; tragedy, on the contrary, has terror and compassion. The proper passion of the epopeia is admiration; though the epopeia, as a medium between the two others, takes in both their kinds of passions: as we see in the griefs of the fourth book of the Iliad, and the games and diversions of the fifth. Admiration, in effect, is consistent with each; we admire with joy the things that surpass us agreeably, and with terror and grief those that amaze and afflict us.

Besides the general passion, which distinguishes the epic from dramatic poems, each epopeia has its peculiar passion, which distinguishes it from other epic poems. This peculiar passion still follows the character of the hero. Thus wrath and terror reign in the Iliad, because Achilles is watchful, and εν των ανθρώποις του ἁρπακτικού, the most terrible of men. And, on the contrary, the Æneid is all in the tender, softer passions; such being the character of Æneas. The prudence of Ulysses not allowing these excesses, we find none of them in the Odyssey.

As to the conducing of the passions, to make them have their effect, there are two things required; viz. that the audience be prepared or disposed to receive them; and that several incompatible passions be not mixed together.

The necessity of disposing the audience is founded on the natural necessity of taking up things where they are, in order to remove them elsewhere. The application of this maxim
is calm; a man is calm and at ease, and you would put him in a passion by a discourse made on purpose. You must begin, then, in a calm manner; by this means you join yourself to him; and afterwards, walking together, he will not fail to follow you in all the passions, to which you lead him insensibly.

If you shew your anger at first, you will be as ridiculous, and will have as little effect, as Ajax in the Metamorphoses; in whom the ingenious Ovid gives a fine example of this failing. He begins his harangue in the height of passion, and with the most violent figures, before his judges, who are in the deepest tranquillity.

"Sigeia torvo, Litora propsectis, callice que in litore, vultu; Protentansque manus, Agimus, prob Jupiter! inquit, Ante rates caufam, & mecum confertur Ulyfes."

The necessary dispositions arise from some preceding discourse, or, at least, from some action, which has already begun to raise the passions before they are mentioned. The orators themselves sometimes use this last means; for though ordinarily they do not raise the passions till the end of their discourse, yet when they find their audience already moved, it would be ridiculous in them, by an unseemly tranquillity, to lay them again.

Thus, the last time Catiline came to the senate, the fathers were so shocked at his presence, that those near the place where he sat down, rose up, retired, and left him alone. On this occasion, Cicero had too much sense to begin his oration with the usual tranquillity and coolness of exordiums: by this means, he would have palled and abated the indignation of the senators against Catiline, which it was his business to raise up in flame; and he would have eaved the parricide of that confirmation the behaviour of the senators had given him, and which it was Cicero’s business and design to aggravate. Omitting, therefore, the first part of this oration, he takes his auditors in the condition he finds them, continues and augments their passions: "Quoquâ tandem abutere, Catilina, patientia nostra? Quam diu nos etiam furor ille tuns eludit? Quem ad finem fecus effrenata jactabit audacia? Niluhne te nocturnum praedidium palati, nihil urbis vigiliae, nihil tumor populi, nihil, &c."

"The poets are full of instances of this kind, where the passions are prepared or kept up by actions. Dido, in Virgil, begins a discourse like Ajax: Probat Jupiter, ibi bis, ait, &c. But then the motions are here well disposed; Dido is before represented under terrible apprehensions of Aeneas’s quitting her, &c."

Seneca’s conduct, indeed, is quite opposite to this rule. If he has a passion to raise, he is sure first to take from his audience any disposition they might have to be affected. If they be in grief, fear, or the expectation of something horrible, &c. he will begin with some fine description of the place, &c. In the Troades, Hebeus and Andromache being prepared to hear the violent and barbarous death of their son Alcyon, whom the Greeks precipitated from the top of a tower; of what avail was it to tell them, that, of the spectators that crowded from all quarters to see the execution, some placed themselves on stones, which the ruins of the walls made to project; that others shook their legs, as being placed too high, &c."

"Alta rupes, cujus e cacumine Ericlus limimos turba libravit pedes."

The second thing required in the management of the passions is, that they be found pure, and disengaged from any thing that might prevent their effect.

"Polythyrii, therefore, i.e. a multiplicity of fables, actions, or histories, must be avoided; all adventures much broken, and hard to be retained, and all intrigues intricate, and difficult to conceive, are at once to be excluded. These embarrass the mind, and require so much attention, that there is none to spare for the passions. The soul must be free and disengaged to feel; on the contrary, we divert ourselves even from our real ministers, by an application to other things.

But, of all others, the greatest enemies to the passions are the passions themselves: they oppose and destroy each other; and if two opposite ones, e. g. joy and sorrow, meet in the same object, they will neither of them stand it. It is the nature of those passions that imposes the law: the blood and spirits cannot move gently and equally, as in a state of tranquillity, and, at the same time, be stopped and suspended with a violence occasioned by admittance. Nor can they be in either of those situations, while fear calls them from the outer parts of the body, to affright them about the heart, or rage fends them into the muscles, and makes them act there with violence very opposite to the operations of fear.

The causes and effect, therefore, of the passions in the soul are to be studied, in order to be able to manage them with all their force. Virgil furnishes two examples of what we have said about the simplicity and engagement of each passion, in the deaths of Camilla and Pallus. See the Aeneid."

Passions, in Rhetorics, are objects that demand particular attention, both in the composition and delivery of public discourses. Accordingly one branch of rhetorical invention relates to the passions, and a suitable address to them forms a distinguishing part of the conclusion, or peroration. As the passions are moving springs of action in the human frame, the orator who disregards them is not likely to accomplish the end at which he aims. As it is often highly necessary, it will likewise require his greatest skill, to engage them in his interest. Accordingly Quinctilian calls this "the soul and spirit of his art," and without doubt, nothing more discovers its empire over the minds of men, than this power which it possesses of exciting, appeasing, and fusing their passions, agreeably to the design of the speaker. The orator who engages the passions of his hearers will be thus aided on many occasions in convincing their judgment, and more especially in persuading them to pursue the course of conduct which he recommends. The passions are constituent parts of our frame as well as the understanding; and unless they are called forth into exercise, and when roused, properly directed and governed, we shall need some of the most powerful incentives to our inquiry after truth and to the regulation of our conduct agreeably to the conviction of our minds. Although the passions are liable to be perverted and abused, this is no reason why they should not be employed to important and useful purposes; more especially as this is the most likely method of guarding against the danger and injury, to which the want of due direction and control would expose us. Quinctilian makes it a necessary qualification of an orator, that he should be an honest man, and one who will not abuse his art. He will therefore engage the passions in the interest of truth and virtue; and he will thus render them instrumental in promoting the most useful purposes. The Stoics, who pretended to eradicate the passions, attempted what was in itself impossible, and in its confquences prejudicial to mankind. For while they appeared zealous adherents of the government of reason, they fearfully left it any thing to govern; for the authority of reason is principally exercised in ruling and moderating
derating the passions, which, when duly regulated, are the
springs and motives to virtue. The passions, therefore,
are not to be extirpated, as the Stoics affected, but put
under the direction and conduct of reason. The charge
that has been brought against the art of oratory, for giving
rules to influence the passions, is groundless and unjust; since
the proper use of the passions is not to hinder the exercise of
reason, but to engage men to act agreeably to reason. And
if an ill use be sometimes made of this, it is the fault not of
the art, but of the artful. But that an orator may be
enabled to manage this part of his province to the best ad-
antage, it is necessary that he should, in some measure, be
acquainted with the nature, causes and objects of the pas-
sions. The passions to which the orator more particularly
addresses himself differ according to the nature of the discours.
In demonstrative orations, whenulatory, love, admi-
ration, and emulation are usually excited; but in invective,
hated, envy, and contempt. In deliberative subjects, either
the hope of gratifying some desire is set in view; or the fear
of some impending evil. And in judicial discourses, almost
all the passions have place, but more especially resentment
and pity; insomuch that most of the ancient rhetoricians
mention only these two. The objects of the passions are
either things or persons, and orators make use of both, in
putting in motion these springs of the human mind. With
regard to things, the nature and circumstances of them are
to be considered; and different passions applied to, in order
to induce people either to pursue or avoid them. Persons
may be considered either as agents or patients. In the
former sense, different regards are due to them, according
to the different qualities with which they are invested, and
a suitable course of actions. So because virtue exerts effeem,
and vice hatred; answerable regards are paid to virtuous,
or vicious men. But in considering them as pa-
ients, whatever befalls them according to their deserts, be
the thing good or ill, others are generally pleased; and if
the contrary happens, it gives them an uneasiness. So that
if some good thing accrues to one, who does not deserve it,
it causes indignation; and where a misfortune happens to
a good man, it occasions pity. And thus persons are apt
to be affected with respect to the circumstances of others.
But every one is naturally inclined to think well of himself,
that every prosperous occurrence is but answerable to his
merit, and that every misfortune comes undeservedly. And
sometimes there is joined with the occurrence the considera-
tion of the agent, or person, who occasioned it; and the
design in doing it is often more regarded, than the thing
itself. The orator therefore will observe what circumstances
either of things, or persons, or both, will furnish him with
motives, proper to apply to those passions he desires to
excite in the minds of his hearers. Thus Cicero, in his or-
ations for Plancus and Sylla, moves his hearers from the cir-
cumstances of the men; but in his accufation of Verres, very
frequently from the barbarity and horrid nature of his
crime; and from both in his defense of Quintus.
But the same passion may be excited by very different
methods. This is plain from the writings of those Roman
fathers, which are yet extant; for they have all the same
design, and that is to engage men to a love of virtue, and
hatred of vice; but their manner is very different, suited
to the genius of each writer. Horace endeavours to recom-
mend virtue, by laughing vice out of countenance. Persius
moves us to an abhorrence and detestation of vice, with
the gravity and severity of a philosopher. And Juvenal by
open and vehement invectives. So orators make use of all
these methods in exciting the passions, as may be seen by
their discourses, and particularly those of Cicero. But it
is not convenient to dwell long upon the same passion. For
the image thus wrought up in the minds of the hearers, does
not last a great while, but they soon return to reflection.
When the emotion therefore is once carried as high as it
well can be, they should be left under its influence, and the
speaker proceed to some new matter, before it declines
again. Moreover, orators sometimes endeavour to rouse
contrary passions to each other, as they are concerned for
opposite parties. So the accuser excites anger and relent-
ment, but the defendant pity and compassion. At other
times, one thinks it sufficient to allay and take off that
passion which the other has raised, and bring the hearers
to a calm and sedate consideration of the matter before
them.

But this especially is to be regarded, that the orator ex-
presses the same passion himself, with which he endeavours
to affect others, and that not only in his action, and voice, but
likewise in his language; and therefore his words, and man-
nner of expression, should be suited to that perturbation and
disorder of mind, which he designs to represent. However,
a decency and propriety of character are always carefully
to be observed. For as Cicero very well remarks: "A ne-
glect of this is not only very culpable in life, but likewise in
discourse. Nor do the same things equally become every
speaker, or every audience, every time, and every place."
And therefore he greatly commends that painter, who
designing to represent in a picture the face of Sphinge,
Agamenmon's daughter, drew Calchas the priest
with a sad countenance; Ulysses, her father's great friend,
more dejected; and her uncle Menelaus, most discomfited;
but threw a veil over the face of Agamenmon himself, as,
being unable to express that excess of sorrow, which he
thought was proper to appear in his countenance. And this
judiciousness of character is admirably well observed by Cicero
himself, in his defense of Milo. For as Milo was always
known to be a man of the greatest resolution, and most
undaunted courage, it was very improper to introduce him, as
the usual method then was in capital cases, moving pity, and
begging for mercy. Cicero therefore takes this part upon
himself, and what he could not do with any propriety in the
person of Milo, he performs in his own address to the
These remarks are observed by Dr. Blair, that the higher eloquence (fem.
ELOQUENCE) is the originating of passion; or of that state of
mind in which it is agitated and fired, by some object it has
in view. A man may convince, and even persuade others to
act, by mere reason and argument. But that degree of elo-
quence which gains the admiration of mankind, and pro-
perly denomintes one an orator, is never found without
warmth or passion. Passion, under due restraint, exalts all
the human powers; it renders the mind infinitely more en-
lightened, more penetrating, more vigorous and masterly,
than it is in its calm moments. A man, actuated by a
strong passion, becomes much greater than he is at other
times: he is conscious of more strength and force; he
utters greater sentiments, conceives higher designs, and
executes them with a boldness and a facility, of which, on
other occasions, he could not think himself capable. But
the power of passion is particularly felt with respect to per-
fusion. Almost every man, in passion, is eloquent. Then,
he is at no loss for words and arguments. He transmits to
others, by a fort of contagious sympathy, the warm senti-
ments which he feels: his looks and gestures are all per-
suasive; and Nature here shews herself infinitely more
powerful than art. This is the foundation of that just and
noted rule: "Si vis me flere, dolendum est primum ipso tibi." Admitting this principle, that all high eloquence
flows
Passion, in Heraldry. Croft of Passion is a croft thus
called, because in shape of that on which our Saviour suf-
ered; i.e. not crossed in the middle, but nearer the top;
with arms short, in proportion to the length of the shaft.
Passion of our Lord Jesus Christ, Order of, an order of
knighthood said to have been instituted on the conclusion
of the peace between Richard II. king of England, and
the French king Charles VI., with a view of protecting and
afflicting such Christians as were oppressed in the Holy
Land. The badge of the order was "a red crost four faders' broad,
pered with gold, and charged on the centre with a cartouche,
or octagon shield, thereon a holy lamb," which
crost was worn by the knights, fixed on their habit, which
was white.

Passion, Noble, Order of the, was instituted in the year
1724, by John George, duke of Saxony Weifenfels, with
a view to inspire the nobility of his dominions with great
and elevated sentiments. The ensign of the order is "a
broad white riband edged with gold," worn scarffwise from
right to left; pendant to which is a medal of gold; and on
it "a star of eight points, charged with a crost gules, sur-
rounded with an oval blue, thereon the letters J. G. in a
cypher in gold;" the ground of the medal without the star
enamelled white, with these words "J'AIX L'IGNORER
QUE VIENT PAR LA VERTU;" on the reverse are the arms
of the principality of Querfurft, with this inscription, "SOCIETE
DE LA NOBLE PASSION, INNSTITUDE PAR J. G. D. D. S. Q.
1724."

Passion-Flower, in Botany. See Passiflora.

Passion-Week, the week next preceding Easter.
It is thus called from our Saviour's passion, i.e. his cru-
cifixion, &c. which happened on the Friday of this week,
now called Good Friday.

Passionato, in the Italian Muse, intimates that
the part to which it is annexed ought to be played passion-
ately, or in a moving and affecting manner.

Passionei, Dominico, cardinal, in Biography, was
born of a noble family, at Fosilombrote, in the duchy of
Urbino, in the year 1652. He was educated at the Cle-
mente college in Rome, and at this early period of life he
began to collect the copious library which he afterwards
rendered so useful to men of learning. In 1706 he visited
Paris, and contracted an acquaintance with Mabillon and
Montfaucon, and other eminent scholars of this metropolis.
In 1708 he went to Holland, in the character of a nego-
ciator. The belligerent powers in the Spanish succession-
war, had sent deputies thither to treat for peace; and pope
Clement XI., who could not have a nuncio in that country,
secretly commissioned Passionei to take care of the interests
of the Holy See. His efforts were successful in procuring
the evacuation of the papal territories by the German troops.
In the year 1715, he was amply recompensed for his labours,
by the poits of privy chamberlain, and domestic prelate to
that pope, and afterwards by other high official situations.
He was employed in legations as well by Clement XI. as
by his successors. Benedict XIV. entrusted him with the
most important affairs, and in 1755 nominated him to the
office of librarian of the Vatican. He exerted himself in
augmenting the riches of this celebrated collection, and ex-
tended its usefulness to literature by his correspondences.
The Academy of Inscriptions and Belles Lettres chuse him
the fame year one of the foreign associates. He died of an
apoplexy in 1761. He was justly regarded as a great bene-
factor to learning, by the generous affluence that he afforded
to its votaries, and the liberal communication of his literary
treasures. As an author, he joined Fontainici in a revision
of the "Liber diurnus Romanorum Pontificum," and he
wrote some scriptural paraphrases, commentaries, and tran-
slations, and a funeral oration on prince Eugene. He also
compiled the "Acta Legationis Helveticæ," which has
been found a useful guide to succeeding nuncios. He had
a nephew Benedict Passioeni, who published at Lucca, in 1705,
a volume containing all the Latin and Greek inscriptions
collected by this cardinal.

Passir, in Geography, a sea-port town, on the E.
coast of the island of Borneo, on a river which runs into the
firths of Macassar, about 45 miles from its mouth, with
two fathoms water. The town contains about 300 wooden
houses, on the N. side of the river, most of them inhabited
by Bugggeu merchants, who carry on a considerable trade
in opium, Hindoostan piece-goods, spices, gold, wax, &c.
The house or wooden fort of the sultan, a Malay prince,
is situated on the S. side, a very little way from the river.
S. lat. 1° 57'. E. long. 116 10'.

Passive, a term of relation, implying a thing to
suffer, or undergo the action of some other; which, in respect
hereof, is denominated active.
In all generations, philosophers conceive an active power,
and a passive.
In civil life, we say, such a person, in such an election,
has both an active voice, and a passive, i.e. he is both capa-
bale of electing, and of being elected.
Some also use the term "passive debt," for a debt which
we owe another, in contradistinction to an active debt, which
is owing to us.
The ancient chemists divide their principles, or elements,
into active and passive. Passive are such as have no active force inherent in themselves, and which only act by being joined with some of the others.

**Passive Obedience**, a doctrine held by the nonjurors, or high-churchmen, who maintained, that it was never lawful for the people, under any provocation or pretext whatever, to resist their sovereign. This doctrine has been warmly opposed by many, who think it both lawful and necessary, in certain circumstances, and in cases of an urgent and momentous nature, to resist the prince for the happiness of the people. In the present advanced state of civil and religious liberty, this doctrine is now almost exploded in our country.

**Passive Qualities.** See Quality.

**Passive Understanding.** See Understanding.

**Passive Prayer.** In the Language of Mystic Divines, is a total subjection or ligature of the intellectual faculties, in virtue whereof, the soul remains, of itself, and to its own power, impotent with regard to the producing of any effects. See Prayer.

The passive voice, says Fenelon, is only passive in the sense of the name as contemplation is so, i. e. it does not exclude possible, disinterested acts, but only unquiet ones, or such as tend to our own interest.

In the passive voice, the soul has not properly any activity, any function of its own: it is a mere inefficacy of the soul, to which the feeblest impulse of grace gives motion.

**Passive, in Grammar.** denotes a second voice or inflection of verbs, which, of active, become passive, by affixing, in the modern languages, new auxiliary verbs; and, in the ancient, by new terminations. See Verb, Voice.

The English verbs become passive, by taking the auxiliary verb *I am*, in lieu of *I have*, with which the active are conjugated; the French, by *Je suis*, in lieu of *J'ai*; the Italian, by *Io ffo*, for *Io ho*, &c.

Latin verbs become passive, by changing their terminations; as *amor*, for *amo*, &c. *amari*, for *amare*, &c.

English passive verbs are nothing else, in effect, but the verb *I am* in all its inflexions, joined to the particle passive; as I am praised, in Latin, *laudor*; in French, *Je suis loué*; I have been praised, *J'ai été loué*, *loudatus sum*, &c.

Mr. Harris, who confines all verbs, that are strictly so called, as energies, distinguishes active and passive verbs in the following manner. Every energy, he says, is naturally situated between two subtleties, an energizer, which is active, and a subject, which is passive. Hence then, if the energizer lead the sentence, the energy follows its character, and becomes what we call a verb active. (See Active.) Thus we say, *Brutus amat, Brutus loves*. On the contrary, if the passive subject be principal, it follows the character of this too; and becomes what we call a verb passive. Thus we say, *Portia amatur, Portia is loved.*

**Passive, Neuter.** is a verb that has a passive conjugation, but a neuter ligification.

Of these there are a very small number in Latin, more in French, and fewer in English; as, *I am entered, ingratus sum, Je suis entré, &c.*

Grammarians are frequently mistaken here, taking verbs for neutrals passive, which, in effect, are actives, and only differ in that they act on themselves, by adding the pronoun personal; and which, on that footing, should rather be neutrals active than neutrals passive.

Some admit of no genuine passive verbs in the modern tongues; such we mean as answer to the notion of passives in the ancient, where all is done by different terminations.

On which footing, there should be none but actives passive, and neutrals passive.

**Passive Vassalage.** See VASSALAGE.

**PASSO, in Mufic.** See PASSAGE.

**PASSO, in Geography.** a town of Portugal, in the province of Beira; seven miles E.S.E. of Lamego.

**PASSODE', a town of Naples, in Capitanata; in latitude W.S.W. of Victa.**

**PASSOVER, **a solemn feast, celebrated among the Jews, on the fourteenth day of the moon next after the vernal equinox, or the 14th day of the first month, that is, of the ecclesiastical year, which commenced with the flight of the Israelites out of Egypt; and which had the two names of Abib and Nisan. On the 14th day at even, the paschal lamb was to be killed and eaten, and from thence the feast was to be kept seven days, till the 21st. Exod. xii. 6. 8. 15. Lev. xxiii. 5; 6.

This feast was called, by the ancient Latins and Greeks, *Paccha, not from *pax*, I suffer, as Chrysofom, Ireneus, and Tertullian, weakly imagine, but from the Hebrew קחא, *pachach, passage, leap;* the design of the feast being to commemorate the destroying angel's *passing* over the houses of the Israelites, when he entered in, and destroyed the first-born in those of the Egyptians. Exod. xii. 27.

Many erroneously imagine, that it was in memory of their passing the Red sea that the pasover was instituted; though it is certain the feast was held, and had its name, before the Israelites took a step of their way out of Egypt, and consequently several days before their passing the Red sea.

Besides the pasover celebrated on the fourteenth of the first month, there was a second pasover held on the fourteenth of the second month after the equinox, instituted by God in favour of travellers, and sick persons, who could not attend at the first, nor be at Jerusalem on the day.

The Greeks, and even some of the Catholic doctors, and several considerable critics, from the thirteenth, eighteenth, and nineteenth chapters of St. John, take occasion to conclude, that Jesus anticipated the day marked for the pasover in the law; but the authority of three evengelists seems to evince the contrary. See Whitby’s Dissertation on this subject, in an appendix to the fourteenth chapter of St. Mark.

F. Lamy is of opinion, that he did not attend at the passover the last year of his life; which sentiment has drawn upon him abundance of opprobria.

F. Hardouin maintains, that the Galileans celebrated the pasover on one day, and the Jews on another.

Some divines have maintained, and not without a considerable degree of probability, that the pasover had a typical reference to Christ. Accordingly the apostle (1 Cor. v. 7.) calls him “our pasover.” Godwin and Wittius have flatted a variety of particulars, in which this type refemles its antitype; but in accommodating allusions of this kind, the imagination is too apt to mislead the judgment.

**PASSOURA, in Botany, a genus of *Aublet’s, of which the flower is totally unknown.** He describes the fruit as follows. *Peric. Capsule oblong, triangular, of one cell, and three valves. Seeds orbicular, three affixed to a longitudinal partition in the middle of each valve.* No account is given of the origin of the name. The tree, which is a native of the Timouros woods in Guiana and bare fruit in May, is described by Aublet as having a trunk fifteen or eighteen feet high, branched to the summit. Leaves opposite, stalked, ovate, acute, smooth, entire. Fruit forming a terminal spike, yellowish. Seeds spherical, green.

Jussieu has suggested, that it is very closely allied to *Rima,*
RIANA, Aubl. Guian. t. 94, in which cattle must be called in Pentandra Monogyna.

PASS-PAROLE. See PASS-Parole.

PASS-PARTOUT, a matter-key; or key that opens indiscriminately several locks belonging to the same lodge or apartment.

PASSPORT, a licence or letter from a prince or governor, granting liberty and safe-conduct to travel, enter and go out of his territories, freely, and without molestation.

The passport is properly given to friends, and the safe-conduct to enemies.

For the provision by Magna Charta, in favour of merchandise, see merchant.

The violation of safe-conducts, or passports, expressly granted by the king or his ambassadors to the subjects of a foreign power in time of mutual war, or committing acts of hostility against such as are in amity, league, or truce with us, who are here under a general implied safe-conduct, are breaches of the public faith, without which there can be no intercourse or commerce between one nation and another; and such offences may, according to the writers upon the law of nations, be a just ground of a national war. And it is enacted by the statute 21 Hen. VI. cap. 4. now in force, that if any of the king's subjects attempt, or offend, upon the seas, or in any port within the king's obedience, or against any stranger in amity, league, or truce, or under safe-conduct, and especially by attacking his person, or spoiling him, or robbing him of his goods; the lord chancellor, with any of the judges of either of the king's bench or common pleas, may cause full restitution and indemns to be made to the party injured.

Passier takes passport to have been introduced for passe-partout. Balzac mentions a very honourable passport given by a statesman to a philosopher in these terms: "If there be any one on land, or sea, hardy enough to molest Panaon, let him consider whether he be strong enough to wage war with Caesar."

PASSPORT is also used for a licence, granted by a prince, for the importing or exporting merchandise, moveables, &c. without paying the duties.

Merchants sometimes procure such passports for certain kinds of commodities; and they are always given to ambassadors and ministers, for their baggage, equipage, &c.

PASSPORT is also a licence obtained for the importing or exporting of merchandizes deemed contraband, and declared high by tariffs, &c., as gold, silver, precious stones, ammunition of war, horses, corn, wool, &c. upon paying duties.

PASSPORT, or Passe, in Sea Language, denotes a permission granted by any state to navigate in some particular sea, without hindrance or molestation from it. It contains the name of the vessel, and that of the master, together with her tonnage, and the number of her crew, certifying that she belongs to the subjects of a particular state, and requiring all persons at peace with that state to suffer her to proceed on her voyage without interruption.

PASULATUM, a name given by the ancients to a medicine composed of the pulp of raisins puffed through a sieve, sometimes alone, sometimes with other ingredients.

PASSUM, a name given by the ancients to a kind of wine made of grapes, which had been suffered to remain on the vines till March, withered and dried up; it is hence used also by some of the moderns to express raisin wine.

PASSUMACAN BAY, in Geography, a bay on the east coast of the island of Luzon; 15 miles S. of cape Engano.

PASSUMPSICK, a small river of America, in Vermont, which, pursuing a southern course, discharges itself into Connecticut river, below the Fifteen Mile Falls, in the town of Barnet.

PASS-VOLANT, or PASS-VOLANT. See Faggot.

In France, the passe-volants are condemned to be marked on the cheek with a fleur-de-lis.

PASSYUNK, in Geography, a town of America, in Philadelphia county, Pennsylvania, containing 864 inhabitants.

PASTACA, a river of Quito, which rises near Riobamba, and runs into the Mar agon, 50 miles W. of St. Joachim de Conuaguas.

PASTE, in Cookery, a soft composition of flour, wrought up with proper fluids, as water, milk, or the like, to serve for cake or collops, therein to bake meats, fruits, &c.

Paste is the basis or foundation of pies, tarts, patties, pallies, and other works of pastry.

PASTE is also used in Confectionary, &c., for a preparation of some past, made by beating the pulp thereof with some fluid, or other admixture, into a soft pappy consistence, spreading it into a dish, and drying it with sugar, till it becomes as puffy as an ordinary paffe. See CONFECTIONS.

It is used occasionally for making the crusts and bottoms of pies, &c.

Thus, with proper admixtures, they make almond pails, apple pails, apricot pails, cherry, currant, lemon, plum, peach, and pear pails.

PASTE is also used for a preparation of wheaten flour, boiled up, and incorporated with water; used by various artificers, as upholstersers, saddlers, bookbinders. &c. instead of glue or size, to fasten or cement their cloths, leathers, papers, &c.

When paste is used by bookbinders, or for paper-hangings to rooms, it is usual to mix a fourth, fifth, or sixth, of the weight of the flour of powdered resin; and where it is wanted still more tenacious, gum Arabic, or any kind of size, may be added. Paste may be preferred, by dissolving a little sublimated, in the proportion of a dram to a quart, in the water employed for making it, which will prevent not only rats and mice, but any other kinds of vermin and insects, from preying upon it.

PASTES, in the Glass Trade, a sort of composition of the glass kind, made from calcined crystal, lead, and metallic preparations, to imitate the several natural gems. These are no way inferior to the native stones, when carefully made and well polished, in brightnes and transparency, but want their hardnefs.

The general rules to be observed in making them are these: 1. That all the vessels in which they are made are firmly luted, and the lute left to dry before they are put into the fire. 2. That such vessels are chosen for the work as will bear the fire well. 3. That the powders be prepared on a porphyry stone, not in a metal mortar, which would communicate a tinge to them. 4. That the just proportion in the quantities of the several ingredients be nicely observed. 5. That the materials be all well mixed; and if not sufficiently baked the first time, to be committed to the fire again, without breaking the pot; for, if this be not observed, they will be full of blisters and air-bladders. 6. That a small vacuity be always left at the top of the pot, to give room to the swelling of the ingredients.

To make a paffe of extreme hardnefs, and capable of all the
the colours of the gems, with great lustre and beauty, take of prepared crystall, ten pounds; half of powder, six pounds; fulphur of lead, two pounds; mix all these well together, into a fine powder; make the whole, with common water, into a hard paste; and make of this paste small cakes, of about three ounces weight each, with a hole in them, made in their middle; dry these in the sun, and afterwards calcine them in the straight part of a potter’s furnace; after this powder them, and levigate them into a perfect fineness on a porphyry, and set this powder in pots in a glafs furnace to purify for three days; then cast the whole into water, and afterwards return it into the furnace, where let it stand fifteen days; in which time all foulness and blisters will disappear, and the past will greatly resemble the natural jewels. To give this the colour of the emerald, add to it brass thrice calcined; for a green, brass simply calcined to redness; for a fapphire, add zaffcr, with manganese; and for a topaz, manganese and tartar. All the gems are thus imitated in paste, by the same way of working as the making of the coloured glasfs; and this is so hard, that they very much approach to the natural gems.

The colours in all the common gems, made of the several pastes, may be made deeper or lighter, according to the works for which the glases are designed; and it is a necessary general rule, that small glases for rings, &c. require a deeper colour, and large ones a paler. Besides the colours made from manganfe, verdigris, and zaffcr, which are the ingredients commonly used, there are other very fine ones, which care and skill may prepare: very fine red may be made from gold, and one not much inferior to that from iron; a very fine green from brafs or copper, and a fky-colour from filver; and a much finer one from the common small garnets of B-hemia, which are of little value. The gems also afford glorious colours like their own.

The fine blue from filver is, probably, only from the small quantity of copper used in the alloy.

A very singular and excellent way of making the paste to imitate the coloured gems is this: take a quantity of faccharum sufturum, or sugar of lead, made with vinegar in the common way; let it in sand, in a glafs-b-dy well luted from the neck downwards; leave the mouth of the glafs open, and continue the fire twenty-four hours; then take out the falt, and if it be not red, but yellowish, powder it fine, and return it into the felf, and keep it in the fand-heat twenty-four hours more, till it becomes as red as cinnabar. The fire must not be made too strong as to melt it, for then all the process is spoilt. Pour diffiluted vinegar on this calcined falt, and separate the folution from the dregs: let the decanted liquor fand six days in an earthen vefsel, to give time for the finer fediment to fubfide: filter this liquor, and evaporate it in a glafs body, and there will remain a moft pure falt of lead; dry this well, then difolve it in felf water; let the folution fand six days in a glased pan; let it fubfide, then filter the clear folution, and evaporate it to a yet more pure white and sweet falt; repeat this operation three times; put the now perfectly pure falt into a glafs vefsel, let it in a fand-heat for feveral days, and it will be calcined to a fine inapparent powder, of a lively red. This is called the fulphur of lead. Nert’s Art of Glafs.

Take all the ingredients as in the common composition of the pastes of the several colours, only instead of red lead, use this powder, and the produce will well reward the trouble of the operation, as experience has often proved.

A paste proper for receiving colours may be readily made by well pounding and mixing six pounds of white fand, calcined, three pounds of red lead, two pounds of perfured pearl-affes, and one pound of nitre. A softer paste may be made, in the same manner, of fix pounds of white fand calcined; red lead, and perfured pearl-affes, of each three pounds; one pound of nitre, half a pound of borax, and three ounces of arsene. For common use, a pound of common falt may be substituted for the borax. This glafs will be very f-f, and will not bear much wear, if employed for rings, buckles, or fuch imitations of stones, as are expofed to much rubbe: but for ear-rings, ornaments worn on the breast, and thofe little used, it may halt a considerable time.

In order to give paste different colours, the process is as follows.

Paste reffembling amethyst.—Take ten pounds of either of the compositions described under Colouring of Glass; one ounce and a half of manganese, and one dram of zaffcr; powder and fufe them together. See Amethyst.

Paste perfectly black.—Take ten pounds of either of the compositions just referred to, one ounce of zaffcr, fix drams of manganese, and five drams of iron, highly calcined; and proceed as before.

Paste, Blue.—Take of the fame composition ten pounds; of zaffcr, fix drams; and of manganese, two drams; and proceed as with the foregoing.

Paste reffembling the chryrifite.—Take of either of the compositions for paste above described, prepared without falt-petre, ten pounds, and of calcined iron five drams; and purify the fame process as with the red. See Chryrifite.

Paste reffembling the red cornelian.—Take of the compositions mentioned under Colouring of Glass, two pounds; of glafs of antimony, one pound; of the calcined vitriol, called scarlet ochre, two ounces; and of manganese, one dram. Fuse the glafs of antimony and manganese with the composition; then powder them, and mix them with the other, by grinding them together, and fuse them with a gentle heat.

Paste reffembling white cornelian.—Take of the composition just referred to, two pounds; and of yellow ochre, well washed, two drams; and of calcined bones, one ounce. Mix them and fuse them with a gentle heat.

Paste reffembling the diamond.—Take of the white fand, fix pounds; of red lead, four pounds; of pearl-affes, purifed, three pounds; of nitre, two pounds; of arsene, five ounces; and of manganese one feruple. Powder and fuse them.

Paste reffembling the eagle-marine.—Take ten pounds of the composition under Glass; three ounces of copper, highly calcined with fulphur; and one feruple of zaffcr. Proceed as before.

Paste like emerald.—Take of the fame composition with the lead, nine pounds; three ounces of copper, precipitated from aquafortis, and two drams of precipitated iron. See Emerald.

Paste like garnet.—Take two pounds of the composition under Glass; two pounds of the glafs of antimony; and two drams of manganese. For viniger garnet, take of the composition for paste, described in this article, two pounds; one pound of glafs of antimony, and half an ounce of iron, highly calcined; mix the iron with the uncoloured paste, and fuse them; then add the glafs of antimony, powdered, and continue them in the heat till the whole is incorporated. See Granite.

Paste, gold, or full yellow colour.—Take of the composition for pale ten pounds, and one ounce and a half of iron strongly calcined; proceeding as with the others.

Paste, deep purple.—Take of either of the compositions for pale ten pounds; of manganese, one ounce; and of zaffcr, half an ounce.

Paste,
PASTE, resembling ruby.—Take one pound of either of the compositions for paste, and two drams of calcasaffi, or precipitation of gold by tin; powder the paste, and grind the calc of gold with it in a glaze, first, or agate mortar, and then fuse them together. A cheaper ruby paste may be made with half a pound of either of the above compositions, half a pound of glafs of antimony, and one dram and a half of the calc of gold; proceeding as before.

PASTE resembling sapphire.—Take of the composition for paste, ten pounds; of zaffer, three drams and one scruple; and of the calc calsaffi one dram. Powder and fuse them. Or the fame may be done, by mixing with the paste one-eighth of its weight of smalt. See SAPPHIRE.

PASTE, like topaz.—Take of the composition under glass ten pounds, omitting the salt-petre; and an equal quantity of the gold-coloured hard glafs. Powder and fuse them. See TOPAZ.

PASTE, like turquoise.—Take of the composition for blue paste, already described, ten pounds; of calcined bone, horn, or ivory, half a pound. Powder and fuse them.

PASTE, opaque white.—Take of the composition for paste, ten pounds; and one pound of calcined horn, ivory, or bone; and proceed as before.

PASTE, semi-transparent white, like opal. See OPAL.

PASTE for angling.—There are many receipts which particular people are fond of; but the following composition seems one of the best: take equal quantities of fresh butter and fish's fish, about half as much of good old cheese, and the crum of an old flat loaf, as much as will, when they are all beaten in a morter, make the whole into a paste; add a little wool or tow, that it may keep the better on the hook. The place should be bated with blood and grains over night, and in the morning this paste will be found an excellent bait. See FISHING.

PASTES for birds, a general sort of food made by the people who breed up birds from the nest, and suitit almost all kinds.

It is made in the following manner: grind half a peck of large beans, well dried, to a very fine meal; take of this meal two pounds; of the beat sweet almonds blanched, one pound; thence must be well beat together in a morter, till perfectly mixed; then to a quarter of a pound of fresh butter, in a sauce-pan well tinned, add the paste, and mix all well together over a charcoal fire, stirring it as it boils with a wooden spoon; then add the yolks of four eggs, and a little saffron, and finally a small quantity of the finest virgin honey. When these are well incorparated, and are tolerably thin and without lumps, the whole is to be poured into a colander, made with fuch holes as will let the composition pass through; if any of it is so thick that it will not go through, it must be beat again in a morter, and by that means made fit to pass the holes, and mix with the rest. When the whole is done, it is to be put into a pot, and a little clarified honey being melted and poured on it, it will keep very well for fix months or longer.

PASTEBOARD, a kind of thick paper, formed of several sheets paled together.

There is also a coarse kind of pasteboard, made of old paper, and old pasteboard, beaten in a mortar with water, and reduced into a kind of pulp; to which is added a little paste, to give the paper a confistency, after which it is formed into a mould, and, to fhine it, laid in a press, to squeeze out all the water, and reduce it to its proper thickness.

Each kind is distinguished by numerouf, which expref{s the fineliefs and value: the finest is covered on both fides with a very white smooth paper; others only on one fide; and others on both fides with common paper.

The chief use of pasteboard is in the binding of books, and the making of letter-cafes, hat-cafes, gloves, &c. See BOOK-BINDING.

For the duty on pasteboard, see PAPER.

PASTE, in Geography, a town of Atfatic Turkey, in the province of Diarbekir; 56 miles W.N.W. of Diarbekir.

PASTEL. See PASTIL.

PASTERN of a horse, the distance between the fetlock or joint next the foot and the coronet of the hoof.

This part should be short, especially in the middle-sized horses; because long patterns are weak, and cannot so well endure travel.

PASTERN Joint, is the joint above the pattern.

The pattern joint, after travelling, is very apt to be crowned, i.e. to have a swelling round it, beneath the skin, in form of a circle, a third of an inch broad.

PASTICCIO, literally means, in Italian, a pie or paty; but in music implies an opera composed of detached airs by different composers, frequently introduced without any connection with the drama, character, or situation of the fide plot.

PASTIL, or PASTIL, among Painters, &c. a fort of paste, made of several colours, ground up with gum-water, either together or separately, in order to make crayons to paint with on paper or parchment. See CRAYON.

PASTIL, Pastillus, is also used for a dry composition, yielding a fragrant smell when burnt in a perfuming pan, to clear and scent the air of a chamber.

It is composed of odorous refins, mixed with aromatic woods or drugs pulverifed, and incorporated with mucilages of gum tragacanth. Some call thefe compositions offelets of Cyprus.

There are also pastils for the mouth, chewed to procure a sweet breath. These have several names, and confift of several preparations. As muscadine, conferves, &c.

PASTIL, or Pafillus, is fometimes used for the plant other-wife called wood.

PASTIL, in Confectionary, is a preparation of fugar with lemean-water, &c. boiled up with gum-water, strained, beat up, and, by the addition of more dry fugar, worked into a phable paste, and thus formed into round or oblong figures, and dried in a fove. See LOZENGE.

Gen. Ch. General mode of many rays, flat; partial of many rays. General involucre none; partial none. Perianth obsolete. Cor. Unifertal, uniform; flowers all ferte; partial of five, lanceolate, involute, undivided petals. Stam. Filaments five, capillary; authors roundish. Piff. German inferior; fyltes two, reflexed; fligmas obtufe. Peric. Fruit much compressed, elliptical, divisible into two parts. Seeds two, elliptical, girt round the margin, nearly flat on both fides.
Fruit elliptical, compressed almost flat. Petals involute, entire. Involutum neither general nor partial.

PASTINACA.

PASTINACA.

Method of Culture. — This in the first or is easily ef- fected by bowing fresh feed in the latter end of February, or beginning of the following month, upon a bed prepared in a spot of the best light, rich, deep soil, in one of the most open airy quarters of the garden, by being trenched in one full spade deep at least, or if two the better, where the depth of good staple admit, that the roots have a due depth of loose soil to run down straight to their full length. And if the ground be previously trenched up in rough ridges in winter, especially where stiff or wet, and he ex- posed some time to the sun and air, it will be much im- proved for this purpose. At the time of bowing, the ground should be made level and even on the surface, but not raked till after the feed is sown, which should be performed while the ground is fresh tilled, or before the surface becomes too dry, as, in raking, the clods will readily fall under the rake to bury the feed regularly.

And the feed should lie from broad-cast thinly, either all over the surface, or the ground may be divided into four- feet-wide beds, as most convenient, but for large quantities the former is the most eligible practice. Done in the same way, it is the practice with some to tread down the feeds evenly, and minish with an even good raking, to cover them equally, smoothing the surface. In about three weeks the feeds begin to germin- nate, and the plants soon appear above ground. When they are two or three inches high, they should be thinned to regular distances, and cleaned from weeds; which may be done either by hand or small hoeing; but the latter is preferable for the benefit of the crop, and considerably the most expeditious; it should generally be performed by a three or four-inch hoe. Dry weather should be chosen for the purpose, and the plants cut out to about ten or twelve inches distance, as they should have large room, cutting up all weeds as the work proceeds. After this, no more cul- ture is required till the future progress of the weeds renders another hoeing necessary; and probably another repetition may also be required, till the plants are in full leaf, when they cover the ground, and bid defiance to any further interrup- tion from weeds.

In autumn, about October, the roots will be arrived nearly at their full growth; when the leaves begin to turn yellow and decay, which is a certain sign of their maturity, they may then be dug up for use, as they are wanted. They may also either remain in the ground all winter, and be taken up as wanted, or a quantity may be dug up in autumn, and their tops pared off close, and then buried all winter in sand, in a shed or other dry place, to be ready at all times for use: some should also be left in the ground for spring service, as January or the beginning of February, digging them up just before they begin to shoot, and laying them in the sand; as by taking them up at this time, it re- tends their effect for shooting, so that they continue in tolerable perfection until the latter end of April or longer. But in order to have parsnips in due perfection, great care is necessary to have feed only from some of the finest rooted plants; for which purpose, a quantity of the large, long, straight roots should be selected, trimming off their ruts, and planting them in rows three feet asunder, and two dis- tant in the lines, about an inch deep over their tops; in which method they will shoot up strongly in spring for flowering, and ripen feed in the latter end of August, or early in September; when in a dry day, the umbels of feed should be cut off and spread upon mats to dry and harden, 3 G afterwards.
afterwards thrashing out the seeds, and putting them up in bags for use.

And the second sort may be raised, by souring the seeds in the places where the plants are to remain, at the same season as the above, keeping the plants afterwards properly thinned and cleared from weeds.

The first is an useful succulent root, which contains a large proportion of nutritious matter; but the latter is chiefly cultivated for affording variety in the borders or other parts of pleasure-grounds.

*Pastinaca Marina,* in *Ichthyology,* the name of a fish, called in English the *poison-fish,* *fire-faire,* or *sting-ray.* It is one of the flat cartilaginous fishes, and something like the common skate. It is a species of the raia, or ray-fish, and distinguished by Artedi from the other species, by the name of the smooth-bodied ray, with no fins to the tail, but with a long, bony, serrated spine in it. See *Raja Pastinaca.*

This fish is the πασαρί of Aristotle and Oppian, and is called by the modern Italians, *bacco.*

Its tail, in which all its poison is said to be lodged, is long, smooth, and round, with a thorn, or dart, of a finger's length, toothed on each side like a saw, with the teeth flanding upwards, or toward the head. This is placed at the distance of about one-third of the length of the tail, and that from this place grows very slender, and ends in a very slender point. It grows, sometimes, to ten pounds weight; and when the tail is cut off, is commonly sold in the markets of Italy, and elsewhere.

Authors give us many remarkable accounts of the poison of this fish, which it communicates to animals by the bite of its tail. They mention also two kinds of it; that is, besides the ordinary species, which is smooth, another called the *paillina marina afera,* which is rough and prickly.

Mr. Pennant observes, that there is no credit due to the generally received opinion of its venomous qualities, though even Linnaeus has adopted it. The spine is the weapon of offence belonging to the fish, which is capable of giving a very bad wound, attended with dangerous symptoms, when it happens on a tender part, or to a person with a bad habit of body. Pennant's *British Zool.* vol. iii. p. 95.

*Pasticnion,* a term sometimes used in *Agriculture,* for the act of opening, loofening, and preparing the earth for planting.

*Pusto,* in *Geography,* a town of Peru; 80 miles N.N.E. of Lima.

*Pisto,* St Juan de, a town of South America, in the province of Popayan, capital of a dioces, in the vicerealty of New Granada, containing above 7000 inhabitants; 80 miles S.S.W. of Popayan. N. lat. 1° 15'. W. long. 76° 46'.

*Pastophorí.* Πασάφορα, among the ancients, priests whose business it was, at solemn festivals, to carry the shrine of the deity, when they were to pray to him for rain, fair weather, or the like.

*Pastophoria,* in *Antiquity,* the apartments, near the temples, where the pastophori were lodged.

Clemens Alexandrinus, describing the temples of the Egyptians, says, that, after having passed through magnificent courts, you are conducted to a temple, which is at the farther end of these courts, and then a pastophorus gravely lifts up the veil, which is the door, to shew you the deity within; which is nothing but a dog or a cat, or some other animal. These pastophori also supported the shrine, or niche of these ridiculous divinities, when they were carried in procession. Apuleius speaks of the pastophori that carried the Syrian goddesses.

In the temple of Jerusalem there were two courts fur-
PASTORAL.

it is, that this species of poetry has, at all times, allured many readers and excited many writers. Nevertheless, there is hardly any species of poetry more difficult to be carried to perfection, or in which fewer writers have excelled. Pastoral life is described by the author now cited in three different flates of it; either as it now is, when shepherds are reduced to a mean, servile, and laborious condition; or such as it may be supposed to have been, in the more early and simple ages, when flocks and herds were numerous, and shepherds, though unrefined in their manners, were respectable in their filation; or such as it never was, nor can be, when to the close, innocence, and simplicity of the early ages, we attempt to add the polished taste and cultivated manners, of modern times. The first of these flates is too grofs and mean, and the last too refined and unnatural, to become the groundwork of pastoral poetry. Theocritus is confidered for having deviated too much to the first extreme: and some of the French and Italian writers of pastoral have erred in making their shepherds discourse like courtiers and scholars: and in either way a person may retain the name, whilst he wants the spirit of pastoral poetry. He that would succeed in this species of composition must keep in the middle filation between these two extremes. The great charm of pastoral poetry arises from the view which it exhibits of the tranquillity and happiness of a rural life. This pleasing illusion the poet must be careful to maintain. The true spirit of a pastoral poet is conspicuously displayed by Virgil in the following beautiful lines of the first eclogue, in which he has brought together as agreeable an assemblage of images of rural pleasant as can any where be found.

"Fortunate Senex! hic inter flumina nota, &c."

"Happy old man! here mid th' accentum'd streams And fared springs, you'll thin the foarching beams; While from yon willow fence, the pasture's bound, The bees that fuck their flowery stores around, Shall sweetly mingle, with the whispering boughs, Their lulling murmurs, and invite repofe. While from steep rocks the pruner's song is heard; Nor the soft cooing dove, thy favor'd bird, Meanwhile shall cease to breath her melting strain; Nor turtles from th' aerial elms to plain." Wharton.

Pastoral poetry offers to our consideration its scenery, its characters, and the subjécts and actions which it should exhibit. As to the scenery, it muft be laid in the country, and the poet's merit much depends on describing it beautifullty. Virgil is, in this respect, deemed to have been excelled by Theocritus, whose descriptions of natural beauties are richer and more picturesque than those of the other. The following description exhibits rural scenery painted in very lively colours.

"On soft beds recline
Of lentil, and young branches of the vine;
Poplars and elms above, their foliage spread,
Lent a cool shade, and wav'd the breezy head;
Below, a stream, from the nymph's sacred cave,
In free meanders led its murm'r'ring wave;
In the warm fun-beams, verdant shades among,
Shrill grashoppers renew'd their plaintive song;
At distance far, conceal'd in shades, alone,
Sweet Philomela pour'd her tuneful moan:

The lark, the goldfinch, warbled lays of love,
And sweetly penive,' coo'd the turtle dove;
While honey bees, for ever on the wing,
Hum'd round the flowers, or flit the silver spring.
The rich, ripe feafon gratified the fene
With summer's sweets, and autumn's redolence.
Apples and pears lay flrew'd in heaps around,
And the plum's loaded branches kifs'd the ground." Fawkes.

As to the characters, or persons, that are proper to be introduced into pastoral poetry, they muft be shepherds, or persons wholly engaged in rural occupations; whose innocence and freedom from the cares of the world may, in our imagination, form an agreeable contrast with the manners and characters of those who are engaged in the baffle of life.

In the choice of the subjécts of pastoral poetry, the prin'-

cipal difficulty of this kind of writing occurs. The active scenes of country life will be thought by many, and perhaps not without reason, too barren of incidents. The tenor of the shepherd's life is uniform, and does not admit of that variety which renders poetry interesting. Hence it is that, of all poems, the moft meagre commonly in the subjéct, and the leaf dividend in the tirain, is the pastoral. Common-place topics have been thronned over by all eclogue writers, since the days of Theocritus and Virgil; and to this circumstance is owing much of that infipidity which prevails in pastoral composition. But why, says Dr. Blair, may not pastoral poetry take a wider range? Human nature, and human passions, are much the same in every rank of life; and whenever these passions operate on objects that are within the rural sphere, there may be a proper subjéct for pastoral.

The two great fathers of pastoral poetry are Theocritus and Virgil. In theo Idylls of the former, which are properly pastoral, there are many great beauties. He is distinguished for the simplicity of his sentiments; for the great sweetness, and harmony of his numbers; and for the richness of his scenery and description. He is the original after which Virgil has copied; but he has followed him with judgment, and in some respects improved upon him. Moschus and Bion, two other Greek poets, have also considerable merit in the pastoral style; and if they want the simplicity of Theocritus, they excelle him in tenderness and delicacy.

The modern writers of pastoral have generally contented themselves with imitating the ancient poets. Sanzarius, indeed, a famous Latin poet in the age of Leo X., attempted a bold innovation, by compounding Pictatory eclogues; changing the scene from woods to the sea, and from the life of shepherds to that of fishermen. But he has gained no followers among all the moderns. Mr. Gefner, a poet of Switzerland, has been, in the judgment of Dr. Blair, the most successful in his pastoral compositions. He has introduced into his Idylls many new ideas. His rural scenery is striking, and his descriptions are lively. He presents pastoral life to us, with all the embellishments of which it is susceptible, but without any excess of refinement. The chief merit of this poet consists in his writing to the heart; and he has enriched the subjécts of his Idylls with incidents, which give rise to much tender sentiment. Scenes of domestic felicity are beautifully painted. The mutual affection of husbands and wives, of parents and children, of brothers and sisters, as well as of lovers, are displayed in a pleasing and touching manner.

Neither Mr. Pope's, nor Mr. Philips's pastoral, do any great honour, in our author's opinion, to the English poetry. Mr. Gay published his Shepherd's Week, in six pastoral, with a design of ridiculing that sort of simplicity which

3 G 2 Philips
Philips and his partizans extolled, and they are an ingenious burlesque of pastoral writing, when it rises no higher than the manners of modern clowns and rustics. Mr. Shenstone's pastoral ballad, in four parts, may justly be reckoned, says Dr. B., one of the most elegant poems of this kind in the English language.

Pastoral writing has appeared in later ages under the form of a regular drama, blending plot, characters, and passions, with the simplicity and innocence of rural manners. Accordingly pastoral has been defined a dramatic piece, in which the persons are clad like nymphs and shepherds, and set their own amours. The scene is always in the fields or woods; whence Tasso calls pastoral "favole boscareccia." Such are the Pastoral Fido of Guarini; the Aminta, of Tasso; the Sylvia, of Mairet, the French poet; and the Comus of Milton, &c. Tasso alludes to himself the honour of having invented pastoral; but the first idea of this kind of drama seems to be Boccaccio's, who made the first attempt of this kind in 1552. But Tasso's Aminta, which did not appear till the year 1573, effecting what had been done by Boccaccio, the first author was forgot, and Tasso left as the inventor.

It is certain this kind of pastoral fable, composed according to the rules of the fable, was unknown among the ancients. The Greeks and Latins have indeed introduced shepherds in their eclogues; but these eclogues had nothing theatrical in them: nor were the shepherds ever brought upon the stage.

Tasso's Aminta claims the preference, as it is less intricate in the plot and conduct, and less strained and affected in the sentiments than the Pastoral Fido of Guarini. Both poëses great beauties, and are entitled to the reputation they have gained. Dr. Blair mentions another pastoral drama, which will bear being brought into comparison with any composition of this kind, in any language; that is, Allan Ramsay's Gentle Shepherd. The characters are well drawn, and the incidents affecting ; the feenary and manners lively and just. It affords a strong proof, both of the power which nature and simplicity poëses, to reach the heart, in every fort of writing; and of the variety of pleasing characters and subjects, with which pastoral poetry, when properly managed, is capable of being enlivened. Blair's Lectures, vol. iii.,

Pastoral Column. See Column.
Pastor. See Grotte.
PASTOR STAG. Ital. and Fr., in Music, an air of the pastoral kind, is generally in Siciliana time. "French airs called pastoral (according to Roussel) are generally in 64 measure, or two triplets in a bar, and in the character of the mazurka. Italian pastoral airs more accent, more grace, as much sweetest, and are less impish; their measure is always #. A mazurka; the celebrated pastoral at the end of Corelli's eighth concerto, is in 4.

Among French pastoral, they have whole dramas, called opéra champêtres, the personages of which are shepherds, and the music ought to be suitable to their state, simple and rustic, such as we suppose their manners to be.

A pastoral is also a piece of music, set to words relative to pastoral life, or a melody which imitates the songs of the shepherds, which is equally sweet, tender, and natural. The air of a dance composed in the same character, is also called a pastoral.

PASTORIUS, JOACHIM, in Biography, a writer of history, was born in the year 1610, in Great Glogau, in Silesia. He was brought up to the medical profession, and received the title of honorary professor at Elbing and Danzig, but the avowal of Socinian principles subjected him to various ill offices. At length his constancy gave way, and he conformed to the Roman Catholic religion; he was almost immediately ennobled, created apostolic prothonotary, advanced to other high offices, and finally made historiographer, secretary, and commissary of the kingdom of Poland. He died at Frauenberg, in Prussia, in 1681. He was author of a number of historical pieces, written in the Latin language, and he published the Aristotelian Ethics of Ciclius, with a life of the author, and some orations and poems. Moreri.

PASTRY, that branch of cookery which teaches the preparation of pates, with several favoroy ingredients of flesh, fruits, spices, sugar, butter, &c.

Pasty is chiefly convenient in the making of pies, patties, tarts, cakes, bincists, &c.

PASTURE, PASTURE, in our law-books, is any place where cattle are occasionally fed. By which it differs from patera, which is a place set wholly apart for feeding, and never ploughed.

"Patera omne genus paucern significat, in pratis, in fipula, in agris, in campis: sed paterus est locus principalius deputatus pecoris pascentis, ut puta in montibus, moris, malis, et plantis non cultus nec aratis."

Linnaeus.

PASTURE, Common of. See Common of Pature.
PASTURE, Admeasurement of. See Admeasurement.
Pasture, in Agriculture, a field kept fed down by cattle, sheep, or other animals. These differ considerably according to the modes in which they are managed, some being almost wholly appropriated to the fattening of animals, under which fystem they are termed grazing, or fattening pastures; while those which are almost solely applied to the support of such animals as afford useful products, such as cheese or butter, are denominated dairy pastures. The situations and inclosures of pastures have also some effect on the manner of employing them, the lower and more inclosed kinds being in general more adapted to the fattening system, while the higher are more suited to sheep-pastures. The state of the fward may likewise have some influence in the same way, as the new law is made to be more proper for the f Cromack, while the old grazed lands are better for feeding. See the following article.

PASTURE LAND, a general name for all forts of land reserved for the purposes of pasturing and feeding cattle upon. Pasture ground is of two sorts: the one is low meadow land, which is often overflowed; and the other is upland, which lies high and dry. The first of these will produce a much greater quantity of hay than the latter, and will not require mowing or dreeving to often: but the hay produced on the upland is much preferable to the other; as is also the meat which is fed in the upland, more valued than that which is fed in rich meadows: though the latter will make the fatter and larger cattle, as is seen by those which are brought from the low rich lands in Lincolnshire. But where the people are nice in their butcher's meat, they often give a much larger price for such as has been fed on the downs, or in short, upland pastures, than for the other, which is much larger. Besides this, dry pastures have an advantage over the meadows, that they may be fed all the winter, and are not so subject to poison in wet weather; nor will there be so many bad weeds produced, which are great advantages, and which, in a great meaure, recom pense for the smaller produce of grasses.

The author of a late pastoral work has stated, that the grounds that are the most perfectly adapted to this life, are all those which have a considerable depth of good mould; and, at the same time that they afford a good herbage, are so dry in their nature, as to admit animals to feed upon them at almost all
PASTURE-LAND.

all seasons, without injury by poaching. Coarse rushy lands may, however, in many cases, be converted into good pastures, by proper attention in draining, and cutting over the rushes in the early part of the spring, as by this means the water enters their stems, and the plants decay, the young shoots being afterwards eaten by young flocks, and the good grazs plants allowed to flourish. He likewise adds, that there is also another fort of land that may be employed in this way, which is that of the moory kind, consisting of much imperfectly reduced vegetable matter, proceeding from the leaves and roots of various decayed vegetable productions, that require to be brought into a suitable condition for the support of grazs plants by proper drainage, and the application of sublimes of the foill kind. And he observes, that pasture lands should likewise, as much as possible, possess properties in the nature of their graffs that are the most advantageous for the particular method of management under which they are to be conducted. In this view, some may be more adapted to the producing of milk and butter, others of cheese, and others again of feeding or fattening animals. It is in some measure on this account, as well as that of local convenience, that different modes of management are employed on grazs lands.

And it is suggested, that the difference of situation in pasture lands has likewise much influence in directing the ufe to which they may be applied with the greatest benefit. The higher and more elevated grounds being, in general, more proper for sheep, while thoile of the lower and more inclosed kinds are mostly better suited for the purpose of neat cattle, or other animals under the fattening sytem. And besides, the age of the lay makes a difference in some cases; new laid-down pasture lands being commonly found more proper for the support of young flock animals, while those that have been long in the flate of fward, are in general better adapted to the feeding or fattening flock. It is also obvious, that the mode of inclosing has some effect in the same way; as when the inclosures are of a moderate size, they are found more suitable for the purposes of feeding, than where the contrary is the cafe.

It may be observed, that this fort of grafs lands, as well as that of the hay kind, is subject to be overrun and much injured in its produce, both by mois, coarse plants, and ants as well as mole-hills. These should therefore be constantly removed, or spread about as soon as possible, and prevented from obstructing the complete pasturage of the lands, in the manner that is recommended under these different heads.

It is suggested, that on the marsh grazing lands in Kent, where ant-hills frequently occur, they have a mode of extinguishing them in an early and expeditious way, and of bringing the surface level at the same time, which is by the ufe of an implement, eight or nine feet in breadth, which is armed with a fort of strong cutting blade. When in ufe it is drawn by a horse directed by a boy, and guided behind by a man, and is capable of often cutting off several of the hills at one stroke, and of course of clearing a number of acres in a very short space of time. There are various other implements in ufe for this fort of work, in different parts of the island, which answer the intention in a very perfect manner.

There can be no doubt that pastures, when not well attended to, must frequently be prevented from being properly fed by various kinds of shrubby plants, such as those of the alder, brack, broom, furze, and other forts that spring or shoot out upon the surface, and which should always be extirpated as soon as possible, as by remaining upon and shading the ground, they render the herbage feem, coarse, and improper for the food of cattle. This fort of work may be performed by cutting them closely down, as they rise in the early fpring months, by a strong fythe; but a better practice is to dig them or plough them completely out, where it can be done, which should be the cafe while it is under the flate of fillage, in order to its being laid down to the condition of fward.

And the shrubby, black, and other thorns and briers, that spring up from suckers on the edges of the hedge-rows of pasture grounds, should likewise be extiripated, especially where sheep are pastured, as they do great mischief by pulling and entangling their coats. Besides, much ground is often full in this way, and the appearance of the fence can be kept up by digging them out. Many farmers, after the plants are focked up, the earth about them might be thrown into a compost with a small proportion of well-rotted dung, and spread upon the land with much benefit; and at the same time the land thus cleared be brought into a proper condition for being down with grazs feeds.

Besides, where pasture lands are productive in grazs of the more sharp coarse-bladed kinds, which rise into tufts or tuftocks, and such as are known to agricultors under the titles of pink or carnation grazs, and there are other forts of aquatic plants presenting themselves, it is a certain indication that the foil is too retentive of moisture, and not only lands in need of draining, but also of being kept in a clofe flate of feeding by different forts of flock, so that every part of them may be kept quite pared down by the animals.

It has been well suggested, that the manuring of pasture lands is a business much less in practice than ought perhaps to be the cafe; as where the foil is not good, and they are kept in a constant flate of feeding or pasturage, it would seem probable that their fertility must in some measure decrease, if proper means be not taken to preserve and keep it up, even though they should be fed down with fheep, which is unquestionably, in this view, the most favourable fort of flock. It is indeed hardly to be supposed, that the small proportion of excrementitious matter that is dropped at random during the feeding of animals, especially the larger kinds, under an exposure to the dissipating and wafting effects of the atmosphere, at different seasons, where no other forts of food than that of the natural grazs of the pastures is consumed, can in such forts of land be adequate to the restoratian of the great degree of fertility that is constantly conveyed away in the time of pasturing. In the better kinds of pasture lands, where the produce of grafs is considerable, improvement may, and undoubtedly does take place by feeding them, especially by fheep, as the defcharges of the animals are not only more abundant, but a proportion of old grafs is left to decay during the winter fseason, and in that way make an annual addition to their fertility. It appears probable to this writer, however it may differ from opinions that have been held on this subject by some cultivators, from much closer attention to the management of grafs lands of the less rich kinds in the flate of pasturage; that, in such cafes, unless attention be paid to improve their condition by some other means than merely that of the manure dispersed over the land by the animals in simply consuming the herbage, they must in time become gradually deteriorated, and the quantity of pasturage be diminished so as to support smaller proportions of flock than was formerly the cafe. This supposition seems indeed, in some degree, supported by the condition of downs, and other unclosed lands, that have been in a flate of pasturage for a great length of time; as in these cafes, if feeding had rendered them more fertile, they must long since have been enabled to carry a vastly increased proportion of flock; which is certainly not the cafe, as has been strongly re-marked
marked long ago, by Dr. Anderson in his useful Essays on Rural Affairs.

But that feeding down pasture lands, of these as well as other kinds, in a judicious manner, has the effect of rendering the herbage more fine, and better for the support of flock in general, there cannot be the smallest doubt; though it does not certainly follow that the fertility of the land, in such cafes as have been jilted mentioned, is thereby really improved, as has been supposed by some employed in the business of grazing in particular situations and circumstances. Where the pastures, as has been jilt observed, are let at so much per head, to afford a large quantity of herbage for being converted into manure, and sufficient to permit a portion annually to revert to the state of vegetable mould by its undergoing the process of putrefaction, a considerate proportion of the profit, may, with doubt, be the cafe under the lathering system, especially where sheep constitute the principal flock. And in most cafes, the feeding of the herbage by this practice must be advantageous. It seems, therefore, not improbable, that the bettering of the condition of the herbage, by feeding the lands with sheep, may have occasionally led to the supposition, that the fertility of the ground was thereby, in all cafes, really improved. That an increase of fertility is produced, in most instances, by the pasturing of lands with sheep, is not disputed; it is only in particular circumstances that the contrary is contended to take place. And in all cafes the injury that may be sustained in this way, must evidently be very small, when compared with that which takes place from repeated mowing without the application of suitable dressings to the lands.

The improvement of the fertility of pasture grounds may be effected in different ways, as either by the direct application of manure in its natural state, such as that of rotten dung, lime, marle, or in that of earthy compost, occasionally spread over their surfaces in a thin even manner; or indirectly by the folding or confining of sheep upon the land during the time they consume other farts of green food, such as turnips, &c. The latter mode is unquestionably the most advantageous and convenient, as it is in but very few situations that the former can be practised without injury to the arable or hay lands. By proper attention in this way the more poor pasture grounds might soon, and at little expense, be brought into a good state of pasturage; which could seldom or ever be the case without some such means of increasing their productiveness.

The writer of the Report of Salop cattle, that upon upland meadows, the manure from the chaff at the barn-doors mixed with foil, ashes, and shovellings, is very properly applied. But that the farmer's pastures are more neglected than any other part of his land, as very little manure is ever put upon them; they consider it as more wanted elsewhere. All grafs lands at a distance from towns are, in general, too much neglected. The barn-door muck and ashes, mixed with the shovellings of roads and clearings of ditches and ponds, should be more frequently applied to such as cannot be watered. Ponds may be frequently made on the sides of roads and river-cours, to catch the fine foils that are washed down by the rains in winter: this should form part of a compait. It is added that, for the hay fields, which are shut up for a crop at Candlemas, or before; the best time of manuring them is immediately after the hay harvest. Some farmers do this work in winter, when the ground is sufficiently hardened by the severity of continued frost. For the purpose of manuring, the diligent husbandman provides a large compait mixen. With this view he cleans his ponds, he fecours his ditches, he hovels his fold, he collects his ashes, he sends to the lime-kiln, he provides fern, weeds, flexible, &c; in a word, he amasses all materials that will increase the bulk, and promote the fermentation, of a general dunghill. Melioration of soil is best obtained by an unremitting attention to this business of manuring. Hereby the quantity of grafs is greatly increased, and the quality of it much improved. Two tons of hay per acre is produced instead of one, and trefoil and white clover flourish and abound instead of mofs and rufhes. And for the improvement of pastures as well as meadow-lands, it is advised to suffer no weeds to seed, nor mole or ant-hills to continue; the land to be either mowed or grazed bare once in every year. Such as is mowed should be manured in the autumn of every second year with dung or compost, containing of dung and earth or mud, at the rate of about ten cubic yards to the acre. Close attention should be paid to examining the streams of water, by the assistance of the spirit level, for generally the water from the ummits will be found to cover much more land than is expected; and where it takes its course through several properties, it may be agreed to be used to the mutual benefit of the owners, by flippulating the times for each to use it, in due proportion to the quantity they respectively have suitable to that purpose. He knows of no improvement upon grafs land (after being drained when necessary) greater than this, though but little attended to in comparison of the large tracts that may be improved. See After-grass and Meadow.

Pasture Lands, Stocking of, the art of eating them down with the greatest economy and advantage by one or more farts of live flock. This is a point of management in grafs husbandry that has hitherto been but little attended to by farmers in general. It is obvious, however, that a great deal must depend upon its being judiciously performed, both in respect to the improvement of the flock, and the lathing of the grafs, as, under some circumstances, much more waste will be incurred than under others. A practical writer has observed, that the most proper period for turning the flock into the pastures in the spring season has been a matter of dispute among those employed in the management of grafs lands; some contending, that it should be done early, before the natural grafs has rifen to too great a bite, while others maintain the contrary opinion. And that there are probably inconveniences attending each of these extremes, as in the first the flock, especially when the fattening kind, may sustain injury from the want of a sufficient bite to permit the animals to fill themselves in an expeditious manner; and in the latter, there may not only be much waste by the flock not being capable of keeping it under, but great loss and inconvenience from its running up in tufts to feed, and by that means rendering the pastures patchy and unevenly fed down, by which the extent of real pasturage is lessened. That it has been also observed by Mr. Marshall, in his Rural Economy of Yorkshire, that by turning the flock upon the pastures when there is a full bite, the better farts of grafses are only consumed, the more coarse herbage being rejected and let run to seed, by which the lands are greatly injured at the time as well as in future; while, on the contrary, if the flock be allowed to enter during the time such coarse plants are in their more tender early growth, and before the pasture is covered with better herbage, the whole of the other plants will be fed down in a regular manner with the grafs. And that the want of a full bite on the first turning out of the first flock is of advantage to the animals, as they become more gradually accustomed to the change from dry food to succulent herbage. And it is supposed that fattening flock only
only require a full bite on being at first put upon the pasture. The first of these writers further states, that in answer to the objection that has been made, that early turning upon pastures exposes them more to the effects of drought in the spring months, it is said, that it is in a great measure ill founded, since cattle milk and thrive well in such casks. It is not, Mr. Marshall remarks, the length of grass, but the quantity of nourishment which it contains, that makes cattle pay for their pasturing. And it is not sup-posed improbable, but that the richness of the herbage may in some degree depend on the fun or heat of the seafon. Facts and observations are however here much wanted, as little, till within these few years, has been attempted in respect to the most advantageous system of feeding down pastures. The former of the writers, whom we have just mentioned, has observed, that as the flate of the grasfs, which is the most favourable to the feeding of the flock, and their expeditious filling themselves and taking their reft, as well as that of their wailing the leafy foble proportion of the food, would feem to be that of a middle degree of growth; it is not improbable, but that that may be the most proper and advantageous period for breaking the pastures; the exact time of which must obviously be regulated by the nature of the foil, the fimulation of the land, and the state of the seafon, as well as the circumstances of the farmer; but that from the end of March to the latter end of April, or beginning of the following month, according to the forwardness of the feafon, may be the most advantageous in the southern districts, while in fome of the north it may be deferred a week longer or more with propriety and advantage in many cafes.

In regard to the general eating down of pastures lands, there is much difference of opinion, some advising that it should be done in as clofe a manner as poifible, others, that this should never be the cafe. It would feem, however, that the clofenefs or degree of feeding that is the moft proper should be directed by the nature of the grasfs and the time at which it is performed, as where the herbage is of the coarfer kind and confumed in the autumnal feafon, it may be done much more clofeby than in the contrary circumstances, as fuch forts of grasfs muft always be improved by fuch clofe feeding, and no injury can be foultained at fuch feafons from the roots of the grasfs being left too much exposed, which would be the cafe in the latter spring or early summer months, from the continually increasing heat at fuch periods. The advice, that has been given by an intelligent observer on this fubjedt, may in general be adopted with propriety, which is, to be cautious not to overlook, as by that means great lots may be foultained, as land when fed too bare is apt to burn in the fummer and to be chilled in the winter. Besides, the necks of the roots are fo injued by very clofe biting, that they do not afford to quick or free a spring or growth to the feceffion of blade as there would otherwife be. But, on the other hand, it is not recommended to leave a long bite of grasfs on the land; a middle degree will fuit ali lands the bett, and afford the moft benefit to the persons who occupy them. This advice of Mr. Kent's deferves to be well attended to, as being founded in real practice.

It has been further flated, that by the too thin ftocking of pastures, though lots may be foultained in their not supporting the proper number of animals, as well as from the injury which is done by the grasfs plants running to much up to tents, the broken grasfs in fuch cafes, can be mown when in fufficient proportion for hay; but the difadventages of over-ftocking are scarcely capable of being repaired, according to Mr. Marshall, as besides the lands being often ex-poled to much injury by the crowns of the plants being so clofeby pared down, especially in the finer kinds of grasfs, the cattle, from fuffering a check in their feeding, are long in regaining their former thriving difpofition; that, of course, almost the whole of the produce of pasture lands may, in this way, be often thrown away, and that it is an error that young farmers are extremely liable to fall into. It is therefore ob-vious that the medium degree of ftocking, which has been advised above, is, in general, to be carefully adopted from the experience obtained upon the land; in the procuring of which it is bett to begin by an under proportion of flock, that the effect may be the better perceived.

Among graziers there has been a considerable difference of opinion in refpeét to the manner of ftocking, or feeding down such lands; some contending that it should be done with only one fort of flock, while others suppose that they should be mixed, in order to produce the beft effects both on the lands and flock; Mr. Kent has suppoled that the moft various the kinds of cattle are that are fed upon the pastures at different times, the better. But it has not been fown, the author of Practical Agriculture says, on what principle this advantage depends. If the different modes of feeding in the different animals be attended to, and minutely examined, it will be found that though some forts may consume grasfs when in a more luxuriant state of growth than others, they are all fondcl of pafluring on that which is the moft sweet and tender. This is rendered extremely obvious by the obser-vations of an attentive inquirer, who has found, that although hordes appear partial to particular patches of sward, he has never been able to discover any peculiarity in the fall or the herbage of fuch barely eaten spots. It has been suppoled that they have been fed down by fuch animals at firt in fo clofe a manner merely by accident, but that afterwards they are kept in fuch a clofe state of feeding from their peculiar fweetnefs depending on the peculiar fhortnefs of the herbage. It would, however, feem more probable, from the circumstance of the animals being almost wholly directed by the tale in the choice of their food, that the sweet or tender nature of the herbage in thefe parts first induced them to feed upon and consume them in fo clofe a manner, as well as the continuing the clofe eating them down afterwards.

The fame thing is obferved to happen in the vicinity of preferred covers, with hares and rabbits, from their keeping spots of barley or other grain crops clofeby fed down. And sheep are well known to ramble over the whole of the pastures in order to nibble and pick out the moft sweet and delicate morfels. The feeding of neat cattle is, perhaps, fets particular and delicate in this refpeét; but where not forced by hunger they moftly appear to fix upon fuch parts of the land as poifefs the moft sweet and palatable herbage, rejecting the coarfer parts where it is lefs tender and agreeable. It is contended that, if the conclusion be therefore well founded, that flock of all forts prefer the beft, sweetefl, and moft tender herbage, it is evident that no mixture of animals can infuere the even and regular feeding down of pastures, as they will, in fome degree, be all attracted by the sweetefl and moft tender parts, and those of the more coarfe four kinds be in confegnence almost wholly rejected.

An agricultur of great experience and nice obervation, the Rev. Mr. Clofe, has remar ked, that in pastures, flock naturally pick the moft palatable grasfs firt, leaving the others to run up to beets; and though it is admitted that one fort may have a preference for one species of grasf, and another for another, there is no mixing the animals in such a manner as to prevent this circumstance from taking place. It is wholly impracticable to proportion each kind of flock in such a manner to the species of grasfs that may be moft agree-
able to it, as to prevent the fearciscy of one fort and the abundance of the other. It is of course obvious, that there are therefore not only difficulties in the regular feeding down of pastures, from the cattle being more fond of some forts of herbage than others, but also, from the inhability of the grazer to proportion them in a way that may fully answer the purpose which he has in view. These observations, at the same time that they showed the difficility of the husband, convince us of the advantage and importance of keeping pasturcl lands regularly and evenly fed, which is perhaps only to be fully understood by one fort of flock properly succeeding another, till the want of the finer sorts of herbage obliges them to feed upon those that are of a more coarse nature. In this, as well as other views, the fattening flock should be first turned into the lands, and kept upon them as long as they continue to improve in a proper manner; these may then be succeeded by the other sorts of cattle that require to be brought into condition, and the more yound store flock may consume the remainder of the grs, according to the intentions of the farmer. That great utility and advantage may be derived from often shifting the cattle, by having recourse to a head flock and proper followers, there can be little doubt. The few writers that have touched upon the subject of grass husbandry, have, in general, indeed, recommended the practice as highly beneficial both in respect to the pasture and the flock. And Mr. Marshall, in his Rural Economy of Yorkshire, speaks of this being a defect in the grass land management of that district. The correct grass farmer should, therefore, be more attentive to this part of his management than is commonly the case, taking care that the changes of his flock are made in a reasonable and judicious manner, and without either the flock or the land suffering any injury from it.

It is suggested that this is probably a practice from which greater utility may be derived than that of permitting many different sorts of flock upon the ground at the same time, as, besides their not answering the intention of feeding the pastures down with more regularity and evenness, they are inconvenient and disadvantageous in other respects. For when the pastures are fed down with a mixed flock, the animal's demand thrive or fatten so well as where the contrary is the case. They are too much driven about and disturbed by the different kinds feeding each other, especially where horses and neat cattle are put together. A mixed flock is also improper in another point of view; many sorts of animals feed closer and more expeditiously than others; of course, when there happens to be any fearciscy of feed, some of the kinds may be greatly injured from the want of proper support. The horse, like the sheep, feeds closer and quick, while the contrary is the case with the cow; it would of course seem improper to mix horses with neat cattle in the pasturing of grass lands, though the practice has been prevalent in many places. It has indeed been observed, that sheep and horses may feed and thrive het together, both from the similarity of their manner of eating and that of the former consuming the rich luxuriant herbage which springs in confluence of the manure dropped in the seafon, while the latter prefer the lefs vigorous, but the more clean grs. It is a practice, however, that has sometimes been found useful to mix sheep with neat cattle. The notion of deriving advantages from the mixing of flock, from the circumstances of some forts having a greater dislike to feed near their own dung, and lefs towards that of others, is probably not founded on just observation, as a lambs have a fixed averc for both their own and that of other animals, and none of them will feed near either till compelled by the fearciscy of food. This averc for does not perhaps depend wholly on the dung, but it is in some measure avoided in consequence of the grs becoming rank and coarse about such places, and of course more four and unpalatable to the animals.

But very little attention has, till lately, been bellowed upon the manner of feeding down grs lands, the hairs being molly left to chance, accident, or the caprice of the farmer. It is, however, obviously a matter of vital importance, not only in so far as it respects the economy of the pastures, but the success and proper progress of the flock that confines it to by improper management that proportion may be wathfully eaten down in a short space of time without the flock being brought more forward, that under a better system would last out longer with a greater increafe or progres in the animals that feed upon it. And that, as it is a matter of consequence to keep pastures and grazing-grounds as even as possible, a proportion of flock fitted to produce this purpose should always be put upon the lands. On the rich and more fertile kinds where the grs springs quick and in great abundance, more flock will be necessary to effect this purpose than where the contrary is the case. It has been found, on the marshi lands in Lincolnshire, that where the most grs is left in the autumn the herbage is the coarser and the world in the succeeding year. In the extensive feeding tract of Romney Marth, the close feeding system is also found to answer in the most perfect manner. These facts shew the necessity of hard flocking on the richer deperitions of land. In other parts of the field of the districts, on turning upon a full bite in the spring, they flock in such a manner as to prevent the gran from becoming coarser by running up to them. The necessity of keeping over the rough tuffy parts by the fythe is thus avoided, except in very wet seasons. And it is a practical remark of a cautious observer, on describing a field not sufficiently stocked, that on the marsh just mentioned, the grazing farmers would be ruined if they suffered too much gran on their lands. It seems to be a bad practice to allow the grs in pastures to advance to such a state as to require to be fweet over by the fythe, though it may be right to do it under such circumstances, in order to prevent the greater injury that might otherwise be produced. It appears extremely probable, that by permitting the gran plants to run up to feed-deems, that the pastures may suffer vast injury, not only by the exhaustion of the fliet that takes place during the efforts of the plants to form and fill the feeds, but in consequence of their whole vegetative powers being directcd to that purpose, from their feeding forth few or no leaves. This is extremely evident in all the coarser grs, and fully explains the utility of keeping them closely fed down, as by fuch means a more abundant grsly herbage is provided for the support of flock. There are various observations that seem to support this opinion. Thus it has been recommended to flock pasture lands in such a manner as will keep the gran in a young succulent late; as in this way there is a benefit, by the whole of the produce being consumed, and at the same time the items of the gran plants are prevented from feeding, which exhausts the roots and the lands; the fii of coarse preferred in a better state of fertility, more shoots are thrown out, the fward is rendered more close, and a more constant verdure kept up.

Therefore the true principle of grazing, in the opinion of this writer, is to eat all, and particularly at those seasons when vegetation is rapid, that it may not weaken the turf and foil, but by keeping the grs in a young state, have the shoots more vigorous.

And it is practically remarked, that, as for the purpose of feeding the larger sorts of neat cattle, it is necessary for the
the grass to have grown to a pretty full bite before they are turned in, and of course numerous feed-frooms to be formed; it seems not improbable, but that the superior benefit of feeding with sheep may depend upon the circumstance of their eating more closely, and thereby preventing such effects from taking place. That of course, in the stocking of pasture grounds, the growth of the grass should be particularly attended to, and the proportion of stock adapted to it; care being always taken to have a full proportion during the summer months, from May to August; a proper reserve being then made for the winter season; as Mr. Price has well suggested, in this business, that the farmer should be as careful as possible to neither over or under-stock, as by either means he must sustain loss and inconvenience, in the different respects that have been already noticed.

But on this interesting point of management there is another matter, upon which farmers have differed very considerably in their opinions; each contending, as in many other cases, for the propriety of their practice, on the ground of experience. It is that of giving the flock, of whatever sort it may be, the whole range of the lands, however extensive, at once; or having them divided, so as to let it have the grass at different times, in a fresh, unbroken, and untrampled state. This is a question, which, from its involved nature, and from few experiments having been made directly in respect to it, that is not readily decided; yet much in the economy of feeding down grass land depends upon it. The observations of Mr. Young may perhaps throw some light upon it. When cattle, whether cows, fattening beasts, or young flocks, are turned out to grass, it is requisite to consider the best method of feeding. There are two opinions on this point directly contrary to each other. First, it is alleged by one set of graziers, that, to let the grass be fed in comfort of ever so many acres, the cattle should have it all at once: if it is divided into eight or ten fields, the gates of all to be wet open, for the flock to feed where they like. Secondly, those of the other set advance, that large fields of fifty, eighty, or an hundred acres, should be divided, that the farmer may change his flock from one to the other, and give the grass fresh and fresh. And each of these parties assert, that they know themselves to be right from experience. But that is impossible: one must undoubtedly be wrong. Let us consider the point from reason: it is one that will never be decided fairly from experiment; for two pieces of grass, each of eighty or an hundred acres, contiguous and perfectly alike, are not to be met with in the king's dominions; and, if they were, two sets of flock, exactly similar, would not be found. The divisions into fields by hedges and ditches, for the purposes of draining and shelter, is not the inquiry, the comparison not being fair; as such divisions may be fed at once, by letting all the gates open, as well as one field. The inquiry is, whether the cattle will spoil the grass more in one way than in the other? and whether the grass will go as far in one as in the other, by fattening and feeding the beasts as well? The argument of giving the grass fresh and fresh appears to be rather vague; for it supposes that the cattle will not eat it fresh, if they have the whole range at once, which may be a mistake; they will not be seen in the evening where they were feeding in the morning, but vary their food in the manner most agreeable to themselves; and we may in general observe, that the fagacious animals, when left to their own conduct, manage such points better than we can for them. As to the treading and spilling, it is an equal objection to both methods; the legs of the beasts are not tied in small cloths, any more than in large ones. In cafe all the smaller pieces have not water, the objections to feeding them separate are much greater.

On the other hand, it must be admitted that there are disadvantages attending this way of pasturing; for a time the trampling may be greater, as cattle are disposed to beat a sort of march around the fields, on first turning in, and also on some kinds of disturbance. But the greater evil is that of disturbing a large herd, instead of a small one: this a dog may effect in one inclosure, unseen from others, and consequently the flock in them left without interruption; and, perhaps, a motive greater than this, its having been observed that, cattle, and sheep also, do better when well proportioned to their pasture, when divided into small lots rather than large ones.

Mr. Young here leaves the matter without any decision. There are, however, a variety of circumstances that would seem to shew the mode of feeding in divisions to have the superioriety over that of turning upon the whole at a time. There can be no doubt but that much greater waste of grass is made in turning upon the whole at once, especially if the full proportion of animals for the land be put in; as it must be well known to the practical farmer, that when grass has been once trampled upon, flock of all sorts reject or eat it with great reluctance. And is cow farming, where small numbers are often turned upon the land at one time, in order to procure the greatest possible abundance of milk for a short period, as is frequently the case near London, and other large towns, no one can have avoided observing the uncommon loss and destruction of food that is the consequence.

The writer has attended to many circumstances of this nature, in which he is convinced that the same proportion of flock might have been equally well kept for one-fourth of the time longer, by having the grass consumed by the same flock in suitable divisions.

It is stated by a writer in the third volume of the Farmer's Magazine, that in the management of pasturage, he would carry on a successive flock, and a series of pasture fields, so as to give three shifts. Thus, the fattening flock is to get the top of the pasture first broken upon. Before the pasture is eaten too bare, this flock is to be removed into a second field of fresh grass, and is to be followed on the first field by the keeping flock. Before the second field is too bare, the fatteners are to be removed into the third, and the keepers into the second. While these two flocks are employed in this shift, in eating the second and third fields, the firk field has time to get again into full herbage. It is certainly, he thinks, needful to enlarge on this course, as the principles and practice are both sufficiently obvious.

And in a late practical work it is noticed, that the experience of a writer, who has examined farms husbandry with much minuteness and attention in different districts, would seem also, in some measure, to favour the same conclusion, while it shews the benefit of one sort of flock following another; as he advises that, in all cases where fattening cattle or dairy cows constitute a part of the flock, and where soil, situation, and water will admit, every range of grazing lands should have three divisions; one for the head flock, as the cows and fattening animals; another for followers, such as the rearing or other lean flock; and a third for being preferred in order to freethen, for the reception of the principal flock. Besides, he is decidedly of opinion, that whether the ground may consist of one, two, or a greater number of divisions, not a weed should be suffered to seed, or a tuft of stale grass to stand on it; but once, at least, in the summer season, be levelled down by the scythe; as, by such means, weeds may be converted into nourishment, and

VOL. XXVI.
waste into after-grafs. But it has been seen above, that by proper flocking, there need not be any necessity for the operation of the leythe; as the practice of close feeding renders it unnecessary, and at the same time affords a superior advantage to the grazer.

The proportions of flock of different sorts, that can be properly supported on any given space of pasture ground, must vary considerably, according to the natural goodness of the soil, the properties of the graps, and the differences in the sizes of the animals. And there is likewise another circumstance which should be attended to, which is the length of time the land has been in the state of sward; as new layers are seldom capable of carrying so much flock on the acre as those of the older kinds. But it is also a point that ought to be attended to, that those layers should be offered as much as possible with feed.

Mr. Young advises, that, in the flocking of graps lands, the farmer should attend well to the proportion between his flock and the quantity of his feed. Let him remember, when he flocks his grounds, that he should be pretty nice in this proportion: for if he overflocks, his lots will be certain and great; and if he does not throw in as many cattle as he ought, then he will suffer in his profit.

The exact number of animals, whether of the cattle or other kinds, that may be grazed on the acre, is not easily ascertained, so as to avoid leading the farmer into error, as it will differ fo greatly in different situations and circumstances. Besides, it is unnecessary, as the proportion of different sorts of flock that may be admitted upon grazing lands, in different districts, has been shewn, in speaking of the manner of feeding or fattening animals at graps, in considering the practice of grazing. See Grazing.

Lands employed for the purpose of pasture are frequently occupied by flock during the autumn and winter, as well as the spring and summer months: it is, however, only those of the very dry kinds that can be turned upon in the winter season, especially by heavy cattle; and it is probably, in all cases, a much better practice to confine that sort of flock wholly to the fold-yards at such feasons, as by offering them to be turned upon the pastures, there must be a great loss in the waft of manure. And it has been found an advantageous practice by some, to shut up their pastures late in the autumn, according to the state of the graps, and other circumstances; eating them down as close and evenly as possible, previous to the flock being removed; and keeping them perfectly free, till they are wanted for ewes and lambs in the early part of the year, or for cattle at a later period, as when the first fhoots appear in the spring, which, from being intermixed with those of the autumn, are supposed to afford more nourishment for the support of the flock, than when either of them are eaten separately.

In the Agricultural Report of Perthshire, it is advised that, in fields that are patured by cattle, care should be taken that all such plants as are hurtful to flock be completely eradicated from them; as much injury is often done by them to the cattle, as well as the products which they afford. The plants most prejudicial in this way are those of the hemlock, henebane, nightshade, and yew kinds. It has been suggested, that while the graps is plentiful, there is not much danger of their feeding upon such plants; but when it becomes scarce, and they are confined, it is likely to take place, especially in the spring seasoan, when they are fond of devouring young shoots of almost any kind. And a writer in the Farmer's Magazine strongly advises the following practice, which he has uniformly followed himself, and is thoroughly sensible of its beneficial effects: it is regularly to cut down all weeds, that spring up in the fields, in spite of the flock, before they get into feed. This is by no means expensive, as two or three children are sufficient to keep down the weeds of a large pature farm. And it is an old and true proverb in husbandry, that "once feeding causes seven years' weeding."

It is indispensably necessary to attend to the circumstance of pastures being well supplied with water, as, without having this in some degree at command, it is impossible that the flock can thrive well, or answer in the most perfect manner in other views. Where they are not, therefore, supplied by brooks or streams running through them, it will be necessary to have recourse to the forming of ponds or pools for the purpose in the fields. And in situations where the natural depth of the clay is of considerable thickness, there is little difficulty in the constructing of such watering ponds, for as to be perfectly retentive or water-tight; but in loose porous soils, the basins is not executed without considerable care and attention, as well as much art. See Watering Ponds.

It is advised, in the Treatise on Landed Property, that in laying out perennial pasture lands, as those of grazing and cow grounds, attention should be particularly paid to the circumstance of water; and that wherever good water is naturally found, or can be brought conveniently by art, to that point the pasture grounds ought to tend, in order that they may have a due supply of so necessary an article to the pasturing of them with cattle.

The first improvement of upland pasture, before eating it down with flock, when not inclosed, is by fencing it in, and dividing it into small fields of four, five, six, eight, or ten acres each; planting timber trees in the hedge-rows, which will fence the graps from the dry pinching winds in March, which prevent it from growing in large, open, exposed lands; so that, if April proves a dry month, the land produces very little graps: whereas, in the sheltered fields, the graps begins to grow early in March, covers the ground, and prevents the fum from parching the roots, whereby it keeps growing, so as to afford a tolerable bite, if the spring shou'd prove dry. But, in fencing in the land, it must be observed not to make the inclosures too small, especially where the hedge-rows are planted with trees; because, when the trees are advanced to a considerable height, they spread over the land, and, where they are close, render the graps four, and in that way, instead of being of advantage, greatly injure the pasture. A second improvement of upland pasture is that of making the turf or sward good, where, either from the badness of the soil, or for want of proper care, the graps has been destroyed by ruffs, busses, or mole-hills. Where the surface of the land is rough, clayey, and cold, it may be best improved by paring it off, and burning it in the manner directed under that head, breaking it up, and then laying it down again to sward; but if it is hot sandy land, then chalk, lime, marle, or clay, are very proper manures to apply upon it, but this should be laid in pretty good quantities, otherwise it will be of little service to the land. Where the ground is over-run with coarse plants, as ruffs, &c. it will be a great advantage to it, to cut or grub them up towards the latter part of summer; and, after they are dried, to burn them, and spread the ashes over the ground just before the autumnal rains; at which time the surface of the land should be levelled, and fown with graps-feeds, which will come up in a short time, and make good graps the following spring. So also, when the land is full of ant-hills, these should be pared off as above, and either burnt for the ashes, or spread immediately on the ground, when
when they are pared off, observing to bow the bare patches with grass-feeds in the autumn. See Ant-Hill.

And where the land has been thus managed, it will be of great service to roll the turf, in the months of February and March, with an heavy wooden roller, in moist weather, that the roll may make an impression; this will render the surface level, and cause the turf to thicken, so as to have what the people usually term a good bottom. The grass will likewise be sweeter, and bad weeds be destroyed.

Another improvement of these pastures is, by judicious feeding as above. Where this is not practised, the land must be manured at least every third year; but where a farmer has much arable land in his possession, he will not care to part with his manure to the tiller. Therefore every farmer should endeavour to proportion his pastures to his arable land, especially where manure is scarce; otherwise he will soon find his error; as the pasture is the foundation of all the profit which may arise from the arable land.

But whenever such upland pastures are to be mended by manure, there should be a regard had to the nature of the soil, and a proper fort of manure applied; as for instance, all hot sandy lands should have a cold manure; neat's dung, swine's dung, and earthy composts are very proper for such lands; but for cold lands, horse-dung, ashes, and other warm manures are more proper. And when these are applied, it should be done in autumn, before the rains have soaked the ground, and rendered it too soft to cart on; and it should be carefully spread, breaking all the clods as small as possible, and then harrowed with bulches, to let it down to the roots of the grasses. When the manure is laid on at this season, the rains in winter will wash down the valuable parts, so that the following spring the grasses will receive the advantage of it.

And there should also be great care had to the destroying of weeds and coarse plants in pastures every spring and autumn as above; for where this is not practised, they ripen their seeds, which spread over the ground, and fill it so as soon to overpower the grasses, and destroy them. Besides, it is very difficult to root them out, after they have gotten such possession. But in these pastures, the grasses seldom degenerate if the land is tolerably good; whereas in the low pastures, which are overflowed in winter, in a few years it often turns to a harsh rushy nature.

Perhaps there is no part of husbandry, which, till of late, farmers were, in general, more ignorant of, than that of the management of pastures; most of them supposed, that when old pastures were ploughed up, they could never be brought to have a good fward again; of course their common method of managing their land, after ploughing, was to fallow, with their crops of barley, some grass-feeds, as they call them; that is, either red clover, which they intended to stand two years after the corn was taken off the ground, or rye-grasses mixed with trefoil; but as most of these are but biennial plants, whose roots decay soon after their seeds are perfected; so to the ground, having no crop upon it, was again ploughed for corn; and this was the confant round which the lands were employed in by most farmers: they had not any notion of laying down their lands to grass for any longer continuance. Modern husbandry has, however, shewn that it is possible to lay down land, which has been in tillage, with grasses, in such a manner, as that the sward shall be as good, if not better than any natural grasses, and of as long duration. See Laying down to Grasfs.

In the improvement of wet pastures, it has been suggested that the first thing to be done is, to make large deep ditches round every field, and if the fields are large, to divide them into smaller, of five, six, or seven acres each, by new ditches; nothing is attended with a more sudden improve-

ment of all the ground near the borders of the fields than good ditches. They are generally made fix feet deep perpendicularly, seven feet wide at top, and three at bottom. They should be made in such a manner that no water can remain in them, but have a descent from one to another to carry it quickly off. As soon as the ditching is done, the next work is to land-drain the whole field in such a manner that every part of them may be laid dry. If there is the least fall in any part, or any place more wet than another, the drains should be cut through them. If the surface be exactly level, the depth of the drain should vary, so that the water may every where have a defect. These drains are made, in general, thirty-two inches deep, twenty inches wide at the top, and four wide at the bottom. They are filled eight inches deep with either stones or wood; but the former are the most effectual and lasting to those who are not delirous of having the difference of expense. However, wood answer very well in many cases. See Draining of Land, and Water, Removing of, from Land.

The prodigious advantage of these drains appears the very first year, especially if the season proves wet; the grasses being fresh, vigorous, and sweet. And the materials taken out of the ditches should, after being well mixed with dung, or other manure, be spread evenly over the surface of the ground. The expense of this sort of improvement will vary greatly according to the nature of the land, the situation, and other circumstances.

PASTUS, the procurement of provision, which the king's or lord's tenants are bound to make for them at certain days or seasons, or as often as they make a progress to their lands.

This, in many places, has been converted into a pecuniary fee, as in the procurations of the clergy.

PASTY, in Cookery, a work of paflry; being a preparation of some proper meat, as beef, venison, lamb, or the like, well boned, beaten up to a pulp, and highly seasoned; put up in a paftie, and then baked in an oven. They also make veal pasties, umbel pasties, kidney pasties, marron pasties, &c.

PASZBERG, or Pas, in Geography, a town of Ilriia; 25 miles S.S.E. of Trieste.

PATA, a town on the N. coast of the island of Lucon. N. lat. 18° 15'. E. long. 121° 20'.—Alfo, a small island in the Sooolo Archipelaigo. N. lat. 5° 45'. E. long. 121° 10'.

PATA, in Ornithology, the name by which the Portuguese in Brazil call a large and very beautiful American duck, known among others by its Brazilian name, Ipsiquita.

PATABEA, in Botany, a plant described and figured by Aublet, the derivation of whose name we are unable to trace. Jussieu considers the genus as allied to Lonicera tuba-lina of Linneus. Aubl. Guian. t. 1. fig. 43. Juff. 208. Lamarck Dict. v. 5. 52. Illust. t. 65. Chats and Order, Tetrandria Monogyna. Nat. Ord. Rubiaceae, Juss.

Gen. Ch. Cal. Perianth inferior, of one leaf, turbinate, with four, acute, little teeth. Cor. of one petal; tube oblong, inferrted into the disc above the germen; limb cleft into four, oblong, acute lobes. Stam. Filaments four, short, inserted into the tube at its throat; anthers oblong, two-celled. Pif!. Germen inferior, firmly united to the bottom of the calyx, crenated by the disc; fyle oblong, cloven; filaments two, obtuse. Peric. and seeds unknown.

Eff. Ch. Calyx four-toothed. Flowers in little heads, which are scaly on the outside. Corolla tubular, four-cleft. Anthers nearly fertile.

1. P. Coecina. Aubl. Guian. t. 43. "Native of woods and forests in Guiana, particularly at Orapo, where it flowers
in the month of June. The stem of this shrub is four or five feet in height, furnished with numerous branches even to its summit, scattered in all directions; the smaller ones knobbled and opposite. Leaves opposite, stalked, oval, smooth, pointed, paler beneath. Stipulae two, oblong, acute, at the base of each footstalk. Flowers red, in a terminal head, separated from each other by little scales.

PATACA, in Commerce, coins of Brail, of 600 and 640 rees' value, which are current only in that country, and whose intrinsic value is 10 per cent. less than that of the Portuguese coins. The Spanish patacas, or dollars, are reckoned in Lisbon at 830 rees, more or less. The aley of the old pataca of Brail, of 640 rees, is worse than the English standard; being 2 dwt.; its weight is 12 dwt. 42 gr.; its content in pure silver grains 268.3; and its flering value 31.15d. The pataca of 600 rees (1755) is 4 dwt. worse than the English standard; its weight 1 dwt. 72 gr.; its content in pure silver grains 246.4; and its flering value 21.10d.

The aley of the pataca of 640 rees (1768) is 4 dwt. worse than the English standard; its weight 1 dwt. 92 gr.; its content in pure silver grains 247.8; and its flering value 21.10d. The aley of the pataca of 640 rees (1801) is 7 dwt. worse than the English standard; its weight 1 dwt. 92 gr.; its content 262.2; and its flering value 32.04d: the half, quarter, &c. pieces are in proportion. The impression on the pataca is the arms of Portugal, with 640 on the side, and the date near the top; legend, the name and title of the reigning sovereign, with the addition of N.B. Brgisia dominus or domini, lord or lady of Brail; reverse, an armillary sphere, placed on a crores; legend, SUBQ. SIGN. NATA STABIL.; i.e. SUBQUE SIGNO NATA STABIL.; born under a steady sign. There is a pataca of 600 rees bearing the letter L, with a crown over it, 600 on the side, and the date at the bottom; reverse, an armillary sphere, with an R in the centre.

PATACA is also the name given to the German dollars in Egypt; which formerly passed for 85 medini, but have been raised to 90 medini. In making bargains, however, where patacas are to be received in payment, it is necessary previously to settle the value of the coin.

Contrasts also at Grand Cairo are made in funducli and Mahbub fequins. The funducli are reckoned at 146 medini; and three Mahbubs are equal to four patacas, so that the Mahbub is worth 120 medini.

PATACA Chica and PATACA Gourda, two monies of account at Algiers, the former being eight temini or 232 aspers. The pataca chica is worth 11d. flering: the pataca gourda, or piaifere, contains three patacas chicas, a Sultanian paffes for 83 patacas chicas, more or less, a fequin for 10, and a Portugalone dobraon, or Joanne, of 640 rees, for 36. A Spanish dollar is worth from 42 to 44 patacas chicas.

PATTACK, in Geography, a town of Hindostan, in Palna. It contains 4,000 souls.

PATACON, or PATAGON, in Commerce, a silver coin in Switzerland, and also at Liege in Germany. The patacon of Bern consists of 3 livres 6 sous, or 33 batzes; the livre, according to the Tariff of 1755, being equal to 11 21/2 d. flering.

The patacon, or ecu, of Geneva, which is sometimes used in accounts, is a real coin, worth 3 livres, or 10½ florins.

The patacon, or crown of Bern (and the half in proportion) appears by the aley to be 7 dwt. worse than the English standard; 18 dwt. 22 gr. in weight; its content in pure silver 411.5; and in value 41. 9½d. flering. The old patacon, or ecu, of Brail, is 14 dwt. worse than the English standard; 18 dwt. 4 gr. in weight; in content of pure silver 377.9; and in value 41. 4½d. flering. The patacon, or ecu, of 1795 (the double and half patagons, and rix-dollars in proportion) is 10 oz. 2½ dwt. worse than the English standard; in weight 16 dwt. 14 gr.; in content of pure silver 529.3; and in value 31. 16d. flering. The patacon of Geneva is 1 oz. worse than the English standard; in weight 17 dwt. 9 gr.; in content of pure silver 551; and in value 41. 1d. flering.

The account of account at Liege is 4 florins, 8 ecusin or 80 florins. The patacon is also a silver coin of 4½ current florins, or 8½ ecusins. The patacon weighs 429.5 English grains, and is 10 oz. 8½ dwt. fine; it is therefore worth 43. 4½d. flering; but the patacon of account is worth only 43. 2½d. the ecu weighs 7½ English grains, and is 7 oz. 5 dwt. fine. A deterioration of the coins took place about the year 1792, as the patacon then coined is found to weigh only 423 grains, and to be 10 oz. 5 dwt. fine, which reduces its value to 43. 3½d: since that period there has been no coinage at Liege, the city and its territory having been shortly after united to France, and the new French monies and coins introduced there.

The old patagon of Liege is 14 dwt.; worse than the English standard; in weight 17 dwt. 205 gr.; and in value 43. 4½d. flering. The patagon of 1792 is 17 dwt.; worse than the English standard; in weight 17 dwt. 15 gr.; in content of pure silver 562.3; and in value 43. 2½d. flering.

The impression on the patagon of Basil is a view of the city, over which is the name BASHLIE: retaive, a griffin supporting the arms of the city; legend, DOMINE CONSERVAT ANIMOS IN PACE. But the new ecus of 1795, &c. bear the arms of the city, with a hat and feathers, and the legend, REPUBLICA BASILIENSI; and on the reverse, a wreath of oak, inclining the legend as on the ducat. The impression on the patagon of Bern is a man recling on his sword, legend, DEUS PROVIDENS: reverse, arms of the city; legend, REPUBLICA BERCHNIENSIS. The old patagon or ecu of Geneva, has upon it a two-headed eagle crowned; legend, POST TENEORAS LUX; reverse, arms of Geneva, and over them a sun, with the letters I. H. S. in the centre; legend, REPUBLICA GENEVE. The ecus of 1794 bears the head of a woman with a mural crown, legend, REPUBLIQUE GENEVOISE, and under it EGALITÉ, LIBERTÉ, INDEPENDENCE; reverse, two ears of corn, and between them the words PRIX DU TRAVAIL, L'AN III. DE L'ÉGALITÉ; legend, APRES LES TENEURES LA LUMIÈRE. But the ecus coined since that period have a sun with the letters I. H. S. in the centre; the legend, POST TENEORAS LUX, WITH XII FLORINS, IN SOLIS; reverse, the arms of Geneva encircled by a wreath of oak; legend, GENEVE REPUBLIQUE, L'AN V. DE L'ÉGALITÉ. The half ecus bears the same impreisions, except that it is marked within the fun VI FLORIN. IV S. VIT. d.

PATADE, in Geography, a town of Hindostan, in the circar of Aurungabad; 30 miles N. of Darroo.

PATACCI, or PATAIL, in Mythology, images of certain gods carried by the Phoenicians on the prows, or, as others say, on the flers, of their galleys.

Herodotus, lib. iv. calls them παλανι. The word is Phoenician, and derived from p goal, i.e. titulus. (See Bocchart's Chanaa, lib. ii. cap. 5.) But Scaliger does not agree. He derives the name from the Hebrew word patach, insculpere, to engrave; and Bocchard from patach, confidente, to trull in; neither of which etymologies agrees to the use which the Phoenicians, and after them the Greeks, made of the gods pataci. Morin derives it from παλανι, monkey, this animal having been an object of worship among the Egyptians, and hence might have been honoured by their neighbours.
Mr. Elfiner has observed, that Herodotus does not call the _paitac_ gods; but that they obtained this dignity from the liberality of Hefychius and Sididas, and other ancient lexicographers, who placed them at the feet of ships, whereas Herodotus placed them at the prow. This ancient historian intimates that they represented little pigmies, and that they were so small that they provoked the scorn of Canebyes, when he entered into the temple of Vulcan in Egypt.

Scniger, Bochart, and Seldan, have taken some pains about this subject.

Mr. Morin has also given us a learned dissertation on this head, in the Memores de l’Acad., des Inscript. & Belles Lettres, tom. i. but Mr. Elfiner thinks it defective in point of evidence.

**PATAGOA, in Geography, the river of Brazil, which runs into the sea near Rio Janeiro.**

**PATAGONIA, or as it is called by some geographers, “The Magellanic Lands,” and by others “Thuehua,” a country of South America, bounded on the N. by the viceroyalty of La Plata or Buenos Ayres, on the E. by the Atlantic ocean, on the S. by the Straits of Magellan or Magellans, and on the W. by the South Pacific ocean; extending from about 64° 30' to 74° 30' W. long., and from about 38° to 54° S. lat. The boundaries of this country, however, are not accurately ascertained, and its figure is very irregular. This country was first discovered by Magellan in the year 1519, (see Straits of Magellan); but his account of it is defective and erroneous. The inhabitants have been represented by Dr. Robertson, as occupying that vall, but least known, region of America, which extends from the river De la Plata to the Straits of Magellan. Their proper faction, however, is in that part of the interior country which lies on the banks of the river Negro; but in the hunting season, they often rove as far as the Straits already mentioned, which separate Terra del Fuego from the main land. The first accounts of this people were brought to Europe by the companions of Magellan, who deferr’d them as a gigantic race, above eight feet high, and strong in proportion to their enormous size. Several navigators have, in the course of the last century, visited the country of the Patagonians; but, like their predecessors, they differ in their account of its inhabitants. Commodore Byron and his men, who entered the Straits in 1764, represent them to be of a gigantic stature, and to realize the tales of monsters in a human shape. One of them, who appeared to be a chief, had the skin of some wild beast thrown over his shoulders, and was painted so as to exhibit a hideous appearance: round one eye was a large circle of white, a circle of black surrounded the other, and the rest of his face was streaked with paint of different colours. Captain Byron did not misuse him; but judging of his stature by its proportion to his own, he concluded it could not be much less than seven feet. This was the general size of the men, and the women proportionably large. They were all painted and clothed nearly in the same manner: their teeth were as white as ivory, remarkably even and well set; but, except the skins, which they wore with the hair inwards, most of them were naked, some few only having upon their legs a kind of boot, with a short pointed flick fastened to each heel, which served as a spur. When they were prevailed upon to set down, they accepted a quantity of yellow and white beads, which were distributed among them, with pleasure. They did not appear to be wholly strangers to European ornaments; for one woman among them, of an enormous size, and having her face frightfully painted, had bracelets, either of brass, or very pale gold, upon her arms, and some beads of blue glass strung upon two plaits of her hair. These apparent giants had with them a great number of dogs, with which, it was supposed, they chased the wild animals which served them for food. Their horses, though not large, nor in good condition, seemed to be nimble, and well broken. Their bridles was a leather thong, with a bit of a small piece of wood, and their saddles resembled the pads used among the country people in England. The women rode astride, and both men and women without stirrups; and yet they galloped without fear over the spit on the shore, the stones of which were large, loose, and slippery. Such is the account given by Byron, in Hawkesworth’s Voyages, vol. i. Mr. C. Clarke, an officer of Byron’s ship, in a letter published in the Philosophical Transactions, vol. liii describes the Patagonians as of a copper colour, with long black hair, and says, that some of them were certainly nine feet, if they did not exceed this stature. They are stout and well made: the women, he says, were from seven and a half to eight feet, though there was hardly a man less than eight feet. It does not appear, however, that these people were actually measured. The country is represented as something hilly: the soil, in that part which lies off Port Defere, is sandy, producing nothing but a coarse harf graps. Captain Wallis, who visited this coast in 1766, measured those that appeared to be the tallest among them. One of these was fix feet seven inches high, several more were fix feet five inches, and fix feet six inches; but the stature of moit was from five feet ten inches to fix feet. Captain Carteret’s account agrees with that of captain Wallis. (See Philosophical Transactions, vol. lx.) These seem to have been the same people, whose size had been so much over-rated in the year 1764; for several of them had beads, and red baize, such as that which had been put on board captain Wallis’s ship, and which he naturally concluded they had got from captain Byron. In 1767 they were again measured by M. Bougainville, whose account agrees nearly with that of captain Wallis. To these testimonies we may here add another of great weight. In the year 1762, Don Bernardo Ibagnez de Echavarri accompanied the Marquis de Valdehrinos to Buenos Ayres, and refield there several years. He observes, that the southern extremity of America is inhabited, not by the fabulous Patagonians, who have been supposed to occupy this district, but by Indians of the same stature with Spaniards, among whom no one was seen that exceeded in height two varas and two or three inches, i.e. about 80 or 81.332 English inches, if Echavarri makes his computation according to the vara of Madrid. This agrees nearly with the measurement of captain Wallis. Mr. Falkner, who refield as a millenary forty-eight years in the southern parts of America, says, that “the Patagonians, or Puelches, are a large bodied people: but I never heard of that gigantic race which others have mentioned, though I have seen persons of all the different tribes of Southern Indians.” Captain Wallis describes them as being of a deep copper colour, like that of the Indians in North America, with straight hair as harsh as hog’s bristles, which was tied back with a cotton string: they are well made, robust, and bony, but their hands and feet are remarkably small. They were clothed with the skins of the guanaco, an animal resembling a deer, without horns, and having a hump on its back: these skins were fewed together in pieces about fix feet long and five feet wide, wrapped round the body, and fastened with a girdle, with the hairy side inwards: some of them had a square piece of cloth made of the downy hair of the same animal, through which a hole being cut for the head, the reef hung round them about as low
low as the knee. They also wore a kind of drawers, and buff-
kins, reaching from the mid-leg to the instep before, and be-
hind brought under the heel: the rest of the foot was without any
covering: round their eyes were the circles already men-
tioned, and they were painted on their arms, and on
other parts of the face. The eye-lids of all the young
women were painted black. They talked much, but their
language, a single word or two excepted, was unintelligible.
Every one had a muffle weapon, stuck into the girdle.
This weapon consisted of two round stones, covered with
leather, and weighing about a pound, which were fastened
to the ends of a string about eight feet long. This they
used as a fling, keeping one end in the hand, and whirling
the other round the head, till with the force it had ac-
quired, they discharged it upon the object. In the man-
gagement of this double-headed shot they are so expert,
as to be able to hit a mark not larger than a shilling, with
both the stones, at the distance of fifteen yards: it is not,
however, their custom to strike either the guanico or octir
with them, in the chase, but they discharge them so that
the cord comes against the legs of the octirnch, or two of
the legs of the guanico, and so twisted round them by the
force and swung of the balls, that the animal, being unable to run,
became an easy prey to the hunter. They eat their flesh
raw, and the painch of the octirnch without any preparation
besides turning it inside out and draining it. Each of these
people, both men and women, fays captain Wallis, had a
horse with a decent saddle, trurps, and bridle. The men
had wooden spurs, except one who had a large pair of such
as are worn in Spain, brafs trurps, and a Spanish fcymitar,
without a fceabbar: but notwithstanding these dilinitions,
hed not appear to have any authority over the rest: the
women had no spurs. Their horses, about fourteen hands
high, appeared to be of a Spanish breed. Although they had
no objection to familiar intercourse, manifested no intention
of mischief, and jumped into the English boats with alacrity
and joy, and when in them fungen several of their country
fongs; when on board they exprefl no curiosity or wonder
which the multiplicity of objects around them had a ten-
dency to excite: they partook of the ships provisions
without hesitation or scruple, but they would drink nothing
besides water. The animals on board, particularly the hogs
and sheep, and the Guinea hens and turkies, engaged their
attention, but they seemed not to find anything which they
would except the apparel; and only one of them, who
was an old man, alided for that. When the first volley was
fired by the marines in their exercife, they were struck with
altonishment and terror; the old man, in particular, threw
himself down upon the deck, pointed to the mufkets, and
then flirking his breaft with his hand, lay fome time mo-
tionlesfs, with his eyes flit; thus, as it was fpupofed, in-
tending to fhew that he was not unacquainted with fire-
arms, and their fatal effect. The rir fnifing the people
on board merry, and finding themselves unhurt, foon refumed
their cheerfulnes and good humour, and heard a fcond
and a third volley fired without much emotion: but the old
man continued proflrate upon the deck for some time, and
never recovered his fpirits till the fire was over. Although
they were pleafed with the beads and other trinkets which
were distributed among them, and feemed very defirous of
hatchets and bill-hooks, they did not give the lead intima-
tion that they would part with any provisions; therefore
no traffic was carried on between them and the English
navigators.

This country confihs, for the greateft part of it, of open
deferts and favannas, with a few willow trees on the rivers;
and seems to enjoy a temperate but rather cool climate.

But separated in the middle by the vaft mountains of the
Andes, one part of it, and also its inhabitants, differ
widely from the other. To the northward of La Plata
this part of South America is covered with wood and fored
with an inexhaustible fund of large timber: but to the
southward of that river the eye can fearely discover a
fingle tree or shrub fit for any mechanical purpose; but
even this feemingly barren country has fome good pafures,
and numerous droves of wild horned cattle, and every dilirch
abounds with hofes, which are fuppofed to have been
brought hither by the Spaniards.

It has been fuppofed, that the Patagonians, called also
Tehuelas, are defendants of the natives of the Canaries,
who were a tall people; and it is faid that they bury their
death on the eafhern fhores, as looking towards the country
of their ancestors. Bougainville fuppofes, that they lead
the life of Tartars. They are faid to ramble through the
immense plains of South America, being confantly on
horseback, purfuing the game or wild beafits with which
these plains abound, and drefling or covering themselves
with skins. They also refeemble the Tartars in another
repect, by piluggling the caravans and travellers.

In a country which lies E. of Bootan, it is faid there
are men of gigantic stature, being not less than eight feet high.
See Turner's Tibet, p. 156.

PAGATONULA, in Botany, altered by Limneus from
the original name PATAGONICA, belonng on it by Dil-
lienis, in his Hortus Elthamensis, v. 2. 324. t. 226. f. 293.
—It was fo called from being a native of Patagonia.

SUCH generic names however as are taken from countries being
very exceflional, it is fortunate that the prefent one,
has been abolished, the plant belonging to another genus.

Cordia.

PATAIA, or PTHAY, in Geography, a town of Hun-
gary; 7 miles N. of Colocza.

PATAK, a town of Hungary, on the Latorcez, in
which the Protestant have a college; 25 miles S.S.E. of
Cafehan.

PATAIA, a town of Sweden, in Tavalland; 45
miles N.N.E. of Jamfo.

PATA, one of the receptacles for inners, or hells
of the Hindoos; for a list of which, see Naraka.

The name pata does not, however, occur there. It means
rather the lower regions, a fort of purgatory perhaps, over
which the buthe prefides, who is, however, usually fyled king
of hell. (See Yama.) It is this word, probably, that
some European writers have altered to Padalos. As con-
fort to Yama, who is a form of Siva, Parvati aflumes the
name of Pata-adesi; which fee.

PATA-DAVI, in Mythology, a name of the Hindo
goddes Parvati, in her character of confort of Yama, re
gent of the lower, or infernal regions. In this character the
coresponds with Proferpine, or Hecate, and, like the Gre-
cian goddes, has a triple character; and is sometimes called
Tri-fakti-devi, and Tri-fakti-devi-kumari, meaning the god-
des with three poers, and the three-potent-virgin-god-
des. Thus the triple-virgin-goddes Diana is fo named as
a terrestrial deity, and Parvati is similarly named Bhu-
devi, goddes of the earth. Luna and Svardevi are fe-
vell the celestial goddes, and Pata-devi-corresponds with
Proferpine, in their fubterrene, or infernal delignations. See
further hereon under the articles Parvati and Yama.

PATANAM, in Geography, a town of Hindoothan, in
Maravar; 40 miles N.W. of Ramanadaporum.

PATANI, the capital of a kingdom of the fame name,
in the peninsula of Malacca; 250 miles N. of Malacca.
N. lat. 6° 58'. E. long. 10° 40'. See M dalacca.

PATA-
PATANJALI, in *Philosophy*, one of the systems or schools among the Hindoos. It corresponds, in many points, with that of the Sutras, and its promulgator Patanjali, with Zeno; but the commentators on the Hindoo systems have buried the facculene works of the founders in such a mass of illustration, as they term it, that their precise differences are not easily determinable. The system called Sankya is two-fold; one division was promulgated by *Kapila*, of which some notice is taken under that article, and the other by Patanjali. See *Philosophy of the Hindoos*, and *Sankya*.

PATAPA, in *Geography*, a town on the N. coast of the island of Samar. N. lat. 12° 40'. E. long. 125° 14'.

PATAPSCO, a river of America, in Maryland, which rises in York county, Pennsylvania, and pursuing a S. and S.E. course till it reaches Elkridge Landing, about eight miles S.W. of Baltimore, turns easterly over falls, and widens into a broad bay-like stream to its mouth, formed in Chesapeake bay by N. point, and Bodkin point on the S., the lat being in N. lat. 39° 8' 50". It is about 30 or 40 yards wide full before it communicates with the balon, on which floods the large commercial town of Baltimore. By the left diverge it was called Bolus river, from the red earth found near it, resembling bole armeniac. It is navigable for vessels drawing 18 feet water to Fell's point at Baltimore; but its navigation further is prevented by the falls a little above Elkridge Landing.

PATARD, or Patac, in *Commerce*, a copper coin in Flanders. Pataces are florins or gilders of 20 florins or florins, each of which was formerly subdivided into 16 pence, but for a long time they have been divided into 12 parts or deniers. Accounts were formerly kept at Dunkirk, as at Antwerp, in florins, patards, and pence. The following proportions subsisted among the old monies of Dunkirk: 1. Flemish florins = 7/3 livres Tournois = 20 florins = 120 patards = 150 sous = 240 pence or gros = 1800 deniers = 1080 florins. But of late years the new French system of francs and centimes has been adopted, and the new coins of France are also used at Dunkirk. At Liége, a patard, or florin, is reckoned at 14 sous, or 15 deniers; however, the present current coins are chiefly those of France.

PATARINS. See *Ali运营管理* and *Paulicians*.

PATARNE, in *Geography*, a town of France, in the department of the Sarthe, and chief place of a canton, in the district of Mamers. The place contains 717, and the canton 9941 inhabitants, on a territory of 175 kilometres, in 17 communes.

PATASPOUR, a town of Bengal; 28 miles S.S.E. of Midnapour. N. lat. 22° 34'. E. long. 87° 37'.

PATATE, a town or village of South America, in the audience of Quito, and jurisdiction of the alteno of Hamberts, situated between Riobamba and Latacunga. Patate is famous for its plenty of sugar-canes, and the fineness of its sugar.

PATAVINITY, Patavinitas, among *Critics*, a fault objected to Titus Livy, which he derived from his country Padua, by the ancients called Patavium. Afinius Pollio, as we are informed by Quintilian, taxed Livy with Patavinity. But what this Patavinity consisted in, the critics have been much puzzled to find out.

Morhof believes it to be a certain turn of expression, and some phratres peculiar to the Paduane. All we know for certain is, that it was a fault in the language of Livy, not in the sentiments or manners. In all probability it is one of those delicacies that are lost in a dead language.

Dan. Georg. Morhof has an express treatise, "De Patavinite Liviana," printed at Kiel in 1685, where he explains, very learnedly, the urbanity and peregrinity of the Latin tongue.

PATAVIRCA, in *Geography*, a town of Peru, in the jurisdiction of Santa, or Guarmi, containing of about 60 houses; and lying upon the road from Pata to Lima, 67 miles N. of that city. In its vicinith, at the distance of about three quarters of a league, and near the sea-coast, are the ruins of a palace of the Indian princes. S. lat. 10° 24'.

PATAVIUM, in *Ancient Geography*, a town of Italy, in Venetia. The honour of its foundation is ascribed to Antenor. It was situated in a country so fertile, that Constantine Palæodius is said to have declared, that throughout the East, he did not know a place so proper for the seat of the terrestrial paradise. Its citizens were distinguished at Rome more than those of other towns, as they had a right of suffrage in common with the Roman citizens themselves. It was taken and destroyed by Attila, about the year 490 or 492, and soon after re-established by Narce. It was taken by the Lombards in 601, and reduced to ashes; but Charlemagne restored its former luster. See *Pavia*.

We learn from Tacitus (Annal. 1. vii. c. 28.) that this city was accustomed to celebrate the antiquity of its origin, and the name of its founder, in annual games, said to have been instituted by that hero. Livy informs us (1. xii. 2.) that a Naumachia, exhibited annually on one of the rivers that water the town, perpetuated the memory of a signal victory obtained by the Pudians, long before their union with Rome, over a Lacedemonian fleet, commanded by Cleonymus. They are also said to have not unfrequently assisted the Romans, and contributed in no small degree to their viotories, particularly over the Gauls, the common enemy of both states, while an immense population furnished them with the means of giving effect to their measures, by sending powerful armies into the field. Padua afterwards submitted to the genius of Rome, but submitted with dignity, and was accordingly treated not as a conquered, but an allied republic. She was admitted to a participation not only of the franchise, but even of the riches of Rome, as she could count at one period 500 Roman knights among her citizens, and drew by her manufactures, from the emporium of the world, no small share of the tribute of the provinces. After having shared the glory of Rome, Padua partook of her disasters; like her she was plundered by Alaric and Attila; and, like her, half depopulated by the flight of her difmayed inhabitants, and obliged to bend under the yoke of a succedaneous of barbarian invaders. Padua was, after the expulsion of the Goths, subjected to the Lombards, the Franks, and the Germans. At length it shook off the yoke, and with its sister states, Verona, Vicenza, Ferrara, and Mantua, experienced the advantages and disadvantages of republicanism, occasionally blessed with the enjoyment of freedom, and occasionally, with all its forms, lingering under the rod of a powerful usurper. At length, in the 15th century, Padua united itself to the Venetian territory, and under the influence of its laws acknowledged the supreme authority of that republic. At a late period it suffered much by fire and sword, as well as by earthquakes and pestilence. Nevertheless, it is still a great, and in many respects a beautiful city, as its circumference is near seven miles, its population about 40,000 persons, and notwithstanding the general narrowness of its streets, many of its buildings, public and private, are truly magnificent. The abbey of St. Giunina deferves particular attention; it was planned by Palladio, and built by Andrea Riccio in the highest style of architecture. The piazza before it, called Prato della Valle, is perhaps one of the largest and noblest in Europe. The cathedral deferves
PAT

defers to be ranked in the class of eminent buildings; and
the church, called "Il Santo," from St. Antony of Padua,
is of Gothic architecture, and was enriched, before the late
French invasion, with a valuable treasury; the tomb of the
saint, however, still remains, adorned with fine marble, and
most exquisite sculpture. The town-hall, "Il Salone," is
remarkable for its magnitude, being 312 feet long, 108
broad, and 108 high, and contains a monument in honour of
Livy, with an ancient bust. In ancient times, Padua was
famous for its woollen manufactures, celebrated in prose by
Strabo, and in verse by Martial; it still retains much of its
reputation in this respect, its wool, and woollen articles,
being considered as the best in Italy. But the principal
glory of Padua arises from its literary pursuits, and an
ancient, and well directed propensity to literary science.
The university was founded about the 11th century, and its
foundation was to Padua the commencement of an era of
glory and prosperity. Students, amounting in number to
15,000, are said to have crowded its school's during ages.
Of 15,000 students, 6,000 only remain; though the lecturers
are men of zeal and abilities, the plan of studies, the result
of long and successful experience, and its libraries, collec-
tions and cabinets of every kind numerous and magnificent.
Its decline is owing to the establishment of similar institu-
tions in other countries, and to the general diffusion of the
means of knowledge. Besides the university, in which is an
agricultural lecture, encouraged by the allotment of 15 acres
of land for experiments, Padua has several academies, which
have been established at different times, and are supported
with spirit. Eutartes' Classical Tour through Italy, vol. 1.

PATAY, in Geography, a town of France, in the department
of the Loiret, and chief place of a canton, in the district of
Orleans; 12 miles N.N.W. of Orleans. The town contains
939, and the canton 6198 inhabitants, on a territory of 2253
kilometres, in 15 communes. This place is famous for the
defeat of the English by the French, under the conduct of
the celebrated Maid of Orleans, in the year 1429.

PATAZ. See CAXAMARQUILLA.

PATCHEPALIAM, a town of Hindooftan, in Coim-
betore; 13 miles N.N.E. of Coimbetore.

PATCHI. A river of Bootan, called by the Bootans
Jumta Chieu, or the junction of three rivers, viz. the Hatchieu,
the Tchintchieu, and the Patchiue.

PATCHWARY, a town of Bengal; 32 miles S. of
Rajenmal.

PATCOOM, a town of Bengal; 50 miles S.W. of Ro-
gonatpour. N. lat. 23° 3'. E. long. 87° 2'.

PATE, in Fortification, a kind of platform, like what
they call a horse-fence; not always regular, but generally
oval, encompassed only with a parapet, and having nothing
to flank it. It is usually erected in marly grounds, to
cover a gate of a town, or the like.

PATE, in Geography, a small island of France, in the river
Gironde, near Bave.

PATEABARRY, a town of Bengal; 20 miles S. of
Moorshedabad.

PATEAGUR, a town of Hindooftan, in the ciscar of
Sollepour; 35 miles N.W. of Sollepour.

PATEE, or Patee, a term, in Heraldry, for a crois,
small in the centre, and widening towards the extremes.
The field, fable, a crois patee, argent; by the name of Crois.

This form of a crois is also called forme.

It is also a term used by some to express a fort of irregular
line, differing from the indented, ingrafted, and all the other
regular and common lines, and called by some the dove-tail
line.

It is somewhat like the joint called by our joiners by this
last name, but it is not in general use, and is by some
reckoned among what the French call the claire.

PATEEBIA, in Geography, a town of Hindooftan, in
Benares; eight miles S. of Chunar.

PATEES, PATTY See Petty.

PATEGOW, in Geography, a town of Hindooftan, in
the ciscar of Hindoofta; eight miles S. of Baridah.

PATEL, in Biography, a French landscape; aint much
esteemed. The place of his birth, and the date of it, are
equally unknown. The execution of his picture is of an
eady, light, and agreeable character; and his general taste
of a pleasing nature; but he does not rank above the class
of artists merely agreeable.

PATEL, or PUTAIA, in Geography, a town of Thibet,
in the district of Laffa, where it is situated, upon a mountain,
the temple or palace of the grand Lama; five miles E. of
Laffa.

PATELLA, in Anatomy, the knee-pan, a small bone
situated in the tendon of the extensor muscles of the knee,
and occupying the front of the joint. See Extremities.

PATELLA, Fractures of. See Fracture.

PATELLA, Dislocations of. See Luxation.

PATELLA, the Lithot, in Natural History, a genus of
worms of the class and order Vermes Testacea, of which
there are about 250 species described. The animal is a
limax; the shell is univalve, subconic, shaped like a bafoon,
and without a spire. In all cafes the shells of this species
are attached to some hard body. Their summit is some-
times acute, sometimes obtuse, flattened, turned back or per-
forated. The rock, or other hard body to which they are
always found adhering, serves as a kind of second or under
shell to prevent them from injury; hence they have by some
naturalists, though erroneously, been classed among the bi-
valves. The shells have been analysed, and they are found
to consist chiefly of carbonate of lime. When exposed to
a red heat, they emit a smell like horn; and when disolved
in acids, a semi-liquid gelatious matter was left behind.
The various species, which are so numerous, are distingui-
shed by the peculiarities in their shells. The species are sepa-
rated into five sections.

Species.

Section A. Furnished with an internal lip; shell entire.

EUSBURIS. Shell orbicular, perforate outwardly; lip
vaulted perpendicular. This species, of which there is a
variety, inhabits the Indian and American seas. It is an
inch wide.

NERITIOIDEA. Shell ovate, with a subspirai tip; lip
lateral. The native place of this species is not known. It
is generally found adhering to other testaceous substrances.
The shell is the size of a cherry, and the inhabitant is red.

SINENSIS. Shell subconic, smooth; lip somewhat lateral.
It inhabits the Mediterranean, Atlantic, and Indian seas.
The shell is very thin and pellucid, sometimes it is of a chel-
ecnut colour speckled with minute grey dots, but generally it
is white, with brown spots and rays.

PORCELLANA. Shell oval, with a recurved tip; lip
placed behind, and flat. It inhabits India and Coree. The
shell is convex, within white, the outside red, with white
sealy spots, and transverse undulate blue lines.

FOWNIATA. Shell oval, obliquely recurved behind; lip
placed behind, and concave. This is found in the Medi-
terranean and near the island of Barbadoes.

AULEATA. Shell oval, brown, with prickly flreiz; the
the crown is recurved. This is found in the American islands.

**TROCHIFORMS.** Shell conic, longitudinally plaited; internal lip lateral. It inhabits Tranguitar and the Falkland islands.

**AURICULA.** Shell roundish, with radiate grooves and flutes; crown recurved; umbilical cavity ear-shaped. It inhabits Bocas, Santa Cruz, and St. Thomas's islands.

**RUGOSA.** Shell ovate, thin, hyaline, obtusely wrinkled transversely; margin unequal; lip unequally repand, hyaline. It inhabits China and is generally found in the Buckinum Spiratum.

**GOHENNIS.** Shell oval, flat, thin, white, glossy, lamellate on the outside. This is found adhering to rocks at Goree, and is about half an inch in diameter.

**CONTRA.** Shell granulate with white, with very fine perpendicular oblique ribs; the lip is very thin, oblique and covering half the cavity. This is a very small shell.

**EXPLANATA.** Shell white, very finely fluted; crown inclining downwards, and dilated, behind which the shell is depressed.

**PLICATA.** Shell conic ovoid, with ferruginous rays within, with longitudinal finely striate pleura.

**STRIATA.** Shell conic, white and fluted, with undulate grooves; the crown is a little lateral.

**ECHINATA.** Shell conic, prickly, glabrous within. It is found foillie near Criqon. The shell is calcareous and white, covered on the outside with prickles.

**Section B.** With the margin angular or irregularly toothed.

**CREPIDULA.** Shell oval, flattened, smooth, the lip flat behind. It is found in the Mediterranean, especially about the coasts of Barbary.

**LACINIOSA.** Shell with elevated unequal rays, thicker and obtuse on the outside. This is an inhabitant of India.

**SACCHARINA.** The shell of this species is angular, with seven carinate obtuse ribs. It is found at Java and Barbadoes.

**BARBARA.** Shell toothed, with nineteen elevated vaulted mucrostrate rays. It is found near the Falkland islands.

**GRANULARIS.** Shell toothed, with elevated angular imbricate flutes. It inhabits Southern Europe, and the Cape of Good Hope.

**GRANATINA.** Shell angular, with numerous muricate flutes. It inhabits Jamaica and Southern Europe, is from one to three inches long.

*VULGATA.* Shell with about fourteen obfolete angles, and dilated acute crenate margin; crown central. This is described and figured in Donovan's Shells; it inhabits the marine rocks of Europe and India. It is about two inches high, and from three to four wide: in the older shells the margin is nearly even, and the number of ribs irregular.

*DEPRESSA.* Shell with fourteen angles, oblong; crown lateral. This is described and figured in Pennant's British Zoology. It inhabits the rocks of Europe.

**CERULEA.** Shell crenate, subangular, with numerous unequal flutes; it is blue. This is an inhabitant of the Mediterranean.

**TUBERCULATA.** The shell of this species is slightly toothed, conic, tuberculate, retuse behind. The shell is yellowish, with white tubercles disposed in rows.

**LEPAS.** Shell roundish, pectinate, with imbricate tuberculate transversely striate rays; crown incurved. There are two varieties, the one found in Chili, the other in the Falkland islands. The second is usually named the Bronze limpet.

**TRICOSTATA.** Shell oval, three-ribbed, white, fluted at the sides; internal margin crenate and a little jagged. It is found in the Indian ocean.

**MYTHALA.** Shell carinate, rounded on the fore-part, with undulate flutes, brown, ochraceous within, the hinder margin crenate. Found in different parts of South America, and is an inch and a quarter long.

**OVATA.** Shell toothed, oval, rather conical, ribbed, white, brown between the ribs, within with brown grooves.

**STELLATA.** Shell angular, ovate, depressed, with ten elevated rays, and shorter intermediate ribs.

**ISLANDICA.** Shell solid, ovate, gibbous, unequally ribbed, within glabrous, with alternate crenices and horny rays; margin crenate. It inhabits, as its specific name denotes, the shores of Iceland, and is about one inch and a half long.

**CYPRIA.** Shell oval, subpellucid, ribbed, the ribs are occasionally tuberculate, and foliaceous on the outside. It inhabits the shores of Cyprus.

**CONTA.** Shell ovate, a little gibbous, white, with crowded unequal tuberculate rounded ribs.

**LEOCOPELEA.** Shell ovate, dusky, with crowded white smooth unequal ribs.

**STRIGATA.** The shell of this species is a little rugged, white, with brown flexuous flutes branching outwards, with two brown spots in the bottom of the hollow.

**OCRORADITA.** Shell convex, with eight larger tuberculate ribs besides lesser ones. It inhabits the American islands.

**RUBRA.** Shell toothed, red under the brown skin, with elevated round ribs, and lesser imbricate ones, within white.

**HEPATICA.** Shell ovate, gibbous, thin, toothed, and of a liver colour, with elevated carinate, obtusely spined flutes.

**BADIA.** Shell subconvex, brown, within bay, with twelve larger rays each surrounded by a rib, and as many lesser ones.

**FUSCENS.** Shell flattened and brown, with ten elevated flutes; crown of a different colour; bottom with a pale liver coloured spot, edged with glaucous and gold; the inner margin in brown. The shell is from two to four inches long; more or less convex.

**MACULOSA.** Shell flattened, the fore part narrow and rounded; yellowish, spotted with brown, with a white crown; with flat rounded equal rays.

**ROTUNDATA.** Shell subovate, flattened, varied with brown, with rounded flat ribs and a differently coloured crown and bottom.

**PECTEN.** Shell ovate, obscurely edged with white, radiate, with distant flat flutes pointed outward; crown grey at bottom with a spot surrounded with a white belt. It is found in North America.

**CORRUGATA.** Shell ovate, wrinkled, crenate; crown with a white circle; within crenicous, radiate with white; bottom pale edged brown edged with white.

**ALBORADITA.** Shell ovate, each side brown, radiate with white, with elevated pectinate flutes; the crown is white and the bottom yellowish. It is about half an inch long, with unequal spines.

**OLIVACEA.** Shell ovate and olive colour; within brown, varied with white, with elevated unequal flutes; the margin with two rows of unequal spines; crown yellow; bottom silvery, with a brown centre. The shell is half an inch
inch long, and the bottom is surrounded with a white belt.

**Cerea.** Shell ovate, both sides waxen colour, perpendicularly flariate, with nineteen flattened ribs and white bottom.

**Impressa.** Shell ovate, with elevated, transversely flariate, brownish flirze, spotted with white, and reaching half way down; crown with a white impressed circumference.

**Aurantia.** Shell ovate, solid; citron undulate with brown, with elevated crowded wrinkled flirze and white bottom.

**Cingulum.** Shell ovate, denticulate, cinereous, with three black belts, within milk-white, with elevated unequal flirze, nodulous on the outside, and pinious at the margin.

**Oculata.** Shell ovate, white, with flattened ribs of unequal length, brownish between them; crown with a brown belt.

**Magellanica.** Shell thin, ovate, white, with a nodulous margin, within perlaceous, with elevated flirze; crown pointed, brown; bottom brown. It inhabits the straits of Magellan.

**Ochroleuca.** Shell ochraceous, with three yellow bands, and elevated, acute, unequal flirze; crown white; bottom fivery.

**Dentata.** Shell white, denticulate, with elevated, acute, unequal flirze; crown surrounded with a double row of cinereous dots, and a dusky-grey band.

**Nodosa.** Shell yellow, radiate with brown, with elevated, nodulous, unequal flirze; crown and bottom white.

**Cineria.** Shell toothed, cinereous, with unequal elevated flirze, between which it is brown and rugged; crown pointed, milk-white.

**Exalbida.** Shell whitish, with brown rays, and elevated, rounded, unequal flirze, between which it is rugged; crown obtuse, white, with a broad interrupted brown band, and another marginal one.

**Cancellata.** Shell cinereous and brown, with decussate flirze and two rows of tubercles; the crown is yellowish, and the bottom has a white spot. There is a variety that is grey, with dusky rays, and a few yellow flirze; within dirty yellow with a white bottom. It is found in Jamaica, and is about one inch and a half long.

**Levis.** Shell rounded, smooth, yellowish, with a broad cinereous margin band spotted with brown, and another narrow one; margin dilated, acute, and a little rugged.

**Argentea.** Shell smooth, thick, a little fivery, with eleven brown rays; margin fivery; crown pale yellow; bottom ivory, with a double white ring. This is about two inches long, but is very rare.

**Cuprea.** Shell white, with strong, rounded, brown ribs, within perlaceous; crown and bottom coppery.

**Rubida.** Shell pale, liver-coloured both sides, with alternate larger and lesser carinate ribs; it has a flat and white crown.

**Glaabra.** Shell brown, glabrous above, with elevated crowded white flirze beneath; crown obtuse, white, with a fulvous border; bottom fulvous.

**Flaveola.** Shell yellowish, varied with brown; with flattened unequal ribs; crown obtuse; bottom varied reddish and white.

**Infundibulum.** Shell denticulate, compressed on each side, rounded, yellow, with perpendicular flirze and carinate ribs; bottom varied with white and cinereous.

**Cyathus.** Shell rounded, glabrous, white.

**Sinica.** Shell ovate, entirely yellow, with undulate grooves, within flirze perpendicularly; margin scalloped. It is found in China, and is about three inches and a half long.

**Punctata.** Shell roundish, white, with many-coloured dots, radiate at the base, and surrounded with two brown rings; margin a little flexuous.

**Lugubris.** Shell ovate, with annular flirze, blackish, with elevated unequal flirze; margin crenate; crown and bottom white.

**Ulyssiponensis.** Shell ovate, toothed, yellowish, with elevated flattened flirze; crown pointed, and of an orange colour.

**Umbella.** Shell oblong, red, with elevated, unequal, white flirze; the margin is crenate. It inhabits Africa, in numerous varieties. The shell is rarely of a straw-colour; it is sometimes spotted or clouded.

**Crenata.** Shell thin, pellucid, flirate, blackish, with olive rays, within glaucous or cinereous; crown pointed; margin crenate; bottom milk-white. It is found on the shores of Africa, Malaga, and Libion.

**Ferruginea.** Shell ferruginous, with angular or undulate ruffet lines, and cinereous belts, within milk-white, with elevated knotty flirze; the margin is plaited.

**Metagramma.** Shell oval, ochraceous, with elevated black flirze, within fivery, spotted; crown pointed, white; bottom with a straw-colour spot.

**Repanda.** Shell ovate, thin, within fivery, with brownish rays, and thin undulate flirze, with bay-coloured granulations. The margin is flexuous. It inhabits the seas of Magellan.

**Angulosa.** Shell oval, white, with very thin flirze, and varied with red spots and dots; margin eight-angled.

**Tigridia.** Shell oval, smooth, polished; pellucid, flirate with seven yellowish ribs; the colour is blueish-olive, dotted with brown; the margin is feven-angled.

**Monospis.** Shell oblong, flattish, bay fritate with white, within milk-white, with eleven elevated unequal flirze; crown rounded, white. It inhabits the American islands.

**Chloroflicta.** Shell ovate, toothed, brown, dotted with green, with eleven elevated, hollow, broader flirze, and as many narrower ones; the crown is white.

**Margaritacea.** Shell thin, unequally flirate, white, within perlaceous; crown with an orange mark, surrounded with a yellowish ring; the margin crenate. This is an Iceland shell.

**Tenuissima.** Shell oval, thin, ochraceous, with angular chefunet lines, and elevated, obtuse, hollow, unequal flirze.

**Mitrula.** Shell solid, sub-conic, transversely plaited, with a flexuous margin. It inhabits Barbadoes.

**Plicaria.** Shell ovate, toothed, with thirty elevated, obtuse, undulate, and transversely wrinkled flirze. Found in the straits of Magellan.

**Pentagona.** Shell whitish, obtusely pentangular, with a dilated crenate margin; crown obtuse; bottom reddish.

**Ænea.** Shell ovate, tender, pellucid, with elevated flirze, covered with a whitish cuticle, under which it is fivery, with ruffet rays; crown and bottom coppery. It inhabits the straits of Magellan.

**Conchacea.** Shell thin, oblong-ovate, with very fine undulate flirze, yellowish, with elevated darker rays; crown recurved. It inhabits South America, and refembles the common muscle, except in the hinge.

**Manxna.** Shell ovate, fivery, with elevated flattened flirze; crown obtuse, coppery; bottom with an oval bay mark; the margin is flexuous.

**Candidissima.** Shell orbicular, fritate, white, with a brownish band, dotted with brown, within grey, with unequal flirze; margin transversely wrinkled.
PATELLA.

Section C. With a pointed recurved tip or crown.

* Hungarica. Shell entire, conic, pointed, fritiate, with a hooked recurved crown. This is described and figured in Donovan’s British Shells; and likewise in Pennant’s British Zoology, vol. iv. It inhabits the American, Mediterranean, and Atlantic seas.

Imbricata. Shell entire, oblong, imbricate, the crown placed behind.

* Mamillaris. Shell entire, conic, fritiate, sub-diaphragmous, with a reflected smooth crown. This is described and figured by Pennant, and it inhabits the shores of the Mediterranean and Africa.

Tricarinata. Shell trifurcated, with three ribs on the fore-part.

Pectinata. Shell entire, ovate, with wrinkled slightly branched fritze; crown nearly central, reflected, and pointed. It is found on the shores of the Mediterranean, and is about two inches long.

Lutea. Shell entire, oval, convex, fritiate, with a sub-marginal, reflected, mucronate crown. It inhabits divers parts of India, and is about the size of a melon seed.

Cristata. Crown recurved; back crested, carinate.

* Lacustris. Shell very entire, oval, membranous, with a nearly central, mucronate, reflected shell. It inhabits the fresh waters of Europe.

* Fluviatilis. Shell very entire, oval, a little horny, with a marginal mucronate crown; aperture oval. This is very like the last, and inhabits, like it, the fresh waters of Europe.

Cerca. Shell entire, with elevated dots, and fritze; crown acute, straight. Found in the bays of Norway, on stones. The shell is white, with from sixty to eighty fritze; the inhabited is white, ovate, without the least appearance of eyes.

Virginica. Shell very entire, white, with red bands. This is found on the fuel, in the bays of Norway.

Tessellata. Shell, very entire, of a whitish colour, tesselated with red. Found on the rocks and fuel about Norway.

Fulva. Shell very entire, orange, with a mucronate and nearly vertical crown. It inhabits Norway, on fuel and tesselate fuel late.

Subspiralis. Shell ovate, with an obtuse sub-spiral tip.

Found in Norway.

Ambigua. Shell ovate, with a slightly toothed margin, and a rather acute and reflected point. Inhabits Norway.

Rubicunda. Shell very entire, rather conical, smooth, and reddish. It inhabits the deeps of Greenland.

Borniana. Shell ovate, very entire, with very fine longitudinal fritze, white, with red veins.

Calyptra. Shell entire, with imbricate ribs; the crown is hooked; the margin fimbriate. Inhabits North America.

Melanoleuca. Shell fritiate, very entire, alternately black and white.

Pectunculus. Shell oblong, convex, with elevated nodulous fritze, slightly toothed, within polished; crown curved forwards.

Fasciata. Shell ovate, white, with a brown band, and elevated acute fritze; the margin is dilated, crenate, and cincereous within.

Elegans. The shell of this species has decussate fritze that are white, radiate with red, denticulate; the crown is grey.

Squamosa. Shell with elevated fritze, transversely undulate on the outside, brown, ulvery towards the margin, crown bronzed, hooked.

Squalida. Shell entire, brown, within whitish with a blueish bottom; the margin blueish, radiate with brown, with elevated oblique fritze; crown knotty.

Cochlea. Shell smooth, sub-angular, yellow, radiate with brown; crown obtuse, white; bottom with a whitish spot.

Candida. Shell ovate, smooth, on both sides white, with a rosy belt on the outside.

Trigona. Shell compresse, convex in the middle, cancellate, white, with a brownish band on the outside, and margin within; crown marginal, obtuse.

Minima. Shell rounded, convex, thin, smooth, whitish with reddish spots; crown very obtuse, and white. It inhabits Feroe island.

Tranquebarica. Shell ovate, thin, pellucid, with very fine crowded fritze, chevrons with white scales, within milk-white, with a brown spot at the bottom; the crown is marked with an azure spot. It inhabits Tranquebar, as its name imports.

Perversa. Shell oblong, horny, very thin, pellucid, glabrous, with a ferruginous base. It is found in Africa. The point of the crown is bent back towards the hind parts of the shell.

Cernua. Shell with decussate grooves, thin, pale fleshy-colour, with an oblong aperture.

Incurva. Shell entirely white, flat; point of the crown twilled.

Interrupta. Shell oval, depressed, glabrous, brownish, with green dots disposed in oblique interrupted rays; crown with an obtuse hook.

Section D. Very entire, and not pointed at the tip or crown.

Afra. Shell conic, fritiate, greenish or pale brown, within white; crown glabrous, white, obtuse, central; margin glabrous. It inhabits the island Gorée.

Lusitanica. Shell conic, white, with brown rays marked with fritze, granulate with black; crown acute, not radiate, and surounded with a chevrons ring. It inhabits Portugal, on the sea rock, and is very small.

Radiata. Shell rounded, convex, grey, with decussate fritze; crown pointed, central, and marked with twelve orange radiate lines; the bottom is horny. It inhabits Jamaica.

Areolata. Shell pyramidal, reddish-grey, with very thin circular fritze, crossed by longitudinal ones; crowned violet. It resembles the P. magellanica of a former fiction, but is more depressed, and broader at the base.

Flammea. Shell ovate, with very fine annulate fritze, reddish-grey, with undulate brown rays; the crown is acute, central, white in the middle.

Indica. Shell reddish-grey, with radiate fritze, glabrous, narrower on one side; crown acute, smooth, surounded with a reddish ring. It inhabits India, is nearly four inches long, and resembles the P. ruticola, to be deferred hereafter.

Surinamensis. Shell thick, subovate, yellowish, with black rays, and longitudinal unequal fritze, and surounded with knotty belts; crown obtuse, smooth and white. It inhabits Surinam.

Vitellina. Shell ovate, yellow, with an unequally fritiate base, and obtuse whitish crown.

Sanguinolenta. Shell ovate, convex, white, folild, with intermixed, capillary, and flexuous elevated longitudinal fritze; the crown is surounded with a broad ring, dotted with red. It is found in Africa.

Levigata. Shell ovate, yellow, within blueish-white, with oblique fritze, the crown is white, smooth, and polished.

312 Punctulata.
PUNCTULATA. Shell rounded, white, with many-colored dots, radiate towards the base, and surrounded with two brown rings.

*PELLUCIDA. Shell very entire, ovate, gibbous, pellucid, with four blue rays. This is described and figured by Donovan, Pennant, Litter, and others. It is about the size of a walnut, and is found in the European and Northern seas.

TESTUDINARIA. Shell very entire, acute, smooth, glabrous. It inhabits the Indian and Northern seas in numerous varieties.

TESTUDINARIS. Shell very entire, ovate, and flria; a variety has its crown obtuse, and nearly central. It inhabits the seas about Greenland, among fiuci.

COMPRESSA. Shell very entire, oval, oblong, flria, smooth, compressed on the back. It inhabits India, and is about four inches long.

RUPTA. Shell very entire, conic, with fifty obtuse flria.

FUSCA. Shell very entire, ovate, obtuse, with elevated flria.

NOTATA. Shell entire, flria, with a sub-mucrocrate ereci crown, whitish white, with a black heart-shaped spot white in the middle. It inhabits the Mediterranean.

CRUCATA. Shell very entire, oval, sub-convex, brown, with a white cross.

RADIANZ. Shell entire, oval, pellucid, depressed, flria, horny, radiate, with black spots. It inhabits Newfoundland.

ROTA. Shell roundish, the inside somewhat filvery, the outside with reddish fringes and a yellowish border. It inhabits the Indian and American seas.

UMBELLATA. Shell entire, roundish, diaphanous, depressed, with yellowish rays within; crown pale yellow, margin very acute. It is about four inches and a half long, and is found in the Indian ocean.

PASTULATA. Shell thin, oval, depressed, radiate, white, dotted with red, within smooth.

SYMMECTRA. Shell ovate, conical, solid, brown, divided into partitions by perpendicular white lines, within smooth, white; margin cut arcwise.

CYTRINA. Shell ovate, convex, with very fine decussate flria, white, with two broad yellow bands, within whitish, with a milk-white bottom; crown brownish.

CAPENSIS. Shell ovate, with decussate flria, the longitudinal ones alternately brown and white, within somewhat parallel, with a white bottom. It inhabits the Cape of Good Hope.

ANOMALA. Shell coarse, brown, orbicular, with a submarginal crown. It inhabits the deeps of the Norway seas, on rocks and dead terebellaceous substances. The shell of this species is very minute, rough, with very fine railed dots, sometimes cinerous, beneath blue; the inhabitant confines of two reddish tough twisted mafles, fringed down the whole length; the fringes composed of crowded yellow rigid crisp hairs united to the rest of the body by a blue tendion; ovaries branched, orange; eggs globular.

GUTTATA. Shell finely flria, and varied with dots of different colors; the bottom is dullish. It is about an inch and a half long, and resembles the complea.

MYTILIFORMIS. Shell glabrous, lead color, with a white horse-hoe shaped band within. It inhabits the Ferrole island, adhering to zoophytes.

SCUTIFORMIS. Shell oval, thin, black, with white perpendicular flattened flria.

COCHLEAR. Shell white, flatish, one part narrow, canulate within, with a blueish callus shaped like a horse-hoe, the other part rounded.

CRATICULATA. Shell oval, thin, depressed, cancellate, radiate.

CRUENTATA. Shell oval, a little convex, varied with red, and slightly toothed, with elevated unequal rough flria.

PAPYRACEA. Shell depressed, thin, hyaline, dotted with red, with chefins rays outwardly, and crowded thinner, and granulate thicker flria.

CYLINDRICA. Shell oval, flat, with crowded longitudinal size of unequal thicknats, and many granulate.

DECUSATA. Shell somewhat convex, white, with crowded red dots, within radiate with red and white, with decussate glabrous flria, and a few longitudinal thicker white ones.

HEMATOSTRICTA. Shell thin, depressed, white, dotted with red, within brownish, spotted, flria; crown varied with cinereous and brownish.

ASTEROIDES. Shell flatish, cancellate, cinereous, with a chefins flar and rays towards the margin; crown smooth, grey, surrounded with brown dots.

OVALIS. Shell oval, somewhat convex, thin, with crowded flria, grey, with blackish rays and spots.

RUBELLA. Shell a little convex, flria, reddish; crown whitish, spotted with red; the bottom part is whitish.

SPECTABILIS. Shell flatish, a little wrinkled, flria, reddish-white, with a chefins band towards the crown, and another bay one at the margin.

CONSPOURECATA. Shell solid, flatish, flria, black, with flria dots, within blueish, crown dirty-yellow.

MELANOSTRICTA. Shell solid, flatish, flria, whitish, with circumgranular rays and black dots, within blueish; crown a little pointed and whitish.

ATRA. Shell black, flria, with a paler crown; bottom with a brownish mark surrounded with a white horse-hoe shaped band.

SPECULARIS. Shell oval, convex, solid, glabrous, liver-colour, within and the crown brownish, the latter surrounded with a white border, and interrupted brownish band.

CANESCENS. Shell oval, black, within blueish, flria, the larger flria flattened and grey; crown obtuse, brownish, with a whitish area.

VIRESCENS. Shell oblong, flatish, dilated on each side and flria, oliveaceous, radiate, and spotted with white, within blue.

PULLA. Shell rounded, convex, longitudinally flria, and transversely wrinkled, brownish, within rufus-brown, with whitish and brownish rays, and two milk-white bands above.

REVOLUTA. Shell sub-oval, crenate, flria, ochraceous, with red spots and rays, broader on one side; margin revolute.

SQUAMATA. Shell ovate, convex, flria, the flria scalar, varied with white and black; crown nearly central, grey.

TESTACEA. Shell ovate, very finely flria, teteaceous, with three transverse brownish rings, within pale yellow, with a whitish bottom.

CAPILLARIS. Shell ovate, thin, brown, with darker bands, and paler flria, within brownish; crown and bottom white.

Glaucu. Shell ovate, narrower on one side, very finely flria, blueish, with a white band towards the margin, and another blueish one; crown and margin white.

OSCURA. Shell ovate, flatish, flria, varied with yellowish and brown, dotted with green, within brown, crown bay.
PATELLA.

Exoleta. Shell oval, sub-convex, unequally fribate, white, with a few black lines reaching half way; bottom with an ochraceous spot.

Affinis. Shell oval, flattish, solid, with a few black rays reaching half way; the bottom is marked with a white spot.

* Rotalis. Shell white, opaque, flat, round, with a regular toothed margin. It is found occasionally at Sandwich; is very entire and minute.

Fusca. Shell ovate, convex, very finely fribate, and varied with brown.

Mellia. Shell rounded, solid, glabrous, honey-colour, within white; crown brownish; margin spotted with brown, and dilvery within; bottom with a liver-colur spot.

Ancone. Shell solid, glabrous, a little pointed, pale chefnt, within pale flesh-colour.

Guineensis. Shell ovate, convex, very smooth, one side broader and chefnt-coloured, the other with the crown pale yellow; margin flesh-coloured on each side.

Complanata. Shell depressed-hemispherical, oblongly obovoid, varied with white and brownish.

Virgo. Shell ovate, longitu dinal fribate, white with brown rays and crown, within peracous.

Nivea. Shell subconic, solid, glabrous, snowly, with transverse concentric rings. Inhabitats America.

Grisea. Shell oval, with crowded radiate grooves, within polished; crown nearly central. It inhabits Africa.

Navicular. Shell narrow, with decussate fribae, rosy with a whitish callous belt on one side in the middle, and whitish bottom, the margin is revolute on each side.

Cingulata. Shell suboval, obliquely fribate, fribrous, with two elevated obcompute bars; crown nearly central.

Scarpa. Shell clear white, with undulate fribae, narrow, the broader side with an acute callus, the narrower side repand.

* Parva. Shell small, entire, without globs, white, faintly radiate with red. This is described and figured by Donovan. It is found on the Devonshire coasts, but is very rare.

Section E. With the crown or tip perforated.

* Fissura. Shell oval, conic, with reticulate fribae, cleft on the fore-part; crown recurved. It is found on divers parts of the coasts of Europe and Barbary, and in this country. It has been described by Donovan, Pennant, and others.

Fissurella. Shell grooved and perforated on the fore-part; crown recurved. It is found adhering to stones in the Iceland seas.

Fustula. Shell oval, gibbous, convex, with reticulate fribae, and crenate margin. It inhabits the Mediterranean, Atlantic, and Indian seas.

* Glaeca. Shell ovate, convex, reticulate; the margin crenate upwards. Described and figured by Donovan, Pennant, Lister, and other naturalists.

Nimbosa. Shell ovate, fribate, rugged, brown, with an oblong perforation. It inhabits the Mediterranean and Atlantic.

Nubecula. Shell subovate, rugged, white, radiate with red, with an ovate perforation. It inhabits the Mediterranean, and resembles the last species.

Picta. Shell ovate, solid, clouded, white and green, with oblique, undulate, alternate violet and white rays. It inhabits the fribae of Magellan.

Barbadensis. Shell oblong, unequally fribate, within smooth, milk-white, with greenish bands; margin crenulate. It inhabits Barbadoes.

Jamaicensis. Shell whitish, transversely annulate, with longitudinal fribae covered with foliaceous tubercles, which are larger outwardly. This is found on the coasts of Jamaica and Barbadoes.

Caffra. Shell ovate, compressed, fribate, very finely annulate, and radiate with black; bottom milk-white; perforation nearly central. It inhabits the Cape of Good Hope.

Perforata. Shell a little convex, transversely wrinkled, brownish with irrugured-coloured rays and spots, within longitudinal fribae alternately larger and fealey.

Porphyrozonia. Shell oblong, compressed, unequally fribate, white with five purple interrupted belts, within greenish-white. It inhabits North America. The perforation is very minute, orbicular, and surrounded on the inside with a red circle.

Rosea. Shell very thinly fribate, with alternate rosy and white rays; the perforation is oval.

Scutella. Shell each side repand, compressed; perforation radiate with grooves.

Avellana. Shell thin, white, with very fine fribae; perforation oblong, and divided by a ligament. There is a variety of which the margin is a little revolute on each side.

Spinosa. Shell ovate, convex, white, with elevated fribae, growing thicker towards the margin, and marked with four rows of tubercles, the exterior tubercles are spinous.

Denticulata. Shell ovate, gibbous, whitish radiate with brown, within green, with elevated fribae; margin dentate, crenate within.

Nudulosa. Shell ovate, convex, with elevated nodulous fribae, crossing thinner transversal ones, within white; crown black.

Angusta. Shell depressed, white, with elevated fribae, every fourth of which is larger; perforation very narrow, and surrounded with a chefnt band on the outside, and a green one within.

Inequalis. Shell ovate, convex, with decussate fribae, white, somewhat triangular on the broader side; perforation surrounded with an elevated ring, round which is a red line.

Minuta. Shell oval, pyramidal, reddish, with twelve elevated white fribae; bottom white; perforation oval, and nearly central; margin dentate.

Conspersa. Shell ovate, convex, fribate, yellowish, with red dots, and three oblique rays; within smooth, white.

Rubescens. Shell oval, fribate reddish, with a white band in the middle; within it is white; margin entire; perforation linear.

Sanguinea. Shell oval, thin, red, within greenish-white, with longitudinal fribae crossing finer transversal ones, which are rugged outwardly.

Ventricosa. Shell oval, ventricose, with decussate red fribae, within white; crown depressed, with an oribcular perforation; margin entire.

Triadonta. Shell ovate, flattish, fribate, white with three brown rays, within whitish, perforation linear; margin entire.

Tenus. Shell oval, a little convex, pellucid, longitudinally fribate, white, with five half-brown rays; within yellow.

Melanoxonia. Shell convex, rosy, with an interrupted black
black band, and elevated unequal white friz; within smooth, white; margin denticulate.

Effusa. Shell convex, rosy, with elevated nodulous white, alternately larger friz; perforation round and large.

Puniccea. Shell convex, crenated, with unequal, crowded decussate friz; within smooth, with alternate green and white bands; the perforation is round.

Rufescens. Shell convex, white shaded with red, and here and there friz with red, with granulate friz; within it is smooth and white.

Dissimilis. Shell convex, above clear white, cancellate, longitudinally friz towards the margin, with a rosy band.

Lactea. Shell convex, white, with unequal acute glabrous friz; within smooth; the crown is rosy; the perforation large and orbicular.

Pyramidalis. Shell convex, rosy, friziate, with twelve smooth ribs; within smooth and greenish-white.

Bicolor. Shell narrow, alternately radiate with crenated and white, with unequal, thick, lamellate friz; within smooth, white, margin crenulate.

Erythrosephala. Shell convex, white, with red lines outwardly, and elevated rugged contrary friz, ten of them larger; the margin repand and inflected.

Verrucosa. Shell above brown, friziate, terminated by a knotty belt, beneath radiate with red, with acute nodulous ribs; margin denticulate, repand.

Contaminata. Shell convex, with nodulous unequal ribs, the larger ones yellowish-brown, and marked with black dots disposed in interrupted circles, within greenish-white; the crown is crenate.

Atrata. Shell a little convex, narrow, white with red lines, outwardly spotted with black, with elevated, convex, unequal friz; the perforation is oblong, with a crenate margin.

Candicans. Shell white, crenated-coloured towards the margin, with twenty alternately larger ribs; the crown is reddish, with an oblong perforation.

Succinta. Shell ovate, pointed, white, above smooth, with an elevated belt in the middle, dotted with ferruginous towards the margin, with elevated unequal smooth friz; margin denticulate.

Pusilla. Shell flattish, white, sub-orbicular, with twenty alternately less and shorter elevated friz; the perforation is round, and surrounded on each side with a reddish circle.

Flavescens. The shell of this species is very thin, pointed, finely friziate, yellowish, with fine brown rays; margin denticulate; crown crenate, with an oblong perforation.

Antiquata. Shell a little convex, oblongly friziate; white with red friz on the outside. The perforation is oblong and unequal.

Galeata. Shell solid, ovate, compressed, within white; crown a little recurved, obtuse, with a linear perforation; margin crenate.

Personata. Shell convex, with decussate lines and black rays. It inhabits the Falkland isles.

Patella, in the History of Insects, a name given by Liliér, and some others, to a certain little hufl or shell, found on the bark of the cherry, plum, and rofe trees, and some others, containing an animal within, and useful in colouring. These patellas are of a globular form, except when they adhere to the tree, and are of a flaming crenate colour in most kinds. The husk itself strikes a very fine crimson colour on paper, and within it is found a white maggot of no value: this, in time, hatches into a very small but beautiful bee.

The whole size of this bee is not more than that of half the body of an ant. They have the flyng of bees, and the three spots placed in a triangle on the forehead, which are supposed to be eyes. They are black, and have a large round whitish or pale yellow spot upon the back. The upper pair of wings are shaded and spotted, but the other pair are clear.

The shells or husks deserve a trial, to find whether the colour they yield might not be brought to use; it is to be observed, that the deepest coloured husks afford the finest and deepest purple; they must be also used while the creature contained in them is in the maggot form; for when it is changed into the bee form, the shell is dry and colourless.

Dr. Liliér, who had observed these patellas, went so far, on comparing them with the common kernes, as to declare that they were of the same nature with that production; but this history of their being the workmanship of a bee, to preserve her young maggot in, is not agreeable to the true history of the kernes; for that is an insect of a very peculiar kind. This author has been too justly cenured for his precipitancy of judging of things, and perhaps has fallen into an error by means of it here.

It is very possible that this patella may be the same sort of animals with the kernes, but then it produces its young within this shell or husk, which is no other than the skin of the body of the mother animal; but as there are many flies, whose worms or maggots are lodged in the bodies of other animals, it may be, that this little bee here described, may love to lay its egg in the body of the proper infect now mentioned, and the maggot hatched from that egg may eat up the proper propery, and, undergoing its own natural changes, there, fly out at length in form of the bee. This may have been the case in some few which Dr. Liliér examined, and he may have been misled by this to suppose it the natural change of the infect. Phil. Tranf. N. 72.

Patella Fera, the wild limpet, a name very improperly given by Rondeletius and Aldrovand, to the auris marina, or concha Veneris. This is by no means of the patella kind. See Ear-shell.

Patellaria, in Botany, from patella, a dish with a broad brim, a name first adopted by Ehrhart, in his Physophylliacum, for some of the Lichen tribe; and retained by Hoffmann, Pl. Lichenof, v. 1. 54, for what Linnaeus termed leprofusellati. Acharius, in his Prodromus 36, receives it on a larger scale, so as to admit the leprofusellati, at least in part; such as afterwards, in his Methodus, constituted the genus of Leccida. Patellaria is, in that work, funk in his mikifarious genus Parmelia; and though its idea is restored, in his more recent Lichenumphoria, the name has given place, apparently without necessity, to Lecanora. See Lichenes and Parmelia.

Patellariae, in Mythology, among the Romans, placed by Plautus in the lowelts, and called by Horace also the little gods.

Patena, in the Roman Church, the cover or lid of the chalice, made of the same metal with it, serving to hold the particles of the hoft, and give the people to kiss, when they make an offering.

It has its name patena, a patendo; and this is a general name, in Colomella, for any broad flat vessel.

Patenede, in Geography, a town of the island of Ceylon, near the E. coast; 78 miles E. of Candy. N. lat. 7° E. long. 82°.

Patents, or Letters Patent, in Law, the king’s letters, sealed with the great seal, serving to convey the
title or property of some grant, favour, privilege of a new establishment, or the like. See Letters Patent.

They have their name from being delivered open, ut patant universis: or way of contradiction from letters de cachet, or littera clausa, or clofe rolls, which are sealed.

Grants or letters patent must first pass by bill; which is prepared by the attorney or solicitor-general, in consequence of a warrant from the crown; and is then signed, that is, superscribed at the top, with the king's own sign manual, and sealed with his privy signet, which is always in the custody of the principal secretary of state; and then sometimes it immediately passes under the great seal, in which case the patent is superscribed in these words, “per ipsum regem; by the king himself.” Otherwise the course is to carry an extract of the bill to the keeper of the privy seal, who makes out a writ or warrant thereupon to the chancery; so that the sign manual is the warrant to the privy seal, and the privy seal is the warrant to the great seal: and in this last case the patent is superscribed, “per breve de privato sigillo, by writ of privy seal.”

It is to be noted, that patents differ from writs: a coroner is made by writs, not by patent.

To this office, enacted 18 Jac. I. belongs a clerk, &c.

Patent, Letters, under the royal authority, confer on a person the exclusive privilege of making and selling any thing, so that no person be restrained in what he had before, or in using his lawful trade. The latter part of the definition of letters patent, or of a monopoly conferred by letters patent, will apply only to such as have been granted since the statute of the 21st of James. c. 2, commonly called the statute of Monopolies; prior to that period, letters patent conferred a monopoly as interfered with the rights of other people, and restricted the freedom of trade.

Monopoly, in the latter acceptation of the word, has already been considered under its proper head; it existed in this kingdom unrestrained till the time of king John, who first granted municipal franchises. In the 25th year of the reign of Edward III. a statute was passed, which granted a free trade equally to foreigners and natives; this statute, however, was afterwards repealed; and monopolies that not only excluded foreigners from the advantages of English trade, but also injured the English nation at large, in order that the favourites of monarchs might be rewarded, or that the crown might be enriched, were established. During the reign of queen Elizabeth, they had spread so widely over the commercial transactions of the country, as to threaten the utter ruin of trade; when a list of only part of the commodities, which had been appropriated to monopolists, was read in the house of commons, a member cried, “Is not bread in the number?” “Bread,” said every one with astonishment; “yes, I allure you,” replied he, “if affairs go on at this rate, we shall have bread reduced to a monopoly before next parliament.” At this period, most extraordinary powers were granted to the patentees; especially to those who held the exclusive privilege of selling salt petre; they had the power of entering every house, and of committing what have they pleased in flables, cellars, or wherever they suspected salt petre might be gathered. Home.

It might have been supposed, that such a flagitious princes as Elizabeth would have perceived the evil consequences of granting monopolies; but either the reduced state of the royal funds, or her fondness for favourites, blinded her to the true interests of her people. Towards the end of her reign, however, the clamour of the country was so loud and general, that she felt a meagre to parliament, that she would immediately cancel the most oppressive of the exclusive privileges she had granted.

Before proceeding to the consideration of the statute of James I. already alluded to, it may be proper very briefly to take a view of the statute law, as it respects patents prior to that period. Monopolies are expressly contrary to Magna Charta. (29, 30.) The statute of Edward III. declared all grants by monopolies void; and when Philip and Mary granted by letters patent, to the mayor, bailiffs, and burgesses of Southampton, the exclusive privilege of importing Malmsey wine at that place, the judges were unanimous in their opinion, that the statute was void, as being against the freedom of trade. The principal statutes relating to patents in the 16th, and in the beginning of the 17th century, were in the 6th of Henry VIII., the 4th of Edward VI., and the 13th and 43d of Elizabeth.

The 21st of James I. c. 3, is regarded as the declaration statute, by which the law on this subject is determined, and the 6th section of this statute particularly relates to patents for new inventions: this section contains the exception to the general law of the statute; the general law is, that all monopolies, and all commissions, grants, licences, letters patent, &c. for the sole making, selling, using, &c. of any thing, shall be void; the exception clause declares, that the law of the statute shall not extend to any letters patent, for the term of 14 years or under, granted to the true and first inventor, or inventors of manufactures, &c. which others, at the time of making such letters patent, shall not use. Sir Edward Coke, in his explication of this statute, gives it as his opinion, that the new manufacture, to which letters patent may be granted, must not be generally inconvenient; and this construction seems to have been adopted in his time, as he says, “that a patent for a fulling-mill to thin bonnets and caps, was fet aside, on the ground, that it was held inconvenient to turn labouring men to idleness. But this construction does not prevail now, and, indeed, if it did, it would effectually defeat the object of the fifth section of the statute of monopolies.

In the letters patent which are granted for new inventions, the improvements or inventions are first stated; the prayer of the petitioner to have the exclusive benefit for himself, or his assigns, for fourteen years, is next given; and this prayer is declared to be complied with, according to the statute. After commanding all subjects not to interfere with the patent right, and influing a mandate to all officers not to molest the patentee in the exercise of it, the letters patent declare the patent void, if it appear that the grant is contrary to law, or prejudicial to the subject; or if the thing invented have been in use before the date of the grant; or if the patentee be not the inventor; or if it interfere with prior letters patent; or if the patent be transferred to more than five persons, or to any who act as a corporate body; or finally, if the nature of the invention be not described, or the description be not enrolled within one calendar month after the date of the letters patent. The letters patent conclude with a declaration, that they shall be construed in the most beneficial sense for the patentee.

A writ of scire facias, to repeal letters patent, lies in three cases: 1. when the king grants the same thing to two or more persons; 2. when the king is deceived in his grant; and 3. when the grant is against law. The following rules are laid down by chief justice Lee, respecting the cases in which mistakes do not vitiate the grant: 1. If the king’s intention is manifest, a false recital in a thing not material, will not vitiate the grant. 2. It is not vitiated in cases where the king is deceived, not by the false forgelion of the party, but by his own mistake, upon the furnnul and information of the party. And 3. Although the king is misled in point of law, or matter of fact, if that is not part
part of the consideration of the grant, it will not vitiate it.

Patents for new inventions are granted for a term of fourteen years; and any royal grant for such purpose beyond that term is void. The fourteen years are accounted to commence from the date of the first letters patent. The patent right, however, may be extended by act of parliament.

A patent may be granted for an improvement on an old manufacture; but the improvement must be material and useful; and the patent extends to the improvement only. The statute confers a manufacture brought from abroad into the kingdom (provided it has not been practiced before) as a new manufacture, and entitled to letters patent. No old manufacture in use before, can be prohibited by the grant of the sole use of a new invention; nor can a patent be granted for a method, or principle; its object must be some substantial thing produced.

The following rules are laid down by judge Butler, respecting the description required in the specification, which by the patent grant, the patentee is to cause to be enrolled in the high court of chancery. The invention or improvement must be described, and described in such a manner, that others of the same trade may be taught to do the same thing for which the patent is granted: 1. He must describe it in such a manner, that the public, after the expiration of the term, may have the use of the invention in as cheap and beneficial way as the patentee himself; and therefore, if the specification describes many parts of a machine, &c., and the patentee uses only a few of them, or does not state how they are to be put together, the patent is void. 2. If the specification be in any part materially false or defective, the patent is against law, and cannot be supported.

The enrolment of the specification in the high court of chancery, where it is open to the inspection of every one, enables those who are inclined to purchase the machine, invention, &c., to become acquainted with its nature and merits; and, at the same time, prevents such as are employing their skill, time, and money on improvements, or inventions of a similar nature, from merely doing what has been done before.

With respect to the form of the specification, it must be under the hand and seal of the inventor; the enrolment must take place within one calendar month after the date of the letters patent; if the patentee fails over this time, it cannot be enlarged without an act of parliament for that express purpose.

When a patentee brings an action against any person for infringing his patent, it is incumbent on him to shew, that the invention was new, and that the specification is full and complete.

It is frequently for the convenience or interest of a person, who has invented or improved a machine, &c., to delay taking out a patent for it; in such case, he may enter a caveat. A caveat will protect his invention or improvement for the space of one year, after which, if he has not brought his contrivance to maturity, he may renew it again for an equal period, and so on for any successive number of years. The caveat must be delivered at the chambers of the attorney and solicitor-general; and if an application be made for a patent for an invention of the same nature, notice is given to the person who has entered the caveat; if he requires it, the attorney-general gives a separate audience to each of the rival inventors, and makes his report to the king, according to his opinion respecting the priority of invention. A petition to the king, stating the nature of the invention, and praying letters patent, accompanied by an oath taken before a master in chancery, that the invention is new, are the steps preparatory to taking out a patent. Separate patents must be taken out for England, Scotland, and Ireland; but in a patent for England, the patentee may, on the payment of a small additional sum, have the colonies and plantations abroad included. The petition and oath are referred by the secretary of state for home department to the attorney-general, and on his report, recommending letters patent, his majesty issues his warrant, in conformance of which the bill is made out, which is the grant of his majesty, and of this the patent is the transcript; the nature of the specification, and the payment of its cost, have been already mentioned.

Having thus considered letters patent in general, we shall conclude with a few remarks on them, as a subject of political economy. It is plain from what we have stated, that they are the remains of that system of monopoly, which formerly prevailed in this and all the other countries of Europe; and so far, at first sight, they may appear objectionable. But when we consider the object for which they are granted, we shall probably be of opinion, that it takes them completely out of the force of those objections, which are so justly brought against all monopolies.

It is evident, that so man will bellow his time, ingenuity, and money, in endeavouring to invent or improve any thing, unless, when he has succeeded, he is secure in being rewarded. This reward can be secured to him, only by granting him, for a certain number of years, the exclusive privilege of his invention or improvement; or by government purchasing it from him. In the former case, while his patent right lasts, he has a monopoly; he may put what prices on his invention he pleases; or he may execute it in a careless or improper manner; but, on the other hand, the public will in a great measure be protected from too high a price, by the alternative, they have of following the old methods; and if they gain by purchasing the new invention, the price put upon it by the inventor can hardly be said to be exorbitant. With respect to his doing his work in a careless manner, the public are equally guarded against this; for by such conduct, he would act against his own interest, and the sale of his invention.

If, indeed, we could suppose that government would examine, in all cases, thoroughly, impartially, and scientifically, into the merits of every invention, it might be better for them to throw it open to the public, by rewarding the inventor, though in this case, the nation at large would pay for what directly and materially benefited only certain classes, whereas, by letters patent, those reward the inventor, whose interest it is to reward him. On the whole, therefore, the present mode is the best, with perhaps this alteration, that the letters patent should vary in their duration, according to the importance of the invention, and the money and time expended by the inventor.
tween neighbouring flates, and endeavour amicably to accommodate the same.

PATERNA, among Antiquaries, a goblet, or vessel, used by the Romans in their sacrifices, in which they received the blood of their victims, offered their consecrated meats to the gods, and with which they made libations.

The word is formed from patero, I am open, good patera, because it had a great aperture; in contradistinction to bottles, &c.

On medals, the patera is seen in the hands of several deities; and frequently in the hands of princes, to mark the facerdotal authority joined with the imperial, &c.

Hence F. Joubert observes, that besides the patera, there is frequently an altar, upon which the patera seems to be pouring its contents.

The patera was of gold, silver, marble, bals, glass, or earth; and they used to enclose it in urns with the ashes of the deceased, after it had served for the libations of wine and liquors at the funeral. See PATRA.

The patera is an ornament in architecture, frequently introduced in friezes, fascias, and impolls, over which are hung tassels of hanks or flowers; and they are sometimes used by themselves, to ornament a space; and in this case it is common to hang a string of hanks or drapery over them: sometimes they are much enriched with foliage, and have a mask or a head in the centre.

PATERNA, in Geography, a town of Sicily, in the valley of Demons, built on the ruins of Ilybha, so celebrated for its honey. Hybha was ruined by the Saracens, who built a castle there, upon an ancient crater. The Normans erected a new building on the foundation of this ruined castle, which serves as a prison. The ruins of many baths erected here are still visible. The waters of different qualities which supplied these baths are now lost and so intermingled, as to cause the petilential air of Paterno, which, nevertheless, contains a population of from 10 to 15,000 persons; 15 miles W. of Catania.—Alfo, a town of Naples, in Principato Ultra, three miles N. of Monte Marano.

PATER-NOSTER, the Lord's prayer, a form so called from the two initial words thereof in Latin.

Pater-noster is also used for a chaplet or string of beads; because serving to number the rehearsals of that prayer.

PATER-NOSTERS, in Architecture, a sort of ornaments cut in form of beads, either round, or oval; used on baguettes, alfragals, &c.

PATER-NOSTERS, in Geography. rocks in the Atlantic, on the S. side of the entrance into the bay of St. Helena. S. lat. 32° 20'.—Alfo, rocks near the N. coast of the ifland of Jersey.

PATER-NOSTERS, Little, a clufher of thirteen rocks in the Eait Indian fea, between the iflands of Borneo and Celebes, called by the Malays, "Pulo Balabataken." They are covered with trees, and have navigable channels between them.

PATER-NOSTRES, Great, a clufher of ifhols and iflets in the Eait Indian fea, about 120 miles long from N.E. to S.W. and 50 broad. S. lat. 6° 30' to 7° 43'. E. long. 117° 10' to 119° 10'.

PATER-NOSTRE', in Heraldry. A crofs pater-noitre is a crofs made of beads. This crofs is to be fo shadowed in drawing, as that the sphericity of the beads may appear, to distinguish them from befants.

Gen. Ch. Cal. Sheath many-flowered, of two compressed, keeled, rigid leaves, embracing each other, with numerous inner membranous scales, separating the flowers. Cen. of one petal, falver-shaped, regular; tube very flender, about as long as the seath; limb in fix deep segments, three of them very large, obvate, horizontal, the three alternate ones very small, erect. Stam. Filaments three, united into a tube nearly all the way up, longer than the shorter segments of the corolla; anthers erect, oblong. Pet'nemen within the sheath, below the corolla, angular; style caudate, about as long as the stamens, generally swelling towards the top, contracted at the apex; stigma three, dilated, somewhat hooded, undivided. Peric. Capsule membranous, prismatic, with three blunt angles, three cells and three valves. Seeds numerous, roundish.

3 K

Obf.
Obf. There can scarcely be a doubt that this is the fame genus which Labillardiere calls Genusofis, however incorrec
tly he may have described it; happily however his name for it is exceptionable, being compounded of an established
name, Iris.

The species known are seven, all perennial herbaceous
fibrous rooted plants, with either none, or a short, moth
dle, flem. Leaves sword-shaped, narrow and compact.
Flower-stalk either radical, or terminal, simple, naked.
Flowers coming out in succession, handsome, but very short
lived, blue, without spots. Authors and fuggestion yellow.
Capsules nearly folidule, involuted with the fheaths. Seed:
usually inserted into the inner angle of the cell; sometimes
into a central column.—The species, as far as known, are
all natives of New Holland, moftly without the tropic,
growing in open, barren, fowy or sandy places, near the
shore; rarely in moift meadows.

—Stigmas defexed. Sheath, and upper part of the flalk,
silky. Leaves ftraight, finely fringed, doubly frigated,
woolly at the base of their keel.—Native of the country
about Port Jackson, as well as of the tropical part of New
Holland. It was one of the firit plants of which fpeci-
mens were fent to England by the fettlers. Meffrs. Lee and
Kennedy raifed it from feed, and it flowered with them in
1807, being kept in the greenhouse. The leaves are fe-
veral, erect, narrow, rigid, and elastifc, about a foot high,
in two ranks. Flowers violet, not unlike Tradefcantia virginica
at the flirit glace, but rather larger, without fcent.

2. P. lanata. Woolly Paterfonia.—Stalk round, frigated,
longitudinally woolly, as well as the fheath. Leaves fliely
 convex, finely frigated; woolly at the base.—Obferved by
Mr. Brown, in the fouth part of New Holland. The
fignment were not remarked.

3. P. longifolia. Long-leaved Paterfonia.—Stigmas def-
exed. Sheath and flalk silky. Leaves linear, narrow,
many times longer than the flalk; fringed below the middle
with fpreadging or infixed hairs.—From Port Jack-
fon.

Inner segments of the corolla but one-fourth as long as the
fube of the fiamens. Sheath fioy. Flower-stalk smooth,
longer than the flem. Keel of the leaves woolly at the fape.
—From Port Jackson.

Inner segments of the corolla half as long as the flube
of the fiamens. Flower-flalk longer than the flem, very smooth
and fhining, like the fheath. Keel of the leaves woolly at the
fape.—From the fame country.

6. P. glauca. Glaucescent Paterfonia. (Genofiris fra-ils;
Labill. Nov. Holl. v. 1. 13. t. 9.)—Stigma erect. Style
feightly thickened at the top. Sheath about three-feeded,
frigated, smooth. Leaves linear, rather convex, naked at
the edges and fape, twice as long as the flender, thread-
like, silky smooth flalk.—Gathered by Labillardiere, in Van
Damen’s land; by Mr. Brown near Port Jackson. The
vanes are enveloped at the flape by numerous shorter leaf-
like fcales. Corolla blue, rather smaller than in P. fericus.

Style of equal thicknes throughouit. Sheath about five-
feeded, even. Stalk very smooth, as long as the fword-
shaped leaves, which are naked at the edges and fape.—
Native of the fouth-west coast of New Holland, where it
was gathered by Mr. Brown, to whose work we are indebted
for the specific definitions of all the species.

PATEThIJSÆ. Vnvs, a name given by the ancients to
grapes which were suffered to remain on the vine till they
were greatly dried and withered. They were also called
patata ws, and were suffered to hang thus to make a
peculiar wine called paffum.

PATGONG, in Geography, a town of Hindooflan, in
Bengal; 120 miles W. of Beyhar.

PATH, in Rural Economy, a track or road across a field:
that path across arable land is as great a loss as a crooked
hedge, and shouid always be avoided as much as possible, both
in arable and pasture grounds, in the laying them out at
firt, where they are directed, on the inclining of wale or
other lands.

Path of the Vertex, a term frequently used by Mr. Flan-
neled, in his doctrine of the sphere, signifying a circle,
described by any point of the earth’s surface, as the earth
turns round its axis.

This point is considered as vertical to the earth’s centre,
and is the fame with what is called the vertex or zenith in
the Ptolemaic projection.

The demi-diameter of this path of the vertex is always
equal to the complement of the latitude of the point or
place that defcribes it; that is, to the place’s distance from
the pole of the world.

Pathy, the name given by us to the fly called in Latin
bumifaga; it is found in foot-paths, and supped to live by
fucking the ground; it is of a grey colour, flreeked with
dulkly white.

PATHETIC, pathie, from path, passion, emotion,
something that relates to the passions; and particularly
that is proper to awake or excite them.

In oratory, pathetic is applied to that part of a discourse,
or to that mode of exprefion, that is immediately addrcfled
to the Paffions (which fie), and which seems to render it in-
teresting and imprefive. In this part of a discourse, if any
writer, eloquence reigns, and exerts its power. Or the head
of the pathetic, Dr. Blair has laid down the following useful
directions. It should bef be considered whether the subjeft
admit of the pathetic, and render it proper; and if this be
the cafe, in what part of the discourse it fhould be attempted.

An attempt to excite the passions in a wrong place, may
expose an orator to ridicule. He should be careful, in
the first place, to bring over to his fide the understanding and
judgment; otherwife he is not likely to produce any benefi-
cial or permanent effect. That the emotion may not
only remain, when he ceafes to speak, molt writers affign
the pathetic to the peroration or conclusion, as its natural
place; and when all other things are equal, this is the
impression that one would choose to make last, leaving
the minds of the hearers warmed with the subject, after
argument and reafoning had produced their full effeét. But
wherever the pathetic is introduced, it is recommended,
secondly, never to fet apart a head of a difcourfe, in form, for
raising any paffion; never to give warning that you are
about to be pathetic, nor to call upon your hearers to follow
you in the attempt. This almost never fails to prove a
refrigerant to paffion. The indirect method of making
impression is likely to be more fucceflful. This may often
be done more happily, in a few infufions inspired by natural
warmth, than in a long and studied address. Thirdly, it fhould
be considered, that there is a great difference between fhow-
ing the hearers that they ought to be moved, and actually
moving them. To every emotion or paffion Nature has
adapted a fet of correpifonding objeets; and without fetting
there before the mind, it is not in the power of any orator
to raise that emotion. The foundation of all fucceflful
execution in the way of pathetic oratory, is to paint the
object of that paffion which we wish to raife, in the most
natural and flieking manner; to defcribe it with fuch cir-
cumstances
pat

Every passion is most strongly excited by emotion; next to the influence of sense is that of memory; and next to memory is the influence of the imagination. Of this power, therefore, the orator must avail himself, so as to strike the imagination of the hearers with circumstances, which, in language and gesture, resemble those of fame and remembrance. For this purpose, fourthly, the only effectual method is to move yourselves. The inward emotion of the speaker adds a pathos to his words, his looks, his gestures, and his whole manner, which excites a power almost irresistible over those who hear him. Fifthly, it is necessary to attend to the proper language of the passions. We should observe in what manner any one expresses himself who is under the power of a real and strong passion; and we shall always find his language unaffected and simple. It may be animal, indeed, with bold and strong figures, but it will have no ornament or fancy. He is not at leisure to follow out the play of the imagination. A person who takes time to polish and adorn his style, will infallibly cool his own ardour; and then he will touch the heart no more; his composition will become stiff; and it will be the language of one who describes but does not feel. Although he may amuse the fancy, he will not reach the heart. In the former case, labour may appear; but the latter must be the work of nature only. Sixthly, nothing of a foreign nature should be interwoven with the pathetic part of a discourse. All digressions must be avoided; beauties must be sacrificed; comparisons are always dangerous, and generally quite improper, in the midst of passion. Reasoning is unmeaning, especially if it be pursued in a long and subtle train, when the principal aim is to excite warm emotions. Lastly, the pathetic should not be prolonged too much. Warm emotions are too violent to be lasting. Study the proper time and mode of making a transition from the passion to the calm, recollecting a maxim, which, though trite, is just, that nothing dries up sooner than a tear. Beware, therefore, of straining passion too far, and of raising it to unnatural heights, as well as of prolonging its duration. Dr. Blair, to whose "Lectures" (vol. ii.) we refer for the illustration and application of these rules, closes with setting before his readers the example of Cicero in his last oration against Verres, wherein he describes the cruelty exercised by Verres, when governor of Sicily, against one Gavius, a Roman citizen. But our limits forbid our enlarging. See PERSUADATION and STYLE.

PATHEtIC, in Music. The general import of this word, which is purely English, is so well known, as seemingly to need no explanation; yet, to render music pathetic, so many circumstances must concur, that it has been thought necessary by Rousseau to point them out. The poetry, the musical composition, the figure, countenance, tone of voice, expression, and situation of the character represented, must all combine to produce the full effect of a pathetic air. All are requisite in dramatic and theatrical music, which tend to move and paint the great passions, particularly those of grief and sorrow.

All the expression which the French can give to pathetic airs, is to drag, reinforce the notes, and howl; and is so a flow a movement, that all sentiment of measure is effaced. Hence the French think, that whatever is flow is pathetic, and all that is pathetic ought to be flow. They have airs which become gay and playful, or tender and pathetic, as they happen to be sung quick or slow. Such is the advantage of French melody; it serves for whatever they please: fier avois, est, cum violets, arbor.

But Italian music has not the same advantages. Each long, each melody, has its distinct character so strongly impressed on it, that it is impossible to destroy the pathos of its accent and melody, which is felt in all measures, even in those the most lively. French airs change their character, as the time is accelerated or retarded. Each Italian air has its movement so determined, that it cannot be altered without annihilating the melody. An air thus disguised, does not change its character, it loses it; it is no longer melody, it is nothing.

If the pathetic character is not in the movement, we cannot say that it is in the genus, the melody, or the harmony: as there are pieces equally pathetic in the three genera, the three modes, and all the harmony imaginable. The true pathetic is in the accents of passion, which are not to be taught by rule; but let genius find, and the heart feel, without applying to art to give the law.

Nieuwent in tells us of a musician at Venice, who excelled in the pathetic to that degree, that he was able to play any of his auditors into distraction; he adds, that the great means he made use of was the variety of motions, &c.

PATHETICUS, in Anatomy, a name given by some anatomists to the nerve of the fourth pair, or nervus trochlearis. See Nerve.

PATHHEAD, in Geography, a considerable manufacturing town in the parish of Dyfart, and county of Fifo, Scotland, is situated on the activity of a hill, looking towards the Frith of Forth, at a short distance to the north-eastward of the ancient burgh of Kirkcaldy. It is divided into two parts, one called Dunnikier, and the other Sinclair-town, from the estates on which they happen to be respectively placed. Formerly Pathhead was noted for the number of its nail manufactories; but these have now considerably declined, and the inhabitants are chiefly engaged in different branches of weaving. There is no regular market held in this town; but it has the privilege of a large annual fair for woolen and linen cloths. According to the parliamentary returns of 1811, it contains 357 houses, and 1502 inhabitants.

On a free-stone rock, which projects into the Frith immediately below Pathhead, stand the venerable ruins of Riven's, or Raven's-Craig castle, which was granted, with the neighbouring lands, by James III. of Scotland, to William St. Clair, or Sinclair, earl of Orkney, on his resignation of that title. During the time of the commonwealth it was garrisoned by a party of Cromwell's troops, but is now uninhabitable. Beauties of Scotland, vol. iv. Sinclair's Statistical Account, vol. xvin.

PATHOGNOMONIC, in Medicine, from παθογνωμονικός, a disease, and παθωτής, I know, an epithet signifying that a symptom, or concourse of symptoms, to which it is applied, is inseparable from, or exclusively characteristic of, a particular disease, and found in no other. There is, perhaps, no disease in which any single symptom can be strictly said to be pathognomonic; but the concise definitions of diseases given by the neologists, should exhibit the congeries of symptoms which are pathognomonic. Thus the four symptoms, "fever, cough, dyspnoea, and pain in the chest," which constitute Dr. Cullen's definition of pneumonia, are the pathognomonic symptoms of inflammation of the lungs. See NOSELOGY.

PATHOLOGY, from παθος, a disease, and λόγος, a discourse, signifies the science or doctrine of diseases.

As Physiology teaches the nature of the functions of the living body in a state of health; so Pathology relates to the various derangements of these functions, which constitute disease. Its objects, therefore, are to ascertain the various symptoms which characterize the different disorders of each

3 K 2
organ of the body, and especially the diagnostic and patholog-
nomonic symptoms, which afford the means of discrimination
between diseases, which resemble each other; to determine the
causes, both predisposing and exciting, by which diseases are
induced; to point out the prognosis, or the tendency and
probable event of each disease, from the changes and combi-
nation of the symptoms; and, lastly, to teach the indications
of cure, and the nature and operation of the remedies adapted
to the various circumstances and periods of diseases.

The general doctrines of pathology, however, we have
already anticipated, under the head of Disease, an article
of more popular reference. See also Cause, in Medicine;
and Nosology, under which a classification of diseases will
be found.

PATIO, in Geography. See PATT.

PATIA, a river of South America, which rises near
Popayan, and runs into the Pacific ocean. N. lat. 2° 13'.

PATIALA, a town of Hindooftan, in the circlip
of Sirhind; 12 miles S.W. of Sirhind. N. lat. 30° 18'. E.
long. 76° 5'.

PATIENCE, in Botany, the name by which some
people call the monk's rhubarb; but the French, from
whom we have borrowed the word, mean by it all the
species of the lapathum or dock kind.

Pateience, in Ethics, is that virtue which prefers the
mind firm and unbroken, under the evils of life; so that
the spirits are kept from becoming tumultuous, and precip-
itating the sufferer into indolent or repenting thoughts,
words, or actions; and by which he is disposed to pay
calm attention to the reasons of sacred philosophy, and to
observe them.

Pateience, in Geography, a small island near the coast
of America, in Naragansett bay, belonging to the state of
Rhode island.

PATIENT, among Physicians, a person under the direc-
tion of a physician, or surgeon, to be cured of some disease.

Agent and Patient. See AGENT.

PATIENTIA, Straits of, in Geography, a channel of
the East Indian sea, between the island of Buhain, and the
S. coart of Gilofo.

PATIENTIAL, Musculus, in Anatomy, the levator
scapulae, so called, because it was supposed to be prin-
cipally concerned in shrugging up the shoulders. See
LEVATOR.

PATIMA, in Botany, a genus so named by Aublet from
t. 77. Juff. 207. Lamarck Dict. v. 5. 76. Illust. 1. 159.
—Cafts and order, Pentandria Monographia. Nat. Ord. Ru-
batilus. Juff.

Gen. Ch. Cal. Perianth superior, of one leaf, the limb
with about five incisions. Cor. and Stam. unknown. Pett.
Germen inferior, firmly united to the bottom of the calyx;
style and stigma wanting. Peric. Berry green, roundish,
crowned with the margin of the calyx, of four, five, or six
cells. Seeds numerous, very small, imbedded in soft pulp.

ObI. Juffieu and Lamarck observe, that, although
Aublet was unacquainted with some parts of the flower of
this plant, yet he has shown enough to satisfy them that it must
be monopetalous, and of the natural order of Rubiaces.

Eff. Ch. Calyx superior, almost entire, of six obtuse
angles. Berry crowned by the calyx, mottly five-celled,
many-seeded.

1. P. guianensis. Aubl. Guian. t. 77.—Native of low
marshy places in Guiana, bearing fruit in May.—Root peren-
nial. Stems numerous, shrubby, erect, three feet high, tu-
bular, cylindrical. Leaves opposite, on long stalks, very
large, ovate-oblong, acute, smooth, entire. Stipulis ina-
foliacceous, in pairs, short, acute, permanent, at the base
of the footstalk. Fruit axillary, consisting of green berries,
on longish solitary stalks.

PATIN, Guy, in Biography, a physician distingui-
shed for his wit and learning, was born at Hodenc, in Bray,
near Beauvais, in August, 1601. His parents being in humble
life, though respectable, his first views were not very ele-
vated. He was employed to study, afterwards, to a printing-
office at Paris, as corrector of the press, where his abilities gained
him the esteem and friendship of Riolan, a celebrated phy-
ician. In consequence of this connection, he was led to turn
his attention to medicine, and took the degree of doctor in
that faculty in 1627, and was admitted a member of the
Parisian body. He continued to reside as a practitioner in
that metropolis, where he was more esteemed, however, for
his learning, and the fatical vivacity of his conversation,
than for his medical skill. Indeed, he was too much attached
to personal independence to publish his way at court or among
the great, yet he had many persons of distinction among his
friends, particularly the president de Lamoignon, who
enjoyed his society as the greatest relaxation from the labour
of public business. Patin was, however, very zealous for the
maintenance of the honours and privileges of his faculty, and
was elected dean in the two successive years 1650 and 1651;
and, soon afterwards, was appointed succesor to Riolan the
younger, in the chair of medicine at the College Royal. He
expressed himself in Latin with so much facility and elegance,
that his theses became the centre of attraction to the fasible
idlers of Paris. He was a great opponent of all innovations in
medicine, but more especially of the doctrines and drugs
introduced by the chemical physicians; and he purred a violent
course in the dispute, which at that time agitated the phy-
sicians of Paris, respecting the virtues of antimony.
He was even profuse in his personalities against all who de-
defended that medicine, and drew up a long register of the un-
successful cases in which it had been employed, which he
called the Antimonial Martyrology. He derided, however,
the complicated and colly compounds and specifics, which the
generality of practitioners were in the habit of preferring;
and was of opinion, that by means of the lancet and
purgatives, and a few simple expeditious, every thing within
the power of the healing art might be accomplished; a ra-
tional and just view of the subject, if it had not been per-
verted by other false theories, and by strong prejudices with
respect to bloodletting, and some particular articles of med-
cine.

This learned physician died in 1673, in the seventy-first
year of his age. He had read much, and had collected an
extensive and valuable library, with the contents of which he
was well acquainted: but he wrote few works in his own
profession, and of these of little importance. He had projected
a history of celebrated physicians, but this he never ac-
complished. After his death a great number of his letters were
published, which have been the chief means of preserving his
memory. Of these there are two collections; one address-
ed to various friends, printed in 1685 and 1692, two volumes
12mo; the other all written to his friend Charles Spon, of
Geneva, and published by that family in 1718, two volumes
12mo. Patin's letters are an amusing miscellany of political
and literary intelligence, biographical anecdotes, free op-
inions, medical history and criticism, with a plentiful mixture
of fpleen and farceum. It is difficult to say whether he lashes
most severely the court and ministry, the clergy, or the che-

dical
nical doctors; but the pictures which he gives of the manners and sentiments of the time are in most respects equally just and lively. Eloy Dict. Hist. Gen. Bing.

PATIN, CHARLES, a physician and distinguished antiquary, was the second son of the preceding, and was born at Paris in February, 1633. His father educated him with great care, and he made a very extraordinary progress in learning, having, at the age of fourteen, sustained theses in philosophy in Greek and Latin, before a large and splendid audience, at which there were thirty-four bishops present, besides many other persons of distinction. He was intended to be brought up to the bar, and even became a licentiate in law at Poictiers, and afterwards an advocate in the parliament of Paris: but he afterwards abandoned the profession of the law, and chose that of physic, in which he took the degree of doctor in 1676. He had not only begun to practice with reputation and success, but had also taught in the schools of the faculty of Paris, when he was obliged to quit France, from the fear of imprisonment. The cause of this disgrace is somewhat doubtful. By some it has been said, that, having been sent into Holland by a great prince, in order to buy up all the copies of a work of court scandal, and burn them on the spot, he favored a number of them, and dispersed them among his friends. His father, however, in one of his letters, lamenting his son's misfortune, gives no hint of such a fact, but mentions the discovery of some obnoxious books in his library. After spending a few years in traveling through Holland, England, Germany, and Switzerland, to Italy, he at length settled with his family at Padua, where he soon acquired the public esteem. In 1676, he was appointed to an extraordinary professorship of medicine in that university; and in 1681, he was transferred to the first chair of surgery; and ultimately, in 1683, to that of medicine. He fulfilled the duties of these stations with much distinction, that the republic of Venice conferred on him the dignity of a knighthood of St. Mark. He was also elected a member of the Academia Naturae Curiosorum, and he was for a long time chief and director of the Academy of the Ricovrati. He died at Padua, on the second of October, 1693. He left a considerable number of learned works, amounting to nearly 40, in the Latin, French, and Italian languages. Few of these relate to medicine, and those only in the form of detached observations; such as “Oratio Inauguralis de optimo Medicorum Sociâ.” “Oratio de Fideibus,” “De Avicenna,” “De Scorbuto,” &c. The works by which he is best known, relate to the numismatic, or medallie science, in which he was a great proficient. The following are upon that subject. “Famihae Romanae antiquis numismatibus ab urbe condita ad tempora D. Augusti,” 1663, folio. This is chiefly founded on the work of Fulvius Urtinus. “Introduction à l’Histoire par la Connaissance des Medailles,” 1665, 12mo. “Imperatorum Romanorum Numismata,” 1671, folio. “Theaurum Numismatum,” 1672, 4to. “Practica delle Medaglile,” 1673, 12mo. “Suetonianus ex Numismatibus illustratus,” 1675, 4to.; and some other pieces. In the way of medical biography, he published the lives of the professors of Padua, with the title of “Lyceum Padatium, live Icones et Vitae Professorum Patavii, anno 1682. decincentum.” Pat. 1682, 4to.

The wife and two daughters of Charles Patin were learned women, and all members of the Academy of Ricovrati; at Padua, in which they distinguished themselves. Charlotte-Catherine, the eldest daughter, pronounced a Latin oration on the raising of the siege of Vienna, and published “Tabella felecta,” which contained an explanation of forty-one engravings from the most celebrated painters. Gabrielle-Charlotte, the youngest daughter, published a panegyrical oration on Louis XIV., and a Latin dissertation on the phœnix on a medal of Caracalla, Venice, 1683. His wife was author of a collection of moral and Christian reflections. Eloy Dict. Hist. de la Med. Gen. Bing.

PATIN-MA, in the Ange. See PATTIN-MA.

PATINA, a name given to the ruff of medals. See Confiruation of Medals.

This ruff, which, when genuine, gives value to medals, is sometimes counterfeited, and a false patina is substituted for that which is true. The false varnish is black, green, and shining, besides being very tender when touched with a needle or burin; while the ancient has none of these qualities, and is as hard as the coin itself. Sometimes, says Mr. Pinkerton, a light-green coat-like varnish is given, spotted with a kind of iron marks. It is made of sulphur, verdigris, and vinegar; and is often diffused, among other marks, by hair-strokes of the brush with which it was laid on. Vico, cited by Pinkerton, gives the following hints concerning false patina. He says it is green, black, ruffet or brown, grey, and iron-colour. The green is made with verdigris; the black is smoke of sulphur; the grey is formed of chalk steeped in wine, in which the coin is left for some days. The ruff is next to the natural, because it is a kind of froth which the fire forms from ancient coins; but when false it is too thinning. To make it, they often take the large brass coins of the Ptolemies, because they are frequently corroded, and making them red-hot in the fire, put the coins upon them; and there adheres a fine patina. The proceeds of iron colour Vico does not explain. Sometimes, he adds, they take an old defaced coin, covered with real ancient patina, and stamp it anew; but the patina is then too bright in the cavities, and too dull in the protruberances. It may further be observed, that the trial of brass coins with the tongue is not to be despised; for, if modern, the patina tastes bitter, or pungent; while, if ancient, it is quite tasteless.

PATINO, in Geography, an island in the Grecian Archipelago, which was the ancient Patmos. See PATMOS.

PATINOON, a town of Hindostan, in Marawar; 72 miles N.W. of Ramnadapuram.

PATIOQUA, a town of Mexico, in the province of Guazaca; 62 miles S. of St. Yago de los Valles.

PATIS, in Ornithology, the name of a small sea-bird, described by Ovidius, and seeming to be the same with the flamink, described by Heron, in his epitile to Clusius. It is a little larger than our sparrow, and skims the surface of the water very nimbly, and is supposed a forerunner of swans.

PATIIX, or Grande River, in Geography, a river of Brazil, which runs into the Atlantic, S. lat. 15° 50'

PATKUL, JOHN REINHOLD, in Biography, was born of a noble family in Livonia, a northern province belonging to the crown of Sweden. The Livonians having been stripped of their privileges, and great part of their estates, by Charles XI., Patkul was deputed to make their complaint; which he did with such eloquence and courage, that the king, laying his hand upon his shoulder, said, "you have spoken in behalf of your country as a brave man, and I esteem you for it." Charles, however, who added the beneficet of hypocrify to the fer-city of a tyrant, was determined to punish the zeal and honesty which he had just before applauded, and in a very few days afterwards caused Patkul to be declared guilty of high treason, and condemned him to death. The hero, however, found means to escape into Poland, where he continued till Charles was dead. He now hoped that his sentence might have been revered, but being disappointed in this expectation, he applied to Augustus, king of Poland, and solicit
excited him to attempt the conquest of Livonia from the Swedes; which he said might be easily effected, as the people were ready to shake off their yoke; and the king of Sweden, being a child, was incapable of compelling their submission. Augustus took the hint, possessed himself of Livonia, and afterwards, when Charles XII. entered the province to recover it, Patkul commanded in the Saxon army against him. Charles was victorious, and Patkul entered into the service of the czar of Russia, with whom Augustus was in strict alliance. The czar sent Patkul, with the title of his ambassador, into Saxony, to prevail with Augustus to meet him at Grooto, that they might confer on the fate of their affairs. This conference took place, and immediately afterwards the czar went from Grooto to quell a rebellion in Atracian. As soon as the czar was gone, Augustus, to the surprise of all Europe, ordered Patkul, who was then at Dresden, to be seized as a traitor criminal. The czar claimed him as his ambassador, and Charles demanded that he should be put into his hands. The latter obtained his wish, and cruelly put him to death, in the year 1707. Charles XII. has been generally cen~ured for not extending to him his mercy, but it must not be forgotten that Patkul had incited foreign powers to attack his country when the king was a mere child, hoping that, under such circumstances, it would become an easy conquest. It has been said also in behalf of the king, that this is the only infallence of his cruelty, and that in ordering the execution of Patkul he thought he was doing his duty. Nothing, however, can palliate the unfeeling barbarity of putting the veteran to the rack. The monarch was one of the credulous philosophers of the time, who believed in the possibility of discovering the methods of transmuting the hafer metals into gold. Patkul, while under sentence of death, contrived to far impose on the senate at Stockholm, as to persuade them that he had, in their presence, converted to gold a quantity of lbs. precious metal. An account of the experiment was transmitted to the king, accompanied with a petition for the life of so valuable a subject; but Charles, blending magnanimity with severity, replied, that he would not do that for interest which he had refused at the call of humanity and the intricacies of friendship.

PATLADAH, in Geography, a circar of Bengal, bounded on the N.E. by Curriharry, on the S. and S.E. by Dacca, and on the W. by Goragot and Islamabad; about 30 miles long, and 16 broad. The chief towns are Chilmary and Dewangan. PATMOS, in Ancient Geography, an island in the Grecian archipelago, now denominated by navigators "St. Jean de Patino," celebrated in ecclesiastical history, on account of its being the place of St. John's exile, and still more from the revelations and visions which he received there, and which form the subjects of the Apocalypse, or Revelation, exhibits little more than an island and rocks and numerous caves. Some Calympers, or Greek monks, who inhabit a monastery built on an eminence, still shew the grotto where the sacred writer received his communications and wrote his book. But in this convent there is no library, and, indeed, it would be of little use, as among the 80 monks who reside there, three only were found who could read, and they made little use of their scanty knowledge. This island is little more than six leagues in circuit; considerably longer than breadth, its direction being from N. to S., and its form very irregular. Its coasts are intersected by a variety of gulfs and coves, and are remarkable for the number of good harbours which they present to navigators, among which that of "Scala" is one of the finest in the Archipelago. But notwithstanding the advantages which these harbours might afford it as a place of trade, it presents to the view of the observer a very wretched appearance. Valleys, which might infuse abundance, are uncultivated, and from their state of abandonment and nakedness, offer, with the hills that surround them, only the same aspect of ruggedness and misfortune. Population, which follows in the train of agriculture and industry, is here singularly diminished, and while the monasteries swarm with flaggards, the fields become deserted. In the summer few men remain here; they all migrate to a distance to seek means of subsistence, or carry on with their calques, a traffic which feeds, but does not enrich them. The women remain intruded with domestic cares, and to make the most of a few pieces of land draining the absence of their fathers or husbands; and that timid tribe hide or shut themselves up when they see strangers land in their island. Such is the account given of this desolate spot by Sonnini. Although it is delineate of wood and rivers, and almost without gardens, its spring-water is pure and its air healthy. The inhabitants are chiefly Greek Christians, sailors or ship-builders, who fail as far as Venice, whither they carry cotton and stockings of their own manufacture. The island abounds with rabbits, pigeons, partridges, and quails. The abbot of the convent already mentioned is prince of the island, and pays annually 1000 crowns to the grand feignor, besides presents to the captain pacha: 16 miles S.W. of Samos. N. lat. 37° 24'. E. long. 26° 24'.

PATMOUR, in Geography, a town of Hindooftan, in Groedna; 25 miles N.E. of Rachore.

PATNA, a very ancient city of Hindooftan, erected on or near the site of Patalkuta, or Patpoloober, afterwards denominated Palibothra. This is the chief city of Bahar, and is very extensive and populous; built along the four chief banks of the Ganges, about 400 miles from Calcutta, and 500 from the mouth of the river. As it is seated on an eminence, it is secure against the inundations, which, at particular seasons, are prejudicial and dangerous. Having been often the seat of war, it is fortified in the Indian manner with a wall and a small citadel. It is a place of very considerable trade. Moft of the salt brought inland from the East India company is manufactured within the province of Bahar. N lat. 25° 34'. E. long. 85° 21'.

PATNA, a town of the province of Bukovina; 30 miles W. of Suceava.—Alloa, a river of Moidavia, which runs into the Milebow, at Foedna.

PATNOU EA, a town of Hindooftan, in the circar of Kerich: 55 miles N.W. of Maltoy.

PATOCA, a town of Hindooftan, in Dowlatabad: 30 miles N.W. of Dowlatabad.

PATOMA, a river of Russia, which runs into the Lena, N. lat. 59° 55'. E. long. 116° 24'.

PATOMACK. See PATWACK.

PATONCE, in Heraldry. A cross patione is a cross flory at the ends; from which it only differs in this, that the ends, instead of turning down like a fleur-de-lis, are extended somewhat in the patee form. He bears gules; a crois patione, argent; by the name of Latimer.

PATOMACK, a river of Hin- door, which runs into the bay, N. lat. 15° 55'. W. long. 84° 25'.

PATOMACK, a river of Brazil, which runs into the Atlantic, S. lat. 28° 28'.—Alloa, a town of Mexico, in the province of Zacatecas; 80 miles N. of Zacatecas.

PATOU, a town of Hindooftan, in the circar of Aurungabad: 45 miles E. of Aurungabad.

PATOUAL, a town of Hindooftan, in Bagliana; 18 miles S.E. of Bahbelan.

PATWACK, a large river of America, which rises by two branches, the northern and southern, originating in and
and near the Alleghany mountains, and forms, through its whole course, part of the boundary between the states of Virginia and Maryland. It runs by many flourishing towns, the chief of which are Shepherdstown, Georgetown, Washington city, Alexandria, New Marlborough, and Charlestown, or Port Tobacco. It is seven miles and a half wide at its mouth, and its foundings are few fathoms. The distance from the capes of Virginia to the termination of the tide-water in this river, is above 300 miles, and it is navigable for ships of the greatest burden through nearly that distance; and the inland navigation it affords is much extended by the numerous and long rivers that run into it.

PATQUASHAGAMA LAKE, a lake of Canada, 450 miles W. of Quebec. N. lat. 48° 20'. W. long. 82° 5'.

PATRA, a town of Hindooistan, in Guzerat; 18 miles N.N.E. of Aoomod.

Patra, a vessel of capacity among the Hindoos, to which, under a mythological aspect, a great deal of mysticism is attached. It is seen in the land of Parvati, and of some other deities of avenging character, in the shape of a small basin or cup, and is said to be the purpose of receiving the blood of her victims, which she is poetically represented to quaff. The patra is, however, little more mystically contemplated in India, as an emblem or type of the world, and is then called Argha-patra.

The argha means a cup or dish, in which fruits or flowers are offered to the deities, and ought to be shaped like a boat, as some are still seen, but more usually of a round form. A rim round the argha represents the mysterious Yoni, and a bo6 or convexity in the centre refers to the navel of Vishnu, whence, according to some popular fables, the creative Brahma sprang on a lotus to perform his great work. We shall here notice no farther on this point than the coincidence of wild umbilical mysteries common to the mythologies of India, Egypt, and Greece. Such mythological coincidences are striking and curious, and we shall proceed to notice some connected with the subject of this article. The name, form, and use of it as a drinking-veil, or for oblation, reminds us at once of the patera of the ancients. See PATERA.

In vol. xiv. of the Archæologia, a description and plate are given of a Roman patera and vase dug up when sinking a ditch in Effex in June 1800. They were found near an ancient Roman road between Camulodunum and Camboritum. "The metal vase and patera merit attention, as more similar to the first have been figured or described in the works of the society; nor do I know that any like either have been presented for their inspection. The vase is of that form which Montfaucun has figured in his vol. pl. 19. fig. 10., and calls a praefericulum, used by the Romans at their sacrifices, for pouring wine into the patera. See p. 88, where he controverts Fellus's opinion that the praefericula were without handles. Another more nearly resembling that here presented is given in his vol. pl. 24. fig. 9, and called by Beger an epichysis, but not allowed to be such by Montfaucun. The metal patera which belongs to the above, differs from the earthen patera, in general, by being boggled in the centre, a circumstance not easily to be accounted for, unless it was for the firmer fixing the praefericulum upon, when placed with the body at the time of interment." With the above Roman antiquities were found severall little cups of Samian ware. "The uses of these elegant little cups have not," the antiquary continues, "that I know of, been ascertained by any author. The real purposes to which they were applied may remain at present in obscurity."

The learned author of this communication, Thomas Walsh, Esq. F. A. S. earnestly invites an explanation of these several Roman antiquities. It is, perhaps, no explanation to state that the Hindoos, in their sacrifices and ceremonies, have immemorially used, and still use, articles exactly similar to those exhibited, with the above communication, in vol. xiv. of the Archæologia, pl. 4. and 5. But it is curious to see how nearly they agree in form. A comparison of the article in the plates just adverted to, with those in plates 83, 86, and 105. of the Hindoo Pantheon, will strikingly convince this. The "sacrificial vase," in the latter plate, has the same form, though more elaborately ornamented, as the above described praefericulum; and the others exhibit metallic circular patera, and the central emboffment, which, though "not easily accounted for," is found among Hindoo mystics to have very profound allusions. The Roman patera has also the mysterious rim or Yoni, respecting which the reader may consult the work last referred to Dr. Clarke, in his recently published "Travels," notices that "the pateras used by priestesses in the rites of Ceres, had this pyramidal node or cone in the centre. A priestess is represented holding one of these, on a bas-relief, in the vestibule of Cambridge University Library." Vol. ii. p. 344.

Greek marbles, No. xv. p. 37. Similar articles are still used in the rites of the Hindoo Ceres; and are also the "little cups" described and exhibited in the Archæol, as above referred to, and in many of the plates of the Hindoo Pantheon. In India they are used for holding clarified butter, a common ingredient in the frequent oblations to fire; and ungents, and holy water, in the Sradha or funeral obsequies, and in other rites and ceremonies.

Adverting for a moment to the place near which the Roman patera was found, we may remark, without laying any stress on it, that Camulodunum might, by a determined etymoquity, be derived from the Sanscrit word Kama, or goddes Kamala, see that article. And long after this remark was written, we find such a derivation adopted in the 11th vol. of the Asiatic Researches, art. ii. ch. 4.

It is shown under the article SIVA of this work, that any objects conical or pyramidal are peculiarly typical of that deity. The mysticums connected with that igneous form, he being a perfonification of fire with the Hindoos, are endless. Sufficient, probably, thereon will be found under the articles LINGA, MERU, YONI, and others thence referred to; if not, the reader may farther consult those articles in the Hindoo Pantheon.

PATRÆ, or PATRAS, in Ancient Geography, a town of Achaia, on a promontory, N. of mount Panachaicus. It was more anciently called "Aroé," derived, as it is said, from apó, I labour, and applied to it, probably from its being the first place of Achaia in which the inhabitants occupied themselves in labour. Patras, one of the chiefs of the Achaeans who were driven from Lacedaemon on the arrival of the Heraclida, enlarged and fortified Aroé, and gave it its own name. Of all the Achæans the inhabitants of Patras were the only persons who defended the Ætolians, when they were attacked by the Gauls. This incursion was probably that of the year 278 B.C., and this followed the irritation of this people into Macedonia, in the preceding year, when they were defeated. Augustus, allured by the situation of Patras, collected the scattered inhabitants, and re-established them. He also united several towns under its dominion, and conferred on the inhabitants all the advantages enjoyed by Roman colonies. In the time of Paunalias this town was adorned with a statue of Diana Laphria, an odeum, which, next to that of Athens, was the most beautiful in Greece, and a fountain near the temple of Ceres, where oracles were inscribed for the relief of bodily maladies. Paunalias says, that Patras contained more women than men, and that they employed...
ployed themselves in spinning the silk of the country, and in the manufacture of flufs.

**PATRAS**, in Geography, a feet-port town of the Morea, situated on the S. coast of the entrance into the gulf of Lepanto. (See the preceding article.) This town is the fee of a Greek archbishop, and contains about 80 Christian families, 250 of Turks, and 108 of Jews. Confus from England, Holland, and Venice, have been accustomed to refuse here. The principal articles of trade are coarse oil, flilk, honey, wheat, manna, &c. In the year 1447 this place made a brave defence against sultan Murat, and held out till peace was concluded, when the Morea was surrendered to the Turks. The port is choked with mud, and the road for vessels is very indifferent; 28 miles N.E. of Chiarenza. N. lat. 38° 33′ E. long. 21° 41′.

**PATREE**, a town of Hindooftan, in Guzerat; 70 miles W. of Amedabad.

**PATRES CONSCRIPTI**, in Antiquity, a denomination given to the senators of Rome.

The first hundred senators, appointed by Romulus, were called simply patres, fathers; another hundred being added by Romulus and Tatius, upon the union of the two people, these latter were called patres minorum gentium, and the former majorum gentium.

At length Tarquinius Priscus, making up the number three hundred, the two latter classes were called patres conscripti, because auctor, or written down to the former.

Livy gives a different account of their origin. See CONSCRIPTI.

Thofe afterwards chosen from among the knights were called patres adlecti.

**PATREZ**, a name for a fort of vermiciell, a pale made of flour and water, and formed into heads. This and all other kinds of palms, which are often flained with saffron.

**PATRI, GLORIA,** See GLORIA.

**PATRIA**, in Geography, a town of Naples, in Lavora, near a lake to which it gives name; 13 miles N.W. of Naples.

**PATRIAM, TRIAL PER, in Law.** See JURy.

**PATRIARCH, PATRARCHA**, formed of pater, father, and patric, chief, one of those first fathers who lived towards the beginning of the world; and who became famous by a long line of descendants.

Abraham, Isaac, and Jacob, and his twelve sons, are the patriarchs of the Old Testament. Seth, Enoch, &c. were antediluvian patriarchs.

Long life and a number of children were the blessings of the patriarchs.

The patriarchal government consisted in the fathers of families, and their first-born after them, exereting all kinds of ecclesiatical and civil authority in their respective households; and to this government, which continued till the time of the Israelites dwelling in Egypt, some have ascribed an absolute and despotic power, extending even to the punishment by death. In proof of this, they allege the curse pronounced by Noah upon Canaan, Gen. ix. 25; but it is replied that in this affair Noah seems to have acted rather as a prophet than a patriarch. Another instance of unfounded despotic power is Abraham’s turning Hagar and Ishmael out of his family, Gen. xxii. 9, &c.; but this furnishes no evidence of any fqugar authority vested in the patriarchs as such, and peculiar to those ages. The third instance alleged to the fame purpose is that of Jacob’s denounced a curse upon Simeon and Levi, Gen. xiix. 7, which is maintained by others to be an instance of prophetic inspiration more than of patriarchal authority. The fourth instance is that of Judah with regard to Tamar, Gen. xxxviii. 24; concerning which it is observed, that Jacob, the father of Judah, was still living, that Tamar was not one of his own family; and that she had been guilty of adultery, the punishment of which was death by burning, and that Judah on this occasion might speak only as a protector. Jennings’s Jewish Antiq. vol. i. p. 1, &c. Sydney’s Discourses concerning Government, chap. i. sect. 7.

**Patriarch** is also used, in Chriftendom, for the bishops in possession of some of the grand fees, independent of the papal jurisdiction; or for the chief bishop over several countries or provinces, as an archbishop is of several dioceces; who hath several archbishops under him.

The patriarchate has been always esteemed the supreme dignity in the church: so that, to rise by degrees, the bishop had only under him the territory of the city of which he was bishop; the metropolitan commanded a province, and had for suffragans the bishops of his province; the primate was the chief of a diocese, and had several metropolitans under him; and the patriarch had under him several dioceces, and the pri- mates themselves were under him. But this order was not always observed.

Ufher, Pagi, De Marca, and Morinus, attribute the estabishment of the grand patriarchates to the apostles. They suppose that the apostles, according to the description of the world then given by geographers, pitched on the three principal cities in the three parts of the known world; viz. Rome, in Europe; Antioch, in Asia; and Alexandria, in Africa; and thus formed a trinity of patriarchs.

Others, far from attributing this institution to the apostles, maintain that the name patriarch was unknown at the time of the council of Nice; and that, for a long time afterwards, patriarchs and primates were confounded together; as being all equally chief of dioceces, and equally superior to metropolitans, who were only chief of provinces. Hence it is that Socrates gives the title patriarch to all the chiefs of dioceces, and reckons ten of them. In effect, it does not appear, that the dignity of patriarch was appropriated to the five grand fees of Rome, Conflantinople, Alexandria, Antioch, and Jerusalem, till after the council of Chalcedon, in 451. For when the council of Nice regulated the limits and prerogatives of the three patriarchs of Rome, Antioch, and Alexandria, it did not give them the title of patriarchs, though it allowed them the pre-eminence and privileges thereof. Thus, when the council of Conflantinople adjudged the second place to the bishop of Conflantinople, who, till then, was only a suffragan of Heraclea, it said nothing of the patriarchate.

Nor is the term patriarch found in the decree of the council of Chalcedon, whereby the fifth place is assigned to the bishop of Jerusalem; nor did these five patriarchs govern all the churches.

There were still many independent chiefs of dioceces, who, far from owning the jurisdiction of the grand patriarchs, called themselves patriarchs: such as that of Aquileia; nor was Carthage ever subject to the patriarch of Alexandria.

Moheim supposes, that those prelates who enjoyed a certain degree of pre-eminence over the rest of the episcopal order, were distinguished by the Jewish title of patriarchs in the fourth century. Escl. Hist. vol. i.

The authority of the patriarchs grew by inefinible degrees, till at length we find, that about the close of the fifth century, all affairs of moment, within the compafs of their patriarchate, came before them; either at first hand, or by appeals from the metropolitans.

They consecrated bishops, assembled yearly in council the clergy of their respective distrits; pronounced a decisive judgment in thotic cases where acceptions were brought against
against bishops; and appointed vicars or deputys, clothed with their authority, for the preservation of order and tranquility in the remotest provinces.

Nothing, in short, was done without consulting them; and their decrees were executed with the same regularity and respect as those of the princes.

It must, however, be observed, that the authority of the patriarchs was not acknowledged through all the provinces without exception. Several districts, both in the eastern and western empires, were exempted from their jurisdiction.

The Latin church was unacquainted with patriarchs till the sixth century; and the churches of Gaul, Britain, &c. were never subject to the authority of the patriarch of Rome, whose authority only extended to the subburbaric provinces. There was no primacy, no exarchate nor patriarchate, owned here; but the bishops, with the metropolitans, governed the church in common.

Indeed, after the name patriarch became frequent in the West, it was attributed to the bishops of Bourges and Lyons; but it was only in the first signification, viz. as heads of dioceses. Du Cange adds, that there have been some abbots, who have borne the title of patriarchs.

Patriarch is also applied to the chief of several churches in the East, who live out of communion with the Roman church; such are the patriarch of the Armenians, residing in the monastery of St. Gregory; the patriarch of the Abyssinians, called Abuna; the patriarchs of the Cophts, the Jacobites, &c. See ARMMENNS, COPHTA, JACOBITAE, &c. See also GREEK CHURCH.

Patriarchal, in Heraldry. A patriarchal cross is that where the shaft is twice crossed; the lower arms of traverse being longer, and the upper shorter. Such a cross is false to the patriarchs, as the triple cross does to the pope.

Patricia, in Geography, a town of Italy, in the Campagna di Roma; 13 miles S. of Rome.

PATRICK, PATRICUS, in ancient Rome, a title given to the defendants of the hundred, or, according to others, of the two hundred first seneiores chosen by Romulus, and by him called patries, fathers.

Romulus established this order in imitation of the Athenians, who were divided into two classes, viz. the ωνεδως, patricios, and δημοκρατος, popularares.

Patricians, therefore, were originally the ancient nobility; in opposition to the plebeians.

They were the only persons whom Romulus allowed to aspire after the magistracy; and they exercised all the functions of the priesthood till the year of Rome 495.

But the cognizance and character of these ancient families being almost lost and extinguished, by a long course of years, and frequent changes in the Empire; a new kind of patricians were at length set on foot, who had no pretensions from birth, but whose title depended wholly on the emperor's favour.

This new patriciate, Zoilus tells us, was erected by Constantine, who conferred the quality on his counsellors, calling them patricii, not because descended from the ancient fathers of the Senate, but because they were the fathers of the republic, or of the empire.

This dignity, in time, became the highest of the empire. Julian calls it summam dignitatem; in effect, the patricians seem to have had the precedence of the consuls, and to have taken place before them in the Senate; though F. Faber affords the contrary. What embroils the question is, that the two dignities often met in the same person; because the patriciate was only conferred on those who had gone through the first offices of the empire, or had been consuls.

Pope Adrian made Charlemagne take the title of patrician before he assumed the quality of emperor; and other popes have given the title to other kings and princes, by reason of its eminence.

Patrician, Patricius, is also a title of honour frequently conferred on men of the first quality in the time of our Anglo-Saxon kings. See THANE.

Patrician, in Ecclesiastical Writers, denote ancient sectaries who disturbed the church in the beginning of the third century; thus called from their founder Patricius, preceptor of a Marcionite called Symmachus.

His distinguishing tenet was, that the substance of the flesh is not the work of God, but that of the devil; on which account his adherents bore an implacable hatred to their own flesh; which sometimes carried them so far as to kill themselves.

They were also called Tatianites; and made a branch of the Eneratica.

Patricide, Patricidium, the fame with patricide.

Patrick, Simon, in Biography, a learned English prelate, was the son of a mercer at Gainborough, in Lincolnshire, where he was born in the year 1626. Great care was taken of his education; and having been well grounded in classical learning, he was, in 1644, sent to Queen's college, Cambridge. He took his degree of B.A. in 1647, and in the following year was chosen fellow of his college. In 1651 he took his degree of M.A. and about the same time received holy orders from Dr. Joseph Hall, bishop of Norwich. He next became domestic chaplain to Sir Walter St. John of Battersea, who presented him to that living towards the beginning of the year 1658. In 1661 Mr. Patrick was elected master of Queen's college by a majority of fellows, notwithstanding the king's recommendation of Mr. Anthony Sparrow; but the affair being brought before the king and council, judgment was speedily given against our author, and some, if not all, of the fellows who had voted for him were ejected. Upon the election of Dr. Manton from the rectory of St. Paul's, Covent-Garden, in 1665, Mr. Patrick was presented to that benefice by the earl of Bedford; and he won the affection of the parishioners, not only by his preaching and exemplary manners, but particularly by his constant residence among them, during the time of that awful calamity the plague. In the year 1666, being disguised at some circumstances that happened at Cambridge, he entered himself of Christchurch college, Oxford, where he was at first incorporated bachelor, and soon afterwards was admitted doctor of divinity; and about the same time, he was appointed chaplain in ordinary to the king. In 1672 Dr. Patrick was made a prebendary of Welminster; and his next promotion was to the deanship of Peterborough, in 1679, where he completed and published, in the year 1686, "The History of the Church of Peterborough," from the manuscript of Simon Gunton, formerly a prebendary of that church. Dr. Patrick made very considerate additions to it, and added a supplement, containing a fuller account of the abbeys and bishops of Peterborough than had been drawn up by Mr. Gunton. In 1680 Dr. Patrick had the offer of the valuable living of St. Martin's-in-the-Fields from the lord chancellor Finch; but he declined accepting it, on account of the regard which he felt for his parishioners of Covent-Garden; and on this occasion
he recommended Dr. Thomas Tenenfon, who was presented to that rectory. During the reign of James II., Dr. Patrick, in opposition to all his worldly interests, shewed his zealous attachment to the Protestant religion, by writing and preaching against the errors of the church of Rome. The sovereign endeavored to reason with the doctor on the subject, but to no purpose: he told the king very plainly, "that he could not give up a religion that was so well proved as that of the Protestants." His zeal went much farther than this; he opposed, to the utmost of his power, the reading of the king's declaration for liberty of conscience, which was published in favour of the Papists; and he advised Dr. Tenenfon in establishing a school at St. Martin's, to counteract the influence of the Popish one opened at the Savoy, for the purpose of making converts of the children of poor Protestants. At the revolution, he was called upon to preach before the prince and princes of Orange, who paid him particular attention; and in 1689 he was nominated to fill the vacant see of Chichester. He was next employed, with others of the episcopal bench, in settling the affairs of the church of Ireland; with which view, they first back all the clergy who fled into England for refuge from the tyranny and persecution of the late reign. In the year 1691 the bishop was translated to the see of Ely, of which he proved himself a liberal benefactor, by the improvements which he introduced into its temporalities. At the same time he consecrated his labours to the interests of piety and virtue, by many valuable writings. He died at Ely in 1701, in the 81st year of his age. His works were numerous, but the most important are his "Commentaries" upon the historical books of the Old Testament, and "Paraphrases" on the books of Job, Psalms, Proverbs, Ecclesiastes, and Solomon's Songs. These were collected into three volumes, folio, and, with Lowth's "Commentaries" upon the Prophets, Arnold's upon the Apocrypha, and Whitby on the New Testament, form a complete collection, in high estimation. Biog. Brit. Toulmin's Neal.

Patrick, in Geography, a country of Virginia, in America, containing 6662 free, and 6473 black people. Patrick's, S., a small island in the Irish sea, near the east coast of Ireland. N. lat. 53 36', W. long. 6° 5'. Patrick's, S., a small town, the chief of Camden county, Georgia, situated on Great Satilla river, about 32 miles from its mouth.

Patrick's, St., Purgatory. See Long Deb. Patrick, Order of St., is an institution which took place in Ireland in the year 1783. It was on the 5th day of February in this year, that his majesty ordered letters-patent to be passed under the great seal of the kingdom of Ireland, for creating a society or brotherhood, to be called knights of the illusrious order of St. Patrick; of which his majesty, his heirs, and successors, shall perpetually be sovereigns; and his majesty's lieutenant-general, and general-governor of Ireland, &c. for the time being, shall officiate as grandmasters; and also for appointing prince Edward, and several of the prime nobility of Ireland, knights-companions of the said illusrious order.

The badge of this order is a sable red on a field azure, surmounted with a shamrock, or trefoil vert, charged with three imperial crowns or, within a garter, on which is the motto QUIS SEPAREBIT, "who shall separate them," MDCCCLXXXIII. The whole is surmounted by a star of silver, with eight points; all which is embroidered, and worn on the outer garment of the knights of the order. The collar is of fine gold, composed of four harps and five roses, alternately joined or linked together by ten knots enamelled white: the rose gules, surmounted by a border or, and enamelled azure. In the centre before is an imperial crown, to which is pendant an harp, and thereto the jewel of the order, being a cross fitchet enamelled red, charged with a sky-blue enamelled trefoi, surmounted with three imperial crowns of gold; the whole surrounded with a border of gold, on which the motto is enamelled blue. This jewel, except on public days, is worn pendant to a sky-blue ribbon, and ornamented with jewellery, agreeably to the will of the soverign.

This order is to consist of the sovereign, a grand master, a prince of the blood royal, and thirteen knights, making, in the whole sixteen; and eight officers, viz. the prelate of the order, the chancellor, registrar, secretary, genellogist, usher of the black rod, Usher king of arms, attenant on the order, and A'honne serving at arms. The lord lieutenant for the time being is the grand master. New Ann. Revizor, 1785. Debrrett's Peerage.

Patrick, St., See Dili.

Patrimonio, in Geography, a town of the island of Corfu: 4 miles W. of Bafia.

Patrimonio, or Patrimony of St. Peter, a province of Italy, so called, as it is said, because it was granted by the emperor Constantine to support a church, which he had built in honour of St. Peter, and for the use of the pope. This country is bounded on the north by the Orvietan and part of Umbria, on the east by the Salina and Campagna di Roma, on the south-west by the Mediterranean, and on the north-west by the duchy of Calafro; about 43 miles long, and 32 broad. It is fertile in corn and fruit, and yields a considerable quantity of alum. The principal places in it are Viterbo, Monte Fiascone, Bolsena, Civita Castellana, and Civita Vecchia.

Patrimonio, Patrimonium, a right or estate, which a person inherits from his ancestors.

The name patrimonio was also anciently given to the effects or revenues, with which a church or religious house was endowed, in which fene authors still lay the patrimony of the church of Rimini, of Milan, &c.

The church of Rome, at the time of the fall of the Roman empire, acquired considerable territories, partly by purchase, and partly by the generosity of princes, &c. not only in Italy, but also in Sicily, and other remoter parts of Europe. These were called the patrimony of St. Peter, which were afterwards augmented by the benefactions of Pepin, king of France, who added the exarchate of Ravenna and the Champaer one who gave to the see of several towns and provinces, which belong at this time to the estate of the church, over which the pontiff exercises sovereign authority.

To make what belonged to the churches the more respected, they usually gave their patrimondies the names of the saints they held in the highest veneration.

The church of Ravenna called its inheritance the patrimony of St. Apollinarius; that of Milan the patrimony of St. Ambrose, as is observed by Fra. Paolo.

Patrington, in Geography, is a small market-town and parish, in the fourth division of the wapentake of Holme, and east riding of Yorkshire, England. The town is situated 18 miles S.S.E. from Kingston-upon-Hull, and 153 miles N. by E. from London. It is of great antiquity, and, according to Camden, was the ancient Pratiarium of Antoninus; and with his opinion the best informed antiquaries coincide, as its distance from the neighbouring station of Delgofita agrees with that mentioned in the Itinerary, whether we place the latter at Loudfellough, or at Market-Weighton. The buildings of this town are much dispersed.
The parith church is a large and spacious edifice; its tower is surmounted by a lofty spire. The market is held here on Saturday weekly, and is much frequented by corn dealers. Here are, besides, three fairs during the year, principally for drapery, millinery goods, shoes, and other articles of dress. Patrington stands within less than a mile of the estuary of the Humber, which forms here a small creek, capable of affording shelter and anchorage to vessels of all burden. According to the parliamentary returns of 1811, the town and parish contain 190 houses, and a population of 1,016 inhabitants.

About a mile and a half to the north-west of Patrington is the pleasant village of Wimblehead, which is adorned with two elegant villas, the seats of Sir Robert d'Arcy Hidyard, bart., and of Henry Masters, esq. The seat of the former is denominated Wimblehead-hall, and both being seated upon gently rising ground, command a beautiful prospect of the town of Patrington, the Humber, and Skrink island. This island has its name from the circumstance of its having been entirely under water till the reign of Charles I., when it began to appear by the receding of the ocean. At first, only a few acres were left dry at low water; but as it increased in extent every year, it was at length embanked, and laid down as pasture land. Other embankments, however, were made at subsequent periods, in proportion as the waters retired; so that the island is now of considerable extent, and only separated from the Holderness marishes by a ditch a few feet in breadth. The last embankment was effected in 1838, and included an area of 4570 acres. Skrink island is divided into several farms, and a church has lately been built upon it, for the accommodation of the inhabitants.

The soil is peculiarly fertile.

Spurn-head, or Spurn-point, situated about ten miles to the south-east of Patrington, constitutes the extremity of the noted "Oceum Promontorium" of Ptolemy, which projects nearly half-way across the entrance into the Humber. Its present name of Spurn-head is of Saxon origin; the verb "spurnen," in that language, signifying to explore or spy out. A light house is placed here, as a guide to vessels navigating the estuary. Somewhere in this vicinity was an anciently the celebrated sea-port Ravenpur, or Ravenfeather, remarkable in the annals of England as the landing-place of Henry IV., A.D. 1399, and of Edward IV., A.D. 1471, when these princes came to contend for the possession of the English sceptre. This town has long since been swa lowed up, either by the ocean, or by the Humber; so that the spot on which it stood is uncertain. Several other towns and villages hereabouts have experienced a similar fate. Among them are mentioned Frimley, Thelthorpe, Redmayr, Pennyfimer, Upfal, and Pottenfleet; all of which Dr. Gibbon supposed were overflowed in the 29th or 30th year of Edward III., when the tides are recorded to have risen to a most extraordinary height. The inundation of Ravenpur, however, must have taken place at a much later period.

Near the village of Hallham, about three miles and a half beyond that of Wimblehead, is a superb mausoleum, erected by the late William Confortable, esq., as a burying-place for that family. The architecture of this building displays an union of elegance and simplicity, which at once captivates the eye, and is appropriate to the nature of the structure. The position of this mausoleum is lofty, and the surrounding grounds are covered with trees. Beauties of England and Wales, vol. xvi. by John Bigland.

PATRINI and MATRINI, among the Romans, children whose father and mother were both living.

It was by a certain number of these that hymns were sung to supplicate the gods.

PATRIOT is a denomination given to a person who, under a free government, loves his country, and exerts all his power for promoting its glory and welfare. Whence patriotism is used to denote the love of one's country. Rome, Athens, and Lacedaemon, owed their existence and glory to patriotism, founded on noble principles, and supported by distinguishing virtues. But the most perfect patriotism is that which comprehends the rights of mankind in general. The author of the Spirit of Laws seems to have been actuated by sentiments of universal patriotism.

PATRIPASSIANS, PATRIPASSIANS, a name given to the Sabellians, because they did not believe it was the Son, but the Father himself that suffered and was crucified.

The council of Antioch, held by the Eusebians in 345, says, that those whom the Romans call Patripassians, the eastern people called Sabellians; it adds the reason of the name Patripassians in their condemnation; viz. that by the incarnation of the Father, they rendered him incomprehensible and impassible.

The Patripassian heresy was first broached by Praxas, who was scourged by Victorinus, at the beginning of the third century. They confessed Christ to be God, and that God suffered and died for us; but they confounded the divine persons, and denied in effect the Trinity; meaning by Father, Son, and Spirit, not three persons, but one person under three names. So that he who suffered for us, was according to them as much Father as Son. Tertullian wrote expressly against Praxas.

Hermogenes espoused the error of the Patripassians, whence they came to be denominated also Hermogenians. Afterwards Noetius gave into it, which occasioned them the name of Noetians. His disciple Sabellius the Libyan followed, about the year 250, whence they are called Sabellians. Lastly, because Sabellius was of Pentapolis, and the heresy spread much there, it was called the Pentapolitan doctrine.

PATRIS, Dower ex A/Senlis, in Law. See Dower.

PATRIS, in Geography, a town of Hindoostan, in the circuit of Aurungabad; six miles S.E. of Aurungabad.

PATRIZI, Francesco, in Biography, a philosopher and man of letters, was born, in 1539, in the island of Cerifa, on the coast of Dalmatia, but he derived his origin from the family of Patrizi, in Sienna. He was educated at Padua under the most eminent masters of the time. In 1553 he began to appear as an author by some miscellaneous Italian tracts. In 1557, with the view of obtaining the patronage of the duke of Ferrara, he published a paganical poem on the house of Este, entitled "L'Eridano," in a novel kind of heroic verse of thirteen syllables. After this, for several years, he passed an unsettled kind of life, in which he twice visited the isle of Cyprus, where he took up his abode for seven years, and which he finally quitted on its reduction by the Turks in 1571. He also travelled into France and Spain, and spent three years in the latter country, collecting a treasure of ancient Greek MSS. which he left on his return to Italy. In 1578 he was invited to Ferrara by duke Alphonso II. to teach philosophy in the university of that city. Afterwards, upon the accession of Clement VIII. to the popedom, he was appointed public professor of the Platonic philosophy at Rome, an office which he held with high reputation till his death, in 1597. He was chiefly distinguished by his attainments in ancient philosophy. His work entitled "Dissertiones Peri-
PATROCLUS, in Biography, a Grecian chief, signified in the Trojan war, was the son of Menoeceus, by Sthenelus, who is named by some authors Philomena, or Polynoe. The murder of Clytemnestra, the son of Amphiathanus, by accident, in the time of his youth, obliged him to fly from Opus, where his father reigned. He went to the court of Peleus, king of Thessaly, was very cordially received, and contracted the intimate friendship with Achilles, the king's son. When the Greeks went to the Trojan war, Patroclus went with them in the express desire of his father, who had visited the court of Peleus, and he accordingly embarked with ten ships from Thessaly. He was the constant companion of Achilles; lodged in the same tent; and when he refused to appear in the field of battle, because he had been offended by Agamemnon, Patroclus imitated his example, and by his absence was the cause of much evil to the Greeks. At length, however, Nestor prevailed upon him to return to the war, and Achilles permitted him to appear in his armour. The bravery of Patroclus, together with the terror which the sight of the arms of Achilles inspired, soon routed the victorious armies of the Trojans, and obliged them to fly to the city for safety. He would have broken down the walls, but Apollo, who interested himself for the Trojans, opposed him, and Hector, at the instigation of that god, dismounted from the chariot to attack him as he attempted to slay one of the Trojans whom he had slain. This engagement was obliterated, but Patroclus was at length overpowered by the valor of Hector, and the interpolation of Apollo. His arms became the property of the conqueror, and Hector would have beheaded him, had not Ajax and Menelaus prevented it. His body was at last recovered, and carried to the Grecian camp, where Achilles received it with the loudest lamentations. His funeral obsequies were observed with the greatest solemnity. Achilles sacrificed near the burning pile twelve young Trojans, four of his horses, and two of his dogs; and the whole was concluded by the exhibition of funeral games, in which the conquerors were liberally rewarded by Achilles. The death of Patroclus gave rise to new events. Achilles forgot his resentment against Agamemnon, left the field to avenge the fall of his friend; and his anger was allayed only by the slaughter of Hector, who had more powerfully kindled his wrath by appearing at the head of the Trojan armies in the armour which had been taken from the body of Patroclus.

PATRUL, or PATRouLLE, anciently Patoull, in War, a round, or march made by the guards, or watch in the night-time, from the beating of the tattoo till the reveille, to observe what passés in the streets, and to secure the peace and tranquility of a city or camp.

The patrol consists generally of a body of six or twelve men, detached from a corps de guard, and commanded by a sergeant.

When the enemy is near at hand, patrols consist of an officer and thirty or forty men, as well infantry as cavalry.

PATRON, PATRONUS, a term used in various acceptations, though all reducible to the relation of a protector, or guardian.

In the church of Rome, a saint, whose name a person bears, or under whose protection he is put, and whom he takes particular care to invoke; or a saint in whose name a church or order is founded; or a person who first established it, and who is chosen protector of it; are called the patrons thereof. Thus, St. Peter and St. Paul are the patrons of the church of St. Genevieve, St. Denis is the patron of the city of Paris, St. George of England, St. Benedict the patron of the Benedicines, St. Michael of the armourers, St. Ignatius of the Jesuits, &c.

Patron, Patronus, among the Romans, was an appellation given to a matter who had freed his slave.

Hence, as the right and relation of matter expired, that of patron commenced.

For the Romans, in giving their slaves their freedom, did not deprive themselves of all rights and privileges in them; the law still subjected the freed-men to considerable services and devoirs toward their patrons, the neglect of which was always very severely punished.

The principal right, which patrons had, was that of being the legal heirs of their freed-men, if they died without lawful issue, born after their enfranchisement, and infeque.

By the Papian law it was farther provided, that if the estate of the freed-man were one hundred thousand florins, and he had three children, the patron should have a child's portion.

Patron was also a name, which the people of Rome gave to a person of power, under whose protection they put themselves.

The common people usually chose some person of eminence and authority to whom they paid all kind of homage and respect; denominating themselves his clients; and the patron on his side granted them his credit and protection.

By this reciprocal relation was the patron bound to his client, and the client to his patron.

Hence the appellation of patroni was given to those lawyers, who defended the cause of their clients in matters of law, in contradistinction to the procuratores: they were called advocati. See Advocate.

Patron, in the Canon and Common Law, denotes a person who founds or endows a church or benefice, and renders to himself the right of patronage.

The king is patron paramount of all ecclesiastical benefices in England.

Patron, in Navigation, is a name given in the Mediterranean to a person who commands the vessel, and is sometimes...
sometimes the person who flees it; the former, in other places, being called matter; the fecond, pilot.

PATRONA, or PADRON, in Geography, a town of Syria, near the sea-coast, said to have been founded by Itobalus, contemporary and ally of Ahab, king of Israel; its ancient name was "Bitrys" or "Botryum." Mr. Maudrell found in this place the remains of an old church and monastery, which, as well as the town, were in a state of ruin; 20 miles S.W. of Tripoli. N. lat. 44° 12'. E. long. 35° 35'.

PATRONEAGE, PATRONATUS, the right of giving or disposing of a church or benefice, properly belonging to the founder or endower thereof. See ADVOWSON.

The right of patronage was introduced among Christians towards the close of the fourth century, with no other view than to encourage the opulent to erect a great number of churches, by giving them the privilege of appointing the ministers that were to officiate in them.

Patronage conficts in having the nomination, or presentation to the benefice by him founded or endowed; in having the honourable rights of the church; in being interred in the chancel, &c.

Of patronages, some are lay, others ecclesiastical.

Patronage, Lay, is a right attached to a perfon, either as founder, or as heir of the founder; or as possessor of a fee to which the patronage is annexed.

Patronage, Ecclesiastical, is that which a person is entitled to by virtue of some benefice which he holds.

If an ecclesiastic have a right of patronage on his own account, independent of his ecclesiastical capacity; this is still lay patronage. Lay patronage, again, is real or personal.

Patronage, Real, is that attached to the glebe, or to certain lands and hereditaments.

Patronage, Personal, is that belonging immediately to the founder of the church, and transferrable to his children and family; without being annexed to any fee.

Personal patronage cannot be alienated or sold; real may, together with the glebe to which it is annexed. There must ever be some body or matter to fix it, in order to its being transferred to another.

The origin of the right of patronage, we find in the tenth century of the council of Orange: where it is expressed, that a founder may precent to the diocesan the clerks he thinks proper for his church. And by a law of Justinian it is ordained, that the founders of churches may not put clerks in them on their own authority, but only present them to the bishop.

Some canons look on the right of patronage, as a kind of ecclesiastical servitude. The right of patronage flees, but is not lost, while a person is out of the communion of the church.

Patronage, Disturbance of, is an hindrance or obstruction of a patron to present his clerk to a benefice. Disturbers of a right of advowson may be the pseudo-patron by preenting to a church to which he has no right, and thereby making it liegious or disputable; his clerk, by demanding or obtaining infition; and the ordinary, by refusing to admit the real patron’s clerk, or admitting the clerk of the pretender. These disturbances are vexations and injurious to him who hath the right; and, therefore, the law (besides the writ of the right of advowson, which is a final and conclusive remedy) hath given him two inferior processes for his relief; an affize of darrein prenciement, and a writ of quare impedita, in which the patron is always the plaintiff, and not the clerk.

Patronage, Arms of, in Heraldry, are thofe, at the top of which are some marks of subjicction and dependence. Thus the city of Paris bears three fleurs-de-lis in chief, to shew her subjicction to the king.

The cardinals on the top of their arms bear thofe of the pope, who gave them the hat, to shew that they are his creatures. See Arms.

PATRONYMIC, His. patronym, formed from or, father, and or, name, among Grammarians, is applied to thofe names which the Greeks gave to the race, or lineage; and which were taken from him who was the founder thereof.

Thus the descendants of Aceus were called Aceidize; and thofe of Hercules, Heraclida.

These patronymic names the Romans called gentilita, which amount to much the fame with our surnames.

Thus, thofe of the late reigning family in France, we call the Bourbons; thofe of the late in England, the Stuarts, &c.

PATROON GALLEY. See Galley.

PATROUILLE. See Patrol.

PATROURA, in Geography, a town of Hindoostan, in Bogglicound; 25 miles S.E. of Makoonda.

PATRU, OLIVER, in Biography, a distingjuished French writer, was born at Paris in 1662. He was intended by his father for the bar, and he cultivated with great affinity the talent of writing and speaking with purity. He visited Rome, and on his return his reputation procured him admission into the French academy in 1640. At his reception he delivered an oration of thanks, which pleased that body so well, that it became thenceforth the rule for every new member to pronounce a similar harangue. Patru was connected with most of the eminent literary characters in France of that period, and was consulted as an oracle upon every question relative to language. Boileau, Racine, and other wits, read their works to him, and profited by his remarks. Racine, it is said, frequently shank from the severity of his animadversions, but Boileau was fully sensible of their value.

Patru fell into a state of indigence, and Boileau purchased his library, and generously permitted him to retain it during his life. "That a poet," says his biographer, "should be the pecuniary benefactor of a celebrated pleader, seems contrary to the usual order of things; but Patru was probably more intent in polishing his style, than in turning over law-books and hunting for clients. He was a man of a philosophic turn, generous, companionable, and not depressed by the frowns of fortune. His opinions were sceptical, on which account he was visited by Buffon in his last illness, for the purpose of exhorting him to edify the public by some demonstrations of religious conviction. It will more become me, said Patru, to be silent, for men in their last moments talk only through weakness or vanity." On his death-bed he had a visit from the minister Colbert, who brought him a donation of 500 crowns. He died in January 1681, in his 77th year. Patru is chiefly known as an author by his "Philosophers;" but he likewise wrote harangues, letters, and the lives of some friends, which have in a good measure loft their reputation. The full edition of his works is of 1752, in two vols.4to. Moreri.

PATSA, in Geography, a town of Hindoostan, in the circuit of Surgoopa; 25 miles N.E. of Surgoopa.

PATSAAN, a small island on the E side of the gulf of Bothnia. N. lat. 60° 48'. E. long. 20° 58'.

PATSCHKRAU, a town of Silecia, in the principality of Neiff, 13 miles W. of Neiff. N. lat. 50° 18'. E. long. 16° 50'.

PATSISHIKAMISTICK, a river of Canada, which runs into the Sable, N. lat. 49° 45'. W. long. 72° 36'.

PATTA,
PATTA, or Pati, an island in the Indian sea, near the coast of Africa, about 10 miles in circumference; chiefly inhabited by Arabians, with whom the English, Portuguese, and Indians trade for ivory and slaves; it is brated near the coast, at the mouth of a river of the same name. S. lat. 1° 56'. E. long. 12° 21'.

PATTALIA, in Ancient Geography, a town of India, that has been commonly referred to the Delta of the Isis. Alexander arrived at this place about the middle of August, 326 years B.C., and having made proper arrangements for the safety and convenience of his fleet and army, and having viewed also the two principal mouths of the Isis, on which he experienced some degree of luriprise, if not of terror, from the "bore," or sudden influx of the tide, he departed by land for Sula, leaving Nearcush with the fleet to follow as soon as the Eteoian winds should cease. Nearcush failed in October with the N.E. monsoon, conducting, according to Dr. Gillies, in his elegant History of Greece, "the first European fleet which navigated the Indian seas." Pattala is supposed to have been the site of the modern city of Twia, which fea. According to a tradition among the people of Sindia, Pattala is the place in the desert of India, whereas Pattala is placed in the inferior delta. Rewell's Memoir.

PATTALIA, in Natural History, a word used by Aristo.,
tole and the rest of the old Greek writers, to express a flag or deer of two years old.

PATTALLY, in Geography, a town of Hindooslan, in Bahar; 33 miles E. N.E. of Hispyeur.

PATTAN, Lelit, a city of Afia, in Napal or Napaud, the capital of an independent kingdom, S.W. of Cathmanda or Catmanda; containing near 24,000 houses; the southern boundary of this kingdom is at the distance of four days' journey, bordering on the kingdom of Macwanpur. N. lat. 28° 5'. E. long. 85° 10'.

PATTAN, a town of Hindooslan, in Mewat; 16 miles S.W. of Cotpurly. - Allo, a town of Hindooslan, in Villapour; 20 miles N.W. of Sattarah.

PATTANCHERU, a town of Hindooslan, in Golconda; 20 miles W.N.W. of Hydbradar.

PATTAPOO-WINEPEE, a lake of North America. N. lat. 44° 50'. W. long. 96°.

PATTANA, a river of Thibet, which runs into the Ganges, on the borders of Hindooslan.

PATTMBACHES, one of the smallnest Molucca islands. N. lat. 0° 34'. E. long. 127° 21'.

PATTEN-SHOE, in the management of horoses' feet, is a term applied to that sort of shoe which has a kind of half ball of iron welded to it underneath, which is hollow within. It is intended for the use of such horses as are lame in the hop, being put upon the found foot, in order that the animal, by not being able to stand upon that foot without pain, may be under the necessity of supporting itself upon the lame foot, and in that way counteract the disposition in the flies to contract or draw up the haunch. It is the method of practice with some, where horses are newly lame in the shoulders, either to peg the other foot, or let on a patten-sole, in the view of bringing the lame shoulder upon the stretch; but with others it is the custom to immediately turn them out to grass; both of which some think very exceptionable, as well as that of procuring and the most ready ways of rendering them incurably lame; the patten-shoe being simply necessary in long standing lameness, where the tendons of the muscles have been a long while contracted or drawn up.

PATTEN'S CREEK, in Geography, a river of America, in Kentucky, which runs into the Ohio, N. lat. 38° 22'. W. long. 85° 50'.

PATTENSBURG, a small town of America, in Botetourt county, Virginia, situated upon James' river; 26 miles from Lexington.

PATTENSEN, a town of Welphalia, in the principality of Calenber, formerly encompassed with walls, moats, and ramparts; 6 miles S. of Hanover.

PATTERTGAUT, a town of Hindooslan, in the Sub bah of Delhi; 20 miles W. of Coel.

PATTERTGOTA, a town of Hindooslan, in Bengal; 10 miles E. of Pucuclo.- Allo, a town of Afia; 15 miles E. of Gentiah.- Afco, a town of Bengal; 22 miles S.W. of Dmagemour.- Ailo, a town of Bengal; 18 miles E. of Belhopour.

PATTERGUR, a town of Hindooslan, in the circur of Sambal; 4 miles N.E. of Nidjpibad.

PATTERPURRA, a town of Bengal; 47 miles S.W. of Burdwan.

PATTERRA, a town of Bengal; 3 miles E. of Midnapour.

PATTERSON, a town of America, in Bergen county, New Jersey, established in consequence of an act of the legislature of New Jersey in 1791, incorporating a manufacturing company with peculiar privileges. Its situation on the Great Falls of Passaic river is healthy and agreeable. It contains about 50 dwelling houses, besides the buildings ap propriate to the manufactures of all kinds, which it was propcised to carry on in this place, the most convenient for the purposes of any on the continent; but they did not succeed to the degree that was expected; 19 miles N.E. of Morrlcdwn. N. lat. 40° 12'. W. long. 74° 57'.

PATTERSOT, a town of Prussia, in the circle of Natangen; 6 miles S.W. of Brandenburg.

PATTWERWALDT, a town of Prussia, in the circle of Natangen; 24 miles E.S.E. of Ko. igberg.

PATTES, in Heradys, the paws of a beast. See Paw.

PATTI, PATI, or Piatii, in Geography, a fea-port town of Sicily, in the valley of Demona, situated on the N. coast, in a bay or gulf to which it gives name, built on the ruins of Tindaro, by count Roger, after he had vanquished the Saracens; the site of a bishop's suffragan of Melfina; 52 miles W. of Melfina. N. lat. 38° 10'. E. long. 15° 2'.- Alla, a river of Sicily, which runs into the sea, one mile E. of Patti.

PATTIAD, a town of Hindooslan, in Guzerat; 35 miles N.W. of Gogo.

PATTIARY, a town of Hindooslan, in Oude; 55 miles E.N.E. of Agra. N. lat. 27° 35'. E. long. 79° 26'.

PATTICAUT, a town of Hindooslan, in Cochinn; 38 miles E.N.E. of Cranogore.

PATTIGAM, a town of Hindooslan, in Orissa; 30 miles N. of Orissa.

PATTMES, a town of Bavaria; 8 miles N. of Aicha.

PATTSCHOW, or Paetzow, a town of Bohemia, in the circle of Bchen; 58 miles S. of Prague. N. lat. 49° 50'. E. long. 14° 50'.

PATTUNGAH, a town of Hindooslan, in Orissa; 18 miles N. of Sonnapour.

PATTYAH, a town of Hindooslan, in Oude; 22 miles S.S.W. of Cangore.

PATTYPOUR, a town of Hindooslan, in Bahar; 53 miles S.S.W. of Patna.

PATUCKET, a small village of America, about four miles N.E. of Providence in Rhode island, a place of considerable trade and manufactures. Through this village runs Patucket or Pawtucket river, which empties into Seekhounk river at this place. The river Patucket, called in its more northerly course Blackstone's river, has a beautiful fall of water,
water, directly over which has been built a bridge on the line, which divides the commonwealth of Massachusetts from the state of Rhode Island; distant about 40 miles S. by W. from Boston.

PATURAGES, a town of France, in the department of Jajmeppe, and chief place of a canton, in the district of Monz. The place contains 3208, and the canton 14,126 inhabitants, on a territory of 117½ kilometres, in 17 comunmes.

PATUXENT, or Patuxet, a navigable river of America, in Maryland, which rises near the source of Patapsco river, and runs into the W. side of Chesapeake bay, between Drum and Hog island points; 15 or 20 miles N. of the mouth of the Patowmack. It admits vessels of 250 tons to Nottingham, nearly 46 miles from its mouth, and of boats to Queen Anne, 12 miles higher.

PATZLAWITZ, a town of Moravia, in the circle of Omutz; 18 miles S. of Olmutz.

PAU, a town of France, and chief place of a district, in the department of the Lower Pyrenees; situated on a river called the "Gave de Pau." It is divided into the Faït and Well parts; the former contains 5800, and its canton 9708 inhabitants, on a territory of 728½ kilometres, in 10 comunmes; and the latter 2785, and its canton 12,503 inhabitants, on a territory of 122½ kilometres, in 11 comunmes. It was, before the revolution, the capital of Bearn, and the seat of a parliament, a governor, a benefice, &c. and contained an university, an academy of sciences, two hospitals, a college, and several events. This place has manufactures, linen, &c. and its lanes are highly esteemed. The environs are planted with vineyards. 

PAVIÓN, N. long. 18°.

PAVIA, a town of Spain, in the province of Catalonia; 12 miles N.W. of Gernoa.

PAVAGE, Pavagium, in our old Law Books, money paid towards the paving of streets, or highways.

PAVAIS, Pavache, or Talleva, in Ancient Armour, was a large shield, or rather a portable mantlet, capable of covering a man from head to foot, and probably of sufficient thickness to repel the missive weapons then in use. These were, in sieges, carried by servants whose business it was to cover their masters with them, whilst they with their bows and arrows fired at the enemy on the ramparts. In the list of the army that accompanied king Edward III. to Cahis, we find many "Paviers:" these were probably men trained to the use of the pavisas, which must have required dexterity as well as courage. Pavaches were sometimes supported by props; they were also used at sea to defend the fides of the vessels, like the present netting of our ships of war: this defence was called a "pavifade," and may be seen in the representation of ancient ships. The pavisas was rectangular at top, the fides being evertually parallel, but the angle is rounded off at the bottom. Under the protection of the pavaches, workmen also approached to the foot of the wall in order to slap it.

PAVAKA, in Mythology, is the Hindoo regent of fire, and is a deity frequently invoked in the variety of sacrificial ceremonies observed by that faneritical race. The element of fire being of such vital importance in all the operations of nature, and in its evident and hidden phenomena so striking and mysterious, it has, of course, excited the wonder and invited the research of the vulgar and the wife of all ages and nations. The fun, the supposed source of heat, is naturally joined with his offspring in the awe and adoration with which each is contemplated; and among the Hindoos, as with other polytheists, we find the attributes and characters of the regent of light and heat often coalescing. The Hindoos have, however, depicted their fire-king in colours and forms not common to others. He is painted of a deep red; with two faces, three legs, and seven arms, riding on a ram, and bearing a flag with that animal on its field. Few, if any, of the numerous ceremonies of the Brahmas are complete without invocatory oblations to the all-pervading element of fire, or to its perfonification, under the name of Pavaka or Agni; the latter is indeed his most popular and common name. In sacrificial ceremonies, as ordained by Menu (see Menu), Agni is generally the deity primarily invoked. A Brahman is directed in his domestic fire for dressing the food that he daily offers to the gods, to make an oblation, "First, to Agni, god of fire, and to the name of the sun, the lunar god, severally; then to both of them at once." (C. iii. v. 85.) Again, in offering to the Dī Manes: "The divine manes are always pleased with an oblation in empty glasses, naturally clean, on the banks of rivers, and in solitary spots. First, as it is ordained, having satisfied Agni, Soma, and Yama, with clarified butter, let him proceed to satisfy the manes of his progenitors." Ib. c. iii. v. 207, 211.

The Brahmas subdivides the igneous element, first, into two, the folar and terrestial; or creative and destructive fire. Here Agni, as its general perfonification, coalesces with Brahma and Siva, and hence it has been fummed his two faces. Terrestrial fire is again subdivided into three, viz. the nupial, the ceremonial or funeral, and the sacrificial. Agni’s three faces may allude to thefe, or to the influence of fire over the three regions of the universe. The fun is preceded by a seven-headed horde, or by venus horde yoked to his car; allusive, it is suppoed, to the prismatic variety of a ray of light; and fire, like the fun, is suppoed by the Hindoo philosophers to emit seven rays. This number is in many other repeated in invocations to Agni and Surya, the latter their Phoebus or Apollo. (See Surya.) Hence the number of arms bestowed on Agni.

The following verses from Menu are illustrative of the attributes of Agni connected with the faced triad of fices.

"Ch. xi. v. 220. "Due reverence to these three (the parents and preceptor) is confidered as the highest devotion; and without their approbation, no man must perform any other duty.

"230. "Since they alone are held equal to the three worlds; they alone, to the three principal orders; they alone, to the three Vedas; they alone, to the three fires.

"231. "The natural father is considered as the Garbapatra, or nupial fire; the mother, as the dalbhaba, or ceremonial; the spiritual guide, as the abhramuniya, or sacrificial: this triad of fires is most venerable.

"232. "By honouring his mother, he gains this terrestrian world; by honouring his father, the intermediate, or ethereal; and by affilidous attention to his preceptor, even the celestial world of Brahma."

Like other Hindoo duties, Agni has a wife or half, of whom some mention is made under the article SVAHA, who appears to have been a form of Lakshmi. (See that article.) In one of the tales of the Puranas, it is related how "Lakshmi performed tapasya for 100,000 years, in the flower of the padma or lotus, standing on one foot, (see Padma and Tapas), in order to obtain Vichaha. She then found Sri Krishna or Vrahma, who said, ‘Thou shalt be my wife when I suffuse the shape of Varaha; but in the mean time be the faktit of Agni, which fakti, or energy, burns every thing: be also the wife of Siva. Valmi, Agni, or Fire, for an hundred years of the gods, will have no other with but to please thee.’ She conceived by him: the gelation lasted twelve years, and three beautiful sons were born unto
unto her; Dakshinagni, Garbapatya, and Ahavanya, three faced fires." (Af. Ref. vol. xi. art. 2.) In this manner the theogonical legends of the Puranas run into each other; very confudedly as would seem on partial examination, but connectedly, as it is said, will appear wherein that mass of romantic fables shall have been competently inspected. See Purana.

The number seven, we have seen, is that of the arms of Agni, and of many allusions to him in his form of fire. In the ceremony called vigoda, a comprehensive one to all the gods, which is the meaning of the word, including the essentials of the whole detail of daily sacrifice, and practised therefore chiefly by Brahmanas not exclusively engaged in the priesthood, the mystical number frequently occurs in this invocation: for instance, to Agni. "Fire! seven are thy fuels; seven thy tongues; seven thy holy fages; seven thy beloved abodes; seven ways do seven sacrificial worship thee; thy sources are seven; may this oblation be efficacious." An explanation of this mysterious passage is given by Mr. Colebrooke, in his "Essay on the Religious Ceremonies of the Hindoos," in the seventh volume of the Af. Ref.

We have noticed three of the sons of Agni or Pavaka, in the three faced fires, by Lakshmi, in her form of his fakti. He had three other sons, perhaps by a different wife, named Uttama, Tanaa, and Ruvata, whose names occur in the list of seven Venuus, or fages, under the article MENU. Their names have probably some allusions, direct or inferve, to fire, or heat; or light. By another wife he had nine sons. Another son is noticed in the form of an ape under the article NILA. He had also seven brothers, whose names are varied significations of flame.

The three sons of Agni above named, are on other occasions called sons of Brahma, as mentioned under the article MENU, above referred to. Between Agni or Brahma we see here some identity: both are also painted red. It is in reference to his creative heat that he is connected with Brahma. He is also called Vahni, a name likewise of Sarafwati, the comfort of Brahma. A passage above quoted has shown that the spouse of Agni coalesces with those of the other two persons of the Hindoo head: as doth Agni: his igneous property concentrated, connects him with the destructive Siva, who is also fire; and his light, so intimately related to fire, with Vishnu the conservator. This triple connection between the deity of heat and the three great powers, is similar to what is remarked of the sun under the article Surya.

Sir W. Jones, in his "Disertation on the Gods of Greece, Italy, and India," has the following passage, applicable to the subject of our present article:

"The worship of solar or sical fire may be ascribed, like that of Osiris and Isis, to the second source of mythology, or an enthusiastic admiration of nature's wonderful powers; and it seems, as far as I can yet understand the Vedas, to be the principal worship recommended in them. We have seen that Mahadeva himself is perfonified by fire; but subordinate to him is the god Agni, often called Pavaka, or the Purlifier, who answers to the Vulcan of Egypt, where he was a deity of high rank; and Agni's wife, Swaha, resembles the younger Velia, or Veltha, as the Eolians pronounced the Greek word for a hearth. Bhanavi, or Venus, is the comfort of the supreme destructive and generative power; but the Greeks and Romans, whose systems are less regular than that of the Indians, married her to their divine artist, whom they also named Hephaistos, or Vulcan, and who seems to be the Indian Vifwakarma, the forger of arms for the gods, and inventor of the Agnialler, or fiery shaft, in the war between them and the Daityas, or Tritons." Vol. i. art. 9.

We thus find that the Indian Venus, like her of the Greeks and Romans, is the companion of the fiery god, both as Lakshmi and Bhavani, or Parvatii; for in a former extract from a Purana it was shewn that Lakshmi was befowled on Agni by Vishnu, and became his fakti, or energy, and mother of his fiery triple offspring, and also was bade to become the wife of Siva.

With the Hindoos, purification is referred to in divers modes, according to the nature of the sin; and fire is the universal efficacious. Hence the name Pavaka means the Purlifier. Under the article KARNIAGNI an instance is given of its efficacy in the case of great enormity, and under SATI something farther will be found on that point. Under KARTIKYA and KRITINA some puranic fables are noticed, in which Agni bore a part.

To this deity a portion of the Vedas is ascribed, as having been revealed or promulged by him. (See VEDA.) Seven books of the Yajurveda he is the reputed author of: and one of the Puranas, which details his history, is called the Agni Purani. See an outline of its contents under Purana. He is therein also named Agnidiha, Anala, and Jivani: to the latter appellation it is added, "he, who does good to all; from whom sprung the Vedas." Under the article MARUT it is noticed, that the Hindoos have guardians over the cardinal and intermediate points of the heavens. Among these is Pavaka; and he rules or governs the south-eal. In the Gita, when Kirshna describes his own pre-eminence among all things and creatures, he fays to Arjun, "Among the Vafus, I am Pavaka." See Kirshna and VASU.

Among the offspring of Agni may be noticed the commander of the celestial armies, named KARTIOYA, who is hence called Agnija, and Agnibhuva; but he is more commonly reputed the son of Siva; the instrumentality of the god of fire having been apparently confined to warming or inflaming the frigidity of Siva to a due pitch; the charms of his confort Parvati appearing, by the puranic fables, to have been unequal to that effect; and a warlike being, at the then critical period, essential to the safety of the gods. This fiery parentage of Kartinya is noticed under that article, and under MUNI: in the latter, the following correction is necessary: second column, third line from the bottom, instead of many-mothered for, read many-mothered son.

Pavan. PAVANA, the air of an ancient flately dance, which has been long out of use. It had its name from the dancer's assuming the dignity of the peacock; or, perhaps, from Pavana, an Indian author of a fyltem of music that goes under his name. In all fets of licions for the virginal, from the time of queen Elizabeth to the reign of Charles I., there was a Pavan, which served as an adagio, or flow movement to the galtard, as the faraband did afterwards to the courant.

PAVANA, in Mythology, is the Hindoo regent of the winds, and of the north-west quarter of the heavens; the Hindoos having, as noticed under the article MARUT, a separate ruler or guardian for each cardinal and intermediate point. The name of this deity is usually pronounced Pavan; and we may herein recognize the Faunus of ancient Italy; a contraction of Fawanus, the north-west wind of the Mediterranean mythology, derived probably from a faun or antelope, aep emblem of its celerity, and allotted, therefore, in India, as a vehicle for Pavana, who, in pictures, usually appears so mounted. The Puranas contain particulaer directions to artists in respect to delineating the gods.
In the Matsya Purana, the following point out the attributes of the one in question. "Let Pavana be painted young, clothed in robes of many colours, mounted on a fleet antelope, and with a standard in his hand, which the wind waves behind him as he cleaves the air." A further influence of analogy in the European and Indian mythological tales, and connected with this article, will be found under **Maruty**, a name of Haruman, a simian hero, reputed son of Pavana, one of whose names is *Morat*, which see; a word, like Pavav, meaning the wind. He is lord or chief of the maruts, or winds. *Vayu* is another of his names, and Anila and Yah. This deity is honoured by frequent invocation and sacrifice in the Brahmanical ceremonies. An influence is given under **Nirriti**. One of the Puranas is named after this deity, and feigned to have been promulgated by him; but as the found of Pavana immediately preceding *purana*, would be harsh in the faithful ear of the Brahmanas, that poetical feat, to avoid this cacophony, always call it after another of the names of the winds regent *Vayupurana*. See **Purana**.

**Pavana**, in *Botany*, the name of the plant which produces the grana tiglin of the flops. It is a species of *ricinus*.

**Pavana Wood**, when fresh, operates very violently, both by vomit and itoel; when dried, it is much more gentle, never vomiting at all; but at present it is fearcely heard of in the flops.

**Pavara, in Geography**, a town of Peru, in the dioceze of Guimania; 20 miles E. of Guanca Velca.

**Pavarcotta**, a town of Peru, which gives name to a juridiction, in the dioceze of La Paz; 32 miles N. of Puno, which is the capital of the juridiction. This juridiction borders S. on that of Chucuito, and has the same temperatere; and is therefore obliged to recur to other provinces for the greatest part of its grain, and efceulent vegetables; but abounds in all kinds of cattle, both of the European and American kinds. The Indians of the region weave bags with their wool, and sell them to great advantage.

The mountains in this province contain several silver mines, and among the reft the famous Laycacota, in which the metal was often cut out of the mine with a chisel; but its prodigious riches accelerated the death of its owner, Joseph Salcedo; soon after which the waters broke into it, nor have any labour and expense been sufficient for draining it, so that it has been abandoned. Few of the other mines are wrought.

**Pauarcambo**, a juridiction of Peru, in the dioceze of Cufco, which commences eight leagues E. of Cufco, and is of considerable extent. In the time of the Incas it produced the greatest quantity of cocoa, with which it carried on a very profitible commerce. But since this shrub has been planted in other provinces, it has greatly declined. The fibre is equally fertile in other productions.—Alto, a river, that rises about 50 miles S.W. of Cufco, and after a northerly course of about 200 miles, through the juridiction to which it gives name, joins the Maranon at to 45'; but in fact it is the river fyled by La Cruz Yananari.

**Paucon*, Alexis, in *Biography*, a mathematician, was born near Laflay, in Mayenne, in 1732. He received his education in the mathematical and naval academy at Nantes, after which he went to Paris, where his integrity and talents obtained for him a considerable share of patronage. He died in the year 1799. His works are: 1. "Theory of the Force of Archimedes." 2. "A Treatise on the Weights, Measures, and Monies of all Countries, ancient and modern." 3. "Theory of the Laws of Nature, with a Disertation on the Pyramids of Egypt."

**Pavement**, a layer or stratum of flone, or other matter, serving to cover and strengthen the ground of divers places, for the more commodious walking on, or for the passage of carriages.

The word is formed from the Latin *pavimentum*, of *pavire*, to beat down the earth, in order to make it firm and strong.

In England, the pavements of the grand streets, &c. are usually of flint or rubble-stone; courts, flables, kitchens, halls, churches, &c. are paved with tiles, bricks, flags, or fire-stone, sometimes with a kind of free-stone, and rag-stone.

In some cities, e. gr. of Venice, the streets, &c. are paved with brick; churches sometimes are paved with marble, and sometimes with mosaic work, as the church of St. Mark, at Venice. In France, the public roads, streets, courts, &c. are paved with gres or grit, a kind of free-stone.

In Amsterdam, and the chief cities of Holland, they call their brick pavement the *baargh-mafler's* pavement, to distinguish it from the flone or flint pavement, which usually takes up the middle of the street, and which serves for carriages; the brick which borders it being destined for the passage of people on-foot.

Pavements of free-stone, flint, and flags, in streets, &c. are laid dry, i.e. in a bed of sand; those of courts, flables, ground-rooms, &c. are laid in a mortar of lime and sand; or in lime and cement, especially if there be vaults or cellars underneath. Some masons, after laying a floor dry, especially of brick, spread a thin mortar over it; sweeping it backwards and forwards to fill up the joints. The several kinds of pavement are as various as the materials of which they are composed, and whence they derive the name by which they are distinguished: as, 1. *Pebble-paving*, which is done with flones collected from the sea-beach, mostly brought from the islands of Guernsey and Jersey; they are very durable, indeed the most so of any flone used for this purpose. They are used of various sizes, but those which are from six to nine inches deep, are esteemed the most serviceable. When they are about three inches deep they are denominated holders, or bowlers; these are used for paving court-yards, and other places not accustomed to receive carriages with heavy weights; when laid in geometrical figures they have a very pleasing appearance.

2. *Rag-paving* was formerly much used in London, but is very inferior to the pebbles; it is dug in the vicinity of Maidstone, in Kent, from whence it has the name of Kentish rag-stone; there are squared flones of this material for paving coach-tracks and footways.

3. *Purbeck pitchens*; squared flones used in footways; they are brought from the island of Purbeck, and also frequently used in court-yards; they are in general from six to ten inches square, and about five inches deep.

4. *Squared paving*, for distinction by some called *Scotch paving*, because the first of the kind paved in the manner that has been and continues to be paved, came from Scotland; the first was a clear close flone, called blue wynn, which is now disused, because it has been found inferior to others since introduced in the order they are hereafter placed.

5. *Granite*, a hard material, brought also from Scotland, of a reddish colour, very superior to the blue wynn quarry.

6. *Guernsey*, which is the belt, and now almost the only flone in use; it is the same flone with the pebble before spoken of, but broken with iron hammers, and squared to any dimensions required of a primitoidal figure, with its smallest base downwards. The whole of the foregoing paving should be bedded and paved in small gravel.
7. Purbeck paving, for footways, is in general got in large surfaces, about two inches and a half thick; the blue fort is the hardest and the belt of this kind of paving.

8. Yorkshire paving, is an exceeding good material for the same purpose, and is got of almost any dimensions of the same thickness of the Purbeck; this stone will not admit the wet to pass through it, nor is it affected by the frost.

9. Ryegrass, or fire-flame paving, is used for hearths, stoves, ovens, and such places as are liable to great heat, which does not affect this stone, if kept dry.

10. Newcastle flags, are stones about two feet square, and one and a half, or two inches thick; they answer very well for paving out-offices; they are somewhat like the Yorkshire.

11. Portland paving, with stone from the island of Portland; this is sometimes ornamented with black marble dots.

12. Swaledale paving, is a black slate dug in Leicestershire, and looks well for paving halls, or in parti-coloured paving.

13. Marble paving, is mostly variegated with different marbles, sometimes inlaid in mosaic.

14. Flat brick paving, done with brick laid in sand, mortar, or grout, as when liquid lime is poured into the joints.

15. Brick on edge paving, done with brick laid edgeways in the same manner.

16. Bricks are also laid flat or edgeways in herring-bone.

17. Bricks are also sometimes set endways in sand, mortar, or grout.

18. Paving is also performed with paving bricks.

19. With ten-inch tiles.

20. With foot-tiles.

21. With clinkers for stables and out-offices.

22. With the bones of animals, for gardens, &c. And

23. We have knob-paving, with large gravel-stones for porticoes, garden-lects, &c.

Pavers work is done by the square yard: and the content is found by multiplying the length by the breadth.

Pavements of churches, &c. frequently consist of stones of several colours; chiefly black and white, and of several forms, but chiefly square, and lozenge, artfully disposed. Indeed, there needs no great variety of colours to make a surpising diversity of figures and arrangements. M. Truchet, in the Memoirs of the French Academy, has shewn by the rules of combination, that two square stones, divided diagonally into two colours, may be joined together chequerwise sixty-four different ways: which appears surprizing enough; since two letters, or figures, can only be combined two ways.

The reason is, that letters only change their situation with regard to the first and second; the top and bottom remaining the same: but in the arrangement of these stones, each admits of four several situations, in each of which the other square may be changed fifteen times, which gives sixty-four combinations.

Indeed, from a farther examination of these sixty-four combinations, he found there were only thirty-two different figures; each figure being repeated twice in the same situation, though in a different combination; so that the two only differed from each other by the transposition of the dark and light parts.

The paving of streets is one of the most benefial regulations of police that have been transmitted to us from our ancestors. Several cities had paved streets before the commencement of the Christian era; nevertheless those which are at present the ornament of Europe, Rome excepted, were defective of this great advantage till almost the 12th or 13th century. It is probable that those people who first carried on the greatest trade, were the first who paid attention to have good streets and highways, in order to facilitate that intercourse which is so necessary to keep up the spirit of commerce. Accordingly we are told by Strabon (Orig. i. xvi. c. 16.) that the Carthaginians had the first paved streets, and that their example was soon copied by the Romans. Long before that period, however, Semiramis paved highways, as appears by the vain-glorious inscription which the herielf caused to be put up. (Strabo, l. xvi. Dies. Sicular, l. ii. v. 13. Polybeni, Stratagem, l. vii. c. 26.) The streets of Thebes, and probably those of Jerusalem, were paved. But neither the streets of Rome, nor the roads around it, were paved during the time of its kings. In the year 188, after the abolition of the monarchical form of government, Appius Claudius, being then cenfor, constructed the first real highway, called after him the Appian way, and on account of its excellence, the queen of roads. The time when the streets were first paved cannot be precisely ascertained; some have referred this improvement to the year 578, after the building of the city; others to 754, and others to 459; at which several periods some parts of the city and suburbs might have been paved. That streets paved with lava, having deep ruts made by the wheels of carriages, and raised banks on each side, for the accommodation of foot-passengers, were found both at Herculesleum and Pompei, is well known.

Of olden cities, the oldest pavement is commonly ascribed to that of Paris; but it is certain that Cordova in Spain was paved nearly as the middle of the 6th century, or about the year 850. The capital of France was not paved in the 12th century, but the orders for this purpose were fulfilled by the government in the year 1184, on which occasion it is said that the name of Lutetia, deduced from its dircines, was changed into that of Paris. Nevertheless, in the year 1641, the streets in many quarters of Paris were not paved. That the streets of London were not paved at the end of the 11th century, is ascertained by all historians. It does not appear when paving was first introduced; but it was gradually extended as trade and opulence increased. Several of the principal streets, such as Holborn, which are at present in the middle of the city, were paved for the first time by royal command in the year 1417; others were paved under Henry VIII., some in the suburbs in 1544, others in 1571 and 1605, and the great market of Smithfield, in 1614.

Pavement of Terrace, is that which serves for covering in manner of a platform; whether it be over a vault or a wooden floor.

Those over vaults are usually stones squared, and bedded in lead. Those on wood, called by the Latin pavimento contignata, are either stones with beds for bridges, tiles for ceiling of rooms, or layers of mortar made of cement and lime, with flints or bricks laid flat: as is still practised by the citizens and southern people a-top of their houses.

All those pavements which lie open were called by the Latin pavimento fabulata.

Pavement, Mosaic. See Mosaic Work.

Pavement, Tessellated. See Tessellated.

Paventia, in Mythology, the tutelary goddesses of children. Among the Romans this goddess was invoked to avert from them frightful objects.

P AV

Obi. We have already hinted the difficulty of establishing a certain distinctive character between this genus and Ixora; see that article. Whether the greater length of the flyle, more entire stigma, and less deeply divided calyx of Pavetta be of any great weight, a comparison of all the species of both genera together can alone determine.

1. P. indica. Linn. Sp. Pl. 160. Suppl. 121? Wild. n. 1. Ait. n. 1. (P. fea Malkamothe; Rheed. Hort. Mal. v. 5. 19. t. 10.)—Leaves elliptic-lanceolate, smooth, as well as the flower-flalks. Calyx very slightly toothed. Style twice the length of the corolla. Found in many parts of the Malabar coast, from whence Dr. Roxburgh sent us specimens. A humble spreading evergreen shrub. Leaves opposite, ranked, thin, smooth and shining, with many straight tranverse ribs. Stipulas broad, triangular, firmly combined with the foot-stalks, quite smooth. Flowers very numerous, white, fragrant, in smooth, slender, repeatedly forked, cymose panicles. Burman's Ind. t. 13. f. 31. accords in no respect with our plant. The plant of Ruophii, v. 4. t. 47, cited by Wildenow, after Linn. Mant. 331, is surely our Ixora flaminia, and has neither the form nor colour of Pavetta.

2. P. tenerifsis. Roxb. MSS.—Leaves elliptical, downy, as well as the flower-flalks. Calyx cloven half way down. Style twice as long as the corolla. Sent from India by Dr. Roxburgh, along with the former, from which it seems to differ chiefly in its broader leaves, which, like the flower-flalks and calyx are downy, especially when young. The teeth of the calyx are much more conspicuous than in P. indica, and this character appears of consequence, from the consideration of other species.

3. P. pilosa. "Vahl. Symb. v. 3. 12." Willd. n. 2.—"Branches and calyx villous and hoary. Leaves lanceolate-elliptical. Flowers in tufts."—Native of Arabia Felix. We know nothing of this but from Wildenow. The inflorescence is probably like P. indica, as Vahl uses the same term for both.

4. P. longiflora. "Vahl Symb. v. 3. 12." Willd. n. 3.—"Branches smooth. Leaves lanceolate-elliptical. Stipulas hairy on the inface. Calyx four-cleft. Flowers in tufts."—Native of Arabia Felix, where it was gathered by Forskall, as well as the latter. The calyx appears to be more deeply divided than in the first species, or perhaps the latter.

5. P. caffra. Linn. Suppl. 121. Thumb. Prodr. 29. Wild. n. 4. (Crima capenasi; Houttuyn Linn. Ppl. Syll. v. 5. 357. t. 40. f. 1. Willd.)—Leaves obovate, smooth. Flowers in terminal heads. Teeth of the calyx awl-shaped, above half the length of the tube of the corolla. —Gathered by Sparrmann and Thunberg at the Cape of Good Hope. The length of the calyx is very remarkable, as well as the long white dense hairs, clothing the common receptacle, or inner side of the bractea. The flyle is twice as long as the corolla.

6. P. barbata. Leaves lanceolate-oblong, pointed, smooth. Panicles forked, divaricated, smooth. Tube of the corolla but half the length of the five-cleft limb, bristly at the mouth.—Gathered by the late Mr. Christopher Smith, at Honimoa, or Honima, April 2, 1797. He suspected it to be a Pavetta, and we can only presume it to be so. The whole appearance agrees with the figure of the next, and the flowers, as in that, are five-cleft; but their short tube distinguishes them from every other species. The anthers are very long, equal to the corolla; nor does the stigma, which is cylindrical and acute, though curved, project beyond them. The calyx is a little hairy, lightly toothed, decidedly bell-shaped. The leaves are courtvass, a foot long, two inches broad, with taper points. Panicies axillary, many-flowered.

7. P. pentandra. Swartz. Ind. Occ. 233. Willd. n. 5. (Jalumnum arboreum, foli. foliis, bacca nigro-violaceis; Plum. 1c. 149. t. 156. f. 1. Cerafo affinis arbor laceraflora racemosa, fructu caruleo, monopyreno, telicatuato; Sloane. Jan. v. 2. 95. t. 202. f. 2.)—Leaves elliptic-lanceolate, pointed, smooth. Panicles forked, divaricated, smooth. Tube of the corolla twice as long as the five-cleft limb, naked at the mouth. Native of uncultivated hills in Jamaica, where it is called Wild Coffee. The leaves appear to be broader, and less courtvass, than in the lat. The flens is the height of a man, or much more. Flowers white, highly fragrant, produced in the vernal months.

Swartz considers the Stereobredirnium of Schreber, fee that article, akin to this plant, which he says is, in a manner, intermediate between the three very closely allied genera of Psheloria, Coffea and Pavetta. We cannot help advertmg to Wildenow's continuing the erroneous reference to Sloane, from Swartz's Prodromus, though he quotes the page in that author's Florca Ind. Occ., where the mistake is expressly pointed out and rectified.

PAUGANARY, in Geography, a town of Hindoostan, in Maravara; 10 miles S. of Tripatora.

PAVIA, in Botany, so called by Boerhaave in honour of Peter Pavius, who was professor of Phytic at Leyden, and to whom the care of the Botanic Garden there was confided in May 1592. The botanical Professorship being conferred upon Clusius two months afterwards, Bontius and Pavius were associated with him in this charge for several years. In 1609 the whole devolved upon Pavius, and he continued to enrich and improve the garden till his death in 1617. He does not appear to have published any thing, not even a catalogue of the garden. The present plant is now referred by botanists to another genus, viz Aesculus, in which it bears the specific name of Pavis, and is well known in our gardens as the Scarlet Horse-cheetnut.

PAVIA, in Geography, a city of Italy, and capital of the department of the Tefino, situated on a beautiful plain, on the river Tefino. It was once the capital of Lombardy, but few evidences remain of its having been once thus distinguished. The fortifications of the citizen have been neglected; the streets are broad and straight, and have some good buildings. Pavia is the seat of a bishop, and besides the cathedral, contains 18 parish churches, and 38 convents. The university was founded by Charlemagne, and re-established by Charles IV. It is still in good repute, its professors having distinguished themselves in natural history, and is regarded as the first in Italy. This city was founded by the Gauls; but they were expelled by the Romans, and the

3 M 2

Romans
PAV

Romans by the Goths, about the middle of the fifth century. In 476 or 477, Odocius granted the inhabitants an exemption from taxes for five years, in order to enable them to rebuild the town, which had been ruined, and which till that time had been denominated Tilinum; and when it was rebuilt, it was called Papia or Pavia. In 568 it was taken by the Lombards, and became their capital; but this disunion terminated with Didier, who was taken prisoner by Charlemagne in the year 774. afterwards it became the prey of several tyrants, till it fell under the dominion of the dukes of Milan. After several disfaters, this town was taken in 1800 by the French, who found in it immense stores belonging to the Austrians; 17 miles S. of Milan. N. lat. 45° 10'. E. long. 9° 9'.

Pavia, Duchy of, or the Pavoes, is now part of the department of the Telineo, and is bounded on the N. by the Milanese, on the E. by the Lodossin and Placentia, on the S. by the territory of Genoa, and on the W. by the Lutilen and Tortonege.

Pavicula, among the Romans, a rammer, or instrument for beating down and levelling a spot of ground.

It consists of a block of wood one foot long and half a foot thick, with a long handle.

Pavignano, in Geography, a town of Italy, in the department of the Mela; 10 miles E.N.E. of Brescia.

Pavillon, in Architecture, signifies a kind of turret, or building usually infalted, and contained under a single roof; sometimes square, and sometimes in form of a dome; thus called from the resemblance of its roof to a tent.

The word comes from the Italian pavilione, tent; and that from the Latin papilla.

Pavilions are sometimes also projecting pieces, in the front of a building, marking the middle of them. Sometimes, the pavillon flanks a corner, in which case it is called an angular pavilion. The Louvre is flanked with four pavilions. The pavilions are usually higher than the rest of the building.

There are pavilions built in gardens, popularly called summer-houses, pleasure-houses, &c. Some castles or forts confit only of a single pavilion.

Pavilion, in Heraldry, denotes a covering in form of a tent, which invets, or wraps up, the armories of divers kings and sovereigns depending only on God, and their sword.

The French heralds hold, that none but sovereign monarchs may bear the pavilion entire, and in all its parts.

The pavilion consists of two parts: the top, which is the chapauc, or coronet; and the curtain, which makes the mantle. Those who are eleevate, or have any dependence, may the heralds, must take off the head, and retain nothing but the curtains.

The use of pavilions and mantles in armories are derived from the ancient lambrequins, which are sometimes found stretched out in form of coverings; and tucked back on either side.

Others will have it derived from the ancient tournaments, where they were expofed the arms of the knight, in rich tapestry-work, on tents and pavilions, with the chets of the quadris planted to shelter themselves in, till the time of entering the lists.

Pavilion, in War, denotes a tent raised on poles to lodge under in the summer time. See Tent.

Pavilion is also sometimes applied to flags, colours, ensigns, standards, banners, &c. all which authors usually confound with one another.

The custom of bearing pointed pavilons, as at present, first came from the Mahometan Arabs, at the time when they conquered Spain. Till then, all colours were stretched on cross pieces like church-banners; whence they were called in Latin, vexilla quasi volitela, a diminutive of vols. fait.

The pirates all along the coasts of the Atlantic, and Barbary, bear hexagonal pavilions, gules, charged with a little Turk, dresed in his turban; though contrary to their law, which prohibits the making any image of a man; from an opinion that those who make the figure here will be obliged to furnish a foul for it at the day of judgment, or, in default thereof, be damned.

But this portrait, it seems, is that of Hali Sulphicar, Mahomet's son-in-law, to whose party the Africans adhere; and who appointed his picture to be represented on their banners; imagining himself so terrible to the Christians, that the mere sight of his image would put them to flight; as we are told by Leucelavius.

Pavilions, among Jewellers, the under sides and corners of the brillants, lying between the girdle and the collet.

Pauillac, in Geography, a town of France, in the department of the Girone; and chief place of a canton, in the district of Lefparre; 10 miles S.E. of Lefparre. The place contains 1443, and the canton 6941, inhabitants, on a territory of 165 kilometres, in 25 communes.

Pavlons, Stephen, in Biography, a man of letters, was born at Paris in 1632. He was educated for the law, and obtained the post of advocate-general of Metz, but a delicate constitution, and a love of study and refinement, caused him to resign that office, and devote himself to literature. The mildness of his manners, and the charms of his conversation, procured him many distinguished friends, and during the fits of the gout, to which he was a martyr, his chair was surrounded by perfons of rank and eminence. He refused the office of preceptor to a young prince, though it seemed to open the way to a good fortune. Lewis XIV. gave him a pension of 2000 livres. He died in 1704, at the age of 73. He was a member both of the French academy, and that of Inscriptions, without having solicited a seat in either. His literary reputation was chiefly founded on his poems, which were characterized by easy, gaiety, and great delicacy. The most complete edition of his works was printed at Paris in two vols. 12mo 1747. Moreni.

Pauilly, in Geography, a town of France, in the department of the Lower Seine, and chief place of a canton, in the district of Rouen; nine miles N.W. of Rouen. The place contains 2245, and the canton 14584, inhabitants, on a territory of 155 kilometres, in 25 communes.

Pavisade, and Pavisors. See Pavais.

Paukatchuck, in Geography, a small river of America, which runs into Stonington harbour, and forms a part of the division line between Connecticut and Rhode Island.

Paul, St., called also Saul, in Sacred Biography, an eminent apostle of Jesus Christ, was a descendant of the patriarch Abraham, of the tribe of Benjamin, and a native of Tarfus, then the chief city of Cilicia. He was also by birth a citizen of Rome. (Acts, xvi. 37; xvii. 26.) This privilege he claimed by his birth, and not, as Dr. Lardner has shown, by his nativity at Tarfus, which does not appear to have been a municipium, or town of Roman citizens. The excellent writer just named supposes, that some of St. Paul's ancestors had obtained the privilege of citizenship for services performed to the Roman commonwealth in the wars. (Vid. Grotius ad Act. xxii. 28.) His father was a Pharisee, and he himself was of the same sect. (Acts, xxii. 1. xxvi. 5. Philip. iii. 5.) His sister's son and some others of his relations, were Christians, and had been so before his conversion; and this circumstance is alleged as a proof of the virtue and piety of his family. That St. Paul was educated in Greek literature in his early life.

5
life at Tarsus, may be inferred from the place of his nativity, which was celebrated for polite learning, and also from his quotations of several Greek poets. (Acts, xvii. 28. 1 Cor. xv. 33. Titus, i. 12.) It appears that he was likewise for some time under the instructions of Gamaliel, a celebrated Jewish rabbi, at Jerusalem, and that he had made great proficiency in the study of the law, and the traditions, much esteemed by that people. (Acts, xxii. 3. xxvi. 5. Gal. i. 14.) He seems to have been a person of great natural abilities, of quick apprehension, strong passions, and firm resolution, and thus qualified for signal service, as a teacher of such principles as he should embrace, whatever they were. He appears likewise to have been always unblamable in his life, and strictly faithful to the dictates of his conscience, according to the knowledge which he had. This appears from his appeals to the Jews, (Acts, xxxi. 1. xxvi. 4, 5.) and from the indelible impression which he exprelles upon a famous recollection of his former and later conduct. (Philip, iii. 6. 1 Tim. i. 13. 2 Tim. i. 3.) For some time after the first appearance of Christianity in the world, he was a bitter enemy, and furious opposer of all who made profestation of it. Nevertheless he did not long persist in that course; but was converted, in an extraordinary manner, to that faith himself; and ever after he was a steady friend, and zealous advocate for it, and very successful in defending and propagating it, diligently improving the gifts and qualifications extraordinarily vouchsafed for that purpose.

These particulars are recorded in those writings which are in the highest esteem, and reckoned sacred among Christians, and indeed well known to all the world.

Dr. Lardner has taken great pains to settle the time of his conversion; and this has been thought the more necessary, as various opinions have been entertained among ancient writers, cited by Vitruus in his Annotationes upon Epitome's Eccle. Hist. and also among the moderns. Cave thought that Stephen was stoned and Paul converted in the year of our Lord's ascension, A.D. 33, or the beginning of the year following. Pearson supposes, that Stephen was stoned in 34, and Paul converted in 35, near the end of the year. Frederic Spanheim, after diligent inquiry, fixes the conversion of Paul in the year 40, the exit of Caius Caligula; and inclines to defer it to the first of Claudius, or the year 41. Vitruus and J. A. Fabricius adopt the same opinion. Lenfant and Beaufobre place his conversion in the year 36, and his first coming to Jerusalem after it in 39; and this opinion is thought by Dr. Lardner to be nearer the truth than any of the foregoing. Upon the whole Lardner concludes that Paul was converted in 37, or possibly, before the end of the year 36; and Stephen was stoned in the beginning of the same year, or, at the fonnet, near the end of the year 35. The first notice we have of Paul is in the account of St. Stephen's martyrdom; and it is probable, that he had not long before made his appearance in the world. If we advert to his situation and circumstances, we shall discover the proper vindication of his moral character. It is probable, that he had not seen Jesus during his abode on earth; and it is possible that he did not come from Tarsus to Judea, till after the close of our Lord's ministry; nor is it any unfair supposition, that he had not any acquaintance with any of Christ's apostles, and that he had not seen any miracles wrought by them, before he became a persecutor; and afterwards, he would not admit of instruction from the followers of Jesus. Whilst he was under the tuition of Gamaliel, we may reasonably imagine, that he knew little of the public affairs of Judea, though he was in that country; but when he came from the schools, animated with a high degree of zeal for the law of Moses, and for the traditions of its elders, and found a number of men, called followers of Jesus, who spake of him as the Messiah, and as raised from the dead, representing him as greater than Moses himself, he was filled with indignation, and thought that it was his duty to oppose them to the utmost, which he did till Jesus met him and reclaimed him. Although he spake of himself as injurious (1 Tim. i. 13. Acts, xxvi. 10., yet we may suppose that, even then, he would not have injure any man, in his person or property, from worldly considerations. The moving principle by which he was actuated was not envy, malice, covetousness, or any worldly view, but a false zeal for God and religion; and this induced him to be a persecutor, which is a character, in certain circumstances, not inconsistent with integrity. This might have been the case, with respect to Paul, who was a young man, little acquainted with the world, and just emerging from a Jewisli school, where he had been engaged in the study of the law, and the Rabbinical interpretations of it. To this purpose Chrysostom distinguishes between Paul and the Jews; observing that he had a sincere zeal for religion, according to his knowledge at that time, and that they had no concern for Jerusalem, and aimed at nothing but their own honour. But although Paul was sincere, and did not act contrary to conviction, his conduct cannot be justified. He should have examined; he should have taken care to be well informed; if, upon his first coming out into the world, he had pursued this course, he might have received satisfaction, and consequently might have been prevented from acting that part against Jesus, and his disciples, which he afterwards bewailed. His prejudices, however, were strong; and they were not to be overcome in an ordinary way. But though he was prejudiced, he was not obli- nate. Our blessed Lord knew him to be tractable, and open to conviction; and he knew, that the measures which he adopted for this purpose would change his heart, and melt him down to ready obedience. The event corresponded to expectation. Although he sat out for Damascus under the full influence of enmity against the disciples of Jesus, he was soon changed, as the history (Acts, ix. 5—6) relates. He trembles and acquiesces, all his rage was fandued, and he became a disciple of Jesus.

Satisfied in his own mind, he imagined that others would manifest a disposition similar to his own, and that an account of his conversion, with all the reasons and circumstances of it, which he was prepared to lay before his countrymen, the Jews, must persuade them. Jesus better knew the disposition and character of the people, whom he thought of convincing and reclaiming; and therefore, instead of permitting him to labour unprofitably among them, renewed his orders to Paul, to proceed, without delay, in the work of preaching to the Gentiles, on which he had already entered. The event proved that the over-ruling providence of God disproved of his perfom and concerns more wisely and more beneficially than he was capable of judging and acting for himself. It was a very happy and favourable circumstance, that he did not return to Judea immediately after his conversion; because the violent persecution, which commenced about the time of Stephen's death, had continued at least three years after Paul left Judea to go to Damascus.

Dr. Lardner has taken pains to settle Paul's age at the time of his conversion. Vitruus supposes that he was born near the end of Herod's reign, about the same time with our Saviour. In the epistle to Philemon, (v. 9.) written about the year of the vulgar era 62, he calls himself Paul the aged; and this must lead us to suppose, that he was then 60 years of age, or not much less. In the account of the martyrdom of Stephen, he is called a young man (Acts, vii. 58;) but among the ancients the term youth is used with latitude: and
from some circumstances related of him at that time (Acts, xxvi. 10—12.) we have reason to conclude, that he was arrived to years of maturity, or discretion; and that at the time of his conversion he was of an age at which men are able to judge concerning the evidence of things, and so form a reasonable determination with regard to their future conduct.

It has been generally suppossed, that Paul was called to the apostleship at the time of his conversion, or very soon after it. Spanheim, Witius, Cave, Pearce, Bapirage, and Hallet are of this opinion. The requisite qualification of an apostle appears to have been, that he should see Christ in person, and that after his resurrection. (See Acts, i. 21, 22.) Accordingly Paul, when he claims the character of an apostle, speaks of his having seen Christ, as a fact well-known and uncontested. (1 Cor. i. 18.)

In his way to Damascus, Christ had personally appeared to him. (Acts, ix. 3—6.) The learned author, of whose research we are availing ourselves in the compilation of this article, thinks it highly probable, from all the accounts which we have of Paul's wonderful conversion, (Acts, ix. xxii. and xxvi.) that he received his apostolical commission from the mouth of Christ in person, when he called to him from heaven, and spoke to him in the way to Damascus. As he was, from the beginning, called, and appointed to be an apostle, he was by degrees qualified for it as his commission opened; and in time he was called out by divine providence to the full execution of it.

Paul, having been baptized by Ananias at Damascus, layed for a short time with the disciples there, and then went into Arabia, where he probably might meet with some believers. (Acts, ii. 14—21.) Whilist he remained in Arabia, he was fully instructed, as we may reasonably think, by special revelation, in the doctrines preached by Jesus Christ, when on earth, and all the things said and done by him, and his sufferings, crucifixion, resurrection, and ascension, the fulness of the ancient prophecies in Jesus, the Christ, the Son of David, and the Son of Abraham; and received also the holy ghost, in a measure equal to that of other apostles. He was thus qualified to preach the gospel, and to testify the resurrection of Jesus, and to prove him to be the Christ, without receiving either instruction or gifts from other apostles. Having been some time in Arabia, he returned to Damascus; but here a design being formed against his life, he removed to Jerusalem. (Acts, ix. 20—23.) The period of three years, or three years and somewhat more, which elapsed from Paul's conversion to his coming to Jerusalem, reaches, according to Lardner's computation, from near the end of the year 39 to near the end of 39, or the beginning of the year 40, or from the beginning of the year 37 to the former part of the year 40. Paul travelled through the countries of Cilicia and Syria, during the remainder of the year 40, and the whole of 41, and 42, or the greatest part of the last-mentioned year, till about the beginning of the year 43, preaching, undoubtedly, in the name of Jesus, to native Jews, and to proselytes of the Jewish religion. Afterwards he went to Antioch, and began to preach to Gentiles. Here he probably had the rapture, mentioned by him (2 Cor. xii.) Having fulfilled the commission mentioned Acts, xi. 27—30, by a journey to Jerusalem, where, in the year 44 he had the trance taken notice of in his speech to the Jewish people (Acts, xxii. 17—21), Paul, and also Barnabas, who had accompanied him, soon after this, left Antioch, and made a farther progress in preaching the gospel to Gentile people. For this journey Pearson allots three years, viz. 45, 46, 47; and somewhat more. Tillerson thinks, it might have been performed in two years, from 44 to 45; or from the beginning of the year 45 to the former part of the year 47, which is Lardner's opinion. Having made some stay at Antioch after their return, they attended a council at Jerusalem, held in the year of Christ 49, or in the beginning of the year 50, and afterwards returned to Antioch. In the beginning of the year 50. St. Paul and Barnabas set out from Antioch; and having gone through Syria and Cilicia, they came to Phrygia; and it is very probable, that Paul preached in the chief cities of that country, Hierapolis, Laodicea, and Colosse. St. Paul also went to Galatia, and there founded many churches; but they were forbidden to preach in Asia, properly so called. After passing through several countries and cities, mentioned in the book of Acts, ch. xvi. xvii. St. Paul went to Corinth, where he might have been before the end of the year 51. Here he tarried a year and six months, i.e., as Lardner supposes, the remainder of the year 51, the whole of 52, and part of 53. Having passed through Galatia and Phrygia, he came to Ephesus, before the end of the year 54, in October or November; and here he remained till the year 56, about pentecost. As the emperor Claudius died Oct. 13, in the year 54, the tidings of his death, and the accession of Nero, might not have reached Ephesus before the beginning of the year 55. Soon after St. Paul determined to visit Rome, propising first to go to Macedonia, Greece, and Jerusalem. (Acts, xix., xx.) Some time before pentecost, or about that season, in the year 56, Paul left Ephesus to go into Macedonia. Here he laid about a year; at Corinth he laid three months; and there must have elapsed an interval of two years, or nearly as much, between Paul's leaving Ephesus and coming to Troas, in his way to Jerusalem. At this time Paul was in Illyricum and Crete. He arrived in Jerusalem at the pentecost in the year 58. From Jerusalem he was sent away to Rome near the end of the year 62. (See Acts, xxii. 17, ch. xxvi. 1—32.) In ch. xxvii. and xxviii. 1—16, we have a very distinct relation of Paul's voyage to Rome; where he arrived in the spring of the year 61; and he was released from his confinement in the former part of the year 63. It has been a subject of debate, whether Paul went after he had obtained his liberty. Some think that he went from Rome to Spain; but Lardner is of opinion that he came from Rome to Jerusalem, as soon and as directly as he could. Here he made a short stay, and from Judea he went to Ephesus; from Ephesus he might go to Laodicea and Colosse, and, possibly, he returned to Rome by Troas, Philippi, and Corinth. It is the opinion of Pagani and Bapirage, that Peter and Paul suffered martyrdom in the year of Christ 65. Or onius, they say, having given an account of Nero's persecution of the Christians, and of the death of the two apostles in it, adds, that it was followed by a pellience in the city, and other disasters. Sulpicius Severus has given an account of the fire at Rome, and Nero's persecution of the Christians, and also of the martyrdom of Peter and Paul therein; adding, that while these things were doing at Rome, the Jews, being uneasy under the oppressions of their governor Gellius Florus, began to rebel; upon which savage Bapirage observes, the Jewish war began in May 66; and therefore the martyrdoms of the apostles happened in the year before, that is, 55. Ephraem places the death of Peter and Paul in the 12th year of Nero, part of which, as he says, fell in the year 65. Dr. Lardner does not presume to affirm positively the year of the martyrdom of these two apostles; he is of opinion that they did not survive the year 65; but he cannot say whether their martyrdoms happened in the year 64 or 65. If Peter and Paul were come to Rome before the city was set on fire, and before the persecution of the Christians began, which is not improbable, they
they might be taken up and soon put to death before the end of the year 63. Lardner's Works, vol. vi.

For an account of the undesign'd and usual, but very remarkable, coincidence or correspondence, between the circumstances that are recorded in the history of St. Paul's preaching and traveling, and others, similar to them, which are either explicitly stated, or obviously implied, in the epistles of the same apostle; and of the conclusion that results from this coincidence in favour of the truth of the history, and the genuineness of the epistles, we refer to archdeacon Paley's excellent work, entitled " Horae Paulineae." See Acts of the Apostles, and Paley.

Lord Lyttleton, in his "Letter to Gilbert Wake, esq."

has deduced from the conversion and apostleship of St. Paul, an argument, which, duly considered, amounts to itself a demonstration sufficient to prove Christlikeness to be a divine revelation. Although within our limits we cannot do full justice to the admirable reasoning of this distinguished advocate for our holy religion, we shall endeavour to give such an abstract of it as may satisfy our own conviction of the truth of Christlikeness, and promote similar sentiments concerning it in the minds of our readers. Our noble author, having cited from the book of the Acts (ch. ix. 12. 18. xx. 6. 13. 14. xxii. 10–16. xxvii. 1, &c.) the account which St. Paul himself gives of his conversion and preaching, and which is recorded in his history by a contemporary author, and a companion of the apostle, compares these records with the manner in which St. Paul speaks of himself in the epistles written by him to the several churches which he planted, and the authenticity of which cannot be doubted without overturning all rules, by which the authority and genuineness of any writings can be proved or confirmed. (See Galat. i. 11–16. Philisp. ii. 4–8. 1 Tim. i. 12. 13. 2 Cor. i. 1. Col. i. 1. 1 Tim. i. 1. Gal. i. 1. 1 Cor. xv. 2.) He then states, that the person who attests these things of himself, and of whom they are related in so authentic a manner, either was an impostor, who said what he knew to be false with an intent to deceive, or an enthusiast, who, by the force of an overheated imagination, imposed upon himself; or, he was deceived by the fraud of others, and all that he said must be imputed to the power of that deceit; or what he declared to have been the cause of his conversion, and to have happened in consequence of it, did all really happen; and therefore the Christian religion is a divine revelation.

That the apostle was not an impostor, who said what he knew to be false with an intent to deceive, our author undertakes to prove, by shewing that he could have no rational motives to engage in such an imposture, nor could have possibly carried it on with any success by the means which we know he employed. His inducement to such an imposture must have been one of these two, either the hope of advancing himself by it in his temporal interest, credit, or power, or the gratification of some of his passions under the authority of it, and by the means it afforded. From the circumstances in which St. Paul declared his conversion to the faith of Christlikeness, and which our author has recited, it appears to every reasonable person's satisfaction, that he could have had no hope of increasing his wealth. The certain consequence of his taking the part he did, was not only the loss of all that he had, but of all hopes of acquiring more. Tho' whom he left were the dupers of wealth, of dignity, and of power, in Judea; tho' with whom he united were indigent men, oppressed, and deprived of all means of improving their fortunes. Tho' among them, who had more than the reft, shared what they had with their brethren; and even with this affliction, the whole community was hardly supplied with the necessaries of life, and even in churches which he afterwards planted himself, which were much more wealthy than that of Jerusalem, St. Paul was so far from availing himself of their charity, in order to draw that wealth to himself, that he often refused to take any part of it for the necessaries of life. (See 1 Cor. xv. 8. 2 Cor. xii. 14. 2 Thess. ii. 4. 5. 6. 9. 2 Thess. iii. 8. Acts. xx. 33. 34.)

As to credit or reputation, that also lay altogether on the side he forsook. The fact he embraced was under the greatest and most universal contempt of any then in the world; the chiefs and leaders of it were men of the lowest birth, education, and rank; they had not a single advantage of parts or learning, or other human endowments to recommend them; the doctrines they taught were contrary to those which they, who were accounted the wifest and the most knowing of their nation, professed; the wonderful works they did were imputed either to magic or to imposture; the very author and head of their faith had been condemned as a criminal, and died on the cross between two thieves. Could the disciple of Gamaliel think he should gain any credit or reputation by becoming a teacher in a college of philosophers? Could he flatter himself, that, either in or out of Judea, the doctrines he taught could do him any honour? He knew and professed the contrary. Experience soon convinced him that, in all parts of the world, contempt was the portion of any one who engaged in teaching a mystery so unpalatable to all mankind, to all their passions and prejudices, and so irreconcilable to the pride of human reason, as "Christ crucified," which was "a stumbling block to the Jews, and to the Greeks foolishness." "We are made (says he to the Corinthians) as the filth of the world, the off-scouring of all things unto this day." Yet he went on as zealously as he set out, and was "not ashamed of the gospel of Christ." The desire of glory, or the ambition of "making himself a great name," was, therefore, not his motive to embrace Christianity. But was it the love of power? Power I over whom? over a flock of sheep driven to the slaughter, whose shepherd himself had been murdered a little before. All he could hope from that power, was to be marked out in a particular manner for the fame knife, which he had seen to bloody drawn against him. Could he expect more mercy from the chief priests and the rulers, than they had shown to Jesus himself? Would not their anger be more fiercely directed against the deferrer and betrayer of their cause than against any other of the apostles? Was power over so mean and despifed a class of men worth the attempting with so much danger? But let it be considered, what power St. Paul actually assumed and exercised over the Christians. Did he pretend to any superiority over the other apostles? So far from it, that he declared himself the laft of them (Ephef. iii. 8.) and less than the laft of all saints. (1 Cor. xv. 9.) In the churches which he himself planted, he never pretended to any primacy or power above the other apostles. (See 1 Cor. i. 12. 13. 1 Cor. iii. 5. 2 Cor. iv. 5.) The authority which St. Paul exercised over Christians was purely of a spiritual nature, tending to their instruction and edification, without any mixture of that civil dominion in which alone an impostor can find his account. In this respect his authority was very different from the dominion acquired and exercised under a pretence of divine inspiration, by many ancient legislator; by Minos, Rhadamanthus, Tript-lemus, Lycurgus, Numa, Zaleucus, Zoroaster, Xamolxis: nay, even by Pythagoras, who joined legislation to his philosophy, and, like the others, pretended to miracles and revelations from God, to give a more venerable sanction to the laws which he preferred. Such, in later times, was attained by Odin among the Goths, by Mahomet among the Arabians, by Mango Capac among the
the Peruvians, by the Sog family among the Perians, and that of the Zerifs among the Moors: and to such a dominion did many false Messiahs among the Jews aspire. In such and similar instances, a spiritual authority was only defined as a foundation for temporal power, or as a support of it. How different were the views and conduct of St. Paul! He made no innovation in government or civil affairs: he meddled not in legislation, he formed no commonwealths, he raised no feudalities, he affected no temporal power. He both taught and practised obedience to civil rulers; nor did he practice any of those soothing arts by which ambitious and cunning men recommend themselves to the favour of those whom they endeavour to subjugate to their power. What was wrong in his discipules he reproved in a manner becoming a teacher from God; and as were his discipoure when prefent with them, so were likewise his writings, when abfent. (See Phil. iii. 15, 16, 17.) If it be said that he affeded an absolute spiritual power over the churches which he formed, it may be replied, that he preached Christ Jesus, and not himself. He even renounced any advantage which a higher education, superior learning, and more use of the world might have afforded him for claiming to himself any superiority over the other apoftles. (See 1 Cor. ii. 1, 2. 5.) An impofitor, on the contrary, would have availed himfelf of these advantages for securing pre-eminence and influence to himfelf.

As St. Paul had nothing to gain by his new profeflion, let us confider what he gave up, and what he had reafon to fear. He gave up a fortune which he had a fair opportunity of advancing: he gave up that reputation which he had acquired by the labours and studies of his whole life, and by a behaviour, which had been blameless, touching the righteousnefs which is in the law (Phil. iii. 6, 7); he gave up his friends, his relations, and family, from whom he extrafed himfelf for life; he gave up that religion, in which he had profefed above many of his equals in his own nation, and tho-fe traditions of his fathers, which he had been more exceeding zealously of. (Gal. i. 14.) Such were the facrices which he made in becoming a Christian. The inconvemiences he had to fear were, the implacable vengeance of those whom he depreated: that fort of contempt, which is hard to bear, the contempt of those whole good opinion he had most eagerly fough: and those other complicated evils, which he describes in the 11th chapter of the Second epiftle to the Corinthians; evils, the left of which were fufficient to have frightened any impofitor even from the moft hopeful and profitable cheat.

The next object of enquiry is, whether the gratification of any other paffion, besides the defire of wealth, fame, or power, under the authority of the religion to the profeflion and service of which he was devoted, or by the means which it afforded, could be his inducement to becoming a disciple and apoftle of Christ. His writings and his conduct furnifh the moft satisfactory answer to this enquiry. The former breathe nothing but the ftrongeft morality, obedience to the order and government of magiftrates, with the utmost abhorrence of all licentiousnefs, idlenefs, or foole behaviour, under the cloak of religion (Rom. xi. xii. Col. iii.); and the latter, both before and after his conversion to Chriftianity, does not bear any mark of a licentious disposition. See his appeal to the Thesflalians, (1 Theff. ii. 10. See also 2 Cor. i. 12. iv. 2. vii. 2.) If it should be again faid, that although St. Paul could have no felfih or interefled view in undertaking fuch an impofitor, yet for the fake of its moral doctrines, he might be inclined to support the Chriftian faith, and make ufe of some pious frauds to advance a religion, which, though erroneous and falle in its theological tenets, and in the fake upon which it was founded, was in its precepts and influence beneficial to mankind. In difcutting this fake, it should be recollected, that the circumstances of St. Paul were very different from tho-fe of fome good men in the Heathen world, who pretended to divine revelation, and introduced or supported doctrines and forms of religion which they knew to be falle, under a notion of public utility. They not only did it ferve good ends, but were fecure of its doing no harm. Thus when Lycurgus perfuaded the Spartans, or Numa the Romans, that the laws of the one were inspired by Apollo, and those of the other by Egeria; when they taught their people to put great faith in oracles, or in augury, no temporal mischief, either to them or to their people, could attend the reception of that belief. It drew on no perfeotions no enmity with the world. But at the time when St. Paul undertook the preaching of the gospel, to perfuade any man to be a Chriftian, was to perfuade him to expose himfelf to all the calamities human nature could fuffer. This St. Paul knew. (See Theff. iii. 4. 2 Cor. vi. 14, 5. Eph. vi. 10—16. Phil. i. 28—30. Col. i. 9—11. Rom. viii. 35, 36.) Could any man who had in his nature the leaf ray of humanity subject his fellow-creatures to fo many fufferings, as were juftly to be expected, and even actually announced; or could one that had in his mind the leaf ray of reafon, perfuade himfelf to share them with tho-fe he deceived, in order to advance a religion which he knew to be falle, merely for the fake of its moral doctrines? Such an extravagance is too abfurd to be even fuppofed. The cafe of St. Paul was, in one repect, different from that of the other apoftles. To them it may be objected, by tho-fe who are refolved not to credit their testimony, that having been deeply engaged with Jesus, during his life, they were obfliged to continue the fame profefions after his death, for the fupport of their own credit, or from having gone too far to recede. This can by no means he faid of St. Paul. If there can be any force in this reafoning, it tends to convince us, that St. Paul muft actually have continued a Jew, and an enemy of Chrift Jesus. If they were engaged on one fide, he was as strongly engaged on the other. If vame witheld them from changing fides, much more ought it to have restrained him, who, being of a much higher education and rank in life than they, had more credit to lofe, and muft be fuppofed to have been much more fenfible to that fort of blame. The only difference was, that they, by quitting their matter after his death, might have preferved themselves; whereas he, by quitting the Jews and taking up the crofs of Chrift, certainly brought on his own deftruction. Upon the whole we may very juftly conclude, that when a man of St. Paul's understanding embraced the faith of Chrift, he was in reality convinced of the truth of it, and that, confequently, he was not an impofitor, who faid what he knew to be falle, with an intent to deceive. If it be again faid, that St. Paul might have been capricious, and might have acted without any rational motive; to this kind of argument it may be replied, that if he had been fo unaccountably wild and abfurd as to undertake an impofitor fo unprofitable and dangerous both to himself and to tho-fe who were deceived by it, he could not possibly have carried it on with any succefs by the means which he is known to have employed. His impofitor was fuch, that it could not have been carried on by one man alone. He could not have acted as he did, but in confederacy at leaft with the apoftles; but till he came to Da-masus, he had no communication with the apoftles; he acted in no concert with them, and learnt nothing from them.
them, except the doctrines which they had publicly taught to all the world. When he came there, he told the Jews, to whom he had brought letters from the high-priest and the synagogue against the disciples of Christ, of his having seen, in the way, a light from heaven, and heard Christ Jesus reproaching him with his persecution, and commanding him to go into the city, where it should be told him what he was to do. But to account for his choosing this method of declaring himself a convert to Christ, we must suppose that all who came with him, when he pretended he had his vision, were his accomplices: and yet, how can we suppose, that all these men should be willing to join in this imposture? They were either officers of justice, employed in executing the orders of the high-priest and the rulers against the Christians; or they were persons chosen for this expedition because they might be trusted for their zeal in promoting its object. The instructor at Damasæus, to whom he was referred, must also have been his accomplice; and yet they appear to be absolute strangers to one another. But how could this man venture to act such a dangerous part, without the consent of the other disciples, especially of the apostles, or by what means could he obtain their consent? But would it not have been more easy to have made Saul present at some pretended miracle wrought by the disciples, or by Ananias himself, when none were able to discover the fraud, and have imputed his conversion to that, or to the arguments used by some of his prisoners whom he might have disconcerted with, and questioned about their faith, and the grounds of it, in order to colour his intended conversion? This would have been the safest, and also the most natural method of bringing about such a change, instead of ascribing it to an event which lay so open to detection. If this story had been an imposture, and Ananias had joined with Paul in carrying it on, is it not strange, that, after their meeting at Damasæus, we should never hear of their conferring together; or acting in concert? But dismissing this part of the busines; how could Paul get himself owned and received as an apostle by the apostles? This was necessary to be done without delay, but instead of attending to this very important, and, indeed, essential object, St. Paul went into Arabia, and then returned again to Damasæus; nor did he go to Jerusalem till after an interval of three years. (Gal. i. 17, 18.) He had also exposed himself to danger, when at Antioch he wished Peter to the face, and reproved him before all the disciples, because he was to be blamed. (Gal. ii. 11—14.)

Accomplices in a fraud are obliged to shew greater regard to each other; such freedom belongs only to truth. Moreover, in the erstwhile he undertook of going to the Gentiles, making himself their apostle, and converting them to the religion of Christ, he had many difficulties to encounter among the Gentiles themselves. In this erstwhile, he had to contend with the policy and power of the magistrates; with the interest, credit, and craft of the priests; with the prejudices and passions of the people; and with the wisdom and pride of the philosophers. His success against this combined opposition he ascribes to the efficacy of divine power. (1 Cor. ii. 4. Thess. i. 5.) If that power attended him, it would enable him to overcome all these difficulties that obstructed his enterprise; but then he was not an impostor. Our enquiry, therefore, must be, whether (supposing him to have been an impostor) he could, by pretending to miracles, have overcome all these difficulties, and carried on his work with success? For this purpose, two circumstances were principally necessary; an apt disposition in those whom miracles are designed to impose upon, and a powerful confederacy to carry on and attest the cheat. But what prepossessions could have been in the minds of the Gentiles, either in favour of Paul or the doctrines he taught; or rather, what prepossessions could be stronger than those, which they undoubtedly had against both? Without the advantage of this predispersion, and the assurance it would have afforded, was there any confederacy strong enough to impose his false miracles upon the Gentiles, who were both unprepared and indisposed to receive them? The contrary is apparent from the nature of the case, and the history of the apostle.

Our illustrious author, having proved that St. Paul was not an impostor, proceeds to consider whether he was an enthusiast, who, by the force of an overheated imagination, imposed upon himself. The ingredients, he says, of which enthusiasm is generally composed, are, great heat of temper, melancholy, ignorance, credulity, and vanity or self-conceit. He then shews, that none of these qualities, which displease the mind to enthusiasm, and which are characteristic of it, belonged to St. Paul. His zeal indeed was eager and warm, but tempered with prudence, and even with the civilities and decorums of life, as appears by his behaviour to Agrippa, Festus, and Felix: not the blind, inconsiderate, indecent zeal of an enthusiast. As to melancholy, it neither appears by his writings, nor by any thing told of him in the Acts of the Apostles, nor by any other evidence, that St. Paul was inclined to it more than other men. As to ignorance, St. Paul was so far from it, that he appears to have been master, not of the Jewish learning alone, but of the Greek. The history of his life, likewise shews, that St. Paul could not be justly chargeable with credulity. On the contrary, he seems to have been slow and hard of belief in the most extreme degree, having paid no regard to all the miracles performed by our Saviour, to the fame of which he could not be a stranger, as he lived at Jerusalem: nor to that signal one wrought, after his resurrection, and in his name, by Peter and John, upon the lame man at the beautiful gate of the temple; nor to the evidence given in consequence of it by Peter, in presence of the high-priest, the rulers, elders, and scribes, that Christ was raised from the dead. Other circumstances are enumerated, which amply vindicate the apostle from this charge. From vanity or self-conceit St. Paul was as free as any man, as we may collect from all that we see in his writings, or know of his life. Throughout his epistles, there is not one word that shows of vanity, nor is any action recorded of him, in which the least mark of it appears. See Eph. iii. 8. 1 Cor. xv. 9. 1 Tim. i. 15, 16. 2 Cor. xi. 12. xi. 1. 15—19. 35. xii. 2. 6. 1 Cor. xv. 10. xiv. 3. 4.

Allowing, for the sake of argument, that St. Paul was an enthusiast, our author shews that he could not have imposed on himself by any power of enthusiasm, either in regard to the miracle that caused his conversion, or to the confessional effects of it, or to some other circumstances to which he bears testimony in his epistles. Although the power of imagination in enthusiastic minds is very strong, yet it always acts in conformity to the opinions imprinted upon it at the time of its operation, and can no more act against them than a rapid river can carry a boat against the current of its own stream. The mind of St. Paul, in his way to Damasæus, was strongly prepossessed with opinions against Christ and his followers. His passions concurred at that time in giving those opinions a more active force; and therefore whatever delusive his imagination might nafe to impose on his reason, must at that time have been raised agreeably to the notions imprinted upon it, and by which it was heated to a degree of enthusiasm, not

Vol. XXVI.
in direct contradiction to all those notions, while they remained in their full force. With respect to the vision that is recorded in this part of his history, it is plain that it could not have been a phantom of his own invention, because he was not alone when he saw it: many others were in company, whose minds were no better disposed than his to the Christian faith, and it must be supposed, against all motive and all possibility, that the imaginations of all these persons were, at the same time, so strangely affected, as to make them believe that they saw and heard what in reality never occurred. But supposing, that, as Saul and his companions were journeying towards Damascus, an extraordinary meteor did actually appear, how shall we account for the diametrically opposed visions heard by Saul, to which he made answer, and for what followed, agreeably to these words, on his arrival at Damascus? That St. Paul saw Christ, both now and after this time, appears not only by what he relates Acts, xxii. 17, 18; but by other passages in his epistles, 1 Cor. ix. 1. xvi. 8. Acts, ix. 17. From him, as he affirms in many places of his epistles, he learned the gospel by immediate revelation, and by him was sent to the Gentiles: Acts, xi. 12. xxii. 11. If St. Paul had been a mere delirium, how can we account for the miracles which he wrought, and for the progress he made in converting the Gentile world? If the difficulties that impeded his efforts for this purpose were such as the ablest impostors could not have overcome, how much more insurmountable were they to a madman? Of all the miracles recorded in scripture, none are more clear from any possible imputation of being the effect of an enthusiastic imagination than that of perfons speaking languages which they had never learned: and it is a power which has never been pretended to by any enthusiast, ancient or modern.

Having shewn that St. Paul could not be an enthusiast, who, by the force of an over-heated imagination, imposed on himself, our noble author proceeds to enquire, whether he was deceived by the fraud of others, and whether all that he said of himself can be imputed to the power of that deceit? But this supposition is so palpably absurd, that we need not enlarge in the confutation of it.

If, then, the apostle was not deceived by the fraud of others, and what he said of himself cannot be imputed to the power of that deceit, no more than to wilful imposture or enthusiasm, it must follow, that what he related to have been the cause of his conversion, and to have happened in consequence of it, did actually happen, and therefore the Christian religion is a divine revelation.

See two excellent sermons on the subject of this article by Dr. Duchal, in his Prefumptive Arguments, &c., forming the fourth volume of his sermons, but published separately.

Paul's Art. See Art.

Paul of Samosata, in Biography, is named from the place of his birth, was a celebrated prelate of the third century, after whom several Christians as entertained the same opinions were generally called Paulians, till the council of Nice. In the year 260 he was chosen bishop of Antioch, and by his talents and character recommended himself to the favour of Zenobia, the celebrated consort of Odenatus. He rendered himself obnoxious to the orthodox by denying the doctrine of the pre-existence of Christ, and maintaining that he was a mere man, on whom the wisdom of God descended from heaven, and dwelt in him, enabling him to work miracles, and instruct nations. A council was assembled at Antioch in the year 264, before which Paul was accused of a dangerous heresy, and of a life and conversation unworthy of the episcopal character. The result of this accusation was, that Paul was admonished. For this mild sentence he was probably indebted to the prudence and moderation of Firmilian, bishop of Ctesarea, who presided in the council, and prevented those who composed it, by his influence, from adopting harsher measures. In the year 269 or 270, a second council was assembled at Antioch, in order to take into consideration the principles and conduct of the bishop. Firmilian was summoned to this council, but died on his journey towards Antioch, and it was owing to this event that the enemies of Paul succeeded in their design, and procured a sentence which condemned him to be deposed from his episcopal dignity.

Paul refused submission to the decree of the council, and retained possession of the house of the church, and was supported in this step both by the protection of Zenobia, and the good will of the people. When that prince was driven from Antioch, Paul became the emperor Aurelian's messenger to expel him, with whose request he complied in the year 272 or 273. What became of Paul after this event is not known; it has been thought by some writers, that those who adhered to him were formed into a separate society by Lucian, who suffered martyrdom in the year 312. There is no doubt that Paul was author of some publications that have not come down to our times, because his adversaries say that there was fearlessly a page in his works without citations out of the Old and New Testament. According to the judicious and candid Lardner, who formed his judgment after much consideration, Paul had a great mind, with a mixture of haughtiness, and too much affectation for human applause. He was generally well respected in his diocese, and by the neighbouring bishops, in esteem with the great, and beloved by the common people. He preached frequently, and was a good speaker. Lardner's Credibility. Moehm's Ecc. Hist.

Paul I. pope, was a native of Rome, and brother to his predecessor Stephen II. He became deacon of the Roman church, and in the year 756, Stephen sent him with rich presents to the king of the Lombards, in order to obtain confirmation of the treaty of peace in which that prince had entered with his predecessor pope Zachary. In this object he succeeded without much difficulty, and the king granted an extension of the term agreed on for forty years longer, that he might divert the pope from interfering with the design he had then formed, and soon after carried into execution, of subjugating the exarchate of Ravenna. Upon the death of Stephen in 757, the Roman people were divided about the choice of a successor, some declaring for the deacon Paul, and others for the archdeacon Theophylact. At length, after a vacancy of more than a month, the nobility, clergy, and magistrates, all zealously promoting the interests of Paul, the election was carried in his favour, and this is the only instance which occurs in the whole history of the popes, of two brothers being raised successively to the papal chair. No sooner had Paul secured his election, than he dispatched a messenger to Pepin, king of France, to acquaint him with his promotion, and to entreat his protection, and that of the French nation in general, for the temporal dominions of the church. He had the satisfaction of receiving from that prince, in answer to the letters by his messenger, the most friendly congratulations on his exaltation to the papacy, and the strongest assurances of his resolution to maintain St. Peter and his successors in the full possession and quiet enjoyment of what he had given them, and to employ...
ploy for that purpose, if necessary, the whole force of the kingdom, of which he was lord.

During the pontificate of Stephen II. Pepin had conquered from the Lombards some of their dominions, which he had bestowed on the Roman fee by an instrument of donation, and compelled the king to confirm the grant. This donation raised the bishop of Rome to the rank of prince, and may be considered as the foundation of the temporal grandeur of the popes. As, however, the places which were to have been yielded up to the Roman see, had not been evacuated by the Lombards before the death of their king; Paul, as soon as he was ordained, made a demand of them from his successor Deifiderius. This prince professed the utmost readiness to satisfy the pope; but allegation that the affairs of his kingdom engaged all his attention, he requested that till these should be settled, his holiness would excuse him in not complying with his demand. Of this delay the pope complained in a letter to Pepin. Indeed, much of his time, during the whole of his pontificate, was occupied in writing to Pepin, or in his two sons, letters of complaint against the emperor, and in endeavouring, by frequent legations, as well as by letters, to keep the French, the Greeks, and the Lombards, ever at variance. To counteract this policy, the emperor and the king of the Lombards made every effort to gain Pepin, and to persuade him to withdraw his protection from the pope, representing him to be a public incendiary, who, instead of striving to unite the Christian princes, made it his study to create divisions among them, with no other view than that he might aggravate himself at their expense. Pepin, however, remained the steady friend of his holiness through life. Paul died in 767, after he had presided over the Roman church ten years and a month. He gave sufficient evidence of his piety, by founding or repairing numerous churches. Thirty-one of his Letters have come down to us, of which twelve are inserted in the sixth volume of the Collect. Concil. and the whole are in the "Caroline Code," so called from Charlemagne, who himself formed the collection which was published by James Gretzer in the year 1613. Moreri.

PAUL II. pope, originally known by the name of Peter Barbo, was descended from an ancient family, and born at Venice in the year 1417. He was educated in the mercantile line, and was on the point of embarking with some property on board a ship, when he received intelligence that his maternal uncle had been promoted to the papacy under the name of Eugenius IV. He now thought there were good prospects opened to him—in the church, immediately quitted his business for study, and though he made but little progress in literature and the sciences, he was, in the course of a very few years, preferred by his uncle to the archdeaconry of Bologna, the bishopric of Cervia in the Romagna, the office of apostolical protonotary, and in the year 1440 to the dignity of cardinal. By his address and obliging manners, he recommended himself to several succeeding popes, of whom Calixtus III. gave him the appointment of legate in Campania. While he continued a cardinal, men of all ranks and conditions had free access to him, and he made it his study to gratify, as far as lay in his power, all who applied to him. Upon the death of Pius II. in 1464, Barbo was chosen pope. As he was a handfome man, and extremely proud of his person, he intended his intention of taking at his coronation the name of Formosus, but he was dissuaded from this design by the cardinals, and he chose the name of Paul II. One of the first public measures of Paul's government, was a declaration in favour of Ferdinand, king of Naples, against the family of Anjou; and as the party of the latter had begun to revive in the kingdom, many of the barons being dissatisfied with the arbitrary government of Ferdinand, he sent a considerable body of troops to the assistance of that prince, who was thus enabled speedily to quell the insurgents, and to restore peace to the kingdom. At this period, when a fene of his obligations to Paul was yet fresh in the king's memory, the pope applied to him for the arrears of the tribute due from the kings of Naples to the papal see, which had never yet been paid either by himself or his father Alphonso. Ferdinand, however, refused, which had nearly caused a civil war, but the affair was accommodated, upon the king promising to pay what was in justice due to the apostolic chamber, whenever he conveniently could.

Among the departments of the Roman government one was filled by persons called abbreviators, whose business was to abridge the bulls and letters of the pope. This employment Paul considered as useless, and discharged the persons who filled it, though most of them were men of great learning and abilities. In this number was the historian Platina, who represented to his holiness the injustice of diffusing them from offices which they had purchased, when not chargeable with any neglect of duty, without returning the money. This remonstrance offended the pope; but Platina went farther, and intimated that he and his brethren would appeal to the kings and princes of Christendom, who solemnly incensed the pope that he had him thrown into prison under charge of high treason. His sufferings were very great, and continued four months, before he could obtain his release; and even then Paul was not contented, and would not forgive the holiness with which the historian had dared to reflect his injustice. In the year 1466, the pope had the mortification to hear of the ruin of one of his plans for maintaining the authority of the Roman see, by punishing offenders against its injunctions. In Bohemia the principles of John Hus had obtained a wide diffusion, and Podiebrad, the king of the country, had, from his accession to the crown, favoured those who espoused them, inflicting that the sacrament should be administered to all communicants in both kinds. The pope, enraged at his conduct, not only excommunicated him, but caused a crusade to be preached all over Germany against this Christian prince, while the Turks were pursuing their conquests without opposition. The indulgences that were granted to those who took the cross, proved the means of speedily raising a numerous army, which, however, Podiebrad soon put to flight with great slaughter, and returned triumphant to Prague with a number of prisoners, exceeding that of his whole army. After the defeat, the pope contented himself with infusing his anathemas, declaring the king of Bohemia a rebel to the church, and incapable of holding any dignity whatever. During the following year Paul gave orders for arresting Platina, under the pretence of his being engaged in a conspiracy against his person and government; the historian nobly vindicated himself from the heavy charge, but the mericles tyrant, instead of releasing, ordered him to be put to the rack. He was accordingly tortured with the utmost cruelty, but it had no effect upon his mind. Many of his known friends, the most eminent characters of the time, were also arrested, and exposed to the same kind of treatment, to some of whom it proved fatal. Mr. Roscoe, in speaking upon this subject, says: "During the pontificate of Paul II., letters and science experienced at Rome a cruel and unrelenting persecution, and their professors exhibited in their sufferings a degree of constancy and resolution, which in another cause might have advanced them to the rank of martyrs. The imprisonment of Platina, who, on being arbitrarily deprived of a respectable office, to which he
he was appointed by Pius II., had dared to thunder in the ears of the pope the dreaded name of a general council, might, perhaps, admit of some justification; but this was only a prelude to the devotion which Paul made among the men of learning, who, during his pontificate, had chosen the city of Rome as their refidence. A number of these uniting together, had formed a society for the research of antiquities, chiefly with a view to elucidate the works of ancient authors, from medals, inscriptions, and other remains of art. As an incitement to, or as characteristic of, their studies, they had assumed classic names, and thereby gave the first instance of a practice, which has since become general among the academicians of Italy. While these men were employing themselves, in a manner that did honour to their age and country, Paul was indulging his tolly and vanity in ridiculous and contemptible exhibitions; and happy had it been if he had confined his attention to these amusements; but on a pretext of a conspiracy against his person, he feized upon many members of the academy, which he was pleased to consider as a dangerous and seditious assembly, acculling them of having, by the adoption of heathen names, marked their aversion to the Christian religion.

In the year 1467, the pope brought about a reconciliation between several states of Italy, which had taken up arms as auxiliaries to the opposite factions in Florence. Soon after this event the emperor Frederic arrived at Rome, in consequence of a vow, and was entertained with great magnificence by the pope; and they agreed, as a proper expedient to engage the Christian princes in a league against the Turks, that letters should be written, in their joint names, to princes and states of Christendom, inviting them to send their ambassadors to Rome, in order to treat about means for defending their faith. About the same time, Paul was infligated by his ambition to obtain possession of the city of Rimini, and he called in the Venetians to aid him in the project; but after an appeal to arms, the forces of the church and its allies were completely defeated, and Paul was at length compelled to accede to such terms as the conquerors thought proper to dictate.

In 1471 the pope published a bull, by which he reduced the jubilee circle to twenty-five years, and thus accelerated the return of a molt abortive and superfluous ceremony. To him, however, it was of little moment, as he died suddenly of an apoplexy, in July of the same year, after a pontificate of almost seven years. The historian Platina, who could scarcely be deemed an impartial judge, charges him with avarice and simony; with selling even benefices to the highest bidders. With respect to the former of these charges, that there was no solid foundation for it is quite clear from Platina’s own account, who speaks of him as profuse in his expences in buildings; in entertaining distinguished personages; in relieving the poor and decayed nobility; in purchasing, at any price, jewels and precious stones to adorn the papal crown, and in exhibiting public shows for the entertainment of the Roman people. Mathieu, the historian of Lewis XI. says, that he was greedy of money, and little cared by what means he acquired it, but was too fond of pomp to hoard it up in his coffers. He created eleven cardinals during his pontificate, among whom were two of his own nephews, although he had, previously to his election, taken a solemn oath not to increase the number of cardinals, or introduce more than one relation to that high dignity. Two of the letters of this pontificate are in the thirteenth volume of the Collect. Consil. and several others in the fourth volume of d’Arcerey’s Speculum; and in Chremb’s Bullarium Magnum. This pope met with a most zealous apologist in one of the ablest men of the half century, who published a work entitled "Paul II. Vita ex Codice Anglica Bibliothecae Defumpta, præmiis ipius Vinicidius adversum Platinam, analoge Obrectatorem," 1740. Moreri. Bower: Rofcoe’s Life of Lorenzo de Medici.

Paul III. pope, originally called Alexander Farnefe, was of Roman descent, from an ancient and noble family, and born about the year 1467, at Carino in Tuscany. He purfued his studies under the celebrated professors whom the Medici family had invited to Florence, where he was, at a very early age, distinguished by his application to, and proficiency in the different branches of literature. By pope Innocent VIII. he was appointed apostolical prothonotary, and by Alexander VI. he was advanced to the bishopric of Monte Fiascone, by whom he was, in 1493, raised to the dignity of cardinal, when he was but twenty-six years of age. He was warmly patronized likewise by Julius II., Leo X., and Clement VII. By the latter he was successively nominated to the bishoprics of Palestrina, Sabina, Porto, and Oflia. The fame pope appointed him to the legation of Viterbo, and received important services from him during the time of his imprisonment. So highly did Clement elevate the character of Alexander, that when he was feizable that his end was approaching, he recommended him to the cardinals as the most worthy of the whole college to be his successor.

The death of Clement happened on the 25th of September 1534, and on the 13th of October following, the thirty-four cardinals present in the conclave concurred unanimously in voting for the cardinal Farnefe. To this unanimitly two circumstances contributed: one was his having arrived to the advanced age of sixty-seven, and the other the general belief that his constitution was broken up.

At the coronation the new pope assumed the name of Paul III., and the first object to which he directed his attention was to crush the progress of the Reformation, which he forewore was pregnant with ruin to the authority and interests of the papal fee. He was, like his predecessor, enraged at the innovations in Germany, and equally averse from any scheme for reforming either the doctrines of the church, or the abuses of the court of Rome. (See Luther.) At the same time he concluded an alliance with the emperor Charles V. and the Venetians against the Turks, and is said to have entertained such confidence of ultimate success, that he even made a partition of the Turkifh empire with his allies. This object, as well as the extirpation of herey, he had much at heart, but he confidered peace between the emperor, and the king of France, who were then at war, to be an essential preliminary to both. He accordingly proposed an interview between the two monarchs at Nice, and offered to repair thither in person, that he might act as mediator in compounding all differences. After long negociations, he prevailed upon them to sign a truce for ten years, and in the mean time to fend ambassadors to Rome to disfuze their pretentions at leisure. During the private conference of the pope with the emperor at their interview, a marriage treaty, which had been some time negociating, was concluded between Oiovio Farnefe, the pope’s grandfon, and Margaret, the emperor’s natural daughter, and the widow of Alexander de Medici, who had been lately murdered by one of his own family. Soon after Paul’s return to Italy, he dispatched cardinal de Medici with a grand retinue to Florence, who conducted the princes to this city, where he was received by the pope, the cardinals, and the Roman nobility, and the nuptials were celebrated with extraordinary pomp and magnificence. In the year 1535 the pope thundered out his bull of excommunion against king Henry VIII. of England, by which the monarch was deprived of his kingdom, his subjects were abfolved from their allegiance, and the whole island laid under an interdict. But Henry’s power was not to be thus shaken,
thanked, and the insolence of the pope only stimulated the king to imitate his tyranny, by persecuting all, without distinction, who refused to renounce the papal supremacy, and acknowledged any other. The year 1540 was rendered memorable by the establishment of the order of the Jansenists, and about the same time different diets were held in Germany for the purpose of terminating the religious disputes, and the divisions arising from them among the members of the empire, the result of which was various concessions to the Protestants, which suspended all prosecutions carried on against them in the imperial chamber, and left them in the full possession of the privileges which they had ever enjoyed. These proceedings gave great offence to the pope, who complained of them: during an interview which he had with the emperor at Lucca in 1541, when he suggested various things relating to the proper method of putting an end to the disputes about religion, and to the extinguishing of those mutual animosities between that prince and the king of France, which threatened to break out again into open hostility. In the year 1545, Paul, finding it impossible to avoid any longer calling a general council, lent John Morone, bishop of Modena, to announce to the diet of the empire at Spire, his determination of assembling such a council without delay, and to propose that Trent should be the place of its meeting. This proposal met with the approbation of the Catholic princes of the diet, but the Protestants totally objected to it. Without taking any notice of their opposition, Paul immediately published a bull, nominated three cardinals to preside as his legates, and fixed the day for opening the council, which was on the first of the following November. His legates repaired to Trent at the time appointed, where they remained several months; but as no persons appeared there, except a few prelates from the ecclesiastical states, the pope recalled them and prorogued the council. Having learnt, about this time, that the principles of Luther met with a favourable reception in many parts of Italy, he appointed a congregation of fix cardinals, with full power to act as inquisitors of the faith at Rome. He also initiated the emperor to attempt the introduction of that tribunal into the kingdom of Naples, but the design was frustrated by the spirited opposition of the Neapolitans, cf. all ranks and conditions, who flew to arms upon the first step that was taken towards carrying it into execution, and obliged the viceroy to drive out of Naples all who belonged to that bloody office. During the summer of this year, the pope, with a view to the aggrandizement of his family, knowing the emperor’s great want of money to carry on his war against France, offered him 150,000 ducats, if he would befriend the duke of Milan on his grandson, Oettavio Farinfe, which proposal the emperor rejected. Paul now returned home greatly mortified, and his ill humour was not a little increased by the information, that the emperor had counted the Protestants, and granted them extraordinary indulgences at the diet of Spire, in order to secure their concurrence with the other members of the diet, in declaring war against France in the name of the empire, and granting extraordinary aids in troops and money; he also learnt that Charles had contracted an alliance with the excommunicated heretic, Henry VIII. of England. In the year 1545 the pope summoned the council of Trent to assemble anew in the month of November, but before that meeting the emperor gave the Protestants reason to suspect his hostile intentions against them; and he and the pope being intent upon one common object, viz. the suppresion of the reformers, they mutually sacrificed to it their emotions of jealousy or refentment, that they might the more effectually pursue what each deemed to be of greater importance. Still, however, Charles contrived to amuse the Protestants with professions of his pacific and favourable intentions towards them, and employed every art to quiet their fears and jealousies, though events soon occurred which convinced them of his perjury. On the 13th of December 1545, the general council was opened at Trent, though in yet only twenty-five bishops had arrived, and those were Italian or Spanish, the first appearance of an assembly of men, who assumed authority as representatives of the universal church, and proceeded to determine the most important points of doctrine in its name. (See Trent.) The council showed an eagerness in condemning the opinions of the Protestants, which was soon followed by a striking inrush of the pope’s resolution to punish those who embraced them. The appeal of the canons of Cologne against their archbishop having been carried to Rome, Paul eagerly seized that opportunity of displaying his zeal for the abolished church, and as no person appeared in behalf of the archbishop, he was held to be convicted of the crime of heresy, and a papal bull was issued, depriving him of his ecclesiastical dignity, inflicting on him the sentence of excommunication, and absolving his subjects from the oath of allegiance, which they had taken to him as their civil superior. Charles now saw, that he should be soon obliged to declare openly, what part he would take in the business. At the same time, he was strongly urged to commence operations against them by the pope. At length he agreed to the proposals of the pontiff, who proud of having been the author of such a formidable confederacy against the Lutheran heresy, and happy in thinking that the glory of extirpating it was referred for his pontificate, published the articles of his league with the emperor, and published a bull containing the most liberal promises to all who should engage in this holy enterprise. This war of religion commenced in 1546, and the papal troops, amounting fully to the number which Paul had stipulated to furnish, commanded by Oettavio Farinfe, the pope’s grandson, assisted by able officers, formed in the long wars between Charles and Francis, feasibly joined the imperial army. Immediately upon hearing of the rapid successes of the emperor’s troops, the pope saw the danger that would redound to his fame, from an extension of the imperial authority, and ordered his grandson to return instantly to Italy with all the troops under his command, while he recalled, at the same time, the licence, which he had granted for the appropriation of church lands in Spain to the emperor’s use. He also forewarned, that if Charles acquired absolute power in Germany, he would become master of the council, should it continue to meet at Trent; for this reason he translated the council to Bologna. These circumstances occasioned a breach between the emperor and the pope, which was rendered irreparable by the affiliation of the pope’s son. Peter Lewis Farinfe, one of the most odious tyrants that ever disgraced the world, and the loss of the city of Piacenza, which had declared for the emperor. The pope impatiently demanded satisfaction of the emperor for both injuries, but Charles etched all his demands, and resolved to keep possession of the city together with its dependent territories. Paul would willingly have attacked the emperor by force of arms, but having in vain solicited the allegiance of France and the republic of Venice, he was obliged to endure the injuries which his own weaknesses would not allow him to revenge. Various other causes of dispute occurred, and at length, in 1548, Charles resolved to terminate all differences by his famous system of doctrine, known by the name of the Interim, which fee. Paul condemned the Interim in the strongest terms, and in a short time
time after he dissolved the council, the weakness of whose measures had become the object of contempt to all Christendom. As the pope advanced in years, he grew more strongly attached to his family, and more jealous of his authority, but in the midst of his schemes for the aggrandizement of the latter, his grandson Octavio threatened to join the emperor, which so much irritated his holiness, that he was resolved to proceed against his relation with the utmost severity, from which, however, he was prevented by his death, which occurred in 1549, when he was in the eighty-second year of his age, and had held the Roman see more than fifteen years. It is difficult to appreciate the character of this pope. Cardinal Quirini has displayed much talent in defending his probity and general measures, while others represent him as a perfidious politician, whose great qualities were diffimulation and fraud; who was wholly intent upon raising his family, and ever ready to sacrifice the good of the church or state to the grandeur and interests of his illegitimate offspring. Besides his natural fan, Peter Lewis, he had a natural daughter, named Constanza, married into the Sforza family, sent them children, Alexander Farnese, and Guido. Afcanio Sforza, he created cardinals for their daughter; when they had scarcely arrived to the years of manhood. He is said to have been well versed in most branches of literature, and a generous encourager of learned men. He wrote a commentary upon Cicero's "Epistles to Atticus" before his promotion to the pontificate, and after that period came to his friend Sadolet and to Erafimus, which have been applauded for the purity of the Latin style. Morei. Bower. Mod. Un. Hist.

Paul IV., whose former name was John Peter Carafa, was the son of count Montorio, a nobleman of an illustrious family in the kingdom of Naples, and born in the year 1476. Being deified for the church, he from his early years applied to study with the greatest industry, acquired a profound knowledge in scholastic theology, and a considerable knowledge of the learned languages and of polite literature, the study of which had lately been revived in Italy. His mind, naturally gloomy and severe, was more formed to imbibe the spirit of the former, than to receive an warmer of elegance. He married to the former, with which he was required rather the qualities and passions of a monk, than the talents requisite for the conduct of the affairs of the world. When he was only eighteen years of age, he was made chamberlain to pope Alexander VI., and in the year 1504, pope Julius II. created him an archbishop. After this he was sent by the same pontiff as nuncio to Ferdinand, king of Arragon, when that prince took possession of the kingdom of Naples. In 1513, pope Leo. X. sent him in the same character to Henry VIII., king of England, at whose court he lived three years. Upon his return, he was appointed to other missions, but becoming disgusted with public life, he languished to be in a situation more adapted to his taste and temper, and having relinquished the paths of ambition, refused a valuable archbishopric, which was offered him by Charles V., and even resigned all his ecclesiastical preferments in the year 1524. He then retired to mount Pincio, where he conformed himself to the rules which he had laid down for others who entered that body, preferring the solitude of a monastic life, with the honour of being the founder of a new order, to the highest dignities and greatest grandeur which the court of Rome could offer. In this retreat he continued many years, till pope Paul III., induced by the fame of his sanctity, called him to Rome, in order to consult him concerning the most proper and effectual means for suppressing heresy, and re-establishing the ancient authority of the church. In 1536, the pope prevailed upon him to accept a cardinal's hat. He now shewed himself, what he had ever been in his heart, a bitter enemy to all innovation, and a furious zealot against Lutheranism. Upon the death of pope Marcellus II. in 1555, the conclave united in the choice of cardinal Carafa, who was then at the advanced age of seventy-nine. At his coronation, out of gratitude to Paul III., he took the name of Paul IV. The Roman curiaries, from the known austerity of his character, anticipated a severe and violent pontificate, and that monastic manners would be substituted in the room of the gaiety and magnificence to which they had been accustomed. Paul, however, began his government by ordering his coronation to be conducted with greater pomp and ceremony than usual, and when he was asked in what manner he chose to live, he haughtily replied, as becomes a great prince. He used great pomp in his first consistory, when he allowed audience to the ambassadors of Mary, queen of England, who came to tender his obedience to the papal see, on which occasion he gave the title of a kingdom to Ireland. Afterwards, he infilled that all ecclesiastical possessions, which had been seized by Henry VIII., should be restored to the church, and that Peter spence should be immediately collected for the use of the Roman see. Having now attained to the highest dignity to which he could aspire, his principal object appears to have been the aggrandizement of his nephews; on the eldest count Montorio, he bestowed the dukedom of Palliano; and on the second he conferred the government of Rome, with the title of marquis de Montbello; and the youngest, who had hitherto served as a soldier of fortune in the armies of Spain and France, he created a cardinal, and nominated him to the important legation of Bologna. The ambition of Paul's nephews was too great to be satisfied with the dignities to which they had been appointed. Their aims were directed to sovereignty and independent establishments, which they had no prospect of obtaining but by dispossessing the emperor of some of his Italian dominions, and to attempt such an undertaking both Paul and his nephews were invited by motives of resentment as well as interest. Paul proposed an alliance offensive and defensive with the French king against the emperor, in which Henry VIII. joined as a party. Scarcely, however, had the treaty between the pope and the king of France been signed two months, before Henry forgot the obligations under which it laid him, and agreed to a truce with the emperor, who was upon the point of resigning all his hereditary dominions to his son Philip, and of retiring from the world. When the news reached Rome, that this truce was actually concluded, and sworn to by Henry as well as the emperor and his son, in Feb. 1556, it excited in the pope and his nephews the utmost astonishment and consternation. They now began to dread the vengeance, which, they were aware, they fully merited. Paul had recourse to intrigue and negociation. He affected, as father of the church, to approve highly of the truce, as an happy expedient for putting a stop to the effusion of Christian blood, and he exhorted the rival princes to embrace the favourable opportunity of letting on foot a negociation for a definitive peace, offering himself to be a mediator between them. Under this pretext he nominated cardinal Rebiba his nuncio to the court of Bruxelles, and his nephew, cardinal Carafa, to that of Paris. The real design of the latter was to solicit the French king to renounce the treaty of truce, and to renew his engagements with the holy see; and he was commanded by his uncle to spare neither treaties, nor promissies, nor bribes, to gain his point. By the
the infatuation of the pope war was renewed, and the imperial forces soon made their way to the gates of Rome. The pope now gladly fought a truce, which was granted first for ten, and then for forty days; during which, various schemes of peace were proposed, without any sincerity on the part of the pope. He had but one object in view, viz. the destruction of his enemies; and on the arrival of the French troops, he became more arrogant than ever, and banished all thoughts from his mind but those of war and revenge. Holieries were again renewed, and with so much force against the cause of the church, that Paul, proud and obstinate as he was, found it necessary to accommodate himself to the exigency of his situation. He accordingly employed the mediation of the Venetians, and of Cosimo de' Medici, in order to obtain peace; and so reasonable was Philip in his expectations, that though he had the pope at his feet, yet he allowed him to finish the war, without any detriment to the papal fee. The conqueror, owing to his superfluous attachment to the church, appeared in the abject character of a humble suppliant, and acknowledged his error; while he who had been the most arrogant hypocrisie, though completely vanquished, retained his usual haughtiness, and was treated with every mark of superiority. Paul now had leisure, and he applied that leisure to render his favourite tribunal of the inquisition a more efficient instrument for the eradication of heresy. With this view, he directed the inquisitors to draw up a catalogue of such books as were thought proper to be condemned, as impious and heretical. This Index Expurgatorius was published two years afterwards, and all were prohibited, under pain of excommunication, perpetual infamy, and other arbitrary punishments, from possessing any of the books mentioned in that catalogue. The pope likewise ordered the tribunal of the inquisition to take cognizance of several crimes, which before had been under the jurisdiction of the other courts; and he deftcredly incurred universal odium, by being so active and diligent in his inquiry after criminals, that he quickly filled all the prisons of the inquisition. In the year 1558, the college of the electors of the empire having been assembled at Frankfort, the prince of Orange laid before them the instrument with which he had been entrusted by Charles V., containing his resignation of the imperial crown, and the transfer of it to Ferdinand, king of the Romans, which the college accepted and approved, and put Ferdinand in possession of all the ensigns of imperial dignity. When the new emperor sent his chancellor to acquaint the pope with this transaction, Paul declared all the proceedings at Frankfort illegal and invalid, as tranferred without his authority, and refused to acknowledge Ferdinand as emperor so long as he lived. The fame pretensions were maintained by him in the instance of queen Elizabeth of England, who announced to him by her ambassador that she had acceded to the throne; he haughtily declared that the kingdom was a fief of the holy see, and that she had no right to assume the crown without his leave. She nobly defied his claims, threw off the papal yoke, and, after the example of her father and brother, allied, with the concurrence of parliament, the supremacy in all matters, ecclesiastical as well as temporal, within her dominions. The mortification which this event occasioned to Paul was increased by the intelligence which he received from his nuncio in Germany, that at the diet of Augsburg, in 1558, Ferdinand had confirmed the treaty of Palfau, which established the peace of religion, and also the decrees of the subfletuent diets. He was equally displeased with the peace concluded between France and Spain, since, by one of the articles, the respective sovereigns bound themselves to labour in concert for procuring the convocation of a general council, in order to promote the reformation of the church, and to devise expedients for establishing unity and concord in the religious world. Shortly after this, the pope was very deorious of convincing the world, that he had sincerely at heart a correction of abuses in the church; and with this view, he ordered all bishops to proceed to their own dioceses, and all who had embraced a monastic life to return to their monasteries, admitting of no excuse whatsoever with regard to the last; and he executed his mandate with such severity, that many of the vagrant monks were imprisoned, and some of them sent to the galleys. Toward the close of life, he exhibited his impartiality in the punishment of crimes, by directing his severity against his nephews, who, in many instances, abused the truths repented in his lifetime. He also suppressed some new and very unpopular taxes, which he pretended had been imposed without his knowledge. It was now almost too late to act upon a new course of practice; he was unable to remedy the evils of his administration, as he died in Augulf 1559, in the 84th year of his age, and after a pontificate of little more than four years. Such had been his arrogance, tyranny, and oppressions, and he had rendered himself so universally the object of hatred, that when he was upon his death-bed, the Romans rose tumultuously, cursed his name and family, and then flying to the Capitol, struck off the head of a statue erected to him but three months before, which they dragged with a thousand inflicts through the public streets of the city, and at last threw it into the Tiber. The populace then crowded to the prion of the inquisition, forced open the doors, releaved several hundred prisoners, then set fire to the buildings, which was soon reduced to ashes, with all the papers and records of that court. An edict was then published for abolishing the arms of the Caraffa family, and in a single year, all the property descended to the pope, was extorted from its owners, and the whole was appropriated to the purposes of the pope. Paul was the author of a treatise, "De Symbolo;" another, "De emendanda Ecclesiae ad Paulum III.;" besides the rules which his monastery was governed, entitled "Regula Theatinorum." Moreri. Bower. Robertson's Hist. of Charles V. Mod. Un. Hist.

Paul V. pope, formerly called Camillo Borghese, was descended from a family of distinction at Sienna, and born at Rome in 1552. He was educated to the profession of the law, took the degree of doctor, and acquired such reputation for his knowledge of it, that he was made refendary of both dignities. In 1558 pope Gregory XIV. appointed him to fill the important office of auditor of the chamber. By Clement VIII. he was promoted to the college of cardinals, and sent nuncio to Spain; and on his return, the same pontiff nominated him his vicar, which is one of the four principal dignities in the Roman church. Upon the death of Leo XI. in 1669, he was unanimously elected pope, his vigorous age of fifty-three being the only objection brought forwards against him. At his coronation he took the name of Paul V., and almost immediately afterwards discovered his spirit of nepotism, by Hewting the cardinal's lat on Scipio Caffarelli, his father's son; and by appointing his two brothers, Francis and John Baptist, to the important offices of governor of the Vatican, and governor of St. Angelo. No one of his predecessors exceeded this pontiff in zeal for advancing the ecclesiastical authority and jurisdiction of the papal fee, or shewed himself more violent in endeavouring to execute his vengeance upon such as encroached upon his pretended prerogatives. His zeal in defence of the pretended rights and powers of his see was particularly displayed in the rash and unsuccessful contest into which he entered with the republic of Venice, in the
year 1626. The Venetians had published several laws for restraining the licentiousness of the clergy, and for other purposes necessary for the well-being of their state, which the pope ordered to be reprinted. This they refused, and justified their conduct with great spirit. When Paul found that they opposed his demands, his fury was inflamed to the highest pitch. Having suffered himself to be publicly libeled as "Vice-God upon earth, the monarch of Christendom, and the supporter of papal omnipotence," he was resolved to keep up his character, by pouring down upon the republic the full weight of his vengeance. It was, however, to no purpose: the Venetians refilled, and carried their point; and, at the same time, they banished the Jesuits and Capuchins, who had thought proper openly to break the laws of the state, by obeying the pope.

About this time, the form of the oath of allegiance, required to be taken by Papish recants in England, having been submitted to the confederation of the college of cardinals, they were unanimously of opinion that no true Catholic could take it with a safe conscience; upon which the pope dispatched a brief to this kingdom, prohibiting all Papists from submitting to it, and exhorting them patiently to endure all manner of persecution rather than comply. During the year 1609, an ambassador arrived at Rome, from the king of Congo in Africa, to request that the pope would send with him, on his return, learned missionaries to propagate Christiandity in that country; but the death of the ambassador, soon after his arrival, occasioned that design to be postponed to some future time. In the same year, the pope received letters from the king of Per^ia, which were soon afterwards followed by an ambassador from the prince. These letters and this minifter were supposed to have been sent at the instigation of some of the king's Armenian subje^cts, who had embraced the Catholic creed, with a view to procure arrangements for their benefit. In the year 1610, Paul was earnestly solicited to enter into a defensive alliance with the king of France and the princes of Italy, which he declined, lest he should thereby be involved in war. While the subject was in agitation, intelligence arrived at Rome of the affiliation of Henry IV., at which his holiness expressed great sorrow, and afflicted personally at his obsequies, which were celebrated with much solemnity at Rome. In 1614 the pope received information that a treaty was negotiating between the king of Great Britain and the queen-regent of France, for a marriage between the prince of Wales and her second daughter, Christine: he ordered his nuncio in the French court to remonstrate against the proposed alliance, as prejudicial to the church. Another subject on which he ordered his nuncio to remonstrate was a decree of the parliament of Paris, condemning a treatise of Suarez, a Jesuit, which justified the murder of Henry IV., and of heretical kings in general, of which, to his disgrace, the pope had declared his approbation, to be burnt by the hands of the common hangman. This decree he complained of, as an infringement on the privileges of the holy see, which referred to itself the power of judging and determining the tendency of such works; and he demanded satisfaction, by the formal annulling of the decree: but he could obtain no other satisfaction than the suspension of its execution. He met with a similar mortification, in an unsuccessful endeavour which he made to prevail with the states of France to order the publication of the decrees of the council of Trent. In the course of the following year, Paul's attention was chiefly engaged by the old controversy between the Franciscans and Dominicans, concerning the immaculate conception of the Virgin Mary. Shortly after this, he was involved in a dispute with the court of France, which demanded the effigies of the marshal d'Ancre at Rome, for the use of the French king. A compromise was agreed upon between the contending parties: more than half was given to Lewis XIII., and the remainder was allowed to the pope towards the building of St. Peter's church. In the year 1619 the pope published an universal jubilee, in order to implore the assistance of the Almighty for the defence of the church, which was endangered by a general insurrection of the Protestants of Bohemia, and other countries under the Austrian dominions, who had been provoked to fly to arms by the oppressions with which they were harassed. The pope sent assistance in money to the emperor, who, in the course of the following year, gained a decisive victory, which obliged the insurgents to submit. Paul survived the news of this victory only a few months, and died at Rome in January 1621, in the 69th year of his age, after a pontificate of nearly 16 years. Paul V. was distinguished for talents and learning, and would have appeared to great advantage in the page of history, had he not suffered his ambition and furious zeal for the authority of the holy see to lead him into measures which he could not support, and had he not sacrificed the wealth of the state to the aggrandizement of his nephew, cardinal Borghiefe. As a friend to literature, he published a bull, commanding all the religious orders to maintain professors in the Hebrew, Arabic, Greek, and Latin languages. In adorning and beautifying the city with magnificent buildings, he is said to have ravished Sixtus V. He extended and improved the Vatican palace and library. He built two magnificent palaces for his relations, one in the city, and the other without the walls; and in both he collected the most valuable works in sculpture and painting, and the finest monuments of antiquity that he could purchase. He brought water to several parts of the city, by aqueducts and subterranean channels, from some places at nearly 40 miles distance; and he embellished the streets with a great number of fountains. He was likewise liberal in his charitable donations, and in his aims to the poor.

Paul, Father, whole name, before he entered into monastic life, was Peter Sarpi. He was born at Venice, August 14, 1552. His father followed trade, but with so little success, that on his death his family were extremely ill provided for. Peter was taken under the care of a maternal uncle, who, being himself a schoolmaster, cultivated the talents of his nephew with unwearied application. He was formed, by the turn of his mind, that he had a capacity adequate to the most difficult departments in literature, and having, at the age of thirteen, made himself master of school learning, he turned his studies to philosophy and the mathematics. He entered also on the study of logic under Capella of Cremona, who was of the order of the Servites, and in this order Peter Sarpi, notwithstanding the remonstrances of his friends, determined to enter himself. In 1566 he took the habit of the order, though at that time only fourteen years of age, a period of life in most persons very improper for engagements of this nature, but in him attended with such maturity of thought, and in such a settled temper, that he never seemed to regret the choice he then made, and which he confirmed by a solemn public profession in 1572. At a general chapter of the Servites, held at Mantua, Paul, for he had now assumed that name, being but twenty years of age, distinguished himself so much in a public disputition by his genius and learning, that William, duc^e of Mantua, a great patron of letters, solicited the con^tent of his superiors to retain him at his court, and not only made him public professor of divinity in the cathedral, and reader of divinity and the canon law in that city,
city, but honoured him with many proofs of his esteem. The honours and buffle of a court did not accord with his temper and disposition; he quitted it many years after thirds, and retired to his beloved privacy. He was at this period but twenty-two years of age, and was intimately acquainted not only with the Latin, Greek, Hebrew, and Chaldee Languages, but with philosophy, the mathematics, canon and civil law, and all parts of natural philosophy and chemistry that were then pursued by men of science. He now took priest's orders, and was distinguished by the illustrious cardinal Borromeo with his confidence, and employed by him on many occasions, which excited the enmity of his contemporaries, who, jealous of his celebrity, and having nothing to urge against his conduct, charged him with denying that the Trinity could be proved from the first chapter of Genesis: the Inquisition, however, before whom the accusation was brought, thought the charge too ridiculous to be attended to for a moment. After this he paffed successively through the dignities of his order, of which he was chosen provincial for the province of Venice at the age of twenty-six years; and he discharged this poff, with such honour, that in 1579 he was appointed, with two other, to draw up new regulations and statutes for his order. He performed this bufinefs with much success, and when his office of provincial was expired, he retired for three years to the study of natural and experimental philosophy and anatomy, in which he made many important discoveries. Aquapandente, the famous anatomist, says that he was indebted to father Paul for his knowledge of the principles of viion, and there are pretty good proofs that he was not unacquainted with the circulation of the blood. He was now chosen proctor-general of his order, and during his residence at Rome was greatly esteemed by pope Sixtus V., and contracted an intimacy with cardinal Bel- larmine and other eminent personages.

His enemies were still on the alert, and accused him of having written a letter in cyphers, which they explained, and said the true meaning was, that he hated the court of Rome, in which preferment was not to be obtained but by dishonest and corrupt means. This accusation was paffed over, but not forgotten, and it made such impression on that court, that he was afterwards denied a bishopric by Clement VIII. He now retired from public life, and from much of his time in studies devoted to practical pieties. The most active scene of his life began about the year 1615, when pope Paul V. exasperated by some decrees of the senate of Venice, that appeared to him to interfere with the rights of the church, laid the whole state under an interdict. Both parties having proceeded to extremities, employed their ablest writers to defend their measures. On the pope's side, among others, cardinal Bellarmine entered the lists, and with his confederate authors, defended the papal claims with great feeruility of language, and very sophistical reafonings. On this occasion father Paul was most eminently distinguished by his "Defence of the Rights of the Supreme Magiftrate;" his "Treatie of Excommunication," and other writings; for which he was cited before the Inquisition at Rome, but he thought it prudent not to obey the fummons. He was full purfued with unceafing activity by the agents of the pope, and one night, fix months after a pretended accommodation had taken place, he was attacked by five ruffians armed with flillettoes, who gave him no fels than fifteen stabbs, three of which wounded him in such a manner, that he was left for dead. The affaffins fled for refuge to the nuncio, and were afterwards received into the pope's dominions. It has been faid, on good authority, that they were purfued by the justice of heaven, and that all, except one man, who died in prison, perifhed by a violent death.

On his recovery he retired to his convent, where he employed himself in writing the "History of the Council of Trent," which bishop Burnet regards as the completest model of historical writing ever produced. Another writer considers it as equivalent to any producfion of antiquity, in which, he fays, "the reader will find liberty without licentiousnefs, pietr without hypocrisy, freedom of speech without neglect of decency, severity without rigour, and extenfive learning without offentation." In this and other works of lefs importance he spent the remainder of his life, till the beginning of the year 1622, when he died. As his end was evidently approaching, the brethren of his convent came to pronounce the lafl prayers, with which he could only join in his thoughts, being able to articulate no more than these words, "Eiii perpetua," which were understood to be a prayer for the prosperity of his country. At his death he had attained to his 71t year, hated by the court of Rome and its adherents as their most formidable enemy, and honoured by all the learned for his abilities, and by the good for his integrity. His detefation of the corruption of the Roman church appears in all his writings; but there is a paffage in one of his lectures frequently referred to on the subject, which we shall transcribe. "There is nothing more effential than to ruin the reputation of the Jefuits. By the ruin of the Jefuits, Rome will be ruined; and if Rome be ruined, religion will reform itfelf." Father Paul was buried with great pomp at the public charge, and a magnificent monument was erected to his memory.

Paul, emperor of Ruffia, fon of Peter III. and Catharine II. was born in 1754. He was brought up by his mother, and eftznged by her from all public affairs. In 1773 he was married to the daughter of the handgrave of Helle Darmftadt, who died two years afterwards. In 1776 he took for his second wife a princefs of Wirtemburg Stutgard, niece to the king of Pruffia, and in 1783 he made the grand tour of Europe. His desire of serving in the war of 1787 against the Turks was thwarted by his mother, and he continued to reside with his family at his palace with few favours. The sudden death of Catharine, in November 1796, made him master of a vast empire, for the government of which he was neither fitted by nature nor education. Catharine had never admitted him to any participation of power, and kept him in a state of almost total ignorance of the affairs of government. Although by birth he was generalifimo of the armies, prefident of the admiralty, and grand admiral of the Baltic, he was never permitted to head even a regiment, and was interdicted from visiting the fleet at Cronftadt. From these circumstances, it is evident that the emperors either had conceived some jealousy of her fon, or faw in him a mental imbecility that appeared to her to difqualify him for the arduous concerns of government. He was, however, not without qualities valuable in a sovereign. He had a strong attachment to justice, with an openness and franknefs which rendered him accessible to truth when properly prefented to him. His general intentions were good, though not unfrequently warped by prejudice and caprice.

It was commonly believed, that a short time before his death Catharine had taken measures to exclude Paul from the succession, and to introduce Alexander in his stead. The plan, however, did not succeed, and Paul, on the day following his mother's death, made his public entry into St. Peterburgh, amidst the acclamations of the people. Paul began his reign with breaking the power of the guards, Paul...
In many respects he shewed himself hostile to the memory of his mother, and it was probably in that spirit that he caused solemn obsequies to be performed for his unfortunate father, compelling the principal agents in his afflation to affilt in the ceremonial. He abolished many of her institutions, and displayed the same relentless desire of change that the heredid had propounded. Trifling alterations in the dres and accoutrements of the foddiers, and the detail of military tactics, continued to occupy his attention. "Every day," said a bystander, "in the court of the palace, in a plain deep green uniform, great boots, and a large hat, he spends his morning in exercising his guards. Surrounded by his sons and aides-camps, flamping his heels on the pavement to keep the self-warm, his bald head bare, his trunk nofe cocked up to the wind, one was perpetually behind his back, and with the other rafing and falling his cane, in due time, and crying one, two; he prides himself in braving a cold of fifteen degrees of Reaumur without furs."

Soon after his accession, he gave an asylum to Lewis XVIII., and affigned him a large tract of land for his maintenance; and in order to prevent the spread of free inquiry, or, as he faid, the spread of revolutionary principles, he laid the prefs under the most rigorous restrictions, and abolished the schools for the instruction of the lower classes, which Catharine had established. In 1798 he determined to employ his arms for the reftoration of the ancient government of France, and in confequence of a treaty between him and the emperor of Germany, a Russian army of 45,000 men, under field-marshals Suvoroff, joined the Imperialists in the Austrian territories in Italy. They penetrated into Switzerland in 1799, and at frill obtained great fuccefs, carrying all before them; but want of proper co-operation and plan at length defeated their purpofe, and Suvoroff, in the autumn of the fall, was hurried back the remainder of his army. Paul, in great rage, gave his faithful commander a very ungracious reception, and he threatened to withdraw from a confederacy, which he charged with failure in its engagements. The honour of grand master of Malta, conferred upon him, induced him, in the following year, to renew his exertions; but during the course of it his politics changed, he refused farther fubfides from England, and entirely feemed from the alliance. Sarcely had he deferted the allies, when he became out of humour with the Britifh court, which had taken pofteflion of Malta, and his next political object was to form a new maritime confederacy in the north, for the purpofe of enforcing the claim of neutrals to a free navigation. He engaged Sweden and Denmark in the caufe, and in the winter of 1800, he laid an embargo upon all Britifh fhips in his ports, confining the commanders, and fending the feamen to a diftance up the country. At this period he feemed to have entered into the French interel; but defpotical power, joining with ftrong paffions and weak intellects, had now brought him to a state of capricious folly, little removed from infancy. He was particularly making regulations of the moft abfurdf and troublesome kind. Their general spirit was the main- tenance of absolute authority in all its rigour, and the profoundly reftpect for the imperial dignity; but no one could lefs inspire it by his perfon and manners. Though not without a degree of generofity and good nature, the indulgence of his ungoverned caprice was daily converting him into a brutal tyrant, like fome of the worft emperors of Rome. While accounts of his strange proceedings were circulating throughout Europe, he himself caufed to be inferted in the Peterburgh court gazette, "That the emperor of Russia, finding that the powers of Europe cannot agree among themselves, and being defirous to put an end to a war which has defolated it for eleven years, intends to point out a spot, to which he will invite all the other fovereigns to repair and fight in single combat, bringing with them as fecdons and efiures, their moft enlightened miniifters and able generals, fuch as Thurgof, Pitt, Bernuforff, and that the emperor himself propofes being attended by generals count Pahlen and Khotolof." This paragraph was immediately copied or translated into all the public papers, and it was faid by many, that it was the composition of Paul himself, which has fince been confirmed by Kotefebue, who was employed by the emperor of Ruffia to translate the original into the German language, for the express purpofe of giving it a more grand and magnificent air. This fally was, in general, regarded as fo decisive a proof of derangement, that the public was prepared to expect one of those revolutions to which the throne of Ruffia is peculiarly liable. Accordingly, on the night of March 23, 1801, Paul was found dead in his bed, and though it was currently reported that he was cut off by a froke of apoplexy, it was soon generally known that he had been affifflated in the death of the night, and that the perpetrators of the horrid deed had retired from the palace without the least molestation, and returned to their respective homes. As soon as the fact was discovered, medical affiftance was called in, with the hope of reftoring what might be only fupended animation; but these attempts proved fruitless. At feven o'clock, on the morning of the 23d, the intelligence of the death of Paul, and the fucceffion of the grand duke Alexander, were announced to the people. By eight o'clock the principal nobility had paid their homage to the new emperor, who was solemnly proclaimed. Paul died in the 47th year of his age, and the fifth of his reign, leaving two fons, of whom Alexander, the elder, succeeded him.

Paul Warnered, or, as he is often called, Paul the deacon, an eminent historian of the middle ages, was born of Lombard origina in the eighth century, at Cadiz del Friuli. He was educated in the court of Racis, king of the Lombards, and afterwards ordained deacon of Aquileia. Defiderius, the last king of the Lombards, invited him to his court, employed him as a notary or secretary, and raised him to the polls of counfellor and chancellor. After the kingdom of Defiderius was overthrown, and the monarch made prisoner by Charlemagne in 774, the private history of Paul becomes obscure, and it is very differently related by different biographers. It is generally supposed that he flirft retired to his native country of Friul, and that after the overthrow and death of Rodgrigo, duke of that province in 776, he took the monaflic habit. By some means his literary merit became known to Charlemagne, who took him into France, and perhaps employed him in his plans of promoting learning in his dominions. He was well acquainted with the Greek and Latin languages, and instructed in the former three clergymen who were selected to accompany the emperor's daughter, Rotrude, to Constantinople, where she was united to the fon of the emperors Irene. A remaining attachment to his sovereign Defiderius subjected Paul to the fulpicions of some designing in his behalf, on which account he was banifhed; and he would probably have undergone the losf of his hands, or of his eyes, had not Charlemagne been unwilling to disable so eloquent a writer. It is farther suppos'd that he escaped from his banifhment, and took refuge in the court of Arigio, prince of Benevento; and that on the death of that prince in 787, he retired to the celebrated monastery of Monte Calino, where he ended his days, but at what time is
not known, though it is thought about the year 799. He was a considerable writer: his Latin poetry may rank with the best of that period; it consists chiefly of hymns, of panegyrics of saints and eminent personages, and other short pieces. One of the most interesting is an elegy addressed to Charlemagne, in order to obtain the liberty of a brother who was brought prisoner into France after the defeat of Dufodier. Of his prose writings the most valuable is entitled "De Gellis Longobardorum," in six books, which is the only history of that nation which we possess: and it contains facts that can no where else be found, and affords some curious views of rude society. Several editions of it have been published, and Muratori has edited it in his great collection of the Italian historians. Paul likewise contributed to the Roman history entitled "Mucelilla," in which he was the continuator of Eutropius. He also wrote an abridged history of the first bishops of Metz, and other pieces of ecclesiastical biography, and made a collection of homilies by the order of Charlemagne. Gen. Biog.

Paul, St., in Geography, a town of France, in the department of the Taras, and chief place of a canton, in the diocletian of Lavaur. The place contains 926, and the canton 6670 inhabitants, on a territory of 170 kilometres, in 14 communes.

Paul, St., a town of Brazil, in the captainship of St. Vincent. It is a kind of independent republic, composed of the banditti of several nations, who pay a tribute of gold to the king of Portugal. It is surrounded by inaccessible mountains and thick forests. S. lat. 23° 25'. W. long. 43° 52'.—Alfo, a government of the same name, situated to the W. of Rio Janeiro; the principal productions are grain and cotton. The population is computed at 11,120 whites, 32,172 Indians, and 9000 blacks or mulattoes. (See Paulists.)—Alfo, a town of New Mexico, situated at the confluent of the two main head branches of the Rio Bravo.—Alfo, the most southern of the Pearl islands, in the gulf of Panama. In a safe channel on the N. side there is a place for careening of ships.

Paul, St., a town of France, and principal place of a diocletian, in the department of the Var; 7 miles W. of Nice. N. lat. 43° 41'. E. long. 7° 11'.—Alfo, a town of France, in the department of the Upper Vienne; 9 miles S.E. of Limoges.—Alfo, a town of France, in the department of the Leman lake, on the lake of Geneva; 10 miles E. of Thonon.—Alfo, a town of the island of Bourbon.—Alfo, a town of France, in the department of the Gard; 10 miles N.E. of Uzes.—Alfo, a town of the island of Malta; 6 miles N.W. of Malta.—Alfo, an island in the Indian sea, N. of Amsterdam. It is overgrown with shrubs and trees, and is said to abound with fresh water, but affords no good anchorage, nor any place of easy landing. S. lat. 37° 51'. E. long. 61° 2'.—Alfo, an island in the gulf of St. Lawrence; 9 miles N.E. from the N. cape of the island of Cape Breton.—Alfo, a river of Guinea, which runs into the Atlantic; 5 miles N. of Cape Mefurada.

Paul's Bay, St., a bay on the N.W. coast of Newfoundland. N. lat. 45° 20'. W. long. 57° 35'.—Alfo, a bay on the W. coast of Newfoundland; 10 miles N.E. of Bonne bay. —Alfo, a bay on the N.W. shore of the river St. Lawrence, about six leagues below Cape Torment, where a chain of mountains, 400 leagues in length, terminates from the westward.

Paul-de-Fenouillet, St., a town of France, in the department of the Eait Pyrenees, and chief place of a canton, in the district of Perpignan; 28 miles W.N.W. of Perpignan.

Paul-de-Omagnac, St., a town of Brafi, in the government of Paris, on the river Amazon. S. lat. 3° 35'.
His doctrine seems to have amounted to this: that the Son and the Holy Ghost exalt in God in the same manner as the faculties of reason and activity do in man; that Christ was born a mere man; but that the reason or wisdom of the Father descended into him, and by him wrought miracles upon earth, and instructed the nations; and finally, that, on account of this union of the divine word with the man Jesus, Christ might, though improperly, be called God. It is also said, that he did not baptize in the name of the Father and the Son, &c. For which reason the council of Nice ordered those baptized by him to be re-baptized.

Being condemned by Dionysius Alexandrinus in a council, he abjured his errors, to avoid deposition; but soon after he renewed them, and was finally deposed by another council in 360.

Paulicians, a branch of the ancient Manichees, so called from their chieftain, one Paulus, an Armenian, in the seventh century: who with his brother John, both of Samosata, formed this sect; though others are of opinion, that they were thus called from another Paul, an Armenian by birth, who lived under the reign of Justinian II. A certain zealot, called Conflantius, revived, in the seventh century, under the government of Constans, this drooping faction, which had suffered much from the violence of its adversaries, and was ready to expire under the severity of the imperial edicts, and of those penal laws which were executed against its adherents with the utmost rigour. However, the Paulicians, by their number, and the censure of the emperor Nicephorus, became formidable to all the East.

But the cruel rage of persecution, which had for some years been suspended, broke forth with redoubled violence under the reigns of Michael Curopalates, and Leo the Armenian, who inflicted capital punishment on six of the Paulicians as refused to return into the bosom of the church.

The empress Theodora, tutelary of the emperor Michael, in 845, would oblige them either to be converted, or to quit the empire: upon which several of them were put to death, and more retired among the Saracens; but they were not all exterminated.

Upon this, they entered into a league with the Saracens, and, choosing for their chief an officer of the greatest resolution and valour, whose name was Carbeas, they declared against the Greeks a war which was carried on during this whole century, with the greatest vehemence and fury. During these commotions, some Paulicians, towards the conclusion of this century, spread abroad their doctrines among the Bulgarians: many of them, either from a principle of zeal for the propagation of their opinions, or from a desire of getting rid of the persecution and oppression they suffered under the Grecian yoke, retired, about the close of the eleventh century, from Bulgaria and Thrace, and formed settlements in other countries. The first migration was into Italy, from whence, in process of time, they sent colonies into almost all the other provinces of Europe, and formed gradually a considerable number of religious assemblies of persons, who adhered to their doctrine, and who were afterwards percutted with the utmost vehemence by the Roman pontiffs. In Italy they were called Patarini, from a certain place called Pataria, being a part of the city of Milan, where they held their assemblies; and Cathari or Gazaris, from Gazaris, or the Lesser Tartary. In France they were called Albigenses. The first religious assemblies the Paulicians had formed in Europe, is said to have been discovered at Orleans, in 1017, under the reign of Robert; many of whom were condemned to be burnt alive. The ancient Paulicians, according to Photius, expressed the utmost abhorrence of Manes and his doctrine. The Greek writers confirme their errors under the fix following particulars. 1. They denied that this inferior and visible world is the production of the Supreme Being, and they distinguish the Creator of this world, and of human bodies, from the most high God, who dwells in the heavens: and hence some have been led to conceive, that they were a branch of the Gnostics rather than of the Manichees. 2. They treated contemptuously the Virgin Mary, or, according to the usual manner of speaking among the Greeks, they refused to adore and worship her. 3. They refused to celebrate under the institution of the institution of the Eucharist. 4. They loaded the crosses of Christ with contempt and reproach; but which we are only to understand, that they refused to follow the absurd and superflitious practice of the Greeks, who paid to the pretended wood of the crosses a certain sort of religious homage. 5. They rejected, after the example of the greatest part of the Gnostics, the books of the Old Testament, and looked upon the writers of that sacred history, as inspired by the creator of this world, and not by the supreme God. 6. They excluded prebishops and elders from all part in the administration of the church. Muheim's EccL Hist. vol. ii. 8vo.

Paulien, St., in Geography, a town of France, in the department of the Upper Loire, and chief place of a canton, in the district of Le Puy. The place contains 2292, and the canton 5712 inhabitants, on a territory of 112½ square kilometres, in 7 communis.

Paulingtoun, or Pawling, a township of America, in Dutchess county, New York, lying on the western boundary of Connecticut; containing 4269 inhabitants, of whom 24 are free.

Paulinskill, a river of America, in New Jersey, which runs into the Delaware, N. lat. 40° 54'. E. long. 75° 56'.

Paulinus, Pontius Meropius, or Paulinus Nolnus, in Biography, a celebrated prelate and ecclesiastical writer in the fifth century, was descended from a Roman patrician family, and born at the town now called Bourdeaux, in the year 353. He was a pupil of the celebrated Decius Auffinius, under whom he made a considerable progress in literature, and cultivated the study of rhetoric and poetry with success. Auffinius being called to Rome, Paulinus quitted his native place and followed him to that city, where he acquired much reputation as a preacher in the forum. He soon established for himself a character, and was raised while young to the confular dignity. Having married a Spanish lady named Therania, he took leave of public affairs, and indulged his inclination for seeing foreign countries, visiting almost all the western provinces of the Roman empire. In the course of his travels he formed an intimacy with several Christians of high note, and was baptized by Delphinius, bishop of Bourdeaux, in the year 391. After this he went to Spain, and took up his residence at Barcelona; where he and his wife, having lost their only child, spent their time in devout contemplation and ascetic exercises, applying the greatest part of their property to benevolent and charitable purposes. In 393 he was ordained presbyter, having had the assurance that he should be allowed to go to Italy. During the following year he arrived at Rome, where he was treated with the utmost respect by all ranks, till perceiving the pope and clergy were growing jealous of his high reputation, he withdrew to a country house in the vicinity of Nola, in Campania. In 409, or perhaps sooner, he was ordained bishop of Nola. The early part of his episcopate was disturbed by the incursions of the Goths, who conquered
PAU
quered and plundered the city of Nola; but he spent the remainder of his life in tranquillity, a bright example of piety, benevolence, and charity, and the object not only of veneration, but of delight, to persons of all ranks and parties. He died in 431, in the 78th year of his age. His works consist of “Letters” and “Poems,” which are partly instructive, but chiefly of a lively and entertaining cast. They are correct, perspicuous, and elegant. The best edition of the works of Paulinus is that published at Paris in 1684, in two volumes 4to., the first of which contains his genuine pieces, the second such as are doubtful. Moreri.

Gibbon, vol. v.

PAULINUS, an English bishop, who flourished in the early part of the seventh century, was called the Apostle of Yorkshire, having been the first English bishop in York, a dignity that was probably conferred upon him about the year 626. He built a church at Almonbury, and dedicated it to St. Alban, where he preached to and converted the Brigantes. Camden mentions a cross at Dewborough, which had been erected to him, with this inscription, “Paulinus hic prædicit et celebravit.” At this period York was so small, that there was not so much as a church in it in which king Edwin could be baptized. Paulinus, it should seem, from the Huns and others, was particularly patronized by Ethelburga, Edwin’s queen. She is said to have made Christianity fashionable by her example; and her bishop, we are told, baptized 10,000 people in the river Swale. In Northerumberland he baptized Segbert, king of the East Saxons. According to Bede, “Paulinus coming with the king and queen to the royal manor called Ad Gebrin, now Yevering, laid there 36 days, employed in the duties of catechizing and baptizing. In all this time he did nothing but instruct the people, who flocked to him from all the surrounding villages, in the doctrine of Christ and salvation; and after they were instructed, baptizing them in the neighbouring river Glen.” He built some churches. See our articles Lincolnshire and Nottinghamshire.

PAULINUS, patriarch of Aquileia in the eighth century, and who is honoured by the Catholics with the title of saint, on account of his zeal in behalf of the doctrine of the Trinity, was a native of Germany. He is greatly distinguished by his laborious application, and zeal for the advancement of learning and science. By his erudition he recommended himself to the patronage of the emperor Charlemagne, who bestowed on him various substantial marks of his favour, and, towards the close of the year 776, promoted him to the patriarchy of Aquileia. From this time he became celebrated as a writer in defence of the Trinity. A complete edition of all his works, with learned notes and commentaries, was published at Venice in 1737, by John Francis Madrifi, a priest of the congregation of the Oratory. He died in the year 804.

PAULINZELLA, in Geography, a town of Germany, in the county of Schwartzburg-Rudolstadt; 8 miles W. of Rudolstadt.

PAULISTAS, or as they are quaintly styled, Memelites, a free-booting society of Brazil. Their town of St. Paul stands on a hill, about 150 paces is height, whence issue two rivulets, one to the S. the other to the W., which afterwards join, and fall into the Harcamбу, that pails at the distance of a league to the N., a river full of fish, and capable of receiving large barges, but liable to inundations in the rainy season. On the N. of this river the mountains extend E. and W. for more than 40 leagues, while on the S.W. the chain seems to wind towards the mountains of Chiuitos in the Spanish possessions: the Paraña pafiling with stupendous rapids of 12 leagues, the general breadth of the chain being from 12 to 20. In the vicinity of St. Paul, the mountains present mines of gold of the purity of 22 carats, which is found in irregular masses, and in dust. The climate is benign, owing to the freth air from the mountains, but the winter is cold and frosty. United by equal want of religion and morals, the first inhabitants of this town formed a republic, like that of robbers in a cavern. Malefactors of all nations and colours, Portuguese, Spaniards, Negroes, Indians, and all possible mixtures of mankind, formed about 100 families, which gradually rose to 1000. The Paulists declared themselves a free people, and they seemed to have mastered the title in the civil sense of it, as they were completely free from all laws, morals, sentiments, and virtues; but they contented to pay the Portuguese a fifth part of the gold which they drew from the mines or forests (lavadores). All strangers who did not bring certificates of having been regular thieves, were refused admittance into this hopeful colony; and there was a marked aversion from any multiplication of professions, as they rejected any robber who was at the same time a spy. The first trial of a new citizen, was to make an excursion, and bring in two Indians prisoners, to be employed in the mines, or in digging the grounds. Virtuous actions were carefully punished with death; and no citizen was permitted to retire from the society. Supplied with fire-arms from unknown quarters, they often defended the large rivers, carrying terror and destruction into the Spanish possessions in Paraguay; and an army would have been necessary ever to reduce them to the Portuguese domination. Where they suspected that force would not avail, they assumed the black gowns of the Jefuits, and proceeded with great fervour to the Indians, on the advantages of religion and civilization, and the heinous offences of robbery and murder, especially warning them against those devils the Paulists, who were accustomed to breakfast on nuns and little children. When they had catechized a sufficient number, they persuaded them to follow their teachers to a convenient spot, where they would find abundance of all the necessaries of life. The poor Indians, accustomed to the same procedure on the part of the Jefuits, allowed themselves to be conducted by these wolves in wool, who, when they had led them to the trap, feized and carried them off captives. This new mode of preaching began to disgust the savages; and the Jefuits found it difficult to avoid the total loss of their character, by the artifices of these new brethren, as the Indians could not possibly distinguish between a Jefuit and a Paulist. To the sword of the faith they were found to join that of the fleth, and to arm all their converts, not with patience but with fucces. The Paulists began to lose their advantages, both as preachers and as pirates; and the bonds of society having begun to be broken by the introduction of some virtues, the city was yielded to the Portuguese monarchy, which is still contented to receive a fifth part of the mines. Pokerton’s Geog. vol. iii.

PAULLINI, CHRISTIAN FRANCIS, in Biography, a physician and naturalist, was born at Liefenach, in Thuringia, in February 1643. He studied at the universities of Konigberg, Copenhagen, Kiel, and Rostock, was crowned poet at Hamburgh, made master of arts at Wittemberg, and took the degree of doctor of phyfic at Leyden. After his graduation he pursued his travels, visiting Norway, Sweden, &c., and was prevented from extending his journey to Italy by sickness. He then settled in the practice of his profession, which he carried on at Hamburgh, Altona, and in Holstein. He was honoured with the title of count palatine for his public services; and was appointed by the bishop of Munfter to the offices of his first physician and historiographer. In 1689, however, he returned to Liefenach, where
he died in 1712, after having laboured under a palsy for seven years. He was a member of the academies Nature Curatorium, and Ricovrati. He published a considerable number of works, chiefly monographs, or separate dissertations on subjects of natural history; such as his "Cynographia currofa, seu Canis descriptio;" "Bufo breviter descriptus;" "Sacra herba, seu nobilis Salvia descripta;" "Tractatus de Augilla;" "Tabulae descripta;" "Lagophgia currofa;" "Lycographia;" "Oonographia;" "De angula Liber Ingleo," etc. He printed in these papers an admiration of the marvellous, rather than of the useful; and the same may be said of his "Observationes Phycico-Medicas," which, however, contain some things worthy of attention. He likewise wrote "Theatrum illustrium Viororum Corboe Saxonico," and some other works. Eloc Dict. Hilt. Gen. Biog.

PAULLINIA, in Botany, so named by Linneus in the first edition of his Genera Plantarum, in memory of the old Danish professor and physician Simon Pauli, who was born at Rottcho, in 1603, and died, if we mistake not, at Copenhagen, in 1680. He published in 1639, a Latin quarto, on Medicinal Plants, entitled Quadrupartitum Botanicum; and in 1648 a thicker volume, in Danish, with wooden cuts, called Flora Danica, which however embraces the garden plants, as well as the native ones, known in Denmark at the time of its publication. He wrote also against Tobacco and Tea, and his work was translated into English by the late Dr. James, in 1749. The most remarkable circumstance attending it is his contending, with the positive views usual to those in the wrong, that the Chinese Tea is no other than our European Myrica Gale; an error which Bartholin very cautiously and respectfully corrects, in his Acta Medica, v. 4. 1, where the true Tea is, not very accurately, figured.—Linn. Gen. 106. Schreb. 265. Willd. Sp. Pl. v. 2. 460. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 2. 422. Juss. 247. Lamarck Illir. t. 318. fig. 45. Gaertn. t. 79. (Cururu; Plum. Gen. 34. t. 35.)—Cliffs and order, Olandria Trigynia. Nat. Ord. Tribulata, Linn. Sapiindi, Juff.

Gen. Ch. Cal. Perianth inferior, of five ovate, concave, spreading, permanent, unequal leaves. Cor. Petals four, obovate-oblong, twice as large as the calyx, furnished with claws; two of them more than different than the rest. Nectaries two; one of four oblong scales, inserted into the claws of the petals; the other of four glands at the base of the petals. Stam. Filaments eight, simple, short, connected at their base; anthers small. Fil. German superior, two-lobed, three-fidled, obtuse; sileges three, thread-shaped, fleshy; figmas simple, spreading. Peric. Capsule large, turbinate, three-lobed, of three cells and three keeled valves, the partitions from the central column. Seeds solitary, nearly ovate, each with a divided pungent tunic.

Eff. Ch. Calyx of five unequal leaves. Petals four. Nectaries of four scales and four glands. Capsule turbinate, of three cells, the partitions from the central column. Seeds solitary, with a cloven tunic.

Obf. Mr. Schumacher, in the third volume of the Copenhagen Transactions, has followed Plumier in making two genera of the Limxan Paullinia, and he is followed by Willdenow. (See Seriana.) He adopts the term Samara for the fruit of Seriana, which consists of three connected capsules, that do not burst, winged at their base, and whose nearly globose seeds do not seem to have any tunic. Such is the case in the true Paullinia Seriana of Limneon, and several other species; but what Gætner has figured for the last-named plant, is no other than the barbarea, a true Paullinia. We know not whether Mr. Schumacher has found out this mistake, as we have not seen his work, but must quote it on the authority of Willdenow, to whose fourteen species we add one hitherto nondescript, and two from Lamarck's Dictionary.

1. P. nolofa. Willd. n. 1. Jacq. Enum. Amer. 35. Obf. fac. 3. 11. t. 62. f. 3.—Leaves ternate, obscurely toothed; the middle leaflet ovate. Footstalk without wings. Clusters longer than the leaves. Native of South America. Jacquin never saw this, but in a dried state, nor does it appear to have fallen in the way of any other botanist. He describes the stem as thorny, climbing, round, unarmed, furrowed and smooth. Leaves smooth on both sides, more or less unequally toothed, nearly fiddle on their common stalk, which has no wing or border, obtuse, rather coriaceous, the middlemost nearly twice as large as the rest. Clusters six inches long, their common stalks waxy, here and there tumid and knotty, the upper half bearing many scattered, branched, bracteate, many-flowered partial stalks; half an inch long.

2. P. Cururu. Linn. Sp. Pl. 524. Willd. n. 2. Jacq. ib. t. 61. f. 4. (Cururu caudens trilophus; Plum. C. 102. t. 111. f. 2.)—Leaves ternate, with tooth-like ferrature. Footstalk winged. Clusters about as long as the leaves. Capsule pear-shaped. Native of South America.—Stem climbing, with long, axillary, simple or divided tendrils. Footstalks two inches long, winged, entire; gradually dilated upwards. Leaves long, ovate, furnished with one central and many transverse ribs. Clusters axillary, many-flowered. Capsule with three blunt angles, and as many intermediate ferratures.

3. P. dasyphora.—Leaves ternate, obscurely ferrature. Footstalk winged. Clusters aggregate, much branched, one-fourth as long as the footstalks.—Sent by Mutis from New Granada, to Linneus, who never described it. The stem is triangular and furrowed. We perceive no tendrils. Leaves like the last, but broader and more elliptical, their lateral veins hairy on one side at their origin. Clusters hardly an inch long, downy, axillary, aggregate, repeatedly branched. Calyx hairy, as is likewise, in some degree, the obovate pointed capsula. Seeds large, polished, of a chestnut brown.

4. P. carthaginensis. Jacq. Obf. fac. 3. 11. t. 62. f. 6. Willd. n. 3.—Leaves twice ternate, cut. Footstalks all winged. Stem without prickles.—Gathered by Jacquin about Carthagena in South America. He describes the leaves as more deeply cut than in the rabbit, almost pinnaed, and very thin, not all coriaceous. The whole plant is without prickles.

5. P. carica. Jacq. ib. t. 62. f. 7. Willd. n. 4.—Leaves twice ternate, obtuse, slightly ferrature. Partial footstalks winged; common one, like the branches, prickly.—Native of the Caribee islands. Leaves smaller and blunter than those of the last, with flight and distant ferratures; their common stalk betit with hooked prickles, which are also plentiful on the branches.

—Native of Carazoa.—The stem is unarmed, furrowed, with downy ruly angles, the furrows, in the upper part, as Schumacher well observes, marked with ruly dots. Leaves from four to six inches long, smooth, with coriaceous than usual, distantly and coercely ferrature, the terminal leaflet largest, tapering at each end. We have not seen this fruit.

PAULLINIA.

381. t. 79.)—Leaves twice ternate, obtuse, coriaceous, nearly entire. Footstalks finely winged. Valves of the capsule downy, half-sawtoothed.—Native of the West Indies. The leaves are highly polished on their upper side, paler and opaque beneath, two or three inches long. Clusters on long stalks, each accompanied with a pair of tendrils. Capsules veiny, downy, of a rally red, their valves much compressed, equally winged.

8. P. polyphylla. Linna. Sp. Pl. ed. 1. 366. (P. folia supra decomposita; Linn. Hort. Cliff. 152. Cordis indi folio et facie frutescenis portoricenlis; Pluk. Phys. t. 168. f. 5.)—Leaves doubly pinnate, ovate, cut. Footstalks winged, with hairy ribs. Angles of the stem fringed with spreading hairs. Flowers at the fork of the tendril.—Native of South America. The stem climbs by means of axillary tendrils, and has many angles, with dense spreading hairs, and separated by smooth furrows. The tendrils and footstalks are hairy in a similar manner, the latter all winged. Leaves about half an inch long, ovate, more or less cut or lobed, sometimes tapering at the base, nearly smooth on both sides, with hairy ribs and edges. Tendrils about three inches long before they divide into two spiral frow branchlets, at the base of which stand a small downy tuft of flowers. Of the fruit we can discover nothing, but Pluketn heard it was of a fliquofe kind, which term rather agrees with *Paulinia* than with *Seriana*, and the close affinity of this species to the following, precludes all doubt of its genus. The great confusion which envelopes this species, could be dispelled only by the original specimen of Linnaeus, who in the second edition of his Sp. Pl. confounded with it what is now properly called *Seriana trietus natta*, Willd. Sp. Pl. v. 2. 466. A leaf of Plumer's figure, which belongs to this last, is actually copied by Jacquin, and cited by Willdenow, for *P. polyphylla*, of which Pluket's plate above quoted is the only genuine representation we can discover.

9. P. bipinnata. Poiret in Lam. Dict. t. 5. 99. (P. polyphylla; Willd. n. 7?)—Leaves doubly pinnate, ovate, finely notched at the summit. Footstalks downy, winged towards the end. Stem finely downy. Flowers at the fork of the tendril.—Gathered by Commerson in Brazil. One of his specimens is before us, marked, with a doubt, *P. polyphylla*, Linn. and it appears to be what Schumacher, whom Willdenow copies, has actually described as such. This plant however differs essentially from the last, in the dense pubescence of its stem, as well as of its footstalks, and, though in a less degree, of the backs of its leaves, whose shape is obovate and obtuse, with two or three irregular shallow notches. The tendrils too are very much shorter and thicker, and their spiral branches are downy. Capsule near an inch long, downy, fariated, its valves half-obovate, much compressed. Abrupt and wavy at the summit.

10. P. tetragona. Aubl. Guian. v. 1. 325. Willd. n. 8.—Leaves once or twice pinnate, ovate, distinctly serrated, smooth. Footstalks scarcely winged. Clusters compound, axillary, much shorter than the leaves. Valves of the capsule wedge-shaped, with a blunt terminal tooth.—Observed by Aublet at Cayenne. We have a specimen, gathered by Dr. Mertzer in the Caraeas, which accords as much as possible with our original one of Aublet, except that the former being in flower, the latter in fruit, with only one leaflet, an absolute decision can hardly be made. The leaves evidently appear by both specimens to be distinctly toothed, though Aublet says they are entire, and he quotes Rumphius's *Fruits quadrifoliati*, v. 5. 4. t. 5, which is doubtless very different, except that the stem in both plants splits into four portions, serving to make balsaks or cordage. The branches, tendrils, and common footstalk, in Mertzer's plant, are lissip with prominent rigid hairs. The whole leaf is a foot long, of five pairs of opposite leaflets, with an odd one; the lowest pair again pinnate, each of five leaflets, of which one is ternate; the second pair ternate, having small lateral leaflets; the rest all simple, full two inches long and one broad; the whole are reticulated with imprecise veins, and of a light green, smooth, except the middle on the upper side. Flowers in compound, axillary, aggregate, slightly hairy. Clusters, three inches long, accompanied by many broad, ribbed, smooth, fringed *buccatus*. Calyx downy at the edges and base, in both specimens. Capsule, in that of Aublet, near an inch long, narrower than in the last species, each valve crowned with a blunt tooth at the outer angle, the inside, and the central column, finely woolly.

11. P. rhodoidea. Poiret in Lam. Dict. t. 5. 90.—Leaves pinnate; leaflets ternate, pointed, toothed, downy beneath. Footstalks winged. Valves of the capsule slightly bordered.—Gathered by Commerson at Brazil, according to Poiret. We find no specimen that answers to his description entirely. He compares the leaves to those of *Melia Azedarach*; but they are downy and rusty beneath. The clusters appear to spring from the division of the tendril, as in N. 8 and 9. The capsules are pear-shaped, a little rounded, flaked, marked at each furrow with a short membrane, which originates from the upper part of the peduncle. This peduncle can only mean the stalk of the capsule or gemmifer, not of the flower. M. Poiret contends that its border, or wing, is analogous to the remarkable one in *Seriana*, and hence he would keep the two genera united; but the valvar capsule is an important difference.

12. P. Perseptilum. Swartz. Ind. Occ. v. 2. 595. Schwmach. Copenh. Trans. v. 3. p. 2. 122. t. 11. f. 1. Willd. n. 9.—Leaves pinnate, smooth, ovate, pointed, cut. Footstalk naked. Capsule with lanceolate horizontal wings.—Gathered by Mr. Maffon in the island of St. Christopher. We have seen no specimen. Swartz says the stem is hairy, round and smooth, climbing by means of axillary rigid tendrils, hardly so long as the leaves, which are pinnate, of two pair of leaflets with an odd one; their footstalk round, fariated, without wings. Clusters axillary, simple, erect, shorter than the leaves, of many small whitish flowers. Capsules flaked, large, ovate, obtuse, three-foiled, with three valves, terminated by three lanceolate, obtuse, thick, membranous, horizontal wings.

13. P. pinata. Linn. Sp. Pl. 525. Willd. n. 10. Jacq. Obs. t. 2. 12. t. 62. f. 12. Gartn. t. 79? (Clematis pentaphylla, pediculus alalis, fructu racemoso tricoceo et cocino; Plum. Amer. 76. t. 91. Cururu frondens pentaphylla; Plum. Gen. 33.).—Leaves pinnate, smooth, elliptic-lanceolate, pointed, bluntly serrated. Footstalk winged. Capsule pear-shaped, three-lobed.—Native of the West Indies, in dry sandy places, not unfrequent. The leaves are a span long, of two pair of shining veiny leaflets, with an odd one; their stalk rather broadly winged throughout. Clusters solitary between the branches of each tendril, downy; sometimes sessile and axillary, without a tendril. Fruit one inch and a half long, scarlet, with three furrows, according to Plummer, but no wings, the seeds black and polished, each with a white tender corky tuning. Gartnner represents it exactly obvolute, without lobes or furrows, and the parties opposite to the centre of each valve, which does not agree with Plummer, and we suspect he may have committed an error in this case, as we well with regard to *Seriana*; see our seventh species. Linnaeus received from Brown's herbarium a Jamaica specimen, under the name of *P. pinata*, which is certainly different from what we have described, having three pair of much smaller leaflets, the wing
of whole common flalk is greatly dilated at each side into a triangular form. For want of fructification, the genus is doubtful, but we take the plant to be a *Himannia*; perhaps a luxuriant branch of *W. pinnata*.

14. *P. tenuifolia*. Jacq. Enum. Amer. 37. Obs. falc. 19. t. 10. falc. 3. 12. t. 61. f. 13. Willd. n. 11.—Leaves pinnate, ovate, obtuse, wavy, downy on both sides. Footstalk winged. Capsules downy.—Native of South America, where it was discovered by Houtouin. The whole plant is clothed with short dense soft pubescence. Branches round. Leaflets broad-ovate, wavy or partly ferrated, above an inch long, two pair, with a larger odd one, tapering at the base. Clusters from between the forks of the tendrils. *Capsules* turbinate, short, three-lobed. Linneus had for this a totally different plant in the Upfal garden, with a large leaf, like a *Rhus*, to which his remark in both editions of *Syll. Veg.* refers. This has fix pair of pointed ferrated leaflets, with an odd one, and the upper half only of the common flalk is winged. Refepting the genus, nothing can be determined.

15. *P. cauliflora*. Jacq. Coll. v. 4. 176. L. Rar. t. 458. Willd. n. 33.—Leaves pinnate, ovate-lanceolate, entire, smooth; the lower pair ternate. Footstalk winged. Flowers in dense axillary tufts.—Native of Caracas. It flowered at Vienna, in the stove, from October to January, but produced no fruit. The flalk climbs, by means of tendrils, as in the other species. Leaves about six inches long, composed of one pair of ternate leaflets, two pair of simple, and an odd one, the latter near two inches long; all pale at the back. Flowers numerous, small, white, in seifile, round, dense tufts, either axillary, along with the common tendrils, or proceeding from various parts of the old leaflets flalk.

16. *P. japonica*. Thunb. Japon. 170. Willd. n. 13.—Leaves pinnate, of four pair of three or five-cleft leaflets, with an odd one; the second pair ternate. Footstalks winged. Panicles opposite to the leaves. Stem herbaceous. Gathered by Thunberg in Japan, where it is called *Bak Ren*. "The flalk is herbaceous, climbing, smooth, angular, without prickles, scarcely so thick as a straw. Leaves alternate, flalked, smooth; the lowest pair of leaflets nearly sessile, ovate, an inch long, cut into two or three entire segments; the next pair ternate, with a winged partial flalk, their lateral partial leaflets ovate, either undivided or cleft, the middlemost three-cleft; the flalk of the leaf pinnate, consisting of a bordered jointed flalk, two pair of oblong leaflets, in three or five segments, and a larger terminal one in three segments. The common flower-flalk resembles the flalk, and is two inches long. Flowers panicked, opposite to the leaves. Common flower-flalk the length of the leaves; partial ones very short." Such is Thunberg's account, but as he says nothing of the fruit, and we have seen no specimen, the genus (whether Paulinia or Seriana) must remain in uncertainty.

17. *P. divaricosa*. Jacq. Enum. Amer. 36. Obs. falc. 3. 12. t. 62. f. 14. Willd. n. 14.—Leaves doubly pinnate, obovate, obtuse, nearly entire. Footstalks winged. Stem round, nearly smooth.—Native of South America. As far as we can judge by Jacquin's description and figure, this ought to have been placed near *polyphylla* and *bilimnata*.

18. *P. furfuracea*. Linnasus. Enum. t. 458. L. E. Fig. 15. Willd. n. 15.—Leaves are composed of obovate obtuse leaflets, about the size of the latter, (being scarce, except the terminal one, half an inch long,) but nearly smooth, almost or entirely undivided, and all their footstalks are winged, except the base of the general one. The first pair of divisions of the leaf are pinnate, of five leaflets, the second, third, and terminal ones are ternate, the last not larger than its neighbours. The flalk is shrubby. Clusters accompanied by tendrils, or rather, as we presume, springing from the latter at their division.

It appears to us that this genus, as well as its near relations, *Seriana*, requires more accurate attention than either of them has yet received from botanical travellers. In our gardens they are now scarcely at all known, though some species of *Paulinia* were cultivated by Miller.

PAULMOW, in Geography, a town of Bengal; five miles N.W. of Curruckdeah.

PAULO, Marco, in Biography, a celebrated traveller, son of Nicholas Paulo, a Venetian, who went with his brother Matthew, about the year 1225, to Constantinople, in the reign of Baudoin. While they were on this expedition Marco was born. On their return through the deserts, they arrived at the city where Kublai, grand khan of the Tartars, refused. This prince was highly entertained with the account which they gave him of the European manners and customs, and appointed them his ambassadors to the pope, in order to demand of his holiness a hundred millionaries. They accordingly came to Italy, obtained from the Roman pontiff two Dominicans, the one an Italian, and the other an Aulic, and carried with them young Marco, for whom the Tartar prince expressed a singular affection. This youth was at an early period taught the different dialects of Tartary, and was afterwards employed in embassies which gave him the opportunity of traversing Tartary, China, and other eastern countries. After a residence of seventeen years at the court of the great khan, the three Venetians came back to their own country, in the year 1295, with immense wealth. A short time after his return, Marco served his country at sea against the Genoese, his galley in a naval engagement was sunk, and himself taken prisoner and carried to Genoa. He remained there many years in confinement; and, as well to amuse his melancholy, as to gratify those who desired it of him, sent for his notes from Venice, and composed the history of his own and his father's voyages in Italian, under this title, "Delle maraviglie del mondo da lui vedute," &c., of which the first edition appeared at Venice in 1496. This work has been translated into several foreign languages, and has been inserted in various collections. The best editions are one in Latin, published by Andrew Müller at Cologne in 1671, and one in French, to be found in the collection of voyages published by Bergeron, at the Hague in 1750, in two voles. In the narrative there are many things not easily believed, but the greater part of his accounts has been verified by succeeding travellers. He not only gave better accounts of China than had been before received; but likewise furnished a description of Japan, of several islands of the East Indies, of Madagascar, and the coasts of Africa, so that from his work it might be easily collected that a direct passage by sea to the East Indies was not only possible, but practicable.

PAULO, in Geography, a town of South America, in New Granada; 25 miles E.N.E. of Tunja.

PAVILOGRAD, a town of Russia, in the government of Ekaterinolav; 32 miles E. of Ekaterinolav. N. lat. 47° 10'. E. long. 35° 54'.

PAVLOSK, a Russian fortress, in the province of Tauris, constructed for defending the straits of Taman, between the Black sea and the sea of Azof; six miles S. of Kerch.

PAVLOV, a town of Russia, on the N. coast of the Tchudskoe lake; 20 miles S. of Narva.

PAVLOVA, a town of Russia, in the government of Irkutski, on the Lena; 16 miles N. of Orloga.

PAVLOVSK, a town of Russia, in the government of Voronez.
PAV

PAVLOVSKAI A, a town of Ruffia, in the government of Ekaterinograd, on the Don; 32 miles E. of Ekaterinograd.

PAULUN, a town of Hindostan, in the circar of Kutchwara; six miles S.E. of Raajegur.

PAULUS, Cyrus Florus, called Paul the Silentian, because he was at the head of the royal secretaries, officers whose business it was to prevent Noise in the palace, flourished in the sixth century, under the emperor Julianus. He is said to have been of an illustrious family, and peculiarly of hereditary office, but has been still more distinguished for learning and eloquence. He was author of poems in the Greek language, among which was one giving the history and description of the church of St. Sophia in Constantinople in more than a thousand hexameter lines. This has come down to our times, and was published in the collection of Byzantine historians, with a translation and notes by Ducange. He also composed a poem on the Pythian Thermis, and some epigrams in the Anthology. See Gibbon, vol. vii. in which is a fine description of St. Sophia, taken partly from the work of Paulus.

PAULUS Hook, in Geography, a fortified poll of North America, in Bergen county, state of New Jersey, on the North river, where the river is 2000 yards wide, opposite to the city of New York. In 1780 this river was 100 frozen, that carriages with heavy burdens passed over it.

PAUNCH, or PUNCH, on Ship-board, a sort of thick and strong rag, formed by interweaving twirls of rope-cord as close as possible. See MATTs.

PAUNCHWAY, a small boat in Bengal, attendant on the Budgeeows, which feed. The paunchways move more slowly than the budgeeows; but they are nearly of the same construction, with this difference, that the greatest breadth is somewhat further aft and the stern lower. We shall here add that another boat of this country, called "Moorpunkey," is curiously constructed; these boats are very long and narrow, sometimes extending to upwards of 100 feet in length, and not more than eight feet in breadth; they are always paddled, sometimes by 40 men, and are steered by a large paddle from the stern, which rides either in the shape of a peacock, a fnaile, or some other animal; the paddlers are directed by a man who stands up, and sometimes makes use of a branch of a plant, to regulate their motions, using much gesticulation, and telling his story to excite either laughter, or exertion. In one part of the stern is a canopy supported by pillars, in which are seated the owner and his friends, who partake of the refreshing breezes of the evening. These boats are very expensive, owing to the beautiful decorations of painted and gilt ornaments, which are highly varnished, and exhibit a considerable degree of taste.

PAUNDURA, in Geography, a town of Hindostan, in Oude; 12 miles S.W. of Gazypour.

PAUNGARTENBERG, a town of Austria; six miles S.W. of Grein.

PAUNRAN, a town of Hindostan, in Mohurunge; 20 miles N. of Harriopour.

PAVO, Peacock, in Ajetonomy, a constellation of the southern hemisphere, unknown to the ancients, and not visible in our northern parts of the world, containing fourteen stars. See Constellation.

Pavo, in Ichthyology, a species of Chrsotden, and also of Labrus; which see respectively.

Pavo, the Peacock, in Ornithology, a genus of birds of the order Gallinæ, of which there are four species, according Vol. XXVI.

PAV to Linnaeus. The generic character is, bill convex, robust; the head is covered with feathers turned back; the nostrils are large; the feathers of the rump long, broad, expandable, and covered with rich eye-like spots.

Species.

Cristatus; Crested Peacock. Of this species there are three varieties. viz. 1. Head with a compressed crest; 2.ipes solitary. 2. Cheek, throat, belly, and uveo-coverts, white. 3. Body entirely white. This species inhabits Asia and Africa, and is domiciliated every where; it is three feet eight inches long; feeds on the highest places, and utters a loud and harsh cry; it is proud and vindictive, and feeds chiefly on grain and insects; it lays five or six eggs; in some private places, which are grey-white: the young do not attain all their elegance till the third year. The bill and legs of this beautiful bird are brown; irides yellow; crest gold-green of twenty-four feathers, barred at the tip, and with white shafts; the line above and beneath the eyes white; head, neck, breast, back and rump green-gold; feathers of the rump, usually called tail-feathers, sometimes five feet long; the real tail-feathers are eighteen in number, grey-brown, about 18 inches long; capulars and lesser wing-coverts reddish-brown, varied with black, middle ones blue, with a gloss of green-gold, and greater and puruous wings rufous; quill-feathers rufous, some of them varied with rufous, blackish and green; belly and vent greenish-black; thighs yellowish. The female has a shorter crest, and has no pur; the feathers of the rump not so long or elegant; the irides are of a lead colour, the bill and fringe on the breast white; the neck is green, the rest of the body and wings brownish.

The crest peacock exhibits in India, in its wild state, all the maturity of growth, and glow of colour. It was an article of importation from that country to Palestine, in the reign of Solomon, in those fleets which conveyed, once in three years, to the court of that monarch invaluable treasures of art and nature. The female of this species is particularly solicitous to conceal her eggs from the male, which not unfrequently destroys them. They both feed chiefly on insects and grain, and prefer elevated situations for roosting, choosing the tops of housetops and the highest trees for this purpose. Among the Romans they were regarded as great luxuries, and the young ones are now esteemed a delicacy. Their voice is extremely harsh and diffidant, and in perfect contrast to that beauty exhibited in their plumage, which seems to combine all that delights the eye in the soft and delicate tints of the finest flowers, all that dazzles in the sparkling lustre of the gem, and all that astonishes in the grand display of the rainbow. See Plate III. Gallinae of Ornithology.

Bicalcaratus; Iris Peacock. Brown; head sub-crested; 3 purrs. This is found in China, and is larger than a pheasant. The bill is blackish, the upper mandible from the nostril to the tip red; irides yellow; crown black; face naked; temples white; neck shining brown, with black lines; upper part of the back, shoulders, and wing-coverts brown, with yellowish stripes, the feathers near the tip with a large purple-gold spot; lower part of the back and rump spotted with white; body beneath brown, with transverse black streaks; quill-feathers dusky; legs brown. Individuals of this species have occasionally been brought to England, but they have not found the climate congenial to their habits.

Tibetanus; Thibet Peacock, is about the size of a pintado, or more than two feet in length. The specific character is cincereus streaked with blackish; head sub-crested, 3 P and
and two spurs. The head, neck, and under parts, are ash-coloured, marked with blackish lines; the wing-coverts, back and rump are grey, with small white dots; besides which, on the wing-coverts and back, are large round spots of a fine blue, changing in different lights to violet and green-gold. This bird, as its specific name denotes, inhabits the kingdom of Thibet. The Chinesc give it the name of Chin-tchen-khi.

**MUTIEUS; Japan Peacock.** Head with a fuscule crest, and it has no spurs. It is found in the Japanese islands, and is of the size of a large P. criatus. The bill of this species is large, and cincereous; area of the eyes red; irides yellow; body blue, mixed with green; head and neck greenish, with blue spots, and a white streak down the middle; belly, wing-coverts, secondary quill-feathers, and thistles cincereous, with black spots, the belly with white streaks; primary quill-feathers green, with transverse black lines, and yellowish white towards the tip, which is black; feathers of the rump bay, with white shafts. The belly of the female is black.

**PAVOASAAS, in Geography, a town of Africa, and capital of the island of St. Thomas, with a good harbour; the residence of the governor, and of the bishop.**

**PAVOISES. See PAVAI.**

**PAVONIA, in Botany, received that appellation from Cavanilles, in honour of his countryman Joseph Pavan, who shared the labour of various botanical excursions, through Chili and Peru, with Dombev and Ruiz, and who is named, in conjunction with the latter, as author of the splendid Flora Peruana. Mutis had dedicated for the fame purpose the beautiful flower, figured long ago in various old books, under the denomination of Flora Tigris, which has but recently become known in the gardens of Europe. This however Linneus referred to Ferraria; and his son, in publishing it, seems to have thought the specific name alluded to the peacock-like spots of the corolla; for he prints it as an adjective, pavonia. Many perons have fo understood it. This plant is since restored to the rank of a genus; see Tigrinia.**

Gen. Ch. Cal. Perianth inferior, permanent, double; the outer of many linear-lanceolate leaves, rarely combined at the base; inner of one leaf, cup-shaped, divided half way down, rarely more, into five segments. *Cor.* Petals five, roundish, tapering at the base, a little oblique, spreading, united below to the tube of the filament. *Stam.* Filaments numerous, combined in the form of a tube, about whose apex and surface they become separate; anthers kidney-shaped. *Pil.* Germin globose, furrowed; style thread-shaped, longer than the filaments, in ten segments at the top; stigma globose. *Peric.* Capsules five, angular at the inner side, convex at the outer, of one cell and two valves, burting in the upper part. *Styl.* Solitary, ovate-oblong, acute. *Eff.* Ch. Calyx double; the outer of many leaves or fegments. Stigmas ten. Capsules five, of two valves. Seeds solitary.

This genus, separated from Cavanilles from Hibiscus, see that article, is rather artificial, there being no difference whatever in habit, and the technical marks of distinction not of the most decisive kind. There are the ten filigrams, which, in Hibiscus, are only five, and the finally distinct bivalve capsules, with solitary seeds. In *Hibiscus* the seeds are commonly numerous, in each cell of a five-valved five-celled capsule. This last-named genus being ever-burthened with species, it is commodious to leffen their number by any allowable means, and as we prefix the Hortus Rewenfsis, which fo generally follows Willdenow, we do not scruple to admit it. This author reckons up fifteen species.

1. *P. premoins* (P. cuneifolia; Cav. Diff. 139. t. 45. f. 1). *Hibiscus praemorsus*; Linn. Suppl. 359. Jacq. Ic. Ram. t. 141.)—Leaves roundish-wedge-shaped, abrupt, toothed, downy. Native of the Cape of Good Hope, cultivated in green-houses. The peculiar shape of the leaves at once distinguishes this species. The *fem* is shrill, as in every other, except the 7th and 15th. Flowers lemon-coloured, one inch and a half wide; the segments of their outer calyx numerous and fetaceous.

2. *P. leptocara.* Cav. Diff. 351. (P. Typhala; Cav. Diff. t. 197. Urena leptocara; Linn. Suppl. 368.)—Leaves lanceolate, serrated. Outer calyx of five ovate leaves. Flowers capitata.—Native of Surinam. It is the *Hibiscus s流传fusus* of the Pl. Surinam. in St. v. 8. 260, and is known by the Linnean herbarium only. The leaves are from three to five inches long, pointed, closely serrated. *Flowers* yellow, in terminal heads. The inner calyx, smaller than the outer, is rather deeply divided, but not to the base, and the latter has but five leaves, which is a smaller number than the character requires. The *capsules* are those of a true *Pavonia*, but each is tipped with three points, half its own length, barbed with numerous recurved prickles. This species is very nearly related to the next, for which Cavanilles has figured it, not very correctly as to the calyx, whose divisions he makes not sufficiently deep, at least in the outer one, whereas Linneus, on the other hand, errs in laying the inner calyx of five leaves.

3. *P. Typhala.* Cav. Diff. 134. (Urena Typhala; Linn. Mant. 358.)—Leaves oblong-lanceolate, serrated. Outer calyx of about seven linear leaves. Stem paniced. Flowers somewhate umbellate.—Native of the West Indies. This species, of which a specimen is preferred in the herbarium of the younger Linneus, has not been well distinguished from the last, which has been generally mistaken for it. The present differs essentially in its paniced many-flowered *fem*, but especially in having the outer calyx of six or seven narrow linear leaves, or deep segments; whereas the former has five ovate ones. The barbed points are moreover as long as the capsules themselves, and the corolla is said to be white. The calyx of the true *Typhala* answers exactly to the generic character, but the preceding species is closely allied to this, that they cannot be generally distinguished, though the latter has but five segments in its outer calyx.

4. *P. bafata.* Cav. Diff. 138. t. 47. f. 2.—Leaves oblong, haftate, bluntly toothed; deeply downy beneath. Stalks axillary, single-flowered.—Gathered by Commeron at Monte Video. Branches round, subdivided. Leaves dependent, about an inch long; befrinkled with fllary hairs above; densily clothed with fimilar white pubescence beneath, as is the inner calyx especially. The outer calyx is of six, rarely only five, ovate leaves, shorter than the inner. *Capsules* reticulated, downy, without points or appendages.

5. *P. spinifex.* Cav. Diff. 133. t. 45. f. 2; and arilata, t. 45. f. 3. (Hibiscus spinifex; Linn. Sp. Pl. 978. Jacq. Hort. Vind. v. 2. 46. t. 103.)—Leaves broad-ovate, doubly crenate. Stalks axillary, single-flowered. Capsules with spreading smooth spines.—Native of South America. The leaves are two or three inches long, and half as broad, roughish to the touch. Flowers large, yellow. *Capsules* each tipped with three or four spreading, smooth, not barbed, awns or spines.

Stamens and style declining.—Gathered in Otaheite by Sir Joseph Banks, who communicated it to Cavanius. Flowers large, yellow. Segments of the outer calyx very narrow, and longer than in the last. 

8. P. racemosa. Swartz Ind. Occ. v. 2. 1215. (P. fipicata; Cav. Diff. 135. t. 46. f. 1. Malahie fcebra; Trew. Ehret. 50. t. 90.)—Leaves ovate, pointed, nearly entire. Flowers in a terminal cluster. Outer calyx of eight lanceolate leaves. —Native of bogs, amongst other thurs and trees, in Jamaica. The nearly entire, naked leaves, roughish to the touch only, and the long terminal solitary clysters, of pale yellow, not very large, flowers, readily distinguishes this species. The leaves in our specimens are very nearly entire; Ehret represents them serrated prettily copiously.

niola and Jamaica. The habit is compared by Swartz to Althea bitifolia of Linneus. Leaves not quite smooth, ferrat, sometimes almost fringed as well as angular. Flowers yellow, rather large. Outer calyx of ten or twelve linear leathery leaves. Capules rough. We have seen neither specimen nor figure.

10. P. paniculata. Cav. Diff. 135. t. 46. f. 2.—Leaves roundish-heart-shaped, serrated, with one or three points. Clusters compound, hairy. Stamens and style declining.—Native of Peru, near the source of the river Maraggon. Dombey. It seems, as Willdenow remarks, nearly akin to the last. The flowers are yellow, very numerous. Stamens drooping. Style ascending at the extremity.

12. P. cocinea. Cav. Diff. 140. t. 47. f. 1. (Malva folio fedezeo, flore cocineo; Plum. Le. 162. t. 169. f. 2.)—Leaves heart-shaped, three-lobed, ferrated. Stalks axillary, single-flowered, ascending. Outer calyx of five linear-lanceolate leaves. —Native of Hispamia, not of Dominica. Linneus misquotes the figure of Plumier, for Hibiscus (or rather Aphantia) Malaeozicus. The flowers appear to be large, standing erect in an elegant manner, the lower part of the petals coloring in the form of a tube, the extremities drooping. Plumier represents more than five leaves to the outer calyx, but Cavanius examined a specimen.

13. P. Columnel. Cav. Diff. 138. t. 48. f. 3.—Leaves with five angles, ferrated, nearly smooth; the uppermost oblong and undivided. Stalks axillary, single-flowered, shorter than the footstalks. Outer calyx of five linear-lanceolate leaves. —Found by Commeron in the ille of Bourbon, growing abundantly by the sides of the roads cut through the woods. The leaves are shaped somewhat like those of a vine. Flowers small, purplish, not unlike a common Mallow.

15. P. zeylanica. Cav. Diff. 134. t. 48. f. 2. (Hibiscus zeylanica; Linn. Sp. Pl. 981. Burm. Ind. t. 48. f. 3.)—Leaves roundish-heart-shaped, cut, lobed, or deeply divided, bluntly toothed. Stalks axillary, single-flowered, equal to the footstalks. Outer calyx of ten linearly bluntly leaves.—Native of Ceylon. Root annual. Stem herbaceous, downy, somewhat branched. The leaves vary greatly as to their divisions, being sometimes divided to the very base into five oblong blunt segments. Flowers small, red. This species is now and then seen in gardens, but valued rather for the sake of rarity than beauty. Scopoli has figured the deeply divided variety, under the name of Hibiscus arenarius, Delic. Inf. Hafe. 3. t. 2, which we do not find quoted.

16. P. spirolata. Cav. Le. v. 5. 20. t. 434.—Leaves heart-shaped, serrated, pointed, somewhat lobed. Stalks axillary, single-flowered. Outer calyx of many linear fringed leaves. Petals convoluted, each with a lateral tooth. —Gathered by Louis Née, in the island of Tobago, five leaves from Panama, flowering and fruiting in November. The stem is thorny, six feet high. Leaves joints like those of the tenth species, but it is not said whether they are smooth or otherwise. Outer calyx of nine linear hairy leaves. Petals scarlet, rolled together like those of Aphantia Malaeozicus, but larger, the stamens and style projecting far beyond them. This species is unnoticed by Willdenow, and might perhaps be introduced between the tenth and eleventh. S.

Pavonia, or Pavonina, in Ornithology, a species of An-
draceae. —See Herron.

Pavonius Lapis, the peacock-flone, a name given by Ludovicus Dulcis, and other writers of his time, to a flower of which they fay many idle things, such as its having the virtue of gaining a perfons love to another, and the like. They have left us no defcription of it, but probably it was one of the variegated agates.

Pavoor, in Geography, a town of Hindooftan; 15 miles N.W. of Tinewelly.

Paupakelly, a town of Hindooftan, in Golconda; 20 miles S. of Byaren.
Paupanassum, a town of Hindooftan; 20 miles W.S.W. of Tinewelly.
Paupanassy, a town of Hindooftan, in the Carnatic; 12 miles N.E. of Tanjore.
Pauper, in Law. See Forma Pauperis, and Poor.
Paurédrastyae, in Natural History, the name of a genus of crystals. The word is derived from the Greek, a few, a few, a few, or plane, the particu late name, or the, a column, and expresses a foli of composed of but a few sides or planes, and having no column. The bodies of this genus are crystals, composed of two pyramids joined bafe to bafe, without the intervention of a column; these being both hexagonal, and confequently the whole body composed only of twelve planes; the others of the fame structure being composed of eleven. Of this genus there are only four known species.

Paurey, in Geography, a town of Africa, on the Slave coast. N. lat. 6° 10'. E. long. 6° 15'.
Pauwrzitz. See Bauwrzitz.
PAU

PAUSA, a town of Saxony, in the Vogtland; 72 miles W.S.W. of Dresden. N. lat. 50° 21'. E. long. 11° 58'.

PAUSANIA, in Antiquity, a festival in which were solemn games, wherein freeborn Spartans only contended. It had its name from Pausanias, the Spartan general, under whose conduct the Greeks overcame Mardonius, in the famous battle at Platea, there being always an oration in praise of him.

PAUSANIAS, in Biography, a celebrated Lacedaemonian commander, who fell at the famous battle of Thermopylae; was the son of Cleombrotus, and nephew of Leonidas. He obtained a high rank in the magistracy of his country, and when Mardonius, the Persian general, invaded Greece with a mighty host, Pausanias was appointed commander-in-chief of the hired army raised to oppose him. He brought on a general engagement at Platea, in the year 479 B.C., in which Mardonius was killed, and his army defeated with great slaughter. With the assistance of the Athenians, the camp of Mardonius was taken with an immense booty. Pausanias exhibited a greatness of mind in rejecting the proposal of one of the leaders, that the body of the Persian general should be fought for, in order that it might be treated with the same indignity that had been offered to that of Leonidas. He proceeded to punish the traitors to the cause of Greece, and marching to Thebes, obliged that city to deliver up the heads of the Persian party, whom he put to death. The effect of success upon his own mind was to nourish a spirit of pride and arrogance, and inspire ambitious designs. He affirmed to himself all the honour of the victory of Platea, and upon a golden tripod, which he presented to the temple of Delph, he put an inscription that was honourable to himself alone. In the command of the united fleet, which had been given him for the purpose of freeing the Greek cities from Persian garrisons, he behaved with great partiality to his own subjects, and oppressed many enemies; while the justice of Aristeides, and the affability of Cimon, gained all hearts, and restored to the Athenians the naval supremacy of Greece. Suspicions were entertained that he meant to assume the full control of Greece, and to get the power of the country in his own hands, and on this account he was recalled to Sparta, and underwent a trial for his life, but as the evidence was inconclusive, he was fined and liberated. When he returned to the army, he openly adopted the Persian habit and manners, and went into all the exequies of that luxury which he had formerly deprecated. It was supposed that his mind was deranged, owing to the following tragical incident. Having been captured by the charms of Cleonice, a young woman of good family at Byzantium, her parents not daring to refuse his solicitations, obliged her to comply with his desires. To save her blushes, it was agreed that the lights should be extinguished when she entered his chamber. In the dark she unfortunately stumbled over one of the lamps; the noise of which suddenly awakening Pausanias, he fancied an affianced was coming to murder him, and, starting up, plunged a dagger into her breast. When he discovered the fatal error, he was almost distraught, and from that moment imagined that the blood of Cleonice was perpetually crying out for vengeance. He left Byzantium, and repaired to Heraclea, where he found perfons who pretended to evoke and pacify the spirits of the deceased. That of Cleonice was called up before him, and made to say to him, "When you come to Sparta, you shall find a termination to your sufferings." He went thither, full occupied with the thought of betraying his country to the Persians. For this purpose, he carried on a correspondence with Artabazus, a fatrap; and all the meffengers he sent were put to death, that they might not betray him on their return. It is said that he in vain attempted to engage Themistocles, who was at that time an exile, to concur in his measures, and being impatient, he wrote a peremptory letter to Artabazus, which he committed to one Argillus, his particular favourite. The young man, alarmed by the reflection, that none of the former meffengers returned, unsealed the packet entrusted to his care, and finding a direction to put him to death, immediately dislocted the matter to the ephors. They resolved to apprehend him, but being apprized of their intention, he fled into the temple of Minerva, from whence he could not be taken. While they were hesitating as to what could be done, the mother of Pausanias brought a brick, and let it against the door of the temple; her example was followed, till he was completely immured. When he was dead with hunger, his body was brought out, and interred by his friends. Corn. Nep. Univer. Hist.

PAUSANIAS, a Greek topographical writer, who flourished in the second century, under Adrian, and the Antonines, was probably a native of Caearea, in Cappadocia, and lived under the celebrated Herodes Atticus. Though as a speaker defective in his pronunciation, he obtained a high reputation by his compositions. He declared both at Athens and Rome, in which last named city he died at an advanced age, he seems to have been a great traveller, and besides his work on Greece that is extant, he composed descriptions of Syria and Phœnicia. The "Description of Greece" is highly valuable to the antiquary, and contains much information no where else he can meet with. It is a kind of itinerary through Greece, in ten books, in which the author notes every thing remarkable that fell under his observation, such as temples, theatres, fountains, statues, paintings, public monuments of all kinds, the feites and dimensions of ruined cities, and the scenes of important transactions. In some parts he gives historical details, and in those his style, which is frequently negligent, rises to a degree of dignity. His work abounds with fabulous narrations, but what he himself saw, there is no reason to suppose he misrepresented. His work was first published in 1516, at the press of Aldus. The best edition has been reckoned that of Kuhnbus, Greek and Latin, 1666, but others give the preference to the modern one of J. F. Facius, Litp. 1794-7, in four volumes, 8vo. There is a French translation in high estimation, by the abbé Gedoy. Mon.-

PAUSARY, PAUSARIUS, in ancient Rome, an officer who, in the solemn pomp or procession of the goddess Isis, directed the steps, or palæs.

In these ceremonies, there were frequent stands at places, prepared for the purpose, wherein the statues of Isis and Anubis were set down; much after the manner of resting-places in the procession of the holy sacrifice in the Romish church.

These stands were called manfones: the regulation of which was the office of these pausaries.

From an inscription quoted by Salmaius it appears, that the Romans had a kind of college or corporation of pausaries.

PAUSARIES, PAUSARIUS, was also a name given to an officer in the Roman galley, who gave the signal to the rowers, and marked the times and pæules: to the end they might act in concert, and row all together.

This was always done with a musical instrument. Hyginus says, that, in the ship Argo, Orpheus did the office with his lyre.

PAUSE,
PAUSE.

A pause, a stop or cessation of speaking, singing, playing, or the like.

The word is formed from the Latin *pause*, which we find used in Lucretius and Plautus in the same sense.

The use of pausing in grammar is, to make the proper pauses in certain places. See *Point* and *Punctuation*.

The use of these pauses is equally necessary to the speaker and to the hearer: to the speaker, that he may take breath, without which he cannot proceed far in his delivery, and that he may relieve the organs of speech by these temporary rests, which otherwise would be soon tired by continued and uninterrupted action; to the hearer, that the ear also may be relieved from the fatigue which it would otherwise endure from a contiguity of sound, and that the understanding may have sufficient time to mark the distinction of sentences, and their several members.

Pauses in common discourse, and in most compositions in prose, have, besides the duration, marks of a kinder sort annexed to them to point out their nature; and these are certain notes of the voice, which declare of what kind the pauses are, at the instant they are made; and inform the mind what it is to expect from them; whether the sense is still to be continued in the same sentence; whether the preceding one is to be the last member of the sentence; or whether the sentence is closed, and a new one is to begin. By means of these notes or tones, the speaker may proportion his pauses to the importance of the thought, and not merely to the grammatical structure of words in sentences. A pause, or sentiment of peculiar moment, may be preceded or closed by a longer pause than usual: a pause may be also made before some very emphatical word, but this is a liberty that should be used with great caution. An ingenious writer on this subject observes, that pauses in general depend upon emphasis: words are sufficiently distinguished from each other by accent; but to point out their meaning, when ranged in sentences, emphases and pauses are necessary. Accent, says this writer, is the link which connects syllables together, and forms them into words; emphasis is the link which connects words together, and forms them into members of sentences; but that there may be no mistake to which emphasis the words belong, at the end of every such member of a sentence there ought to be a perceptible pause. Shedd's *Lectures*, p. 75, &c. See *Comma*, *Colon*, *Points*, &c.

Pauses are commonly distinguished into those that are emphatical and those that mark the division of sentences. An emphatical pause is made, after something has been said of peculiar moment, and on which we wish to fix the hearer's attention. Sometimes such a thing is introduced with a pause of this nature. Such pauses have the effect of a strong emphasis, and are subject to the same rules, especially to the caution of not repeating them too frequently: for as they excite uncommon attention, and of course raise expectation, they will occasion disappointment and disgust, if the importance of the matter be not fully answerable to such expectation. But the most frequent and the principal use of pause is to mark the divisions of the sentence, and, as we have already said, to allow the speaker to draw his breath. The proper and graceful adjustment of such pauses is one of the most nice and difficult articles in delivery. The speaker, in order to avoid mangling his sentences, and totally losing the force of the emphasis, should be careful to provide a full supply of breath for what he is to utter. It is a great mistake, says Dr. Blair, to imagine that the breath must be drawn only at the end of a period, when the voice is allowed a fall. It may safely be gathered at the intervals of the period, when the voice is only suspended for a moment; and, by this management, we may have always a sufficient stock for carrying on the longest sentences, without improper interruptions. If any one, as the same ingenious author observes, shall have formed to himself a certain melody or tune, which requires rolls and pauses of its own, distinct from those of the sen- tence, he has undoubtedly contracted bad word habits into which a public speaker can fall.

It is the sentence which should always rule the pauses of the voice; for whenever there is any sensible suspension of the voice, the hearer is always led to expect something corresponding in the meaning. Pauses, in public discourse, must be formed on the manner in which we utter ourselves in ordinary, sensible conversation; and not upon the fluff artificial manner, which we acquire from reading books according to the common punctuation, which is often arbitrary, capricious, and false, and dictates an uniformity of tone in the pauses, that is extremely disagreeable. In order to render pauses graceful and expressive, they must not only be made in the right place, but also be accompanied with a proper tone of voice, by which the nature of these pauses is intimated, much more than by the length of them, which can never be exactly measured. Sometimes it is only a slight and simple suspension of voice that is proper; sometimes a degree of cadence in the voice is required; and sometimes that peculiar tone and cadence, which denote the sentence finished. In all these cases, we are to regulate ourselves by attending to the manner in which Nature teaches us to speak, when engaged in real and earnest discourse with others.

In reading or reciting verse, there is a peculiar difficulty in making the pauses justly. The difficulty arises from the melody of verse, which dictates to the ear pauses or rests of its own; and to adjust and compound the pause properly with the pauses of the sentence, so as neither to hurt the ear nor offend the understanding, is so very nice a matter, that it is no wonder we seldom meet with good readers of poetry. There are two kinds of pauses that belong to the music of verse: one is the pause at the end of the line; and the other, the caesural pause in the middle of it. With regard to the pause at the end of the line, which marks the strain or verse to be finished, rhyme renders this always sensible, and in some measure compels us to observe it in our pronunciation. In blank verse, where a greater liberty is allowed of running the lines into one another, sometimes without any suspension in the en- tle, it has been questioned, whether, in reading such verse, we should consider the pause at the close of the line. On the stage, where the appearance of speaking in verse should always be avoided, there can be no doubt, in the opinion of Dr. Blair, that the close of such lines as make no pause in the sentence should not be rendered perceptible to the ear. But on other occasions, this would be improper: for what is the use of melody, or for what end has the poet composed in verse, if, in reading his lines, we suppress his numbers; and degrade them by our pronunciation, into mere prose? We ought, therefore, certainly to read blank verse so as to make every line sensible to the ear. At the same time, in doing so, every appearance of sing-song and tone must be carefully avoided. The close of the line, where it makes no pause in the meaning, ought to be marked not by such a tone as is used in finishing a sentence; but without either setting the voice fall, or elevating it, it should be marked only by such a slight suspension of sound, as may distinguish the pause from one line to another, without injuring the meaning.

The other kind of musical pause is that which falls somewhere about the middle of the verse, and divides it into two hemistichs; a pause not so great as that which belongs to the
the close of the line, but still sensible to an ordinary ear. This, which is called the caesural pause, falls uniformly, in the French laconic verse, on the middle of the line. In the English, it may fall after the fourth, fifth, sixth, or seventh syllables in the line, and no other. Where the verse is so constructed, that this caesural pause coincides with the flight of the pause or division in the sense, the line can be read easily; as in the two first verses of Mr. Pope’s Mezzé :

"Ye nymphs of Solyma! begin the song; To heavenly themes, sublimer strains belong."

But if it shall happen that words, which have such a brief and intimate connection, as not to bear even a momentary separation, are divided from one another by this caesural pause, we then feel a sort of struggle between the sense and the sound, which renders it difficult to read such lines gracefully. The rule of proper pronunciation, in such cases, is to regard only the pause which the sense forms, and to read the line accordingly. The neglect of the caesural pause may make the line sound somewhat unharmoniously; but the effect would be much worse, if the sense were sacrificed to the sound. For instance, in the following line of Milton:

"What in me is dark, Illuminate; what is low, raise and support..."

The sense clearly dictates the pause after "illumine," at the end of the third syllable, which, in reading, ought to be made accordingly; though, if the melody only were to be regarded, "illumine" should be connected with what follows, and the pause not made till the fourth or fifth syllable. So, in the following line of Mr. Pope’s (Epistle to Arbuthnot):

"I fit, with sad civility I read."

The ear plainly points out the caesural pause as falling after "sad," the fourth syllable. But it would be very bad reading to make any pause there, so as to separate "sad" and "civility." The sense admits of no other pause than after the second syllable "fit," which, therefore, must be the only pause made in the reading.

It is a distinguishing advantage of our English verse, that it allows the pause to be varied through four different syllables in the line; for as the pause is placed after one or other of these syllables, the melody of the verse is much changed, its air and cadence are diversified. By these means, uncommon richness and variety are added to English verification. When the pause falls earliest, that is, after the fourth syllable, the briskest melody is thereby formed, and the most spirited air given to the line. In the following lines of the Rape of the Lock, Mr. Pope has, with exquisite propriety, fitted the construction of the verse to the subject:

"On her white breast | a sparkling crost the wore, Which Jewels might kifs | and infidels adore; Her lively locks | a sprightly mind diffufe, Quick as her eyes | and as unfixed thofe. Favours to none | to all the fames extends, Oft the rejets | but never once offends."

Where the pause falls after the fifth syllable, which divides the line into two equal portions, the melody is sensibly altered. The verse loses that brisk and sprightly air, which it had with the former pause, and becomes more smooth, gentle, and flowing.

"Eternal sunshine | of the spotlesfs mind, Each prayer accepted | and each with refign’d."
Mantua me genuit. Calabri rapuere, tenet nunc Parthenope, cecini paeuna, rura, duces.

An Italian author, supposed to be Pietro de' Stefano, affirms us that he himself had seen, about the year 1526, the urn supposed to contain the poet's ashes, standing in the middle of the sepulchre, supported by nine little marble pillars, with the inscription just quoted on the frieze. He adds, that Robert of Anjou, apprehensive lest such a precious relic should be carried off or destroyed during the wars then raging in the kingdom, took the urn and pillars from the tomb, and deposited them in the Castel Nuovo. This extreme precaution eventually occasioned the loss which it was meant to prevent: for notwithstanding the most laborious search and frequent inquiries made by the orders of Alphonso of Aragon, they were never more discovered. Some, indeed, have alleged, that the tomb just mentioned is not the sepulchre of Virgil. Among these we may reckon Clavierius and Addison. The reader will learn with regret that Virgil's tomb, consecrated as it ought to have been to genius and meditation, is sometimes converted into the retreat of afilains, or the lurking-place of Sibirri. Few places, however, are in themselves more picturesque, and from the recollection inseparably interwoven with it, no spot is more interesting than the tomb of Virgil. The whole hulk of Paflilippo is covered with country seats and gardens, for summer resort, being protected from the hot feet and well. In the middle of the passage is a church or chapel; but the dust raised by the horses and carriages is very offensive.

PAUSUS, a word used by the old physicians for a remission in acute diseases.

PAUSUS, in Entomology, a genus of insects of the order Coleoptera. The generic character is as follows; antennae two-jointed, the upper joint very large, inflected, hooked, pedicellate; head pointing forwards, with a convex jugular triangle; thorax narrow, unequal, scutellate; shells flexile, deflected, truncate; fore-feet placed at the fore-part of the breast, thighs with minute appendages, the tarsi four-jointed. Five species are enumerated in Gmelin's edition of Linnaeus, of which the first and second are fully described in the 4th volume of the Transactions of the Linnaean Society. This genus was not known when the 12th edition of the Systema Naturae first appeared; and it obtained its present rank in 1775, owing to a dissertation published by Linnaeus at Uppsal. At this period one species only was mentioned. The etymology of the generic term is thought to be from the Greek παυεινα, signifying a paufe, cessation, or rest, because Linnaeus, now old and infirm, and sinking under the weight of age and infirmity, saw no probability of continuing any longer his career of glory. He might therefore be supposed to say, "hic meta laborum," as it really proved, at least with regard to insects, Pausus being the last he ever described. Such is the account given by Dr. Azzelinus in the work already referred to.

Species.

MICROCEPHALUS. The head of the species is unarm'd; the club is an oblong; shells as long as the body, not punctured, thanks linear. This rare insect is a native of Sierra Leonza, the Banana, and neighbouring islands. The body is of a dark cheifiu-brown; the head is, as its name denotes, uncommonly small; the shield is two-parted; jugular triangle minute; pivots of the antenna black, upper joint of the club much larger than the head; the thorax broader than the head, and the wings are footy.

SPHEROCERUS. Head horned, club globular; shells shorter than the abdomen, punctured; thanks dilated at the tip. This is found at Sierra Leonza; the body is polished, cheinfu, a little narrower than the last; the horn between the eyes is straight, conical, tip with a tuft of erathargious hairs; the eyes are larger; the thorax is of the same breadth as the head, the wings are of a shining changeable violet. We shall give part of Dr. Azzelinus' description of this insect in his own words: "The body is..." says he, "a house building for the governor, on an eminence called Thornton Hill, at the south end of Free-town, in Sierra Leonza; and in the beginning of the year 1795, several apartments having been got ready, so as to be habitable, one of them was allotted to me, and I removed into it in the end of the month of January. I had not resided there many days, when one evening, having just lighted my candle and begun to write, I observed something dropping down from the ceiling before me upon the table; which from its singular appearance attracted my attention. It remained for a little while quite immovable, as if stunned or frightened, but began very slowly and stealthily. I then caught it, and from the remembrance I had of the Linnaean species, I directly took it for a non-descript of this genus. Some days after, coming into my room from supper, with a light in my hand, and having put it upon the table, there instantly fell another down from the ceiling. The third I was favoured with by the then governor Mr. Dawes, who informed me that it had dropped down before him on the table, just when he had entered his room, and was going to write. The other three, which I afterwards collected, were also got upon similar occasions, and from thence I thought I had some reason to conclude that it was a nocturnal animal; that it becomes numbered by candle-light; that it lives in wood, and prefers newly-built houses. After the end of February I never saw any more. The last which I caught I put into a box, and left confined there for a day or two. One evening going to look at it, and happening to stand between the light and the box, so that my shadow fell upon the insect, I observed, to my great astonishment, the globes of the antenna like two lanterns, spreading a dim phosphoric light. This singular phenomenon raised my curiosity, and, after having examined it several times that night, I resolved to repeat my observations the following day. But the animal, being exhausted, died before morning, and the light disappeared."
ferruginous, supposed to be the Cerocoma ruficollis of Fabri-
ous.

PAUTE, in Geography, a town of South America, in
the audience of Quito; 23 miles E. of Cuenca.

PAUTE, or St. Tago, a river of Peru, which runs into the
Maranon; five miles W. of St. Francisco de Borja.

PAUTO, a town of New Granada; 25 miles E. of Tunja.

PAUTRE, ANTOINE le, in Biography, an eminent
French architect, was born at Paris in 1614. He distin-
guished himself by his taste in the decoration of buildings.
Several edifices from his designs were erected in the capital
and its neighbourhood, of which the most noted were the
wings of St. Cloud; the church of the nunnery of Port-
Royal, and the hotels of Gevres and Beauvais. He was ap-
pointed architect to the king's brother, and afterwards to
the king himself. He was a member of the Academy of
Architecture from its first institution, and published a work
on that art, entitled "Les Œuvres d'Architecture d'Antoine
le Pautre," of which the first edition appeared in 1632. He
died in 1691. He had a brother an eminent engraver, who
died in 1682; and his son, Peter, who was born in 1660,
was eminent as a sculptor. He studied fourteen years at
Rome, and on his return was employed in several public
works, of which the most celebrated is a group of Eneas
bearing Archilochos on his shoulders, and holding Acanthus
in his hand, which was placed in the garden of the Thuilleries.
He died in 1744, at the age of eighty-four.

PAUTUCKE, in Geography, a town of America, in the
state of Massachusetts; 33 miles S.S.W. of Boston.

PAUW, N. de, in Biography, a German canon, distin-
guished himself by his philosophical writings, of which the
principal were "Recherches Philosophiques sur les Ameri-
cains, les Egyptiens, et les Chinois," in two vols. 1758;
1787, reprinted at Paris in seven vols. Svo. "In these
works," says his biographer, "there are much learning and
ingenuity, but joined with a bold spirit of conjecture, and a
disposition to contradict all received notions." They were
very popular at the time of their appearance, but have
lost a great part of their original reputation. The author
was in high estimation with Frederick the Great, as one of
the free speculators of the time, and was, of course, ob-
noxious to the clergy. His private character was excellent.
He died at Xanten, near Aix-la-Chapelle, in 1799; a nephew
of his was Anacharis Cloots, who was famous at the com-
 mencement of the French revolution.

PAUXI, in Ornithology, the name of an American bird
described by Nieremberg. See Crax Pauxi.

PAUXIS, in Geography, a fortress of Erafil, in the go-
 vernment of Parr, on the N. side of the river Amazon.
S. lat. 1° 56'. W. long. 58° 10'.

PAUZEN, a town of Bohemia, in the circle of Boles-
lav; 10 miles E. of Jung Buntzel.

PAUZK, PAUTZ, or PAZEG, a town of Prussian Po-
 merania; 24 miles N.E. of Dantziick. N. lat. 54° 30';
E. long. 18° 3'.

PAX, in the Manage. A horse is said to paw the ground
when his leg being either tired or painful, he does not
rest it upon the ground, and fears to hurt himself as he
walks.

Paw Patté, in Heraldry, the fore-foot of a heaft cut off
short. If the whole leg be cut off, it is called gambé. Lion's
paws are much used in armoury.

PAWAH, in Geography, a town of Hindoostan, in
Bahar; 40 miles S.W. of Bahar.

PAWARAH, a town of Hindoostan; 43 miles N.W.
of Benares.

PAWEN, a small island in the bay of Guung Telul,
on the E. coast of the island of Celebes. S. lat. ° 18'.
E. long. 122° 2'.

PAWING, or POGUM, a town of East Friesland, near
the Ems; 32 miles S. of Emden.

PAWLE, in Geog. See PAX.

PAWLET, in Geography, a township of America, in
Rutland county, Vermont, containing 1936 inhabitants.
It is watered by Pawlet river, which joins Wood creek,
and the confluent stream falls into South bay at Fiddler's
Elbow.

PAWLOCZ, a town of Russian Poland, in the palat-
inate of Kiev; 60 miles S.W. of Kiev.

PAWN, PIGNUS, a pledge or gage for surety of pay-
ment of money lent. It is said to be derived, a pignus,
quia res que pignori dantur, pignus vel mans traduntur. (Lit.
Dict.) The party that pawns goods hath a general property
in them; they cannot be forfeited by the party that hath
them in pawn, for any offence of his, nor be taken in ex-
ecution for his debt; neither may they otherwise be put in
execution till he debt for which they are pawned is satisfied.

If the pawn is laid up, and the pawnee robbed, he is not
answerable; though if the pawnee use the thing, as a jewel,
watch, &c. that will not be the worse for wearing, which
he might have sold at his peril; and if he is robbed, he is answer-
able to the owner, as the using occasioned the loss, &c.
Ibid. See BAILMENT.

If the pawn is of such a nature that the keeping is a
charge to the pawnee, as a cow, or a horse, &c. he may
milk the one, and ride the other, and this shall go in recomp-
ence for his keeping. Ibid.

Things which will grow the worse by using, as apparel,
&c. he may not use. If a pawnbroker receives plate or
jewels, as a pledge or security, for the repayment of money
lent thereon at a day certain, he has them upon an express
contract or condition, to restore them, if the pledger per-
forms his part by redeeming them in due time (Cro. Jac.
245. Elv 178); for the due execution of which contract
many useful regulations are made by statute 30 Geo. II. c. 24.
See Pawn-Brokers.

PAWN, among Miners, is a pledge of money put into the
bar-maister's hand, at the time when the plaintiff caues the
bar-maister to arrest the mine.

PAWN-Brokers. See Pawn-Brokers, and 39 & 40
Geo. III. c. 99.

PAWNGAGE. See PANNAGE.

PAWNEES, in Geography, the name of an Indian na-
tion, inhabiting a part of Louisiana, confining of three
villages. The number of warriors is 1995, of women 2170,
and of children 2660, according to the statement made in
the "Exploratory Travels in North America."

PAWNGAW, a town of Hindoostan, in Dowlatabad;
20 miles E. of Perinda.

PAWTUCKET FALLS, a cataract of America, in Mer-
rineck river, in the township of Dracut.

PAWTUXET, a village of America, in the township of
Cranston, Providence county, Rhode island.

PAX, a small metallic plate, commonly of silver, with
the representation of the crucifixion engraved upon it, which
was killed by the priest at a certain part of the mafs, he
repeating at the same time Pax tecum, Peace be to you, and
afterwards by the afflictants in token of fraternal charity.

PAX DIJ. See Peace of God.

PAX, Ezelin. See SACRANTRY.
**PAX Regii. See Peace of the King.**

Longe debet esse pax regis a parte sua, ubi residentes fu-erit, quatuor partibus loci illius, hoc et quatuor milliariae & tres quarentenae, & novem aera latitudine, & novem pedes, & novem palmes, & novem graua hordei, &c." Leg. Edw. Conf.ell.

Ad Pacem reiure, to restore to the peace, is to reverse an outlawry: whereby a person is restored to the benefit of the king's peace.

Rex potest dare quod faunm fii, hoc etf, pacem fuan quam utaglatis amittit." Bracton, lib. iii.

**PAXAROS, or Bird Island,** in Geography, a small island near the S. coast of Cuba. N. lat. 19° 56'. W. long. 78° 24'.—Also, an island on the coast of California, in the North Pacific ocean. N. lat. 30° 18'. W. long. 120° 45'.—Also, small islands or rocks in the Pacific ocean, near the coast of Chili. S. lat. 25° 40'.

**PAXIMADES,** an island in the Mediterranean, near the S. coast of the island of Candia. N. lat. 34° 54'. E. long. 24° 43'.

**PAXTON, Upper, Lower, and Middle,** three townships in Dauphin county, Pennsylvania: the first contains 2374, the second 727, and the third, including Swatara, 3208 inhabitants. —Also, a township of Worcester county, Massachusett, 8 miles W. of Worcester, incorporated in 1767, and containing 582 inhabitants.

**PAY of the Army and Navy,** is the flipend or salary allowed for each individual serving in the army or navy; for which we refer the reader to the Registors published annually, and in almost every body's hands.

In our ancient armies, there were, at all times, both before and after the conquest, besides the feudal tenants, flipendiary or mercenary soldiers, natives as well as foreigners. But our earliest information respecting military pay reaches no higher than the reign of king Henry II. Mr. Grofe, in his "Military Antiquities," vol. i. has given an account of the amount of the pay of officers and soldiers at different periods; and from his account it appears, that the pay of the troops, as it was established at the Revolution, underwent very little change till after the commencement of the present war in 1793. But in the course of the present war, the pay and allowance of the officers and soldiers have received considerable augmentation. In 1795 his majesty issued a warrant for granting an addition of 21d. per diem to the subsistence of the non-commissoned officers and men; and to this was afterwards added 3d. per diem, making the pay of the private soldier 1/. per diem. In 1797, the flipendages from all the officers' pay called arrears, were abolished; besides which 12d. per diem was added to the subsistence of each subaltern officer. The pay of the surgeon and his mate (now essential,) was also raised, the former to 10s. and the latter to 3s. a day. In our ancient armies there were, in addition to the regular flipend of the troops, certain allowances, called "regards" (rewards, Duncarke.) Such there are, though under different appellations, at present. Among these we may notice the non-effective and contingent allowances to the captains of troops and companies. Formerly the captains received and kept the subsistence of the non-effective, or men wanting to complete their companies; but this becoming an enormous abuse, has been since restricted to 20l. for each captain per annum. The contingent allowance is proportioned to the strength of the company. There are besides other allowances to officers in general, such as bat, baggage, and forage money in camp, and lodging money in garrison, when there are no barracks. These allowances vary according to circumstances. For particulars, see Grofe, ubi supra.

**PAX Regii. See Peace of the King.**

Full Pay denotes the pecuniary allowance which is made to officers and non-commissoned officers, without any deduction whatsoever. Since the abolition of arrears in 1797, commissioned and warrant officers, &c. (those belonging to the guards excepted,) receive their full pay, or daily subsistence. The private soldiers are subject to temporary deductions, for the purpose of appropriating part of their pay and allowances to the expense of their meffes, including vegetables, &c. and to a fopage not exceeding 1s. 6d. per week, for necessaries, which fopage is to be accounted for every month; and the remainder being 1s. 6d. must be paid weekly to each soldier, subject to the acknowledged deduction, for washing, and for articles to clean his clothing and appointments. The full pay of the British army is given in advance on the 25th of every month, and accounted for to government by the several district and regimental pay-masters, through army agents appointed for that purpose. Non-commissoned officers and private soldiers, serving as marines, are not liable to any deduction whatever from their full pay, on account of provisions. Although the army is now paid its full pay, in consequence of the abolition of the distinction between subsistence and arrears, that pay is nevertheless subject to the usual deductions on account of poundage, hospital, and agency.

**Pay.** Pay is a compensation, or retaining fee, given to officers who have retired from the service through age, inability, &c. or who have been placed upon that list in consequence of a general reduction of the force, or a partial drafting, &c. of the particular corps to which they belonged. The half-pay becomes due on the 25th of June, and on the 25th of December in each year, but it is seldom inducted until three months after the expiration of each of these periods. The only deduction from the half-pay is the poundage, 2d. per cent. The first time this allowance occurs, is in a vote of the house of commons, January 18, 1697. As the officer when disbanded is rewarded with half-pay, to the private soldier in the cavalry has his horfe, and an allowance for his sword given him, with fourteen days' pay to carry him home to any part of England; to any part of Scotland the allowance is twenty-one days' pay; and to any part of Ireland twenty-eight days' subsistence. The infantry likewise have the same allowance of pay for subsistence.

**Pay-Master,** is the person inwrought with the money, and that has the charge of paying it to the regiment. The payment of the land-forces is under the direction of an office, the business of which is conducted by the pay-master general, his deputy, caisiers, clerks, &c. The payment of the navy is under the direction of the treasurer of the navy, a pay-master, and comptant, clerks, &c. There is also a pay-master of the penions, &c. a pay-master of the marines, &c district pay-master, &c. The army pay-office is at Whitehall: and the navy pay-office at Somerset-house.

**Pay-Bills.** Bills belonging to the military department, which are distinguished according to the nature of the service for which they are given. Every captain of a troop or company receives a regular weekly account from his sergeant, of money to be advanced for the effectives of such troop or company; and on the 24th day of each month he makes out a monthly one for the pay-master, who makes out a general abstraction for the agent. The pay-master general's estimate is likewise called the pay-bill.

**Pay-Lists, the monthly accounts which are transmitted by the several regimental and district pay-masters to their agents on the 25th of each month.**
PAY-Sargent. See SERJANT.

To PAY, in Sea Language, is to daub or anoint the surface of any body, in order to preserve it from the injuries of the water, weather, &c. Thus the bottom of a ship is paid with a composition of tallow, sulphur, resin, &c. The sides of a ship are usually paid with tar, turpentine, or resin, or with a composition of tar and oil, to which is sometimes added red ochre, &c. in order to protect the planks from being split by the fun or wind. The lower masts are, for the same reason, paid with the materials of the same sort, if we except those along which their respective fails are frequently hoisted and lowered; such are the masts of sloops and fchooners, which are always paid with tallow for this purpose: for the same reason, all top-masts and top-gallant-masts are also paid with hog's-hard, butter, or tallow. Falconer. See Ship and Wood.

PAYA, in Geography, a town of South America, in the province of Darien; 30 miles E. of St. Marie de Darien.

PAYEE, in Commerce, the person to whom a bill is made payable.

PAYERN, in Geography, a town of Switzerland, in the canton of Berne, formerly an imperial town, under the protection of the dukes of Savoy. It is governed by its own magistrates; 22 miles S.W. of Berne. N. lat. 46° 51'. E. long. 6° 44'.

PAYERSDORFF, a town of Germany, in the margraviate of Bayreuth, near which is a decayed castle; both which were taken by the Swedes under Gustavus Adolphus.

PAY-HO, or PEI-HO, a river of China, which rises in the north part of the province of Pe-tcheli, and runs into the gulf of Levao-tong. N. lat. 39° 3'.

PAY-HOU, a lake of China, in Pe-tcheli; 140 miles S. of Pe-king.

PAYAN, a town of Peru, in the diocese of Truxillo; 15 miles N. of Truxillo.

PAYING-OFF, in Sea Language, denotes the movement by which a ship's head falls to leeward of the point where it was previously directed; particularly when, by neglect of the helmsman, she had inclined to windward of her course, so as to make the head falls under the wind, and retard her velocity.

PAYING-OFF is likewise used to signify the payment of the ship's officers and crew, and the discharge of the ship from service, in order to be laid up at the moorings.

PAYING-Out, or Paying-away, is the act of slackening a cable, or other rope, so as to let it run out of the vesi for some particular purpose. See CABLE.

PAYMENT, the discharge of a debt, either by money truly told, or by bills of exchange, &c. See DEBT, &c.

PAYMENT, Prompt, a popular term in England and Amsterdam. It is when a debtor acquires what he owes, before the expiration of the term granted by the creditor. The ordinary discount for prompt payment on merchaizes, is one per cent.

PAYMENTS, Equation of. See EQUATION OF PAYMENTS.

PAYMOGO, in Geography, a town of Spain, in the province of Seville, on the frontier of Portugal; 35 miles N. of Ayamonte.

PAYNESVILLE, a town of America, in Trumbull county, state of Ohio, on lake Erie, near the mouth of Grand river; in 1802 it had about 150 inhabitants.

PAYO, St., a town of Portugal, in the province of Tras los Montes; 18 miles W. of Mirand-de-Duerco.

PAYRA, a town of South America, in the province of Quito; 12 miles N.W. of Macas.

PAYRAC, a town of France, in the department of the Lot, and chief place of a canton, in the district of Gourdon. The place contains 902, and the canton 1711 inhabitants, on a territory of 140 kilometres, in 12 communes.

Gen. Ch. Cal. Perianth inferior, of one leaf, cloven into five, roundish, acute segments. Cor. Petals five, oblong, narrow, erect, united together, so as to resemble a tube, their tops reflexed; one larger, emarginate, inserted into the disk beneath the germens. Stam. Filaments five, erect, inserted into the disk; anthers oblong, combined, two-celled. Pet. Ger. Strigata superior, placed on the disk; style elongated, stigma two-lobed. Peric. and Seeds unknown.

Ofb. Aublet remarks that he never saw the fruit of this plant in its perfect state, but from an imperfect one, which he cut in halves, it appeared to have two cells.

1. P. guianensis. Aubl. Guian. t. 99.—Native of woods in Guiana, about Sinemari, upwards of twenty miles from the sea. It flowers in October.—This is a shrub from twelve to fifteen feet in height, whose stem is upright and branched. Leaves alternate, falked, large, ovate, acute, smooth, entire. Stipulas two, short, acute, deciduous. Flowers fpioked, axillary, terminal, yellow, each furnished with three glands at its base.

PAYS, Rene Le, in Biography, a writer of celebrity, born at Nantes in 1636, was brought up to bisinesses, and obtained the post of director-general of the gabelle in Dauphiné and Provence. He was first known in the literary world in 1685, by a little production in verse and prose, entitled "Amitiés, Amours, et Amourettes," which was read with great avidity at Paris. It is said that in answer to some enquiries made by ladies as to his pernon, he addressed to the duches of Nemours a "Portrait" of himself, written in the same style. He professed to imitate Vouture, but was severely criticized by Boileau as a very inferior writer. Le Pays, however, instead of being offended with the fatigue, paid a visit to the poet, and obtained his friendship. He published letters, which prove that he had visited England and Holland. He was honored by the duke of Savoy with the knighthood of St. Michael, and was an associate of the academy of Arles. He died in 1690, at the age of fifty-four.

PAYTA, or PAITA, or St. Michel de Payta, in Geography, a town of Peru, in the diocese of Truxillo, founded by Francis Pizarro, in the year 1531. It is small, consisting of houses that are constructed of split canes and mud, covered with leaves, and one story high; the only exception being, that of the governor, which is built of stone. It has a parish-church and chapel, dedicated to our Lady of Mercy. The inhabitants are chiefly Spaniards, Mulattoes, and Metisios, who live chiefly by passengers going or returning from Panama to Lima, the number of whites being incon siderable; all of them confounding about one freight, and about 172 houses, and 35 or 40 families. The port, though little more than a bay, is esteemed the best on the coast, and affords a secure anchoring-place. This is the only place where ships from Acapulco, Sononate, Panama, &c. can touch in their passage to Callao. The voyage is long and tedious, on account of contrary winds, rains, and shifting

PAZARO, a cape of North America, on the W. side of the peninsula of California, near to the south end of it, in about N. lat. 24°, and W. long. 113°.

PAZMANI, Peter, in Biography, a celebrated cardinal, who flourished in the 17th century, was descended from a noble Transylvanian family. The time of his birth is not known, but he entered the order of Jesuits in the year 1587, and distinguished himself by the progres which he made in the different branches of literature, sacred and profane. In the year 1607, he was appointed professor of philosophy, and afterwards of divinity at the college of Graz, in Styria, in which he poltis he acquitted himself with universal satisfaction. He afterwards devoted himself to millions in different parts of the kingdom, and was thought to have laboured very successfully in opposing the progres of the reformed opinions. By his zeal he recommended himself to the emperor Mathias, and the principal Hungarian nobility, and was appointed to the archiepiscopate of Gran, or Strigonia, an office that he did honour to by the establishment of strict discipline, and correcting the relaxed manners of the Hungarian clergy. He founded colleges at Preßburg, Posen, and other places, for the encouragement of literature. In 1629 he was promoted to the high dignity of cardinal, by pope Urban VIII., at the solicitation of the emperor Ferdin-

Pez, a province and diocese of Peru, belonging however to the viceroyalty of Buenos Ayres. This diocese contains fix juridictions, viz. La Paz, Omaluyos, Pacajas, Lariacas, Chucuito, and Paucar-colla, which fee repectively. The juridiction of La Paz is of no great extent; and the city is almost the only place in it that is worthy of any notice. In the adjacent cordillera is a high mountain, called Illimani, which is supposed to contain immense riches; but its summit being perpetually covered with ice and snow, no mine has been opened in this mountain. This province was formerly known by the name of Chucymaypa, which in the

Paya, a town, in Botany, &c. See Lathyrus, Lotus, and Pisum.

Paea, in Agriculture, a sort of plant or pulse generally cultivated...
cultivated as a field crop. It is a sort of crop which is often supposed to be less advantageous to the farmer than several others; but in many situations and circumstances of land, it will be found highly beneficial to the cultivator, from its ameliorating and cleaning properties.

The species and varieties of peas are very numerous; but those employed in field culture are distinguished into two kinds, the early and late; the chief of the former of which are the early charlot, the golden harp, and the common white sorts; and of the latter the various kinds of grey peas, as the marlborough grey, the horn grey, and the purple grey; but the marlborough is the most commonly made use of by most farmers.

Soil.—Peas are a crop that are grown upon almost any sort of soil, but which answer best in those that are dry, and free from flagrant moisture, and which are in a good state of mellowness, and impregnated with calcareous materials. But "all the sorts of early peas should, according to Mr. Young, be cultivated on dry soils only. They will grow on mofl, and even wet ones; but the crop is seldom beneficial. Upon sands, dry sandy loams, gravels, and chalks, they succeed well. They are not, however, to be much recommended on land in tilt. Great success is rarely commanded, especially in a wet season, if they be not on a layer." 

It is a sort of crop cultivated after many different kinds, as almost all those of the grain description, as well as clover, fainfoil, and on old lays newly broken up from sward. But Mr. A. Young, has well remarked, that "a farmer dextrous of keeping his land always in good and clean order, should, in the arrangement of his crops, take great care not to be too free with wheat, barley, and oats, which are all exhausting plants. He should sow beans and peas enough, because they are ameliorating ones, and admit hand-hoeing, to kill the weeds. In those fields in which the common husbandmen sow oats or barley, after wheat, or after each other, let the good cultivator subtilitate pea or beans, or some other ameliorating crop, which will pay him better than white corn, under such circumstances, and at the same time keep his land clean. Pease may be sown, like black oats, on turf ploughed up before winter, and harrowed in." He further remarks, "on the culture of peas, that bad farmers are too apt to sow this pulse when the land will yield nothing else. They have a proverb among them, which signifies, that the seafon does as much for peas as good husbandry; and they from hence take care that good crops shall be owing to seafon alone. Hence arises the general idea of pea being the most uncertain crop of all others. This is owing to their being scarcely ever sown on land that is in good order. Let the good husbandman lay it down as a maxim, that he should sow no crop on land that is not in good order; not merely in respect of fine tillth at the time of sowing, but also of the soil's being in good heart, and clear of weeds. He would not, however, here be underfoot to rank all these crops together, because beans and pea will admit of cleaning while they grow. On that account, if a farmer comes to a field which his predecessor has filled with weeds, a horse-hoed crop of beans will be expedient, when a barley crop would be utterly improper, and, after land has yielded one crop of barley, certainly another should not be sown, but one of pulse substituted. If these ideas are well executed, the pea and beans, in every course, will find the land in heart enough for barley, the foil will always be clean, and the crop good. Peas, when managed in a spirited manner, will not have the reputation of being so very uncertain a crop, which character has, in some measure, been owing to ill conduct."

And the same writer thinks, that the following courses do well for them:

1. Turnips, Alfo, 1. Turnips,
2. Barley, 2. Barley,
3. Clover, 3. Seeds for two, three, or more years,
4. Peas and turnips, 4. Peas and turnips,
5. Barley, 5. Barley,
6. Carrots, 6. Beans,
7. Barley, 7. Clover,
8. Clover, 8. Wheat,

It is stated, that "there is a remarkable circumstance observed by that excellent husbandman, Mr. Overman of Norfolk, relative to peas, which should be in the mind of every farmer fond of a pea crop. It is, that they do not succeed well, if sown oftener than once in ten or eleven years; and he has heard it more generally observed by others, that peas should not be sown too often."

In regard to manuring for this crop, it is observed, that "it is the practice with some farmers to manure for them. But he must confess that he has been always too much against it, that he never did it himself, and therefore can only state his reasons for avoiding it. If land is in heart, and they are put in on a layer, they do not want manure. A very good crop may be gained without it. He has had five, and even five and a half quarters an acre, without any manure applied for this crop. Dung makes them run to long hair, and that is not favourable for podding productively. Dung encourages weeds; and pea, except in the early stage of their growth, do not admit of such hoeing as a farmer would wish to give. Beans cannot have too much dung, but with pea the cafe is different. There are few situations in which the farmer can have such a command of manure to give him a sufficiency. It is, therefore, of much consequence to him, never to spread a load but where it will be sure to answer well. Every man complains of a want of dung; how very careful, therefore, ought all to be, to give it to the crops that will pay bet for the expense." But notwithstanding these useful remarks, manure may in many cafes be employed with advantage for crops of this kind, and in some they cannot probably be grown without it to advantage.

Time of Sowing, and Quantity of Seed.—The time of putting this sort of crops into the ground differs considerably, according to the intentions of the cultivator. When they are grown for podding early for sale green, they should be sown at different times, from January to the end of March, beginning with the driest and most reduced sorts of land. And in this intention, in some southern counties, they are put in in the autumn. But for the general crops, from February to April, as soon as the lands can be brought into proper order, is the proper seafon; the grey sorts being employed in the early fowings, and the white sorts in the later. Mr. Young says, that where the crops cannot be put in in February, they should always be completed in the following month. And that, in sowing on layers, that "the white boiling pea, of many sorts, and under various names, is more tender than the greys, and various kinds of hog peas; but he has many times put them into the ground in February, and though very smart frosts followed, they received no injury. He has uniformly found, that the earlier they were sown the better. There is also a particular motive for being as early as possible; that is, to get them
on in one for turnips. This is most profitable husbandry, and should never be neglected. If they are sown in this month, and a right spot chosen, they will be off the land in June, so that turnips may follow at the common time of fowing that crop.

It is evident that the quantity of feed must be different in different cases and circumstances, and according to the time and manner in which the crop is put into the ground; but in general, it may be from two and a half to three bushels, the early sowings having the largest proportion of feed. In planting every flag, Mr. Young says, two bushels and a half is the usual proportion; but when drilled at greater distances, six or seven pecks will answer in most cases.

Methods of Sowing.—There are different practices pursued in putting this sort of crop into the soil: Mr. Young remarks, that in common management they are sometimes ploughed, and at others harrowed in, circumstances which often make a difference in the crops, as where the land is apt to bind with rain, and the ploughs are ploughed in, they sometimes do not come up at all, not having strength to pierce the plattered surface. But this is an evil that attends only the very binding soils with late fowing. On the other hand, when the feed is only harrowed in, where the land is not very well guarded, much devolution will be committed by the pigeons, and other birds, for which allowances should be made. It is supposed, that where the lands harrow well, all should be harrowed in, except on the lightest lands. But on these, such as loose sands, and other very porous and dry soils, it is a preferable practice to plough them in, as they have a greater depth, and are of course less liable to burn in hot summers.

It has been remarked, that it is usual, in these cases, in many districts, to put the feed into the ground in the broad-cast method; but the drill, or row system, is most to be preferred, as being more regular, having considerably in the proportion of feed, and admitting of cultivation afterwards with more ease and advantage. And that different implements have been contrived for this use, but the most convenient is probably a small light form of wheel-plough, to the body of which a fort of feed-box is attached, through the bottom of which the axis of the plough passes, by which the fowling is regulated, and which is pulled up and prevented from letting the pease be deposited at the ends of the ridges, or other places, as in turning, by a firing attached to the handle. It may be conveniently employed with one or two horses. In regard to the rows, it is observed, that the proper distance of drilling this kind of crop is mostly about twelve or sixteen inches for hand-hoeing; but where the horse-hoe is employed, from two to three feet; and the depth to which the feed is deposited from two to three inches. And that, in some districts, the feed is put by the hand into drills mostly made crossways of the ridges, but occasionally in the direction of them at the distance of about fifteen inches from each other, and afterwards covered in by means of hoes. In some instances, also, a bush-harrow is drawn over the surface, by which the land is rendered smooth and even. But where this sort of crop is cultivated on a lay preparation, the belt method is probably to dibble the feed in. This is the practice constantly followed by the belt cultivators in some districts in Middlesex. Mr. Young, however, advises, that broad-cast pease should be utterly rejected in every case. The only question that can arise in their culture, is between drilling and dibbling. If the former is determined on, the land should have been ploughed late in autumn, with Ducket’s skin couler, into lands adapted to the drill-machine and scarifiers. The surface being then worked shallow, in this month drilling should directly follow. If dibbling is determined on, the land should not be ploughed till the time of planting, and a heavy roller follow the plough. On lighter soils, if the crop has worked the surface, after ploughing, the ground will be in too friable a state, the holes will moulder in, and the feed will be laid too shallow. Dibbling pease on a layer cannot be too much commended. It is an excellent practice in moist cases.

But in respect to the rows, the practice of various farmers differs exceedingly. Equi-distant rows, from nine to eighteen inches, are common. He has seen them at two feet, and even three. In dibbling, it is common in Norfolk and Suffolk to put in three rows, on every flag of nine or ten inches breadth; some farmers one row on such a furrow: and he has known very good crops in most of these distances. If horse-hoeing is intended, double rows at nine inches, with intervals of eighteen, do well: but the greatest crops have been from planting every flag.

It has been suggested, that, though the practice of keeping this sort of feed is seldom had recourse to by the cultivators of pease, it is probable that the later town crops may be greatly benefited by it, as the vegetation of the plants may be rendered more quick, regular, and uniform. And in the Maffons Rutiliques, the same practice is approved of, not only to separate the bad and faulty, but to enable the crop to rise sooner.

It is the custom in Hertfordshire, and some other districts, to sow beans, or even oats, sometimes with the pease, with a view of keeping them up. These mixtures should, however, never be adopted, as the different crops, from their being of an unequal growth, must constantly be liable to injure each other while they are growing on the land.

Culture while Growing.—There can be no doubt but that the use of the hoe in furring the intervals, and earthing up the young plants where the crop has been put in in rows by the drill or dibble, is of essential advantage in promoting their growth, and protecting them from the injuries of the fowls. Where the method of hand-culture prevails, it is the general custom to have recourse to two hoeings; the first, when the plants are about two or three inches in height, and a semi-jut before the period in which they come into blossom. In this way the vigorous vegetation of the young crop is secured, and a fresh supply of nourishment afforded for the setting of the pods and the filling of the pease. At the last of these operations, the rows should be laid down, and the earth well placed up to them, the weeds being previously extirpated by hand-labour. In some parts of Kent, where this fort of crop is much grown, it is the practice, when the distance of the rows is sufficiently great, to prevent the vegetation of weeds, and forward the growth of the pea crops, by occasionally hedge-hoeing, and the use of the break-arrow, the mould being laid up to the roots of the plants at the last operation, by fixing a piece of wood to the arrow. This should, however, only be laid up on one side, the pease being always placed up to that which is the molt fully exposed to the effects of the sun. The hedge-hoeing is performed at the rate of from two to three tillings the acre, according to the nature of the land. These sorts of crops can never be kept too clean, therefore the greatest attention should be paid to them.

It has been stated that there are many inducements to the cultivation of this crop, on suitable soils in the vicinity of large towns, where the demand for green pease is considerable; such as the ready supply of money, that is thus provided for the other expensive operations during the sum-
In the county of Middlesex, Mr. Middleton has flated the expences and produce in cultivating a field of fix acres in the year 1796 to stand as below, though it was not remarkable for more than a common crop.

The advantage in this case ten pounds.

And in the latter crops, that stand to ripen, it is supposed by some to be from three and a half to four quarters the acre; others, however, as Mr. Donaldson, imagine the average of any two crops together not more than about twelve bushels. And that on the whole, if the value of the produce be merely attended to, it may be considered as a less profitable crop than most others. But as a means of ameliorating and improving the soil, at the same time, it is however to be esteemed as of great value.

The greatest danger to the early pea crops is to be apprehended, when the weather during the more early spring months is hot and rainy in the day-time, attended with sharp frosts in the night, as in this way great mischief is often done; the crops becoming attacked with the mildew, and not ripening in a proper manner. And, while the pease are protruding in their growth, and fill more particularly at the periods, when they come into blossom and begin to set their pods, it is of great importance to have rather moist weather, as by that means the vegetation of the crop is promoted in a more perfect manner, and there is a greater chance of the peas being well podded. The chief signs of the healthy and vigorous vegetation of pea crops are those of their leaves posseffing a fine bloom of a bluish call, and having the outermost large leaves of the blossoms extending backwards in some degree.

As the pea crops become ripe, they wither and turn brown in the haulm or straw, and the pods begin to open. In this state they should be cut as soon as possible, in order that there may be the leaff losw sustained by their shedding. In the late or general crops, after they are reaped, or rather cut up by means of a hook, it is the usual practice to put them up into small heaps, termed wads, which are formed by letting small parcels against each other, in order that they may be more perfectly dried both in the feed and ilem, and be kept from being injured by the moisture of the ground. But in the early crops the haulm is hooked up into loose open heaps, which, as soon as they are perfectly dry, are removed from the ground and put into stacks for the purpose of being converted to the food of animals, on which
which they are said to thrive nearly as well as on hay. When intended for horses, the best method would seem to be that of having them cut into chaff and mixed with their other food. Mr. Young affirms, that forward white peas will be fit to cut early in July; if the crop is very great, they must be hooked; but if small, or only middling, mowing will be sufficient. The stalks and leaves of peas being very succulent, they should be taken good care of in wet weather: the tufts, called wads or heaps, should be turned, or they will fall but indifferently, as the bright neurop and plumpets of the grain are considered at market more than with hogs-powf. The straw also, if well harveifed, is very good fodder for all sorts of cattle and for fheep; but if it receives much wet, or if the beans are not turned, it can be used only to litter the farm-yard with.

It is the practice in some districts to remove the halm, as soon as it has been cut up by hooks, constructed with sharp edges for the purpose, to every fifth ridge, or even into an adjoining grass field, in order that it may be the better cured for use as cattle food, and at the same time allow of the land being immediately prepared for the succeeding crop. What are usually termed winter peas, or such crops as have been sown in the autumn, generally afford the largest proportion of cattle fodder, when properly managed in the feeding of it.

Mr. Bannister states, that if wet weather happens whilst the peas lie in wads, it occurs as a considerable loss, many of them being lodged in the field, and of those that remain, a great part will be so considerably injured, as to render the sample of little value. This inability in peas to resist a wet harvest, together with the great uncertainty throughout their growth, and the frequent inadequate return in proportion to the length of halm, has discouraged many farmers from sowing so large a quantity as of other grain; though on light lands which are in tole-able heart, the profit, in a good year, is far from inconsiderable.

It is thought by some of considerable importance in the economy of a farm, when the nature of the soil is suitable, to have recourse to the early forfs; as by such means, the crops may in many cases be cut and secured, while there is leisure, before the commencement of the wheat harvest. And, that where the nature of the soil is dry and warm, and the pea crop of a sufficiently forward kind, it may be easy to obtain a crop of turnips from the same land in the same year, as has been suggested above. But in this view it is the best practice to put the crops in in the row method, and keep them perfectly clean by means of attentive hand and horse-hoeing; as in that way the land will be in such a state of preparation for the turnips, as only to require a flight ploughing, which may be done as fast as the pea crop is removed, and the turnip seed harrowed in as quickly as possible upon the newly turned up earth. In some particular districts a third crop is even put into the same land, the turnip being fold off in the autumn and replaced by collards, for the purpose of greens in the following spring. This, according to Mr. Middleton, is the practice in some places in Middlesex. But it is obviously a method of cultivation that can only be attempted on the warm and fertile kinds of turnip soil, and where the pea crops are early; on the cold heavy and wet descriptions of land, it is obviously impracticable, and wholly improper.

It is stated by a practical writer, that with the marrowfat and other late sorts of peas, the usual practice is either to prepare the land for wheat, or to put in crops of savoys or other late sorts of cabbages, which are the methods of husbandry that may often be had recourse to, even on the more heavy sorts of land, with success. And that from pea crops rendering the lands, on which they are cultivated, more light, open, and porous, they are supposed to be less proper for preceding wheat, than those of beans; on the more stiff sorts of ground, this cannot, however, be an objection of any great consequence, and even on the lighter kinds it may often be obviated, by giving the feed earth early, so that the crop may be put in upon a flake furrow, by the use of the flake-fold, either immediately before or after the grain is deposited in the furrow, and by repeating the same practice occasionally afterwards, as well as by rollings.

Application of Crops.—It is stated, that the portion of peas, that is not consumed as human food, is mostly appropriated to the purposes of fattening hogs and other sorts of domestic animals; and, in particular instances, supplies the place of beans as the provender of labouring horses; but that care should be taken, when used in this way, that they be sufficiently dry, as, when given in their green state, they are said to be apt to produce the gripes and other bowel complaints in these animals. And Mr. Bannister, after observing, that the straw is a very wholesome food for cattle of every kind, suggests, that there is generally a considerable demand for peas of every denomination in the market, the ufs to which they may be applied being so many and so various. The boilers, or yellow peas, always go off briskly; and the hog peas usually fell for精se or a milling per quarter more than beans. For feeding swine the pea is much better adapted than the bean, it having been demonstrated by experience, that hogs fat more kindly when fed with this grain than on beans; and, what is not easy to be accounted for, the flesh of swine, which have been fed on peas, is said, will swell in boiling, and be well tailed; whilst the flesh of the bean-fed hog will shrink in the pot, the fat will boil out, and the meat be less delicate in flavour. It has, therefore, now become a practice with those farmers who are curious in their pork, to feed their hogs on peas and barley-meal, and if they have no peas of their own growth, they rather choose to be at the expense of buying them, than suffer their hogs to eat beans. Nay, so far do some of them carry their prejudice in this particular, as to reject the grey peas for this use, as bearing too great an affinity to the bean, and therefore refer their growths of white peas solely for hog-fatting.

Peas, if the ground is kindly for their growth, and the summer moist, generally produce a great abundance of halm, which takes up a large space in the barn, and for this reason the mow ought always to be trodden with hogs or horses, or in some better way, which will close down the halm into one-sixth part of the compass it would otherwise have occupied. In Leicestershire they set all their peas abroad in flacks, being persuaded that they thence acquire a much better colour than when hosed in the barn.

Malted peas have been found to answer well in the fattening of hogs and turkeys, as well as in the feeding of horses in some cases.

Sowing of Seed-peas.—In the sowing of any particular sorts of peas for feed, they should be carefully looked over while in flower, in order to draw out all such plants as are not of the right sort; as there will always be, in every sort, some roughbils, plants, which, if left to mix, will degenerate the kind. As many rows may be thought sufficient to furnish the desired quantity of feed should then be marked out, and left till their pods turn brown, and begin to split, when they should immediately be gathered up in the halm; and if the farmer has not room to flack them till winter, they may be threshed out, as soon as they are dry, and
and put up in sacks for use; but particular care should be taken not to let them remain too long abroad, after they are ripe; as wet would rot them; and heat, after a flower of rain, make their pods burst in such a manner that the greater part of their seeds would be lost.

**Pea, Chich.** See CicEr.

The chich pea is much cultivated in Spain, being an ingredicent in their dyes, and is there called gareovance. It is cultivated in France alfo, but in England it is rarely fown; and unless the feafon proves warm and dry, the plants decay before the seeds ripen. Miller.

The ancient Hebrews made use of chich peas as their common provifions, when they took the field. They parched them to eat. At this day in Egypt, when people undertake a journey, they lay in a good dock of chich peas, parched in a frying-pan. Bellowius affures us, that at Grand Cairo, and Damofrus, there are abundance of thofes, where people do nothing elfe but fry peas, it being a fort of provifions with which they furnish travellers. In Ethiopia they take barley with them, roafed in the fame manner. In Turkey they lay in a flock of rice on these occasions, which they prepare and shell. The Hebrew term סג, signifies properly any thing roafed in general, and by it is underftood roafed peas, rice, or barley; fome will have even coffee to be meant by it. Bellon. lib. ii. cap. 53. Calm. Difh. Bibl.

**Pea, Everlafting, or earth-nut pea, names fometimes given to the lathybus. See Lathyrus.

**Pea, Everlafting, in Agriculture, a plant of the vetch kind, that may be fometimes cultivated. This is probably another plant of the pea kind that may be cultivated with great advantage as green food for animals.**

Mr. Welton has observed, that tares and vetches are plants of which hores are very foud, and are cultivated with great advantage for that purpofe. The everlafting peas belong to the fame clafs of plants; are much more luxuriant in their growth, and yet are not cultivated, except for orna ment. These plants are well known, and may be found in the gardens of almoft every village in the kingdom. The luxuriance of their growth is fo great, that the narrow-leafed, lathybus pifum, grows to the height of five or fix feet; the other, lathybus latifolius, to eight, ten, or more. They begin to vegetate early in the fpring, and continue growing until fevere frosts ftop them. Another peculiar advantage belonging to them is, that they are perennial-rooted plants, and when once fown, improve in their vigour and growth after the firft year, and continue increafing for feveral fucceffive ones. As may readily be proved by examing the gardens in which they are to be found, where feed may be had, and tried at firft upon a small fcale, with very little trouble and expence, and afterwards increafed. A rood of land, light, and but poor in quality, was fowed with it early in the fpring; the land prepared as for barley. A light furrow was drawn with a light plough, and the feed thinly dropped into it. Another was drawn at a foot distance, and the feed dropped in like manner. An interval was then left at leaft two feet wide; then two more rows, till the whole was fown. The feed was afterwards covered by drawing a light harrow, with wooden tines, backwards and forwards acrofs the land. When the plants came up and grew a little strong, they were thinned with a hoe to a foot distance, that they might have room to spread and branch. The firft year they made no great quantity of fodder, but have since made ample amends.

The second fpring they came up very strong and vigorous, branching out very much. A couple of hores were turned into feed, who were very fond of them, eating them very greedily, though they were taken out of a good natural upland pature. The third year the land was almofl entirely covered, and it yielded a great deal of feed. For ex-periment a few rods were mowed jiff before it flowered, which made good hay, sweet without being ficky.

It is noticed, that this experiment is not desribed longer than the three firft years. Instead of deftrroying the plants by hoewing them where too thick, he would recommend them to be drawn out, and a fresh planting made with them. In gardens, they are generally transplanted from the feed beds the second fpring. And instead of turning hores into feed, he would prefer cutting them either with a fcythe or fickle, and have them given to the hores. It would cer-tainly by that method produce more fodder, and you could find how many times in the fummer they would for cutting, and at what height it is the moft advantageous to cut them.

If the intervals be left three feet wide, instead of two, there would be room to plant in September and October a winter crop, when the peas ceafe growing, as borage, cabbage plants, &c. which would occupy the ground till March, at which time they begin to vegetate.

Others have found much advantage from this plant in the fattening of cattle in fome of the western counties.

**Peace, Pax, in its general signification, stands in oppo- sition to war. The right of making war and peace is one of the prerogatives of the king. In order to make a war completely effectual, it is neceffary with us in England, that it be publicly declared, and duly proclaimed by the king's authority; and then all parts of both the contending nations, from the higheft to the loweft, are bound by it. And wherever the right refides of beginning a national war, there alfo must refide the right of ending it, or the power of making peace. And the fame check of parliamentary imprisonment, for improper or inglorious conduct, in beginning, conduding, or concluding a national war, is in general fufficient to restrain the ministers of the crown from a wanton or injurious exertion of this great prerogative.**

**Peace, in our Laws Books, &c. is restrained to a quiet and inoffensive carriage towards the king, and his people. Lamb. Eirenarch.**

Offences againft the public peace are either fuch as are an actual breach of the peace; or conftruftively fo, by tending to make others break it. Both of these species are either felonious, or not felonious. The felonious breaches of the peace, are ftraitened up to that degree of malignity by virtue of several modern statutes; and, particularly, the "riotous assembling" of 12 persons or more, and not difpofing upon proclamation: "unlawful hunting," in any legal feftri, park, or warren, not being the king's property, by night, or with painted faces, 1 Hen. VII. c. 7, or appearing with the face blacked, or with other difguife, and being armed with offen- sive weapons, to the breach of the public peace, and the terror
terror of his majesty's subjects, 9 Geo. I. c. 22:—fending
any letter without a name, or with a fictitious name, demand-
ing money, &c., or threatening to kill any of his majesty's
subjects, or to fire their houses, &c., 9 Geo. I. c. 22.
27 Geo. II. c. 15:—destroying any lock, flute, or floodgate,
&c., turnpike-gate, &c. The above-mentioned offences are
felonies. Thos. that remain to be enumerated are merely
misdemeanors; viz. affrays, riots, routs, and unlawful offen-
bles, consisting of at least three persons; tumultuous peti-
tioning; forcible entry or detainer; ridding or going armed,
with dangerous or unusual weapons; spreading false news; false
and pretended prophecies. Besides actual breaches of the
peace, any thing that tends to provoke or excite others to
break it, is an offence of the same denomination; such are
calls to fight, either by word or letter, or bearing such
challengers; and libels. See each article.

The English laws have provided various means for pre-
venting offences against the public peace. Where any
man flants in danger of harm from another, and makes
oath thereof before a justice of the peace, he must be
secured by good bond, which is called binding to the peace.
Any justice of the peace may, ex officio, bind all those
who, in his presence, make any affray; or threaten
harm to another; or contend together with hot and angry
words; or go about with unlawful weapons or attendance,
to the terror of the people; and all such as he
knows to be common barretors, and such as are brought
before him by the complainant for a breach of the peace in
his presence, and all such persons, as, having been before bound
to the peace, have broken it and forfeited their recognizances.
(Hawk. P.C. 136.) Also, wherever any private man
hath just cause to fear that another will burn his house, or
do him a corporal injury, by killing, imprisoning, or beating
him; or that he will procure others to do so; he may
demand security of the peace against such person; and every
justice of the peace is bound to grant it, if he who demands
it will make oath, that he is actually under fear of death or
bodily harm; and will swear that he has just cause to be
so, by reason of the other's menaces, attempts, or
having lain in wait for him; and will also farther swear that he does not
require such security out of malice or mere vexation.
(Ibid. 137.) This is called swearing the peace against another; and
if the party does not find such security, as the justice in his
discretion shall require, he may immediately be committed till
he does. (Ibid. 128.) A recognition for keeping the peace,
when given, may be forfeited by any actual violence,
or even an assault, or menace, to the person of him who de-
manded it, if it be a special recognizance; or, if the recogni-
sance be general, by any unlawful action whatsoever, that
either is or tends to a breach of the peace. Blackit. Com.
b. iv. See Good-keeping.

PEACE, Time of, is when the courts of justice are open,
and the judges and ministers of the same may by law protect
men from wrong and violence, and distribute justice to all.
See Coke on Litt.

PEACE of the King, pac regis, mentioned in the stat.
6 Ric. II. &c. is that security which the king promises his
subjects, and others taken into his protection, both for life
and goods.

PEACE of God and the Church, pac Dre & ecclesie,
mentioned in our Ancient Law Books, is that reft and ceffation
which the king's subjects had from trouble and suit of law,
between the terms.

PEACE of the Plough, that whereby the plough, plough-
tacke, and plough-cattle, are secured from distrifges.

Thus fines may be laid to have their peace, because no

PEA

man may be troubled in them for any debt contracted eile-
where.

PEACE, Clerk of the. See Clerk of the Peace.

PEACE, Commissioner and Justices of. See Justices of Peace.

PEACE, Conservator of the. See Conservator.

PEACE, Homage of the. See Homage.

PEACE, in Mythology, a goddess among the Romans, to
whom they erected a variety of magnificent temples. The
temple, which was begun by Claudius, and finished by Vef-
pulian, was not inferior to any in Rome. If we may believe
Suetonius, Josephus, and St. Jerem, the emperor deposited
the precious and rich spoil of the temple of Jerusalem.
In this temple those who professed the fine arts assembled,
in order to dispute about their prerogatives, that in the
presence of the goddess of peace, all heats might be banished
from their debates. This goddess had also in the same city
an altar, which was very much frequented. Monuments re-
present to us peace under the figure of a woman crowned
with laurel, olive, or chaplets of roves, holding in one hand
the caduceus, and in the other ears of corn, the symbol of
plenty, which she poursces. Arilophanes gives her Venus
and the Graces for her companions. See Concord and
Tranquillity.

PEACE, in Geography, an island on the coast of Nova
Scotia, S. of Mirachi point.

PEACE River, a large river of North America, which
runs north-easterly into the Lake of the Hills. In the driest
season, it is a quarter of a mile wide. The lands on this
river are inhabited by the Beaver and Rocky Mountain
Indians, who are an unformed and barbarous race of beings.
Polygamy is practised among them, and the women are in
the lowest state of debasement. At their burials, among
other extravagant tokens of sorrow, the women, if the de-
deces be a favourite son or husband, cut off a finger at the
seift joint. Some of the old women have not a whole finger
left. The men think it below their dignity to shew any
mark of grief. These persons are great gamblers, and purs-
uish this as their employment for several days and nights.
Their habitations are formed by setting up a number of
poles, united at the top, and expanded at the bottom in a
circle of 12 or 15 feet diameter. These are covered with
dreched skins sewed together. This businees, and other
druggeries, are performed by the women, while the men sit
smoking at their cafe.

PEACE, a town of Hindoostan, in Oude; 40 miles S.
of Goorazcopur.

PEACH-TREE, in Botany and Gardening. See Amygdalus.

PEACH-TREE, in the Materia Medica. The fruit of the
peach is known to be grateful and wholesome, seldom dif-
agreeing with the stomach, unless the organ is not in a
healthy state, or the fruit has been eaten to excess. The
flowers, including the calyx as well as the corolla, are the
parts of the pericarp used for medicinal purposes. The
flowers have an agreeable but weak smell, and a bitterish taste. They
are used as a purge for children made into a syrup, and are
by some recommended as great destroyers of worms; but
there is a circumstance attending them which is little taken
notice of, and yet greatly alters their virtue. The custom
of gardeners is, to graft the peach upon the almond or the
plum-tree, and the flowers partake of the nature of the
stock; those which are produced on peach-trees grafted on
plum-trees being much more purgative than those from al-
monds; the reason of which seems plainly, that the plum is
a purgative fruit, the almond not at all so. The flowers of
the least esteemed sorts of peaches are also usually found to
be the best for medicinal use.

3R
In examining these flowers, they are found to contain more than three-fourths of a superfluous humidity. The buds contain a little less than the blown flowers; which is very natural to be supposed, because it is their being afterwards charged with a larger portion of humidity which makes them open. The buttons, or buds of the flowers, are found on experiment, however, to be somewhat more purgative than the flowers when open.

If four pounds of these flowers are distilled in a balneum Marie, they yield twelve or thirteen ounces of a whitish liquor, sweet to the taste, and of an agreeable smell, resembling that of bruised peach kernels; and this is so strong in the water, that a few drops of it will very agreeably scent a larger quantity of any thing. If the buds are used to this purpose, instead of the open flowers, the fame fort of liquor is drawn over; but it is of a somewhat coarser and more earthy smell. The residuum of these distillations put into a retort, and distilled by a reverberatory fire, gradually raised to its several degrees, yields both acid and alkaline substances; and, finally, a red spirit comes over, full of fuliginous particles, and containing some oil, part of which comes with the liquor, and the other part, which is heavier, sinks to the bottom. This is what a chemical analysis finds flows in these flowers, different from other vegetable matters. Spirits of wine draw a very weak tincture from these flowers; it is indeed much weaker than an infusion of them in common water. An infusion in water of half an ounce of fresh peach-flowers, or of a dram of dry ones, (for, as before observed, they contain three-fourths of superfluous moisture) is a very gentle and agreeable purge, and it is said, when sweetened with sugar, to prove an useful purgative and anthelmintic for children.

This method of infusion is much better for thefe and all other purgative flowers, than the taking of the expressed juice; for in that cafe there is always a large quantity of purgative matter remaining in the residuum; which water in a warm infusion is able to take out. The infusion of rofe or peach-flowers keeps also better than their expressed juice.

The juice always turns four very soon; but the infusion, with the common caution of pouring a little oil on the surface will keep good even for years.

When oil is used for this purpose, there should always be taken that it be such as does not freeze easily; for in that case, the air gets in between the cake of frozen oil and the sides of the vessel, and spoils the liquor. Oil of almonds is greatly to be preferred to oil of olives on these occasions; as it freezes with much more difficulty. Another way of preserving the infusions is, the evaporating about half the liquor; and thus they will often keep a long time; as infusions keep better than the juices of plants, this seems to shew, that the former contain more of the principles than the latter.

The young leaves of the peach, made into an infusion in the fame manner as the flowers, are more purgative than they, but lefs agreeable; they are to be taken in the fame manner. Mem. Acad. Par. 1714.

These leaves are found to pollifie an anthelmintic power, and, from a great number of experiments, appear to have been given with invariable success to children and adults. However, as the leaves and flowers of the pernix manifest in some degree the quality of those of the lauro-cerasus, they ought to be used with caution.

**Peach-Colour.** The pale red colour of the blossoms of the peach-tree.

To give this beautiful colour to glafs, add at different times, and in small quantities, the powder of prepared manganese to the mafs for the making of lattimo, or milk-white glafs, while in fusion. This alone gives the peach-colour; but the metal must be immediately worked when of a right tinge, for the colour is very apt to go off.

**Peach-Colour, in the Mango.** See Blossom.

**Peach Gall-Infefts, in Natural History,** a small gall-infeft, found in great plenty on the peach-tree. It is of an oblong figure, flat at the belly, and prominent on the back; pointed, and not unatly resembling in miniature a small boat turned bottom upwards: their longer diameter is usually extended in the same direftion with the length of the branch; sometimes a little obliquely, but scarcely ever perpendicular to that direftion.

Their colour is usually a faint brown, sometimes it approaches to a coffee-colour, sometimes to a bright chfaynut, but more frequently it has something reddifh in it. This infelf lives but a little while after it has laid its eggs, and its dried body makes an excellent covering and defence for them; and what is very remarkable is, that as this infelf is now immovable, and cannot draw itself over its eggs, they are not thrown out behind its body, as the eggs of other animals; but as they are laid, are drawn under the belly, and evenly arranged there.

The eggs are two or twelve days before they hatch, and when hatched, the young animals are in general quiet under the cover of their mother's caraffe for several days.

It is usuall about the beginning of June that the young infcfts get at liberty from under the body of their parent; they may then be found running very nimbly all over the branches of the tree, but are not distingufhable otherwife than by examining the branches with a microscope. The branches, thus covered with these young animals, are in a few days cleared again, and the infcfts found in form of small scales, covering the leaves, and now large enough to be fen by the naked eye.

Not only the gall-infefts of the peach, but all the other species, after a certain time, become immovable fixed to the place where they are, and no longer able to ufe their legs. Their growth is very slow from the time of their hatching, through the months of July, August, September, and October: at the beginning of November they are found somewhat enlarged in breadth, but they are yet no thicker, and this time they are all become of the fame colour, which is somewhat reddifh. In the beginning of March they begin to swell and be filled with the growing eggs; their backs become a little convex, and, viewed with a microscope, appear covered with little tubercles; and one may, at this time, perceive seven or eight long threads, which run from several parts of their bodies: these fall ten themselves to the branch at a distance from the creature, and fix it immovable in its place. In the beginning of April they become much more convex, and though they can no longer walk about, they yet have at this time sufficient motion to fhew an animal life. At this time, by very flow motions, they change their skin; and it is after this change that they assume fo exactly the figure of galls, and grow fo very quickly to their full size. Seven or eight days now make such a change in them, that they are not to be known for the fame animal; but it is not till the beginning of May that they arrive at their utmost size.

About the 15th of May they are in a condition to lay, and as the eggs are discharged, the belly is pulled closer and closer to the back; and when all are laid, becomes the shell before described, and the young ones are hatched under it, and become full of eggs, and do the fame office afterwards to their young.

In the end of April the branches of the peach and other trees, covered with these infcfts, will be found to be greatly frequented by a fort of small flies, beautiful enough to demand
mand attention; their head, breast, body, and legs, are all of a deep red; they have only two wings, but those very large, being nearly twice as long as their bodies; these, in the fly's common posture, are crossed on the back, and the upper almost entirely hides the under one; they are less transparent than those of the common flies, and are of a dusky white, bordered with an edge of a fine bright and beautiful red; but what chiefly distinguishes them from all other species is, that they have two long white threads which run from their hinder part, and are of twice the length of their wings; between these there is also a remarkable part, a sort of tail made like a piercer, and of a third or fourth part of the length of these threads. This is, like all other flies, thicker at its base than at its point, and is bent a little downwards. The antennae of this fly are adorned with long bodies, hairy, and larger at their extremities than at their infections on the antennae. It is easy at first sight to conceive, that these are the flies that had been produced of worms fed in the bodies of the gall-insects of a former year, and that they were now searching an opportunity to deposit their eggs in the bodies of these little creatures, to be hatched into worms there, and thence to come out in flies, as they themselves had done.

The flies examined on the branches with a glafs will also be found to introduce this feeding piercer always at the same place into the body of the gall-insect, and this is that cell in the hinder part of the body, out of which the young ones, when hatched, afterwards and their way. The flies, which lodge their eggs or young worms in the bodies of other insects, if crushed at that season, will be always found to contain fuch eggs or small worms; and the microscope never fails to discover them in the matter crushed out of flies even smaller than these, but in these no observation ever fhes any fuch. See GallInfetFly.

Notwithstanding that the peach gall-insect is the only species in which the male fly has been observed, there is no room to doubt but that the other species all have males of the fame kind.

The orange gall-infect has been observed not universally fecundated, but that there is only a part of the animals that lays eggs; probably the others are those which hatch into the male flies; and the kermes, the nobleft and moft valuable of all the gall-insects, is known often to produce a white winged fly, very like that of the peach gall-insect. And Brunius, who gave some time since a history of the fcarlet grain of Poland, the coccus Poloniacus, a kind of pro-gall-infect; though in the firit account, he gave into the opinion of both fexes being included in each of these animals, and that each was in itself fufficient for the propagation of its species: yet afterwards, to his very great honour, added an account of his having discovered the male of this species, which he defcribes to be a small fly, with a red body and white wings bordered with red; a fly in all respects like the male of the peach gall-infet. Reaumur's Hist. Inf. tom. iv. p. 1, to 44.

Pea by the Cornish Minors. in Mineralogy. See Chlo-rite. N. B. Under that article, read Pea for pearls. Pea Water. See Water.

Pea Wolf. See Lycopersicon.

Pea Island, in Geography, an island of Upper Canada, in lake St. Clair, about seven miles higher than Detroit, nearly opposite to the communication of the Grand Marais with that lake. It contains from 60 to 100 acres of land fit for tillage; the other parts being meadow and marsh. There is little wood in this island; nor is it improved.

PEACHAM, HENRY, in Biography, author of a book, entitled The complete Gentleman, published in the reign of James I. It treats of "nobilitez in general; of dignitie and necessitie of learning in princes and nobilitie; the time of learning; the duty of parents in their children's education; of a gentleman's carriage in the universitie; of lile in speak- ing, writing, and reading books; of cosmography; of memorable observation in the survey of the earth; of geometry; of poetry; of musicke; of statues and medallis; of drawing and painting in cyle; of sundry blazonnes both ancient and modern; of armory or blazing armes; of exercife of body; of reputation and carriage; of travaile; of warre; of fishing."

He was certainly a man of general knowledge, good tale, and acute observation. He refrained a considerable time in Italy, where he learnt mufe of Orazio Vecchi. He was intimate with all the great masters of the time at home; has characterized their several fyles, as well as those of many on the continent. His opinions concerning their works are very accurate, and manifest great knowledge of all that was understood at that time respecting practical mufe. He seems to have been a travelling tutor, for which office he appears to have been particularly well qualified.

But with all his accomplishments, he is said to have been reduced to poverty in his old age, and chiefly to have subsisted by writing little penny books, which are the common amufe- ment of children.

PEACHAM, in Geography, a poft-town of America, in Caledonia county, Vermont, west of Barnet, on Connecticut river; containing 873 inhabitants.

PEACOCK, in Astronomy. See Pea.

PEACOCK, REGINALD, in Biography, a worthy prelate, was successively bishop of St. Afaph and Chichefter, by favour of Humphrey, the good duke of Glocefter; but he was deposed for refiling the papal authority, and denying the doctrine of tranfubfantiation, with other articles of the Roman Catholic faith. He was not equal to suffering in a righteous caufe, but recanted his notions, and his books were publicly burnt. He then retired to an abbey, probably mortified and ahamed of his timidity, where he died about the year 1486.

PEACOCK, in Ornithology. See Pea.

Peacocks were first brought from India, where they are still found, in the wild flates, in falt flocks, in the iflands of Ceylon and Java. From India they were removed to Greece, and being the birds facred to Juno, were prefered about the temple of this deity at Samos: it is therefore probable, that they were brought here originally for the pur- poses of superition, and afterwards cultivated for the ufe of luxury. The peacock frequently accompanies the statues of Juno, and it was from her superior love to it, that she placed in its tail the eyes of Argus, after Mercury had put him to death.

Peacock's crefses were anciently worn among the ornaments of the kings of England.

PEACOCK'S Tail. See Tail.

PEACOCK-Fish, in Ichthyology, one of the larger species of the turdus, or syrrhus, but of a middle nature between the long and the flat-bodied kinds; its uflual flaudard, as to fize, is about three pounds weight; and its colour on the back is blackish and a dusky blue; the blue is discolored in three or four longitudinal parallel lines, on a dusky blackish ground; about the head and gills the blue lines are more bright and numerous; its lower jaw is almoft wholly blue, and its belly is of a fine faffron colour or reddish yellow; it has thick lips, and very sharp, though not very large teeth; its back-fin is, on the anterior part, of a fine deep blue, with an edge of purple, and sometimes of yellow; and the reft of the fin is red at the bottom and yellow at the top, and in
the middle is finely variegated with blue spots; the foremost
nerves of the back-fin are rigid and prickly, and have soft
and flexible rays accompanying them beyond the limb or edge
of the fin, and of more than their own length; its gill-fins
are a mixed red and yellow, and its belly-fin behind the anus
of a pale flesh-colour, with a variegation of blue and yellow;
the other belly-fins are of the same colour, and the tail is
wholly blue. It is a most remarkably beautiful fish, and
from the spots and variegations of its fins has obtained its
name: See CHELADON and LABRUS.

PEAK, or PEEK, in Sail-making, the upper corner of
triangular fads, and upper outer corner of fore and aft
fads.

PEAK, in Geography, a mountain of England, giving
name to a district in the county of Derby, between the
Derwent and the Dove, which last river separates it from
Staffordshire. It is mountainous, rocky, and barren, but
abounds in mines of lead, iron, coal, and anthracite: it also
furnishes mill-stones and grind-stones.

PEAK d'Étoile. See NEW HERRIES.

Peaks of Otter, the highest part of the Blue Ridge, in
the west part of Virginia, or perhaps another in North
America. From its base its height is about 4000 feet.

PEAR, or PEAR, Holmes Bay, a bay on the fourth coast of Jamaica.
N. lat. 17° 59'. W. long. 76° 58'.

PEAR, in Heraldry, is when the field of a coat of arms
is fable, and the powderings are.

PEAR, in Geography, a town of Pegu, on the Irawaddy; 15 miles S. of Prome.

PTEAIDIES, the name of a fonce to which the an-
cients attributed great virtues for promoting delivery.
These fones were found in Macedonia and other places;
and all the description we have of them is, that they re-
fembl(ed) water congealed by froth. Probably the ancients
meant by this name the falaide, or fony icicles, which, as
they hang from the roofs of caverns, greatly resembfe the
droppings of water from the eaves of houses congealed in
frothy weather.

PEAR, in Orcharding, a fine rich fort of fruit, which is
obtained from an orchard-tree of the fame name, and from
the juice of which the liquor called perry is prepared. See
PEAR-TREE, below.

PEAR-TREE, in Botany and Gardening. See PYRUS.

PEAR-TREE, a fruit tree of the orchard kind. There
are many forts of this tree; but for the purpose of perry, the
squash is in much the highest esteem. It is an early fruit,
remar(fable) for the tendernefs of its feth. If it drops ripe
from the tree, it bursts to pieces with the fall. The liquor
made from this fruit is pale, sweet, yet remarkably fide, and
of a strong body; a moft excellent liquor, if duly manufac-
tured from a foul which fuits it. The oldfield is a favourable
old pear, remar(able) for the elegant flavour of its liquor.
The barland pear is in great requite, as producing a perry
which is esteemed fingly benefial in nephritic complaints;
as is the red pear for producing liquor of injular
strength. The haftap and the fack are other pears which
have been ufually grafted: and besides thefe, and a variety
of others, great numbers of kernel fruits are found among
the pear-trees in Herefordshire and other countries. See
ORCHARD and PERRY.

Sorts.—Mr. Knight states, in his valuable Treatife on
the Culture of the Apple and Pear, that “the experiments
he has made on the pear have not been nearly so numerous
as thofe on the apple, and have been confined to a fingle variety,
the Tewford squash; but they have been fully fufficient to
convince him, that the difeafes of both chiefly arife from the
debility of old age, and will be found equally incurable.

Though the pear is more properly a naturalized than ad in-
digenous fuit in this country, it is much more hardy than the
apple, and may certainly be cultivated in almost every
part of England with nearly as much fuccefs as in Here-
fordshire. Like the apple it grows with the greateft lux-
urance in frong deep fols, and in them the finet liquors
are at preft obtained from it; but it will flourish in evey
variety, where it is not incommended with water. Its culture
differs fo little from that of the apple, that the fame rules
are in general equally applicable to both. It is moft suc-
cessfully propagated on fols of its own fpecies, but it will
succeed in fome degree on thofe of the quince, the medlar,
the whitebeam, the common service, and the hawthorn; and
probably on many others. When grafted on its own feeding
fols, which alone he would recommend, the opera-
tion fhould always be performed near the ground, on ac-
count of the rechining top-heavy growth of the young fols.
In raifing fols from the feds of this fruit, a light, foft,
loamy foil fhould be chosen, which is naturally of good
qualify, but which has not been recently manured. In this
the feds, like thofe of the crab-tree, fhould be covered
about an inch deep, as soon as they are taken from the
fruit.” And “much attention muft be paid to them during
the early part of the firft fummer, or great numbers will
perifh. They muft be kept clear from weeds, and be regu-
larly watered in dry weather; and if the mould be fre-
quently turned over the plants, it will be of great advantage
to them; after the middle of Auguft, they become more
hardy, and little care or attention will be required from the
planter.

“A fufficient number of varieties of this fuit, in a good
flate of growth, are in cultivation; but few of them poifof
any high degree of merit. The greater part are extremely
productive of juice, and require to be ground after
they fall, or are blown from the frees. The produce of
fome of them, when it has been nicely manufacuted from
well ripened fruit, often poifofes great excellency; but it is
often at the fame time fweet and acceious; and if, owing to
an unfavourable fegen, the fruit has not been properly
ripened, and an accefs of fermentation cannot be prevented,
the liquor becomes four and unpalatable, and fcarcey good
enough to anwer the meanen purpofes of the farm-house.
He is “much disposed to doubt whether a fingle perry-pear,
poffefling nearly the greatefl degree of excellency of which
this fuit is capable, has yet been in cultivation. It appears
highly probable that fome fuits, which might be kept
for a longer time, or left under the trees to attain a more per-
fect and regular maturity, are likely to afford a more permanent
and generous liquor. One pear, which in fome degree
answer in this defcription, has been much cultivated, the long-
land; and though its produce, being without the fine fla-
avour which is found in fome others, is little attended to by
the merchant, it has qualities which render it extremely
valuable to the farmer: the fruit may be kept fome time
without fufaining any great degree of injury, when bufinefs
of more imporance occupies his attention: the liquor
obtained from it is never very fine, but it is rarely below medi-
ocrity: it poifofes more body than is generally found in
perry, and retains many of its good qualities in every dif-
ferent foid and fituation. It is a fruit he fhould strongly
recommend for culture in cold and exposed fituations, for
which the hardinefs of its blosfom renders it peculiarly well
calculated; but he is afraid it is advancing nearly to that
period when young trees can no longer be raised with ad-
vantage to the planter.

It is noticed, that "the pear is an extremely long-lived
tree, and the fame variety may in confequence be very long
kept
PEAR-TREE.

kept in cultivation. At what period the Teinton squash first sprang from the seed, probably cannot now be ascertained; but he subjects from its present diseased and worn out state, that it existed at least as early as the beginning of the sixteenth century. For another kind, the barland, which was much cultivated in the early part of the seventeenth century, still retain a large store of health and vigour, and the identical trees which supplied the inhabitants of Herefordshire in the seventeenth century with liquor, are likely to do the same good office to those of the nineteenth. He subjects, however, that this variety naturally possessed a greater degree of durability than is common to the species; and that its lofty spiral growth, by rendering it difficult to get grafts from the extremities of the bearing branches, has, in cultivation, made it still more durable. It is yet capable of being propagated; but trees nearly of the same stature with those which now abound, must not again be expected. The tree, which is said to have been the original, grew, he says, in a field called the Barlands, in the parish of Bohbury, and was blown down a few years ago.

"But though he does not think very highly of any of the perry-pears which are now cultivated, he does not know that he can point out the means of acquiring better. Thosdi which he has employed to obtain improved kinds of apple, appear to him to be wholly improper. Every variety of that fruit, which possesses colour and richness, is capable of making fine cider, but a good perry-pear requires an affluence of qualities, which will be rarely found in the same fruit. It must contain a large proportion of sugar, or its juice can never possess sufficient strength; and unless it be at the same time extremely aromatic, the liquor produced from it will be accursed whenever it ceases to be saccharine. In the latter state it will agree with few constitutions, in the former with none. The juice of the bell-perry-pears is so harsh and rough, as to occasion a long continued heat, and irritation in the throat, when the fruit is attempted to be eaten; yet by being finely pressed from the pulp, it becomes rich and sweet, without much roughness than is agreeable to almost every palate. This circumstance appears extraordinary, but it does not stand alone in the vegetable world."

There are many cafes in which similar changes take place with acid vegetable substances. It is stated that "the defects of the apple and pear, when raised from seed, are generally of opposite kinds; in the former the fruit is usually hard and four, in the latter it is apt to be, when thoroughly ripe, sweet and insipid." The mode of cultivation therefore, which would improve the one by bringing it nearer to the highly cultivated state, and lefifening its harshness, would not improbably be injurious to the other by producing the same effects."

It is stated that "an estimate may be formed in the apple of the merit of the fruit by the leaf and growth of the feeding tree, but in the pear these scarcely afford the slightest indication of the future produce. The leaves of those plants which will afterwards afford large rich fruits for the dessert are often small and thin, and the items will be covered with thorns; whilst others, whose leaves and growth flew every mark of a high state of cultivation, will sometimes produce fruits that are small and worthless."

It is not known that "better means can be used in obtaining new varieties of this fruit, than forming a large quantity of seeds from healthy trees of an orchard in which the best kinds only have been planted, and afterwards selecting the plants of the most luxuriant and vigorous growth. But as no estimate can be formed of the value of their future produce, it will be prudent to retain a considerable number till their fruits be known: few of which, he is afraid, must be expected to answer the wishes of the planter."

"He has, during the last twelve years, examined a very large number of feeding pears, and has ascertained that a variety growing on a farm he occupies, but he has never discovered more than one kind which he thought capable of making fine perry. The greater part of these, however, appeared to him to have sprung from the seeds of rich capable pears, and some of them bore a very close resemblance to the fruited of old grafted trees in the neighbouring orchards. There is little reason to believe that the resemblance would have been less between the parent and the feeding fruit, had the former been eminent for the production of fine perry; and it therefore appears probable, that good new kinds may readily be obtained from the seeds of the bell cultivated. But even if few should be found capable of affording fine perry, the produce of all will be valuable to the farmer to mix with crabs, or apples which have been blown prematurely from the tree. The rapid sweetness of the juice of the pear is corrected by the acidity of thefe, and the liquor produced by the mixture often produces much more merit, than could have been expected from the ingredients. It will probably supply the place of small beer, and may be brought into the market at leas than half the price, with sufficient profit to the grower."

It is stated that "at this time which feeding trees will require to attain sufficient maturity to produce fruit, appears to vary in much in different varieties. He has one plant which produced fruit at sixteen years old, and another which, from the concurrent testimony of many old people, who remember its first blossoms, appears to have remained unproductive through the frst seventy years of its existence. It has since borne tolerably well; but its fruit is always without seeds, or internal cavity; and it appears to set with difficulty, much the greater part of the blossoms being constantly unproductive. Possibly its long continued barrenness, and the defects in its fruitification, may both have arisen from some incidental imperfection in the organization of the plant. The fruit is in other respects perfect, and possesifies great merit as a pear for the table."}

It is stated that the directions he has given for planting the apple, are in every respect applicable to the pear; except that this tree being of more luxuriant and lofty growth will require wider intervals. See APPLE-Tree and ORCHARD.

Planting.—In the most closely planted orchards the rows should not "be put at less than eighteen yards distance, nor the trees nearer than eight or nine to each other; and when the ground is to remain in tillage, intervals of twenty-five, or thirty yards, should be allowed between the rows. Attention must also be paid to the forms and stature of the different varieties, and as the fruit of these is rarely mixed with a view to make fine perry, trees of one kind should occupy each row." And that as "in some kinds the fruit grows only on the outside of those branches which are exposed to the sun and air; while in others it occupies every part of the tree; the former will of course require to be planted at greater distances than the latter." Farther, "as the produce of the pear-tree, though of the same variety, and growing on the same stock, ripens extremely irregularly; the planter must therefore have a considerable number of trees of each kind he plants, or he will rarely have a sufficient quantity ready to be ground at the same time. Even when the fruit has fallen spontaneously from the trees, a fourth at least of some kinds will be found immature, or decaying, and totally unfit to make fine perry; and"
and should be (though it rarely or never is) separated from the rest. It is to this want of perfect and regular maturit

y in the fruit that Mr. Knight ascribes a defect, which perry is seldom found wholly free from, which is that of a crude

and harsh acid which dwells on the palate, and which dis
guits the best judges of vinous liquors; and to the fame
cause it may be owing, that perry, when genuine, does not
agree with to many constitutions as cider. It is noticed
that "the pear requires a certain state of maturit to afford

perry in the greatest state of perfection: it should be ripe

without being mellow, or decaying; when it has not ob-
tained the proper state of ripeness, an excess of fermenta-
tion cannot be prevented, and when it has exceeded it, the

liquor, rarely forms kindly, and is extremely apt to be-

come four; probably by having too great a proportion of

its astringency; hence few kinds are found to improve by

being kept after they have fallen from the trees."

Pruning.—"This is not often observed in the culture of

the pear-tree, which is rarely much incumbered with super-

fluous branches; but in some kinds, whose form of growth

resembles the apple-tree, it will sometimes be found ben-

eficial. The directions in this case are the same as those

for the apple. See Apple and Orchard.

Pear-trees are subject to similar diseases as those of the

apple; "the blights of the trees, like those of the apple,

arise either from infects or unfavourable weather, or a com-
bination of both. The blossoms are often rendered abortive,

by a small brown beetle, precisely similar to that found on

the apple-tree, and probably of the same species; and a con-

siderable quantity of its fruit is frequently destroyed by the

larvae of a small green four-winged fly. Each fruit which

contains the latter infects becomes in a few days rounder

than those in the natural state, and grows with much greater

rapidity; but it falls off early in the summer, and if it be ex-

amined whilst growing, it will be found full of small grubs."

But "the pear-tree suffers more frequently from cold than

from infects, and therefore those varieties whose blossoms are

produced rather late in the spring, and are preceded by the

leaves, are generally most productive of fruit; and some

ekinds of the pear, as of the apple, are much more subject

to injury, both from infects and unfavourable weather, than

others. He has one feeding tree whose blossoms appear

capable of bearing the most unfavourable weather without

injury, and which has not once failed to produce a good crop

in the memory of the oldest inhabitant of the village in which

it stands. The fruit is rather too sweet to make good perry,

unless in mixture with other kinds; but it nevertheless forms

a very valuable variety for cold and exposed situations, as it

ripen somewhat early in the autumnal season of the year."

In the Report of the State of Agriculture in Herefordshire,

it is stated that the pear, though in common producing an

inferior liquor, has many advantages over the apple for

general use. It is capable of succeeding in a greater variety

of soil, is more productive of fruit, and less liable, espe-
cially in the pear kinds, to deprestations. Besides, it has a

more ornamental effect, and is of course better calculated

for particular situations. The produce of each full-grown

tree, will mostly be in the proportion of about twenty gal-

lons of liquor. See Apple-Tree.

The particular methods of preparing pears in the manu-

facture of perry, will be confidered hereafter under the pro-

per head. See Perry.

Pear, Avocado, or Alligator, a species of Laurus; which

see.

Pear, Bachelor's, a species of Solanum; which see.

Pear, Garlic. See Cnateva.

Pear, Priightly, or Indian Fig, Opuntia. This, in the

Linnean system, is a species of Calicus; which see.

PEARSE, Zachary, in Biography, a learned prelate of

the church of England, was born at London in the year

1690. The earlier part of his education he received in a

private school at Great Ealing, whence, in 1704, he was

removed to Westminster School, then under the manage-

ment of Dr. Bubb. Here he remained six years, and greatly

distinguishing himself, he was elected one of the king's

scholars. In 1710 he went to Trinity college, Cambridge. He

pursued his academic studies with great diligence and

success, and obtained a high reputation as a classical

scholar. During the first years of his residence at Cam-

bridge, he occasionally amused himself with the lighter

species of composition, some of which he sent to the Guar-
dian and Spectator. In 1716 he published, from the uni-

versity press, an edition of "Cicero de Oratore," with notes

and emendations; which, at the desire of a friend, he dedi-
cated to lord chief-judge Parker, a circumstance which laid

the foundation of his future fortunes. He was first elected

a fellow of Trinity college, and waiting on lord Parker,

to thank him for his interest on that occasion, his lordship

presented him with a purse containing fifty guineas. In the

year 1717, Mr. Pearce entered into deacon's orders; and

in the following year he was ordained priest. It had always

been his wish to devote himself to the clerical profession;

but as he himself has told us, he delayed to do so till he had

attained his twenty-seventh year, in order that he might, by

a due degree of preparation, attain to so much knowledge

of that sacred office, as should be sufficient to answer all the

good purposes for which it was designed. In 1718, lord

Parker having been appointed lord chancellor, Mr. Pearce

was invited to live with him in the capacity of domestic

chaplain; which invitation he gratefully accepted. In 1719

he was presented to the rectory of Stapleford-Abbots, in

Eifex, to which preeminent the lord chancellor added, in

the following year, that of St. Bartholomew, behind the

Royal Exchange, in London. Soon after this, Mr. Pearce

had the honour of being appointed chaplain to his majesty.

In the year 1721 he married a lady possessed of a considera-

ble fortune, by whom he had several children, all of whom died

very young. About a year after his marriage, he was pre-

sented with the vicarage of St. Martin's, and in this pro-

minent situation it was thought right he should take his

doctor's degree; but as he was not of sufficient standing at

the university, application was made for him to Dr. Wake,

archbishop of Canterbury, who granted him that title by

his diploma. In 1724 Dr. Pearce dedicated to his patron,

now the earl of Macclesfield, his edition of Longinus on the

Sublime, with a new Latin version and notes; which,

by the maimerly manner of its execution, contributed greatly

to the increase of his reputation as a scholar and critic.

To the ruin of the earl of Macclesfield, which happened in

1725, it was in some measure owing that several years elapsed,

from this period, before our author received any additional

preference; and for the next he was indebted to the patri-

nage of queen Caroline, though he did not obtain it till after

her decease. In the year 1730 he was nominated dean of

Winchester by sir Robert Waipole, to whose favour he had

been recommended by the late queen. In 1744 the dean

was elected prolocutor of the lower house of convocation

for the province of Canterbury; and in 1748 he was pro-

moted to the bishopric of Bangor. It is generally believed

that he was really averse from accepting the episcopal digni-

ty, and he was still more reluctant to comply with the

felicitations of his friends, by being promoted to the

bishopric.
PEA

bishops of Rochester, together with the deanery of Welmin-
ster. Twice after this he might have been raised to the
high dignity of the bishopric of London, but he declined the
honour. In a short time after the second offer, being at the
advanced age of seventy-three, and thinking himself unable
properly to discharge the duties of his station, he informed
his friend, lord Bath, of his determination to resign both his
bishopric and deanery, and to retire from the active duties of
life; at the same time soliciting his lordship to request
for him the honour of a private audience from his majesty
for that purpose. This favour was granted to him, and
the king, after having taken some time to deliberate, and to
consult his legal advisers on the subject, signified his con-
tent, and the bishop actually kissed hands on the occasion.
A dispute, however, occurred between lord Bath and his
majesty's ministers with respect to a succession, which in
a manner obliged the king to fend again for Dr. Pearce, and
tell him he must think no more about resigning his bishopric.
In 1768 he did, however, obtain the king's consent to his
resigning the deanery of Westminster, and from that time he
discharged his episcopal functions, and pursued his private
studies, with all his remaining vigour till the year 1773,
when he was seized with paralytic affections, that continued
to increase till his death, which took place in June 1774,
when he had attained to the 84th year of his age. Having
no children, and having lost his wife the year before his own
death, he made his brother, William Pearce, esq., his heir
and executor. He bequeathed his library to the dean and
chapter of Westminster, excepting such books as they already
had, and, these, with his MSS., he gave to his chaplain the
reverend John Derby. He left by his will several legacies
to private persons, and to public charities; but his principal
legacy was to a college at Bromley, in Kent, which had been
founded by bishop Warner in 1666, for twenty widows of
clergymen who flock in need of alms. "The fabric is
neat, the apartments are commodious, and the condition of
the inhabitants such as infers no degradation of civil rank.
The revenue assigned by the founder was, in his time, not
only competent but liberal; yet, by the alterations which
the last century has produced in the modes of life, and the
feylen of expence, what was then ample is now become
fieasty, and bishop Pearce left £5000, not to increase the
number, but to advance the happiness of the society, by
such an augmentation of revenue as might relieve them from
penury. In this charity there is no oblation; his bene-
faction scarcely continues his name, but sinks silently into
the ancient fund, and those who shall enjoy the plenty
which it relores, will, in a few years, hardly know to whom
they owe it."  

Dr. Pearce was first known to the public by philological
learning, which he continued to cultivate with advanced age.
"Cicerio de Oratione" was published by him when he was
bachelor of arts, and "Cicerio de Officiis" when he was
dean of Winchester. He did not confine his attention to
the learned languages: he was particularly studious of
Milton's poetry; and when Dr. Bentley published his
imaginary emendations of the "Paradise Lost," Dr. Pearce
wrote a vindication of theestablished text. In domestic
life he was quiet and placid, not at all difficult to be pleased,
no inclined to haras his attendants or inferiors by peevil-
nefs or caprice. In his parochial care he was punctually
diligent, and very seldom omitted to preach. He was
author of several works besides those already mentioned;
among these were "The Miracles of Jesus vindicated;" and
"Two Letters to Dr. Waterland upon the En-
chiridion;" but his great work was not published till 1777,
under the title of "A Commentary, with Notes, on the
Four Evangelists, and the Acts of the Apostles, together
with a new Translation of St. Paul's first Epistle to the
Corinthians, with a Paraphrase and Notes," in 2 vols. 4to.
This work is unquestionably the result of many years'
floridous application, and it reflects lasting honour upon his
learning, critical talents, and intimate knowledge of the
sense and spirit of the sacred writings. It now ranks high
among theological students; but either from the largeness
of the number printed, or from some other cause, unknown
to the writer of this article, the commentary was for many
years almost a dream on the booksellers' shelves. Its
value at present is better appreciated. Mr. Derby, his
lordship's chaplain, gave likewise to the public four volumes
of his lordship's sermons, on subjects of high importance
to the present and future welfare of mankind. Bishop
Pearce was author of N. 121 of the Guardian, and of
572 in vol. viii. of the Spectator, and also of N. 653 in
the same volume, "On the Elegance of the Pulpit."

PEA, or PERLA, or PEARL, or PEARLS, in Natural History, a
hard, white, smooth, shining body, usually roundish, found
in a telescope of shells, of the oyfter kind; and is ranked
in the number of gems.

The fish in which the pearls are found, is three or four
times the size of the common oysters; and is called by natu-
ralists, the "concha margaritacea." The East India pearl-
shell is the "matrix perlarum" (mother of pearl) of Rup-
nius, or the "mytilus margeritiferus" of Linnaeus; and
therefore the general term pearl-oyter must be erroneous.
Some also are found in a species of mya, or mufcle. That
pearls are not peculiar to one kind of shell-fish, as many
have believed, was known to Phin, who says, "quo appare-
non uno concha genere nascit." Many very good pearls
have been found in Colchester oysters; and real pearls are
found under the shell of the sea-hare (aplyta).  

This fish is common in the gulf of Peru, near Ormus
and Bahrein island; about cape Comorin, on the coast of
the island of Ceylon, in the Bornean islands, in Saxony,
and in Scotland, and also in South America. See PEARL.

These pearls are called these pearls univeris, apprehending
that there never was but one in an oyster; but there have
been sometimes found seven in a shell, and an author, who
wants well of their production, pretends to have seen a hun-
dred and fifty in the same fish, but those in different degrees
of perfection. The most perfect drop out first; the rest
remaining longer at the bottom of the shell.

An ingenious writer (Henry J. Le Beck, esq.) has, in
the 5th volume of the Asiatic Researches, given a particular
account of the pearl-fishery at Ceylon, and also of the animal
infolled in the mytilus margaritiferus, from which the pearl
is obtained. "This animal," he says, "is fattened to the upper
and lower shells by two white flat pieces of mucous sub-
stance, which are called by Houtnins ears, and extend about
two inches from the thick part of the body, growing gra-
dually thinner. The extremity of each ear lies loofe, and
is surrounded by a double brown fringed line. These
ears are inserted at the third of an inch from the outer part of
the shell, and are continually moved by the animal. Next to
these, above and below, are fitted two other double fringed
moveable fotibstances, like the bronchiae of a fish. These
ears and fringes are joined to a cylindrical piece of flesh,
the size of a man's thumb, which is harder, and of more
mucosal nature than the rest of the body. It lies about the
centre of the shells, and is firmly attached to the middle
of each. This, in fact, is that part of the pearl fish which
serves
ferres to open and shut the shells. Where this column is fastened, we find on the flesh deep impressions, and on the shell various nodes of round or oblong forms, like imperfect pearls. Between this part, and the hinge (cardo), lies the principal body of the animal, separated from the rest, and shaped like a bag. The mouth is near the hinge of the shell, enveloped in a veil, and has a double flap or lip on each side: from whence we observe the throat (esophagus) deferring like a thread to the stomach. Close to the mouth there is a large muscular tongue, half an inch in length, with an obtuse point; on the concave side of this defers a furrow, which the animal opens and thrusts, and probably uses to convey food to its mouth. The tongue is supposed to be used in the exercise of the locomotive power of the pearl-fish. That they have this power is well known to the divers, who observe that after they have abode in search of food, and also when disturbed by an enemy. In the latter case, it is said, they commonly defend from the summit of the bank to its declivity. Near the middle of the tongue are two bright spots, which seem to be the eyes. In a pretty deep hole near the bafe of the tongue, lies the beard (byssus), fastened by two flethy roots, and consisting of almost one hundred fibres, each an inch long, of a dark green colour, with a metallic luster; they are undivided, parallel, and flattened. In general the byssus is more than three quarters of an inch, without the chest (rima): but if the animal is disturbed, it contracts considerably. The top of each of the threads terminates in a circular gland or head, like the stigma of many plants. With this beard they fasten them- selves to rocks, corals, &c., whatever they choose; by it the young pearl-fish cling to the old ones; and with it the animal procures its food, by extending and contracting it at pleasure. Small shell-fish, on which they partly live, are often found clinging to the former. The stomach lies close to the root of the beard, and has, on its lower side, a pro- tracted cbtusc point. Above the stomach are two small red bodies, like lungs; and from the stomach goes a long channel or gut, which takes a circuit round the muscular column above-mentioned, and ends in the anus, which lies opposite to the mouth, and is covered with a small thin leaf, like a flap. Though the natives pretend to distinguishing the sexes by the appearance of the shell, I could not find any genitalia. The large flat ones they call males, and those that are thick, concave, and vaulted, they call females, or pedo-chhip; but, on a close inspection, I could not observe any visible sexual difference.

"It is remarkable that some of these animals are as red as blood, and that the inside of the shell has the same colour, with the usual pearly lustre, though my servants found a reddish pearl in an oyster of this colour; yet such an event is very rare. The divers attribute this redness to the stiffness of the pearl-fish; though it is only probable that they had it from their first existence. In the fade they will live twenty-four hours after being taken out of the water. This animal is eaten by the lower classes of Indians, either fresh in their curries, or cured by drying: in which state they are exported to the coast; though I do not think them by any means palatable.

"The pearls are only in the softer part of the animal, and never in that firm muscular column above-mentioned. We find them in general near the earth, and on both sides of the mouth."

The formation of pearls has puzzled both ancient and modern naturalists, and given occasion to a great number of hypotheses, many of them wild and extravagant enough. Pliny, and from him Solinus, &c. will have them to be formed of the dew: the fifth, say they, rises every morning to the surface of the water, and there opens its shell, to imbibe the dew of heaven; which, like a liquid pearl, infiltrating into the body of the pearl-oyster, fixes by its salts, and there assumes the colour, hardness, and form of pearl; as some other liquors are converted into crystals in the earth, or the juice of flowers into honey and wax in the body of the bee; but the pearl-oysters grow fast to the rocks, and nobody ever yet saw any of them appear on the surface of the water.

The same absurd opinion is maintained by the natives of Ceylon, and very similar to it, is the account of the formation of pearls recorded in one of the Sanscrit books of the Brahmins.

Others will have pearls to be the eggs of the fishes they are found in; but neither does this confound with the phenomena: for pearls are found throughout the whole sublination of the oyster; in the head, the coat that covers it, the circular muscles that terminate it in the stomach: and, in general, all the flethy and mucous parts; so that there is no appearance that pearls should be in the oysters, what the eggs and spaw are in fowl and fishes. For besides that there is no particular place defined for their formation, anatomists have not been able to find any thing about them that bears any relation to what pafes in this respect in other animals.

Mr. Chemnitz, a celebrated conchologist at Copenhagen, supposes that the pearl is formed by the oyster, in order to defend itself from the attacks of the pholasus and boreworms. But we may be assured that this hypothesis he makes: for although these animals often penetrate the lower layers of the pearl-shells, and there occasion hollow nodes, yet on examination it will be found, that they are never able to pierce the firm layer with which the inside of the shell is lined. How then can the pearls be formed as a defence against exterior worms, when, even on shells that contain them, no worm-holes are to be seen? It is, therefore, more probable these worms take up their habitations in the nodes, in order to protect themselves from the attacks of an enemy, than that they are capable of preying on an animal so well defended as the pearl-fish is.

Others with M. Geoffroy the younger, rank pearls among the bezoars; as comprehending, under that chals, all fomes formed in layers or strata in the bodies of animals. See BEZOAR.

M. Reaumur has a very curious piece on the subject of the formation both of the shells and pearls, in the Memoirs of the French Academy, anno 1717. He observes that pearls are formed like other fomes in the animals; as thofe, e. gr. in the bladder, kidneys, &c. and that they are apparently the effects of a diseafe of the fih. In effect, they are all formed of a juice extravedated out of fome broken veftels, and detained, and fixed among the membranes.

To evince the possibility of this, he shews that the fomes of fia-fish, as well as thofe of snails, &c. are wholly formed of a glutinous flozy matter, oozing out of the body of the animal. Now it is no wonder that an animal, which has veftels wherein circulates a fufficient quantity of flozy juice to build, thicken, and extend a shell, should have enough to form fomes also, in cafe the juice, defined for the growth of the shell, shall chance to overfow, and burst forth in any cavity of the body, or among the membranes.

'To confirm this fyslem, he observes, that the inner surface of the common pearl-muscle, found on the coasts of Provence, is of a pearl, or mother of pearl colour, from one part of its extent, which he determines, to another; after which it becomes reddih: now there are pearls of two colours found in the shell; and the colours of the pearls are
are precisely the same with those of the shell; nay, more, all kind of coloured pearl is found in the corresponding coloured part of the shell; which, indeed, that, in the same place wherein the transpiration of a certain juice had formed, and would have continued to form a similar part of shell of a certain colour; the shells which conveyed that juice being broken, there is formed a little mass or collection of the juice, which, hardening, becomes a pearl of the same colour with the part of the shell to which it corresponded.

Add to this, that the silver, or pearl-coloured part of the shell, is formed of strata, or layers, over one another, like an onion; and the reddish part of little cylindrical short fibres applied against one another. The pearls of the two colours have also this difference of texture; not but they are both composed of concentric couches; but those of the reddish pearls are much less fimbriate; and, besides, they have threads, which, like radii, proceed from their centre to their circumference. These circumstances seem effectually to determine the formation of pearls, and to establish the new fytem beyond contradiction.

The extravagations above-mentioned may be caused by heterogeneous bodies, such as sand, coming in with the food, which the animal, to prevent disagreeable friction, covers with its glutinous matter, and which, as it is successively secreted, forms many rows of lamellae; the thinner of the coats of an onion, and are like different strata of bezoars, only much thinner; that is probable, for if we cut through the centre of a pearl, we often find a foreign particle, which ought to be considered as the nucleus, or primary cause of its formation. The loose pearls may originally have been produced within the body, and on their increase may have separated and fallen into the cavity of the shell. Those compact ones, fixed to the shells, seem to be produced by similar extravagation, occasioned by the friction of some roughnesses on the inside of the shell. These and the pearl-like nodules have a different aspect from the pearls, and are of a darker and bluer colour. In one of the former we found a pretty large true oval pearl, of a very clear water, while the node itself was of a dark blueish colour. The yellow or gold-coloured pearl, is the most esteemed of the natives; some have a bright red lustre; others are grey or blackish, without any shining appearance, and of no value. Sometimes when the grey lamella of a pearl is taken off, under it is found a beautiful genuine pearl. In some, if the first papery fibrous coat be separated from the first coat, you find a worthlesse impure pearl. We tried several of them, taking one lamella off after another, and found clear and impure by turns; and in an impure pearl we met with one of a clear water, though in the centre of all we found a foreign particle. The largest and most perfect pearl which we saw during our stay at Condatch, was about the size of a small pistol-bullet, though we have been told since our departure, many others of the same size have been found. The spotted and irregular ones are fold cheap, and are chiefly used by the native physicians as an ingredient in their medicines.

As to the formation of the pearl-fish, though it is the most natural opinion, that this fish, like all others, produces eggs or spawn, whose exterior surface at first is soft and viscid, but changes, and hardens, by degrees, into a shell; yet we must not leave unmentioned the popular, though erroneous hypothesis, of the Parwas; viz. that in rainy weather, the brooks of the neighbouring lands that empty themselves all along the coasts, run near to leagues on the surface of the sea without mixing therewith. For while the suspended water, they say, retains its natural colour and sweetness; but at length, the heat of the sun, condensing it, forms it into a kind of light transparent frost; this done, it presently divides into an infinity of parts, each of which appears as if animated; moving this way and that like insects. The fishes sometimes catch at them as they pass by; but they form another shell. So thickening and hardening, they at length become heavy enough to sink to the bottom, and assume the figure of pearl-fishers.

We way judge with greater or less probability by the appearance of the pearl-shells, whether they contain pearls or not. Those that have a thick calcareous crust upon them, to which zoophytes of various kinds are fastened, have arrived at their full growth, and commonly contain the best pearls; but those that appear smooth, contain either none, or only small ones.

The art of forcing shell-fish to produce pearls was known, in the first centuries of the Christian era, to the inhabitants of the coasts of the Red sea, as we are told by the philospher Apollonius, (Philobrat. in Vita Apollon. lib. iii. c. 57; edit. Olearii, p. 139) who thought that circumstance worthy of particular notice. The Indians dived into the sea, after they had rendered it calm, and perhaps clearer, by pouring oil into it. They then entered the fish by means of a tube, to open their shells; and having pricked them with a sharp-pointed instrument, received the liquor that flowed from them, in small holes made in an iron vessel, in which they hardened into real pearls. Olearius says, that this account is to be found in no other author: but it has at least been copied by Tzetzes, whose words may in some measure serve as an explanation. Tzetzes Variorum, lib. ii. f. 373.

We are as yet too acquainted with shell-fish to be able to determine with certainty, how much truth there really may be in this relation: but we have great reason to conjecture from it, that the people who lived on the borders of the Red sea were then acquainted with the method of forcing shell-fish to produce pearls; and as the arts in general of the ancient Indians have been preferred without much variation, the proceeds employed by the Chinefe at present, to cause a certain kind of muscles to form pearls, seems to confirm the account given by Phlibobrates. In the beginning of the summer, at the time when the muscles repair to the surface of the water and open their shells, five or fix small holes are made in them; and having pricked them with a thread, are thrown into each of these. At the end of a year, when the muscles are drawn up and opened, the beads are found covered with a pearly crust, in such a manner, that they have a perfect resemblance to real pearls. The truth of this information cannot be doubted, though some experiments made in Bohemia for the fame purpose were not attended with success. It has been confirmed by various persones, and it is very probable, that some operations and secrets, without which the proceeds would prove fruitless even in China, may be unknown to the Europeans. Besides, many observations are known, which seem to shew the possibility of such an effect being produced. Professor Fabricius says, that he saw in the possession of Sir Joseph Banks, at London, large channes, brought from China, in which there were several bits of iron wire, incrusted with a subflance of a perfect pearly nature. These bits of wire, he saith, had been sharp, and it appeared as if the muscles, to secure themselves against the points of the wire, had covered them with this subflance, by which means they had been rendered blunt. May not therefore the process employed by the ancients be still practised? And may not these bits of wire have been the same as those spikes used by the people in the neighbourhood of the Red sea for pricking muscles, and which perhaps
PEARL.

happened from the hands of the Chines workmen and remained in the animals?

The invention therefore of Linnaeus cannot be called altogether new. That great man informed the king and council in the year 1761, that he had discovered an art by which muscles might be made to produce pearls, and he offered to divulge the method for the benefit of the kingdom. This however was not done, but he divulged his secret to one Bagge, a merchant at Gottenburg, for the sum of eighteen thousand copper dollars, which make about five hundred ducats. In the year 1780, the heirs of this merchant wished to sell to the highest bidder the sealed up receipt: but whether the paper was purchased, or who bought it, we do not know; for professor Retzius at Lund, of whom we enquired respecting it, could not inform us. Dr. Stever, in his Life of Linnaeus, vol. i. p. 360, says that the manuscript containing this secret is in the possession of Dr. J. E. Smith, in England. In the year 1763, it was said in the German newspapers, that Linnaeus was ennobled on account of this discovery, and that he bore a pearl in his coat of arms; but both these assertions are false, though professor Fabricius conjectures that the first may be true. Linnaeus received his patent of nobility, which, together with his arms, we have seen, in the year 1756, consequent long before he paid any thing respecting that discovery, of which the patents do not make the least mention. His arms have been taken for a pearl, is an egg, by which Mr. Tilas, whose bufines was it then to blazon the arms of ennobled families, meant to represent all nature, after the manner of the ancient Egyptians. The arms are divided into three fields, each of which, by the colour which forms the ground, express one of the kingdoms of nature; the red signifying the animal, and the green the vegetable, &c. Over the helmet, by way of crest, is placed the linnea: that beautiful little moth, the phalena lineella, thinning with its silvery colours, is displayed around the border instead of feftoons; and below is the following motto, "Famam extendere factis." Linnaeus once shewed us, among his collection of shells, a small box filled with pearls, and said, "Hos uniones con-rectaritificie me: sunt tantum quinque annorum, et tamen tam magni." "These pearls I made by my art, and though so large, they are only five years old." They were deposited near the mya margaritifera, from which most of the Swedish pearls are procured; and the fox, who was however not acquainted with his father's secret, paid the experiments which he made on this kind of Linnaeus himself assured us that they would succeed on all kinds.

We conjecture that Linnaeus alluded to this art, in his writings so early as the year 1746, or long before he ever thought of keeping it a secret. The passage we mean is in the sixth edition of his " Systema Naturae," where he says " Margarita. Teste excrecentia lateri interiori, dum ex-terius latus perforatur." See the article LINNAEUS.

That pearls are produced when the shells have been pierced or injured in a certain manner, is highly probable, and has been in modern times often remarked. It appears also, that the animal has the power of sometimes filling up such openings with a calcareous sub stance, which it deposits in them. This sub stance assumes the figure of the orifice, and the animal particles it contains, gives it its brightness and luftre. Pearl fishers have long known that muscles, the shells of which are rough and irregular, or which exhibit marks of violence, commonly contain pearls, though they are found also in others, in which the same appearances are not observed. We are perfectly aware that experiments which some have made by piercing the shells of muscles, have been unsuccessful; but this does not prove that it is impossible to procure pearls in that manner. Those who made them did not perhaps pierce the proper part of the shell; per haps they made the orifice too large that it weakened the animal; and they may not have chosen the properest fon of the year. The strongest objection, however, which can be made on this subject, is the undeniable truth that the proper valuable pearls are not found adhering to the shell, but in the body only; and that therefore those calcareous balls which fill up holes, cannot be perfect pearls. But from the words of Linnaeus above quoted, we are led to conjecture, that he only made a hole in the shell without piercing it quite through. Linnaeus also may have done some injury to the animal itself, when it opened its shell; for it is certain that tesselaceous animals are frong-lived, and can easily suf fice any violence. It appears by the Transactions of the Swedish Academy, that some have been of opinion that shell-fish might be made to produce pearls by a particular kind of nourishment; and Linnaeus thinks that these excre cences would be more abundant, were the muscles placed in water impregnated with calcareous matter; but professor Linnaeus seems certain that his father employed none of these methods. Beckmann's Hist. of Inventions, vol. ii.

The perfection of pearls, whether round, in form of pearls or olives, or irregular, confuits chiefly in the luftre and clearness of the colour, which jewellers call the water. These valuable pearls are not found in pearl-fish, but in the pearles of other border on the yellow, which some Indians and Arabs prefer to the white; others are of a lead colour; others border on black; and others are quite black. They are all liable to change with wearing: in eighty or a hundred years they usually become of little value, especially the white ones, which often turn yellow, and spoil in forty or fifty years' time.

The difference of colours, doublets, arises from the different parts of the oyster in which they are formed. When the feed happens to be thrown into the melentery or liver, or the parts corresponding thereto, it is no wonder if the impuri ties of the blood change the natural white.

The oriental pearls are the finest, on account of their largeness, colour, and beauty, being of a silver white; whereas the occidental pearls seldom exceed the colour of milk.

In Europe pearls are sold by the carat-weight, the carat containing four grains. In Asia, the weights used for pearls are different, in different places. Linnaeus says, that the square of the square of their weight is the square of their weight; thus, the price of a pearl of one carat being letted at 8t. to find the price of a pearl weighing six carats; first find the square of 6, viz. 36: which multiplied by 8, gives 288 shillings, or 14l. 8s. the price required.

The term pearl is only properly applied to what grows independent of the shell. The shell itself is rather called naure of pearl: those pieces which have grown thereto, and have since been separated by the address of the workman, are called cesms of pearls; which are, in effect, nothing but roughish excre cences, or pieces of the shell, though frequently used for real pearl.

Pearls, F. Bouhlers oberves, have this advantage over precious stones dug out of rocks, &c. that the latter owe their luftre to the induftry of men; nature only, as it were, leaves them out, and leaves the finifhing of them to art: but the former are born with that beautiful water which gives them their value. They are found perfectly po hised in the abysses of the sea; and nature has put the last hand to them before they are separated from their mother.

Pearls have been used as ornaments from the earliest ages.
In the time of Job pearls were accounted to be of great value. Job, ch. xxviii. v. 18.

Pearls of unusual figures, i.e. neither round, nor in the pear form, are called barognas, and our Scotch pearls: those of unusual sizes are called parangons: such as were that of Cleopatra, valued by Pliny at centuries HS, or 80,000l. flering; that brought in 1574 to Philip II. of the size of a pigeon's egg, valued at 14,400 ducats; that of the Emperor Rudolph, purchased by Boetius, called la pergrina, or the incomparable, of the shape of a midnight pear, and weighing thirty carats; and that mentioned by Tavernier, in the hands of the emperors of Persea, in 1633, bought of an Arab for 32,000 tazons, which, at 3k. 9s. the tazon, amounts to 110,400l. flering.

That pearls are calcareous is inferred from Cleopatra's having been able to dissolve her's in vinegar, and by these means to gain a wager from her lover, as we are told by Pliny (lib. ix. cap. 35.), and Macrobius (Saturn. lib. ii. cap. 15.) She must, however, have employed stronger vinegar than that which we use for our tables, as the pearls, on account of their hardness and their natural enamel, cannot be easily dissolved by a weak acid. Cleopatra, perhaps, broke andounded the pearls; and it is probable that the afterwards diluted the vinegar with water, that she might be able to drink it; though dissolved calx destroys acrids and renders them imperceptible to the tongue. We are told that the dissipated Clodius gave to each of his guests a pearl dissolved in vinegar to drink; "ut experientur in gloria palatii," says Pliny, "quid lapertum margarita? atque ut mirae placuerne, ne folus hoc forest, angulos unione convivis acquittedendas dedit." Horace (lib. ii. sat. 3.) says the same.

Caligula, also, "margaritas praestititinas aceto lipo-factis forbebat." Suet. cap. 37. That pearls are soluble in vinegar is remarked in Pautianus, l. viii. c. 18. and Vitruvius, l. viii. c. 3.

Pearls have been reckoned of some use in medicine; but they were only the smallest sort, called seeds of pearls that were used. The quantity required was, that they should be white, clear, and transparent; and truly oriental. They served to make cordial potions, formerly much valued, but now fallen from their ancient reputation; and scarcely ordered by any but charlatans.

The ladies also use certain preparations of pearls, as they are made to believe, for their complexions: such as the whites of pearls; flowers, essences, spirits, tintures, &c. of pearl; but they are all apparently deceits.

Pearls, Ounce. See Ounce.

Pearl-Fisheyr. Pearls are taken in the seas of the East Indies, in hope of America, and in some parts of Europe.

Pearl-Fisheys of the East are, 1. The island of Bahrein, or Bahrain, in the Persian gulf; this the Portuguese were masters of while they held Ormus and Macatay; but it has been returned to the sultan of Persea, since the time that prince, with the assistance of the English, took from them Ormus, and the Araba Macatay. The revenue arising from this fisheyr to the chieft of Bulheer, has been diminished by the pretentions of the Houls, a strong Arabian tribe between Gombrow and Cape Burdilian, who refused to pay for the permission of fishyng. See Bahrein.

2. The fisheyr of Catifea, on the coast of Arabia Felix, over against Bahrein.

3. That of Manaur, a sea-port in the isle of Ceylon. The pearls here fished are the finest in all the East for their water, and roundnes; but they seldom exceed two carats. See Manner of Fishyng for Pearls in the East Indian, farther on.

Lastly, there are pearls fished on the coast of Japan; but they are coarse and irregular, and very little.

The pearls of Bahrein and Catifea are those that were formerly sold in the Indies; they border a little on the yellow, but the Eastern people do not value them the less for it: they esteem it the sign of their being ripe, and mature; and are persuaded, that those which have this yellowish tincture naturally never change their colour; and that, on the contrary, those of the white water do not hold above thirty years before the pearl assumes a filthy yellow colour, by reason of the heat of the climate, and the sense of the persons who wear them. Some of the pearls, taken near the isles of Bahrein on the Arabian side, weigh 50 grains, but those are esteemed large which weigh from 10 to 12 grains.

Pearl American, Fisheys, are all in the great gulf of Mexico, along the coast of the Tern Firma. There are five of them.

1. The fisheyr of Cubagna, an island five leagues from New Andalusia, in 100 deg. north lat.

2. That of the island Marguerites, or Pearl Island.

3. That of Comogote near the Tern Firma.

4. That of the river De la Hach, called La Reneheria.

5. That of St. Martha, sixty leagues from the river de la Hach.

These pearls of these three last fisheys are usually of a good weight, but ill formed and of a livid water. Those of Cubagna seldom exceed five carats, but are found in abundance. But the greatest quality, and the finest, both with regard to weight and water, are those of the island of Marguerites.

Pearl-Fisheyr, in Chinesian Tartary, is near the city Nipefts, situate on a lake of the same name: the pearls here are less beautiful than those of Baharein, and the fisheyr less plentiful. It was this fisheyr that occasioned the war between the Chines and Muscovites, terminated towards the end of the 17th century, by the Jesuits Pereira and Gerebion; when the lake, which is of great extent, was divided between the two nations, each of which had pretended to the whole.

The Turks or Tartars call this valued product "Marguerit," signifying a globe of light; from which, and the Persian name "Mervari," i.e. the offspring of light, was derived "Marguerite," the appellation in southern Europe.

There are some pearl fisheys also in the South sea, but they are very inconsiderable. The fisheys of the Bornean islands were noted in the time of Magalhacens; Pigaletta, his companion, reporting, that a Bornean monarch polished two pearls, found here, as large as pulleetts' eggs.

Pearl-Fisheys of Europe are in some places on the coast of Scotland, particularly in the rivers Teith and Ythan, which furnish a large kind of myra or nuclele, and pearls, some of which are in the shape of a pear, and others pink on one side; and in a river of Saxony called Eliter, where the shells are about six inches long, but the pearls found here are no ways comparable to those of the East Indies, or of America; though they serve for necklaces, which are sold sometimes for a thousand crowns, and upwards. See an account of pearl fishyng, in the north of Ireland, Philos. Tranl. N° 198.

Pearls, Manner of fishyng for, in the East Indies; particularly in the isle of Ceylon. About 12 miles from Manaur, and in the gulf so called, lies the bay of Condatchy, where all the boats are collected for the pearl-fisyng. At this time the bay is crowded with small vessels, and the beach presents an astonishing multitude of people from every quarter of India. Several thousands of people
of different colours, countries, calls, and occupations, continually pailling and repailling; vast numbers of small tents and huts erected on the shore, with the bazar or market place before them; a multitude of boats returning in the afternoon from the pearl banks; the anxious countenances of the boat-owners, while the boats are approaching the shore, and the eagerness and avidity with which they run to them when arrived, in hopes of a rich catch; the vast number of jewellers, brokers, merchants, of all colours and all descriptions, both natives and foreigners, who are occupied in some way or other with the pearls, some separating and assorting them, others weighing and ascertaining their number and value, while others are hawking them about, or drilling and boring them for future use:—all these circumstances tend to impress the mind with the value and importance of that object, which can of itself create this scene.

The banks, where the fishery is carried on, extend several miles along the coast from Manna southward of Aripito, Condathcy, and Pomparipo. The principal bank is opposite to Condathy, and lies out at sea about 20 miles. The first busses, previous to the commencement of the fishery, is to survey the different oyster banks, to ascertain the state of the oysters, and to make a report on the subject to government. If the quantity is found to be sufficient, and in a proper state of maturity, the particular banks to be fished that year are put up for sale to the highest bidder, and are usually purchased by a black merchant. Sometimes the governor attains it more advantageous to fish the banks on its own account, and to dispose of the pearls afterwards to the merchants. When this plan is adopted, boats are hired for the seafon on account of government from different quarters, at a variable price, but usually from five to eight hundred pagodas for each boat. When this plan was pursued, as it generally was by the Dutch, the governor and council of Ceylon aimed a certain per centage on the value of the pearls;—or if the fishing of the banks was disposed of by public sale, they bargained for a stipulated sum to themselves over and above what was paid on account of government. This perquisite was claimed on account of their trouble in surveying and valuing the banks. As it would not be expedient to fih the whole of the banks in one year, they are divided into three or four different portions, one portion of which is fished annually in succession. By this contrivance a sufficient interval is allowed for the oysters to attain their proper growth; and as the portion fished used generally recovers its maturity by the time the half portion has been fished, the fishery becomes almost regularly annual. The oysters are supposed to attain their compleat state of maturity in seven years; for if they be left too long, the pearls become too large, and so disagreeable to the fishes, that they vomit and throw them out of the shell.

The fishing seafon commences in February, and ends about the beginning of April. The period allowed the merchant for fishing the banks is six weeks, or at the most two months; but the interruptions that occur prevent the fishing days from exceeding more than about 30. In a bad season, the purchaser of the fishery is allowed a few days more as a favour. The number of holidays observed by persons of different nations and sects, is one principal cause of a considerable interruption. Many of the divers are of a black race, denominated Marawas and Parawas, that inhabit the opposite coast of Tutucuren; these people, though of the Malabar call, are Roman Catholics, and leave off work on Sundays to attend prayers at the chapel of Aripito. But if stormy days, or Hindoo and Mahometan f festivals (which are never neglected on any account by the natives) occur to interrupt the regular course of fishing, the farmer is some times dircous that the Catholic Marawas should make up for lost time by working on Sundays; but he cannot compel them to do this without an order from the chief civil officer of the government, who is appointed to superintend the fishery. The boats and donies employed in the fishery do not belong to Ceylon, but are brought thither from different parts of the continent; particularly Tutucuren, Caracal, and Negapatam, on the Coromandel coast; and Colang, a fishery place on the Malabar coast, between Cape Comorin and Arriyana. The divers from Colang are accounted the belt, and are only rivalled by the Lubbahs, a tribe of Moors, who remain on the island of Manna, in order to be trained in this art. Before the fishery begins all the boats rendezvous at Condathy, and are here numbered and contracted for.

During the seafon, all the boats regularly fail out and return together. A signal gun is fired at Aripito about ten o'clock at night, when the whole fleet sets sail with the land-breeze. They reach the banks before day-break, and at fun-rise commence fishing. In this they continue buily occupied till the sea-breeze, which arises about noon, warns them to return to the bay. As soon as they appear within sight, another gun is fired, and the colours hoisted, to inform the anxious owners of their return. When the boats come to land, their cargoes are immediately taken out, as it is necessary to have them completely unloaded before night. Whatever may have been the successes of their boats, the owners seldom wear the looks of disappointment; for, although they may have been unsuccessful one day, they look with the most amusement from better fortune to the next; as the Brahmins and conjurers, whom they implicitly trust in defiance of all experience, understand too well the libraty of a man in hopes of good fortune, not to promise them all they can desire.

Each of the boats carries twenty men, with a Tindal or chief boatmen, who acts as pilot. Ten of the men row, and the divers in re-ascending. The other ten are divers; they go down into the sea by five at a time; when the first five come up the other five go down; and, by this method of alternately diving, they give each other time to recruit themselves for a fresh plunge.

In order to accelerate the descent of the divers, large stones are employed: five of these are brought in each boat for the purpose; they are of a reddish granite, common in this country, and of a pyramidal shape, round at top and bottom, with a hole perforated through the smaller end sufficient to admit a rope. Some of the divers use a stone shaped like a half moon, which they fall on the belly when they mean to descend, and thus keep their feet free. These people are compelled all to dive from their very infancy, and fearlessly descend to the bottom in from four to ten fathoms water, in search of the oysters. The diver, when he is about to plunge, seizes the rope, to which one of the stones we have described is attached, with the toes of his right foot, while he takes hold of a bag of net-work with those of his left; it being customary among all the Indians to use their toes in working or holding as well as their fingers; and such is the power of habit, that they can pick up even the smallest thing from the ground with their toes almost as nimblly as an European could with his fingers. The diver, thus prepared, seizes another rope with his right hand, and holding his nostrils shut with the left, plunges into the water, and by the assistance of the stone speedily reaches the bottom. He then hangs the net round his neck, and with much dexterity, and all possible dispatch, collects as many oysters as he can while he is able to remain under water, which is usually about two minutes. He then refumes his former position, makes a signal to those above by pulling the
the rope in his right hand, and is immediately by this means drawn up and brought into the boat, leaving the flume to be pulled up afterwards by the rope attached to it.

The exertion undergone during this procés is so violent, that, upon being brought into the boat, the divers discharge water from their mouths, ears, and nostrils, and frequently even blood. But this does not hinder them from going down again in their turn. They will often make from forty to fifty plunges in one day; and at each plunge bring up about a hundred oysters. Some rub their bodies over with oil, and fluff their ears and noses to prevent the water from entering; while others use no precautions whatever. Although the usual time of remaining under water does not much exceed two minutes, yet there are instances known of divers who could remain four and even five minutes, which was the case with a Caffire boy the last year we visited the fishery. The longest instance ever known was that of a diver who came from Aninga in 1797, and who absolutely remained under water full six minutes.

The effects of a diver, which appears so extraordinary and full of danger to an European, becomes quite familiar to an Indian, owing to the natural supplenees of his limbs, and his habits from his infancy. His chief terror and risk arise from falling in with the ground-shark while at the bottom. This animal is a common and terrible inhabitant of all the seas in these latitudes, and is a source of perpetual uneasiness to the adventurous Indian. Some of the divers, however, are so skillful as to avoid the shark even when they remain under water for a considerable time. But the terrors of this foe are to continually before their eyes, and the uncertainty of escaping him so great, that these superstitious people look for safety in supernatural means. Before they begin diving, the priest, or conjurer, is always consulted, and whatever he says to them is received with the most implicit confidence. The preparation which he enjoins them consists of certain ceremonies according to the cast and sect to which they belong, and on the exact performance of these they lay the greatest stress. Their belief in the efficacy of these superstitious rites can never be removed, however different the event may be from the predictions of their diviners: government therefore wisely gives way to their prejudices, and always keeps in pay some conjurers to attend the divers and remove their fears. For though these people are so skilful and so much masters of their art, yet they will not on any account defecd till the conjurer has performed his ceremonies. His advices are religiously observed, and generally have a tendency to preserve the health of the devotee. The diver is usually enjoined to abstain from eating before he goes to plunge, and to bathe himself in fresh water immediately after his return from the labours of the day.

The conjurers are known in the Malabar language by the name of Pillal Karras, or binders of sharks. During the time of the fishery, they stand on the shore from the morning till the boats return in the afternoon, all the while muttering prayers, diluting their bodies into various strange attitudes, and performing ceremonies to which no one, not even themselves we believe, can attach any meaning. All this while it is necessary for them to abstain from food or drink, otherwise their prayers would be of no avail. These acts of ablution, however, they sometimes dispense with, and regulate themselves with taddy, a species of liquor diffused from the palm tree, till they are no longer able to stand at their devotions.

Some of the conjurers frequently go in the boats with the divers, who are greatly delighted at the idea of having their protectors along with them; but in our opinion, this fancied protection renders the divers more liable to accidents, as it induces them to venture too much and without proper precautions, in full confidence of the infallible power of their guardians. It must not however be imagined that these conjurers are altogether the dupes of their own arts, or that they accompany their votaries to the fishery merely from an anxious care of their safety; their principal purpose in going thither is, if possible, to catch a valuable pearl. As this is the case, it is evident that the superintendent of the fishery must look upon their voyages with a jealous eye; for, however, is the devoted attachment of their votaries, that he is obliged to pass it over in silence, or at least to conceal his suspicions of their real intentions. He must also never hint a doubt of their power over the sharks, as this might render the divers scrupulous of committing themselves to the deep, or indeed deter them from filling at all. The conjurers reap here a rich harvest; for, besides being paid by the government, they get money and presents of all sorts from the black merchants and those successful in filling up the oysters.

The appearance of a single shark is sufficient to spread dismay among the whole body of divers; for as soon as one of them feels a shark he instantly gives the alarm to his companions, who as quickly communicate it to the other boats: a panic speedily freezes the whole, and they often return to the bay without filling any more for that day. The sharks which create all this alarm sometimes turn out to be nothing more than a sharp flume on which the divers happen to alight. False alarms excited in this manner prove very injurious to the progress of the fishery, every means is employed to avert whether they are well or ill founded; and if the latter be the case, the authors of them are punished. These false alarms occurred more than once in the course of the last two or three seasons.

The divers are paid differently according to their private agreement with the boat-owners. They are paid either in money, or with a proportion of the oysters caught, which they take the chance of opening on their own account; the latter is the method most commonly adopted. The agreements with the people who hire out the boats are conducted much in the same manner. They contract either to receive a certain sum for the use of their boats, or pay the chief farmer of the banks a certain sum for permission to fish on their own account. Some of those who pursue the latter plan are very successful and become rich; while others are great losers by the speculation. Oyster lotteries are carried on here to a great extent; they consist of purchasing a quantity of the oysters unopened, and running the chance of either finding or not finding pearls in them. The European officers and gentlemen, who attend here upon duty or through curiosity, are particularly fond of these lotteries, and very frequently make purchases of this sort.

The boat-owners and merchants are very apt to lose many of the belt pearls while the boats are on their return to the bay from the banks, as the oysters, when alive and left for some time undisturbed, frequently open their shells of their own accord: a pearl may then be easily discovered, and the oyster prevented by means of a bit of graft or loft wood from again closing its shell, till an opportunity offers of picking up the pearl. These fellows, who are employed to search among the fish to commit many depredations, and even swallow the pearls to conceal them; when this is suspected, the plan followed by the merchants is to lock the fellows up, and give them strong emetics and purgatives, which have frequently the effect of discovering the stolen goods.

As soon as the oysters are taken out of the boats, they are carried by the different people to whom they belong, and placed
placed in holes or pits dug in the ground to the depth of about two feet, or in small square places cleared and fenced round for the purpose; each person having his own separate division. Mats are spread below them to prevent the oysters from touching the earth; and here they are left to die and rot. As soon as they have passed through a stage of putrefaction, and have become dry, they are easily opened without any danger of injuring the pearls, which might not be the case if they were opened fresh, as at that time to do requires great force. On the shell being opened, the oyster is minutely examined for the pearls; it is usual even to boil the oyster, as the pearl, though commonly found in the shell, is not unfrequently contained in the body of the fish itself.

The trena occasioned by the oysters being left to putrefy is intolerable; and remains for a long while after the fishery is over. It corrupts the atmosphere for several miles round Condatchy, and renders the neighbourhood of that country extremely unpleasant till the monsoons and violent south-west winds set in and purify the air. The nauseous smell, however, is not able to overcome the hopes of gain: for months after the fishing feason, numbers of people are to be seen carelessly searching and poring over the sands and places where the oysters had been laid to putrefy; and some are now and then fortunate enough to find a pearl that amply compensates their trouble in searching after them. In 1757 while Mr. Andrews was collector, a Coochy, or common fellow of the lowest class, got by accident the most valuable pearl feen that feason, and sold it to Mr. Andrews for a large sum.

The pearls found at this fishery are of a whiter colour than those got in the gulf of Ormus, on the Arabian coast, but in other respects are not accounted so pure, or of such an excellent quality; for though the white pearls are more esteemed in Europe, the natives prefer those of a yellowish or golden cast. Off Tutucoreen, which lies on the Coromandel coast, nearly opposite to Condatchy, there is another fishery; but the pearls found there are much inferior to those two species we have mentioned, being tinted with a blue or greyish tinge.

In preparing the pearls, particularly in drilling and boring them, the black people are wonderfully expert. We were very much struck with the instrument they employ in drilling, as well as the dexterity with which they use it. A machine made of wood, and of a shape resembling an obtuse inverted cone, about six inches in length, and four in breadth, is supported upon three feet, each twelve inches long. In the upper flat surface of this machine holes or pits are formed to receive the larger pearls, the smaller ones being in with a little wooden hammer. The drilling instruments are spindles of various sizes according to that of the pearls; they are turned round in a wooden head by means of a bow handle to which they are attached. The pearls being placed in the pits which we have already mentioned, and the point of the spindle adjusted to them, the workman presses on the wooden head of the machine with his left hand, while his right is employed in turning round the bow handle. During the process of drilling, he occasionally moistens the pearl by dipping the little finger of his right hand in a cocoa-nut filled with water, which is placed by him for that purpose; this he does with a dexterity and quickness which fearlessly impede the operation, and can only be acquired by much practice.

They have also a variety of other instruments both for cutting and drilling the pearls. To clean, round, and polish them to that state in which we see them, a powder made of the pearls themselves is employed. These different operations in preparing the pearls occupy a great number of the black men in various parts of the island. In the black town or pettah of Colombo in particular, many of them may every day be seen at this work, which is well worth the attention of any European who is not already acquainted with it.

As the pearl fishery has been formerly, without due consideration, exhausted by the avarice of the Dutch, it is not perhaps at present so productive as it once was. However, the revenue which government derives from it is still considerable, and may by good management be increased. Pearls are considered as the next staple of the island to cinnamon; the concourse of people attracted by it affords a facility for disposing of the other produce; and by proper management, advantage might be taken of the opportunity here offered to introduce British manufactures into various parts of India. Percival's Account of Ceylon. Afniat: Researches, vol. v. p. 303; &c.

**Pearl, Manner of fishing for, in the West Indies.**

The seafar for fishing there is usually from October to March. In this time there set out from Carthagena ten or twelve bars, under the convey of a man of war called l'Armadilla. Each bar has two or three slaves for divers.

Among the bars there is one called Caputana; to which all the rest are obliged to bring at night what they have caught in the day, to prevent frauds. The divers never live long, by reason of the great hardships they suffer; continuing sometimes under water above a quarter of an hour. The method is the same as in the East Indian fisheries.

The Indies esteemed pearls before the discovery of America; and when the Spaniards arrived there, they found great quantities stored up, which the Americans set great value on. But they were almost all imperfect, and their water yellow and smoky, because they used fire in opening the fishers.

As to pearls in form of pearls, though equally perfect, and of equal weight with the round ones, their value is much inferior; however, when two are found that match well, their value is left but by one-third.

**Pearls, To blanch and cleanse.** First soak and cleanse them in bran-water, then in clear warm water, and last of all steep them in mercurial water, then boring and hang them in a glass, close it well, and let them in the sun to dry.

The bran-water is made thus: boil two good handfuls of wheaten bran, in a quart of water, till all the strength of the bran is drawn out, which use thus: take a new glazed earthen pan, in which put your pearls on a fire, and pour the third part of the bran-water upon it: when they have foaked, and the water is just warm, rub your pearls gently with your hands, to clean them the better, and continue this till the water is cold; throw off that, and pour on another third part of the bran-water, that is boiling, proceed with this as you did before, and when cold, throw it away, and pour on the remainder of the water, still proceeding as before. After this, heat fair water, and pour it on your pearls, to refresh them, and to wash away the remains of the bran, by shifting them, and pouring on fresh warm water: this do three, without handling your pearls; then lay them on a sheet of clean white paper, and dry them in a shade; after which dip them into mercurial water, to bring them to perfection. Pollitt, Dict. Com.

**Other Methods in blanching of Pearls.—Pound alabaster to an impalpable powder, rub the pearls therewith, very gently: this will not only cleanse them, but if you let them remain in this powder twenty-four hours afterwards, they will still be...**
PEA

be the better for it. White coral has the same effect, used in the like manner. White tarlet, calcined and divelled of all its moisture, is very good for the same purpose.

Salt dissolved, filtered, coagulated, well dried, and ground, is as effectual as any of the former things for cleaning of pearls, by rubbing them therewith; and if afterward you lay them up in some coarce ground millet, it will contribute to their brightness.

PEARLS, False or Artificial, are counterfeit or fictitious pearls, resembling the true ones in shape, lustre, colour, and polish; popularly called beads.

These anciently were only made of glass, inclosed on the inside with a pearl-coloured varnish, which was first purfued by some artists at Murano; or with a kind of amalgam or coating of quicksilver within; afterwards they used small balls of wax or gum, covered with a pearl-coloured enamel. These were praised on account of their lustre; but as their beauty was destroyed by moisture, they did not continue long in use.

There has since been invented in France another manner of making them, so near the natural in lustre and water, that they deceive a good eye. These are what the ladies now generally wear in defect of true pearl; small necklaces whereof they depile, and the large ones are generally too dear.

PEARLS, False, Method of making. Take of three distilled vinegar, two pounds; Venice turpentine, one pound; mix them together into a mafs, and put them into a cucurbit; fit a head and receiver to it, and after you have luted the joints, set it, when dry, on a sand furnance, to distill the vinegar from it; do not give it too much heat, lest the fluid swell up: after this put the vinegar into another glasses cucurbit, in which there is a quantity of seed pearl, wrapped in a piece of thin silk, but so as not to touch the vinegar; put a cover or head upon the cucurbit, lute it well, and put it in bal. Marie, where you may let it remain a fortnight.

The heat of the balneum will raife the fumes of the vinegar, and they will ftochen the pearls in the fift, and bring them to the confluence of a paffe; which being done, take them out, and mould them to what bignefs, form, and shape you please. Your mould muff be of fine silver, the inside gilt; you must alfo refrain from touching the paffe with your fingers, but use silver gilt utenils, w'h which fill your moulds. When they are moulded, bore them through with a hog's brille or gold wire, and let them dry a little; then thread them again on gold wire, and put them into a glafs; clofe it up and let them in the fun to dry; after they are thoroughly dry, put them in a glafs matrafs into a fream of running water, and leave them there twenty days; by that time they will conftaunt the natural hardnefs and solidity of pearls: then take them out of the matrafs, and hang them in mercurial water, where they will molten, fwell, and affume their oriental beauty; after which shift them into a matrafs hermetically clofed up, to prevent any water coming to them, and let it down into a well, to continue there about eight days: then draw the matrafs up, and in opening it, you will find pearls exactly reembling oriental ones.

The mercurial water is thus prepared: take plate-tin of Cornwall, calcine it, and let the calx be pure and fine; then, with one ounce of the calx and two ounces of prepared mercury, make an amalgam; wash it with fair water, till the water remains infipid and clear; then dry the amalgam thoroughly, put it into a matrafs over the furnace, giving it such a hent as is requisite for sublimation. When the matter is well sublimated, take off the matrafs, and let it cool.

Take out that sublimate, add one ounce of Venice sublimate to it, and grind them together en a marble; put this into another matrafs, clofe it well, and let it inside down in a pail of water, and the whole mafs will diffuse itself, in a little time, into mercurial water: this dry, filter it into a glafs receiver, let it on a gentle fire to coagulate, and it will turn into a cryftalline sublimate; beat this in a glafs mortar, with a glafs pelle, to a fine powder; ftrain it through a fine fieve, and put it into a matrafs, fip it clofe up, and place it in balne Marie; there let it remain till it refolves again into water, which will be fit for the above mentioned ufe. Poftl. Diet. Com.

The fieur Janin, or Jaquin, having obferved, that the fcales of a little fish called the bleaf, found plentifully in the river Marne, had not only all the luflre of the real pearl, but that, after beating them to powder in water, they returned to their former brilliance upon drying; hefhought himfelf of fetting a piece, or little mafs thereof, in the cavity of a bead, or grain of giragol, which is a kind of counterfeit opal made of glafs, and bordering much on the colour of pearl. The difficulty was to get it there, and when it was within, to spread it equally throughout the bead. A little glafs tube, fix or feven inches long, and a line and half in diameter, but very harp at one end, and a little creare prepared for the introducing of the matter, by blowing it with the mouth, after having taken up a drop of this mixture with the pointed extremity of the tube; and to spread it throughout the inner circumference, he contended himself to make it gently a long time, in a little oifer basket lined with paper.

The pulverized scales, ftaben by this motion in the inside of the bead, refume their luflre as they dry. To increase this luflre, in winter, they lay the beads in a hair fiwe, or a bolting cloth, which they fubfend to the ceiling, and under it, at fix feet dilance, they lay heaps of hot afhes. In summer they fubfend them in the fame manner, but without any fire.

The pearls, thus well dried, become very brilliant; and nothing remains but to fip up the aperture, which is done by melting wax, conveyed into it with a tube like that used in introducing the powdered fcales.

After clearing off the superfuous wax, they perforate the pearls with a needle, and ftring them; and thus they form a necklace.

PEARLS, Mother of, is the shell not of the pearl oyster, but of another sea-fish of the oyster kind.

The shell withinfide is very smooth and polifhed, and of the whitenefs and water of pearl itself; and it has the fame luflre withoutfide, after the firft laminæ or leaves, which make the outer coat of this rich shell-fish, have been cleared off with aqua fortis, and the lapidary's mill. It is used in infaid works, and in feveral toys, as snuff-boxes, &c.

PEARLS, Mosé of, are certain excrefences, or prominent places, in form of half-pears; sometimes found in the bottoms of pearl shells.

The lapidaries have the addrefs to faw off these protuberances, to join them together, and to ftre them in feveral works of jewellery, as if they were real pearls.

PEARL, in Heraldry, is ufed by such as blazon with precious stones instead of colour and metals, for argent, or white.

PEARL, in Ichthyology, a name given by us in the parts about London, to that fish which is called in Cornwall, and other parts of the west of England, lug-aleaf: it is the rhombus levius of the generality of authors. See PLEUROSCECTE RHOMBUS.

PEARL.
PEARL Keys, in Geography, islets or rocks in the Spanish main, on the Mosquito shore. N. lat. 17° 26'. W. long. 82° 45'.

PEARL Key Lagoon, a bay on the Mosquito shore. N. lat. 11° 15'. W. long. 85° 12'.

PEARL Islands, a cluster of small islands in the Atlantic, near the coast of Nicaragua. N. lat. 12° 35'. W. long. 83° 30'.

PEARL Islands, or King's Islands, small islands in the bay of Panama; 12 leagues from the city of Panama. They are low, and produce wax, water, fruit, fowls, and hogs, and they afford good harbours for ships. N. lat. 7° 12'. W. long. 81° 45'.

PEARL Island, a small island in the gulf of Mexico, at the mouth of the Mississippi.—Also, a small island in the West Indies. N. lat. 14° 55'. W. long. 70° 15'.

PEARL River, a river of America, which rises in the Chaetau country in the W. part of the Mississippi territory, and pursues a southerly course to the gulf of Mexico, is navigable upwards of 150 miles. Its principal mouths are near the entrance at the E. end of the Regules, through which is the passage to lake Pontchartrain; it has seven feet at its entrance, and deep water afterwards. In 1760 there were some settlements on this river, where were raised tobacco, indigo, cotton, rice, Indian corn, and all sorts of vegetables. The land produces a variety of timber, fit for pipe and hog-head flaves, masts, yards, and all kinds of planks for ship-building.—Also, a river of Chiampa, which runs into the Chinchea sea, N. lat. 10° 54'. E. long. 105° 33'.

PEARL Rocks, a group of low and dangerous rocks in the North Pacific ocean, near the S. extremity of Calvert's island. N. lat. 51° 54'. E. long. 231° 52'.

PEARL-Ash, in Chemistry, Arts, and Manufactures. The crude potash, when first obtained by the combustion of vegetable matter, abounds with a great variety of impurities, consisting of neutral salts, sulphur, charcoal, and some earthy matter.

When this sub stance is washed with clean water, and the insoluble matter allowed to subside, the clear liquor is evaporated in large shallow iron pans. The residuum consists of potash properly so called, still containing some neutral salts, but free from its other impurities. It is a mass of a white colour, from which it is called pearl-ash. In this state it is used by bleachers, glaziers-makes, dyers, and others. The real potash contains, for which it is valued, is combined with carbonic acid in the proportion of 19 of acid to 42 potash. The remainder consists of sulphur and muriat of potash. See Carbonat of Potash.

The goodness of pearl-ashes must be distinguished by the uniform and white appearance of them; they are subjet, however, to a common adulteration, not easily distinguishable by the appearance, which is done by the addition of common salt. In order to discover this fraud, take a small quantity of the suspected salt, and after it has been softened by lying in the air, put it over the fire in a cavel: if it contains any common salt, a cracking and kind of light explosion will take place, as the salt grows hot.

The pearl-ashes are much used in the manufacture of glazes, and require no preparation; except where very great transparence is required, as in the case of looking-glasses, and the belt window-glasses. For this purpose diffuse them in four times their weight of boiling water; when they are diffused, let the solution be put into a clean tub, and suffered to remain there twenty-four hours, or longer. Let the clear part of the fluid be then decanted off from the sediment, and put back into the iron pot in which the solution was made: in this let the water be evaporated away till the salts be left perfectly dry again. Keep those that are not designed for immediate use in stone jars, well secured from moisture and air.

To those who buy large quantities of this article, it may not be unwise to know the means of assaying it. Weigh 100 grains of it before it has been exposed to the air; then lay out a known weight of sulphuric acid, of the specific gravity of 1.8, or such as boils at the temperature of 450'. Diffuse the pearl-ash in its own weight of distilled water. With a small fucking tube add sulphuric acid by a small portion at once, till no more effervescence takes place. The weight of the remainder of the sulphuric acid will show how much has been added to the solution. Then for every grain of sulphuric acid of the above strength taken up, allow .82 of a grain of pure potash. Thus, if 100 grains of the pearl-ash take up 40 grains of sulphuric acid, of the specific gravity 1.8, the pure potash contained in the 100 will be 32.8 grains. See Pota sh.

PEARL-Bailey. (See Bailey.) This affords, to a microscopic observer, a peculiar kind of mint worthy of attention, and very different from the common species. The bodies of these have some brown marks upon them, and have not such long hairs as the common mires have; the hinder part of the body also is of a different make. They have eight legs; and before the head there stand two weapons twice as thick as the legs, and of about half their length; these are divided towards their ends with joints like horns, and at their ends a fort of nails formed with sharp and crooked claws; and one of the longest joints is ferrated at the edge like a saw. These weapons serve not only as arms and hands to seize hold of things, but they also serve as a defence; for as soon as any danger threatens the creature's head, it erects them both, and makes them meet and fold into one another over the head, as we can join our hands and fingers together in the same erect posture. Phil. Tranf. No. 222.

PEARL Colour, in Glass. This beautiful colour is given to glass in the following manner: put tartar calcined to a whiteness into purified crystal, while in fusion, at several times, in small quantities, mixing it very finely every time, till the glass is become of the desired colour: and when it is, work it as quick as can be, for it is a colour that is quickly gone. See Glass.

PEARL Shell or Gafer. See Mica.

PEARL Pin, or Web, in Medicine, an unnatural speck, or thick film over the eye. See Pannus.

PEARL, White, is the powder of pearls, or the finer parts of oyster-shells, much used in miniature paintings. The method of preparing it is to take the oysters, as they are found on the sea-coast, calcined by the sun, or otherwise to dry them over the fire, till they may be easily powdered; to scrape off from these shells all the external or other parts that are not of the most perfect whiteness; and to leav e them well with water on the stone, and wash the powder over till it is thor oughly fine. See Pearl.

PEARL, White, as a cosmetic, or magi fi ry of bismuth, see Bismuth.

PEARLED CROWNS. See Crown.

PEARLSTONE, so called by Jameson, and Perles in Werner, in Mineralogy. Its colours are pearl and smoke-grey, yellowish-grey, flesh-red, and reddish-brown, also greyish-black. It occurs in round and longish vehicles; its lustre is shining and pearly; its fracture is small, and imperfectly conchoidal. It is composed of thin concentric lamellar concretions; transluent on the edges, easily frangible.
gible and soft. According to Klaproth, it is composed of

| 75-25 | Silica. |
| 12. | Alumina. |
| 1.6 | Oxyd of iron. |
| 4.5 | Potash. |
| 2.7 | Lime. |
| 2.5 | Water. |

It occurs in porphyry, and often contains balls of obsidian; and is found near Tokay in Hungary.

PEARN’s Point, in Geography, a cape on the W. coast of the island of Antigua.

PEARSON, John, in Biography, a learned prelate of the church of England, son of a clergyman, who was rector of Creake and Storing, in Norfolk, was born in the year 1612 or 1613. When he was eleven years old he was sent to Eton school, from whence, in 1631 or 1632, he was elected to King’s college, Cambridge. Having taken his degree, he was, in 1635, chosen a fellow of his college. In 1639 he entered into holy orders, and in the following year bishop Davenant collated him to a prebend in the church of Sarum, and about the same time he was appointed chaplain to the lord-keeper Finch, who presented him to a living in Suffolk. On the commencement of the civil wars Mr. Pearson was made chaplain to Lord Goring, and attended him when he went in the king’s service into the west of England. Here he preached a series of sermons, which he afterwards published in a different form, under the title of “An Explication on the Creed, &c.” It was reprinted with additions and improvements in folio, and has been so well received and highly applauded by the learned and judicious, as to have gone through at least twelve or fourteen editions. Soon after the restoration of Charles II. preference, and honours flowed in rapidly on Mr. Pearson. In 1660 he was prebendary of the recoltery of St. Christopher’s in London; created a doctor of divinity at Cambridge by a mandamus from the king; infall a prebend in the cathedral of Ely; nominated archdeacon of Surrey; and appointed master of Jesus college, in Cambridge. In the following year he was one of the assistant managers on the part of the establishment at the Savoy Conference, on which occasion he conducted himself in a manner highly reputable to his character and talents. Mr. Baxter says, that “Dr. Pearson was their true logician and disputant, without whom, as far as I could judge, we should have had nothing from them but Dr. Gunning’s passionate invectives, mixed with some arguments. He disputed accurately, soberly, and calmly, being but once in any passion, breeding in us a great respect for him, and a persuasion, that if he had been independent, he would have been for peace, and that if it were in his power, it would have gone well. He was the strength and honour of that cause, which we doubted whether he heartily maintained.” In June 1661, he was appointed lady Margaret’s protessor of divinity at Cambridge; and he filled that chair with distinguished credit and applause. In 1662 he was elected to the mastership of Trinity college, Cambridge, which led him to resign his other preferments in the church. In 1672 he was raised to the episcopal bench, being nominated the successor of the celebrated Dr. Wilkins in the see of Chester, with which he was permitted to hold the arch deaconry of Surrey, and the rectory of Wigan, in Lancashire. He had previously to this prepared for publication a learned work, which was published in 1672, entitled “Vindicatio Epistolae S. Ignatii—Acceplentur Haec Epistolae Deus adverfarus Vol. XXVI.

David Blondellum.” The work owed its origin to the dispute then agitating concerning episcopacy, and was intended to support the arguments in its favour drawn from the epistles attributed to Ignatius, in opposition to those who did not admit the authenticity of those epistles. On this point Dr. Pearson so far concedes to his opponents as to admit, that of the three Latin and twelve Greek epistles published in Ignatius’ name, the former are spurious, and five of the latter are of doubtful authority; but he maintains the authenticity and genuineness of the seven other Greek epistles, which are mentioned by Eusebius. Dr. Pearson held the bishopic of Chester upwards of thirteen years, but was, for several of those years previously to his death, disqualified for all public service by his infirmities. He died in 1686, when he was in the seventy-fifth year of his age.

He left behind him a number of works, which were creditable to his learning and industry. He was author of a preface to the Golden Remains of the ever-memorable Mr. John Hales of Eton; of “No Necessity of Reformation of the public Doctrine of the Church of England &c.” of the preface to J. Field’s edition of “The Septuagint,” and of “Annales Cyriani,” five tredecim annorum, quibus S. Cyriani inter Chriftianos verutus eft, Historia Chronologica.” He was one of the editors of the “Critici Sacri,” or collection of critics and commentators upon the bible, in nine volumes folio; and from his MSS. were published, after his death, “V. C. Joannis Pearsone S.T.P. Ceftrieni Bus Episcopi, opera Posthuma Chronologica, &c.”

Bishop Pearson was a man of profound and general learning, an exact chronologist, and intimately acquainted with the writings of the fathers and ecclesiastical history. He is described by bishop Burnet, as in all respects the greatest divine of the age, a man of great learning, strong senion, and of a clear judgment. He was a judicious and grave preacher, more instructing than affecting; and a man of a spotless life, and of an excellent character. The fame worthy prelate says, that Dr. Pearson’s “work on the Creed is among the best that our church has produced.” But he adds, that “he was not active in his doceee; too remis and easy in his episcopal function; and was much better divine than a bishop.” He was a melancholy instance of what a great man can fall to; for his memory went from him so entirely, that he became a child some years before he died.

PEASE, in Botany, &c. See Pea.

Pease—broom-damp, in Natural History. See Damp.

Pease-bolt, a provincial term applied to pease-haulm.

PEAT, in Rural Economy, a sort of earth dug out and used in many countries for fuel. It is found in most low grounds that lie betwixt hills, especially if timber has formerly stood upon the spot. It lies at various depths, being often near the surface, and sometimes from six, eight, or ten feet, to twelve or fifteen yards deep, having a stratum of black moory earth over it, such as the soil of many of our low meadows near the banks of rivers; it sometimes lies under a bed of gravel. It is moderately compact, and capable of being cut with a sharp spade into fOME masses, like bricks. Exposed to the air, it dries slowly, and becomes somewhat hard, and very inflammable. The best kind burns in an open grate with a yellowish-blue flame, resembling that of charcoal, and with a lefs quantity of smoke than wood affords. Some varieties are considerably charged with pyrites, and some also with sulphurs of foda and magnesia; and they are thus deteriorated as combustibles. By digestion in boiling water, peat affords a deep brown solution, slightly bitter to the taste, and containing an uncombined vegetable acid, similiar to the fuberic, with a portion of extract, and a little sulphur. By dry distillation, there comes over a watery ammonical liquor, and empyreumatic oil.
PEAT.

It is the opinion of some that it may be laid on land in the most effective manner, by having it mixed up or blended with lime newly flaked in the proportion of one part of the lime to five or fix of the peat; but later trials lead to the conclusion that it may be used more successfully by having it incorporated with some sort of manure, such as that of dung.

In this state of combination very great effects have been produced by it, as suggested above, in numerous instances where it has been employed.

States of Peat Matter.—The earl of Dundonald flates the different preparations of peat, or flates of mixture, in which it may be applied to lands, with good effects in counteracting particular defects, or in rendering them generally more fertile, to be thefie:

"Peat, unmixed,
   --- ditto                  ------ oxygenated,
   --- oxygenated, mixed with dung and urine,
   --- ditto                  ------ alkaline farts,
   --- ditto                  ------ alkaline hepar,
   --- ditto                  ------ Glauber falt and lime,
   --- mixed                  ------ newly flaked lime,
   --- and lime, mixed with peat afte."  

It is suppofted that all these preparations may, according to circumstances, be used to advantage. The consuming peat to afhes by fire, is always to be considered as the least productive, and most uneconomical. The most beneficial and productive of these preparations will be found to be:

Peat with dung and urine;
   alkaline farts;
   ------ alkaline hepar;
   ------ Glauber falt and lime: and
   lime.

In cafes where the fuel does not contain a due proportion of calcareous matter, a preference should always be given to the laft or the two laft of the above preparations, until it shall have received a sufficient supply of an article so indifferently economical as calcareous matter to the production of sweet herbage, leguminous plants, and grain. It is farther suppofted that by the above method of mixing peat with lime in the proportion of five or fix times the weight of the former to that of the latter, no injury can possibly arise from the over proportion of the lime. As the lime, when thus mixed with the peat, will meet with proper matter for it to combine with, or act upon; and the small proportion necessary to be used, when put in comparison to the weight of the peat, will be much lefs than the quantity of lime only, frequently applied at once to land; it is conceived that the bulk, weight, and the expense of the preparation, may direct the farmer in respect to the proportion that may be requisite to effect his purpose in moat cafes.

And in an ingenious pamphlet lately published by lord Meadowbank, the following directions are given for forming peat into a manure to be applied to ground.

Let the peat-mofs, of which compost is to be formed, be thrown out of the pit for some weeks or months, in order to lose its redundant moisture. By this means, it is rendered the lighter to carry, and less compact and weighty, when made up with fresh dung for fermentation; and, accordingly, less dung is required for the purpose, than if the preparation is made with peat taken recently from the pit. The peat taken from near the surface, or at a considerable depth, answers equally well. Then take the peat-mofs to a dry spot, convenient for constructing a dunghill to serve the field to be manured. Lay the cart-loads of it in two rows, and the dung in a row between them. The dung thus lies nearly on the area of the future compost dunghill, and the rows of peat should be near enough each other, that workmen, in making
making up the compost, may be able to throw them together by the spade. In making up, let the workmen begin at one end; and at the extremity of the row of dung, (which should not extend quite so far at that end as the rows of peat on each side of it do,) let them lay a bottom of peat, fix inches deep and fifteen wide, if the grounds admit of it; then throw forward, and lay on about ten inches of dung above the bottom of peat; then add from the side-rows about six inches of peat; then another thin layer of dung; and then cover it over with peat at the end where it was begun, at the two sides, and above. The compost should not be raised above four feet, or four feet and a half high; otherwise it is apt to press too heavily on the under parts, and check the fermentation. When a beginning is thus made, the workmen will proceed working backwards, and adding to the column of compost, as they are furnished with fresh three rows of materials directed to be laid down for them. They must take care not to tread on the compost, or render it too compact; and, of consequence, in proportion as the peat is wet, it should be made up in lumps, and not much broken. And that, in mild weather, seven cart-loads of common farm-dung, tolerably fresh made, is sufficient for twenty-one cart-loads of peat-mofs: but, in cold weather, a large proportion of dung is desirable. To every twenty-eight carts of the compost, when made up, it is of use to throw on, above it, a cart-load of ashes, either made from coal, peat, or wood; or if these cannot be had, half the quantity of flaked lime may be used; the more finely powdered the better. But these additions are no-wise essential to the general success of the compost. It is farther stated that the dung to be used should either have been recently made or kept fresh by compersion; as, by the treading of cattle or swine, or by carts paffing over it. And if there is little or no litter in it, a smaller quantity will serve, provided any fpongy vegetable matter is added at making up the compost, as fresh weeds, the rubbish of a flack-yard, rotator-shaws, sawings of timber, &c. And as some forms of dung, even when fresh, are much more advanced in decomposition than others, it is material to attend to this, for a much less proportion of such dung as is left advanced will serve for the compost, provided care is taken to keep the mass sufficiently open either by a mixture of the above-mentioned substances, or, if there are wanting, by adding the peat piece-meal; that is, first making it up in the usual proportion of three to one of dung; and then, after a time, adding an equal quantity, more or less, of mofs or peat. The dung of this character, of greatest quality, is flammable-dung, with which, under the above precautions, six times the quantity of peat, or more, may be prepared. The fame holds as to pigeon dung, and other fowl dung; and, to a certain extent also, as to that which is collected from towns, and made by animals that feed on grains, refuse of dillilleries, &c. It is still further observed, that the compost, after it is made up, gets into a general heat sooner or later, according to the weather, and the condition of the dung; in summer in ten days or sooner; in winter, perhaps for many weeks, if the cold is severe. It always, however, has been found to come on at last. In order to bring on the heat more expeditiously in a compost made up in froth, a narrow addition of dung and peat has, sometimes after the froth has gone off, been laid along the sides of the compost, scraping down a little the coating of peat upon it, and, in summer, it sometimes rises to high, as to be miscible, by confusing the materials (fire fanging). In that way a fack should be kept in it in different parts, to pull out and feel now and then; for if it approaches to blood heat, it should either be watered, or turned over; and on such an occasion, advantage may be taken to mix it with a little fresh mofs. In June 1756, a compost was formed, only 24 peat to one dung; it heated in July beyond the measure of a thermometer graduated to 110°. Part was allowed to stand, part turned with a half more mofs. Three weeks after, (18th August,) the heat of the former had descended to 84, while that of the latter had got up again to above 110°. The heat subsides, after a time, and, with great variety, according to the weather, the dung, and the perfection of the making up of the compost; which then should be allowed to remain untouched, till within three weeks of uring, when it should be turned over, upside down, and out side in, and all lumps broken; then it comes into a second heat; but soon cools, and should be taken out for use. In this state, the whole, except bits of the old decayed wood, appeared as black freckles, and spreades like garden mould. Use it weight, as farm-yard dung, and it will be found, in a course of cropping, fully to land the comparison. Let it be observed that the object, in making up the compost, is to farm as large a hot-bed as the quantity of dung employed admits of, and then to surround it on all sides, so as to have the whole benefit of the heat and effluvia. Peat, nearly as dry as garden-mould in feed-time, may be mixed with the dung, so as to double the volume and more of it. Workmen must begin with using layers; but, when accoutomed to the jult proportions, if they are furnished with peat moderately dry, and dung not loft in litter, they throw it up together as a mixed mass; and they improve in the art, so as to make a lets proportion of dung serve for the preparation. The addition, recommended, of ashes or lime to the compost, is thought to favour the general perfection of the preparation, and to hafen the second heat. The limed laid on above the dung-hill, as directed, is rendered mild by the vapours that escape during the first heat. It is added that such compost as is made up before January, has hitherto been in good order for the spring cropping, but this may not happen in a long froth. In summer, it is ready in eight or ten weeks; and if there is an anxiety to have it soon prepared, the addition of ashes, or of a little lime, or a good old buildings, or of lime flaked with foul water, applied to the dung ufed in making it up, will quicken the processes considerably. Lime has been mixed previously with the peat; but the compost prepared with that mixture, or with theimple peat, seemed to produce equally good crops. All the land, however, that it has been tried on, has been limed more or less within the twenty-five years.

It is said, farther, that the rich coarse earth, which is frequently found on the surface of peat, is too heavy to be admitted into this compost; but it makes an excellent top-drefing, if previously mixed and turned over with lime. And peat, prepared with the lime alone, has not been found to answer as a good manure. In one instance, viz. on a bit of fellow, with wheat, it was manifeptly pernicious to the land.

In some of these modes, this substance may be rendered capable of extensive application as a manure to land. See Moll and Moss.

PEAT-Aftrs. In Agriculture, the ashes that remain after the combustion of this fort of vegetable material. This is, however, a very saleful and diluting process, as there is seldom one-twentieth part of its weight afforded in ashes. The reft is thus forced off into the air and loft, which by other means might be faved, and contribute to the vegetation and growth of plants. Where, however, the practice of converting it into ashes is had recourse to, it is observed that the peat may be burnt all the sumner feason; as soon as it is dug, some of it is mixed in a heap regularly difposed with faggot-wood, or other ready burning fuel: after a layer or two of it is mixed in this manner, peat alone is piled up to compleat the heap. A heap will confift of from four hun-

trided
dred to a thousand loads. After setting fire to it at a proper place, before on purpose prepared, it is watched if the burning, and the great art is to keep in as much of the smoke as possible, provided that the smoke is not left as a fuel feed the fire. Whenever a crack appears, out of which the smoke escapes, the labourer in that place lays on more peat; and if the fire flackens too much within, which may be easily known by the heat on the outside, the workman must run a strong pole into the heap, in as many places as is necessary to supply it with a quantity of fresh air. When managed in this manner, the work goes on as it should do. It is to be noticed that when once the fire is well kindled, the heaviest rains do no harm whilst it is burning.

And after having procured a sufficient quantity of ashes, the farmer's next care should be to apply them properly to use; and to do this, he must be well acquainted with the nature of the manure he is to lay on his land. With respect to peat-ashes, almost the only danger proceeds from laying them on in too great quantities at improper seasons. Nothing can be better, it is asserted, than peat-ashes for dressing low damp meadows, laying on to the quantity of from fifteen to twenty Winchester bushels on an acre; it is best to lay them on by bands, as they will then be more regularly spread. And this work should be done in January or February or latest, that the ashes may be washed in towards the roots of the grass by the first rains that fall in the spring. If they were spread more forward in the year, and a speedy rain should not succeed, being hot in their nature, they would be apt to burn up the grasses, instead of doing it any service. In regard to the quantity, it must be remembered, that the damper and fuller the soil, the more peat-ashes should be laid on it; but on grass-land, the quantity should never exceed thirty Winchester bushels, and on light warm lands less than half that quantity is sufficiently.

Also, on wheat crops these ashes are of the greatest service, but they must be laid on with the utmost diffrecion. Were they to be spread in any quantity before the winter, after fowing the corn, they would make the wheat too rank, and do more harm than good; was the spreading of this manure, on the contrary, deferred till the spring, the corn could not possibly during the winter season be benefited by it. After due reflection and repeated experience, the method of management was as follows: About the beginning of November, before the hard frosts, he has on every acre of his heavy clayey wheat land, about eight Winchester bushels of these ashes; on his lighter warmer lands in wheat, he fows only four bushels at this season. The winter dressing it, he imagines, of great service: trifling as the quantity may seem, it warms the roots of the plants, brings the crop moderately forward, preserves its verdure, and disposes it to get into a growing state the first fine weather after Christmas. About the latter end of February, or the beginning of March, on the above-mentioned heavy lands in wheat, he fows another dressing of ashes, by fowing of them on every acre eight bushels more; on light lands, in the second dressing, he allows only six bushels. These ashes laid on in the spring are of the greatest service, without any probability of danger; if rain falls within a few days after the dressing is laid on, it is washed in, and has a happy effect on the succeeding crop, co-operating with the manure that was laid on in November; if, on the contrary, dry weather for a long continuance succeeds, the first winter dressing has no effect, and the quantity laid on in the spring is in fact so small, that there is very little probability of its burning or hurting the crop. This method has succeeded very well with him, and he has no reason to think it can fail with others. It is likewise stated as an useful fact, that this excellent manure is of great use in the turnip buf-

bandry, on many accounts, particularly as it much contributes to preserve the young crop from being devoured by the fly. When the writer fows his turnips before he harrows in the seed, he has eight bushels of these ashes frowed on every acre; and when the plants frow their frit leaves above ground, he fows on every acre four bushels more; by this management his crops feld dam fail, when at the same time some of his neighbours fow their turnip-land three or four times over. This hint deferves attention, as pared and burnt land is said to have the same effect in preserving turnip-crops from the dreadful ravages of the fly.

It is further stated, that one of the principal advantages derived from these ashes is, however, the very great service they are of to every kind of artificial failure. Sainfoin receives great benefit from this manure, and so do clover, ray-grafts, and treefoil, provided it is laid on with diffrecion: the proper season is about the month of February: the quantity must be regulated by the nature of the crop and soil; but, in his opinion, it ought scarcely in any inulence to exceed thirty Winchester bushels. Clover, with the help of this manure, grows with great luxuriance, inasmuch that he has often had two large crops of hay from the same field in a year, and good autumn feed afterwards.

The above effects appear in the tares and vetches, and on them it is he believes most of this manure, as they will bear it, being a very succulent plant. The writer had, last summer, a crop of tare-hay that was astonishing, by the help of these ashes, being above three large loads on an acre. The field contained fix acres. It was a dryfth loam, and not very rich. In the beginning of February he caufed ten bushels, Winchester meafure, to be frowed on each acre: immediately after the firft rains had washed them in, the fame quantity was in like manner spread, and about the middle of March he fowled on each acre fix bushels more for the last dressing. He is fond of dividing his entire quantities, thinking his crops are thereby exposed to the danger of being burned, and the manure is besides more gradual and lasting in its effects. His tares came on amazingly; but they ran chiefly to haulm, which was what he wished, not having any defire of faving the feed, but intending to make the crop in hay; his only fear was, that it would rot on the ground before it was in proper condition to cut; but this he luckily escaped, by being long enough dry and by the beneft of the weather. It was fo heavy in the fourth, that he was obliged to pay an extraordinary price for moving it. He thinks the luxuriance of his crop was owing entirely to the invigorating quality of the ashes, which by their fialts, &c. promoted the growth of the plants even to luxuriance.

Before he well knew the great fertilizing quality of these ashes, he loft, by improper management, a fine three-acre piece of hog-pace. He laid on this field, soon after the peafe came up, threefour Winchester bushels of these ashes at one dressing; this brought them forward a great pace; but at harvest, he found to his grief, he had scarcely any corn, for he had overdone it in laying on too much, and the peafe were run all to haulm. Ever since this accident he has declined using them as a common dressing for his peafe, and this he has been the more induced to do, as, in several little experiments he has since made, he has found it extremely difficult to apporition the several quantities which ought to be laid on various foids when fown with peafe; for the quantity that has one year succeeded very well with him, has, the next, owing to the difference of foids, on the same foid, in another part of the fame field, totally disappointed him; so that, for peafe, he esteems it a very critical manure, therefore to be used very cautiously. And he says that the effects of this manure will be visible at least three years, and it does not, like
like some others, leave the land in such an impoverished state when its virtues are exhausted. It is supposed that peat ashes are not to certain a manure for barley and oats as for winter corn; for as these are quick growers, and occupy the land but a few months, this warm manure is often apt to push them forward too fast, and make them run too much to coarse flow, yielding only a lean immature grain. Oats, however, are not so apt to be damaged by it as barley.

And he adds, that peat-ashes approach, in their effects on the several crops on which they are laid, to cool-foot; but two-thirds of the quantity that is used of foot will be sufficient of the ashes, as they are, in a much stronger degree, impregnated with a vegetative power; and they are, besides, in mott places, caver procured in quantities, and at a cheaper rate.

But though this fort of dressing has been found useful on different sorts of land, it has by much the best effects on those of the light chalky kind, being often usefully applied on such as are of a wet nature. And the full quantity is usually about forty bushels to the acre, and the time of applying them is improved lustnulandy in the spring months, as about March or earlier. See Ashes.

PEAT-MOGS, in Rural Economy, a term applied to the earthy material which is dug up for fuel in some districts. It is of very different qualities and properties. See Moss and Peat.

PEATRA, in Geography, a town of European Turkey, in Moldavia; 16 miles S.S.W. of Nienicz.

PEATY-EARTH, in Agriculture, that fort of land which is of a peaty quality, or which contains much vegetable peaty matter. It is generally considered of a good quality. See Peat.

PEaty-LAND, that fort of ground which is of a peaty nature, or which abounds in the peaty material. There are many varieties of this fort of land, some being constituted of this sublunance to several yards depth, while others have it only in a very superficial manner. The former are frequently denominated peat-mos or bogs, and the latter fens. Some of the different modes of bringing peaty-lands into cultivation, have been already noticed under Moss and Moon, but others may be introduced here with propriety. According to the earl of Dundonald, the primary flep towards improving land of this fort, is to take off by proper channels the great feeder of water. This is to be effected by conducting one or more principal drains through them, and by water-courses on the fold or dry land, immediately above the level of them, so that they shall not be inundated by the surface-water or springs of the surrounding higher lands, and shall afterwards only require to be freed from the water that shall fall on their superfcies. This being accomplished, the intermediate parts of the bogs should be drained, partly by open and partly by covered drains; care being taken that they are not made so deep as to lay the bog too dry; by which the peat, becoming oxygenated, and thence infusable, would be incapable of yielding food to vegetables.

By the opposite extreme, unprofitable grafts and aquatic vegetables are produced. It is therefore an object of great importance, in effecting the drainage, to preserve a full command of the water, that it may be regulated at pleasure by the operation. The practical modes of management that are necessary in those cases, are explained more fully in speaking of the nature of mosses. See Moss.

It is farther observed, that should a moss or bog be so circumstanced, as to admit of its being drained through a country which might be improved by a supply of vegetable matter, it would be prudent, previously to making the great or leading drains through the adjacent county or mosses, to concert measures for making a proper communication by a canal, so that the remote lands might be supplied with peat from the mosses, and the moss supplied with lime, marle, clay, earth, sand, shells, and other materials, from the distant country. And that as peat-mosses are frequently found under peat-mosses, they should be bored in different places, to ascertain if they possess this valuable sublunance; or if they contain under the motts a rich clay or limetone gravel: for, in the event of these being found at a moderate depth, the motts or bog may be improved at a much less expense, as the distant carriage of these necessary articles, and the difficulty of carting and laying them on to the surface would thereby be diminished. It is also suggested that the burning a part of the upper surface may, in some cases, be requisite, to afford, when it is otherwise too difficult to be procured, a due proportion of earthy matter. Peat-ashes will, in such cases, act in making a different mechanical arrangement in the soil; but, near the fides of the bogs where surface moul is to be had, a preference should be given to it in mott cases. And the alteration in the mechanical arrangement of the soil being thus effected, the next object is the application of such sublunances as will bring the peat, or inert vegetable matter, into action. These are three main

and alkaline falls, which contribute in different ways to the proposed improvement. Improved peat-mosses, bogs, or reclaimed fen-lands, are the motts the most productive of luxuriant vegetation, although from this cause they do not in general yield, in this northern and humid climate, heat and well-filled grain. Such soils should be principally dedicated to pasture, and should only be ploughed when, not-withstanding the utmost endeavours, the ground produces coarse or rank grasses; but this is in a great measure, or perhaps entirely, to be prevented by the due attention to the following directions: to keeping the water in the ditches at a proper level: to flocking the ground with a due proportion of neat cattle, sheep, and horses; as the one animal will eat the grafts which springs up on the dung of the other, and which otherwise would produce tufts of coarse grafts: to folding of cattle on different parts of each field: to using heavy rollers: and to top-dreplings of alkaline falls, and other saline sublunances: and also to top-dreplings of lime, either by itself, or well mixed with peat or fen mould, in the manner that has been directed above.

And it is advised, that the pasture should always be eaten quite close before winter, excepting such portions of it as are intended for winter food, which likewise should be eaten close off, before the spring vegetation commences; after which time it should not be depastured until the grafts be sufficiently advanced to allow of a good bite. As all plants receive nourishment two ways, by their limbs and leaves, as well as by their roots, the growth of young vegetables must necessarily be much retarded, when deprived, by being constantly eaten down, of one of their sources of sublunance. And as the consolidating the soil of peaty-lands is an object of the first consideration, it is obvious, both on chemical and mechanical principles, that much cropping, and the consequent exposure of fresh surfaces to the action of air, are improper; and that after a few crops are obtained, the ground should be laid down with meadow grafts and white clover, and depastured with as much flock as it will carry. By these means, not only the soil will be consolidated and commodified, and particular grafts or herbage promoted according to the cattle so depastured, but the urine and dung of the cattle, by carefully folding them, will be laid on in such quantities, as will perform rapidly and at once the effect required; whereas, if the same quantity were divided over fifty or a hundred times the surface so folded upon, its operation would fearlessly be perceptible, and the application
of each year's manure so subdivided, would either be washed away, or its beneficial effects lost, before the further quantity necessary could, in a series of fifty or a hundred years, be added to it. Hence a system of under-dunging, or manuring land, may be said to be nearly equal to no dunging at all: on which account the preference, with great reason, has been given, under all circumstances, to the ancient mode of cultivating the infold lands of Scotland. Folding in a proper manner, is particularly recommended for fen-lands and peat-lands, as the immediate effect produced by urine, is that of disolving into mucilaginous sapaneous matter the oxygenated peat. Indeed in all buminess, it is well known, that what is once well done is not to be done again. By this judicious mode of proceeding, the chemical qualities and mechanical arrangement of the soil are fo altered, that, without the grosser mismanagement, it is impossible it should return again to its former unproductive state. If this be properly attended to, the pastures will never grow coarse, or require breaking up, but will continue to improve the longer it is covered to remain in that state. There are other reasons for continuing such lands in pasture, viz. the difficulty, from the softness of the soil, of conveying dung from the farm-yard to the field; and likewise the facility with which loose dung in the heap, by exposure to air, to become oxygenated, and consequently incapable of yielding the food requisite for the support of vegetables. And in the mode of slotting such pastures, it is further recommended to keep the fat, the half fed cattle, and the lean or young flock, in different inclosures, as is the practice in Ireland, and where grazing is well understood in England. The fat cattle should only top the grazings, the half fed should succeed these, and lastly, the lean or store cattle should follow on the same pasture, and eat the herbage close down; repeating this practice as often as the fresh growth of grass will permit its being done with propriety. It is probable that under the above circumstances, the biff fort of flock is that of sheep, as eating the herbage down in a more regular and equal manner; and at the same time contributing more to the improvement of the land, without doing any injury by their treading or otherwise. See Moss.

Peaty Soil, that fort of soil which is constituted chiefly of the peaty material. See Soil.

PauCier, in Anatomy, a name given by Winlow in his "Treatise on the Head," and by other of the French writers, to the mufcle, called by Albinus latissimum coli; and the other detrachens quadratus, and quadratus gene. Santorini has called the part of this which arifes from the cheek, muculus ritorius novus; and some call the whole platina myoides.

Pebbles, Calculi, in Natural History, the name of a genus of fossils, distinguished from the flints and homochroa, by their having a variety of colours. There are defined to be stones, composed of a crystalline matter, debased by earths of various kinds in the same species, and then subjedt to veins, clouds, and other variegations; usually formed by incrustations round a central nucleus, but sometimes the effect of a simple concretion, and veined like the agates, by the disposition which the motion of the fluid they were formed in gave their differently coloured subfluations.

The variety of pebbles of England alone, is so great, that a halfly defcriber would be apt to make almost as many species as he saw specimens. A careful examination will teach us, however, to distinguish them into a certain number of essentially different species, to which all the rest may be referred, as accidental variations. When we find the same subfluations and the same colours, or those resulting from a mixture of the same, such as nature frequently makes in a number of stones, we shall easily be able to determine that these are all of the same species, though in different appearances; and that, whether hard they be divided in one or two, or in twenty crafts laid regularly round a central nucleus, or thrown without a nucleus into irregular lines, or finally blended into a sort of uniform mass.

These are the three classes in which we are liable to find every species of pebble; for if it hath been most naturally and regularly formed by incrustation round a central nucleus, we find that the same in the same species, and the crafts not less regular and certain. If the whole has been halfly formed, and has been the result only of one simple concretion, if that has happened while its different subflurations were all motl and thin, they have blended together and made a mixed mass of the joint colour of them all; but if they have been something harder when this has happened, and too far concreted to diffuse wholly among one another, they are found thrown together into irregular veins. There are the natural differences of all the pebbles; and having regard to these in the several variegations, all the known pebbles may be reduced to thirty-four species.

Hill's Hist. of Foss. p. 572, seq.

In all the strata of pebbles there are constantly found some which are broken, and whose pieces lie very near one another; but as bodies of such hardness could not be broken without some considerable violence, their present situation seems to imply, that they have suffered that great violence in or near the places where they now lie. Besides these, there are others also found which have as plainly had pieces broken off from them, though these pieces are no where to be found; whence it seems equally plain, that whatever has been the cause of their fracture, they have been brought broken, as we find them, from some other place, or else that the pieces broken from them mull at some time or other have been carried from this place to some other distant one.

Several of these broken pebbles have their edges and corners so sharp and even, that it seems evident they never can have been toled about or removed since the breaking; and others have their sides and corners so rounded, and worn away, that they seem to have been roughly rolled, and rolled, and rolled, in the bodies, and that too either with great violence, or for a very long continuance; since such hard bodies could not have been reduced to the condition we now see them in without long friction.

It may be supposed by some that thes stones never were broken, but have been naturally formed of this shape; but it will be easily seen, by any one who accurately surveys their veins or coats, which surround the nucleus like the annular circles of a tree, that they must have been originally entire; and this will be the more plain if they are compared with a stone broken by art. Such pebbles as are found in strata, that lie near the surface of the earth, are much more brittle than those which lie in deeper strata.

The more clear and transparent the sand is which is found among pebbles, the more beautiful the pebbles are generally observed to be.

The use of these stones, and their disposition in the earth, is a subject of great admiration; and may serve as one of the numerous proofs of the over-ruling Providence in the disposition of all natural bodies. The surface of the earth is composed of vegetable mould, made up of different earth mixed with the putrid remains of animal and vegetable bodies; and is of the proper texture and compases for conducting the moisture to the roots of trees and plants; and under this are laid the sands and pebbles which
which serve as a sort of drain to carry off the redundant moisture deeper into the earth, where it may be ready to supply the place of what is constantly rising in exhalations; and left the strata of sand should not be too thick, it is common to find thin ones of clay between, which serve to put a stop to the descent of the moisture, and keep it from passing off too soon; and left the thin strata of clay should yield and give way, and by their softness when wetted, give leave to the particles of sand to blend themselves with, and even force their way through them, there are found in many places thin coats of a poor iron ore, placed regularly above and below the clay; and by that means not only strengthening and supporting the clay, but effectually keeping the sand from making its way into it. Phil. Trans. N° 493.

PEBBLES, Rridged. It is not uncommon to meet with pebbles in our gravel-pits, which have one or more ridges, or white lines, flanding above the surface of the Pe of the stone, in the form of a rib or zone, laid on the stone after its formation. This, however, is not the case; but the line or zone always goes through the whole body of the pebble: the matter forming this ridge is always harder than the rest of the Pe of the stone; and it seems probable, that at first it was not elevated, but level with the rest of the Pe; but not to have been worn away by accidents, and when the whole pebble came in the way of rubbing among harder bodies, this would be left rubbed off, and consequently would be left more elevated than the rest. We daily see on the sea-shores numbers of stones rounded by the continual rolling and tossing among the waves, and in these the softer parts have given way first and been worn into holes, while the harder have been left prominent. It seems probably to have been the case with these pebbles also; but they are not found on the shores; but in our gravel-pits, at a great distance from the sea: and it is evident, that these have had their surfaces thus ground and worn down between the time of their being formed by concretion, and their being deposited where we now find them. The smoothness of the surfaces of some pebbles and flints, which we find with their natural coats or cruts worn off, is another proof of the same thing. These pebbles, in this unnatural naked state, as well as the ribbed and lined ones, are found in our pits, under the strata of earth; and yet they are exactly in the same condition with those which have been tumbled about and rounded on the sea-shores.

PEBBLES, Swallowing of. There are many people of opinion, that the swallowing of pebbles is very beneficial to health, in helping the stomach to digest its food, and a pebble-pot is an old woman's medicine in the colle, in many parts of England. They usually order the small white stones to be picked out of gravel-walks for this purpose, and eat them in large quantities in some sorts of spoon meat, of which milk is an ingredient.

The thing that has given occasion to this practice seems to have been, that people observe the birds to pick up the gravel, and that they are never well unless they have frequent recourse to this to help their digestion: but this is no similar case at all, for the gizzard or stomach of a bird is made very strong, because the creature hath no teeth to chew its food; and this gizzard is lined with a rough coat, by the help of which and these stones, the food they swallow whole is so ground, as to yield its juices to the nourishment of the animal. But the stomach of man is formed so very differently, that it can never require those affinities to the comminution of food. Many people have, however, accustomed themselves to swallow not only these small white stones, but large pebbles, even to the size of a walnut each; these will often pass safely, and people who have long accustomed themselves to swallow them, boast of receiving no injury from them: we can never know, however, that the death of such persons is not owing to them at last; and as they can do no good, it is best always to avoid them.

There is one instance on record, of much mischief done by them, in our Philosophical Transactions, N° 253, p. 192.

PEBBLE, Egyptian, constitutes the second family of the Siliceous genus in the mineralogical arrangement of Kirwan. This stone presents various colours together in the same specimen, either in regular or irregular concentric and alternating stripes or layers, or in dots and dendritical figures. The most usual colours are the yellowish and liver-brown, reddish-brown, ifabella yellow, yellowish-grey, greyish, or reddish-white, milk-white, leek-green, and black, which last is only in dots and dendritical figures. It is found in spherical, or flat rounded masses, which are enveloped in a coarse rough crust. Its internal fibre, 1; external, 0; its transparency, 0; its fracture conchoidal; its hardness, 10; its fp. gr. 2.564, Brillon. Found principally in Egypt, sometimes in Europe, particularly in Lorraine. Kirwan's El. of Mineralogy, vol. i.

PECAQUE, St., in Geography, a town of Mexico, in the province of Xalica; 43 miles N. of Comapoella. La Pequeña. Washington 160. W. long. 101.

PECARI, or TAJACI, in Zoology. See Sus Tajagu. PECOLOM, in Medicine, an obsolete term, which was much used by the humoral pathologists to denote every fort of morbid condition of the humours of the body, to which alone they ascribed almost all diseases. Hence their principal efforts were directed to the correction of the peccant matter, or to its evacuation. See Humoral Pathology.

PECETA, in Commerce, a Spanish silver coin. In 1772 the pecetas and reals were reduced to 9½ dineros fine; the mark being divided into 12 dineros, and the dinero into 24 grains. The old Mexican peceta of two Mexican reals (1736) is by the assay worse than the English standard, 41 dwt.; its weight is 4 dwt. 7½ gr.; its content in pure silver grains 93.6; and its value 11. 1d. sterling. The peceta of two reals of plate (1721) is worse 1 oz. 7 dwt.; its weight 3 dwt. 16½ gr.; its content in pure silver grains 91.9; and its value 10d. sterling. The Mexican peceta (1774) worse 8 dwt.; its weight 4 dwt. 7½ gr.; its content 91.3; and the value 11. 0d. sterling. The peceta of two reals of new plate (1775) worse 1 oz. 9½ dwt.; weight 3 dwt. 18 gr.; content 72.2; and value 10d. sterling.

PECEO, in Geography, a town of France, in the department of the Po; 3 miles S.W. of Cieri.

PECHANTRE, Nicholas de, in Biography, a French poet, was born at Toulouse in 1638. He gained the poetical prize from the academy des Jeux Fleurus three times. His tragedy of Geta was performed at Paris in 1687, with great applause. This was followed by Jugurtha, the Death of Nero, and some others. Pechantre died in the year 1708. Moreri.

PÉCHARE, in Geography, a town of Hindooftan, in the circuit of Chandree; 35 miles W.S.W. of Chandree.

PÉCHBLÈND, in Mineralogy. See Uranium.

PÉCHELEE, in Geography. See Péchelè.

PÉCHEM, in the Materia Medica, a name given by the modern Greek writers to the root weal of the lebens by Avicenna and Serapion. Many have been at a loss to know what this root pechem was; but the virtues ascribed to it are the same with those of the lebens of the Arabians; its description the same, and the division of it into white and red, is also the name as that of the lebens. Nay, the word pechem is only formed of lebens, by changing the 6 into a p, which is very common,
PEC

common, and the aspirate into \( \chi \), or \( ch \), which is as common.

Myrrophis, who treats of this root, says the same thing that the Arabian Avicenna says of belen, namely, that it was the fragments of a woody root, much corrugated and wrinkled on the surface, which was owing to its being so moist whilst fresh, that it always shrank greatly in the drying.

PECHIA, in Geography, a town of Servia, on the Drino; 35 miles N.E. of Ragusa. N. lat. 43° 14'. E. long. 19° 15'.

PECHLARN, or POCHLARN, a town of Aultria, on the right bank of the Danube. The river is very wide, and here the Romans had a harbour for their navy. They called it "Praetara," and it was considered as one of the strongest places in the country. It was formerly the residence of the margraves of Aultria. It was given by the emperor O'ho to the bishop of Ratibon; 45 miles W. of Vienna. N. lat. 48° 14'. E. long. 15° 20'.

PECHLIN, JOHN NICHOLAS, in Biography, an ingenious physician, was born at Leyden in the year 1646. He was educated exclusively in his native city, until he received the degree of doctor in 1667; after which he travelled into Italy, and visited the principal universities of that country. He did not remain long without an opportunity of communicating the extensive knowledge which he had obtained; for in 1673 he was appointed to a professorship at Kiel, in Holstein, where he soon attained a high reputation. In 1678 he was elected a member of the academy "Natura Curiosorum," and in 1691, a fellow of the Royal Society of London. He gained the favour and patronage of the court, and in 1680 was appointed first physician to the duke of Holstein-Gottorp, and subsequently his librarian and counsellor. In 1698 he accompanied that prince in a journey to Stockholm; and again, in 1704, he visited that capital with the hereditary prince, to whom he was appointed tutor, and died there in February, 1706.

Pechlin was author of several works, some of which evince a great degree of good taste and eloquence of style, especially his essay, entitled "Metamorphosis Eleucapi et Apollinis Pancreatici," which was a latine against Sylvius de la Boé and De Graaf, and was published under the fictitious name of Janus Leonierius Veronensis. His other tracts were entitled "De Purgantum Medicamentorum Facultatus," Leyden, 1672; "De Vulneribus Scelotorum," Kiel, 1672; "De Acris et Alimentorum Defectu, et Vitae Sub Aquis," ibid. 1676; "De Habitu et Colori Atheniopum," ibid. 1677. The feat of the colour of Negroes he pointed out in the "Rece mucosum," and imagined it was occasioned by bile. "Theophilus Bibaculus, five de Potu Thea," Francfort, 1684, a poetic eulogium on the virtues of tea; and "Observationum Physico-Medicarum Libri tres," Hamburg, 1691,—a collection containing some curious cases, but also evincing a considerable share of credulity in the author. Eloy Dict. Hist. de la Med.

PECHMEJA, JOHN, a French writer, was born at Villa Franca in 1741. He became professor of eloquence in the college of La Flèche, and died in 1785. His eulogy on the death of Colbert was so well received with the approbation of the academy in 1773; but he is principally known by a work in poetic prose, called "Telepne," 2 vols.

PECHOR, in Geography, a town of Hindooftan, in the circur of Gohud; 25 miles S.E. of Gwalior.

PECHOWLY, a town of Hindooftan, in the circur of Chandaree; 40 miles N.W. of Chandaree.

PECHSTEIN, in Mineralogy. See Pitchstone.

PECHYAGRA, in Medicine, a name given by authors to the gout afflicting the elbow.

PECHYS, a name used by some anatomical writers for the elbow.

PECHYTYRBE, an epithet used by some medical writers for the scurvy.

Peck, Francis, in Biography, was born at Stamford, in Lincolnshire. He was educated at Cambridge, where he took his degree of M.A. He entered holy orders, and became curate of King's Clifton, in Northamptonshire; after which he obtained the rectory of Godby, in Leicestershire, which was the only preferment he ever obtained. In 1721 he published proposals for printing the history and antiques of his native town; and in 1727 he published the work, entitled "Academia terrae Anglicana. or the Anti-quarian Annals of Stamford, in Lincoln, Rutland, and Northampton-shires." His inquiries relative to this single object led him to extend his researches; and in 1729 he printed a sheet of "Queries concerning the Natural History and Antiquities of Leicestershire and Rutland." Though he made considerable progress in collecting materials for a work on those subjects, it never made its appearance. In 1732 he published the first volume of his "Definita Curiosa," or collection of divers scarce and curious pieces, relating chiefly to matters of English history; consisting of choice tracts, memoirs, letters, wills, epitaphs, &c. A second volume followed in 1735, and the whole was reprinted in one volume, quarto, in 1779. In the year 1755 he displayed his industry in "A Complete Catalogue of all the Dicoures written both for and against Popery, in the Time of King James II.," and in 1759 he edited nineteen letters of Dr. Henry Hammond. In the following year he published two volumes, quarto; one entitled "Memoirs of the Life and Actions of Oliver Cromwell," as delivered in three Panegyrics of him written in the Latin Language; with a Collection of divers curious historical Pieces, relating to Oliver Cromwell, and a great Number of other remarkable Perhons. The other was entitled "New Memoirs of the Life and poetical Works of Mr. John Milton," with critical illustrations. This was the last of his publications. He died in 1743, leaving behind him materials for nine different works, which he had in contemplation. Of his MSS. the greater part came into the possession of Sir Thomas Cove, of which the most valuable were five volumes, quarto, written fairly for the press, entitled "Morallon Anglicanum; Supplementum novis adactus." These were presented to the British Museum in 1779.

PECKELSHIEIM, in Geography, a town of Westphalia, in the bishopric of Paderborn; 15 miles S.E. of Paderborn. N. lat. 51° 34'. E. long. 9° 15'.

PECKHAM, a hamlet in the parish of Cambewber, hundred of Brixton, and county of Surrey, England, is situated on the road from London to Greenwich, at the distance of 42 miles from St. Paul's cathedral. In Domesday book the manor is mentioned as belonging to Battersea, and being the property of Odo, bishop of Baieux, half-brother to the Conqueror. At a later period it appears to have been divided into two manors, called Bredinghurt and Bafynges,
PEC

Basings, from perfons of that name who poifioned them, in the reigns of King John and Edward I. The manor of Breding hill was now veiled in the widow of William Shard, et al.; but the manor-house has been lately demolished, and the feite let on building-le-fes. At Pecckham are meeting-houfes for the Anafraptits and Presbyterian. Here is annually held a large show fair, similar to that of St. Bartholomew in Smithfield, London.

The parifh of Camberwell having been inadvertently omitted in its proper place, we deem it advisable to flate a few particulars under this head. It is bounded by the parifh of Newington-Batts, St. George's Southwark, and Rotherhithe, on the efl; by Deptford and Beckenhain, in Kent, on the south; by Croydon, and a detached part of Battersea, on the west; and by Lambeth on the north. At the time of the Domeftey survey it comprehended one manor only, which was held of the Conqueror by afimo, the fheriff; but it was foon afterwards divided, and eventually became feveral diftinct manors, called Camberwell-Buckingham, Milkwell-Camberwell-Freme or Fryen, Dowdale or Uredale, and Deptford Strong. There were also two inferior manors, Camberwell and Cold-Abbev, both of them held of Camberwell-Buckingham. The land in this parifh is mostly poifoned of great fertility, and, exclusive of the feites of the houfes, is laid out "in nearly an equal proportion between arable, pafure, and gardens." Camberwell village is diftant about three miles and a quarter from St. Paul's cathedral in London. The church here was erected about the commencement of the reign of Henry VIII., and confifts of a nave, chancel, and two afles, with a small embattled tower at the west end; the whole compofed of flints and rough flone, except the south-foft wall, which is of brick. The chancel is of a very fin-ular fhape, being the fection of a hexagon. In the eaf! window of the north aisle are feveral full-figure figures painted upon glafs. These are now much mutilated, as well as the incription beneath, which, however, is sufficiently entire to inform us, that they were intended to repreff some members of the Moucamp family, who had their burying-place in this ifte. There are, besides, in the fame window, two imperfect representations of female fafants. This church contains many monuments of the Scotts, Bowyers, and others who have been interred within its walls. In the parifh regifter here are feveral very curious entries: one of which records an inflance of a woman bearing a child at the age of fixty-three.

In this parifh are feveral charity-schools, which are supported chiefly by fubfcription, except the free grammar-school. This was founded and endowed by the Rev. Edward Willon, in the reign of James I., and now affords education to feventy boys. But the chief charitable foundation of which it has to boast is Dulwich-College, fiteduated in the hamlet whence it derives its name. Camberwell parifh contains, according to the population returns of 1811, 2060 houfes, and 11,250 inhabitants. See Dulwich. Lyfon's Environs of London.

PECORA, in the Linnean fystem of Zoology, a term, comprehending a whole order of quadrupeds, in the clas of mammalia. The characters of this order are, that the creatures have no fore-teeth in the upper jaw; the lower jaw has fix or eight fore-teeth, which are placed at a coniderable distance from the molares or grinders. The paps of this order of animals are fiteduated in the groin, and their feet have hoofs. Of this order Linneus enumerates eight genera; the camel, mojebus, cervus or franc, the camelopardalis, the antilope, the capra or goat, the ovis or sheep, and bos or ox.

PECQUET, JOHN, in Biography, a diilinguished anatomi, was a native of Dieppe, and a graduate of the university of Montpellier. He was endowed with an active and intelligent mind, and purfued the study of anatomy with great ardour and ingenuity, which he evinced by the discovery of the thoracic duct and the receptaculum chyli, in 1647, while yet a fudent; by which the hitler imperfectly known fyllem of the lacteals was completed. After this happy indication of his skill, he fettled, with a view to pracfie his profession, in his native town; but foon afterwards going to Paris, he recommenced his anatomical re-afearches, for the purpofe of demonstrating completely the important vessels which he had discovered; and he became acquainted with the most fable anatomists in that metropolis. He succeeded completely in this demonstration, and traced the proprfes of the chyle, which is taken up from the in-terfines, by the lacteal veffels, into his receptacle, and by the thoracic duct to the left subclavian veft. This dis-covery foon gave his name a celebrity throughout Europe; and, as has generally happened in cafes of important dif-coveries, it was doubted and denied by fome, while others contended that it was not new. The work in which he published the discovery was entitled "Expermenta nova Anatomica, quibus incognitum haftenm Chyli Recpe-taculum, et ab eo per Thoraecem in Ramos uqfe subclavlos Vafa lactea delegantur;" to which was subjoined a differta-tion, "De Circulacione Sanguinis et Chyli Motu," 1651. It was reprinted in 1654, together with an effay "De Tho-rcacis lacteis," in antwer to Riolan; and many fubfequent editions have appeared. Pecquet was a man of con-fiderable acquirements, in addition to his anatomical skill, and was a member of the Royal Academy of Sciences from the year 1666. He is faid, however, to have shortened his days by an unfortunate attachment to the use of spirituous liquors. He died at Paris in February, 1674. Eloy Diet. Hist. de la Med.

PECQUET, ANTHONY, a French writer, was born in 1704. He attained the rank of grand master of the wafer-works and foundling of Rouen, and superintendent of the military school. The works by which he is principally known are "An Analysis of the Spirit of Laws, and the Spirit of Polical Maxims," 3 vols.; "The Forrest Laws of France," 2 vols.; "Thoughts on Man." He also translated the Psalter Fido of Guarini, and other Italian works into French. He died in 1762.

PECQUETI RECEPTACULUM, in Anatomy, a dilated portion jutf at the beginning of the thoracic duct, dif-covered by Pecquet. (See Absorbents.) It is often called receptaculum chyli.

PECTEN of the Pubes, the prominent ridge of the os innominatum, fittuated over the foramen ovale, and giving origin to the pectoralis muscle. See EXTREMITIES.

PECTEN, in Natural History, the name of a tribe of shell-fish, the characters of which are these: it is a bivalve shell, futting close in all parts, of a flattened fhape, biflated in the manner of a comb, and often auriculated, fometimes only semi-auriculated, and in fome fpecies not auriculated at all. There are also fome few fpecies which are elate, not flat, as the others, claffed in the Linnean fystem with the ofrea; which fee. See alfo CONCHOLOGY (Ofrea).

This tribe of shells has had its name, pefien, from the longitudinal ftripe with which its furface is covered, which refembeles the teeth of a comb. According to the general character of this shell, it will be easy to perceive that it is
meant to include the cockles as well as the scollops; these being the peptens without ears, and with less flat or elated shells. These are called by all authors by a name which is only diminutive of pepten, pectenculus. And though the having ears is the common mark of distinction between the peptens and the cockles, which last usually have none, yet the genera are not distinct, as some have supposed; for there are shells allowed to be peptens, or scollops, which have yet no ears, and others universally allowed to be pectuncles, or cockles, which have ears. Hence appears the error of Linnæus, who made these two distinct genera, and gave the ears and the equal convexity of both shells as the great characters of them: these, though good marks to distinguish the species by, are by no means unalterable enough to found different genera upon.

The genus of pectuncles, or cockles, has been made by all authors a very extensive one, but the reader will find all the supposed species of it very aptly received into the genus of the cornifor-me, or heart-shell, (see Cordium,) and the peptens.

According to this establishment of the genus of the pepten, the species are to be enumerated under several distinct heads.

Thus, some peptens are auriculated on both sides: of these we have fifteen species.

Of those peptens which are semi-auriculated, we have five species.

Of those peptens which have no ears at all, we have seven species.

This shell-fish is one of the spinners of the sea, having power of spinning or forming threads like the mucle; but they are much shorter and coarser even than those of that fish; so that they can never be wrought into any fort of work, in the manner of the longer and finer threads of the pinna marina. The use of these threads, which the pepten or scollop spins, is to fix the creature to any other body that is near, whether it be a stone, a piece of coral, or another shell. All these threads proceed, as in the muckle, from one common trunk; they make their way out of the shell in those peptens which have only one ear, a little below that ear; in the others, probably they issue out on both sides. It is an evident proof, that the fish has a power of fixing itself at pleasure, to any solid body, by means of these threads, that after forms the scollops are often found stolled upon rocks, where there were none the day before, and yet these are fixed by their threads, as well as those which had remained ever so long in their place. They form their threads in the very same manner with the mucle, only their organ which serves for spinning is shorter, and has a wider hollow, whence the threads are necessarily thicker and shorter. See Muscle.

PECTEN Veneris, in Botany, Venus' Comb, so called because the long parallel beaks of the seeds allude something of the aspect of a long-toothed comb. See SCANDIX.

PECTINALIS, or PECTINEUS, (le pecliné, le pubo-fermon), in Anatomy, a mucle of the thigh, placed at the upper and front part of the limb, and extending from the horizontal portion of the pubes to the upper part of the linea aspera of the femur. It is flattened, elongated, and measures about three finger-breaths above, rather less below. The fascia lata and the crural vessels cover its anterior surface above, the tarsorius lower down. It covers the pubes, the hip joint, the obturator externus, the obturator vessels and nerve, and the second head of the triceps. Its inner edge is parallel to the outer margin of the first head of the triceps, by which it is a little covered; the outer edge is parallel to the psoas magnus. Its upper extremity is fixed to the upper and posterior edge of the pubes, chiefly by fleshy fibres, from the spine or tuberosity of that bone, to the beginning of the linea aspera; and when it descends obliquely outwards and backwards, and, arriving opposite to the little trochanter, is twisted on itself, so that the anterior surface is turned outwards, the posterior inwards; it is then inserted in the line, which descends from the bals of the little trochanter to the beginning of the linea aspera.

The lower part of the pectinalis consists of a flattened tendon, extending upwards on the front of the mucle. The fleshy fibre arise from the pubes by very short aponeuroses, and terminate on the back of the tendon.

It bends the thigh on the pelvis, or vice versâ: it contributes to maintain the pelvis in equilibrium on the lower limbs, when we stand. It will draw the thigh inwards, or towards the opposite limb, and carry it across the other. It rotates the thigh-bone outwards.

PECTINATI MUSCULI, the muscular fibres of the right auricle of the heart, so called because they are arranged in parallel fasciculi, somewhat resembling the teeth of a comb. See Heart.

PECTINATION, Combining of the Head. Frequent pectination is recommended by many physicians to women, and men who wear their hair, as an exerciser; and, at the same time, a kind of friction.

PECTINATUM FOLIUM, in Botany, a simple leaf, whose numerous, deep, parallel segments, resemble the teeth of a comb. See Leaf.

PECTIS, might be so called perhaps, as professor Martin says, from pectus, near comb or trimmed. From looking at the original specimen of P. ciliaris, we are disposed to think that Linnaeus, the author of the name, had more particularly in his mind the idea of a comb, as applicable to the fringed bafes of the leaves.—Linn. Gen. 450.

Gen. Ch. Common calyx cylindrical, of five oblong, obtuse, nearly equal leaves. Cor. compund, radiated; perfect florets about six, rarely fewer or more, in the disk, funnel-shaped, equally five-cleft; female ones in the radius five, rarely fewer, ligulate, ovate, rather longer than the calyx. Stem, in the perfect florets, filaments five, short; anthers united into a cylindrical tube. Pfl. in the perfect florets, germen linear; style thread-shaped; stigma cleft, in the female, germen linear; style thread-shaped; stigmas two, revolute. Peric. none, except the unchanged spreading calyx. Seeds, in all the florets, foliary, linear. Down of three or five chaffy bristles, various in length and breadth. Recept. naked.

1. P. humifusa. Swartz Ind. Occ. v. 3. 1562. Wildl. n. 1. (Jacobæa humifusa, hyperici foliis; Plum. 1c. 8c. t. 95. 2c.)—Leaves spatulate, obtuse, fringed at the base. Flowers stalked. Calyx-leaves elliptical. Stem procumbent. —Native of various islands in the West Indies, in open barren spots, communicated by Dr. Swartz. Root annual, tapering, with many fibres. Stems herbaceous, procumbent, three or four inches long, much branched, square, smooth, leafy. Leaves crowded, opposite; each pair crowing the others, sessile, about half an inch long, spreading, spatulate, obtuse, entire, thickened, and sometimes roughish, at the
PECTIS.

The edge, tipped with a very minute point; their under side paler, besprinkled with glandular dots; the base linear, elongated, clasping the stem, fringed with four or five brilly coarse teeth at each side. Flowers scarcely more than one on each branch, towards the extremity, axillary, on a simple, naked, sometimes downy, flalk, half an inch or more in length. *Calyx* leaves elliptical, folding over each other, hardly half an inch long, strongly keeled, obscurely dotted, obtuse, emarginate, and minutely downy at the summit. *Flowers* yellowish; those of the disk, according to Swartz, ten, rather unequally five-lobed; those of the radius five, short, oblong, entire. *Sepals* all linear-oblong, angular, black, those of the disk often abortive. *Dentate* or specially bristly, hispid at the base, serrate at the edge.

2. *P. profifata*. Cav. l.c. v. 4. t. 324. Willd. n. 2. — Leaves oblong, fringed at the base. *Flowers* small. *Calyx* leaves elliptic-oblong. Stem procumbent. — Native of New Spain. It flowered at Madrid in the autumn of 1795. This seems, as Wildenow remarks, very near the former, from which it differs in having longer leaves, but especially in the want of flalsks to the flowers, which are quite flatile, either at the ends of the branches, or in the fork between them. The *calyx* leaves moreover appear to be much narrower, and fearcely folding over each other, but we have only Casavilles's plate to judge by. *Dox* of five awl-shaped chafy scales. The *leaves* are an inch or more in length; glaucous and dotted, as in the foregoing, underneath.

3. *P. ciliaris*. Linn. Sp. Pl. 1250. Am. Acad. v. 5. 407. (Jacobea folis falcis, ad margines villosis; Plum. l.c. 145. t. 151. f. 2) — Leaves linear-lanceolate; tapering, and strongly fringed, at the base. *Flowers* axillary, flasked. Stem erect. — Native of Jamaica. Flowers small. *Calyx* leaves slender. *Dentata* annual. Stem erect, hardly a span high, divided, or slightly branched, leafy for the most part, obscurely marked with a narrow, downy, intrastomaceous line at each side. *Leaves* opposite, clasping the stem, above an inch long, linear, or somewhat lanceolate, obtuse with a small point; smooth on both sides; copiously and irregularly dotted, but not glaucous, beneath; entire, but rough at the edge with minute teeth; tapering at the base, and fringed in that part, usually for the space of half an inch, with numerous, dilatant, coarct, long, tawny, brilly hairs, directed upwards in a parallel manner. We can find no flowers on either of Browne's two specimens, but in the Amen. Acad. they are described as "axillary and sessile; the calyx yellow and small; the seeds of the disk crowned with five bristles, membranous at the base, those of the radius with two only." Such are all the particulars which we can positively ascertain respecting this plant, whose history is remarkably confused, especially in Wildenow. The only synonyn cited by Linnaeus in Sp. Pl. is Plummer's, which we dare not admit without a query. Its greater firmness may be no objection, but the fringe of the *leaves* extends much too far, and there is a representation of a short external *calyx* to one flower, which cannot agree with any *Pectis*. The latter may be an error of the copier or engraver. We fee no other exception to make, but on the contrary the shape and tintation of the flowers answer perfectly to the above description, which cannot have been made from this plate, because the colour of the *calyx*, and structure of the *seeds*, could not have been learned from it. But what can be the *P. ciliaris* of Swartz's Obs. 307? He describes the *seeds* and branches as diffuse; the *leaves* perforated, as it were, at the margin; the *flowers* flaked, solitary, either in the fumits or forks of the branches. He says his plant inhabits barren places in Hispaniola, flowering in June, and the *leaves* are eaten fresh with bread, having a sweet smell like favory. He quotes Hieracium minutum, longis integris et angustis foliis; Sloane Jum. v. 1. 255; by mistake changing angustis to argenteis, and omitting the figure, which is t. 150. f. 1. Wildenow copies him implicitly of course. Now this figure, though bad, is not unlike our first species, with which however Swartz's description will not agree, nor do we now know any plant that exactly answers to it. The *leaves* in Plummer's t. 86. f. 1. come the nearest as to the dots. See *P. punctata*.

4. *P. linifolia*. Linn. Sp. Pl. 1250. Am. Acad. v. 5. 407. (P. punctata; Jacq. Amer. 216. t. 152. Swartz Obs. 307. Tagetee's native of Hispaniola; his flouris linearibus nigris; Browne Jam. 319. Hieracium fruticosum, angelifimum, gravame folis, capitulis parvis; Sloane Jam. v. 1. 255. t. 149. f. 3. very imperfect.) — Leaves linear, acute, with two or four feteaceous teeth at the bafe. Stem forked, many-flowered. Seed-down of a few spreading awl-shaped bristles. — Native of Jamaica, Hispaniola, and Carthage, flowering from June to October. The root is annual. Stem two or three feet high, much branched and repeatedly forked, erect according to Jacquin, but diffuse according to Browne; the branches angular and smooth. *Leaves* about an inch and a half long, linear and very narrow, tapering at each end, entire, somewhat revolute when dry, smooth, besprinkled with dots beneath, even in Browne's own specimen which is described in Am. Acad., though they are there fail to be *levia*, (as opposed to dotted,) nor are the dots wanting in two other specimens now before us. Jacquin's figure here represents them rather too minute and cipient. At the base of the leaf, on each side, is one or two pair of spreading, bristle-shaped teeth. *Flower-flasks* numerous, foliar from the forks of the stem, fingle-flowered, half an inch long, slender, angular, smooth, often bearing one or two feteaceous *bracteae*. *Flowers* small, yellow, with more or less of a purple tinge; *seeds* of the disk three, rarely but two, their *seeds* crowned with two spreading, smooth, awl-shaped bristles, about the length of their own *corolla*; those of the radius five, with three similar bristles to their *seeds*. In these respects all our species answer to the Linnean description; as also to that of Jacquin, that there can be no doubt of his plant, though we are obliged to prefer the Linnean specific name, of nearly the same date.

5. *P. punctata*. Linn. Sp. Pl. 1250, excluding Jacquin's synonyn. (P. ciliaris; Swartz Obs. 307? Chondrilis folia angustis et ad oras punctatis; Plum. l.c. 74. t. 86. f. 1.) — Leaves oblong, acute, with two or four minute bristles at the base. Stem forked, many-flowered. Seed-down of several short lacered scales. — Native of the West Indies. We have specimens in the herbarium of the younger Linneus, marked *P. punctata*, apparently a manuscript name, every body having confidered the foregoing as the Linnean *punctata*. But that being certainly *linifolia*, and the synonyn of Plummer anwering well to the present, even in the parts of frutification, though the dots of the *leaves* are rather too marginal and regular, we retain for it the name of *punctata*; an appellation by no means discriminative indeed, as every known species is dotted. The size and habit of the plant are like the last; the *seeds* angular, purplish, repeatedly forked, and finally somewhat panigled. The *leaves* however are scarcely more than half as long, and nearly twice as broad, strongly dotted beneath, frequently rough-edged; their base furnished with one or two pair of extremely small bristles, not half the size of what are observable in *linifolia*. *Flower-flasks* much the same, but with more numerous, smaller, more chafy *bractae*. *Flowers* of the disk about *fix*; those of the radius five. *Seed-down* in each of from three to five.
five small, chaffy, fringed and jagged, brown scales, smallest, and perhaps fewest, in the marginal florets. In three instances we find one of these scales, in the disk, elongated into a hispid bristle, extending farther than the corolla; a conclusive proof of the variable ends of the seed down in Petitis, which is notwithstanding a most natural genus. Is it possible that this species can be P. cicliris of Swartz? Perhaps the bristles of the seeds may be sometimes more numerous than we have found them, and then his otherwise unintelligible description of the site and pappus will be accounted for. We cannot ascertain what this author intends by P. linifolia, for which he has merely a reference to Petiver, (Repunculus Jamaicensis, folio tenuissimo,) without page or plate, a citation we are unable to verify. That reference may belong to the real linifolia, though the latter should seem to be Swartz's pappus.

Frequent in New Spain. It has been cultivated for twenty-five years past in the gardens of Spain and France. We obtained it in 1792, from that of Dr. Bellardi at Turin, by the name of P. trifida. Roth says the root is annual, which we believe to be the case; Lamarck makes it perennial. Stem erect, two feet high, leafy, angular, deeply furrowed, smooth, alternately branched, panicked, many-flowered. Leaves alternate, pinnatifid, a most capillary and obtuse, like some of the finer kinds of Arctensia, one inch and a half or two inches long, smooth, very bitter, befrinkled all over with minute glandular dots. Flower-flanks scattered and terminal, angular, roughish, slender, single-flowered, with one linear bract. Calyx turbinate; its leaves obovate, befrinkled with minute shining dots, and beautifully tinged with violet. Corolla yellow; the radiant florets but one or two, ovate; those of the disk about six. Seeds square, with brilUe angles. Down of five or more very beautiful, rather unequal, lanceolate, acute, membranous, glittering scales, all fringed with purple, their edges more or less deeply jagged or fringed. These scales are about as long as the corolla of each floret, and we do not find them ever accompanied with any bristles. A comparison of the seed-down with that of the lant, will sufficiently shew, that the present plant is not authorized to rank as a distinct genus on that account. As to the habit, the leaves being alternate is more material than their division, to which last character the fringes of the other species may be considered as an approach. That they are full of glandular dots we readily perceive; though Lamarck indicates the contrary, as a difference between this plant and Petitis, all whose species, he rightly says, have dotted leaves. Roth appears to have known nothing of Petitis, at least on his first establishment of his genus Schkuhria; nor was he perhaps sufficiently aware of the merits of such an undertaking, in this intricate class. The name of Schkuhria, notwithstanding its unfortunate orthography, is richly entitled to botanical consecration, and we trust that some flable genius will, hereafter, be honoured with the charge of conveying it down to posterity.

S. Petìtis, an ancient musical instrument, of the form or use of which we are not very certain. Athenæus says, that the pétis, magasis, and barbiton, were the same instrument. It has been supposed to have been a discord, a small instrument of two string, with a neck, or finger-board, by which they were held down with the pressure of the fingers, and a compound scale produced.

PEC

PECTORAL, something relating to the breast, petitus. In the Romish church, bishops, and regular abbots, wear a pectoral cross, i.e. a little cross of gold, hanging from the neck down to the breast.

PECTORAL Medicines, in the language of the older physicians, were all those medicines which were supposed to be the relief of the disorders of the breast or lungs. The epithet, however, was indefinite, inasmuch as it included demulcients, attenuants, astringents, and even anodynes, or whatever contributed to ease the breathing and cough. It has, therefore, been discarded. The more limited term, expectorants, is preferable.

PECTORAL Syrup. See Syrup.

PECTORAL Wine. See Wine.

PECTORALE, or PECTORAL, in the Jewish Law. See RATIONALE.

PECTORALES, in Anatomy, two muscles placed on the front of the chest.

The pectoralis major (femoro-humerian) is the largest of the two, covers the front of the chest and of the axilla, and extends from the clavicle, the ilium, and the cartilages of the true ribs, to the front edge of the brachial groove of the humerus. It is broad, and approaches to the triangular figure.

Its anterior surface is covered by the skin, the fibres of the latissimus dorsi being interposed between them above, and the mammary gland about the middle. The pectoral surface covers, towards the inner side, the front of the ilium, to which it is attached; more externally, the cartilages of the true ribs, to which it is also attached, excepting the first and sometimes the last. This attachment is obviated towards the flaccid ends of the cartilages, and occupies a broader space in the lower than in the upper part: it extends through the whole length of the sixth. Below the latter, it covers the rectus and obliquus externus abdominis. It also covers, in faeceptum, beginning from the ilium, the true ribs, the external intercostal muscles, the subclavus, the pectoralis minor, the ferratus magnus, the axillary vessels, the brachial plexus, and the coraco-brachialis and biceps muscles. The surface of the muscle is united to the parts just enumerated by loose cellular tisue, the quantity of which increases as we approach the axilla.

The internal edge is somewhat semicircular in its outline, and is fixed to the middle of the front of the ilium from its upper part, to the articulation of the cartilage of the sixth rib. In front of the eniform cartilage it is confounded with the edge of the opposite muscle, and has a connection with the upper end of the linea alba; a small slip of its fibres is also connected to the upper edge of the aponeurosis of the obliquus externus abdominis, and generally covers the upper slip of that muscle.

The upper edge may be divided into two parts; the first, which is properly superior, is attached to the inner half of the front edge of the clavicle; the second is rather external, and stretched obliquely from the clavicle to the humerus. The latter is directed downwards and outwards, and is nearly parallel to the inner edge of the deltoid, from which it is separated by a cellular line, broader above than below, and containing the cephalic vein. Sometimes the edges of the two muscles are confounded.

The lower edge is connected to the aponeurosis of the obliquus externus, goes obliquely outwards and backwards in front of the chest, then before the axilla, of which it forms the front edge; it then descends a little, and terminates on the humerus. This edge is thin towards the chest, and thicker at the axilla, where the skin turns in a little on its posterior edge.
PEC

The superior and inferior margins of the great pectoral muscle are united at a truncated angle, about two inches broad, attached to the front edge of the bicipital groove. The clavicular and the clavicular portions of the muscle may be more or less distinct from each other: they can sometimes be feattered throughout. The attachments to the clavicle and sternum are by no means of very short aponeuroses: those of the right and left muscles decussate in the front of the sternum. Towards the lower part of the chest, and upper part of the abdomen, a broader aponeurosis is seen, united to that of the oblique exterius. To the humerus the pectoralis major is attached by a broad tendon, from which productions are continued to line the bicipital groove, united to the tendons of the latissimus dorsi, teres major, and suprad pinnatus, and to form a connection with the aponeurosis covering the muscles of the arm. This tendinous insertion, and the muscular fibres connected to it, are twisted on themselves: the fibres of the clavicular portion are on the outside, and pass downwards: those of the pectoral are behind the former, and pass upwards.

The muscular fibres are not all alike in length or direction. Those which come from the clavicle are the shortest, descend from within outwards, and terminate on the front of the tendon. The fibres from the upper part of the sternum are rather longer, go horizontally outwards, and end on the front of the tendon, externally to the former. The remaining fibres go from below upwards, and increase in length and obliquity from above downwards: they end on the posterior surface of the tendon, and are turned in successively, one under the other, as they reach the tendon, so that the lower ones are fixed to the upper part of the tendon.

This muscle executes the reciprocal motions of the chest and arm. If the latter be hanging by the side of the body, the pectoralis major will move it forwards and inwards, so as to carry it across the front of the chest: when the arm has been elevated, it will draw the limb down again: it will also retract the humerus inwards, particularly if it has been turned out. The clavicular portion will co-operate with the deltoid in elevating the humerus. Acting in conjunction with the latissimus dorsi and teres major, it will draw the limb close to the side. When the arm is fixed, as in seizing any body before or above us, this muscle brings the trunk to the arm: hence it is an important agent in climbing.

The pectoralis minor (ferratus minor anticus, coilo-coracoidien) lies on the front and upper part of the chest, and extends from the third, fourth, and fifth ribs to the coracoid process: it is flattened and triangular, with the bases of the triangle turned downwards and inwards, the apex upwards and outwards. The anterior surface is covered by the pectoralis major; the pectoral covers the ribs, the intercostal muscles, the serratus magnus, axillary vessels, and brachial plexus. The upper and lower edges are unattached, and present nothing remarkable: the former is the short one. The bases of the muscle, turned downwards and inwards, is fixed to the upper edge and external surface of the ribs mentioned above, or to the second, third, and fourth, by broad and thin aponeuroses. Thence it is continued backwards and outwards, growing at the same time narrower, and is fixed to the coracoid process, where it is connected to the coraco-brachialis.

The aponeuroses, by which it is fixed to the ribs, have been mentioned: a flattened tendon connects it to the coracoid process: the fibrous fibres are continued obliquely between these, flanting from below upwards, backwards, and outwards: the upper are the shortest.

By drawing the coracoid process downwards and forwards, this muscle rotates the scapula, so that the anterior angle is depressed, and the inferior goes backwards. The serratus magnus alae and levator scapulae assist in producing the same effect. When it concurs with the serratus magnus, the scapula is carried directly forwards. Supposing the shoulder to be firmly fixed, it may elevate the ribs, and thus assist in inspiration: the same remark will hold good of the pectoralis major also: hence, in all thmatic persons, and all those who breathe difficultly, the shoulders are habitually elevated, to bring these muscles into play, and they are more forcibly drawn up in the paroxysms of obstructed respiration.

PECTOREL, in our old writers, armure for the breast, a breast-plate, or petral for a horse. It is mentioned flat. 14 Car. II. cap. 3.

PECTORIS Os, in Anatomy, the name as sternum. Pectoritis Hydrops. See Dropsy of the Breast.

PECTORIS Offa, in fifth. The bones of the breast and belly are bell sought after in the cutaneous and spinous kinds. In the spinous kinds they are the clavicles, the sternum, the scapulae, or bones to which the prime pectorales are attached at their bases, the bones at the roots of the pinnæ vertebrales.

The number, situation, and figure of these differ greatly in the several kinds of fish, and make very essential characters. See Fish, Anatomy of.

PECTORIS Triangularis. See Triangularis and Pectorales.

PECUARI, among the Romans, those who farmed the public pastures, in order to let them to advantage.

PECULI, or PECUL, in Commerce, a weight used in some parts of the East Indies. The bahr of three peculs, or 300 catties, in Bantam weighs 356 lb. avoirdupois. The pecul of 100 catties at Cheribou weighs 125 lb. Dutch troy weight, or 132 lb. avoirdupois. Heavy goods are weighed in Malacca by the pecul of 100 catties, or 1600 taels. The pecul is 135 lb. avoirdupois, and three peculs make a barah. But what is called the China pecul at Malacca weighs 125 lb. avoirdupois. Rice is sold by the coyang of 40 peculs, or 5400 lb. avoirdupois. A coyang of rice in the isle of Amboyna contains 25 peculs. The pecul of pepper at Banjarmasin is 100 catties, or 125 lb. Dutch troy, or 135 lb. 10 oz. avoirdupois. The pecul and catty at Macassar are the same as at Amboyna. The pecul in Siam is 50 catties, and the catty 20 taels, or 80 taels. The Siam pecul weighs 125 lb. avoirdupois, and the catty 41 oz. 4 Dr. avoirdupois. The common weight in Trangania, on the farther peninsula, is the China pecul, which answers to 12 lb. 8 oz. 9 Dr. avoirdupois.

PECULATE, PECULATUS, in the Civil Law, the crime of embezzling the public money, by a person who has the management, receipt, or custody thereof: so called quas pecunia ablatio.

Civil lawyers use peculate for any theft of a thing, either facted, religious, public, or fiscal. Peculate in the case of public money, is prosecuted even on the criminal's heir. The Julian law, among the Romans, punished this crime with death in a majilrate; and with deportation, or banishment, in a private person. With us it is not a capital crime, but subjects the committee of it to a defectutory fine and in prifonment.

PECULIAR, in the Cana Law, a particular parish, or church, which hath jurisdiction within itself, for probate of wills, &c. exempt from the ordinary of the diocese, and the bishops' courts.

There are royal peculliars, and archbishops' peculliars.
The king’s chapel is a royal peculium, exempt from all spiritual jurisdiction, and referred to the visitation and immediate government of the king himself, who is supreme ordinary.

Peculiars of the archbishops are exclusive of the bishops and archdeacons.

It is an ancient privilege of the fee at Canterbury, that wherever any manors or advowsons do belong to it, they forthwith become exempt from the ordinary, and are reputed peculiars. In the province of Canterbury, there are more than a hundred such peculiars. In these pecular jurisdicitions is administered by several commissaries; the chief of whom is the dean of the arches for the thirteen peculiars within the city of London. See Archies.

There are also peculiars of bishops, exclusive of the jurisdiction of the bishop of the diocese in which they are situated: of these the bishop of London hath four parishes within the diocese of Lincoln; and every bishop, who hath a house in the diocese of another bishop, may therein exercise episcopal jurisdiction.

There are also peculiars of bishops in their own diocese, exclusive of archi-diocesan jurisdiction.

The peculiars of dean, deans and chapters, prebendaries, &c. are places in which, by ancient compositions, the bishops have parted with their jurisdiction, as ordinaries to those societies. See Courts of Peculiars.

Peculum, the flock which a person in the power or property of another, as a slave, minor, or the like, may acquire by his own industry, without any advance or assistance from his father or master; but merely by their permission.

The word is usually derived a pecunia et pecoribus; because the whole estate actually confided in money and cattle.

Peculum is also used, among the Romanists, for what each monk or religious reveres, and possest to himself.

Some say, that the peculium of a religious, when preferred to a cure, does not cease to belong to the monastery; and that the property thereof never absolutely reifies in the religious himself.

Pecunia. Money. See Money.

Pecunia, in our old law-books, is sometimes used for cattle, and sometimes for other goods, as well as money.

In the emendation of the laws of Edward the Confessor, by William I., it is ordered, that no nova pecunia, living money, i.e. cattle, be bought or sold, except within cities, and that before these sufficient witnesses.

So in Domeday book, pecunia is frequently used, pro pecude; as pature ad pecuniam ville.

Pecunia Ecclesiae, was anciently used for the estate of the church.

Pecunia Sepulchralis was money formerly paid to the priest at the opening of the grave, for the good and behalf of the deceased soul; and which our Saxon ancestors called foul fect, and anima symbolum.

Pecunia, in Mythology, a goddes among the Romans, whom they invoked with a view of procuring money in abundance. The same as the specie was coined of different metals, especially of gold, silver, and brass, and as one divinity would have too much occupation in taking care of the different coinages a particular one was appointed for each. Three goddesses represented upon some medals of the emperor Commodus and his successors, with a pair of scales, the cornucopia, and a heap of money by them, prove that there was at least that number, and the antiquaries agree that they preceded over the coinage of three metals. Befides these three divinities, there was also “Æs,” or “Aesculana,” for the brass coin.

Pedage, in Geography, a town of Naples, in Calabria Citera; 6 miles S. of Cosenza.

Pedaconda, a town of Hindostan, in Mysoor; 15 miles E. of Chinnam-Balabarum.

Pedage. Pedagium, toll, or a local due exacted on persons, goods, and carriages, passing through certain places.

Pedage is usually levied for the repairing of roads, bridges, and canyways, the paving of streets, &c. — Anciently, those who had the right of pedage, were to keep the roads secure, and answer for all robberies committed on the passengers between fun and fun; which is still observed in some parts of England and in Italy, where there were guards, called stationarii, established for the security of merchants, particularly at Terracina, on the road between Rome and Naples.

Pedagogue, or Pedagogue, παιδαγόγος, formed from παιδιανεν — παιδαγός, leader of boys, a tutor or master, to whom is committed the discipline and instruction of a scholar, to be instructed in grammar and other arts.

M. Fleury observes, that the Greeks gave the name pedagogues to slaves appointed to tend their children, lead them, teach them to walk, conduct them to school, &c. The Romans also give the same denomination to the slaves who were entrusted with the care and instruction of their children.

Pedale, as à pedale, implies a long note in the buffo continuo, or thorough-bass, to be played or sustained without chords. See Tarto Solo.

Pedales. See Abbot.

Pedalinææ, in Botany, a natural order of plants, established by Mr. R. Brown, Prod. Nov. Holl. v. i. 519, and named from Pedalium, which belongs to it; see the next article. The characters are these.

Calyx in five, nearly equal, divisions.

Corolla of one petal, below the germin, irregular; its throat inflated; limb two-lipped.

Stamina four, two longer than the rest, included within the tube, and accompanied by the rudiment of a fifth.

Germen surrounded at the base with a glandular disk, of several cells, with one or two seeds in each. Style one. Stigma divided.

Drupa dry, armed with spines, of several cells.

Herbs with opposite leaves, and axillary flowers accompanied by a pair of bracteas.

Pedalium, a Greek name, chosen for this plant by professor David Van Royen, in allusion, as it seems, to the shape of the fruit. Pedalium is, as professor Martyn says, the rudder of a ship, which each dilated angle, or wing, of the part in question somewhat resembles; but the Greek word also means a flind, button, or head of a nail, and the regular, or artificial figure of the whole fruit, reticulated like illa- gree, might well suggest such an application of it here.

Gen. Ch. Cal. Perianth inferior, minute, in five deep segments; the lower ones longest. Cor. of one petal, slightly ringed; tube triangular, flat in front; limb flat, spreading, in five deep, rounded segments, the upper ones smallest, the lower
lower one largest of all. Stam. Filaments four, shorter than the tube, hairy at the base, two of them short; ; anthers heart-shaped, two-lobed, terminated by a gland, and co-hering in the form of a cross. There is, according to Rottboll, between the shorter filaments, the rudiment of a fifth filament, with a minute anther. *Pfll. Germei conical; style the length of the filaments; stigma cloven, its upper segment reflexed, the lower revolute. *Peric. Drupae dry, fibrous, flat; orna, marked by furrows, and as many angles, each of which bears a horizontal spine at its base. *Seed. Nut of two cells, with four wings, and clothed with the rigid, permanent, branched and entangled fibres of the drupa. Kernels two in each cell, oblong, one above the other, each clothed with a dry membranous bivalve tunic.

Ell. Ch. Calyx in five deep segments. Corolla slightly ringent; its limb in five flat segments. Stigma two-lobed. Drupa dry, fibrous, with four spines. Nut of two cells, with four punctuated seeds.

Obs. This genus is thought to differ from *Josephinia, see that article, in having but two lobes to the stigma instead of four, fewer cells in the fruit, and solitary seeds. Perhaps the genera are not naturally distinct, but we have not compared them in a sufficiently perfect plate to decide. In habit they are very similar. We have corrected the original generic character; not only from the remarks of Rottboll and Gartner, but from the manuscript emendations of Linnaeus himself, annexing his own various conjectures, as to the natural order. What Gartner terms an empty cell, appears merely a hollow stalk to the fruit.

1. *P. Murex. Linn. Sp. Pl. 892. Burm. Ind. 139. t. 45. f. 2. (Murex; Linn. Zeyl. 205. Caka Malii; Rheede Malab. v. 10. 143. t. 72. Gerv.)—Native of maritime situations, in Ceylon, and on the Malabar coast. Root annual. Herb very various as to luxuriance, of a somewhat flabby and glutinous or greasy habit, like Chenosporum album, or *Fet. Hen. Leaves imperfectly opposite, sometimes all alternate, flaked, simple, obovate, obtuse, abrupt, coarsely toothed. Flowers axillary, solitary, flaked, the tube of the corolla about an inch long; their colour apparently white, or pale reddish. Fruit drooping, singularly elegant at an advanced period, when the branched entangled fibres become visible.

Rottboll says the smell of musk is very powerful in the flowering plant. We are told that the herb infused in water gives out an abundant colourless and inaudible mucilage, and that it is used on the coast of Coromandel to turn water into a clear jelly, for what particular use is not mentioned. We find no such result from pouring boiling water on the dried leaves.

PEDALS, keys for the feet in almost all the large organs on the continent of Europe. The invention is recorded by Proutorius, Syntax. Muf. and ascribed to Bernard, a German organist at Venice, so early as the year 1470. (See Organ.) This discovery manifested great progress in the construction and performance of that noble instrument at so early a period; and seems to imply ideas of harmony and effects, beyond the power of human hands.

PEDANEUS, in the Civil Laws, a petty judge who has no formal seat of justice, but bears caufes flanding, and without any tribunal.

The word feems formed from *fanas in pedibus: and is used among the ancients by way of opposition to those magistrates who were seated in the curule chair, in *fella curulii, or had a tribunal or bench raised on high.

The Roman pedanei therefore, were sueh as had no tri-

bunal, nor pretorium; but rendered justice de plano, or plano pede.

From the eightieth-second Novel, it appears that the emperor Zeno established these pedanei in the fee of every province; and that Julianus erected seven of them at Constantinople, in manner of an office: granting them power to judge in any case as high as three hundred crowns.

PEDANT, a schoolmaster, or pedagogue, who profefles to instruct and govern youth, and teach them the liter-

ra humaniores and the arts.

Pedant is also used for a rough unpolished man of letters, who makes an important use of the sciences, and abounds in unfeasable criticisms and observations.

Dacier defines a pedant, a person who has more reading than good sense.

Pedants are people ever armed with quibbles and syl-

logisms; they breathe nothing but dissertation and chicanery, and pursue a proposition to the last limits of logic.

Malebranche describes a pedant as a man full of false erudition, who makes a parade of his knowledge, and is ever quoting some Greek or Latin author, or hunting back to a remote etymology.

St. Evremont says that to paint the folly of a pedant, we must represent him as turning all conversation to some one science or subject with which he is best acquainted.

There are pedants of all conditions, and of all ages. Wicquefort says, an ambassador, always attentive to formalities and ceremonies, is nothing else but a political pedant.

PEDANTRY, or PEDANTISM, the quality or manner of a pedant.

To swell up little and low things, to make a vain show of science, to heap up Greek and Latin without judgment, to tear those to pieces who differ from us about a paffage in Suetonius, or the etymology of a word, to flir up all the world against a man for not admiring Cicero enough, to be interred for the reputation of an ancient as if he were our next of kin, form what we properly call pedantry.

PEDARIAN, in Antiquity, those senators who signified their votes by their feet, not their tongues; that is, such as walked over to the side of those whose opinion they approved of, in divisions of the senate.

The origin of the word Dr. Middleton thinks owing to this, that though the magistrates of Rome had a right to a place and vote in the senate, as well during their office as after it, and before they were put upon the roll by the con-

fars, yet they had not probably a right to speak or debate there on any question, at least in the earlier times of the republic. For this feems to have been the original distinction between them and the ancient senators, as it is plainly intimated in the formule of the consular edict, sent abroad to fummon the senate, which was address'd to all senators, as those who had a right to vote in the senate. From which distinction, these lait, who had only a right to vote, were called, by way of ridicule, pedarian; because they signified their votes by their feet, not their tongues, and, upon every division of the senate, went over to the side of those whose opinions they approved. It was in allusion to this old custom, which feems, however, to have been wholly dropt in the later ages of the republic, that the mace part of the fe-

nate continued still to be called by the name of pedarnans, as we learn from Cicero, who, in giving an account to Atticus of a certain debate and decree of the senate upon it, says, that
that it was made with the eager and general concurrence of the pedarrians, though against the authority of all the con-

furs. Vide Felius in c. c. Senatus, A. Cell. lib. iii. 18.

"Felt in Pedarius. Cicer. ad Attic. 1. 19. Middlet. of

Rom. Sen. p. 86. feq.

PEDITUM FOLIUM, in Botany, a foot-like leaf, is so
called rather by way of contrast to a palmate or hand-like
one, than from any very preface resemblance to the foot of
any animal. It is compound, being in the first instance ter-

nate, and the two lateral leaflets are each, more or less
numerosly, subdivided in front. Helloburus satidus and

niger have this sort of foliage.

PEDATURA, in Roman Antiquity, was used for a space
or proportion of a certain number of feet set out.

The word occurs frequently in writers about military af-
fairs; thus in Hyginus, de Castrametatione, we meet with
"meminerimus itaque ad computationem cohortis equitata
milliariae pedataram ad mille trecentos sexaginta dari debere;" which is to be thus explained: the pedatura, or space al-

lowed for a cohort equitata or provincial cohort, conflitng of

both horse and foot, could not be the same as the peda-

tura of an uniform body of infantry, of the same number,
but must exceed it by 360 feet; for the proportion of the
room of one horseman to one foot soldier, he allows as two
and a half to one. Vide Phil. Trav. N° 482. fect. 3.

PEDDAGUMY, in Geography, a town of Hind-
doofian, in the cirear of Elalore; 10 miles N.W. of Ellore.

PEDDAPOUR, a town of Hindoosian, in the cirear
of Rajamundry; 22 miles E.N.E. of Rajamundry.

PEDDI-BALABARUM, a town of Hindoofian, in
Myf,ore; 16 miles N. of Bangalore.

PEDEE, GREAT, a river of America, which rifes in
the Appalachian mountains, in North Carolina, where it is
called Yadkin river. In South Carolina it takes the name
of Pedee, and after receiving the waters of Lynche’s creek,
Little Pedee, and Black river, joins the Wakkamaw river,
and near George-town. These united streams, with the accret-
ions of a small creek, on which George-town stands, form Win-
yaw bay, which, about 12 miles below, communicates with
the ocean. It is navigable for boats of 60 or 70 tons, about
200 miles.

PEDEE, LITTLE, a river that rifes in severall branches, in
North Carolina, and unites with the Great Pedee in South
Carolina, about 32 miles from the ocean.

PEDEMONT D’ALEST, a town of Naples, in La-
vors; 20 miles N.E. of Capua.

PENDED, or Biren, a town of Illiria, the fee of a
bishop: 25 miles S.S.E. of Trielle. N. lat. 45° 22’. E.
long. 14° 16’.

PEDEIREA, a sea-port town on the W. coast
of Portugal, in the province of Estremadura, containing about
1300 inhabitants; 18 miles S.W. of Leyria. N. lat. 39°
31’. W. long 8° 56’.

PEDERSO, a town of Sweden, in the government
of Wafa; three miles S. of Jacobstalad.

PEDESTAL, formed from peds, pedis, foot, and col-

umn, in Architecture, the lowest part of an order of col-

umns; being that which sustains the column, and serves it
as a foot to stand on.

The Pedestal, called by the Greeks stylobates, and stero-
bates, consists of three principal parts; viz. a square trunk,
or dye, which makes the body; a cornice, the head; and a
baze, the foot of the Pedestal.

The Pedestal is properly an appendage to a column; not
an effential part thereof; though M. le Clerc thinks it is ef-

sential to a complete order.

The proportions or ornaments of the Pedestals are different

in the different orders: Vignola, indeed, and most of the
moderns, make the Pedestal, and its ornaments, in all the
orders, one-third of the height of the column, including
the base and capital: but there deviate from this rule.

M. Perrault makes the proportion of the three constituent
parts of pedestals, the same in all the orders; viz. the base
one-fourth of the Pedestal; the cornice an eighth part; and
the focele, or plinth, of the base, two-thirds of the base it-

self. The height of the dye is, what remains of the whole
height of the Pedestal.

PEDESTAL, Tuscan, is the simplest and lowest of all.

Palladio and Scamozzi make it three modules high; Vignola
five. Its members, in Vignola, are only a plinth, for a
base; the dye; and a talon crowned, for a cornice. This
has rarely any base.

PEDESTAL, Doric, Palladio makes four modules five
minutes high; and Vignola five modules four minutes.

In the antique, we not only do not meet with any pedestals;
but even not with any base, in the Doric order.

The members in Vignola's Doric Pedestal, are the same
with those in the Tuscan, with the addition of a moucheet
in its cornice.

PEDESTAL, Ionic, in Vignola and Serlio, is fix modules
high; in Scamozzi five; in the temple of Fortuna Virilis
it is five modules twenty-five minutes. Its members and or-

naments are molly the same with those of the Doric, only
a little richer. The Pedestal now usually followed, is that of
Vitruvius, though we do not find it in any work of the an-
tique. Some, in lieu hereof, use the Attic base, in imitation
of the ancient.

PEDESTAL, Corinthian, is the richest and most delicate of
all. In Vignola it is seven modules high; in Palladio, five
modules one minute; in Serlio, fix modules fifteen minutes;
in the Coliseum, four modules two minutes.

Its members, in Vignola, are as follow; in the base are
a plinth, for a focele: over that a tore carved; then a reglet,
a gula inverted and enriched, and an alfragal. In the dye are
a reglet, with a congce over it; and near the cornice a reglet,
with a congce underneath. In the cornice is an alfragal, a
frieze, fillet, alfragal, gorge, and a talon. See each under
its proper article.

PEDESTAL, Composite, in Vignola, is of the fame height
with the Corinthian, viz. seven modules; in Scamozzi, five
modules two minutes; in Palladio five modules seven min-
utes; in the Goldsmith's arch, seven modules eight min-
utes.

Its members, in Vignola, are the same with those of the
Corinthian; with this difference, that, whereas they are
most of them enriched with carvings in the Corinthian, they
are all plain in the Composite. Nor must it be omitted, that
there is a difference in the profiles of the base and cornice, in
the two orders.

The generality of architectes, Davler obervers, use tables
or panels, either in releves, or creux, in the dye of pedestals,
without any regard to the character of the order. Those,
in releves, he observes, only fit the Tuscan and Doric; the
three others must be indented: but this, he adds, is a thing
the ancients never practised, as being contrary to the rules
of solidity and strength.

PEDESTAL, Square, is that whose height and width are
equal; as that of the arch of the lions at Verona, of the
Corinthian order; and such some followers of Vitruvius, as
Serlio, Philander, &c. have given to their Tuscan orders.

PEDESTAL, Double, is that which supports two columns,
and is larger in width than height.

PEDESTAL, Continued, is that which supports 2 row of col-

umns without any break or interruption; such is that which

sultans
sustains the fluted Ionic columns of the palace of the Thuri-
lerae on the side of the garden.

Pédstalls of Statues, are those serving to support figures
or statues.

Vitruvius observes, there is no part of architecture more
arbitrary, and in which more liberty may be taken, than
in the pedestals of statues; there being no laws prescribed
for them by antiquity; nor any even settled by the mo-
derns.

There is no settled proportion for these pedestals; but
the height depends on the situation, and the figure they sup-
tain. Yet, when on the ground, the pedestal is usually two-
thirds, or two-fifths, of that of the statue; but always the
more massive the statue, the stronger must be the pedestal.

Their form, character, &c. are to be extraordinary and
ingenious, far from the regularity and simplicity of the
pedestals of columns. The same author gives us a great
variety of forms, oval, triangular, multangular, &c.

PEDESTRIAN STATUS. See Statues.

Pediæan, μιδήαν, in Antiquity. The city of Athens
was antiently divided into three different quarters: one on
the defcent of a hill; another on the sea-shore; and a third
in a plain between the other two.

The inhabitants of the middle region were called Hidæan,
Pediæans, formed from μπεδomatic, plain or flat: or, according to
Archiluce, Peidai: those of the hill, Diacrians: and those
of the shore, Paralians.

These quarters usually composed fo many different fac-
tions. Peiñfratus made use of the Pediæans against the
Diacrians.

In the time of Solon, when a form of government was
to be chosen, the Diacrians would have it democratic: the
Pediæans demanded an ariſtocracy: and the Paralians a mixed
government.

PEDICELLARIA, in Natural History, a genus of the
class and order Vermes. Mollusca. The generic character is,
that it has a body soft and fented on a rigid fixed peduncle;
the aperture is fingle. There are three

Species.

Globifera. This is described as having a spherical
head. It inhabits the Northern seas, among the spines of
the Echinat. The body is minute, and resembling a mucor;
the head is red-dish, having the appearance of a small cherry;
the flem is tawny, and covered with a gelatinous hyaline
skin.

Triphylla. The head of this is three-lobed; the lobes
are nearly fquare and unarm'd; the neck is round. It is
found in the Northern seas, among the spines of Echinat.
The head has red-dish or hyaline lobes, sometimes ovate; the
neck is flexuous and blue; the peduncle or flem is of a
chefnut-brown.

Tridens. Head three-lobed, the lobes are oval and
awned; the neck is round. It inhabits also the Northern
seas, and likewise among the spines of Echinat. The neck
is smooth and hyaline, though sometimes it is reed-dish;
the lobes of the head are sometimes four, and thrie as long as
the neck, rarely unarm'd with awns; the peduncle is red-dish,
and three times as long as the neck.

Pedícullus, in Botany, a partial fower-foke, or the
ultimate subdivision of a general one. See Pedunculus.

Pedicile, Pedicillus, a diminutive of ped, foot,
footstalk: that little stalk whereby the leaf, fruit, or
flower, is fustained, and connected to its branch or flem. (See the preceding article.) Flowers will keep freh a long
time after gathering, by immerging their pedicles in water.
The great secret of preferring fruits for the winter is to

feed up their pedicles with wax. Cherries with the shorted
pedicle are esteemed the best. The piffil of the flower
sometimes becomes the pedicle of the fruit.

Pediculaires, in Botany, a natural order of plants,
so denominated by Jullian, from Pediculæris, which is one of
them; see the next article. It is the second of the eighth
clafs in that author's fytem, and comprises about a third part
of the Perfonate of Linneus; see Personate. For the
characters of Jullian's eighth class, see Gentianæ. He
thus defines the present order.

Calyc divided, permanent, often tubular. Corolla for the
most part irregular. Stamens definite in number. Style one;
with a simple, or rarely two-lobed, stigma. Fruit a capular,
of two cell, with many seeds, and two valves which are
connected by a central projection, forming a partition bear-
ing seeds on both sides, and scarcely separable, the edges of
the valves unconnected with the partition, and finally sepa-
rating. The flem is moistly herbaceous. Leaves either oppo-
site or alternate, each with a fingle bratæa.

The frift fectio, distinguished by having the flaments not
didymous, their number two or more, conflits of Polygala,
Veronica, Sibthorpiæ, and Dysphæra. The fappo and fectio, the
didymous flaments, that is, two long and two short, has Ourjia of Commerson, and
Pirjia of Aublet, with the Linnean Erinus, Manoula, Cof-
tilla, Euphræa, Buchmera, Batfia, Pedicularis, Rhinanthus
and Melampyrum.

A third fectio conflits of four genera akin to true Pediculi-
æ. These are Hybanche, Obolaria, Orobanche and
Labrea; pyræal plants, about whose germination nothing
is, or perhaps can be, known. Their fruit is in a
manner unicorial.

The Pediculaires in general are remarkable for turning
black in drying; but this quality does not belong to Poly-
gala. That indeed is a genus whose whole natural affinity is enve-
loped in much uncertainty, and it seems to us that Linneus,
who refers it to his Lomentææ, comes nearer the truth than
Jullian.

Pediculæris, Loufe-wort, a very noble and beau-
tiful genus of plants; notwithstanding its unpromising
name, derived from pediculus, a louse, which alludes to a
quality attributed to some of the species, of making
their loute that feed upon them improbable: this report might per-
haps arise, as with respect to the Droflera and Hydroclætæ,
from their growing in watery pastures, where sheep become
unhealthy and feafy, whether they feed on any of these
herbs, which is very doubtful, or no.—Linn. Gen. 397.
429. Juff. 101. Lamarck Illufr. t. 517. Michaux Bo-
real-Amer. v. 2. 18. Gætn. t. 53.—Claf and order, Di-
nynæa Angiofermæ. Nat. Ord. Perfonate, Linn. Pedi-
culæris, Jull.

Gen. Ch. Cal. Perianth inferior, of one leaf, ovate-ob-
long, tumid, unequally five-cleft, permanent. Cor. of one
petal, ringent; tube oblong, gibbous; upper lip helmet-
shaped, crect, compressed, emarginate, narrowest; lower
spreading, flat, divided about half-way into three obtufe
segments, the middle one usually narrowest. Stam.
Filaments four, the length of the upper lip, under which they
are concealed, two of them shortly; anthers incumbent,
roundish, compressed. Pyl. German roundish, superior,
style thread-shaped, situated like the flaments but longer;
 stigma obtuse, inflaxed. Peric. Capsule roundish, pointed,
oblque, of two cells, burring at the top; the partitio;
narrow, from the centre of each valve. Seeds several, ovate,
angular, pointed, compressed, with a minute membranous
appendage.
The root is strong and thick, certainly perennial, crowned with a numerous row of fleshy, pale, ovate, undivided leaves, notched and crisped at their edges, but totally different from the doubly pinnatifid superior leaves. These radical leaves seem characteristic of the species. The stem is divided to the very base into several short, spreading, or decumbent, simple, leafy, branches. Flowers rofe-coloured, very elegant; their calyx tubular, mostly smooth, five-lobed; their lower lip in nearly equal segments. — The marquis of Stafford met with a few regular flowers, which had five or six filaments, on some wild plants near his castle of Dunrobin, North Britain, in 1808.

P. caprifolius. Willd. n. 3. (P. n. 15; Gmel. Sb. v. 3. 203. t. 43.) Stem much branched. Calyx oblong, smooth, in two abrupt even segments. Upper lip of the corolla toothed. — Native of Siberia. — We have it also from Labrador, communicated by the late R. Mawfoot, esq. — The stem is a span high, purplish, pubescent, with numerous branches from top to bottom. Leaves pinnatifid, toothed. Calyx with an entire, even border, cut, crisped, or leafy. Corolla yellow, with a purplish upper lip, whose edge is sharply toothed.

P. parviflora. — Stem branched, angular. Calyx ovate, its border leafy, unequally lobed and notched. Upper lip of the corolla without teeth, larger than the lower. — Gathered by Mr. Menzies, on the west coast of North America. The habit is most like that of P. palaüris, but every part is much smaller, nor does it answer to the description in Willdenow of a supposed variety of that species from Kamtschatka, for the upper leaves in ours are all doubly and deeply pinnatifid. The calyx is ovate, ribbed, smooth, with an elegant, broad, leafy, lobed and notched border. We find no teeth whatever on the upper lip of the corolla, which is longer than the lower; the latter is in three small, rounded, nearly equal lobes. The flowers seem to have been red, but the whole herb turns very black in drying. Its height is nearly equal to P. palaüris.

All the following have simple stems.

P. Scoparius Carolinum. Linn. Sp. Pl. 815. Willd. n. 7. Fl. Dan. t. 26. Ehrh. Phyt. 55. (P. alpina, folio ceterach; Helw. Fl. 59. t. 39. Sceptrum Carolinum; Rudb. Lapp. t. 1. Linn. Lapp. ed. 2. 265. t. 4. f. 4. 5.) — Leaves pinnatifid; their segments broad, lobed, finely notched. Lower flowers whorled. Bracteas ovate, undivided. Calyx crested. Corolla closed. — Found in boggy woods in Hungary, Prufia, Mecklenburg, &c. but especially in Lapland, of which last country it is the most celebrated botanical treasure, being the largest and most flatly of this whole genus. We do not find that it has yet been cultivated with success in any garden. The stem is a yard high, erect, straight, naked, except a whorl of leaves near the bottom. Radical leaves most numerous and large, stalked, a span long, deeply pinnatifid, smooth, finely reticulated, the segments more or less pinnatifid, rounded, broad, with minute earlike teeth. Flowers several, in a long, upright spike, the lower ones whorled, the rest chiefly alternate. Bracteas large, ovate, concave, crinate, tinged, like the leaves and stems, with purple. Corolla an inch and a half long, cream-coloured or pale yellow; the lips closed, elegantly tipped with crimson, the segments of the lower one equal, concave; the upper without teeth. — Rudbeck's wooden cut is truly magnificent.

appendage. Receptacle roundish, at the bottom of the cap-

Very few species of Pedicularis were known to the old botanists. Linneus discovered several in Lapland, and Haller has done in Switzerland, and Jacquin in Austria; but the most numerous acquisitions of this kind have been made in Siberia, by Gmelin, Pallas and others. The second edition of Sp. Pl. contains but 14 species; the 14th of Syll. Veg. 17; Willdenow has 34, having received some new Siberian ones from his friend Stephan. Five of the whole have branched stems, the rest are unbranched, though leafy and many-flowered. All are herbaceous, and perhaps perennial, though authors have marked some as annual. This is certainly erroneous with regard to incarnata of Jacquin, and our ffeuuaia, whether the palaüris be annual, as Ray fays, or not. They are with difficulty preserved in a gar-
den, being mostly inhabitants of boggy alpine meadows, infected by a thick growth of snow throughout a long winter, and very susceptible of any recurrence of cold after they begin to vegetate in the spring. The foliage of the whole genus is simply or doubly pinnatifid, with minute, carti-
lagious teeth, and remarkable for an elegantly crisped aspect, with rich shining green or purplish hues. The ino-
dorous flowers form leafy spikes, and are either crimoon or yellowish, but in every case richly variegated with con-
trasted tints.

The species are well made out in Willdenow, nor do we find it requisite to give detailed descriptions or synonyms of them all. A few examples will suffice, with the addition of two species which appear to be new. Only two are natives of Britain, with which our list commences.

P. palaüris. Marsh Lowf-woort, or Tall Red-rattle. Linn. Sp. Pl. 845. Engi. Bot. t. 399. (Pedicularis; Riv. Monop. Irr. t. 92.) — Stem solitary, branched. Calyx ovate, hairy, ribbed, in two principal notched divisions. Lower lip of the corolla larger. — Native of boggy meadows, chiefly in the north of Europe by no means unfrequent in England, flowering in June and July. The root is small and very slender, whether annual or perennial remains a doubt. Stem solitary, twelve to fifteen inches high, angular, with many opposite, lateral, leafy branches; the angles more or less hairy. Leaves scattered, stalked, doubly pinnatifid. Smooth; the segments obtuse, notched, very various in breadth. Flowers numerous, large, rofe-coloured, auxiliary, about the summits of the stem and branches. Calyx ovate, compressed, hairy, pale green or purplish, with a darker green leafy border in two principal lateral divisions, which are strongly crenate and variably lobed, but the whole, taken together, can scarcely be called five-cleft. The lower lip of the corolla is longer and much broader than the upper, in three rounded, dilated, flat segments, minutely fringed. Seeds about five or six in each cell. This is an acrid weed, white, uncutched by horses or cows.

zerland this species is very rare, nor does it seem to be well known on the continent, since Willdenow could express a doubt whether it were distinct from the former, and quote the excellent figure in the Flora Danica with hesitation.
PEDI CULAR I S.

P. flammor. Linn. Sp. Pl. 846. Fl. Lapp. ed. 2. 210 t. 4. f. 2. Tour in Lapland, v. i. 256. Willd. n. 24, excluding the synonym of Fl. Dan. which rather belongs to P. birjuta.—Leaves pinnate; leaflets imbricated, ovate, obtuse, doubly crenate. Calyx oblong, five-toothed. Upper lip of the corolla obtuse.—Native of the Alps of Lapland, Norway, and Dauria; more sparingly of Switzerland. The root is perennial, with many oblong knobs. Leaves are flaccid, flaked, of numerous, crowded, small, dark-thining-green leaflets. Spike somewhat leafy. Calyx oblong, angular, smooth, its teeth feebly leafy. Corolla slender, deep yellow, its upper lip obtuse and brownish or purplish.—This is Haller's n. 315, a rare Swiss species, under which it is remarkable that, both in his Historia and Nomenclator, he copies from the Sp. Pl. of Linnaeus an erroneous citation of Fl. Lapp. t. 11, instead of t. 4; a sign of his not having turned to the plate he quoted. Willdenow has here been more attentive.—Linnaeus judged this species to be P. alpina, folio ceteris. Bauh. Pin. 163, a plant taken up from Gnefen, who but imperfectly describes it. Helwing took the plant of Gnefen to be P. Septem Caradonim, which indeed answers much better to the idea of the leaves of Ceterach than the flammor. P. rofæa. Jacq. Mâc. v. 2. 57. 1. rare t. 115. Willd. n. 56. (P. birjuta; Allion. Pedem. v. 65, t. 5. f. 1.)—Stem nearly naked. Leaves deeply pinnatifid; segments linear, sharply pinnatifid. Flowers crowded. Calyx hairy. Upper lip of the corolla obtuse.—Native of the Alps of Carnithia and the north of Italy. The root is composed of long flabby cylindrical branches, running deep into the ground. Stem three or four inches high, simple, round, purplish, hairy, almost leafless, except at the top. Leaves mostly radical, flaked, finely divided, and acutely toothed. Flowers numerous, of an elegant rose-colour, crowded into a short dense spike or head accompanied by two or three leaves, which are rather smaller, and more febele, than the reflex. Calyx very hairy, in five unequal segments. Upper lip of the corolla oblong, rounded and obtuse; lower in three broad rounded segments, the middle one rather smaller.—Allioni mibtok this for the Linnaean birjuta, which is very different, having a leafy floris, much broader and ovate segments to the leaves, and yellow flowers. We believe the latter to be Fl. Dan. t. 30.—It must also be observed that Wildenow cites under rofæa, Allion's Specimen, t. 11. f. 1; whereas it is t. 12. f. 1, the other being corofoa. P. reftrata. Linn. Sp. Pl. 847. Willd. n. 27. Jacq. Aulfr. t. 205. (P. n. 322; Hall. Helvet. v. i. 140. t. 8. f. 1, not f. 5, as he himself quotes it!)—Stem ascending, slightly leafy. Leaves doubly and deeply pinnatifid and toothed. Flowers scattered, flaked. Segments of the calyx pinnatifid. Upper lip of the corolla beaked.—Native of Switzerland, Austria, Carniola, Italy, and Dauphinie, on the most lofty mountains. The segments of the leaves are shorter and broader than in the last. Stems several, leafy erect. Flowers fewer, more diffused, on longish partial flaks. Calyx much less hairy, with leafy pinnatifid segments. Corolla distinguished by the long inflexed beaked upper lip, which is a deep crimson, the under being rose-coloured, with very broad lateral segments.—Linnaeus unaccountably places this species among such as have branched flaks. P. tuberofoa. Linn. Sp. Pl. 847. Willd. n. 28. (P. n. 323; Hall. Helvet. v. i. 140. t. 10.)—Stem ascending, slightly leafy. Leaves doubly and deeply pinnatifid and toothed. Flowers crowded, nearly fesile. Segments of 3 X 2 the

fylava. We had no description answerable to this species. The floris is simple, little more than a foot high, leafy. Leaves are nearly opposite, two inches in length, oblong, mostly smooth and naked, cut, but not deeply, into numerous, parallel, obtuse segments, with a cartilaginous notched edge. Bracteas similar to the leaves, but gradually smaller. Calyx ovate, very smooth, two-lobed, each lobe crowned with a rounded, leafy, notched appendage. Corolla an inch long, nearly closed, pale or yellowish, with a tinge of red. The limb of the corolla, and the general appearance of the flowers, bring this plant near the Septem Cardonim, from which nevertheless it is abundantly distinct, as well as from P. trifoid, whose corolla is full as large, but downy at the edges, and whose leaves are more finely and deeply divided.

P. recutit. Linn. Sp. Pl. ed. 1. 608. ed. 2. 846. Willd. n. 14. ? Jacq. Aulfr. t. 258? (P. caulif simplici, folis pin- natis, floribus cipicatis, flaminibus eminuntibus: Hall. Helvet. v. i. 138. n. 316. t. 8. f. 2.)—Leaves deeply pinnatifid; their segments lanceolate, pinnatifid, acutely notched. Spike compact, leafy. Upper lip of the corolla crenate, obtuse. Stamens prominent.—Native of lofty mountains in Switzerland. We have Haller's plant, on which this species in Linnaeus entirely depends. That of Jacquin, bent by himself, which Willdenow appears to have had in view, seems somewhat different; the corolla being smaller, its upper lip singularly oblong, rectilinear, and obtuse; nor do the floris seem to project. This last character, however, to which the specific name, such as it is, alludes, is not very obvious at all times. We must leave the final determination of these two plants to those who can compare them fresh. Willdenow has very properly established, by the name of P. elata, n. 15, a tall Siberian species, with a long pale-purple corolla, which Linnaeus confounded with recutit.

P. foliofa. Linn. Mant. 86. Willd. n. 16. Jacq. Aulfr. t. 139. (P. alpina, flore luteo, radice nigra; Bauh. Hist. v. 3. 439.)—Leaves doubly pinnatifid, in linear segments; the floral ones much longer than the flowers. Calyx five-cleft; its upper segment much larger than the rest. Upper lip of the corolla rounded, woolly, very obtuse.—This very fine species is not rare on the Alps of Switzerland, Dauphiny, Savoy, Hungary, and Austria. The root is tapering, de- ferbed by Jacquin as perennial, of a pale yellow. Will- denow marks it biennial, but erroneously. John Davali calls it black, but otherwise his synonym is the only certain and correct one to be found among the old writers. The plant is readily known by the ample finely divided foliage, which accompanies and envelopes its dense floris of pale yellow, numerous, woolly flowers. whose prominent palate is of a deeper hue than the red.—Seeds of this Pedicularis, sent by the late Mr. Davali, are said to have vegetated at Kew; but we know not that the plants survived to blossom, nor have we met with this or any other, in perfection, in any garden.

P. acutili. Scop. Carn. v. 1. 439. t. 31. Wulf. in Jacq. Coll. v. i. 207. t. 14. Willd. n. 23.—Stem none. Leaves doubly pinnatifid. Flower-flaks radical, single-flowered.—Native of the lee elevated mountains of Carniola and Carinthia, where it blossoms early in May, before the snow has disappeared from the more alpine tracts. The root is per-ennial. Leaves several, three or four inches long, with hairy flaks. The flowers are large, of a pale bluish-colour, sprung immediately from the crown of the root, each on a simple hairy flak, about as long as the calyx, which is hairy with a five-cleft leafy border, and feebly half so long as the corolla.
the calyx pinnatifid. Upper lip of the corolla beaked.—Native of the Alps of Switzerland, Italy, and the south of France. Differs from the Iart in being larger, with more subdivided leaves, and yellow flowers, which are nearly leafless, being crowded into a dense leafy spike. The stem is not more erect, nor more leafy, in one than the other. The floral leaves of both are palmate and bipinnate, and the corolla distinguished by its long beak, which has sometimes a notch at the end in the tuberous, as well as, if we mistake not, in the referata.

P. gyroflexa. Villars Dauph. v. 2. 426. t. 9. Wild. n. 29. (P. n. 324; Hall. Helv. v. 1. 140. t. 17. f. 2.)—Stem ascending, slightly leafy. Leaves doubly and very deeply pinnatifid, notched at the base. Upper flowers rowed, lower stalked. Segments of the calyx pinnatifid. Upper lip of the corolla arched, with a short notched beak.—Native of the Alps of Switzerland, Italy, and Dauphiny. Moth like the last in habit, but the segments of the leaves being slightly revolute, give them a more obtuse and crisped aspect. The corolla is rose-coloured, with a much shorter and blunter beak than either of the two last. These species are all nearly akin, and so similar in a dried state, that it is no wonder botanists in general have not well understood them. P. ficifolium of Bellardi, Wild. 30, is confidered very like them all; but as no authentic specimen has fallen in our way, we can throw no light upon its history. The corolla is said to be in colour like the last; its upper lip not beaked, though approaching to that shape, terminating in three teeth, of which the intermediate one is very short.—These are followed in Wildenow by three Siberian species, called rubens, compalla, and achilleaphala, of which we have neither specimen nor figure. The genus concludes with

P. conafa. Linn. Sp. Pl. 8. 387. Wild. n. 34. Allion. Ped. v. 10. f. 4. f. 1. Spec. t. 11. f. 1.—Stem and spike leafy. Leaves doubly and deeply pinnatifid, rough, with bristly teeth. Calyx with five small downy teeth. Upper lip of the corolla claven, with two small acute points. —Native of mountains in the south of France and north of Italy, but not abundantly; more frequent in the meadows of Russia and Siberia. This is a fine species, approaching to P. folia in size, habit, and colour, as well as abundance, of flowers; but the floral leaves are smaller and less prominent, and the corolla is smooth, with a round finis at the extremity of its upper lip, accompanied by a pair of taper teeth. The division of the foliago is very similar in these two species, as also the short downy teeth of the calyx, and they ought to be placed next to each other in a natural disposition of the genus. We have a specimen from Allioni himself, as well as others from Siberia.

Besides the two new species which we have added above to Wildenow's list, there are two in Michaux, Boreal.-Amer. v. 2. 18, not referrible to any that he enumerates, nor do we know anything more of them than the following very different characters.

Our P. auriculata is certainly not referrible to either of these.

PEDICULARIS Morbus, from pediculitis lutea, in Medicine, a morbid condition of the habit, and especially of the skin, in which lice are generated in multitudes, and with difficulty destroyed. This disease has been said even to be fatal. See Phthiriasis.

PEDICULUS, the Louse, in Entomology, a genus of insects of the order Aptera. The generic character is, mouth with a retractor recurveducker without probosces; without feelers; the antenna are as long as the thorax; it has two eyes; the abdomen is depressed; it has six legs formed for running. The insects of this genus live by extracting animal juices; the larve and pupae are four-footed and nimble, resembling the perfect insect. Of these strange and unpleasant animals, some infest the bodies of quadrupeds, others of birds, and some even of insects themselves. It must, however, be observed, that many small insects, infesting other animals, have often been referred to the genus Pediculus, which, in reality, belong to those of Acarus, Monoculus, &c. There are sixty-six species of the genus enumerated by Gmelin.

Species.

* Humanus. The specific character is, abdomen lobed, cinereous. The pediculus humanus, or common louse, is distinguished by its pale livid colour; it is produced from a small oval egg; popularly called by the name of a nit, which is agglutinated by its smaller end to the hair on which it is deposited: from this egg proceeds the insect, complete in all its parts, only much smaller in size. These specimens are far preferable for microscopic observation to the full grown insects,ewing, in a more distinct manner, the disposition of the viscera, muscles, &c. In this late it has such a transparent skin, that we are able to discover more of what palies within its body than in most living creatures. See Louse.

PUBIS; Crab-Louse. Abdomen emarginate behind; legs cheliform, hence its trivial name. In the antenna are five articulations. It is found about the hairs of the groin, and sometimes, though very rarely, on the eye-brows of persons who are not attentive to habits of cleanliness.

RICINODES. The abdomen is orbicular, marked with a white line; the scutellum is composed of three lobes; the snout is white. It is a native of America. It gets into the legs of the naked inhabitants, where it draws blood, and depositing its eggs in the wound occasions very alarming ulcers.

SUIS. Found on the body of swine.

PORELLI. Found on the body of the Cavia cebaya, or Guinea pig.

CAMELI. Head projecting and pointed; body ferruginous; abdomen ovate. It is found on the camel.

* OVIS. This infests the body of the sheep.

BURALI. Yellowish, with dusky-brown streaks; the abdomen has ten conic marginal tubercles. It is found on the buffalo.

* BOVIS. Abdomen with eight transverse ferruginous lines. It inhabits the bodies of oxen, and cattle in general.

* VITULI. The abdomen is of a lead colour, and pointed at the end. Found on the bodies of heifers and cattle.

* EQUI. Found on the body of the horse.

* ASINI. Head projecting, obut; abdomen ovate, brown; legs cheliform. Found on the body of the ass.

VULTURIS. Oblong; abdomen brown, with two yellowish lines. It is found in the East Indies on the vulture, and is a large insect. It is farther characterized as having a flat head, yellowish, with black margins; the thorax is yellowish, with a black margin and dorsal line.

* TINNUNCULI. Head arrow-shaped, and muricate on each side behind. Found on the Falco tinnunculus, or kestrel.

* BUTEO.
PED

**Buteonis.** Abdomen margined; the segments with two impressed dots on each side. It infests the Falco buteo, or buzzard.

**Sturis.** Abdomen ovate, white, edged with red; legs red. Found infesting various species of the frirx and falco.

**Corvi.** Abdomen ovate, with a filiate margin. Found on various species of the crow.

**Corncis.** Abdomen ovate, pale, with lateral black spots, in which is a white pupil. Found on the common crow.

**Inausti.** Thorax narrow; abdomen ovate, pale, diaphanes. It infests the Corvus incausti.

**Pica.** Head obtuse, brown, with four black dots. This is found on the Corvus pica, or magpie.

**Oroil.** White, with a brown line on the abdomen. Found on the roller and ori-le.

**Cuculi.** Abdomen oblong, whitish, with brown bands. It infests the Circulus canorus, or cuckoo.

**Cyni.** Head emarginate; abdomen ovate; the margin filiate with black. It is found on the wild and tame goose.

**Moschate.** This is found on the Anas moschata, or Mfcoy duck.

**Querqueulae.** This infests the Anas querqueula, or garganey.

**Mergi.** White, with a yellowish head; body long. Found on the Mergus lerrer.

**Procellaire.** Long, filiform, brown; with pale legs. It inhabits Brasil, on the procellaria, or petrel.

**Vagelli.** Ovate, pale; thorax with two brown lines. Found on the Procellaria glacialis.

**Diomed.** Head obtuse; body white; sides of the abdomen black. It inhabits Brasil; on the diomedea, or albatross.

**Sterne.** Head triangular; abdomen ovate, pale; the back longitudinally blackish. Found on various species of the tern and gull.

**Platalea.** This species is found on the Platalea leucorodia, or spoon-bill.

**Ardea.** This is found on several species of the ardea, or crane.

**Gruis.** Abdomen sub-clavate, pale, with snowy spicules. It is found on the storks and herons.

**Ciconi.** Long, filiform; abdomen white; the sides dotted with black. It infests herons.

**Charadrius.** This species is found on the Charadrius with brown, or golden plover.

**Fulica.** This infects the Fulica atra, or common coot.

**Recurvirostrum.** This species is oblong, with a triangular grooved head. It is found on the recurvirostra, or avocet.

**Hemiatopt.** Glaucesc; thorax very narrow; abdomen ovate; with pale incisures. Found on the Hema- topus oltregeus, or sea-pie.

**Pavonis.** Head globular, and very large; body filiate, with pale and brown. Found on the peacock.

**Meleagris.** Head triangular, obtuse; abdomen ovate, grey. This infects the turkey.

**Gallin.** Thorax and head mucronate on each side. This species infects poultry, and is destroyed by pepper.

**Phasiani.** Head ovate and large; abdomen globular, obtuse. It is found on the pheasant.

**Caponis.** Abdomen edged with black. Found on common poultry.

**Tetraonis.** This species is found on the Tetrao tetrix, or black game.

**Lagopus.** On the Tetrao lagopus, or ptarmigan.

**Columba.** Body filiform, ferruginous, and clavate behind. Found on common pigeons.

**Emberiz.** Pale brown; abdomen whitish, with lateral brown spots; head triangular. Found on the bunting.

**Paria.** Body ovate; tail ending in four bristles. Found on various species of the parus, or titmonile.

**Motacilla.** Head heart-shaped, rufous; abdomen white and tapering at the base. It is found on the wag-tail.

**Hirundinis.** Palla; abdomen black, spotted with white. Found infesting the Hirundo apus, or swift. The abdomen is bristly on both sides.

**Grallotalpe.** Blood-red, with white legs. Found on the mole cricket. The fscker is long, inflected, black; body red, immaculate.

**Apis.** Body filiform, ferruginous. Inhabits Europe, on bees.

**Farinis.** This is found on the Salmo fario, or trout.

**Anatis.** Whitish; first segment of the thorax round, truncate on each side; the abdomen linear and long. On the wild duck.

**Orygometre.** Oblong; with a heart-shaped head; thorax narrow; segments of the abdomen bristly, with large spotted spicules on each side. This infects the land-rail.

**Alauda.** On the Alauda arvensis, or sky-lark.

**Sturna.** On the Sturnus vulgaris, or starling.

**Curvirostrum.** This is found on the Loxia curvirostra, or grosbeak.

**Pyrrhula.** This infects the Loxia pyrrhula or bullfinch.

**Cloridus.** This is found on the Loxia chloris, or greenfinch.

**Citrinell.** This infects the Emberiza citrinella, or yellow-hammer.

**Curruca.** This is found on the Motacilla curruca, or babbling warbler.

**Rubeola.** On the Motacilla rubeola, or red-breast.

**Pedieus.** In Anatomy, a name given by Richan to the extensor brevis digitorum pedis communis. Some of the French anatomists call it le piedeux.

**Pedigree.** A defunct, or genealogy.

**Pediluviwm.** See Building of the Foot, art. Foot. PEDIMENT, in Architecture, a kind of low pinnacle; serving to crown porticoes, or finish a frontpiece; and placed as an ornament over gates, doors, windows, niches, altars, &c.

The pinnacles of the ancient houses, Vitruvius oberves, gave architeets the first idea of this noble part; which still retains the appearance of its original.

The parts of the pediment are, the tympanum and its cornice. The first is the pannel naked, or area of the pediment, inclosed between the cornice, which crowns it, and the entablature, which serves it as a bafe, or focol.

Architects have taken a great deal of liberty in the form of this member; nor do they vary less as to the proportion of the pediment. The most beautiful, according to Daviler, is that where its height is about one-fifth of the length of its bale.

It is described thus: divide the line ab (Plate XXIII. Miscellanies, fig. 12.) which is the length of the bale, into two equal parts, in the point e; by means of the perpendicular the perpendicular take the part cd equal to ab; and from the point d as a centre, describe the arch aeb. The point
point of the perpendicular, cut in $c$, will be the top of the pediment $aeb$; and the cornice, and the triangular space included therein, the tympanum.

The pediment is usually triangular, and sometimes an equilateral triangle; this is also called a pointed pediment. Sometimes it is circular; though Felibien observes, that we have no instances of round pediments in the antique, beside those in the chappels of the Rotunda. Sometimes its upper cornice is divided into three or four sides, or right lines; sometimes the cornice is cut, or open a top, which is an abuse introduced by the moderns, particularly by Michael Angelo. For the design of this part, at least over doors, windows, &c. being chiefly to shelter the space underneath from the rain, to leave it open in the middle is to frustrate its end.

Sometimes the pediment is formed of a couple of scrolls, or wreaths, like two consoles joined together. See Console.

Sometimes, again, the pediment is without base, or its lower cornice is cut out, all but what is bestowed on two columns, or pilasters, and on these an arch or sweep, raised in lieu of an entablature; of which Serlio gives an instance in the antique, in a Corinthian gate at Pohgny in Umbria; and Daviler a more modern one, in the church of St. Peter at Rome. Under this kind of pediments do also come those little arched cornices which form pediments over doors and windows, supported by two consoles, in lieu either of entablature or columns.

Sometimes the pediment is made double, i.e. a base pediment is made in the tympanum of the larger, on account of some projection in the middle; as in the frontispiece of the church of the Great Jesus at Rome: but this repetition is an abuse in architecture, though authorised by some very good buildings; as the large pavilion of the Louvre, where the Caryatides support three pediments, one in another.

Sometimes the tympanum of the pediment is cut out of, or left open, to let in light; as we see under the portico of the Capitol at Rome. Lastly, this open pediment is sometimes triangular, and enriched with sculpture, as rosettes, leaves, &c. as we find in most of the Gothic churches.

M. le Clerc observes, that the modillions in the cornice of the pediment should always answer exactly those of the entablature. Indeed Vitruvius says, the ancients did not allow any modillions at all in pediments.

The same M. le Clerc observes, that the cornice which serves the pediment as a base, should have no cymatium; by reason the cymatium of the rest of the entablature, when it meets the pediment, fails over it.

This change of determination occasions a considerable difficulty; the cymatium, in this case, appearing too broad in the turn of the angle; to remedy which, the architects have recourse to several expedients. A pointed pediment may crown three arches; but a circular pediment can only crown one agreeably.

One would never use above two pediments over each in the same frontispiece; and even where there are two, it would be proper to have the lower circular, and the upper pointed.

PEDINABARUM, in Geography, a town of Hindoostan; 60 miles S.E. of Travancore.

PEDINAIG-DURGAM, a town of Hindoostan, in Myore: 10 miles S.E. of Vencaffigery.

PEDIR, a town on the N. coast of the island of Sumatra; 20 miles E. of Acheen. N. lat. 5° 13'; E. long. 96° 5'.

PEDIS ABSCEISSO, Cutting off a foot, a punishment anciently inflicted among us; as appears by the laws of William the Conqueror. "Interdicimus ne quis occidatur, vel suppeditetur, pro aliqua culpa. sed eruntur ucelli, abemundant pedes, vel tefitculi, vel manus, &c." Leg. Will. cap. 1. So Inglishus, "fub pena perditionis dexteri fui pedis, &c."

PEDIS MINIMI DIGITI ADDUSSUS, in Anatomy. See ABDUCER.

PEDIS, abductus politus. See ADDUCTOR.

PEDIS, dorsum. See DORSUM.

PEDIS, flexor politus. See FLEXOR.

PEDIS internus, perforans, perforatus, and transferens. See the respective articles.

Transcriptio Pedis. See TRANSCRIPTIO.

PEDITUM ARRATIUM. See ARRATIUM.

PEDLAR. See HAWKER.

PEDMAN, in Geography, a town of Hindoostan, in the cirey of Gunter; 10 miles S.S.W. of Gunter.

PEDN-BOAR POINT, a cape on the S. coast of England, and county of Cornwall; fix miles S.E. of Lizard Point. N. lat. 51° 10'. W. long. 5° 2'.

PEPO, in Natural History, a name given by some writers to the tipula, or father-long-legs; called also by others grama, or the crane-fly.

Pedometer, or Pedometer, formed from ρεπτő, pēt, foot, and μέτρον, métron, measure, way-wiser; a mechanical instrument, in the form of a watch, consisting of various wheels, with teeth catching in one another, all disposed in the same plane; which by means of a chain or string, fastened to a man's foot, or to the wheel of a chariot, advance a notch each step, or each revolution of the wheel; so that the number being marked on the edge of each wheel, one may number the places, or measure exactly the distance from one place to another.

An instrument of this kind has been lately invented and improved by Mr. Ralph Gout of Bunhill Row.

The pedometers of Mr. Ralph Gout have an advantage hitherto unknown, viz. the hour being attached to them, if required, which makes this instrument doubly useful. Thus, on the same dial is exhibited, at one view, time and distance by means of different hands.

Their internal construction is so very simple, as not to endanger their being put out of order, and if required to be cleaned, a person of the smallest capacity may do it, the wheels being all marked for that purpose.

The patentee has been induced to make various trials with his pedometers in public, one in the right, and one in the left side pocket, in order to establish more effectually their high rate of perfection, not only in point of accuracy of the machinery, but to shew the nicety of man's walking.

The same pedometer will, by a proper application to the fiddle, ascertain every pace a horse takes, either in walk, trot, or gallop, and may be made to flop performance in a second, should the horse, in the course of measuring, go from one pace to another. In short, we do not feel the least difficulty in recommending this invention, as the best of the kind ever offered to the public.

Pedometer is sometimes also used for the common surveying wheel, an instrument chiefly used in measuring roads; popularly called the way-wiser. See PERAMBULATOR.

PEDRA, in Geography, a river of Africa, in the kingdom
PEDRA Branca, a large white rock in the Chinefe sea. N. lat. 11° 25'.

PEDRA da Galã, a small island in the Atlantic, near the coast of Africa. N. lat. 21° 48'.

PEDRA da Sareite, a rock or small island in the Atlantic, near the coast of Portugal, at the mouth of the Gulpilha; four miles S. of the bay of Oporto. N. lat. 41° 6'. W. long. 8° 23'.

PEDRA do A, a town of South America, in the government of Carácas; 25 miles S.S.W. of Varinas.

PEDRAGAO, a town of Portugal, in the province of Elfreemadora; 30 miles S.E. of Coimbra.

PEDRAPALORE, a town of Hindooslan, in the Carnatic; 20 miles S. of Wandiwath.

PEDRIS, a river on the N.W. side of Punta des Pádras, at the southern extremity of Amazon river.

PEDRAZA, a town of Spain, in Old Cañille; the birth-place of the emperor Trajan; 21 miles N.E. of Segovia.

PÉDRERO, Peterero, or Paterno, a small piece of ordnance, used on board ships, for the discharging of nails, broken iron, or partridge shot, on an enemy attempting to board.

They are generally open at the breech, and their chamber made to take out, to be loaded that way, instead of at the muzzle.

PEDRO, in Geography, a town on the N.W. coast of the island of Ternate. N. lat. 4° 50'. E. long. 127° 10'.

ALFO, a small island in the Indian sea, near the coast of Madagascar. S. lat. 13° 50'. E. long. 47° 48'.

PEDRO Bay, Great, a bay on the S. coast of Jamaica. N. lat. 17° 53'. W. long. 77° 41'. East of it lies Little Pedro point.

PEDRO Bluff, a cape on the S. coast of Jamaica. N. lat. 17° 52'. W. long. 77° 39'.

PEDRO Munoz, a town of Spain, in New Cañille; 48 miles S.E. of Toledo.

PEDRO Point, a cape on the N. coast of Jamaica. N. lat. 18° 28'. W. long. 78° 12'.

PEDRO, St., a river of Africa, on the Ivory coast, which runs into the Atlantic. N. lat. 4° 50'. W. long. 6° 50'.

ALFO, a town of South America, in the province of Carthagega; 50 miles S. of Mompox. ALFO, a town of S. America, in the province of Venezuela, on the S. coast of lake Maracaibo; 100 miles S. of Maracaibo. ALFO, a town of Bráfil, in the government of Para, on the river Amazons; 440 miles W. of Port Rio Negro. ALFO, a town of S. America, in the province of Moxes, on the Manora; 50 miles S. of Trinidad. ALFO, a town of South America, in the audience of Quito; 20 miles N.W. of St. Jofé de Huales. ALFO, a town of Mexico, in the province of Mechoacan; 15 miles N. of St. Luís de Potosí. ALFO, a small island in the Pacific ocean, near the coast of Terra Firme. N. lat. 47° 42'. ALFO, a sea-port of Mexico, in the province of Guazxaca; 25 miles S. of Guazxaca. N. lat. 16'. W. long. 99° 1'. ALFO, one of the Marquefes islands, call'd by the natives "Onateya," about three leagues in circuit. S. lat. 9° 53'. E. long. 138° 55'. ALFO, a town of the bithopic of Truxillo, and juridiction of Sana, fixtuated in a fertile fea, near the coast of the Pacific ocean; 50 miles N. of Truxillo. S. lat. 7° 26'. ALFO, a town of East Florida; 44 miles E.S.E. of St. Mark. ALFO, a small island near the coast of Spain, fixtuated S.E. of the city of Cadiz, from which it is separated by a narrow strait, called "St. Pedro's Channel." ALFO, a town of the island of Cuba; 31 miles S.W. of Bayamo. ALFO, a town of S. America, in the province of Cordova; 96 miles N. of Cordova. ALFO, a town of New Navarre; 180 miles W. of Cafa Grande. ALFO, a town of Mexico, in the province of Honduras; 15 miles W.N.W. of Naco. ALFO, a bay of the Pacific ocean, on the coast of New Albion, between point Fermi and point Lafeito.

PEDRO Novo, St., a town of Bráfil, on a river which runs into the bay of All-Saints; 50 miles N.W. of St. Salvador. PEDRO de Pablo, St., a town of Mexico, which rifes in Tabaco, and runs into the bay of Campeachy, N. lat. 18° 20'. W. long. 93° 26'.

PEDRO, St., and St. Pablo, a river of Mexico, which rifes near Zacatlan, in the province of Tlaçala, and runs into the gulf of Mexico. N. lat. 10° 52'. W. long. 93° 26'.

PEDRO Nubence, St., a town of Bráfil, on the Urubui; 70 miles N.N.E. of Fort Rio Negro.

PEDRO de Sul, St., a town of Portugal, in the province of Beira; nine miles N.W. of Vizeu.

PEDRO de Taberna, St., a town of Spain, in Aragon; 12 miles N. of Atma.

PEDRÓSA, a town of Spain, in the province of Leon, between Salamanca and Medina del Rio Seco; five leagues from the former.

PEDRUSI, or PEDRUSZI, PAUL, in Geography, was born of a noble family at Mantua in 1646. He entered himself among the Jesuits, and became distinguished for his deep knowledge of history and antiquities. He was chosen by Rannuncio, duke of Parma, to arrange his rich and curious cabinet of medals, and to give explanations of them. In 1664 he began to publish an account of this collection, under the title of "I Cafari in oro raccolti nel Farnece Mufoe, o publicati colle loro congrue interpretazioni," and he continued his labours till his death in 1721. This work, in its complete form, consists of ten volumes, and bears the title of "Mufoe Farnece," of these he published seven volumes; and the eighth was edited by Peter Piovene, a brother Jesuit.

PEDUNCLE, in Botany. See Pedunculus.

PEDUNCULARIA, a name by which some authors have called the flaphsagria, or flavefcare; a plant whose seeds are used to kill vermin.

PEDUNCULUS, the flower-tilk, or, as some call it, peduncle, springs from the stem, and bears the flowers and fruit, but not the leaves. A flower-tilk originating immediately from the root, has an appropriate name, Scapus; see that article; though some prefer pedunculus radicans.

The flower-tilk is either simple or compound; in the frut infall it commonly bears a solitary flower, though it may bear a number of completely felfile ones, conflituting a spike, as in Patamugeton. When compound, the ultimate divisions of this part are called partial flower-tilks. See Pedicellus.

Flower-tilks differ in situation, as well as in degree or mode of subdivision. Pedunculus caulifera springs immediately out of the main stem or trunk, as in Avrbrosa Bilimbi, and Cyamneta caulifera.
P. ramosus grows out of a principal branch, as in Averrhoa Carambola, and many other plants.

P. axillaris, an axillary flower-flalk, is very common, and indeed almost general, when the inflorescence is lateral. It proceeds from the bosom of each leaf; that is, immediately above the insertion of the leaf, or its footstalk. The same term is applied to a flower-flalk situated in the fork of a stem, or above the origin of a branch.

P. oppositifolius is inferred opposite to a leaf, of which several species of Geranium afford examples.

P. internodis, of more rare occurrence, grows from the intermediate part of a branch between two leaves, as in some species of Solanum.

P. interfoliis is placed laterally between the insertion of two leaf-flalks, as in some of the Convolvulus.

P. gemmaceus grows out of a leaf-bud, as in the Barberry, and some kinds of Willow; while in others of the last-mentioned genus, some buds are entirely defined to produce leaves, others flowers.

P. terminalis springs from the extremity of a stem or branch, which is very common. It always puts a period to the growth of such part, though the branch may, and usually does in trees and shrubs, put forth fresh shoots from, or below, the point of insertion of the flower-flalk.

P. lateralis is a general term for a flower-flalk that originates from the side of a stem or branch, whether it be axillary or otherwise.

P. foliarius is either single on a plant, as in the Snowdrop, or only one in the same place, as in the Violet, Thorn-apple, and many common plants.

Pedunculi aggregati, clustered flower-flalks, are such as grow several together from one point, in whatever situation.

P. fimbriis are scattered over the plant or branches, in a few.

P. uniflori, biflori, triflori, are such as bear each one, two or three flowers.

P. pauciflori bear few, multiflori many, flowers.

When there is no flower-flalk at all, the flowers are said to be folicitata, flores solitarii.

Various particulars belonging to flower-flalks may be found at Inflorescence, or under various articles there indicated.

The physiology of the Pedunculus is in many instances curious. Its evident use is to sustain the flower and fruit, and to transmit their requisite matter of nourishment, till the seed is perfected. Hence the part in question, though sometimes curved during the growth of the flower, that the organs of impregnation may be sheltered from rain, often becomes erect for the better support of the seed-vessel, left the seeds should be prematurely, or too suddenly, dropped. The slender and weak flalk of a flower, not unfrequently acquires additional increase and strength, for the support of a heavy fruit. Nevertheless, when its final purpose is answered, that very flalk separates at some defined spot, where a solution of continuity spontaneously takes place, in parts originally so firmly united that no trace of diffusion could be perceived.

PEE, in Geography. See PRIME.

PEE, in Mining. See PRIME.

PEEAYEMEW, in Geography. See PRIME.

PEEBLES, a royal burgh, and the county town of Peebles-shire, or Tweeddale, Scotland, is situated at the distance of twenty-one miles south from Edinburgh, at the confluence of the Eddleston, or Peebles Water, with the Tweed. It is of great antiquity, and was probably a town even in the time of the Gaedae. At all events there were undoubtedly a considerable village, and a church here, before the commencement of the Scoto-Saxon period; "and there was here also as early, perhaps, a royal castle, with a chapel and other accommodations, which a town only can supply." This opinion derives much support from the fact, that Peebles is mentioned in the earliest Scottish records, "as a town of the royal demesne, which yielded a firm into the royal exchequer." According to Dr. Pennycuik, it was occasionally honoured by the residence of the Scottish monarchs, till the death of Alexander III., who conferred on it many special marks of his munificence and favour. In the contests for the succession to the throne which ensued, the inhabitants espoused the cause of Baliol, and were afterwards compelled to submit to the usurpation of Edward I. of England. At this period the town appeared to have been governed by a bailiff, and a certain number of burgesses, as we find them mentioned to have sworn fealty to the English king at Berwick, on the 28th of August 1296. In 1340, it was granted by that prince to Adam de Valence, the warden of Scotland, and his heirs. When it became a royal burgh, with special privileges, is uncertain; but it is known to have sent two representatives to the parliament, called in 1357 to ratify and provide the ransom of David II. This monarch afterwards granted Peebles a charter, dated September 20, 1367, in which it is styled a royal burgh; and the same was subsequently confirmed by king James I., and King James VI, with additional privileges. By virtue of these charters the corporation of the town now consists of seventeen members, a provost, two bailies, a dean of guild, a treasurers, eleven councilors, and one deacon. Its revenue is very considerable, most of the lands in the vicinity being the property of the public. These lands were granted to the town in the year 1560, in consideration of the loyalty, fidelity, and good services of the inhabitants.

The town of Peebles was much more extensive formerly than at present, and occupied a somewhat different site, extending from Eddleston Water westward, to the Meadow-well-branch. Of its buildings at this period little is known, but they were probably of a comparatively superior cast, as many of the houses were occupied by the nobility attending the court, when the monarch resided in the castle. Peebles in fact was to Edinburgh what Windfor now is with respect to London. Previous to the reformation it had three churches, besides several chapels. The high church, which was dedicated to the Virgin Mary, is supposed to have been erected in the eleventh century, on the site of some more ancient fabric. Its ruins still remain at the western extremity of the old town. This church was destroyed at the time of the reformation; when the Cross-church was converted into the parochial place of worship; and continued to be such till the present handsome structure was erected in 1784. Peebles is now divided into two parts, called the Old and New Town. The latter is situated on the eastern bank of the Peebles Water, and appears to have been strongly fortified, both by nature and by art. Over the Tweed is an ancient bridge of five arches; and there are two smaller ones over the Eddleston, to connect the new town with the old. The chief support of the town is its manufacture of carpets, ferge, and linen and cotton cloths; but it is likewise much indebted to its market, which has been long celebrated for oat-meal. The market day is on Tuesday, weekly, and there are besides seven annual fairs.

The chief remains of antiquity in Peebles, are the ruins of the Cross-church, and of that which was dedicated to St. Andrew. The former was part of the conventual church of a monastery founded, according to Boccius, Major, and others, by king Alexander III. Some say it was erected
The church of St. Andrew is of greater antiquity than the Crosses-church. The exact period of its construction is not recorded; but as it is flated to have been consecrated by Joceline, bishop of Glagow, who died A.D. 1199, its date may be fixed a few years previous to that event. Judging from its remains, it feems to have been a large and capacious structure, and is certainly of great age, as all its doors and windows display semi-circular arches, or at least some segment of a circle.

This church was the most ancient parish church in Peebles. After it lost that rank, in favour of the Crosses-church, it was allowed to fall into ruin. A party of Cromwell's soldiers used it for some time as a flable, and at their departure demolished the roof. The only portion of this structure now standing are the square tower, and some fragments of the side walls. The church-yard is still used as a burial ground. Of the royal castle of Peebles no vestiges can be traced, but its site yet retains the name of Castle-hill. For an account of the antiquities in the vicinity, see the next article.

According to the parliamentary returns of 1811, the burgh and parish of Peebles contain 422 houfes, and a population of 2485 feryons.

The Tweed, or Tweedale, one of the southern counties of Scotland, is situated between 55° 25' and 55° 50' of N. latitude, and from 2° 58' to 2° 24' of W. longitude from Greenwich. It is bounded on the south by Dumfriesshire, on the north and north-east by Edinburghshire, on the west by Lanarkshire, and on the east by the county of Selkirk. According to Armstrong's map, it measures in length from north to south about 28 miles, and varies in breadth from 10 to 18 miles; the mean length being 27 miles, and the average breadth 13'. Of consequence, the superficial area ought to be 364,000 square miles, and its contents 233,000 English acres; but from a minute calculation, made by Mr. Chalmers, the real superficialities is estimated at 338 square miles, or 216,320 acres; of which about 20,000 acres are arable, or under tillage. According to the parliamentary returns of 1811, this shire contains 1820 houfes, and 9935 inhabitants.

General View of the County.—Tweedale, when viewed from a distance, seems to form one continued chain of mountains, and may perhaps be generally described as a mountainous country. Upon a narrow investigation, however, it is found to possess many rich and fertile vallies or straths of arable land, lying along the banks of its numerous rivers. Of thefe the vale of the Tweed is the principal, interfeting the centre of the county throughout its whole extent. Hence many vales branch off, following the channels of the several streams which intersect that majestic river. Thefe, as may be conjectured, are various in fize, as well as diversified in appearance. The most considerable and the most fruitful are the vallies of the Lyne and Edellebone waters. In general, the dales and the dingles are molt fertile, and the hills molt plateau in the north and west divisions of the county; while, in the south and eaf, the vales are more barren, and the hills more bleak.

Mountains.—The surface of Peebles-shire rises on both sides of the great central valley of the Tweed, to a very considerable elevation. The highest hills are situated towards the extremities of the county; and, indeed, those bordering on Annandale are the loftiief in southern Scotland. On the boundary with Selkirkshire, Blackhouse hills measure 2350 feet in height above the level of the German ocean; and Seamed Law, about two miles further to the north, mounts to 2135 feet above the fame level. Minchmoor, on the south-east of Peebles-shire, rides 2285 feet; and Windeflaw Law, on the north-east of the county, 2395 feet above the sea. In the parish of Manor are two very high hills, called Scrape and Dollarburn, the latter of which is calculated to reach an elevation of 2740 feet. Cardon, or Cadow-hill, in the parish of Kilbuck, is about 1400 feet above the level of the Tweed, or 2200 feet above the level of the ocean. This is the highest hill on the western side of the shire, but there are many others very little inferior in altitude. In the parish of Kirkurd is a hill called Hell's Cieugh, the summit of which is distinguished by a small cairn, called the Pyked-flane, whence is a view of the country beyond the Forth, and of a chain of hills stretching from the eaf part of Fife, as far as Dunbartonshire. South of the Forth, the view extends as far east as North Berwick, likewise to the Eildon hills near Melrose, and Cheviot hills in Northumberland. Dundreigh, or Druids' hill, in the parish of Eddleston, also commands a most extensive and diversified pafs over Teviotdale, Annandale, Clydefdale, Perthshire, Fifeshire, and the three Lothians. This hill is computed to rise 2100 feet above the level of the ocean. Near the fource of the Tweed the hills are in general extremely beautiful, being covered with woods to their very summits; some of them are of a great height, particularly Hartfield and Broadlaw, which are flated to reach the altitude of 2800 feet from the level of the Forth. Between Minchmoor and Hinderland the hills are more black, craggy, and precipitous, than in any other district of the county, and are frequently intersected by deep and tremendous chams. One of these openings, called Grimfelough, is upwards of half a mile in length, and not less than 300 feet in depth.

Rivers and Lakes.—The rivers of this county are numerous; but all of them, with the exception of the Megget and the North and South Esk, discharge their waters into the Tweed, as the common receiver. This celebrated river, whence the familiar name of the shire is derived, has its fource on the mountainous ridge which separates Tweedale from Annandale, and can boast of giving rise to the three firt rivers in the fouth of Scotland: the Annan, which flows fouthwards into the Solway-frith; the Clyde, which runs north-west into the Clyde-frith; and the Tweed, which directs its course to the German ocean at Berwick. The last-mentioned river flows above 40 miles within the county, in a curvilinear and serpentine direction, dividing it nearly into two equal parts. Its current, particularly in that part of its course above Peebles, during which it descends from a height of 1550 feet, is extremely rapid, as indeed are all the streams in the county. The Tweed is the longest river in Scotland.
Scotland, the distance from its source to its confluence with the ocean being upwards of 100 miles. It abounds with salmon, as well as with trout. Among the rivers which fall into it, belonging to Peebles-shire, the most considerable are the Lyne, the Eddleston, and the Leithen, on the north; and the Manor and the Quair on the fourth. The Lyne rises in the northern confines of the county, at a place called Cauldshankell; and after a course of 21 miles, reaches the Tweed three miles above Peebles. Eddleston water has its source from King-Seat-hill in Eddleston parish, and joins the Tweed at the county town. Leithen water runs a course of 12 miles from Water-Head to about a mile below Inverleithen church, which derives its Celtic name from that influx, or influx, Manor stream originates at Foulbrig, in the southern end of Manor parish, through which it runs a course of 12 miles; and which it drains, as it courses, with other streams to the common channel. The Quair issues from a spring at Glendean banks, and, after watering the magnificent pleasurable grounds, falls into the Tweed near the noble seat of Traquair.

The lakes in Peebles-shire are neither numerous nor extensive. The most considerable of them, the Water loch in Eddleston parish, scarcely exceeds three quarters of a mile in length, and half a mile in breadth. It is, however, a very beautiful sheet of water, and gives birth to the South Esk, which falls into the river Forth, along with the North Esk, at Muffelburgh, in Midlothian. The other lakes within the county are Gamehope loch, and Slipperfield loch; the former of which occupies an uninhabited glen in Tweedsmuir parish, and is emptied by Gamehope rivulet, one of the sources of the Talla water. St. Mary loch, though it bounds this county for more than a mile, and is hence claimed by some Peebles-shire topographers, is properly speaking, a Selkirkshire lake, as it extends several miles into that county. The Megget pours its waters into this lake, where they pass on to the Yarrow and the Etrick, two of the most celebrated rivers in Scottifh song.

Mineral Products.—Peebles-shire, as the mountainous nature of its surface would promise, is fertile in minerals. If credit may be given to our ancient historians, Boece and Buchanan, gold was formerly found in Glen-Gaber water, which traverses the parish of Megget. In Lead-Law, a hill above Linton, several lead mines were formerly wrought, which also produced a considerable supply of silver. The finds of these mines are still apparent, and are distinguished by the appropriate name of Silver-holes. About 60 years ago they were again tried, but the attempt proved unsuccessful; the quantity of ore obtained being scarcely adequate to defray the expenses of the work. In Traquair parish several attempts have been made to discover lead veins, and much ore has been found, but not sufficiently rich in silver to induce any adventurer to open mines.

A specimen of galena ore was discovered, a few years ago, in one of the streams that fall into the Quair. Coal is plentiful, particularly in the north-eastern district of the county, where limetone is also equally abundant. Beds of marble are frequent in the parishes of Linton and Newland. They are apparently formed by oozings and springs from limetone, which encroach or petrify mofs by dépositions of limetone. In these beds the shells of the common snails are observed rotten and friable. Near the lime rocks of Carlips and Spittlehaugh is a bed of blue marle, of a mixed consistency between stone and clay. The prevailing Rone under-flatum in the county is whinf tone, but there are likewise numerous quarries of white and red freestone in different parishes. The slate quarries here have long been celebrated.

In Tranore hill, within Stobo parish, are two seams of excellent blue slate, which has been manufactured for various purposes during several years. In the lands of Lamancha there is a vast variety of clays, and in particular a very thick bed of fire clay, like the Stourbridge clay. In the same lands are many veins of iron ore; one of them is entirely gran ore, and the remainder is mixed with the same ore. Manganesé is also found here, both by itself and incorporated with the iron ores; and there are likewise here some mafes or beds of iron-stone, but there are iron-works yet established. White marble according to Penny-cuick, was formerly dug up at Whiffitt, in Linton parish.

Several mineral springs are found within Peebles-shire, but none of them are particularly distinguished North from the village of Linton is a spring, called "Heaven-aqua water," which bears some affinity to that at Tinbridge. Another spring, similar to the Harrowgate water, appears in the parish of Inverleithen. There is also a copious full-pureous well in the parish of Kerkurd. The water here was analyzed by the late celebrated Dr. Black of Edinburgh, and found to be stronger than the full-pureous water at Moffat. At Lamancha, in Newland parish, is a chalybeate spring, called the "Vertue Well," which contains a large quantity of fixed air, that holds the iron in solution.

Soil and Climate.—The prevailing soil on the hauaths, or flat grounds near the waters, is generally a sandy loam, or a composition of fine earth deposited by the water after floods. The level land, lying a little above the hauaths, is of a rich loam soil, on a gravelly, rocky, or till bottom. Nearly the sources of the several rivers, the soil is frequently of a moyst or moorish nature, particularly in the northern district of the county, where, as already mentioned, the land is the least elevated.

The climate of Peebles-shire is various. In the valley of the Tweed, which may be called the body of the county, it is often mild and warm, while in the higher and more remote parts the cold is extremely intense. Showers of rain are frequent, but the average quantity which falls in this county is much less than in the adjoining counties to the east and west, seldom exceeding twenty-eight inches annually. Many of the hills are covered with snow as early as the commencement of October; and in the autumn months some of the vales suffer greatly from the prevalence of hoar-frosts or frosty mists, which blast vegetation of every kind, and are especially pernicious to potatoes, clover, and peas.

Agriculture.—From the termination of the eleventh, to the beginning of the fourteenth century, the husbandry of this county is said to have been in a much more forward state than in most of the other counties in Scotland. The system, as at present, was then a mixture of farming with grazing. The four centuries which succeeded, however, were unproductive in the highest degree; and it was not till after the union that any amelioration began to take place, and that prejudice was forced, in some measure, to yield to the influence of more rational ideas. Among those who have promoted agricultural improvement since that period, were "the far famed" Archibald, duke of Argyle, sir Alexander Murray of Stanhope, Dr. Pennycook, and James M'Daigal, a farmer near Linton. The exertions of the individual last mentioned were particularly useful in their confences. He introduced the Norfolk rotation of crops, and several other practices before unknown here; and by his successes in their application, rooted in his neighbours a similar spirit of enterprise and improvement. Dairy farming was revived by Thomas Stevenson; and the turnip husbandry was first attempted in 1764 by George Dalzel, innkeeper.
PEEBLES-SHIRE.

innkeeper at Linton, who was likewise the first to cultivate
the potato on an extensive plan, by the plough. But the
greatest spring to the farming prosperity of the county was
fixed about the year 1788, when the lord of Neudpath
granted to all his tenants leaves for fifty-five years, in con-
firmation of certain fines, which his wants or his incapacity in-
duced him to demand. The idea of property for so long a
period stimulated the farmers to erect commodious houses,
to make inclosures, and to lay out their capital in various
improvements; including and planting has since proceeded
rapidly; and the bolt practices in husbandry are adopted.
Oats are the favourite grain, but barley is likewise
particularly extensively cultivated on the belt soils. The turnip
hus-
bandry is carried on to a great extent, and has almost entirely
explored the practice of summer following. Artificial grazes
are raised on the arable lands in every district of the shire.
These, however, bear but a small proportion, in point of
to extent, to the natural pasturage lands, which perhaps occupy
nine-tenths of the whole area of the county, and are still
chiefly appropriated to the rearing and feeding of sheep.
The average extent of sheep farms here is 1500 acres;
but there are many which reach so high as 3000 acres,
and few fall short of 800. Each of them has a portion
of arable land attached to them, some more and some less,
according to their distance from the valies. The com-
mon breed of sheep here is the "the short-tailed compact-bodied
sheep, with black faces and legs." The practice of forcing
sheep with a mixture of tar or train oil, or Orkney butter,
is still continued in this county, though the reasons alleged
for the cullom do not seem very satisfactory. Some say it
improves the wool, but others doubt it, and think its only
advantage is, that it keeps the sheep warm in winter; and
certain it is that Tweedale wool is both coarse and low
priced, and fit only for making carpets, shawls, and such
like articles of woollen manufacture.

Civil Government and Divisions.—Peebles-shire, like every
other county in Scotland, is subjected to the jurisdiction of
a lord lieutenant, and a sheriff-depute, the latter of whom
nominate a substitute to hold courts in his absence. When
it was first elevated to the rank of a sheriffdom is not precisely
fixed by record, but we find mention of two sheriffs in
Tweedale, one in Traquair, and the other at Peebles, about
the year 1184. These two sheriffs were merged into one before
the close of the fourteenth century, under the title of the
latter, and have remained in the same condition ever since.
The parishes within this shire are sixteen in number; and
besides the royal burgh of Peebles, there are five very con-
siderable villages that have markets and annual fairs for sheep,
horses, and cows. These are Linton, Eddleston, Skirling,
Broughton, and Inverleithen.

The situation of Inverleithen is most beautiful; and it
has lately acquired some degree of activity by woollen manu-
facture established there.

Roads.—The improvement in roads within the last fifty
years has been very great in this county. The public roads
indeed are excellent. One from Edinburgh towards Moffat
traverses the whole length of the shire, from north-east to south-
well. Another traverses it in like manner from west to east, from
Biggar, by Peebles and Inverleithen, towards Galla-
shiels and Kelso. This road affords the means of conveying
towards Glasgow all the superfluous grain of this district.
A road also runs from Inverleithen towards Middleton, which
supplies a great part of Peebles-shire with coal. It was made
in 1794, and shortened the line of communication no less than
fourteen miles.

Manufactures.—Tweedale cannot be called a manufactur-
ing county, though a considerable quantity of linen
is made by the inhabitants, none of it comes to sale, the
whole being consumed by their own families. Woollen and
cotton weavers, however, are said to be increasing about
Peebles and its vicinity; where likewise a few flocking
looms. A woollen manufacture has been lately established
at Inverleithen, which from its congenial situation is calcu-
lated to flourish. It is surprising that no woollen manufac-
ture has hitherto been fixed at Linton, considering its fa-
favourable position on the turnpike road to Edinburgh, and
the numerous advantages it possesses with respect to coal,
lime, freedstone, water, and sheep-walks.

Antiquities.—The remains of antiquity in Peebles-shire are
at once numerous and various. Traces of the ancient Brit-
tons can still be discovered here in the names of places; as
also in their religious, sepulchral, and military monuments.
At Hairpins, in Kirkurd parish, are the remains of a Druid
temple, consisting of a number of large stones standing in a
circular form. Another curious druidical temple is situat-
ed on the remarkable peninsula called Sheriffmuir. From
each of two standing stones there run out to the sea, in a
curvature, two rows of smaller stones, which also stand up-
right. A third monument of a similar kind is seen near
Tweedsmuir church, and a fourth, smaller one, on the borders
between Peebles and Selkirk. Several tumuli or
barrows are spread over Kirkurd, Glenholin, and Linton
parishes. In a cairn upon King's Muir, in Peebles parish,
were lately discovered an inverted urn, containing the ashes
of some British warrior, with the blade of his dagger. In
Eddleston parish, near the Ship-Law, there is a barrow called
the "Ship-horns," because resembling the inverted hull of
a ship. A number of sepulchral carvings are also discovered
in the vale of the Tweed, and on Sheriffmni. These, how-
ever, all yield in interest to the grave of Merlin, which is
pointed out under a thorn tree, near the influx of Powfaw
with the Tweed. In that sacred spot, according to tradition,
lie the remains of the prophet, to whom so many wonderful
feats and predictions are attributed in the writings of the
ancient bards.

In Peebles-shire are many hill-forts, undoubtedly of
British construction, and several standing stones, supposed
to be memorials of battles. The forts are generally of a circular
shape, but sometimes deviate from that figure to suit the
summit, or the ground whereon they are placed. On the
hill called Cademuir are four British encampments, one of
which is surrounded by a rampart of stones without cement.
This rampart is in some places double; but in other parts it
is single and of prodigious thicknesses. Janet's brae in Peebles
parish is also distinguished by two entrencheds, which are
each surrounded by a single ditch and vallum. In the same
parish are several other similar works; particularly one on
the summit of Meldum, another on the hill above Hutchin
field, a third near Hayton Craig, a fourth on the hill above
Wham, and a fifth on the hill called Ew-hill-rig. In Manor
parish are likewise many strengths, on Hound-hill, Caver-
hill, and on a small eminence called the Ring-know. On a
height near Inverleithen, are the remains of a British fortress,
which appears to have had three ramparts and ditches. The
other principal British military works, are at Milkinson-
Rings, and North-Shield-Rings, in the parish of Eddleston;
on Terrace-hill, in Newlands parish; on the rising ground
above Linton, and on the top of Lead-Law. Besides these,
however, there are numerous others which our limits will not
permit us to particularize.

The Romans, who were unquestionably the first people
that encroached upon the British aborigines, have left few
traces of their residence here, and these few are confined to
military posts or encampments. Of these the principal one

3 V 2
P E E

is situated on the eastern side of the Lyne, about ten miles to
the eastward of the Watling-street, which traverses the country
within half a mile of the western extremity of the shire.
This entrenchment is called by the common people Randal's
Walls, from a tradition that Randolph, earl of Murray,
had a house within its area. According to Armbrong it
contains fix acres and two roods of ground, which has
been frequently ploughed, when many Roman coins have
been turned up. Another Roman encampment is situated on
the northern side of Upper Whitfield, in the parish of Linton.
It is in the form of a parallelogram, and is surrounded by
a single fosse and rampart, which are now nearly obliterated.
A third entrenchment, in the parish of Manor, is also generally
represented to be of Roman construction.

Among the other antiquities of this county, the most
prominent are its terraces and castles. Respecting the origin
and uses of the former much difficulty prevails; indeed all
that has been advanced concerning them is merely conjectural.
The opinion of Chalmers, however, that they were intended for the accommodation of large bodies of spectators
to witness some sport, carries with it considerable plausibility;
and it likewise seems probable that several of them were
subsequently appropriated for the administration of justice.
Of such works the most considerable are those on
a beautiful green mount, called Terrace-hill, above Newlands.
Along the whole face of this hill there are eleven or twelve
terraces, from fifteen to twenty feet broad, which rise by a
regular gradation to the top. About half a mile to the
north is another castle called "Moot Hill," which has
likewise several tiers of terraces. Similar terraces are to be
seen at Kirkurd, at Skirling, and at Smithfield.

The remains of the castles and fortified towers of this county, are principally seated on the banks of the Tweed,
and alternately on both sides of that river, and in flight of
each other, as happens in Selkirkshire and Berwickshire.
The object of this arrangement was the defence of the country
from the incursions of the border chiefs. On the approach
of an enemy, a fire was immediately lighted on the top of
the nearest castle, and thus notice of the aggression was
spread over a district of at least seventy miles in length in the
course of a few hours. These castles were built of stone and
lime, usually in a turreted form, and for the most part occupied
an eminence of difficult access. Those situated within ten miles above and below Peebles were at least twenty
fix in number, and much resembled each other, except in the
circumstance of greater or less magnitude. At Traquair
the Scottish kings had a castle in the twelfth century, where
they occasionally resided for the purpose of hunting in the
forest. This castle is now completely demolished, as well as
that at Peebles, which is likewise said to have been a royal
residence. On Woodhill are some remains of an ancient
building, which is called Macbeth's castle; and in Broughton
parish is another, bearing the same name, which is tradition-
ally said to have belonged to the celebrated Macbeth. The
remains of Oliver castle, the seat of the Fraers, are seen in
Tweedsmuir parish; and on Fruid water are the remains of
Fruid castle, another baronial mansion, which also belonged
to that powerful family. Drummelzier castle is situated
close to the river Tweed, and about a mile from it is Thanes
castle, or Theses castle, formerly occupied as a fort of re-
doubt by the Tweedies, the lords of Drummelzie, who
domineered here during several ages of anarchy. But these,
and indeed almost all the ancient castles in this shire, are
completely ruined, with the exception of that of Niedpath,
in the vicinity of Peebles, which being of vast strength, still
continues in tolerable preservation, and consequently affords
an excellent specimen of similar building. This castle stands
on a rock, projecting over the north bank of the Tweed,
which here runs through a deep narrow glen well wooded on
both sides. Towards the land it commands an important
pafs. The walls are eleven feet in thickness, and cemented
with lime almost as hard as the stong whinlione of which
they are built. Niedpath was anciently the chief residence of
the Fraers above-mentioned, and was most probably the
birth-place of the brave sir Simon Fraer, the lait of the
family in the male line, who, in 1303, with only thousand
men repulsed and defeated the English, thirty thousand
strong, in three successive battles, fought in one day on
Rodyn moor. In the reign of Charles I. it was garnisoned
for the king, and held out against Cromwell longer than any
place in Scotland, south of the Forth. The situation of this
castle is extremely beautiful and commanding. Penny-
cuick, who says it was of old called the "castle of Peebles,"
celebrated it thus:

"The noble Niedpath Peebles doth overlooks
With its fair bridge and Tweed's meandering brooks,
Upon a rock it proud and flatly stands,
And to the fields about gives forth commands."

Caledonia, or An Account of Historical and Topographical
of North Britain, by George Chalmers, F.R.S. 400. edit. 1810.
Beauties of Scotland, vol. ii. Sinclair's Statistical Account of
Scotland, vols. iii. iv. xii. xvi. Armstrong's Companion to the
Map of Tweedale.

Peeing-ghye, a town of the Birman empire, situated on
the Irrawaddy, from which a great quantity of teak timber
is carried to Rangoon. The forests extend along the
western mountains: the trees are felled in the dry season,
and when the monsoon sets in are borne by the torrents
to this town and Sahlaham, a little above it. Peeing-ghye is
about 20 miles N.W. of Mayadoum.

Peeck, in the Sea Language, a term used in various
seas; e.g., an anchor is faid to be a-peek, when the ship,
being about to weigh, comes over her anchor, so that the
cable hangs perpendicularly between the hawse and the anchor;
the bringing of a ship into which position they call
hearing a-peek.

A ship is said to ride a-peek, when, lying with her main
and fore-yards hoisted up, one end of her yards is brought
down to the shrouds, and the other raised upon end; which
is chiefly done when the lies at rest in rivers, left other
ships, falling foul of her, should break her yards.

Peeck, to ride a broad, denotes much the same, excepting
that the yards here are only raised to half the height.
To Peeck the mizen, is to put the mizen yard perpendic
ular to the main.

Peeck is a name given to the upper corner of all those falls
which are extended by a gaff, or by a yard which crosses
the maff obliquely, as the mizen yard of a ship, the main
yard of a bylander, &c. The upper extremity of those
yards and gaffs is aUso called the peek or peak.

Peeck is also used for the room in the hold, from the hatches
forward to the stem: in this place men of war keep their
powder, and merchantmen their victuals.

Peeck-haliards, are the ropes or tackles by which the outer
end of the gaff is hoisted as opposed to the throat haliards,
which are applied to the inner end.

Peeck's Hill, in Geography, a small hill-town of Amer-
ica, in West Cheshire county, New York, on the E. side of
Hudson river, and N. side of the creek of its name, five
miles from its mouth: 50 miles N. of New York.

Peeleas, a small island in the Sollobo Archipelago.
N. lat. 6 53'. E. long. 121 45'.
Peele, George, in Biography, a dramatic writer in
the
the reign of queen Elizabeth, was a native of Devonshire,
and a student of Christ-church college, Oxford, where
he took his degree of M.A. in 1579. He was a good pastoral
poet, and his plays were acted with great applause in
the university.

PEELE, in Geography, a small sea-port town, situated on
the western wall of the Isle of Man, in the Irish channel,
was formerly denominated Holm, and appears, from its re-
mainst, to have been a place of considerable importance in
the times of Mankith independence. The annexation of Man
to the British crown, and the subseqent destruction of the
smuggling trade, however, have reduced it greatly. The
harbour, indeed, is now almost entirely neglected, notwith-
standing it is an excellent refort for shipping, and the pier
is completely destroyed. In short, this town offers to the pre-
sent traveller an appearance of decayed grandeur; and is
consequently more an object of interest and curiosity than
inviting as a place of residence, for the man of busineses or
of pleasure. Woods, in his account of the Isle of Man, com-
putes the population of Peele at about twelve hundred
persons. The only church in the town, now used for divine
service, is that dedicated to St. Peter, but there are besides
the ruins of another two dedicated to St. Patrick and St. Ger-
main. These island within the cattle, on a small rocky island,
which is separated from the western extremity of the town
by a narrow channel, scarcely a foot deep at low water.
This island and cattle are connected with the mainland by a
strong wall, shelving to the top, which was built many years
ago to secure the harbour. The entrance is on the eastern
side, by a flight of steps now so ruinous as to be dangerous of
access. The walls of this fortress measure about four
feet in thickness, and are flanked with towers; the whole
inclining a space of somewhat more than two acres of ground.
Before the sale of the Royalty of Man to the British go-
vernment, a garrifon of troops, in the pay of the lord of the
island, was stationed here; but since that event the cattle has
been altogether neglected, and the entire area is occupied by
the ruins of various buildings, walls, and dwelling houses.
About the centre of it is a square pyramidal mound of
dirt, terminating obtusely, and having each of its sides di-
rected to one of the cardinal points. This tumulus is sur-
rounded by a ditch five feet and a half broad, and is supposed
either to have been an eminence whence an officer might
harangue his troops, or the burial place of some great per-
sonage. Near this mound stand the ruined churches above-
mentioned, both of which are of considerable antiquity.
Patrick's, however, is by far the older of the two, and is
probably of earlier date than the era of the Norman con-
quest. St. German's was built about the year 1245, and is
the cathedral of the island, but has not, for many years,
been used for any other purpose than a burying-place. Its
dimensions are seventy-six feet by twenty; and beneath one
part of it is the ecclesiastical priory or dungeon, where such
persons were confined as were so unfortunate as to incur the
spiritual censure. The length of this vault is thirty-four
feet, and its breadth sixteen. The bottom is of earth, and
at one corner are the remains of an uncovered well, which
mull have rendered the place damp in the extreme. The
only light or air is admitted through a small hole in the
wall.

Three miles from Peele is the Tinwald mount, where the
Manks parliaments and great councils were convened, and
where also the superior courts held judicial proceedings at
stated periods. It is an artificial eminence of very singular
appearance, and of unknown antiquity. According to some
ezymologicals, its name is a compound of the Danish word tiss
or ting, signifying an assembly or meeting, and eald, a field or
fenced place. Several modern authors, however, derive it
from the British words tyng and eald, signifying "the juridical
hill." The approach to the summit of this mount is by a
flight of turf steps on the eastern side. The diameter at the
top is about seven feet, and three feet below it is an annular
plot four feet wide, which is succeeded by another fix feet
broad, and this by a third still wider. The circumference of
the outer circle is nearly eighty yards; all the angles are
rounded, and almost the whole surface is of turf.

At a short distance from the Tinwald is a small chapel de-
icated to St. John, rebuilt about fourteen years ago, after
the model of the former chapel, which had fallen completely
to ruin. It has no pews, never being used for divine service
except on the day of the promulgation of the laws. An
Account of the Paft and Present State of the Isle of Man,
by George Woods, Svo. 1811.

PEELING, a town of America, in Grafton county,
New Hampshire, containing 83 inhabitants.

PEEM, a town of the duchy of Holstein; 9 miles W.
of Euty.

PEEMDAHATTA, a town of Hindoostan, in the
circar of Ruttapour; 25 miles N.N.E. of Dundah.

PEENANG, or Prince of Walet's Island. See PINANG.

PEENE, a river which runs into the Baltic, W. of the
isle of Ufedon; separating in part of its course the river
Pomerania from Antwerp Pomerania. N. lat. 54° 10'. E.
long. 13° 50'.

PEENEMUNDE SCHANZ, a town and fort in the
isle of Ufedon, which it commands, as well as the entrance
and mouth of the Peene, near which it stands; 6 miles N.
of Wolgast. N. lat. 54° 10'. E. long. 15° 48'.

PEENPACK, a town of New York, in Orange county;
25 miles W. of Newburgh.

PEEPAROLI, a town of Bengal; 6 miles from Na-
tore.—Also, a town of Hindoostan, in Rohilcund; 15
miles W.S.W. of Budayoon.

PEEPULY, a town of Hindoostan, in Cattack; 5 miles
S. of Cattack.

PEER, Par, primarily denotes an equal, or one of the
same rank and condition. Hence, in some councils, or as-
semblies, we find, "with the conent of our peers, bishops,
abbot, &c."

Peer, afterwards, was applied to the vaifsals, or tenants of
the same lord, who were obliged to serve and attend him in
his courts.

They were called peers, past, because equal in function;
and peers in fees, or fees, because holding tees of the lord;
or because their busineses in court was to sit and judge, under
their lord, of disputes arising concerning fees.

The number of peers required to sit in a court was at
least four; and when there happened to be too many peers
in the same lordship, the lord usually chose out twelve,
who had the titles of peers, by way of distinction and
eminence.

There are also inlinates of women who have afflanted at
judgment, on account of their tenements, not of their being
wives of peers. The origin of these peers of fees is as an-
cient as that of the fees they were appointed to judge of:
from these we derive our common juries, and our peers of
the realm.

Peer of the Realm, denotes a noble lord, or person who
has a seat and vote in the upper house of parliament;
which is hence called the house of peers. See NOBILITY.

The right of peerage seems to have been originally terri-
torial; that is, annexed to lands, honors, castles, manors,
and the like; the proprietors and possessors of which were
(in right of those estates) allowed to be peers of the
realm,
realm, and were summoned to parliament to do suit and service to the king: and when the land was alienated, the dignity paffed with it as an appanage.

Thus, the bishops fitt in the house of lords, in right of succession to certain ancient baronies annexed, or fuppofed to be annexed, to their epifcopal lands; and though they are lords of parliament, they are not properly of the degree of nobility, their blood is not ennobled, nor their peerage hereditary: and, therefore, they are tried not by peers, but by a common jury: and when one of the nobility is tried by his peers in parliament, the spiritual lords muft withdraw, and make their proxies. See Bishop.

But afterwards, when alienations became frequent, the dignity of peerage was confined to the lineage of the party ennobled, and instead of territorial, became personal. Peers are now created by writ or patent. The creation by writ, or the king’s letter, is a summons to attend the house of peers, by the title or duty of that barony which the king is pleased to confer; that by patent, is a royal grant to a subject of any dignity and degree of peerage. The creation by writ is the more ancient, but a man is not ennobled thereby. It takes the seat in the house of lords; and some are of opinion, that there must be at least two writs of summons, and a fitting in two different parliaments, to evidence an hereditary barony (Whitelocke of Parl. p. 114.); and, therefore, the most usual, because the surest way is to grant the dignity by patent, which ensues to a man and his heirs, according to the limitation thereof, though he never makes use of it. Creation by writ, however, has one advantage over that by patent; for a person created by writ holds the dignity to him and his heirs, without any words to that purport in the writ; but in letters patent, there must be words to direct the inheritance; or else the dignity ensues only to the grantee for life. For a man or woman may be created noble for their own lives, and the dignity not descend to their heirs at all, or descend only to some particular heirs; as where a peerage is limited to a man, and the heirs male of his body by Elizabeth his present lady, and not to such heirs of any former or future wife. Co. Litt. 9. 16.

Peers of the realm are by their birth hereditary counsellors of the crown, and may be called together by the king, to impart their advice in all matters of importance to the realm, either in time of parliament, or when there is no parliament in being (Co. Litt. 110.); accordingly Bracton, (1. i. c. 8.) speaking of the nobility of his time, says, they might properly be called “confusa, unconfulo; reges enim tales libi associant ad confudendum.” And in our law-books (7 Rep. 54. 9 Rep. 49. 12 Rep. 96.) it is laid down, that peers are created for two reasons; “1. ad confudendum; 2. ad defendendum regem;” on which account the law gives them certain great and high privileges; such as freedom from arrests, &c. even when no parliament is sitting; because it intends, that they are always affiling the king with their counsel for the commonwealth; or keeping the realm in safety by their prowess and valour. Influences of the peers to advise the king, have been in former times very frequent; though now fallen into disuse, by reason of the more regular meetings of parliament. In cases of emergency, our princes have at several times, in a later period, thought proper to call for and consult as many of the nobility as could be easily got together; such was particularly the case with king James II., after the landing of the prince of Orange; and with the prince of Orange himself, before he summoned that convention parliament, which afterwards called him to the throne. Besides, it is usually considered as the right of each particular peer of the realm to demand an audience of the king, and to lay before him, with decency and respect, such matters as he shall judge of importance to the public weal. The claims of peerage may be hereafter easily settled, since by a flandering order of the house of lords, on May 1767, they are directed to take exact accounts, and preserve regular entries of all peers and peeresses of England, and their respective descendants; and it is required that an exact pedigree of each peer and his family, shall, on the day of his first admission, be delivered to the house by Garter, the principal king at arms.

As to the privileges of peers, see NOBILITY and PARLIAMENT. See also CLERGY, BENEFICI OF.

The house of lords have a right to take cognizances originally of all public accounts, and to enquire into any misapplication, or default in the distribution of public monies; or of any other mismanagement whatsoever.

Towards the latter end of the reign of king Charles I., the house of lords afforded their jurisdiction of hearing appeals from the chancery, which they do upon a paper petition, without any writ directed from the king; and for this their foundation is, that they are the great court of the king, and that therefore the chancery is derived out of it, and by consequence that a petition will bring the cause and record before them. This was much controverted by the commons in the reign of Charles II., but is now pretty well submitted to, because it has been thought too much, that the chancellor should bind the whole property of the kingdom without appeal.

PEERS, PARSES OF FRANCE, were, before the revolution, the twelve grand lords of that kingdom. The inftitution of these peers is very uncertain; some refer it to Hugh Ccapet, at the time when the dukes and counts changed the offices they then held of the king into perpetual fiefs: but this is improbable; Champagne, one of the titles, not being the erected into a county. Indeed, Paquier observes, that it is an old tradition, that there have been twelve peers in all ages. Of these peers, six were dukes, and six counts, comites; of these, again, six were ecclesiastics, and six laymen.

The archbishops of Rheims and the bishops of Laon, and Langres, were dukes and peers; and the bishops of Noyons, Chalon on the Marne, and Beauvais, were counts and peers.

The dukes of Burgundy, Normandy, and Aquitain, were lay peers and dukes; and the counts of Flanders, Champagne, and Toulouse, lay peers and counts.

These lay peers asfifted at the coronation of the king, in ceremony, and by way of representatives; where each performed the functions attached to his respective dignity; though their peerships were in reality all, except that of Flanders, reunited to the crown. Six lords of the first quality were chosen to represent them. The ecclesiastical peers usually asfifted in perfon. At a later period, the title peer, in France, was belowed, as in England, on every lord, or perfon, whose fee was erected into a lordship or peership.

The word peer, according to Paquier, is derived from patricius, the first dignity in the eastern empire; on the model whereof he supposes these peers to have been inflituted. But others, with more probability, derive the title from the pares curiae, or peers of feres, because of their being equal to each other.

These peers curiae, on whose model they suppose the peers of realms to have been erected, were a kind of vaffals, depending all on the same lord, whom they were obliged to attend and assist in court.

All feudal matters, or disputes, among vaffals, relating to their fees or dependencies, were terminated by the inferior
rior lord of the two contending parties, and by their peers in fee.

If the process were between the lord and the vassal, the lord took no cognizance of it, and the peers alone judged it.

Hence all lords or nobles, being *pares nobilitatis*, i.e., all equally intituled to the privileges of nobility, are denominated *pares regni*, *peers of the realm*.

Some authors attribute the first institution of peers of the realm to Charlemagne, but with little probability; since most of the chiefs, who bear the names of duchies, &c., or give titles to the peers, were not erected into duchies, &c., till long after; the dukes, &c., in those days, being no more than simple governors of provinces, without any other title or privileges.

The more probable opinion is, that peers were first intituled by Philip the Young of France, about the year 1179, and that they first acted in capacity of peers at the coronation of his son.

**PEER, in Building.** See Peer.

**PEER, in Geography, a town of France, in the department of the Lower Meuse, and chief place of a canton, in the district of Haffelt; 52 miles N. of Liege. The place contains 1005; and the canton 5537 inhabitants, on a territory of 187½ kilometres, in 8 communes.—Also, a small island in the East Indian Sea. S. lat. 5° 18’. E. long. 118° 20’.

**PEERAGE,** the dignity of a peer attached to a duchy, earldom, barony, or the like.

The king of England confers peerage at pleasure. King George I. offered his parliament to resign that branch of his prerogative, and to have the number of peers limited.

The reason intimated was, the inconvenience accruing to the state from an arbitrary and immoderate use thereof; the prince having it in his power to throw what number of his creatures he pleases into the upper house of parliament.

The twelve peers created at once in the reign of queen Anne, was a main argument in behalf of the peerage bill. But though a bill for this purpose passed the house of lords, it miscarried in the house of commons, whose leading members were then desirous to keep the avenues to the other house as open and easy as possible. It is recorded as a laying of king Charles, that if his friends could but secure him a house of commons, he would put his whole troop of guards into the upper house, but he would have the peers.

**PEERAGE, to hold land in,** in the Ancient Customs, was a tenure which obliged the person to afflit the lord’s bailiff in his judgments; as all the ancient vassals, called peers, did.

**PEERESS.** As we have noblemen of several ranks, so we may have noblewomen, and these may be by creation, defunct, or marriage; and first, king Henry VIII. made Anne Bulen marchioness of Pembroke; king James I. created the lady Compton, wife to Sir Thomas Compton, countess of Buckingham, in the lifetime of her husband, without any addition of honour to him; and also the same king made the lady Finch vice-countess of Maidstone, and afterwards countess of Winchelica, to her and the heirs of her body; and king George I. made the lady Schellenberg duchess of Kendal.

A woman noble by creation or defunct, marrying one under the degree of nobility, still remaineth noble, but if the be noble by marriage only, the loseth her dignity if the marry afterward a commoner; though not if the second husband be noble, and inferior in dignity to the first husband; and by the courtesy of England, women noble by marriage, always retain their nobility. 1 Infat. 16. 1 Infat. 50. 6 Rep. 53

A countess or baroness (either in her own right, or by marriage) may not be arrested for debt or trespass; for though, in respect of their sex, they cannot sit in parliament, they are nevertheless peers of the realm, and shall be tried by their peers, &c. 20 Hen. VI. c. 9.

**PEERGAW, in Geography, a town of Hindooftan, in Dowkatabad; 55 miles S. of Amedesagur.

**PEERGOTCHY, a town of Bengal; 28 miles W. of Dinagepore.

**PEERGUNGE, a town of Bengal; 39 miles N.E. of Purnesh.

**PEERNAGUR, a town of Hindooftan, in Oude; 17 miles of Manickpore.

**PEERPARD, a town of Bengal; 5 miles N. of Raj-ormal.

**PEER-PUNCHHEL, mountains which form the southern boundary of Cashemire.

**PEERWALTH, a town of Austria; 13 miles S. of Ip.

**PEESKEN, a town of Pruffian Pomerelia; 17 miles S.S.W. of Marenburg.

**PEEVIT, or Pewit, in Ornithology, a bird of the larus kind, with a black head, and a grey-coloured body. See Larus Ridihundus.

**PEGANELON, a word used by the ancients to express oil, in which the leaves and flowers of rue had been infuded and infolated.

**PEGANERON, a name given by some old authors to a platter in which rue was a principal ingredient, from peganon, the Greek name of rue.

**GEN. Ch. Gal. Perianth inferior, of five linear, straight, acute, permanent, often toothed leaves, the length of the corolla. Cor. Petals five, oblong-obate, flitely spreading. Stam. Filaments fifteen, awl-shaped, not half so long as the corolla, dilated at the base into a cup-like nectary under the germen; anthers oblong, terminal, erect. Pyk. German roundish, three-lobed, elevated on a short stalk; style thread-shaped, erect equal to the filaments; stigma oblong, triangular. Peric. Capsule roundish, with three blunt angles, of three cells and three valves, with partitions from the centre of each valve. Seeds several, obovate, acute, roughish.

**ElL. Ch. Peta five. Calyx of five leaves. Capsule with three cells and three valves; the partitions contrary to the valves. Seeds many.

Obf. Linnaeus remarks that Peganum differs from Rutl as Calogras from Eunonymus; whatever is deducted in number from the pilif, being added to the filaments, and vice versa.

PEGASUS, in Astronomy, the name of a constellation of the northern hemisphere, figured in form of a flying horse. The stars in this constellation, in Ptolemy's Catalogue, are twenty, in Tycho's nineteen, in Hevelius's thirty-eight, in the Britannic Catalogue eighty-nine.

Species.

DRACONE. This species has a conical snout; it is a small fish, three or four inches in length, and is remarkable for the size of its pectoral fins, which are supposed to enable it, like the eel, to climb, and for other fins, to support it for a few seconds in the air, while it springs occasionally over the surface of the water. The thorax, or superior part of the body, is of a broad, slightly flattened, quadrate form, and is marked, both above and beneath, by several radiated shields, or bony tubercles of considerable size; from each side of the abdomen springs a lengthened cirrus, which may be considered as supplying the place of a ventral fin; from the thorax the body suddenly decreases in diameter, and is marked into several divisions or transverse segments; the tail is small and slightly rounded; the pectoral fins are, as it has been already observed, large in proportion to the size of the animal, and of a rounder shape, with a kind of scaploped or indented outline; the eyes are large and protrusible, and the snout of a subconical form, but with a slight dilatation towards the tip, so as to appear spatulate when viewed from above; the colour of the whole animal is whitish, with a flight caft of pale brown.

Volans. Snout eniform, and denticulate. The length of this fish is about three inches; the snout is much elongated, and slightly rounded, and slightly dilated at the tip; it is marked by a longitudinal channel, and enatom or denticulated on the edges; the head is a homoboidal depression, and behind it are two deep sub-pentagonal cavities; the last joints of the body next the tail are pointed on each side.

Natans. The snout of this species is eniform and unarmed. It is about the length of the Volans, but much more slender; in respect to colour it is yellowish-brown, whitish beneath; the snout slender, slightly dilated and rounded at the tip; marked above and beneath by a middle furrow; the pectoral fins rounded and of a moderate size; the dorsal fin is situated on the middle of the back; segments of the abdomen about eleven or twelve in number; the tail is small and slightly rounded; the ventral cirri flender and flexible.

PEGASUS, in Mythology, a winged horse, whose origin is thus related by Hesiod: Perseus, it is said, cut off the head of Medusa, one of the Gorgons, and from the blood that flowed from it sprang the hero Chrysaor, and the horse Pegasus; Chrysaor derived his name from a golden fowrd which he had in his hand at his birth. He fell afterwards in love with Callirhoe, the daughter of the Ocean, and had by her Geryon, the famous giant with three heads. Pegasus was so named, because he was born near the fountains of
of the ocean: he instantly left the earth, and winged his way to the mansions of the gods. There he now resides, in the palace of Jupiter himself, whose thunder and lightning he bears. According to Pindar, the horse Pegasus, who is represented by Hesiod as having taken flight to the mansions of the gods, was afterwards broken by Minerva, and given to Bellerophon, who mounted him to combat the Chimaera; but that hero having attempted to ascend to heaven on the wings of that horse, was thrown down to the earth, and Pegasus was placed among the stars. Ovid, among other fictions, says, that Pegasus, flying through the airy regions, went into Mauritania, where he transformed Atlas, who had given him a sad reception, into that mountain which has since borne his name. From hence, continues he, he went into Ethiopia, where he rescued Andromeda from the monster that was ready to devour her, and punished Phineus his rival, together with all those who had sired with him, by shewing them the Gorgon’s head, which turned them all into stones. For an explanation of the fable of the Gorgons, see GORGONS. Under that article we shall find that the three Gorgons were ships, called by the names which they bore, that Perseus’s expedition was a sea voyage, and that Pegasus was a ship with fins, which Perseus carried into Greece, after having made use of it to rescue Andromeda. Virgil gives the epithet nine wings to a ship, “remigio alarum.” If Hesiod, and after him the other poets, say that Pegasus sprang from the blood of Medusa, the reason is, says Banier, that Perseus did not carry off the ship which was so called, till after a sharp engagement, in which much blood was shed. Pegasus was, in a manner, the offspring of that Gorgon, because he belonged to her father Phorcys’s fleet. When Pausanias says that Pegasus was broken by Minerva, we may suppose him to mean, that Perseus found occasion for a great share of prudence in managing to advantage a ship with fins, the use of which was then unknown to him. If, according to Ovid, Perseus mounted Pegasus for his Mauritanian expedition, it is unnecessary to say that it was meant of a ship, and not of a horse. It may however he alleged, that, according to Hesiod, Pegasus, as soon as he was born, left the earth and flew away to the mansions of the gods. A plausible meaning may be given to this circumstance by saying that Perseus, upon his return into Greece, as an acknowledgment to the gods for his happy voyage, consecrated the prow of the ship Pegasus in Jupiter’s temple, according to usual custom; and if this temple stood upon Mount Olympus, which was accounted heaven, and the mansion of the immortal gods, nothing more would be wanting for developing this part of the fable. As for the poets that are later than Hesiod, who make Pegasus to have taken flight upon Mount Parnassus, where, with a blow of his foot, he made the fountain Hippocrene to spring up, and which became so famous afterwards for the seat of Apollo and the Muses, we may suppose, that Perseus consecrated likewise in the temple of Apollo, which was in that mountain, some other part of his ship. Chrysaor, who issued at the same time with Pegasus from the blood of Medusa, with a golden sword in his hand, was some ingenious artist who wrought in gold and ivory; an explanation corresponding both to his name and the sword in his hand. Phorcys employed him to work the elephants’ teeth, and the horns of the other animals which his ships brought home; and the meaning of his marrying the beautiful Callirrhoe was, that Phorcys, in order to engage to great an artist to remain in his dominions, procured for him a considerable match. Banier’s Mythology, vol. iii.

Vol. XXVI.

PEGASUS, in Ornithology, the grey-bellied humming-bird of Latham, a species of Trochilus, which fees.

PEGAU, in Geography, a town of Saxony, in the circle of Leipfic, on the Elter, containing two churches and a convent; 10 miles S.S.W. of Leipfic. N. lat. 51° 12’. E. long. 12° 12’.—Alfo, a town of Lower Sfria; seven miles N. of Gratz.

PEGERSK, a town of Russia, in the government of Pikov, near the lake Tchudikoe; 20 miles W.N.W. of Pikov. N. lat. 57° 53’. E. long. 27° 32’.

PEGMA, among the Romans, a wooden machine, ufed in theatrical entertainments, which was raised and let down by secret engines, whence it was said to grow. See Pegmatres.

PEGMATES, or rather Pegmares, in Antiquity, a name given to certain gladiators, as well as artificers among the Romans. The ancients sometimes exhibited rows of a fort of moving machines, called pegmates: these were scaffolds variously adorned, somewhat after the manner of those now raised for fire-works.

These scaffolds, being made to play, and rise aloft, either threw up into the air the matters with which they were charged; and, among the ref, men, who were thus sacrificed to afford the people diversion; or else they precipitated them into holes dug in the ground, where they lighted their funeral piles; or finally into the dens of wild beasts.

Both the miserable people thus sacrificed, and the workmen that made and played the machines, were called pegmates, or pegmares.

According to Cafaubon, fire was set to the scaffold: and the pegmates were to lave themselves through the flames, and the wreck of the machine.

Lipius only says, that the pegmates were such gladiators as fought on scaffolds erected for that purpose. They were also called petauriles, q. d. flers in the air.

PEGNA COVA, in Geography, a town of Portugal, in the province of Beira; seven miles N.E. of Coimbra.

PEGNA da Francia, a town of Spain, in the province of Leon, anciently called Lancia; 24 miles S.S.E. of Civid Rodrigo.

PEGNA García, a town of Portugal, in Beira, on the confines of Spain; 26 miles E. of Caifel Branco. N. lat. 39° 50’. W. long. 6° 39’.

PEGNA Macor, a fortified town of Portugal, in Beira, on the confines of Spain, containing three churches, a convent, and hospital, and about 2000 houses; 30 miles N.E. of Caifel Branco. N. lat. 39° 50’. W. long. 6° 40’.

PEGNA Mayor, a town of Spain, in Galicia; 12 miles E.S.E. of Lugo.

PEGNAFEL, a town of Spain, in Old Caifile, situated at the foot of a mountain, and defended with a caffle; 25 miles S.E. of Valadiold.

PEGNA-FIRMA, a town on the W. coast of Portugal, at the mouth of the river Mongole; nine miles S. of Peniche.

PEGNAFLOR, a town of Spain, in Asturias, on the W. side of the Pravia; seven miles N.W. of Oviedo.—Alfo, a town of Spain, in the province of Nordova, on the Guadalquivir; 32 miles S.W. of Cordova.

PEGÑARANDA, a town of Spain, in Old Caifile; 18 miles W. of Ofma.—Alfo, a town of Spain, in the province of Leon; 30 miles S.E. of Salamanca.

PEGNITZ, a river of Germany, which runs into the Rednitz, at Furth.—Alfo, a town of Germany, in the principality of Culmbach; on a river of the fame name; 10 miles S. of Bayreuth. N. lat. 49° 45’. E. long. 11° 33’.

3 Z PEGO.
PEGOMANTIA, Pegu, in Antiquity, a species of divination, which was performed with fountain water, by throwing into it a kind of dice. When they funk to the bottom they drew happy presages; but if they remained on the surface of the water, it was a bad omen. See Hydromancy.

PEGONGMEW, in Geography. See PAGAHM.

PEGORELLA, in Ichthyology, a name by which some have called a fish of the truttaceous kind, caught in the Mediterranean, and more usually called callarias; which is a species of Genus.

PEGUE, or BAGOO, in Geography, a country of Asia, the southern part of which was the Golden Chersonese of the ancients, is bounded on the N. by Arracan and Ava, on the E. and S. by Siam and the sea, and on the W. by part of Arracan and the bay of Bengal. This country occupies the sea-coast as far as Martaban; Prome and its northern frontier and Siam subjoined on the east. It is for the most part a level country, surrounded by mountains, which serve as a frontier on the land side, but towards the sea it is liable to invasion, and also in its interior parts by means of the rivers which pass through the mountains. Thrice rivers, the chief of which are that of Pegu (or Syriam), and that of Ava (or Irrawaddy), so called from the capitals situated on their banks, still continue to roll down particles of gold; and it is probable, that their lands must in ancient time have yielded this precious metal in greater abundance. Hence it is not unlikely that the practice of gilding the roofs and spires of temples and palaces may have been derived from a remote period, more especially as we are informed, that Shoemadoo was built about 500 years before the Christian era, and this splendid appearance might naturally give rise to the classical appellation of the country. We learn from Colonel Symes, that gold is discovered in the sandy beds of streams which descend from the mountains. Between the keen Duam and the Irrawaddy to the northward, is a small river called Sho Lien Kioou, or the stream of golden sand. The air of this kingdom is very healthy; the soil is very rich, and productive of corn, fruit, and roots; and it produces various kinds of timber, particularly the teak. The animals that principally abound in Pegu are elephants. Besides the mines of the richer metals which are found in this country, it abounds with inferior minerals. But the most singular product of Pegu is the ruby, which is found in a mountain between Syriam and Pegu, and which exceeds in value that of any other country. The gem called the Syriam is also found only in Pegu. But for a further account of the productions and inhabitants of this country, as well as of the various revolutions which it has undergone, we refer to the article BIRMAN Empire. See also ARRACAN and AVA.

PEGUE, a city of Asia, and formerly capital of the kingdom of the same name, distant by water from Rangoon about 90 miles, mostly in a northward direction, but on account of the windings of the river, by land in a straight line much less. This city, in the year 1600, was one of the most splendid, large, and populous, in the whole of Asia; and is described by those who saw it in its prosperity as spacious, beautiful, and strong, surrounded with stone walls and very wide ditches. The extent of the ancient city may still be accurately traced by the ruins of the ditch and wall that encompassed it; from these it appears to have been a quadrangle, each side measuring nearly one mile and a half; the ditch, which was once no contemptible defence, is about 60 yards, and its depth 10 or 12 feet. The fragments of the wall evince that it was a large and laborious structure, about 30 feet high, and at the base not less than 45 feet broad, composed of brick, badly cemented with clay mortar. Small equidistant bastions, about 300 yards asunder, are still discoverable, and there had been a parapet of masonry; but in its present ruinous state, it is covered with weeds and briars, as to exhibit very imperfect vestiges of its former strength. In the centre of each face of the fort, there was a gateway about 30 feet wide; and these gateways were the principal entrances. The passage across the ditch is over a caufway raised on a mound of earth, that serves as a bridge, and was formerly defended by a retrenchment, of which there are now no traces. It is impossible to conceive, says Colonel Symes, a more striking picture of fallen grandeur, and the desolating hand of war, than the inside of these walls displays. Alompra, when he got possession of the city in the year 1757, razed every dwelling to the ground, and differed or led into captivity all the inhabitants. The temples, or praws, which are very numerous, were the only buildings that escaped the fury of the conqueror; and of these the great pyramid of Shoemadoo has alone been reërected and kept in repair. The present king of the Birmans has abrogated some severe penal laws imposed by his predecessors upon the Talens, or native Pegues; and the only distinction distinguishing at present between a Birman and a Talen, consists in the exclusion of the latter from places of public trust and power. Nothing has contributed more to reconcile the Pegues to the Birman yoke, than the restoration of their ancient place of abode, and the preservation and embellishment of the temple of Shoemadoo. Accordingly the king some time ago issued orders to rebuild Pegue, encouraged settlers by grants of ground, and invited the scattered families of former inhabitants to return and repopulate their deserted city. His Birman majesty, on the death of the late Maywsoon, or viceroy, directed his successor, the present governor, to quit Rangoon, and to make Pegue the place of his future residence, and the seat of provincial government of the 32 districts of Hainzawddy, the fanciful name given by the Birmans to the province of Pegu. The success of these measures has been such, that a new town has been built within the site of the ancient city; but Rangoon possesses many advantages over Pegu, in a commercial point of view, that persons of property in b-rines, will not easily be prevailed upon to leave one of the finest ports in the world, to encounter the difficulties of a new settlement, where commerce, if any can subsist, must be very confined for the want of commodious navigation. The present inhabitants who have been induced to return, consist chiefly of Rhaanas, or priests, and poor Talen families, who were glad to gain a settlement in their once magnificent mansion. Their number all together does not, perhaps, exceed five or seven thousand; those who dwell in Pegu, during its former days of splendour, are now nearly extinct, and their descendants and relatives scattered over the provinces of Tongho, Martaban, a d Talavmun; and many also live under the protection of the Siamese. It is apprehended, however, that respect for the favourite temple of worship, and the encouragement, as well as security, held out to those who venture to return, will, in time, accomplish the wise and humane intentions of the Birman monarch.

Pegue, in its renovated and contracted state, seems to be built on the plan of the former city, and occupies about one half of its area. It is fenced round by a blockade from ten to twelve feet high; on the north and east it has the borders on the old wall. The plane of the town is not yet filled with houses, but a number of new ones are building. There is one main street running east and west, crossed at right angles
by two smaller streets not yet finished. At each extremity of the principal street, there is a gate in the rockade, which is shut early in the evening; and after that time entrance during the night is confined to a wicket. Each of these gates is defended by a wretched piece of ordnance, and a few musqueteers, who never poitl fentinels, and are usually asleep in an adjoining shed. There are two interior gates on the north and south side of the rockade. The streets of Pegue are spacious.

The new town is well paved with brick, which the ruins of the old plentifully supply; and on each side of the way there is a drain to carry off the water. The houses of the meanest peafants of Pegue, and throughout the Birman empire, poiflids manifest advantage over Indian dwellings, by being raised from the ground either on wooden posts or bamboos, according to the size of the building. The kious or monaftries of the Rhahaans, and the habitations of the higher ranks, are nifually elevated six or eight, those of the lower classes from two to four feet.

There are no brick buildings either in Pegue or Rangoon, except such as belong to the king, or are dedicated to their divinity Gauda; his majesty having prohibited the use of brick or stone in private buildings, from the apprehension, as we were informed, (fays Col. Symes,) that if people got leave to build brick houses, they might erect brick fortifications, dangerous to the security of the state. The houses, therefore, are all made of mats, or felathing boards, supported on bamboo or poles; but from their being composed of such combustible materials, the inhabitants are under continual dread of fire, against which they take every precaution. The roofs are lightly covered, and at each door flanks a long bamboo, with an iron hook at the end, to pull down the thatch: there is also another pole, with a grating of iron at the extremity, about three feet square, to suppofe flames by prejudice. Almost every house has earthen pots, filled with water, on the roof: and a particular class of people, whose bufinefs it is to prevent and extinguifh fires, perambulate the streets during the night.

These people are called Pagwaat; they are flaves of government; men who have been found guilty of theft, and, through mercy, had their lives spared. They are diitin-guifhed by a black circle on each cheek, caused by gum powder and punctuation; as well as by having on their brow, in Birman characters, the word thif, and the name of the article flolen, as, on one that we alked to be explained to us, Putchoo Khoo, elab thif. These men patrol the streets at night, to put out all fires and lights after a certain hour. They act as confables, and are the public executioners.

The Maywoon's habitation, though not at all a magnificent mansion for the representative of royalty, is, notwithstanding, a building of much respectability, compared to the other houses of Pegue. From an outside view, we judged it to be roomy, and to contain several apartments, exclusive of that in which he gives audience; it poifild, however, but few ornaments. Gilding is forbidden to all subjeds of the Birman empire; liberty even to dacker and paint the pillars of their houses is granted to very few: the naked wood gave an unfurnished appearance to the dwelling of the Maywoon, which, in other respects, seemed well adapted for the accommodation of a Birman family.

The object in Pegue that most attracts and most merits notice, is the noble edifice of Shoemadoo, or the Golden Supreme. This extraordinary pile of buildings is erected on a double terrace, one raised upon another. The lower and greater terrace is about ten feet above the natural level of the ground, forming an exact parallelogram: the upper and leffcr terrace is similar in shape, and rifes about twenty feet above the lower terrace, or thirty above the level of the country. We judged a side of the lower terrace to be 1591 feet; of the upper, 634. The walls that confined the sides of the terrace, both upper and lower, are in a ruinous state; they were formerly covered with plaster, wrought into various figures; the area of the lower is fiwered with the fragments of small decayed buildings, but the upper is kept free from, and is in tolerably good order. There is reafon to conclude that this building and the fortrefs are coeval, as the earth of which the terraces are composed appears to have been taken from the ditch; there being no other excavation in the city, or in its neighbourhood, that could have afforded a tenth part of the quantity.

The terraces are ascended by flights of stone steps, which are now broken and neglected. On each side are dwellings of the Rhahaans, raised on timbers four or five feet from the ground: these houses confift only of a large hall; the wooden pillars that support them are turned with meatnefs; the roofs are covered with tiles, and the fides are made of boards; and there are a number of bare benches in every house, on which the Rhahaans feep; but we faw no other furniture.

Shoemadoo is a pyramidal building, composed of brick and mortar, without excavation or appearance of any fort; octagonal at the base, and spiral at top; each side of the bafe measures 162 feet; this immense breadth diminishes abruptly, and a fimilar binding has not unaptly been compared in fhape to a large speaking trumpet.

Six feet from the ground there is a wide projection that surrounds the bafe, on the plane of which are fifty-feven small spires of equal size, and equidistant; one of them measured twenty-feven feet in height, and forty in circumference at the bottom. On a higher ledge there is another row, confilling of fifty-three spires of fimilar fhape and measurement.

A great variety of mouldings encircle the building; and ornaments somewhat refembling the fleur-de-lis furrounded the lower part of the spire; circular mouldings likewise girt it to a considerable height, above which there are ornaments in flucco not unlike the leaves of a Corinthian capital; and the whole is crowned by a tee, or umbrella, of open iron-work, from which rifes a rod with a gilded pennant.

The tee or umbrella is to be feen on every facred building that is of a spiral form: the raffing and conceafion of this laft and indifpenfable appendage, is an act of high religious folemniity, and a feafon of felfivity and relaxation. The prefei king befaw the teee that covers Shoemadoo. It was made at the capital; and many of the principal nobility came down from Ummerapoora to be præsent at the cere-fmony of its elevation.

The circumference of the tee is fifty-six feet; it rifes on an iron axis fixed in the building, and is farther fecured by large chains strongly riveted to the spire. Round the lower rim of the tee are appended a number of bells, which, agitated by the wind, make a continual jingling.

The tee is gilt, and it is said to be the intention of the king to gild the whole of the spire. All the leffer pagodas are ornamented with proportionable umbrellas, of fimilar workmanship, which are likewise encircled by small bells.

The extreme height of the edifice, from the level of the country, is 361 feet, and above the interior terrace, 331 feet.

On the south-eaft angle of the upper terrace there are two handsome faloons, or kious, lately erected, the roofs com-posed of different flages, supported by pillars; we judged the length of each to be about sixty feet, and the breadth thirty: the ceiling of one is already embellished with gold leaf, and the pillars are lackered ; the decoration of the other is not yet completed. They are made entirely of

wood.
From the upper projection that surrounds the base of Shoemadoo, the prospect of the circumjacent country is extensive and picturesque; but it is a prospect of nature in her rudest state; there are few inhabitants, and scarcely any cultivation. The hills of Martaban rise to the eastward, and the Sitang river, winding along the plains, gives an interrupted view of its waters. To the north-west, about forty miles, are the Galladzet hills, whence the Pegue river takes its rise; hills remarkable only for the unison effects of their atmosphere. In every other direction the eye looks over a bottomless plain, chocked by a wild intermixture of wood and water.

Tradition reports that the temple of Shoemadoo was founded 2300 years ago by two merchants, who were brothers, and who came to Pegue from Talloweene, a district of one day's journey of Martaban. These pious traders at first raised a temple one Birman cubit (22 inches) in height; a cubit was curiously added in one night; the merchants added another cubit, which was again curiously doubled; and thus the building attained the altitude of 12 cubits; and the temple was afterwards gradually augmented by successive monarchs of Pegue.

The cows in the vicinity of Pegue are of a diminutive size, resembling the breed on the coast of Coromandel, but the buffaloes are noble animals, superior to those of any other part of India. These are used both for draft and agriculture. The only article of consequence manufactured at Pegue is flax and cotton cloth; it is well wrought, but they make no more than what suffices for their own consumption.

In the town of Pegue there are only three persons, besides the Maywoon or viceroy, whose artistic and ceremonial positions entitled them to distinction. These officers exercise the functions of magistrates, and hold separate courts at their own houses, for the determination of petty suits; but all causes of importance relating to property, and matters of a high criminal nature, are solemnly tried in open court, in which the three officers unite, and form a tribunal which sits at the "Rhoom," or public hall of justice, and the ultimate decision rests with the Maywoon. N. lat. 17 40'. E. long. 96° 11' 15'.

Pegue, a river of Asia, in the vicinity of the city of the same name. It is called by the natives "Bagoo Kioup," or Pegue rivulet, to distinguish it from Mioup, or river. This river is navigable but a very few miles to the northward of the city of Pegue, and for this it is indebted wholly to the action of the tide. It has no communication with the sea, except by the Rangoon river, and, in the fair season, at low water, is almost dry. This stream has been sometimes mistaken for the Sitang river, about 15 miles E. of Pegue, which is a large and independent body of water, that partly description of the course that in the map is given to what is called the Pegue river.

Pegunnock, a N.W. branch of Paffai river, in New Jersey, North America, which rises in Suffex county. The town of its name lies between it and Rockaway, another branch S. of this river, N.W. of Morristown.

Peel, a town of Aulria; 6 miles W. of Wells.

PEI, a city of China, of the second rank, in So-tchuen, on the Kinchea river, 720 miles S.S.W. of Peking. N. lat. 29° 50'. E. long. 107'.

PEICHELSTEIN, a town of Tyrol; 5 miles S.S.W. of Reuten.

PEJEND, or PAJANA, the most considerable lake of Finland, about 82 miles in length by 15 in breadth, which gives source to the river Kymmen.

PEJEPSCOL, or Pegyskeag, a township of America,
rica, in Cumberland county, Maine, adjoining Poland, Durham, &c. on the westery bank of Great Ameriflogen river, about 30 miles N. of Portland.

PEI-HO, or White River, a river formed by several streams in the province of Pe-teh-li, and which runs into the gulf of Pe-teh-li. The month of the river is traversed by a bar, stretching N.N.E. and S.S.W., over which, at low water, the depth is not more than three or four feet, and in many places it is almost dry. The tides rise and fall six or seven feet at the mouth of the river; the time of high water, at the full and change of the moon, is about half an hour after three; and five or six miles outside of the mouth of the river a large bamboo beam is placed upon the bar, together with some of a smaller size, continued nearly in a straight line to the shore, intended as marks to direct vessels entering into the river. The town of Ta-coo lies within the Pei-ho, and is the first place of any note in this part of the N.E. frontier of China. Yachts, or large covered barges, and boats of barthen, calculated to pass over the shallows of the Pei-ho, may be obtained here, in order to enable persons to proceed as far as this river leads, towards Pekin, the capital of the empire. The proffers upon the Pei-ho is necessarily very slow, as the course of the river is remarkably fenfitive. The fields on each side exhibit a high state of cultivation, and are generally covered with the hoale forshorn, or the tallell of the vegetables producing elegant grain, corn, and other fruits; they are bordered with trees, and the lowest calculation of its increase is one hundred-fold. The houses in the villages near the river are constructed of bricks ill-burnt, or baked in the fun, which, as well as the tiled roofs, are plastered over with a muddy coloured substance, unmixed with lime. Near some of the towns and villages are pyramids about 15 feet high, but of different dimensions as to both length and thicknefs. They confind of bags of falt, heaped together in that form, and covered merely with common matting. As soon as night comes on, the banks of this river are illuminated with varieated lights, from lanterns whose transparent fides were made of different coloured paper. The different numbers of lanterns hoifted on the mafts' head of the various vessels in the river denote the ranks of the passengers they hold; all which, together with the lights from the cabins of the junks, reflected from the water, produce a moving and parti-coloured illumination. The falt, already mentioned, brought from Quan-tong and Fo-chien into the Pei-ho, is sufficient to lead annually nearly 2000 vessels of 200 tons burden each.

At Tien-fing (which fce) two rivers unite; one of which retains the name of Pei-ho; and the other is called "Yun-leang-ho," or grain-bearing river, from the quantities of wheat conveyed upon it from the province of Shen-fee, and sent up by the Pei-ho to the neighbourhood of Pekin. About 36 miles beyond Tien-fing, towards Pekin, the tide of the Pei-ho ceases, and the proffers of the yachts, &c. is effected by rowing with oars, or towing with ropes, and their advance is very slow against the current of the river. Large junks, to the number of 1000, each of which contains not less than 50 persons, and therefore in the whole amount to 50,000, are palling between Tong-choo-fou and Tien-fing; and as many more of other kinds of craft; fo that upon a branch of a single river, the population of its moveable habitations amounts to 100,000 persons. Tong-choo-fou, where the water becomes too shallow for the navigation of yachts of any burden, is 90 miles distant from Tien-fing, and 12 miles from the city of Pekin. The mouth of the river Pei-ho, in the gulf of Pe-teh-li, is in N. lat. 39°.

PEILLAC, a town of France, in the department of the Morbihan; 16 miles E. of Rochefort.

PEILSTEIN, a town of Austria; 4 miles S. of Aigen.

PEINA, a town of Welfphalia, in the bishopric of Hildesheim, a marby county, on the Fulde, formerly reckoned among the fortrefes. The inhabitants are chiefly Lutherans. It has an episcopal palace, a Capuchin convent, and a suburb called the "Danon," which is mostly inhabited by shoekapers and Jews; 15 miles N.N.E. of Hildesheim. N. lat. 52° 10'. E. long. 10° 18'.

PEINT, a town of Hindoostan, in Baglama; 20 miles N.W. of Nafnuck.—Alfo, a town of Hindoostan, in Guzerat; 20 miles S. of Dunderpour.

PEINTADE, in Ornithology. See Numida Melasgrass.

PEIPUS LAKE, or Tschudjoe, in Geography, a lake of Russia, which lies between the governments of Picove, Reval, Riga, and St. Peterburg, extending in length to about 80 and in breadth to 60 verfa. By means of a very broad ftart it is connected with the Picove lake, the length of which is flated to be 50, and the breadth, which is always decreasing, 40 verfa. This latter receives the river Velikaia. Out of the Peipus comes the Narova, which through the Esbach has communication with the Verta-erh lake; and of this, on the other hand, flows the Fellin into the river of Riga; and consequently a very benefical water-paifage might be made between Riga and one of the inland provinces, by way of the Peipus lake. In this lake there are a few small islands, none of which are sufficiently impor- tant to deferve notice except Perka or Bork, called by the Ethelians Porkafaar, which is not only inhabited, but furnished with woods, and has no lefs than three villages upon it. Among the feveral brooks and rivers that flow into the Peipus, the Embach is the most confiderable. The exit is through the Narva river into the gulf of Finland. The multitude of fhift that breed in this lake afford a lucrative occupation to the boors of these parts, and inccrce the revenues of the adjoining cflates, the owners of which let out the parts on which their lands abut at a certain rent. The fhift are principally rebfe, a fpecies of herring, and barbel. Besides these, here are pike, perch, a fpecies of carp, whiting, quell, korubh, gudgeons, &c. The pike and some others are dried in the air and exported; the rebfe are sometimes smoked. N. lat. 58° 59' 10'. E. long. 27° 28' 30'.
PEIRCE.

request of his friends, he preached a Sunday evening lecture at Miles' Lane, London, but he does not appear to have interested himself in the dispute then subsisting between the Independents and Presbyterians. With the ministers of the latter denomination he became well acquainted, and at their solicitation he settled at Cambridge, where he acquired the respect and esteem of many members of the university. From Cambridge he removed to Newbury, in Berkshire, where he appeared to great advantage, in the year 1707, in a controversy with Dr. Wells, a clergyman of Leicestershire, who had attacked the principles and practice of the Dilleniers, and whose mistakes and misrepresentations he ably exposed. Mr. Peirce after this published, at different periods, various able controversial tracts, relating to the rites imposed under the establishment; the validity of the dissenting ministry, and presbyterian ordination; and the imputed sin of schism.

The next work of our author was called for by the appearance of “A Defence of the Doctrine and Discipline of the Church of England,” written in the Latin tongue, and submitted to the judgment of foreign divines, by Dr. Nichols, Latin secretary to the Society for the Propagation of the Gospel. In this work the author had given such a view of the controversy between the Church and Dilleniers, as was intended to expose the latter to the censure and condemnation of their foreign brethren, on which account Mr. Peirce was earnestly solicited to undertake their vindication in the same language, for the purpose of countering the effects of Dr. Nichols' performance. He accordingly published his “Vindicié Pratrum Dissentientium,” in which he gave a full and very satisfactory answer to his antagonist. This work was published in 1717 in the English language, with the title of “A Vindication of the Dilleniers, &c.” It consisted of three parts: the first contains the history of nonconformity; the second treats of the doctrine of the church of England; and the third contains all the heads relating to discipline and worship. It, in fact, presents the reader with a view of almost the whole controversy between the established church and the Dilleniers. In 1718, Mr. Peirce took part in the controversy relating to the Tell Act, and published “Letters” on the subject to a friend, and to Dr. Snape. He had previously to this removed from Newbury to Exeter, having had a general and most unanimous invitation from the three united congregations of the Dilleniers in that city. In this situation he gave the greatest satisfaction in the discharge of the pastoral duties, till there arose a controversy concerning the explanation of the Trinity, which was productive of very disgraceful consequences. He had been educated in the trammels of orthodoxy as it was called, but had, during his ministry, learnt to shake off all those unscriptural phrases, which then, as well as now, were looked on as a kind of tell of a man's religious opinions. He considered the scriptures as the only rule of faith, and from a very early period he took care to use their language in his sermons, when he introduced any doctrinal topics, and as he advanced in years he grew more careful in his adherence to this practice. The doctrine of the Trinity he looked upon as a mystery and was averse from speaking or even thinking upon it. But his attention was unavoidably drawn to it by the clamour which was raised concerning his friend Mr. Whilton, for whom he had a high esteem, and at first he was exceedingly hurt to learn that Mr. Whilton had declared against the current doctrines of the day. He expostulated with his friend, but instead of convincing him of his error, he himself became a convert to the heresy that he had been ready to condemn.

“The reader,” says Mr. Peirce, “will easily imagine that this must have been a terrible shock to me, and that I must have had a great concern upon my mind, when I found myself at a loss about a doctrine, of which I had been all along, long, to a great degree of uncharitableness. However, this caused me to read the Bible with more care, and make it more my prayer to God, that I might be led into the truth.” It was not long before he was fully satisfied that the common opinion was not accordant with the doctrines held forth in scriptures. Being persuaded of holding heretical opinions, he was attacked in the most hostile manner, and there can be no doubt that his opponents professed the power, they would most cheerfully have burnt him at the stake.

They required him to subcribe a left he refused, because he believed that the worth mischief had been done to the church of God by imposing unscriptural creeds and tells upon men, and he said he would never tamely surrender the liberty with which he had been made free. They turned him out of his meeting, and excited the clamour of the mob against him, by defamating him and his friends with the then unparalleled epithet of Ariotes. Under these circumstances, Mr. Peirce found it necessary, for the vindication of his own character, and that of his friends, to lay a true state of the affair before the public, and accordingly published “The Case of the Ministers ejected at Exon.” In 1720 he gave the world a much larger work, entitled “The Western Inquisition, or a Relation of the Controversy which has been lately among the Dilleniers in the West of England,” which contains a full account of the origin, progress, and influence of the nefarious and cruel persecution with which our author was harassed. To this a reply was published, entitled “An Answer to Mr. Peirce's Western Inquisition &c.” Mr. Peirce now took leave of the controversy by a very able and satisfactory piece, entitled “Inquisition Honestly displayed,” or the Western Inquisition defended against the pretended Answer, &c.

From this period Mr. Peirce applied himself to the diligent discharge of his pastoral duties among a respectable people, by whom he was highly honoured and beloved, and to the completion of some explanations of the sacred writings, in which he had made considerable progress. The first fruits of his learned studies were given to the world in 1725, but without his name, in “A Paraphrase and Notes on the Epistle of St. Paul to the Colossians,” 4to; in which he endeavoured to follow the admirable rules and example of Mr. Locke, whom he considered as having done more than any other writer towards rendering St. Paul's epistles easy and intelligible. This publication was well received; and in the same year he gave the world “A Paraphrase and Notes on the Epistle of St. Paul to the Philippians.” He intended to proceed with similar commentaries on all the other Epistles attributed to this apostle, excepting those that had been before paraphrased by Mr. Locke. His next attempt was on “The Epistle to the Hebrews,” which he did not live to finish, for while he was engaged in it, he was attacked by a disorder which put an end to his life, on the 30th of March 1726, in the 53rd year of his age.

The persecution which he had met with during his life purged him even to the grave: for his relations having directed that a Latin inscription, containing an encomium on his learning and virtues, should be cut on a tomb-stone, the rector of the church in which his remains were deposited would not permit it to be placed in his church-yard; stating that he could not, in conscience, suffer a person so notorious for hereby to be warmly recommended to posterity in any place under his care and inspection. When it was afterwards requested that these words might be inscribed on his
his tomb. "Here lies the reverend, learned, and pious Mr. James Peirce," till it was refud, the recit affirming that Mr. Peirce could not be reverend, because he was not lawfully ordained, and that he was not pious, because he taught errors, so that the only inscription allowed, was "Mr. James Peirce's tomb." On a monument erected to his memory in the meeting-house in which he latterly officiated, he is held out to the veneration of posterity, as a rational, judicious, and affecionate preacher; a very laborious and sagacious interpreter of the Holy Scriptures; a sincere lover and tenderous defender of the truth; and a courageous sufferer for maintaining the doctrines of the gospel of Christ, and for affording the liberties of Christians.

After the death of this excellent man, his "Paraphrase and Notes on the Epistle of St. Paul to the Hebrews, with Differtations on several Texts of Scripture," were published in 1727, though evidently left in an unfinished state. The work was afterwards completed by Mr. Jophel Hallet. From Mr. Peirce's MSS. were also published "An Essay in favour of the ancient Practice of giving the Eucharist to Children" and other tracts.

PEIRESC, NICHOLAS-CLAUDE FABRI DE, a considerable promoter of literature, descended from the ancient family of Fabri of Pila in Italy, was born in Providence in 1780. At ten years of age he was sent, with his younger brother, to the Jesuits' college at Avignon, where he continued five years. At the early age of seven he was appointed to the sole superintendence of his brother's education, who was about a year and a half younger than himself. In 1795 he removed to Aix, where he commenced the study of philosophy. At this time he became passionately fond of the medical science, and the remains of antiquity. In 1796 he finished his course of philosophy and mathematics in the Jesuits' college at Tournon, and he afterwards studied the law at Aix. He was sent, in 1803, with his brother and a tutor to travel in Italy, and further prosecute his legal studies at Padua. He paid frequent visits to Venice, and became acquainted with several distinguished persons, particularly with father Paul, and the procurator Fred. Contarii. The fine cabinet of medals polished by the latter was a peculiar object of attention to Peirese, who gave the owner explanations of the Greek inscriptions. Rome was the next object of our youthful traveller's curiosity, and it gave ample gratification to his love of antiquities, and his desire of forming acquaintances among the learned. In 1801 he proceeded to Naples, and having thoroughly surveyed every thing worthy of observation in that city and its vicinity, he completed the tour of Italy, by returning along the coast of the Adriatic to Padua. He there resumed the study of the law, and likewise, at the same time, acquired a knowledge of the oriental languages, in which he was assisted by a learned rabbi named Solomon. Returning to France in 1803, he continued his studies at Montpeier, and in 1804 he took the degree of doctor of laws at Aix, after finishing disputations for three days with great applause. In the following year he went to Paris, and in 1806 he visited England, where he was graciously received by king James. Of the learned men in this country, Camden, on account of his antiquarian knowledge, was particularly acceptable to him. On his return by Holland, he became personally acquainted with Joseph Scaliger and Grotius. After he had finished his travels, he was made counsellor to the parliament of Aix, which office he held, though in 1818 he entered into the ecclesiastical state, and was presented to an abbacy of the Benedictine order.

The great occupation of Peirese during his whole life was the acquisition of knowledge, and the encouragement of learned men, and no person of his time maintained such an extensive correspondence with the literati of different classes and countries.

The chief objects of his enquiries and communications embraced philosophical experiments, natural history, rare products of art, antiques, history, and philosophy. He formed for himself a museum of valuable curiosities, and a copious library, and then liberally opened his stores to authors and students. He has been characterized as a true citizen of the republic of letters, and a kind of general agent of learning throughout civilized Europe. He died in 1847, in the 57th year of his age. His funeral at Aix was conducted with great solemnity, and a collection of eulogies to his memory was printed in a variety of languages. The vast variety of objects which his studies comprehended prevented him from finishing any thing, so as, in his own opinion, to be fit for the public eye, but he left behind him a great number of MSS. on local history and antiquities, mathematics and astronomy, the medallic science, languages, &c. Of the writings of this scholar there have been published 48 Italian letters, addressed to Paolo and Giambattilla Guidal, in the "Lettre d'un homme illustre," a considerable number of letters among those of Camden, and a long and learned dissertation on an ancient tripod found at Frejus, in the Mém. de Literature et de l'Histoire," by Defmalets, in 1731.

PEISDORF, in Geography, a town of Bohemia, in the circle of Koniggratz; 14 miles N.E. of Gitschin.

PEISKREITSCAM, or PYSSLOWICE, a town of Silelia, in the principality of Oppeln; 12 miles W.N.W. of Beuthen.

PEITSCHERDORF, a town of Pruflia, in Barten land; 22 miles S. of Raiffenburg.

PEITZ, a town of Brandenburg, in the Ucker Mark, on a small river which runs into the Spreke. In its vicinity are iron mines, and manufactures of pitch and turpentine; 20 miles E.S.E. of Luban. At the peace of Tilsit, this town was ceded to Saxony. N. lat. 51° 53'. E. long. 14° 45'.

PEIXE, in Ichthyology. See ZEUS GALUS, and CENTRISUS SANTICUS.

PEKAN, in Zoology. See MUSTELA CANADARUS.

PEKEA, in Botany, a West Indian name for a tree of Carenne, which bears an excellent nut, sometimes fold in the fruit-stops of London, by the name of Suwarow nut. Aublet figures this species in his t. 259, and another in t. 238. See RHIZOBULUS.

PEKENEN, in Geography, a town of Africa, on the Grain coast; 15 miles S. of Sanguin.

PEKET, a town on the N. coast of the island of Cumbaya. S. lat. 8° 15'. E. long. 117° 36'.

PE-KIANG, a river of China, which rises near Nan-yang, in the north part of the province of Quan-tong, and runs into the river Cantor, 30 miles below Cantor. This river continues its course through an extent of about 200 miles, to the city of Cantor; from whence it falls, after a further course of about 80 miles, into the southern sea of China, near which it takes, among foreigners, the name of Boces Tigris. For a great part of its course to the northward of Cantor, it lies between two ranges of calcareous hills, conflating of rugged eminences with intervening plains between them, on which are erected small neat houses, surrounded by patches of land under cultivation, and apparently accessible only by the river. In its bed frequently occur heaps of stones, with flakes of wood, forming damns, with sluices, through which the water runs, and in these are placed baskets of wicker-work, which allow the fift to pass, but prevent their regresa; thus rendering them a prey to the proprietors of these faures. As soon as the hills opposite to each other begin
Pekin, or Peking, the capital of the province of Peche-li, and of the whole empire of China proper. Its name is said to signify the "Northern court," and it is so called by way of distinction from the city of Nankin, designated the "Southern court." Pekin was the Cambin, or city of the Chou, in writings of the middle ages, the capital of Cathay, as Nankin was of Mancze. It is situated in a fertile plain, 20 leagues distant from the great wall. The road to it from Tong-chou-foo forms a magnificent avenue, for persons and commodities bound for that capital from the east and from the south. It is perfectly level; the central part, to the width of about 20 feet, is paved with flags of granite, brought from a considerable distance, and of a size from six to sixteen feet in length, and about four feet broad. On each side of this granite pavement is a road unpaved, wide enough for carriages to cross upon it; the road is bordered in many places with trees, particularly willows of a very uncommon girth. The pavement lies over a marble bridge, very wide, and substaniously built, which traverses a rivulet, not subject to inundations; and is little elevated above the level of the roads, which it connects together. Those who enter the city in this direction, arrive at length at one of the eastern suburbs, along a street that is paved, and that exhibits a busy scene of manufacturers, shopkeepers, and buyers. We shall first trace the progress of the embassy under lord Macartney through this city, and then more particularly describe the city itself. To traverse the suburb, required about 15 minutes, when the party arrived before the walls of Pekin. Near the gate of entrance the walls were faced with stone, but elsewhere with brick; over the gate was a watch-tower several stories high. In each story were painted port-holes for cannon. Round the gate, on the outside, was a semi-circular wall, with a lateral gate. The city walls were about 40 feet high; the parapet was deeply crested, but had no regular embrasures, nor did any cannon appear upon the walls; but in the merlons were loop-holes for artillery. The thickness of the walls at the base was about 20 feet, and 12 feet the terre-plaine, upon which the parapet was erected. The outside of the city wall, though not perfectly perpendicular, was smooth, but the inside was upon a considerable level; the rows of bricks which form it being placed, like steps, one above and behind the other, such as are described to be the faces of the Egyptian pyramids. The walls were flanked on the outside by square towers, at about 60 yards distance from each other, and projecting from the curtain between them 40 or 50 feet. Several horsemen might ride abreast upon the ramparts, ascending to them upon slopes of earth raised on the inside.

Few of the houses in Pekin were higher than one story; none more than two: while the width of the street which divided them was considerably above 100 feet, so that it was airy, gay, and lightsome. The street was unpaved, and water sprinkled on it to lay the dust. A light handsome building was erected across it, called by the Chinese "Pei-loo," translated for as a triumphal arch, though not part of it resembles an arch. The whole was made of wood, and confined of three handsome gate-ways, of which the middle is the highest and largest. Over these were constructed three roofs above each other, richly decorated. Large characters painted or gilt upon the uprights or tronfams, indicated the purpose for which the pei-loo was erected. They are meant to compliment particular persons, or to perpetuate the memory of some interesting event.

The first street extended in a line directly to the west, until it was interrupted by the eastern wall of the imperial palace, called the Yellow wall, from the colour of the small roof of varnished tiles, with which the top of it is covered. Various public buildings, seen at the same time, and considered as belonging to the emperor, were covered in the same manner. These roofs, uninterrupted by chimneys, and indented in the fives and ridges into gentle curves, which heightened the effect, were adorned with a variety of figures, either in imitation of real objects, or more commonly as mere works of fancy: the whole thing like gold under a brilliant sun, immediately caught the eye with an appearance of grandeur in that part of buildings where it was not usual to seek for it. Immense magazines of rice were seen near the gate: and looking from it to the left, along the city wall, was perceived an elevated edifice, described as an observatory, erected, in a former dynasty, by the emperor Yong-lfoo, to whom the chief embellishments of Pekin are said to be owing. In front of most of the houses in this main street were shops, painted, gilt, and decorated, in a grand style. Over some of them were broad terraces, covered with shrubs and flowers. Before the doors were hung several lanterns of horn, muffins, silk, and paper, fixed to frames, in varying the form of which the Chinese seemed to have exercised their fancy to the utmost. Outside of the shops, as well as within them, was displayed a variety of goods for sale.

As soon as the persons belonging to the embassy had arrived
PE-KING.

rived at the easterm side of the Yellow wall, they turned along it to the right, and found on its northern side much less bulke than in the former street. Instead of floops all were private houses, not conspicuous in the front. Before each house was a wall or curtain, to prevent passager from seeing into the court into which the street-door opened. This is called the wall of "respect." A halt was made opposite to the treble gates, which are nearly in the centre of this northern side of the palace-wall. It appeared to include a large quantity of ground. It was not level like all the lands with out the wall: some of it was raised in high steep ascent; the rest was so level and flat that the whole surface was covered with water. Out of these artificial lakes, of which the margins were diversified and irregular, small islands arose with a variety of fanciful edifices, interspersed with trees. On the banks of different heights the principal palaces for the emperor were erected. The whole had somewhat the appearance of enchantment. On the summit of the highest eminences were lofty trees surrounding summer-houses, and cabinets contrived for retirement and pleasure. From the spot whence an opportunity thus offered to take a glance through the gates of the palace-wall, of part of what was inclosed within it, the eye, turning to the north, observed through a street extending to the city wall, the great palace, of considerable height, which includes a bell of prodigious size and cylindrical form, that, fixed on the outside with a wooden mallet, emits aound distinctly heard throughout the capital. Beyond it, but more to the westward, was one of the northern gates, the watch-tower over which rendered it visible above the intermediate buildings. Proceeding on beyond the palace-gates directly to the westward, between the Yellow wall and the northern buildings of the city, is a lake of some acres in extent, which in autumn was almost entirely overpread with the peltated leaf of the nymphaea nelmbo, or liin-praife of the Chinese.

The route was continued westerly through the city. Among other buildings was seen a library of foreign MSS. one of which was said to be an Arabic copy of the Koran. Some Mahometans were observed distinguishd by red caps; and also natives of Tartary, or females of a Tartar race. Their feet were not crampd, like those of the Chinese; and their shoes with broad toes, and foles above an inch in thicknes, were as clumsily as those of the original Chinese ladies were diminutive. Some few of the former were well-dressed, with delicate features, and their complexions heightened by the aid of art. A thick patch of vermillion in the middle of the lower lip, seemed to be a favourite mode of using paint. Some of them were fittin in covered carriages, of which, as well as of horses, there are severall to be found for hire in various parts of the town. A few of the Tartar ladies were on horse-back, and rode altiude like men. Several of the streets were narrow, and at the entrance of the gates were erected, near which guards were flattened, for quieting any occasional disturbance in the neighbourhood. These gates are shut at night, and opened only in cases of exigence. The train of the embassy crosed a street which extended N. and S. the whole length of the Tartar city, almoll four miles, and is interrupted only by severall pel-loos, or triumphal fabrics; and passing through many temples and other spacious buildings and magazines, they reached, in little more than two hours from their entrance on the eastern side, to one of the western city gates. Near this gate, and along the outside of the western wall, ran the small rivulet, (here widened into a consideralbe ditch,) which, after amoll surrounding Pekin, runs towards Tong-choo-foo, and falls into the Pei-ho: the fuburb beginning at this western gate, being more extensive than that through which they had entered into the city, took for traversing it upwards of twenty minutes.

The embassy found, in proceeding N.W. from Pekin, the fame kind of granite pavement over which they had travelled to that city from Tong-choo-foo. It led them to the open town of Hai-tien, containing few other buildings besides those intended for the sale of goods, and for the accommodation of artificers, near the autumnal palace of Yueen-min-yuen, which lies a little way beyond it. The town of Hai-tien, besides needfars, abounds in toys and trifles, calculated to suit the rich and idle of both sexes. Between Hai-tien and Yueen-min-yuen, was the villa intended for the ambassador and his suite, which was an inclosure of twelve acres. It contained a garden laid out in perpentine walks, a rivulet winding round an island, a grove of various trees, interspersed with patches of grass ground, and diversified with artificial inequalities, and rocks rudely heaped upon each other. The building in this place consist of several separate pavilions, erected round small courts. The apartments were handsome, and not ill contrived. Several of them were adorned with landscapes, painted in water-colours.

The capital of Pekin bears not in fize the fame propor- tion to the rest of China that London does to Britain. The principal part of it is called the Tartar city, from the circumstance of its having been laid out anew in the 13th century, in the time of the frill Tartar dynasty, or as Du Hakle says, because the houses were allotted to the Manchu-flurs, in the beginning of the prevant dynasty. It is in the form of a parallelogram, of which the four walls face the four cardinal points. They include an area of about four square miles, in the centre of which is the imperial palace, occupying within the Yellow wall at least one square mile, the whole being about one-third larger than London, on its present extended scale; whereas the fifteen ancient provinces of China, independently of the vast accession of territory from the great wall to the neighbourhood of the Capfian sea, bear a proportion to Great Britain of about 15 to 1. Adjoining, indeed, to the southern wall of the Tartar city, is another, called by way of dilinition, the Chinefe city. Here most of the people lodge, who come occasionally upon buufinews from the provinces to the capital. Its walls, which are greatly in decay, include likewise a very considerable space, about nine square miles. A small part only, however, is occupied by buildings, which are indifferent, crowded, and irregular; the reft is empty, and part of it is in cultivation. Within this compafs has been raised the "Sien-nong-tan," or eminence of venerable agriculturists. Thither the emperor repairs every spring, and in compliance with ancient usages, goes through the ceremony of directing with his own hand the plough through a small field, by way of doing honour to the profeflion of a husbandman. When this part of the ceremony is finifhed, a group of peafants chant round him hymns in praise of husbandry, following his example, and making several furrows with the plough in his presence. The produce of the ground he has ploughed is carefully collected, and solemnly announced to surpafs, in quality and quantity, what any other fpo of equal dimenfions had yielded in the year. The celebration of this fentival is made known as far as the remoteft village of the empire. Within the walls of the Chinefe city has likewise been erected the "Tien-tan," or eminence of heaven. The fingle character "ten," or heaven, is incribed upon the principal building in this eminence. Its form is round, in allusion to the vault of the heavenly firmament, as it strikes the eye; in like manner the "tee-ten," a temple dedicated to the earth, which the ancient Chinefe supposed to be a per-
tect square, is of a square form. In the summer festival, when the heat and power of the sun are at their height, the emperor comes in solemn procession to pay obedience, and offer thanks for its benign influence, and in the winter festival similar ceremonies are performed in the temple of the earth. This solemn adoration of heaven and earth is confined to the person of the emperor; and for his convenience is performed at Pekin, where he likewise appears abroad, in a variety of other grand processions, suggested by the mixed views of policy and religion. There are few other ceremonies performed in Pekin.

Pekin is merely the seat of the government of the empire. It is not a port, nor a place of inland trade nor manufacture. No representative diet, nor general states, with numerous retainers, assemble there to affix, or check, or examine, the measures of the crown. It forms no rendezvous for pleasure and dissipations. Pekin owes little of its extent and population to the various circumstances that contribute to aggrandize and enlarge European cities. Most men there have habitually allotted them, or are occupied in attending or providing for those who have. From the operation of a variety of causes in China, there is a constant tendency to level wealth; as there is no right of primogeniture, nor any hereditary dignity, the extremes of wealth and poverty are equally unknown. There are properly but three classes of men in China, men of letters, from whom the mandarins are taken, cultivators of the ground, and mechanics, including merchants. To these we might add a fourth class, viz. the military. In Pekin alone is conferred the highest degree of literature, upon those who, in public examinations, are found most able in the sciences of morality and government, as taught by the ancient Chinese writers; with which studies the history of their country is intimately blended. Among such graduates, all the civil offices in the state are distributed by the emperor; and they compose all the great tribunals of the empire. The candidates for these degrees are such as have succeeded in similar examinations in the principal city of each province. Those who have been chosen in the cities of the second order, or chief towns of every district in the province, are the candidates in the provincial capital. Those who fail in the first and second climes have still a claim on subordinate offices, proportioned to the climes in which they had succeeded. These examinations are carried on with great solemnity, and apparent fairness. Military rank is likewise given to those who are found, upon competition, to excel in the military art, and in warlike exercises. The great tribunals are instituted for the sake of convenience, near the northern gate of the imperial palace at Pekin. To them all the transactions of the empire are regularly transmitted. They are councils of reference from the emperor, to whom they report every business of moment, with the motives for the advice which they offer on the occasion. His imperial majesty generally conforms to the fuggileons of these tribunals, of which there are several, superior and subordinate.

The estimated population of Pekin was supposed, in the last century, by the Jesuit Grimaldi, to amount to sixteen millions. Another millionaire reduces, at least, that of the Tartar city, to one million and a quarter. According to the best information given to the embassy, the whole was about three millions. The low houses of Pekin seem scarcely sufficient for so vast a population; but very little room is occupied by a Chinese family, at least in the middling and lower classes of life. In their houses they have no superfluous apartments. A Chinese dwelling is generally surrounded by a wall, six or seven feet high. Within this inclosure a whole family, of three generations, with all their respective wives and children, will frequently be found. One small room is made to serve for the individuals of each branch of the family, sleeping in different beds, divided only by mats hanging from the ceiling. One common room is used for eating. This arrangement renders the younger orderly and temperate in their conduct, under the authority and example of the older; and it enables the whole to subsist, like soldiers in a mess, with more economy and advantage.

The streets of Pekin are thronged with people, the multitude of whom is increased by the mandarins of rank, appearing always with numerous attendants; and still more by circles of the populace round auctioneers, vendors of medicines, fortune-tellers, singers, jugglers, and story-tellers. The nobility of the court and princes of the blood never appear in public, without being surrounded by a large body of cavalry; and as their preference is required at the palace every day, their train alone would be sufficient to create confusion in the city. Besides, as there is a continual influx of the riches and merchandise of the whole empire into this city, the number of strangers that resort hither is immense. These are carried in chairs, or ride on horsecarts; and they are always attended by a guide acquainted with the streets, and with the houses of the nobility, and principal people of the city. In summer there are to be seen small temporary shops, where people are ferved with water cooled by means of ice; and eating-houses are every where to be met with, with refreshments of tea and fruits. Each kind of provision has a certain day and place appointed for its being exposed to sale. Nevertheless, the crowds of people at Pekin do not prevent it from being healthy. The climate, indeed, lives much in the open air, increasing or diminishing the quantity of their apparel according to the weather. The atmosphere is dry, and does not engender putrid disorders; and excelles productive of them are seldom committed. Great order is preferred among such multitudes; and the commotion of crimes is rare. The police of the capital is so well regulated, that the safety and tranquility of the inhabitants are seldom disturbed. At the end of every crofs street, and at certain distances in it, is a kind of crofs bars, with fentry boxes, in each of which is placed a foldier; and few of these streets are without a guard-houfe. Besides, the proprietor or inhabitant of every tenth houfe, like the ancient tythingmen of England, takes it in turn to keep the peace, and be responsible for the good conduct of his nine neighbours. If any riotous company should assemble, or any disturbances happen within his district, he is to give immediate information of it to the nearest guard-houfe. The soldiers also go their rounds, and instead of crying the hour like on watchmen, strike upon a short tube of bamboo, which gives a dull hollow sound, that prevents those unaccustomed to it from sleeping. The viceroy of Pekin is of the Tartar race, and is styled governor of the nine gates, that being the number of gates belonging to the city. His jurisdiction extends not only over the foldiers, but also over the people in every thing that concerns the police. In the suburbs only public women are registered and licenced: they are not very numerous, being proportioned to the small number of single men, and of husbands absent from their families to be found in the metropolis. In Pekin, as well as in other parts of China, parents are less frequendy neglected than infants are exposed. Female infants are, for the most part, chosen for this cruel sacrifice, because daughters are considered more properly to belong to the families into which they pass by marriage; while the sons continue to be the support and comfort of their own. Note-
PEL

Notwithstanding all the means adopted for restraining this barbarous practice, a missionary, who was not inclined to exaggerate the evil, has reported that in Pekin about 2000 inferiors were every year exposed, of whom a considerable number perished. The missionaries, to their honour it must be acknowledged, have contributed to prevent many, and afterwards to maintain and educate them.

The principal building in Pekin is the imperial palace already mentioned: it stands in the middle of the Tartary, at a little distance from the south gate; and the entrance to it is through a spacious court, to which there is a descent by a marble staircase, ornamented with two large copper lions, and a balustrade of white marble, which runs in the form of a horse-shoe, along the banks of a rivulet, that winds across the palace with a serpentine sweep: the bridges over it are of marble.

At the bottom of this first court arises a façade with three doors: that in the middle is for the emperor only; the mandarins and nobles pass through the sides on the floor. These doors conduct to a second court, which is the largest in the palace; it is about 300 feet long and 50 broad; an immense gallery runs round it, in which are magazines, containing rich effects, belonging to the emperor as his private property; for the public treasure is entrusted to a sovereign tribunal, called "Hou-pon." In this second court is the royal hall, called "Tentingoten," or the hall of the grand union; it is built upon a terrace about 18 feet high, inclosed with a white marble, and ornamented with balustrades of excellent workmanship. Here the mandarins arrange themselves, when they come, on certain days, to renew their homage, and perform those ceremonies that are appointed by the laws of the empire. This hall is almost square, and about 130 feet long; the ceiling is carved, varnished green, and loaded with gilt dragons. The pillars which support the roof within are six feet in circumference towards the base, and are coated with a kind of mallich varnished red; the floor is partly covered with coarse carpets, after the Turkish manner; but the walls have no kind of ornament, neither tapestry, luxures, nor paintings.

The throne, which is in the middle of the hall, consists of a pretty high and very neat alcove. It has no inscription but the character "Ching," which denotes excellent and perfect, as well as most wise and holy. It is ascended by steps in the front and on each side. Tripods and vessels of incense are placed on the sides, and before it is a small table, as an altar, on which are laid offerings of tea and fruit to the spirit of the absent emperor. As the Chinese attribute all the perfections belonging to the deity, they conceive his dominion as virtually extending over the whole world. Believing the majesty of the emperor to be ubiquitary, they sacrifice to him when absent; and it is not therefore surprising that they should adore him when present. The adoration, or "Koteou," they pay him consists in nine prostrations of the body, the forehead being each time made to touch the floor; which is not only a token of the deepest humility and submision, but implies a conviction of the omnipotence of the perfonage to whom this act of veneration is performed. These abject prostrations are required not only from the subjects and tributary princes of the empire, but also from all strangers, however exalted. Upon the platform, opposite to the hall just mentioned, stand large vellums of bronze, in which incense is burnt, when any ceremony is performing. There are also chandelles shaped like birds, and painted of different colours, as well as the wax candles that are lighted up in them. This platform is extended towards the north, and has upon it two lesser halls; one of them is a rotunda, that glitters with varnish, and is lighted by a number of windows. Here the emperor changes his drets before or after any ceremony. The other is a falcon which opens to the north; through this door the emperor must pass, when he goes from his apartment to receive on his throne the homage of the nobility; he is then carried in a chair by officers dressed in long red robes bordered with silk, and caps ornamented with plumes of feathers. We may here observe, that the temples of Pekin have no claim to elegance when compared to its palaces. The religion of the emperor is performed with great magnificence in Tartary, but in China it is new. The mandarins and men of letters venerate Confucius, and assemble in halls of simple construction; and the lower classes of the people are unable to contribute to the erection of splendid edifices for public worship. Besides, their attention is much taken up with their household gods. Every house has its altar and its deities. (See CHINA.) The imperial palace, which presents an assemblage of vast buildings, extensive courts, and magnificent gardens, is flutu upon all sides by a double wall; the intervening space being occupied by houses belonging to the officers of the court and eunuchs, and by different tribunals. The exterior circumference of this palace is reckoned to be 18 league. The extent, grandeur, regular disposition of apartments, and singular structure of the pavilion roofs (already noticed), cannot fail to strike beholders with surprize. N. lat. 39° 35'. E. long. 116° 28'. Earl of Macartney's Embassy, by Sir G. Staunton, vol. ii. Barrow's China, G.PELAD, a kind of alopecia, or deflembered state of the body, occasioning the shedding of the hair, arising from a venereal cause.

PELÆAS, in Orinóbiology, the name by which the ancients called that species of pigeon now known by the name of the livia, and afferofilia; a grey pigeon, of a very small fize, and with some variegations of purple and green. See LIVIA.

PELAGIA, in Natural History, the name by which Pliny, and other of the ancient naturalists, have usually called the purpura.

PELAGIA, St., in Geography, a town of Naples, in the province of Otranto; 3 miles N. of Tarento.

PELAGIÆ, formed of ωασα, marine, or belonging to the sea, in Natural History, a term used to express sea shells and fishes, as never, or very rarely, are found near the shores; but always reside in the deep, or in those parts of the bottom of the sea which are most remote from land.

PELAGIANS, Plagiari, in Ecclesiastical History, the denomination of a sect, well known in the church by the writings of St. Augustine.

The author of this sect, Pelagius, properly called Morgan, was a monk of Bangor: but the learned are at a loss whether it was of the monastery of Bangor in Wales, or that of the same name and order in Ireland. But he was a contemporary with St. Jerom and St. Augustine; and quitted his country to go and live in the East, according to the usum of the monks of those days, who were attached to particular houses like those of our own time.

Cecelius, as some say, a native of Ireland, according to others, of Scotland, and again, as others say, of Campania, in Italy, was the colleague of Pelagius, in forming this sect. They both lived at Rome in great reputation, and were universally esteemed on account of their extraordinary piety and virtue. About the year 410 they pubhished their doctrine, first in Sicily, and afterwards in Africa. From Africa Pelagius passed into Palestine, and Ccelelius remained at Carthage, whences, his errors being condemned in a council, A.D. 412, he went into the East. The former, under the protection of John, bishop of Jerusalem, made a public profession.
proposition of his opinions, and formed disciples in several places. In the year 415 he was accussed by Or Rufus, a Spanish presbyter, whom Augustine had sent into Palestine for that purpose, before an assembly of bishops who met at Jerusalem, but was dismissed without the least censure, and was soon after fully acquitted of all errors by the council of Diospolis, a city of Palestine, known in Scripture by the name of Lydda. However, after this council, Pelagius and Celestius were condemned again, A.D. 416, by the African bishops assembled at Carthage, and those of Numidia assembled at Milevum. Soon after the controversy was brought to Rome, and referred by Pelagius and Celestius to the decision of Zozimus, who was raised to the pontificate, A.D. 417; and he pronounced in their favour, declared them found in the faith, and unjustly perjured by their adversaries. However, he was prevailed upon by the remonstrance of the Africans to change his mind, and he severely condemned those two persons, whom he had honoured with his approbation, and covered with his protection. They were also condemned by the council of Ephasus, A.D. 431; and, in short, the Gauls, Britons, and Africans, by their councils, and emperors, by their edicts and penal laws, demolished this sect in its infancy.

Pelagius absolutely denied all original sin, which he held to be the mere invention of St. Augustine; and taught that men are entire masters of their actions, and perfectly free creatures; in opposition to all predestination, repubcation, election, &c.

He owned, indeed, that the natural power of man needed to be afflicted by the grace of God, to enable him to work out his own salvation; but, by this grace, he only meant outward assistance, viz. the doctrines of the law, and of the gospel.

Though, when pressed by those words of St. Paul, "Deus est enim, qui operatur in nobis," &c. he owned that it is God, in effect, that makes us what is good, when he warns and excites us by the greatness of the glory we are to obtain, and by the promises of rewards; when he makes us love him by revealing his wisdom, &c.

These are Pelagius's own words, as cited by St. Augustine; who confutes him, and shows, that, besides these exterior graces, there are required other real and interior ones.

He owned, that the will of man is indeed aided by a real grace; but he added, that this grace is not absolutely necessary in order to live well; but that it only helps us to do well with the more ease.

Julian, one of his adherents, went farther yet; and owned that the assistance of grace was absolutely necessary to enable us to do perfect works.

In effect, the grand doctrine of the Pelagians was, that a man might accomplish all the commands of God by the mere power of nature; and that the gifts of grace were only necessary to enable him to act well more easily, and more perfectly.

Pelagians, Semi. See Semi-Pelagians.

Pelagius, a pope, in Geography, a river of Louisiana, which runs into the Mississippi, N. lat. 38° 50'. W. long. 91° 50'.

Pelagius, II. pope, in Biography, was a native of Rome, and became a deacon of the Roman church, and was employed in the capacity of nuncio at the court of Constantineople by several of the popes in succession. He was first sent to the imperial residence by pope Agapetus, in the year 535, where he rofe into extraordinary favour with the emperor Julianian, the emperor, and the leading persons at court. About the year 539 he was commisioned, together with Epiphanius, patriarch of Antioch, and Peter, patriarch of Jerusalem, to decide on the case of Paul, who had been banished to Cyrus, on account of a deacon's death, to which he was said to have been privy. Having repaired to Cyrus after the trial of the African prelate, sentence of deposition was pronounced upon him. While Pelagius was returning to Constantineople he met with some Palestine monks on their journey to that city, in order to prefer complaints to the emperor against the followers of Origen; and having promised them his interdict at court, he succeeded in obtaining an edict from Julianian in 541, by which sentence of condemnation was passed upon the Origenists. In the mean time, he had betrayed the interests of pope Silverius at Constantineople, and, to gratify himself with the emprcfs, became privy to the measures for securing the popeandom to Vigilius, the usurper of the see. About the year 545 he returned to Rome, being either recalled by Vigilius, or, according to others, sent by Julian with a large sum of money for the relief of that city, which was reduced to great distress by the incursions of the Goths. In 547 he was deposed by the citizens of Rome on an embassy to Totila, king of the Goths, for the purpose of dissuading that prince by his prayers from besieging the city, when, though he failed in the object of his mission, by his intercession he was the means of preserving the lives and liberties of numbers of the conquered Romans. In the same year Totila sent him in the character of ambassador to Constantineople, to negotiate a peace between the Goths and Romans. He adhered to Vigilius in all his disputes: in all his changes, condemning or approving those articles which the pope condemned or approved. With him he was banished for rejecting the fifth council; but, when the pope recanted, he was with him released from his exile and recalled to Constantineople. He attended Vigilius on his return from the East; and upon the death of the pope in the island of Sicily, in the year 555, he hastened to Rome, the emperor having promised to raise him to that see if he survived Vigilius, upon his engaging to caufe the fifth council to be universally received in the West. When Pelagius arrived at Rome, he found the people and clergy so highly enraged against him, that instead of electing him their bishop, they all with one consent separated themselves from his communion. What induced many to concur in the measure, was a strong report, that, in order to secure the object of his ambition, he had been accessory to the death of his predecessor. But Pelagius, relying on the support of the emperor, resolved to have himself ordained in defiance of the canons, as well as the electors. Having, therefore, engaged two Italian bishops to second his views, but these not being sufficient, he substituted in the room of a third a presbyter of Oltia, and by means of these three he was ordained a bishop. The Roman people still declared against his power, determining never to acknowledge him for their lawful bishop. Under these circumstances Pelagius applied to the emperor, and obtaining his interdict and support, he was acknowledged the lawful bishop. No sooner was he settled in the quiet possession of his see, than he endeavoured to perform his engagement to the emperor, by persuading the western bishops to receive the fifth council. With this view he addressed letters to them, in which he attempted to prove, that the constitution of Vigilius was in no respect derogatory to the decrees of Chalcedon, and consequently that such as did not receive it ought to be deemed schismatics. So far, however, were his letters from producing the desired effect, that the bishops of Tuscany, Liguria, Venetia, Illiricum, Gaul, Spain, and Ireland, declared loudly against that constitution, and the fifth council, and the
Pelagius.

The Italian bishops, as well as the Irish, besides confounding the pope in the strongest terms, separated themselves from his communion.

Thus abandoned by almost all the bishops in the West, and finding his endeavors to satisfy them of his orthodoxy were ineffectual, he wrote to the emperor’s chief general Narses, enjoining him to refrain from authority and power, those whom he denounced for St. Peter, and his fee could not support, or bring to a sense of duty. Narses being of a mild and humane disposition, instead of acting as the pope desired, endeavored by entreaties and persuasion to gain over those Italian bishops who were the subjects of the empire, and though he was at first not successful, by steadily adhering to the symlem of pacification, he in the end prevailed upon some of the bishops of Tuscany and Lagonia to renew their communion with the fee of Rome.

About the year 557, a report was spread in Gaul, that the pope had departed from the genuine Catholic doctrine. Childebert, king of the Franks, sent an ambassador to Rome, for the purpose of examining into its truth, and of demanding of Pelagius a confession of his faith. In compliance with the king’s demand, the pope transmitted to the monarch his confession, accompanied with solemn declarations, that he not only received, but was ready to defend, at the expense of his life, the holy faith of Chalcedon; yet maintaining, that nothing had been defined in the fifth council, but what was entirely agreed to by that faith and doctrine; Pelagius, in the year 560, after the pontificate of nearly five years, during which he had the mortification to see the authority claimed by the pretended successors of St. Peter almost universally disregarded by the western bishops, who perjured in condemning and rejecting a council which he had approved and received, and even suspected the orthodoxy of his creed because he received it. Sixteen letters which have been attributed to him, may be found in the fifth vol. of the Collect. Council of which, however, the first is admitted by the editors of that work to be spurious.

Pelagius II. pope, was of Gothic extraction, and the son of Winigild, but a native of Rome. Upon the death of pope Benedict in 578, the see continued vacant four months, at the expiration of which Pelagius was chosen to fill that dignity. His election having taken place at a time when the Lombards were masters of the greatest part of Italy, and kept Rome itself closely besieged, it was judged expedient that he should be ordained before the emperor’s confirmaiton could be received; but as soon as the siege was raised, he sent Gregory, then deacon in the Roman church, and afterwards his successor in the popedom, to excuse the informality, and to entreat the emperor’s acquiescence in a proceeding which had been rendered necessary by the calamitous circumstances of the times. The Lombards, by their ravages, had now spread such devastation and terror in every part of Italy, that persons who had the character of holy men regarded them as the instruments of the divine vengeance to depopulate the country; and some of them fancied that they had revelations, which foretold them that the Lombards were the fore-runners of the last day, and that the end of the world was at hand. By the report of their visions the credulous multitude was terrified to such a degree, that instead of uniting against the common enemy, they abandoned themselves to delirium, and suffered the barbarians to plunder and despoyle without opposition. In this state of the empire in the West, the church continued to be divided by the schism which had been occasioned by the constitution of pope Vitalis, and not terminated by his successors. The talk of healing that schism, Pelagius considered to be one of the first objects that merited his attention, and he determined to apply to it with the utmost zeal. The Lombards, however, occasioned the most serious alarms to the church, and obliged his holiness to pay more attention to the secular concerns of the state than to its spiritualities. They had conquered the important city of Pavia, and having made it the metropolis of their new kingdom, extended their conquests from thence over the adjacent provinces, threatening to advance a second time against Rome. This threat, they were enabled to carry into execution without delay, since the exarch Longinus had not sufficient forces to meet them in the field. Under constant apprehensions, therefore, that they would speedily make their appearance at the gates of the city, Pelagius sent new legates to the emperor Tiberius, in the year 580, to lay before him an account of the defenceless state of Italy, and to solicit a supply of men and money, that the city of Rome itself might not fall into the hands of the barbarians. But the emperor, though wishing well to the cause, had not his power to lend them any relief. Finding Italy thus abandoned by the emperor, in 581 the pope applied to Guntram, king of Burgundy, who was distinguished for his attachment to the bishops of Rome, and their fee, exhorting and entreating him to renounce the alliance which he had lately concluded with the Lombards, and by turning his arms against them, prevent the entire subjugation of Italy. In this he was likewise unsuccessful. In 584, Pelagius sent three letters to the bishops of Iltia, in which he intimated that the disputes which divided them were foolish and idle; enlarged on the evils attending a division among the Catholic prelates; exorted them, with great tenderness, to return to the unity of the church; and proposed a conference, to be held at Rome, or, if more convenient for them, at Ravenna, which he hoped would end to their satisfaction and his. To these letters the Iltian bishops replied in the order in which they received them; but so far were they from making any impression on their minds, that these prelates came to a determination to decline all communication with Rome. Pelagius, finding that he could not succeed in his design by persuasion, resolved to have recourse to perfonation. He accordingly wrote to the exarch, excising his repentance against the Iltian prelates, by representing them to be incorrigible disturbers of the peace of the empire as well as the church. Zamarogius, instead of following the prudent and humane example of his predecessor Narses, in the pontificate of Pelagius I., suffered himself to be the tyrannical instrument of papal vengeance, and feized and imprisoned the refractory prelates.

From this period we meet with no farther particulars relating to Pelagius before the year 588, when a council was held at Conflantinople, for the trial of Gregory, patriarch of Antioch, who had been accused of incest, and several other very serious crimes. After the patriarch had been honourably acquitted, the council, before it broke up its meeting, confirmed to John of Conflantinople, on his own application, the title of ecumenical or universal bishop, to be enjoyed by him, and his successors in that fee. Though it does not appear that this title was attended with any accelation of power, yet Pelagius was alarmed lest the dignity of his bishops should be eclipsed, and endeavored to excite the whole Christian world against John, as if he intended to engage all ecclesiastical power to himself and his fee. As much disturbed and concerned as if the council had condemned some fundamental article of the Christian religion, he immediately, by the authority, and in the name of St. Peter, declared all the acts of that assembly null and void, excepting their sequitall of Gregory. He also dispatched
messengers to Constantinople with letters to the patriarch, and to his nuncio at the imperial court; the former he commanded to relinquish the anti-christian title which he had assumed, and the latter he enjoined not to communicate, nor affit in divine service on any occasion with the bishop of Constantinople, till he had renounced that distinction. Notwithstanding this, John probably continued the use of his title as long as he lived, though the pope was prevented, by death, from proceeding farther in this affair. In 589 the Catholic cause received an accession of strength by the conversion of the Goths in Spain, who, after having professed the doctrine of Arians during more than two centuries, were persuaded by their king Recaredus to renounce it, and to embrace the Catholic faith. This event gave great satisfaction to the Catholic party, though Pelagius survived but a short time to enjoy it. In consequence of an inundation of the Tiber, which laid the greater part of the city of Rome, and the adjacent country under water, a dreadful dilemma broke out, which proved fatal to Pelagius in February 590, after he had presided over the Roman see eleven years and about a quarter. Ten "Letters," and five "Decrees" under his name, are inserted in the fifth vol. of the Collect. Concil.; some of them are, however, supposititious.

Pelagius, the distinguished leader of a Christian sect. See Pelagians.

Pelagnisi, in Geography, an island in the Grecian Archipelago, about eight miles in circumference. N. lat. 39° 30'. E. long. 24° 8'.

Pelagonia, in Ancient Geography, a country of Macedonia, called also "Tripolitis," on account of its three cities, according to Strabo.—Alfo, a town of the same country.—Alco, a town of the island of Sicily.

Pelagos, in Geography, an island in the Adriatic, near the coast of Dalmatia. This island, and the adjacent rocks, are the remains of an ancient volcano; and its present aspect, which is rugged and ruinous, indicates many violent eruptions; 16 miles 8. W. of Agolta. N. lat. 42° 45'. E. long. 16° 10'.

Pelamys, in Ichthiologia, a name by which the ancients expressed the young brood of the thynnus, or tuna-fish, at a certain age and size; but later writers have appropriated the word for the name of a different species of fish of the same genus, called by others farda; and by some of the two names joined into one, pelamys-farda. It is a sea-fish, of the family of the tunny: but of a smooth skin, and free from scales everywhere, except about the gill-fins; its teeth are large, long, and crooked. These are the external marks by which it is to be known from the young brood of the tunny; but when brought to the table, it is easily distinguished by the hardiness of its flesh.

Pelamys Veneris, a name given by Rondeletius, and some other authors, to the fish more distinctly known by the name of amia.

Pelang, in Geography, a town of the Birman empire; 8 miles N.E. of Pagonmagwe.

Pelani, n. to the Athenians, a kind of cakes used in their libations.

Pelargonium, in Botany, so called from pelargies, a fleck, in allusion to the beak of the fruit, which resembles the bill of that bird; as well as to preserve an analogy with the Geranium, or Crane's bill. The name and the genus were first suggested by Dillenius, in Hort. Eth. 149, and subsequently adopted by Burman and Théritier, as well as by the editors of the first edition of Hortus Kewensis. Pelargonium embraces what are commonly known by the appellation of African Geraniums, and which doubtless constitute a most natural genus, clearly distinguished from Geranium, as well as from Erodium, (see those articles,) by the irregularity of the flower and its tubular nectar, to say nothing of number of filaments.—Burm. Afr. 89. L'Herit. Geraniol, unpublished. Att. Herit. Kew. ed. 1. v. 2. 417. Wild. Sp. Pl. v. 3. 641. Lamark Illutr. t. 574. (Geranium; Linn. Gen. 550. Schreb. 458. Lam. sp. 268.)—Clafs and order, Monandria Heptandria. Nat. Ord. Grumales, Linn. Geran. Julf.

Gen. Ch. Cal. Perianth inferior, in five deep, oblong, permanent segments, the uppermost protracted downwards into a honey-bearing tube, running along the flower-stalk, with which it is united. Cor. Petals five, oblong or roundish, spreading, longer than the calyx, irregular. Stam. Filaments ten, awl-shaped, flat, united at their base into a sort of cup, three of them, rarely five, abortive, and without anthers; anthers few, rarely but five, oblong, varifatile.

Pyt. Germon superior, oblong, with five furrows, beaked; style central, awl-shaped, spirally furrowed, as long as the flowers, permanent; filaments five, reflexed. Peric. Capsules five, aggregate in the raphe of those that remain, sepa­rating at their inferior, pointed at the base, each tipped at its summit with a long, linear, flat, pointed, rigid awn, hairy on its outside, and at length spirally twisted, adhering by its point to the summit of the style. Seeds solitary, erect, ovate.

Eff. Ch. Calyx in five deep segments. the uppermost elongated at the base into a nectariferous tube, running down the flower-stalk. Petals five, irregular. Filaments ten, unequal, three or five of them abortive. Fruit beaked, of five aggregate capsules, each tipped with a long spiral awn, bearded on the inside.

This va!t and favourite genus, for which we are almost entirely indebted to the Cape of Good Hope, consifts of a great number of well-marked species. But that number is greatly augmented, in almost every book, by the admifion of iniporous hybrid species or varieties, which continually crop up from seed wherever many of the primary ones are cultivated, and are for a while propagated by cuttings, or even by seed. Sooner or later, however, they for the most part vanish, even those which we did not heir origin. Wilddeew defines 120 species of Pelargonic, several of which we know to have been the production of European gardens. He arranges them in eight sections. We shall select examples of each, subjoining such remarks as seem to us necessary, but abflaining from the hazardous and unimportant undertaking of claffing, or accounting for, every evanescent variety, with figures of which some authors, otherwise of good credit, have burthened and bewildered the science. All these plants have rather a flufly habit, and more or less of a peculiar scent, in some instances exquisifely agreeable. Some are herbaceous, with a tuberous root, that supplies the place of the shrubby stem observable in many of the others. Their foliage is mostly downy, sometimes glau­cous. Flowers more or less umbellate, rarely endowed with any scent, except what arises from the herbage, though some, whose colours are of the yellowish-green or lurid kind, are deliciously fragrant at night. The prevailing colour, throughout the greater part of the genus, is crimson, scarlet, or light purple, in various beautiful shades and combinations, often intermingled with white. Yellow and blue are both equally rare in this natural order, and the latter scarcely occurs at all in the genus of which we are treating. —Every known species, except perhaps one or two, is perennial. They are greenhouse plants in England, flowering at various seasons, and conducing greatly to the ornament of a collection. In some few instances the number of petals, as well
PELARGONIUM.

well as of the flaments, differs a little from the generic description.

Jacq. Lc. Rar. t. 518. (Geranium longiflorum; Burm. Geran. 50. n. 67. t. 2. Cavan. Diff. 235. t. 102. f. 1. G. prolificum; Linn. Sp. Ph. 950.) Stem none. Umbel compound, leafy. Leaves lanceolate, acute, entire, smooth; the older ones pinnatifid, linear. Petals linear-obovate. Anthers four.—Gathered first by Oldenland at the Cape of Good Hope. Root ovate-oblong. Radical leaves several, on longish stalks, spreading, above two inches long, and near one broad; mostly accompanied by some younger ones, that are deeply pinnatifid, and very narrow. Flower-stalk solitary, three or four inches high, bearing about three unequal, downy, partial flasks, accompanied by a leaf or two, each terminating in a downy umbel, of several rose-coloured flowers. Analogy shews the flask of this plant to be but a sepal, not a true calyx, though it generally elevates a leaf or two from the root. It must however be confessed that, like many others in this genus, it forms an immediate link between a stem and a flower-flask, or rather combines the two.

Jacq. Lc. Rar. t. 521.—Stem none. Umbel compound, somewhat leafy. Leaves lanceolate, acute, entire. Petals linear. Anthers four.—Of this Jacquin's depressum, t. 520, is justly made a variety by Willdenow; and we would venture also to refer it to his citatum, t. 519, which Willdenow, on account of two little occasional appendages to the leaves, terms curculatum, n. 7.—Perhaps they are all but varieties of longiflorum, differing in their narrower petalis, which are buff-coloured, with a deeper purple flamin at the base of some of them. The flower-flasks of all are hairy, at least at their base, as are the umbels and partial flower-flasks. There is a general conformity in their foliage and aspect, which will fearfully allow us to trufl to any apparent specific differences, but we offer our sentiments, on so obscure a tribe, in the way of conjecture only.

P. auritum. Eared Stork's-bill. Willd. n. 8. (Geranium auritum; Burm. Geran. 47. n. 61. G. prolificum; Linn. Sp. Ph. 950. Mant. 433. G. africana, folis pinnatis, floribus ex rubro punctatis; Comm. Hort. v. z. 121. t. 61.) Stem none. Umbels simple or compound. Leaves ovate-oblong, obtuse, simple or ternate, slightly notched, hairy. Petals ovate-oblong, oblong. Anthers five.—Burmann says this is the rarest of all the Cape Geraniains. Linnaeus had it in the Upfal garden, as appears by his herbarium. It is nearly allied to the foregoing, but seems altogether more hairy, and the leaves are most frequently truly ternate, and obtuse. The petals are of a deep crimson. We cannot ascertain the number of anthers, but Linnaeus says they are five.

To this are nearly allied birtatium of Burmann, n. 68. t. 2.
Willd. n. 12, and heterophyllum, Jacq. Lc. Rar. t. 516.
Willd. n. 15. Both vary much in the division of their leaves, but the segments always partake either of a wedge-like or obovate figure, and are by no means linear. They are also constantly hairy.

P. pinnatum. Pinnate Stork's-bill. Ait. Hort. Kew. ed. 1. v. 2. 417. Willd. n. 18. (P. albrragalisfolium; Jacq. Lc. Rar. t. 511. Geranium pinnatum; Linn. Sp. Ph. ed. 1. 67. G. prolificum; Linn. Sp. Ph. 950. G. africana albrragalis folio; Comm. Praulad. 53. t. 3J.—Stem none. Umbels simple or compound. Leaves pinnate; leaflets numerous, ovate, undivided, hairy on both sides. Anthers five.—Commelin received seeds of this from the Cape about the year 1699. Whatever may be thought of the rest of this tribe, the present plant is certainly a very well marked species. The leaves are very like those of several Afragallis. Six or seven of the leaflets are placed in four. The flower-flasks are hairy, sometimes simple, but mostly bearing two umbels, with a small leaf or two. The petals vary in breadth and colouring, but are generally obovate-oblong, pale buff, or cream-coloured, the two uppermost speckled with red. Anthers five.

P. lotatum. Dwarf Yellow Stork's-bill. (Geranium lu-
team; Andr. Repof. t. 423.) Stem none. Umbels mostly simple. Leaves pinnate; leaflets flaked, ovate, acute, divided. Anthers five.—This flowered in 1803, in the collection of Mr. G. Hibbert at Clapham, having been received by him, amongst many other rarities, from the Cape.

We know nothing of it but from Andrew's work, yet we have no doubt of its being distinct from all in Willdenow. The flaked and cloven leaflets are very peculiar. Whether they are smooth or hairy is not mentioned, but the figure expresses the former. The numerous flower-flasks are all drawn simple and smooth, but does any pubescence appear on the umbel or calyx. The petals are linear-obovate, of a full yellow; the two uppermost bearded at the tips. Anthers five.

This species appears to have been one of the first, of its tribe, brought from the Cape into the European gardens. Lin-
naeus cultivated it with success at Upsal. The narrow, deciduous, frequently three-creft leaflets, and especially the tuft of two or three finely hairy at the point of each segment, afford its distinctive characters. The umbels and their flasks are downy. Flowers small and inconspicuous, flesh-coloured, with some purple streaks.

P. rapacum. Turnip-rooted Stork's-bill. Ait. Hort. Kew. ed. 1. v. 2. 418. Willd. n. 22. Jacq. Lc. Rar. t. 510. (Geranium rapacum; Linna. Syll. Nat. ed. 10. v. 2. 1141. G. prolificum; Linn. Sp. Ph. 949. G. africana, myrhidis folio, flore albicante, radice rapiida; Comm. Hort. v. 2. 123. t. 62.) Stem none. Umbel compound. Leaves pinnate; leaflets doubly pinnatifid, linear, downy. Corolla somewhat papilionaceous. This was formerly known in gardens by the name of the Horfe's head Geranium, in allusion to the remarkable shape of the flower, by which alone it is clearly distinguished as a species. Three of the petals, much the broadest, cohere like the wings and keel of a papilionaceous flower, and are white or pale bluish-coloured; the other two, narrower, rose-coloured and spotted, are reflexed, and look like a divided standard of the same kind of blossom. The root is very thick and tulous, often divided. Leaves downy, pinnate; their leaflets doubly pinnatifid, in linear segments, which are variable in length and breadth.—If Linnaeus had seen this alive, he could never have confounded it with any other.

Section 2.—Stem very short. Root tuberous. Four species.

six.—An old plant in the European gardens, yet not very common, flowering in the greenhouse or conservatory in April and May, and highly desirable on account of the nocturnal fragrance of its flowers, which is like that of the bergamot pear, though far superior. The petals are obovate, and of that dull browny or tawny green, appropriated to many night-scented flowers, as *Hesperis triflilis*, *Cheiranthus trifolii*, &c. The leaves are a span or more in breadth, soft and downy, acutely crenate. *Flower-flats* hairy. Umbels downy. Root much like the latex.

P. *trifolium*. Night-scented Stork’s-bill. Wildl. n. 24. (Geranium *trifolium*; Linn. Sp. Pl. 950. Cornat. Canad. 109. t. 110. Cavan. Diff. 261. t. 107. f. 1.)—Stem short. Umbels simple. Leaves hairy, pinnate; leaflets doubly pinnatifid, in oblong acute segments. Root of many jointed knobs.—This is so like the latex in its flowers, that it might be supposed a variety with deeply divided leaves, but it is more caulecent, and the root differs essentially in being composed of many elliptical jointed knobs, instead of conflicting of one great solid body. Cornutt’s plants, published in 1655, however misplaced in a work on Canada plants, is we believe the first that appeared of any African Geranium, or *Pelargonium*, and has also great merit in the execution. He says the roots are celebate.

P. *flavum*. Carrot-leaved Stork’s-bill. Wildl. n. 26. (P. daucoides; Jacq. Ic. Rat. t. 522. Geranium *flavum*; Linn. Mant. 257. G. daucolofolium; Cavan. Diff. 260. t. 120. f. 2. G. africanum, folio flathylini; Riv. Pentap. Irr. t. 107.)—Stem short. Umbels simple. Leaves hairy, repeatedly subdivided, in linear-lanceolate segments. Root of many jointed knobs.—This we are persuaded is but a variety of the last, with more divided and narrower leaves, though Willdenow infers, between the two, a most distinct species, which is the following.

P. *appendiculatum*. Broad Stipulaceous Stork’s-bill. Wildl. n. 25. (Geranium *appendiculatum*; Linn. Suppl. 304. Cavan. Diff. 262. t. 121. f. 2.)—Stem scarcely any. Flower-flats angular. Leaves doubly pinnate, hairy. Stipulas dilated, rounded, coronaceous, ribbed, united with the base of the foot-flats.—It does not appear from whom Linnaeus received his wild African specimina of this very fragular species, which we have not heard of in any garden. The remarkable *flrapus*, often an inch wide, at once distinguishes the plant. Perhaps it ought to fland in the first section, as more akin to several there to be found, than to the *trifolium* and its allies. —The root is nearly globose. Leaves nearly all radical, three or four inches long, extremely hairy, finely divided. *Flower-flats* hairy, rather taller than the leaves, divided a little above the base into two angular, strongly furrowed branches, each bearing a hairy umbel of many smallish rose-coloured *flowers* on long flats. The specimina figured by Cavanilles is the very counterpart of the Linnaean ones, and having been lent by Thunberg, we may presume they were all gathered by him, and that no other botanist has met with this remarkable plant.

Section 3. Stem elongated, herbageous, or somewhat flabubly.

Twenty-six species.

P. *antherae*. Evening-primrose Stork’s-bill. Wildl. n. 37. Jacq. Ic. Rat. t. 523. (Geranium *antherae*; Linn. Suppl. 305.)—Umbels of about three flowers. Leaves opposite, lanceolate, obtuse, with tooth-like serrature, very finely downy on both sides. Stem ascending, herbageous. —Jacqun at first mistook this for *G. ovatum* of Cavanilles; see our next-mentioned species. We have not seen it in any garden. The Linnaean specimina seems to be one of those brought from the Cape by Thunberg, which his venerable preceptor was just able to contemplate with satisfaction, but not to describe. The *flowers* is divided into several herbaceous branches, a span long, spreading, and partly decumbent. *Leaves* on long flats, elongated-lanceolate, deeply and unequally forked. Whole plant clothed with denser, soft pubescence, like some kinds of *Onothera*. Flowers two or three in each umbel, nearly regular, smallish, rose-coloured. *Fruit* large, with a downy beak.

P. *ovale*. Oval Hoary Stork’s-bill. Wildl. n. 29. L’Herit. Geran. t. 28. (G. ovatum; Cavan. Diff. 238. t. 103. f. 3.)—Umbels of about four flowers. Leaves ovate, acute, strongly forked, hoary. Stem trailing. *Anthers* seven. Remembers the leaf in general habit, but differs in the shape of the *leaves*, and their much longer flattles. The *flowers* are much larger, and rather more numerous in each umbel; *fruit* smaller. *Anthers* seven, though Cavanilles says five; but as he saw only dried specimens, we presume he might easily mistake this point, and we rather refer his synonymy to this species, than to the *eriolemon*, under which Willdenow has doubtfully cited him.

P. *eriolemon*. Woolly-stipulaceous Stork’s-bill. Wildl. n. 32. Jacq. Hort. Schonbr. v. 2. 4. t. 132.—Umbels of about four flowers. Leaves elliptical, obtuse, crenate, finely downy. Stem erect. Upper petals notched. Stamina woolly. *Anthers* five.—This species has been much misunderstood. Burmann himself sent it to Linnaeus, doubting whether it was distinct from his own G. *ovale*, Prodr. Cap. 19; and Linnaeus, far more unaccountably, supposed it a variety of his *G. malacoides*, whose son guessed it to be *betulatum*! The specimina however is rightly marked as having but five anthers. The erect though hoarse *flowers*, and obtuse closely crenate *leaves*, at once distinguishes it from the last. The *petals* are white; the two uppermost broad, acutely notched, spotted with crimson at the base. *Anthers* and *style* red.

P. *flapulaceum*. Narrow Stipulaceous Stork’s-bill. Wildl. n. 34. (Geranium *flapulaceum*; Linn. Suppl. 306. Cavan. Diff. 254. t. 125. f. 3.)—Umbels of about three flowers. Leaves heart-shaped, cut and crenate, finely hairy. Stem short, gibbous, somewhat jointed. Stipulas awl-shaped, rigid, permanent. —Thunberg found this at the Cape, and gave it to Linnaeus, as well as to Cavanilles. The *flowers* are very remarkably tumult, fleshly, and jointed, subdivided, though of humble growth, each joint befit with numerous, rigid, thorn-like, permanent *flaps*. The *leaves* are few, flatked, heart-shaped, and obtuse, variously cut and lobed, paler beneath, clothed on both sides with short febrated hairs; their length about an inch. *Flower-flats* three or four inches long, pale, nearly smooth, umbellate. *Flowers* three or four, small. *Fruit* with a hairy beak.

P. *tabulare*. Rough-stemmed Stork’s-bill. Wildl. n. 36. L’Herit. Geran. t. 9. (Geranium *tabulare*; Linn. Sp. Pl. 947. excluding Burmann’s *fyn* G. elongatum; Cavan. Diff. 233. t. 101. f. 3.)—Umbels three-flowered. Leaves kidney-shaped, five-lobed, notched, slightly hairy. Stem ascending, rough with deflexed bristles. —Native of the Cape of Good Hops, but whether of the Table Mountain, as its name implies, is very doubtful, so many things having been confounded under this name. We are however certain of l’Heritier’s plant, on his own authority, though his figure does not well express the peculiar character of the coarse bristles of the *flowers*, inclined rather downwards. The original specimina of Linnaeus is the same. But *G. tabulare* of Burmann and Cavanilles is extremely different, being Willdenow’s *P. planiculiferum*, n. 75, and, if we mistake not, *variegatum*, n. 78.

The true *tabulare* is not one of the most ornamental kinds, and
and therefore cultivators are apt to neglect it. The root is perennial and woody. Stems weak and tender, often dying down to the ground, distinguished by their peculiar hairiness. Leaves on long stalks, dull green, scarcey marked with any concentric shade or zone, but befrinkled with finning tawny hairs. Umbels of about three small, very pale flesh-coloured yellowish flowers, on very long smooth stalks, opposite to the leaves. Flowers hispids. Petals narrow. Antlers five. Style elongated beyond the bead, before it divides into stigmas.

P. alchimilloides. Lady’s-mantle-leaved Stork’s-bill, Wildl. n. 35. (Geranium alchimilloides; Linn. Sp. Pl. 948. Cavan. Diff. 241. t. 103 f. 1. G. africanum, folio alchimille macro; Riv. Pentap. Irr. t. 104.)—Umbels of about five flowers. Leaves kidney-shaped, deeply five-lobed, cut, very hairy. Stem diffuse, rough with deflexed bristles. Stigmas sessile. Very near the last, but well distinguished in the Hortus Kewensis, by the stigmas being sessile, without any elongation of the style beyond the hairy bead. The stem is very hairy with deflexed bristles, the flower-stalks with spreading leaves. Leaves more hairy than in P. tabulare, often marked with a purplish zone; their lobes more straight and deep, coarsely cut at the extremity.

The younger Linnaeus confounded with this a very curious and little-known species, P. articulatum, Wildl. n. 35, adopted by that writer from Cavanilles, who has correctly figured it, t. 122. f. 1. Willdenow has no leaves judiciously placed in between P. fipulaceum and tabulare. The base of the stem is jointed and twollen, clothed with permanent, membranous, somewhat spinous fijolus, resembling fipulaceum; but the rest of the stem, as well as the foliage, are nearly akin to tabulare and alchimilloides. The flowers are larger than in either, apparently yellowish, their two larger petals streaked with purple.

P. odoratissimum. Nutmeg-scented Stork’s-bill. Wildl. n. 38. (Geranium odoratissimum; Linn. Sp. Pl. 948. Cavan. Diff. 241. t. 103 f. 1. G. africanum humile, folly fragrantifimo mollis; Dill. Elth. 157. t. 131.)—Umbels of about five flowers. Leaves roundish-heart-shaped, crenate, very fofly downy. This species is known by the delicate softness of its leaves, and their highly aromatic and powerful smell, which is renewed by rubbing, even after the plant has been dried twenty years or more. For this scent it is chiefly valued, the flowers being small, whitish and incompigious. The coarse engraving of Didennis is more truly excellent, as expressing the soft habit of the plant, than many a fine coloured plate probably would have been.

We doubt much whether G. africanum, Cav. Diff. 242. t. 104. f. 1, can be a variety of this, though it is so considered by Willdenow. The flowers are five times as large, and leaves more hairy. This specific name is truly unfortunate, as applying equally to this whole genus.

P. ulcinosus. Milk-sallow-leaved Stork’s-bill. (P. colubrinum; Jacq. Hort. Schonbr. v. 2. 4. t. 133. Wildl. n. 42. Geranium ulcinosus; Linn. Sp. Pl. 948. G. folio alceo tenue licinato, flore pentapetaloe purpureacerte, femine tenui; Mart. Cent. 16. t. 16.)—Umbels many-flowered. Leaves ternate, deeply three-cleft, laciniated. Stem herbaceous, decumbent, hairy. Neckary shorter than the segments of the calyx. This has the aspect of an European rather than a Cape Geranium, and the shortness of its neckary tube combines with the habit, to bring it very near Erodium. As however that tribe is preeminent, no doubt can remain of the genus. Jacquin, who rafed the plant from Cape seeds, and kept it flowering throughout the winter in his flowe, was not aware of its being a Linnean species, concerning which the herbarium of Linneus removes all doubt. We cannot therefore submit to the alteration of its very expressive specific name. The fertile filaments are usuallv five, though it seems one of them occasionally wants its anther. The petals are small, purple; the two uppermost perfectly marked with an eye like spot.

P. tricolor. Three-coloured Stork’s-bill, Wildl. n. 45. (P. tricolor; Jacq. t. 1. Ra. t. 527.)—Umbels three-flowered. Leaves oblong, bluntish, hoary, cut and somewhat pinnatifid, obscurely three-lobed. Two upper petals glabrous at the base. Seeds of this were sent by Mr. Maflou from the Cape to Kew garden in 1792. It was first published by Mr. C. rtis, and is a favourite plant in collections, though not one of the eafeft to preferre. We notice it here chiefly for its singular beauty. The petals are roundish and nearly uniform in shape, but very different in colour. The three lowermost are usually milk-white, rarely striped slightly with red; the two uppermost of a moft rich and deep blood red, darkly veined, with a velvet-like reflection, their base almofl black, beft with thinning glanular points. Seeds are rarely produced in England, yet the species is very diftinct and permanent.

P. coriandriifolium. Coriander-leaved Stork’s-bill. Wildl. n. 39. Jacq. t. 1. Ra. t. 528. (Geranium coriandriifolium; Linn. Sp. Pl. 949. Cavan. Diff. 243. t. 116 f. 1. G. africanum, folis coriandi; Riv. Pentap. Irr. t. 108.)—Umbels of about three flowers. Leaves bipinnate; leaflets pinnatifid, linear. Anthers five. Petals usually four. Stem herbaceous, rough. An old inhabitant of greenhouseles, whose stem is diffuse, herbaceous, and usually annual, though the root, if properly preferred, is, as at the Cape, in its native country, perennial. The finely divided leaves, and the large flowers, make this worth cultivating for variety. The two upper petals are much the largest, obovate, and veined with purple; the three lower, of which the middlemost is generally wanting, are narrow, and pure white.

Section 4. Stem fbrubby. Leaves neither divided nor angular. Four species.

P. glaucum. Glaucous Spear-leaved Stork’s-bill. L’Herit. Geran. t. 29. Wildl. n. 53. (Geranium glaucum; Linn. Suppl. 266. G. lanceolatum; Cavan. Diff. 243. t. 102 f. 2. Curt. Mag. t. 56.)—Stalks mostly single-flowered. Leaves lanceolate, entire, pointed, sinuate, glaucous. This, one of the most singular of its genus in foliage, was raised by the late Mr. Lee, from seeds picked out of Cape specimens at Sir Joseph Banks’s, about the year 1775. Great disputes have always existd concerning the specific name, glaucum as well as lanceolatum being each so strikingly opposite, that the first which is heard seems entitled to bear down all opposition. That given by Linneus himself, and published by his son, has however prevailed. So glaucous are the leaves, even in a dry state, that they appear to have been white-washed. Their form is lanceolate, inclining to obovate, with a point; their length nearly two inches. The stem is fbrubby and branched, angular, glaucous with a purple tinge. Flower-stalks stout, angular, from one to three inches long, connected with the leaf by a joint, and both together are nearly upright. Sipulas in pairs, lanceolate, acute. Flower-stalks axillary, bearing one, rarely two, elegant flowers, whose partial stalk is often longer than the general one, and accompanied, nearly all the way to its base, by the neatherious tube. Petals obovate,
vate, of a delicate blush-colour, with crimson veins. This species is increased readily by cuttings, like most of the shrubby kinds.

P. betulinum. Birch-leaved Stork’s-bill. Wild. n. 55. Curt. Mag. t. 148. (Geranium betulinum; Linn. Sp. Pl. 945. G. fruticosum, &c.; Burm. Afr. t. 33 f. 1, 2.)—Umbels of about three flowers, downy. Leaves ovate, unequally serrated, nearly smooth.—A handsome well-named species, of which both the varieties, figured by Burmann, are common in every collection, the larger one being preferred. The flowers are pale pink, their upper petals obovate, near an inch long, richly veined with purple. Notably rather short.

P. aceto sum. Sorrel-leaved Stork’s-bill. Wild. n. 56. Curt. Mag. t. 103. (Geranium aceto sum; Linn. Sp. Pl. 247. Cavan. Diff. 239. t. 104. f. 3.)—Umbels of about three flowers, smooth. Leaves roundish-obovate, crenate, smooth. Petals linear. The Dutch brought this very early from the Cape, and it has long been generally diffused throughout Europe. Its perfect smoothness; the somewhat glaucous hue, rounded undivided shape, and acrid flavour of the leaves; with the narrow petal, which are flesh-coloured, with straight pink veins, clearly distinguish the P. aceto sum. Miller speaks of a variety with scarlet flowers, to which we have seen some near approaches.

Section 5. Stems shrubby. Leaves either angular, lobed, or palmate. Thirty-seven species.

P. hybridum. Hybrid Stork’s-bill. Wild. n. 59. (Geranium hybridum; Linn. Mant. 97. Cavan. Diff. 239. t. 105 f. 2. G. africana arborescens, malva folio pingui, varietas; Dill. Elth. 152. t. 125. f. 152.)—Umbels many-flowered. Leaves roundish, crenate, nearly smooth, slightly lobed, unpointed. Petals obovate-oblong, broader than the segments of the calyx.—Dillenius says this was produced from seed of P. inquinans, hereafter mentioned, and he points out its resemblance, in many points, to the aceto sum. Linnaeus therefore called it hybridum. He might have applied a similar name to several others, had he lived to cultivate many of the new-discovered species. The present, whether a real mule, or a permanent intermediate species, has remained for a long course of years in the gardens, being called by Linnaeus, if not entirely, increased by cuttings. The flower is smooth. Leaves very like the aceto sum, but broader, obscurely lobed, and in some degree downy. Flowers of a scarlet red, with much broader petals than the last, but not as broad as those of the inquinans.

P. zonele. Horse-shoe Stork’s-bill. Wild. n. 60. (Geranium zonele; Linn. Sp. Pl. 947. Cavan. Diff. 230. f. 68. f. 2. G. africana arborescens, alchimia hirtula folio, florenus rubricundis; Comm. Prud. 51. t. 1.)—Umbels many-flowered. Leaves heart-shaped, rounded, slightly lobed, toothed, roughish, marked with a concentric zone.—The most popular of all the species, which the Dutch originally obtained from the Cape, in 1709, and whose many varieties are the ornament of every greenhouse and conservatory. Their copious rose-coloured flowers, produced in plentiful succession, are very showy; their leaves are always distinguished by a dark concentric transverse stripe, various in breadth and intensity, and there is a common, but less luxuriant kind, whose foliage is blotted with white or yellow, and whose petals are narrower than those of the rose-coloured variety. P. inquinans. Scarlet Stork’s-bill. Wild. n. 61. (Geranium inquinans; Linn. Sp. Pl. 947. Cavan. Diff. 243. t. 106 f. 2. G. africana arborescens, malva folio pingui, flore roccinio; Dill. Elth. 151. t. 125. f. 151. G. afr. arbor. malva folio lucido, flore elegantissimo kermeino; Mart. Cent. 5. t 3.)—Umbels many-flowered. Leaves orbicular-kidney-shaped, slightly lobed, crenate, downy and vilid. —Martyn says this splendid species was first brought into England about the year 1718. It soon became common, and is justly admired for the vivid scarlet of its copious flowers. The greatest peculiarity of this Pelargonium is that which its name expresses, of staining the finger with a greyly red moisture, exuding from the whole surface of its soft downy branches. There are several varieties, differing in the magnitude or splendour of their flowers. This is supposed to be the mother, aceto sum, the father of P. hybridum above described.

P. heterogamum. Lady Coventry's Stork’s-bill. Ait. Hort. Kew. ed. t. v. 2. 424. Wild. n. 62. L'Herit. Geran. t. 18.—Umbels many-flowered. Leaves orbicular-kidney-shaped, acutely lobed and toothed, hairy. Stem rough with defecled bristles.—This should seem to have been produced between the last-mentioned and P. alchemioides, Wild. n. 37. The pubescence and leaves much resemble the latter; the scarlet flowers, and upright shrubby stem, accord with the former. It is allowed on all hands to be a hybrid plant, and, from the East Indies. Lee informs us that it is Coventry’s greenhouse. The anthers are fuscous. Stigmas elevated on a short simple style, above the hairy beak; not fleshy, as in alchemioides.

P. petalum. Ivy-leaved Stork’s-bill. Wild. n. 65. (Geranium peltatum; Linn. Sp. Pl. 947. Mill. t. 140. Curt. Mag. t. 20.)—Umbels of few flowers. Leaves five-lobed, entire, fleshy, smooth, more or less peltate. A common plant in every greenhouse and window, having been early introduced from the Cape, nor can it be confounded with any other, on account of the five-lobed, dark, shining, ivy-like leaves. The flowers are rose-coloured and hand-like. The scion of the footstalk is usually peltate, or a little way from the base of each leaf. We are however convinced by our own observation, and the practical authority of Mr. Lee, that P. lateripes. Wild. n. 66. L'Herit. Geran. t. 24, which differs in respect from the common peltatum, and has more fleshy angular branches, is nevertheless but a variety, and not a very permanent one.

P. tetragonum. Square-tailed Stork’s-bill. Wild. n. 67. L'Herit. Geran. t. 33. Curtis's Mag. t. 136. (Geranium tetragonum; Linn. Succ. 265. Jacq. 1c. Rar. t. 132. Cavan. Diff. 231. f. 99. 2. G. trigonum; Scop. Del. Infurb. v. 112. t. 5.)—Stalks two-flowered. Branches fleshy; quadrangular. Petals four.—Sent from the Cape by Mr. Maffon, in 1774. The flower, fleshy, somewhat jointed, with three or four prominent angles; small, rounded, lobed, notched leaves, besprinkled with long hairs, and sometimes beautifully variegated with rose-colour and white, as in Curtis’s figure, strikingly mark this species. The flowers are no less peculiar and very handsome; their two upper petals are near one inch a half long, ovate, reflexed, pale pink with bracted crenat veins; two lower small and white, the middle one being wanting. Stamens crimson, with seven anthers. Its succulent nature renders it rather more difficult of cultivation than some others.

whose two upper petals are finely pencilled, and marked with a dark central spot.

P. angustifolium: Angular Hoary Stork's-bill. Alt. Hort. Kew, ed. 1. v. 2. 426. Willd. n. 70. (Geranium acerosifolium; Cavan. Diff. 243. t. 112. f. 2. G. africannum arborescens, folis cucullatis angustulis; Dill. Ethl. 155. t. 129. G. a. bifolii foliis angustis, floribus amplexipurpureis; Mart. Cent. 28. t. 28.)—Umbels many-flowered. Leaves rounded, hooded, angular, toothed.—This perhaps is still more frequently met with in gardens than the last, of which we are disposed to think it a mere variety, differing only in the acute angles of the leaves, and their rather more coarse or unequal teeth. Some experienced cultivators are of our opinion. Linnaeus did not even distinguish the present plant as a variety, but the former is the genuine cucullatum of his herbarium.

P. variegatum. Variegated Glaucescent Stork's-bill. Willd. n. 78. P. faniculifolium; Willd. n. 75. P. cotulaforfolium; Jacq. Ic. Ric. t. 539; Geranium variegatum; Linn. Suppl. 305; Cavan. Diff. 251. t. 118. f. 3? G. tabulare; Burm. Geran. 36. n. 44. t. 1. Cavan. Diff. 232. t. 100. f. 2.)—Umbels of about five flowers. Leaves palmate, five-lobed, flat, glaucous, smooth, sharply toothed. Stipules heart-shaped. Nectary not longer than the calyx.—We feel little reluctance in combining all the above synonomy under one species. The Linnean G. variegatum appears to have been little known to any body, and was rendered more obscure by the doubtful and imperfect figure in Cavanilles, which has only two flowers on a stalk, and views nothing of the length of the nectariosiferous tube. The Linnean specimen has four or five flowers in each umbel, and answers exactly to Jacquin's t. 539, except that the leaves are rather more deeply lobed, with not any appearance of a zone, at least in a dried flat. The flowers appear by Jacquin's figure to vary in size, and Burmann's tabularia exhibits them of still smaller dimensions, perhaps because his plate was taken from a dry specimen. This species therefore, known in our gardens by the name of fanticulifolium, but which ought to retain its original appellation, is readily distinguished by being perfectly smooth and glaucous, with numerous round branches. Leaves on long spreading stalks, more or less deeply five-lobed, the middle lobe often three-cleft, and all of them sharply cut or serrated. Most generally, as it seems, the disk is marked with a brown or purplish, concentric, broken zone. The flippus are of a broad-ovate or heart-shaped form, and vary in size. Umbels on very long stalks, opposite to the leaves, of four or five handsome flowers. Calyx with a few brilly hairs about the base, well expressed by Jacquin, its segments full as long as the nectariosiferous tube, whose termination is very evident. Two upper petals large, obovate, rose-coloured, with a purple central spot, and many dark veins; three lower ones linear and whitish.

Very possibly P. fuscatum, Jacq. Ic. Ric. t. 540. Willd. n. 74, may be a slight variety of variegatum. Its branches are said to be rough when young.

P. grandiflorum. Large-flowered Glaucescent Stork's-bill. Willd. n. 77. (Geranium grandiflorum; Andr. Repof. t. 12.)—Umbels of two or three flowers. Leaves palmate, five-lobed, flat, glaucous, smooth, sharply toothed. Stipules ovate. Nectary thrice as large as the calyx.—Mr. Maffon is said to have sent this species from the Cape in 1792. It is justly admired for the size and beauty of its flowers, which are only two or three on each flat, and essentially distinguished from variegatum by the great length of their nectariosiferous tube, which is about two inches, being thrice that of the calyx. The petals are white; the two uppermost elegantly lined with rose-colour; the rest narrower, and rather shorter. The leaves, and whole habit, exactly agree with our specimen of variegatum; but the flippus are more rounded, or obovate, not heart-shaped. The plate of Cavanilles, done for the last, may very probably have been taken from a specimen of the present species. We suspect moreover that P. patulum, Jacq. Ic. Ric. t. 543. Willd. n. 76, is but too nearly related to this, though, having seen no specimen, we cannot speak with confidence.

P. cotyledonis. Peltate Downy Stork's-bill. Willd. n. 79. L'Hert. Geran. t. 27. (Geranium cotyledonis; Linn. Mant. 569.)—Umbels compound. Leaves heart-shaped, peltate, ruged, mottled downy beneath. Stem pellthy, without thorns.—This is one of the very few species which do not readily blossom in gardens. We never saw the flowers, nor did Linnaeus, Cavanilles, nor Willdenow. The plant was brought to England from Holland in 1768, according to Mr. Fairbairn, but the Hort. Kew. says it is a native of St. Helena, and was introduced by Mr. John Bank. It is however allowed to be likewise a Cape species. The stem peculiarly thick and pellthy, each branch crowned with a number of flaked, peltate, rounded, slightly lobed leaves; finely reticulated, corrugated, and minutely downy above; veiny, and clothed with soft, dense, hoary pubescence beneath. L'Hertier's fine plate represents the flower-flake a foot high, hairy, repeatedly compound, bearing several umbels, of about four flowers each. The petals are roundish, and nearly uniform. Nectary very short.

P. chinatum. Prickly-flaked Stork's-bill. Curt. Mag. t. 309. Willd. n. 80. (P. hamatum; Jacq. Hort. Schoubr. v. 2. t. 135.)—Umbels many-flowered. Leaves roundish, heart-shaped, lobed, crenate, soft, densely downy beneath. Stem pellthy. Stipulas permanent, pinnate.—Somewhat similar to the last, but abundantly distingii, having simple umbels; leaves softer, neither peltate nor rugose, and the stem armed with strong, conical, curved thorns, originating from the permanent flippus. The petals are invariably heart-shaped, nearly regular, pure white, sometimes purple, two of them beautifully flared and spotted with that colour. Nectary running down almost to the very base of each partial flower-flake. Curtis and Jacquin described this plant unknown to each other. It is not yet become common, though both singular and ornamental.

P. atvivale. Botany-bay Stork's-bill. Willd. n. 81.—Umbels many-flowered, capitate. Leaves heart-shaped, crenate, slightly lobed, mostly downy beneath. Nectary very short.—Native of New South Wales.—This is one of those species found in New Holland, and not at the Cape of Good Hope, all which have a general resemblance among themselves, and are not much like any of the African species, except perhaps abdiioides, Willd. n. 41, and capitatum, n. 83, hereafter described. Their habit is downy; flowers generally small, pale purple, in numerous, dense, hairy umbels; leaves heart-shaped, crenate, but slightly lobed; nectary very short. We hope to see them well distinguished in the second part of Mr. Brown's Prodromus. In the mean while we would remark that Willdenow's no. 40, aepthe, Jacq. Coll. v. 4. t. 189. f. 22. f. 3, is one of these New Holland species, and not, we believe, found in Africa. It is leafy hairy than the last, but not entirely smooth. As far as we know this tribe, they have none of the aromatic scent, usual in their genus, nor much beauty. We have specimens of four very distinct ones from Port Jackson.

diffuse. Nectary very short.—The old favourite rofe-
feented Stork's-bill was among the first brought from the
Cape, and is still preferred in collections, though far less
frequently than formerly. The delicate feent of rose-water,
which its herbage exhales when touched, is less powerful
than that of the gravoletis, of which we shall presently
speak. The flowers are pale purple, with dark veins, and,
having very short flat petals, are crowded into a dense
head. One of our New Holland species agrees with them
in this refpeét, and vies with them in size. Indeed though
L'Héritier distinguished the latter by the name of P. extrin-
seum, we can scarcely think it different from capitatum, and
if we are right, the species before us is therefore a native
of New South Wales as well as of southern Africa.

P. tomentosum. Penny-royal Stork's bill. Willd. n. 86.
Jacq. Ic. Rat. t. 537. Curt. Mag. t. 518.—Umbels many-
flowered, somewhat panicled. Leaves heart-shaped, five-
lobed, rather halfate, ferrated, very soft and downy. Nect-
ary very short. —Remarkable for its strong feent, like
pepper-mint or penny-royal. It has been introduced from
the Cape, since the first edition of Hort. Kew, was published.
The ilms is much branched, widely spreading and brittle.
Flowers numerous, but not flowy, white, with crinum
lines, and half the latter colour.

L'Hérit. Geran. t. 17. (Geranium terebinthineum; Cava-
n. Diff. 252 t. 114 f. 1.) —Umbels many-flowered, capi-
tate. Leaves palmate, seven-lobed, their segments oblong,
obtuse; roolute and very rough at the margin. Nectary
about half as long as the calyx. Our readers would hardly
recognise, under the names of gravoletos and terebinthineum,
the deliciously fragrant "Ottar of rofe Geranium," as it
is commonly called, which has supplantcd the old capitatum,
being far more powerful, though perhaps less delicate, in its
feent. This perfumed kind, however, though now so com-
mon, is, it seems, but a variety of one lefs agreeable, and is
first mentioned as such by Cavanilles. The shape of the leaves
readily distinguishes this Pelargonium from every other.
If we were to indulge our imagination in guessing at hybrid
species, the present might be supposed an offspring of capi-
tatum, impregnated by Radula, and that its feent varies ac-
cording as it partakes more of the constitution of one par-
et or the other. We find it not much inclined to pro-
duce hybrids. Willdenow mentions a rofe-feented variety of
Radula, impregnated by gravoletos, and a lefs agreeable
one of gravoletos impregnated by Radula.

L'Hérit. Geran. t. 16. (Geranium Radula; Cavan. Diff.
262 t. 101 f. 1 G. revolutum; Jacq. Ic. Rat. t. 153.)
—Umbels of few flowers. Leaves digitate, doubly pinnatifid,
toothed, linear, revolute, very rough. Nectary nearly as
long as the calyx.—Introduced from the Cape in 1774,
and now frequent in collections. The narrow linear segments
of the deeply divided round leaves, and their strong mint-like
feent, are enough to determine this species, of which we
greatly fuppect Willdenow's afternum, n. 90, and denticulatum,
n. 93, to be varieties.

Section 6. Stems fbrubly. Leaves either three-crease or ternate.

Seventeen species.

P. bicolor. Two-coloured Stork's-bill. Willd. n. 94.
Curt. Mag. t. 201. (Geranium bicolor; Jacq. Hort.
Vind. v. 2. 23 t. 39. Cavan. Diff. 248 t. 111 f. 1.)
—Umbels many-flowered. Leaves heart-shaped, deeply
three-crease, wavy, hairy; their segments obtuse, three-lobed, cut
and toothed. Nectary nearly as long as the flower-flak.—

The native country of this elegant species seems not to have
been ascertained, for we do not find its name in Thunberg's
long list of Cape Geraniurns, nor has it been heard of but
in gardens. Jacquin and Curtis say the feeds are fearely
ever perfected; yet we know not to what particular kind
it is sufficiently allied for us to fume at its hybrid birth.
The petals are deep crimson, with a white edge, not unlike
the pretty Silene quinquervulosa. The leaves are sometimes so
deply divided as to become ternate.

P. fucatum. Rough Stork's-bill. Willd. n. 96. L'Hé-
rit. Geran. t. 31. Jacq. Ic. Rat. t. 542. (Geranium fuc-
Cavan. Diff. 247 t. 108 f. 1.) —Umbels of few flowers.
Leaves wedge-shaped, deeply three-crease, acute, coarflexed.
Nectary the length of the calyx. Meffrs. Kennedy and Lee are faid to have introduced this from the
Cape in 1775. Its fhrublty, much branched ilms, as well as the leaves, are extremely harsh to the touch, especially
in wild feemincn, whence Burman chose the name. The
segments of the foliage vary in breadth. The feent is not
remarkable. The flowers are rofe-coloured and variegated,
but few, small, and inconspicuous, nor is the plant entitled
to such gene favour as many others.

n. 99. L'Hérit. Geran. t. 32 and 33. (Geranium crispum;
Linn. Mant. 257. Cavan. Diff. 252 t. 109 f. 2 G. her-
manniafolium; Linn. Suppl. 305. Herb. Linn.) —Stalks
one or two-flowered. Leaves fhralked, two-ranked, round-
hed-heart-shaped, three-lobed, wavy, parted, toothed, rough.
Stipulas heart-shaped. Nectary the length of the calyx.—
A pretty species, fent from the Cape by Mr. Maffon, in
1774, and valued more particularly for its lemon-ften, re-
sembling that of Verbena triphylla. There are two varieties,
one with leaves about half an inch in diameter, the other
above an inch; in both they are three-crease, more than
half way towards the bafe, and stand on footstalks about
their own length, occasionally more or lefs. Flowers large
in proportion, rofe-coloured, with a purple-eye-like spot
on each of the broad upper petals, flanding, usually folitary,
on long fker, axillary flake, about the upper part of the
branches. The ribs of the leaves, espefially in wild speci-
mens, are extremely rough, with minute hooked bristles.
The larger-leaved variety has more generally two, or even
three, flowers on a flake.

n. 100. Jacq. Ic. Rat. t. 545. (Geranium hermannifolium;
Leaves fhralked, three-crease, wedge-shaped, slightly lobed,
wavy, parted, toothed, rough. Stipulas heart-shaped.
Nectary rather longer than the calyx. —The Linnnaean herba-
rium has no specimen of this species, nor do we know it
but from the books quoted. It seems to differ from the falk
chiefly in the want of footstalks.

P. adulterinum, Willd. n. 101. L'Hérit. Geran. t. 34.
A soft-leaved plant, is acknowledged to be a hybrid produc-
tion, and we are disposed to doubt whether felimiriumum,
Jacq. Hort. Schonbr. v. 2. 3 t. 130, notwithstanding Will-
denow's opinion, be more than a variety of some of the falk
described species, but we have not examined specimens of
either.

(Geranium fulgidum; Linn. Sp. Pl. 945. Cavan. Diff.
255 t. 116 f. 2 G. africana folio alcei, flore cocineo fulgi-
didum; Dill. Eth. 156 t. 130.) —Umbels in pairs, many-
flowered. Leaves do-ny, in three deep segments; the
middle one largell; all pinnatifid and cut. Calyx oblique.
Nectary pouched at the bafe.—An old, but rather tender,
and not very common, species in our greenhouses or flaves,
distinguished
cultivated in Chelsea garden, so early as 1724. It is now not frequently to be met with. The stem is tall, erect, thick and juicy below; much branched and finely hoary above, terminating in numerous small umbels, of meconopsis

white flowers. The perianth is almost twice the length of the calyx, and half as long as the flower-stalk, its base tumid, somewhat like that of *Salix*.

The *P. tenuifolium*.

---

**P. fragilis.** Brittle-flaked Yellow Stork's-bill. Wildl. n. 109. (Geranium fragilis; Andr. Repof. t. 37.)—Umbels many-flowered. Leaves lanceolate, smooth, leathery; petals wedge-shaped, cut; the middle one largest and three-cleft. Nectary as long as the flower-stalk.—Procured from the Cape by Meffrs. Lee and Kennedy in 1792. A tender, succulent species, with buff or yellowish petals, striped with crimson. In these particulars it differs from the rest of those which close this section in Willdenow, though it agrees with them in the form and division of their leaves.

Section 7. Stem flaky. Leaves either pinnatisect or pinnate. Four species.

**P. carnosum.** Fleishy-flaked White Stork's-bill. Wildl. n. 111. (Geranium carnosum; Linn. Sp. Pl. 946. Cavan. Dill. 266. t. 99. f. 1. G. africanum carnosum, petiolaris angustis albicans; Dill. Eth. 153. t. 127.)—Umbels many-flowered. Leaves imbricated, pinnatisect; segments oblong, obtuse, cut and toothed at the extremity. Petals linear. Stem thick and fleshy.—This appears to have been
PELARGONIUM.

n. 120. L'Herit. Geran. t. 12; (P. hirtum; Jacq. Jc.
Rar. t. 536. Wild. n. 119. Geranium hirtum; Burn.
Geran. 48. n. 64, t. 1, excluding the reference to Linnaeus.
Cavan. Diff. 258. t. 117. f. 3.)—Umbels may-flowered.
Leaves oblong, pinnate, thrice compound, hairy, with
linear segments or divided or divided. Nectary length of the
calyx.—Native of the Cape. Introduced into England by
Mr. W. Malcolm, in 1768. We do not hesitate to unite,
in this place, two supposed species of Willdenow; and it is
fortunate that his and Burmann's name of hirtum here becomes
superfluous, that very same appellation having been inad-
vertently applied by Willdenow to his own ninth species, the
filum of Cavan. Diff. 273. t. 109. While we thus, as in
other instances, attempt to correct the imperfections of our
labors, we cannot withhold our testimony to the
merit of his performance, concerning the present genus.
His arrangement of the species is the best we have met with,
and he appears to have practically studied and underlood
most of them; having been milled now and then, chiefly by
a deference to other writers. We hope to find this beautiful
and favorable family of plants fill further illustrated and en-
riched, in the fourth volume of the second edition of Mr.
Aiton's Hortus Kewenis, of which Willdenow's labours
will, in this instance, with advantage, lay the foundation.
S. PELARGONIUM, in Gardening, contains plants of the fine-
shrubby, under-shrubby, evergreen herbaceous perennial
kinds, for the green-house, of which the species culti-
vated are:—the lady's-mantle-leaved crane's-bill (P. alchemi-
loides); the sweet scented crane's-bill (P. odoratifimum);
the gooseberry-leaved crane's-bill (P. glutinosulorum);
the coriander-leaved crane's-bill (P. coriandrifolium); the fleshly-
flecked crane's-bill (P. carnosum); the horn-leaved crane's-
bill (P. capelotheum); the gouty crane's-bill (P. gibbo-
rum); the multifid-leaved crane's-bill (P. radula); the
butterfly crane's-bill (P. papilinaceum); the scarlet-
flowered crane's-bill (P. inquinans); the common horse-
shoe crane's-bill (P. zonale); the two-coloured crane's-bill
(P. bicolor); the balm-scented crane's-bill (P. vitifolium);
the rose-scented crane's-bill (P. capitatum); the camom
honey's-bill (P. glutinosum); the hooved crane's-bill (P. cu-
cullatum); the heart-leaved crane's-bill (P. cordatum);
the prickly-flaked crane's-bill (P. echinatum); the square-
flaked crane's-bill (P. tetragonus); the birch-leaved crane's-bill
(P. betulifolium); the fpeckle-leaved crane's-bill
(P. berteriana); the bearded crane's-bill (P. sanguinette); the
rough-leaved crane's-bill (P. scabrum); the ternate crane's-
bill (P. ternatum); and the three-coloured crane's-bill
(P. tricolor).

The first has a variety with a dark circle in the middle of
the leaves.

In the eighth fort there are two varieties, a larger and a
smaller; and as it is readily raised from seeds, it affords
many seminai variations.

The eleventh fort contains a variety with fine variegated
leaves, and the flowers vary much in colour from purple,
through the different shades of red to high scarlet.

In the fifteenth, several varieties have been produced from
seed.

In the seventeenth there are several varieties.

The eighteenth also varies with petals of a rich purple
colour, in which the spots are similar, but not so con-
spicuous.

In the nineteenth there is a variety with beautifully co-
oured leaves.

And in the twentieth there is a variety with scarlet
flowers raised from seed.

Method of Culture.—All the sorts may be increased by
seeds, which should be sown in the early spring in pots filled
with kitchen-garden mould, plunging them in a moderate
hot-bed. The plants soon appear; when they should have
fresh air as much as possible, to prevent their being drawn up
weak. When the plants have attain'd fame growth, they
should be removed into separate small pots filled with the
same sort of earth, replanting them in the hot-bed till fresh
rooted, and giving proper shades. They should afterwards
be gradually inured to the open air, in order to be placed
out in it, in the summer season, in a sheltered situation.

They may also be raised in the open ground without the
hot-bed, but not so well.

But they are more commonly increased, especially the
shrubby sorts, by cuttings of the young branches, which
should be planted in a shady border in the summer, or in
pots, and plunged in any hot-bed; which is the better
method. When well rooted they may be taken up, and planted
into separate pots, placing them in the shade till they have
taken new root; after which they may be removed into a
sheltered situation, and be treated in the same manner as the
feeding plants. The fifth, seventh, and fifteenth forts have
more succulent flarks than the others; the cuttings should
therefore be planted in pots filled with the same sort of earth,
and plunged into a very moderate hot-bed, where they may
be shaded from the sun in the heat of the day; and have
but little water; for these are very apt to rot with much
moisture. When these are well rooted, they may be re-
moved, and planted in separate pots filled with the same sort
of earth, and placed in the shade till they have taken new
root; then they may be removed into a sheltered situation,
where they may remain till autumn. These sorts should be
sparingly watered, especially in the winter season, as they
are apt to take a mouldiness with moisture, or in a damp
air. They thrive much better in an airy glass-cave than in a
green-house, as in the former they have more sun and air than
in the latter. But all the other shrubby sorts are proper for
the greenhouse, where they only require protection from
froft, but should have a large share of free air when the
weather is mild. They require water every week, in mild
weather once or twice; but it should not be given them in
too great plenty, especially in frothy weather. These plants
should be hardened in the spring gradually, and towards the
middle or end of May be taken out of the greenhouse, and
at first placed under the shelter of trees, where they may
remain a fortnight or three weeks to harden; and when they
may be defended from strong winds, and enjoy the morning sun till eleven o'clock, when they will thrive better than in a warmer situation. And as these sorts grow pretty tall, they soon fill the pots with their roots; and when they stand long unremoved in summer, they frequently put out their roots through the
holes at the bottom of the pots into the ground, when the
plants grow vigorously; but if suffered to continue long in
this manner, it is difficult to remove them; as if their roots
be torn off, all the younger branches decay, and the plants
are frequently killed. The pots should therefore be moved
once in a fortnight or three weeks, in the summer months,
and the roots which may then be pushing through the holes
cut off, to prevent their striking into the ground.

They require allo to be new potted at least twice in the
summer; the first time after they have been three weeks or a
month out of the greenhouse, the second towards the end
of August, or beginning of September, that the plants may
have time to establish their new roots before they are re-
moved into the green-house. When this is performed, all the
roots on the outside of the balls of earth should be care-
fully
fully pared off, and as much of the old earth drawn away from the roots, as can be done with safety to the plants; then, where they require it, they should be put into pots a five larger than those out of which they were taken, putting a quantity of fresh earth into the bottom of each pot, slacking the plants upon it, being careful that the ball about the roots of the plant be not to high as the rim of the pot, that some room may be left to contain the water which may be given to them. Then the cavity all round the ball should be filled up with fresh earth, be gently pressed down, and the bottom of the pot beaten upon the ground, to settle the earth; the plants being then well watered, and the item fatterd for to prevent the wind from displacing the roots before they are fixed in the new earth.

Where such mounds as has been mentioned cannot be procured, fresh hazel loam from a pasture, mixed with a fourth or a fifth part of rotten dung; or, where the earth is inclinable to bind, a mixture of rotten tan; and, where light and warm, a mixture of neat’s-dung may be employed. This compost should be mixed three or four months before it is used, and be turned over three or four times, that the parts may be well incorporated.

The thrubby forts require to be looked over frequently during the winter, while they are in the green-house, to pick off all decayed leaves from them, which if left on will not only render the plants unfitly, but by their falling off make a litter among the other plants; and if they are suffered to rot in the house, they occasion a foul, nasty, damp air, which is very prejudicial to all the plants.

The first fort, from having herbaceous flarks, is best increased by seeds, though cuttings of it will take root.

And the second fort may not only be propagated by seeds, but also from heads slipped off from the short flaky flark; which should have their lower leaves stripped off, and be then planted single in a small pot; or where the heads are small, two or three may be put into one pot; plunging them into a very moderate hot-bed, shading and refreshing them gently with water. They take root in a month or five weeks; when they should be hardened gradually to the open air, where they may remain till autumn, when they must be removed into shelter, as in the other kinds.

The sixth kind is capable of being increased both by seeds and cuttings, but it is found to be more tender than many other forts, and more liable to be injured by damps. The eighth species is readily increased by cuttings; but the twelfth is more difficult to be raised in this way. The thirteenth is easily raised by cuttings, and sometimes by seeds; and the seventeenth readily strikes from cuttings; the eighteenth produces feeds, but is more usually increased by cuttings; and the nineteenth and twentieth are readily propagated in the same way; the twenty-first is likewise raised from cuttings, but they are not very free in striking; the twenty-fourth is raised in this manner without difficulty; but in the twenty-fifth, from the branches running out speedily into flowering flarks, few are formed proper for cuttings, and these are fraught with difficulty.

All these plants are highly ornamental, and afford considerable variety in collections of green-house plants.

PELAGSIANS, in Ancient Geography, the most ancient people of Greece, according to Thucydides, Strabo, and Herodotus. The last author says, that the whole country, which in his time was called Ἀθηναίοι, was in a former period denominated Pelagia. These people, as some fay, were denominated Pelagia, because they were an unfetted wandering people, who often changed their habitations. Others, among whom we may reckon Hefiod, take them to have been Autochthones, which was the designation given to the natives of the country, or rather to all whose original was unknown. If we admit Apollodorus’s authority, in which Servius (on the 2d Æanad) acquiesces, the Pelagia derived their name from one Pelagius, a person of great antiquity, and several persons of this name are mentioned by ancient writers. The ancient Scholast on Apollodorus Rhodius, makes Pelagius to have been the son of Inachus, and this is the name which, according to Hefiod, was the father of Lycaon, king of Arcadia. According to Pausanias (in Arcad.) Pelagius was the first man who appeared in the country, and surpassed all others in the faculties both of his body and mind. As soon as he began to reign, he taught the Arcadians to erect cottages to shelter themselves from the injuries of the weather, and to clothe themselves with boar’s skins. Till that time they had lived upon leaves of trees, herbs, and roots; but instead of these he recommended the use of acorns, or rather a kind of fruit which grew upon the beech-tree; and this food became so common, that long after Pelagius, the Arcadians were represented as a people who lived only upon acorns, and who on this account were terrible and invincible in war. See GREECE.

The writers first cited in this article say, that the Pelagians were first known in Thessaly, and that from thence they extended their migrations through all the other countries of Greece. However, Dionyfius of Halicarnassius says, that they derived their origin from Peloponnesus, and that they left from hence colonies into Thessaly. This author adds, that these people left Thessaly, and spread themselves through Epirus, Italy, Thrace, the isles of Aiga Minor, under the reign of Deucalion. M. de Ghebelin says, that the Pelagii were the polleloflors of the whole country, which extended from the banks of the Danube to the sea of Peloponnesus; that some of them peopled Thrace, Getia, Macedonia, Illyria, Epirus, Thessaly, the Phocide, the Peloponnesus, and Attica; and that others crossed the Danube, and bore the appellation of Daci and Getas. They are said to have replenished all these countries with celebrated cities, and an immense population; to have extended cultivation wherever they went, and to have sent out numerous colonies. On account of these emigrations they were reckoned a wandering people, without arts and sciences.

If we may credit Herodotus, the Pelagi, having settled in Samothracus, introduced thither the worship of the Cabiri and their mysteries, which they afterwards communicated to the Athenians, among whom they fixed their residence when they quitted that land. And this author adds, that from whom they derived their knowledge of these as well as of their mysteries. We learn from Dionyfius Halicarnassius, that some of the Pelagii, who departed from Thessaly, were received at Dodona; and that in obedience to an oracle they passed into Italy, and settled at the mouth of the Po. Those of them that were least able to bear fatigue, were entrusted with the care of their Welfare, and others of them advanced into the country, traversed the mountains, and descended into the country of the Umbrians. Among these people, they obtained some cities, till they were forced to retire among the aborigines, who were the neighbours of the Arcadians; and in process of time they conciliated the aborigines, and were allowed to settle among them. But the country being too small for their accommodation, the Pelagi induced the aborigines to join them in making an irruption into Umbria, where they took possession of Crotona. Here they founded other cities, which were afterwards occupied by the Tyrrenians. The Pelagi founded the town of Lariffs, in Campania, of which country they poifled a part after having expelled from it the Aurunci.

In Italy the Pelagi, after the departure of the Siculi, enjoyed
enjoyed a large and beautiful territory, so that they became rich and powerful. Those who had been left to guard their vessels, built a town to which they gave the name of the river, and gradually became masters of the sea. They sent to the temple at Delphi to invoke the help of their gods; and length, however, they were attacked by their neighbors and obliged to abandon their city. The Pelasgi, who were associated with the aborigines, were overpowered by their barbarian neighbors, so that only a few remained among the aborigines, the greatest part having been dispersed in Greece, and among the Barbarians. According to Dionysius Halicarnassensis it was about two generations before the war of Troy, that the Pelasgi experienced these misfortunes. Ali the towns which they inhabited were destroyed, excepting Croton; but it changed its name and its inhabitants; and in the time of this historian was called Cothorna.

According to the relation of Herodotus, the Pelasgi, under the reign of Deucalion, were in possession of the part of Thessaly called Phthiotis, where they remained till the reign of Darius, grandchild of Deucalion. They then migrated to another part of Thessaly called Effeisotis, situated at the foot of mount Ossa and mount Olympus. From thence they were driven by the Cadmeans, and they established themselves at the foot of Pindus, and were denominated Macedonians.

Dionysius of Halicarnassensis says, that about two generations before the war of Troy, some of the Pelasgi, driven from their cities, returned into Greece. These settled in Attica, the Athenians assigning to them a territory at the foot of mount Hymettus, on condition of their building a wall to encompass the city. Their ingenuity excused the jealousy of the Athenians, and they expelled them from Attica. They then dispersed in different places, and one party settled in the isle of Lemnos. When they were established in this island they determined to avenge themselves on the Athenians; and for this purpose armed their vessels and made a descent on Attica. Here they seized a number of females, who were celebrating the feast of Diana, and taking them to Lemnos, made them their concubines. The offering of these females being introduced in the language of the Athenians, and in their mode of life, conceived an aversion to the legitimate children of the Pelasgi; and this occasioned the murder of the illegitimate children and of their mothers. The Athenians, under the command of Miltiades, drove the Pelasgi from Lemnos, and gave them the territory called Attica, the Pelasgi separating from the continent of Thrace by a canal; by degree they extended themselves to the continent, and occupied Cretonia.

Dionysius informs us, that when some of the Pelasgi, under the reign of Deucalion, passed into Italy, the isle of Crete, and the Cyclades, Sicilia, the Phocide, and Eucaea, others migrated into Asia. According to Strabo, the Lefceans claim the honor in behalf of their ancestors of having been in the war of Troy, under the conduct of Pykeus, a chief of the Pelasgi. All the towns of the maritime coast of Ionia had been at one time inhabited by the Pelasgi; the inhabitants of the isle of Chios also pretend that the Pelasgi of Thessaly were their founders; nor indeed is there a country of Greece, Thrace, and Asia Minor, in which the Pelasgi have not left traces of their power. Soon after the war of Troy, the name of Pelasgi began to sink into oblivion. Those who existed till the time of Herodotus, near the Hellespont, and on the coasts of Thrace, were subject to foreign dominion; and the language which they spoke was the only evidence of their ancient origin. Phucydes says, that the chief cause of the ruin of this nation was the confusion of the Hellenes, who sprang from the Pelasgi themselves. The Hellenes made a league, formed among themselves a separate body, and made conquests. After separation from the Pelasgi, their parents, they estranged themselves from their manners and habits, and by little and little changed their language, in consequence of the commercial intercourse which they had with colonies from the east. Those at length who were originally Pelasgi joined this league, surrendered the name of Pelasgi, and adopted that of Hellenes. Hellenic tribes, that the Athenians, though reckoned to be Pelasgi at the time of the famous emigration of those peoples, were become Hellenes, when the Pelasgi, driven from Italy, returned to Greece. About the same time the Macedonians, the Argians, and the Arcadians, who had been also known under the name of Pelasgians, laid aside the barbarism of their progenitors, and assumed the name of Hellenes. The Pelasgi, according to Herodotus, established at Dodona the most ancient and the most respectable of the oracles of Greece. He adds, that they had no other idols nor temples; that they offered their sacrifices to the gods, and gave neither name nor surname to the deities whom they worshipped.

Dionysius Halicarnassensis, in speaking of the antiquity of the Pelasgians, inhabitants of Falirii and Fethicena, two ancient cities of Etruria, built in the Grecian form, says, in the manner of their religious ceremonies was the same as that of Argos. Fifty women formed the temple, and a girl unmarried, called casephoros, or balbuc-teri, began the sacrifice, besides choruses of virgins, who hymned the gods in the song of their country. "Now as the Romans had an earlier communication with the Etruscans than with the Greeks, this passage renders it very probable that they were obliged to the people of Etruria for their religious ceremonies, and for vocal music.

Strabo, (de bello Puniclo) says in express terms, that the public music, especially such as was used in sacrifices, came from Etruria to the Romans. See also Livy, lib. xxxix.

Pelasgicus Sinus, a gulf of the Thesali, on the coast of the Phthiotide. This gulf had Magnesia on the east, and the Phthiotide on the west; its entrance was a wide strait, between the town of Antron to the south, and the promontory of Antium to the north.

Pelasgiotis, or Pelasgis, a country of the Thessaly, the extent of which is variously assigned by different authors.

The epoch of the arrival of the Pelasgi in Thessaly is fixed by the earlier writers to the year 1882 B.C. It is probable, that they established themselves in the centre of the country, to the S. and N. of the Alpheus; but some say that this province had for its boundaries to the N. Aiaclom and the Peneus to the S. But if the Pelasgiotide be considered as comprehending three parts, viz. Perrhebatia, Pelasgiotidea proper, and the delightful valley of Tempe, the country must have extended to the S. of the Alpheus. From W. to E. its extent was limited by the mountains.

Pelaia, a town in Antiquity, a particular kind of servants among the Athenians.

The pelai were free-born citizens, who by reason of their indigence, were forced to serve for wages. They had no suffrage in public affairs, as not being masters of an estate proper to qualify them for giving their votes; but this restriction was not perpetual. They were otherwise called thetes, and continued in the period of servants only during their own pleasure and necessities; for they had power either to change their masters, or (if they became able to subsist themselves) wholly to release themselves from servitude.

Pechilen, in Geography, a town of Prussia, in Natangen; 25 miles S.S.E. of Konigberg.
PELECANUS.

PELECANUS, or the Pelican, in Ornithology, a genus of birds of the order Anseres. The generic character is, bill straight, hooked at the point, and furnished with a nail; the noddles have an oblieterated slit; the face is rather naked; the legs balance the body equally; the four toes are connected by a membrane.

The birds of this genus are gregarious, fond of fish, and in general remarkable for their extreme voracity. For the moll-yart they keep out at sea, but some of them are found in the interior parts of continents. They have a long bill, in a lateral furrow of which lie the noddles. Several of the tribe are rendered useful to mankind, by being taught to fish for them. There are thirty-one species, divided into six sections according to the structure of the bill.

A. Bill without Teth.

Species.

ONOCROTALUS, or White Pelican. The birds of this species are, as the name imports, white; the gullet is pouched; the bill is red, and from fifteen to sixteen inches long; the upper mandible is depressed and broad, the lower forked; bag at the throat flaccid, membranous, capable of great dilatation; the irides hazel-coloured; the gape of the mouth wide; the head is naked at the sides, covered with a flesh-coloured skin; the hind head is somewhat crested; the body is faintly tinged with flesh-colour; the spurious wings and first quill feathers are black; the legs are of a lead colour. It is larger than a swan, and about five feet long. It inhabits Aésia, Africa, and South America. In fishing, this bird does not immediately swallow its prey, but fills its bag, and returns to the shore to devour at its leisure the fruits of its industry. As it has a very quick digestion, it has generally to fish more than once in a day. At night it retires to rest, a little way on the shore, with its head redling on its breast. In this state it remains almost motionless, till hunger calls it to break its repose. It then flies from its redling-place, and raising itself 30 or 40 feet above the surface of the sea, turns its head with one eye downwards, and continues to fly in that position till it feeds a fish sufficiently near the surface, when it darts down with allomning swiftness, seizes it with unerring certainty, and swallows it in its pouch. It then rises again, and continues the same manoeuvres, till it has procured a competent flock. The female feeds her young with fish, macerated a long time in her bag. The pelican is susceptible of domestication, and may be trained to fish for its mallet. The pelican generally builds in marshy and uncultivated places, particularly on the islands and lakes, making its nest, which is deep, a foot and a half in diameter, of carrés, and lining it with grass of a softer texture. It lays two or more white eggs, which, when hatched, it sometimes hides in the water. When it builds in dry and defert places, it brings water to its young. It walks slowly, flies in flocks, and lives in society with other birds.

ROSEUS; Rose-coloured Pelican. This species is of a rosy colour; the gullet is pouched; the bill and legs are black; the area of the eyes is naked; the pouch yellow. It is about the size of a goose, and inhabits Manila.

FUSCUS; Brown Pelican. This, as its name imports, is cinerous brown; the gullet is pouched. It inhabits America, and is four feet long.

MANILIANIUS; Manilla Pelican. Entirely brown; gullet pouched. It inhabits, as its name shews, Manilla, and is very like the roeves.

PHILIPPENSIS; Philippine Pelican. White; crest varied with white and brown; the gullet is pouched. It is about four feet and a half long, and is found in the Philippine islands.

RUFICERNUS; Red-backed Pelican. Reddish; crested head and neck reddish-white; tail dusky; the gullet is pouched. It is four feet long, and inhabits Africa.

CAROLINENSIS; Charlestown Pelican. Dusky above, beneath white; gullet pouched. There are two other varieties: 1. One is reddish-white beneath; the upper mandible is rounded at the base. 2. The other is on the lower part of the back flitrata and dusky-white. It inhabits America; is above three feet long; the pouch is very large.

ENYTHROHYNCHUS; Rough-billed Pelican. Crested; white; gullet pouched, and streaked with black. It inhabits North America, and is four feet and a half long.

AQUILUS, or Frigate Pelican. The tail is forked; body ferruginous, and orbits black; the bill is red; belly of the female white. It is three feet long; the extent of the wings is full fourteen feet. It inhabits within the tropics. It is mentioned by Dampier, and other navigators, as the frigate bird. From its great expanse of wing it is capable of flying very smoothly, and so high as to be fearlessly visible, seldom taking to land. It feeds on fishes, particularly flying fish, on which it darts with the greatest velocity. It builds on trees or on rocks, and lays one or two eggs of a flesh-colour, and spotted with red.

MINOR; Lesser Frigate Pelican. The tail is forked; body ferruginous; bill and orbits red. It resembles the last, but is less, being only about three feet long.

LUTTOCEPHALUS; White-headed Pelican. The tail of this species is forked; the body brown; head, neck, breast, and belly white; bill dusky.

PALMESTONI; Palmérstan Frigate Pelican. Tail forked; body glossy green-brown, beneath white; throat variegated with black. It inhabits Palmérstan's island in the South Pacific ocean; is about three feet two inches long. The bill is black; the temples feathered; the legs blackish.

CARBO; Corvornat. Tail rounded; body black; head somewhat crested; bill blackish; the bafe of the lower mandible covered with a yellowish skin, extending under the chin, and forming a pouch; irides green; chin white; surrounded with a yellowish arch; tail long and lax, confining of fourteen feathers; thighs with a white spot, dotted with black; legs black. Three feet long; size of a goose, but more slender, and weighs about seven pounds. Inhabits Europe, Aésia, and America. Common on many of our sea-coasts, building its nest on the highest parts of cliffs that hang over the sea, and laying three or more pale green eggs, about the size of those of a goose. In winter these birds disperse along the shores, and visit the fresh waters, where they commit great depredations among the fish. They are remarkably voracious, and have a very quick digestion. Though naturally extremely shy and wary, they are stupid, and easily taken when glutted with food. Their smell, when alive, is more rank and offensive than that of any other bird; and their flesh is so disgusting, that even the Greenlanders will hardly taste it. It is not uncommon to see twenty of these birds together, on the rocks of the sea-coast, with extended wings, drying themselves in the wind. In this attitude they sometimes remain for nearly an hour, without once closing their wings; and as soon as the latter are sufficiently dry to enable the feathers to imbibe the oil, they press this liquor from the receptacle on their rumps, and drefs the feathers with it. It is only in one particular state that the oily matter can be spread on them, namely, when they are somewhat damp; and the instinct of the birds teaches them the proper moment. Corvorants were formerly sometimes trained in this country, as they still are in China, for the
purpose of catching fish for the table. With this view they were kept with great care in the house, and when taken out for fishing, they had a leather thong tied round their neck, to prevent them from swallowing their prey.

**Graculus;** Shag. Tail rounded; body black, brown beneath; tail-feathers twelve; head and neck black, with a green gloss; back and wing-coverts purple-black, glistening at the edges; middle of the belly dusky; legs black. Weighs about four pounds. Length twenty-nine inches. The female weighs about three pounds and a quarter, and is only twenty-seven inches long. Inhabits the northern seas of Europe. Swims with its head erect, and the body under water. On perceiving the flash of a gun, dives instantaneously, and rises at a considerable distance. Has the manners and habits of the preceding, and devours a prodigious quantity of fish. There are two other varieties of this species: in the first the chin is yellow, and the tail wedged. It is found in the Cape of Good Hope. The second is blackish, but beneath it is brown; the feathers above are edged with black. It inhabits Cayenne, and the Caribbean islands, and is about twenty-six inches long.

**Tarexr;** Dwarf Shag. The tail is wedged, the feathers twelve in number; the body is black, with a few scattered white spots. It inhabits the Caspian sea, and is about the size of the garrancy, a species of the Anas genus. The female is brown, without spots. A variety has its chin of a mouse colour, and its legs black.

**Punctatus;** Spotted Shag. Crested; black; tail rounded; wings dark ash, spotted with black; fides of the neck with a white line. It inhabits New Zealand, and is nearly two feet long.

* Cristatus;* Crested Shag. This is found in many parts of the north of Europe, and in our own country. It is of a shining green, beneath it is dusky; bill and legs dusky; head crested; the bill is blackish; irides green; feathers each side the head long, forming a crest; the tail-feathers twelve in number, and of a dusky green; the head often not crested.

**Violaceus;** Violet Shag. Crest erect; body shining violet-black. It inhabits Kamtchatcha, and the neighbouring islands.

**Umiel;** Red-faced Shag. Shining green; throat and orbits white; face naked, blueish-red; wings and tail dusky; legs black. It inhabits Kamtchatcha, and is about thirty-four inches long.

**Carunculatus;** Carunculated Shag. Black, beneath white; face naked, carunculate, red; orbits elevated, blue; wings with a white band. It inhabits New Zealand, and is about twenty inches long.

**Magellanicus;** Magellanic Shag. Black, beneath white; temples and chin naked. reddish; head turned, temples with a white line; tail wedged. It inhabits Terra del Fuego and Staten land islands, at the extremity of South America. It is about thirty inches long.

**Varius;** Pied Shag. Brown, beneath white; rump, wings, and rounded tail black; eye-brows pale; area of the eyes naked, yellow. It inhabits New Zealand; two feet and a half long; it builds in trees; the eggs are of a pale greenish-white.

**Cirrhatus;** Tufted Shag. Black, beneath white; crown crested; wings with a white band; tail rounded; bills and legs yellow. It inhabits New Zealand, and is thirty-four inches long. The orbits are naked; the crest turned back; tail-feathers fourteen; bill and legs yellow.

**Africanus;** African Shag. Brown-black, beneath varied with white and blackish; chin white; wing-coverts blue-grey, edged and tipt with black. It is found in Africa and is about twenty inches in length.

### B. Bill ferrate.

**Species.**

**Thagus;** Saw-billed Pelican. Brown; tail rounded; gutlet pouchcd, and covered with short cinereous feathers. It inhabits Chili; is the size of a turkey; extends its wings about nine feet. The bill of this species is about a foot long, each mandible is hooked; the pouch is very long, and the legs black.

* Bassanus;* Gannet or Soland Goose. Tail wedged; body white; bill and quill-feathers black; face blue; irides yellowish; tail-feathers twelve; eyes surronded with a naked skin of fine blue; legs black, and greenish on the fore part; the feet long. Weighs seven pounds, and inhabits Europe and America. This species of pelican haunts the Bafa island in the frith of Edinburgh. Ailla on the coast of Ayrique, the island of St. Kilda, and hardly any where else in Europe. It arrives at these spots in March, and continues till September. As it must let itself fall before it takes wing, it requires a steep and precipitous breeding station. It makes a rude nest of fletches, grass, sea-plants, and lays one egg. While the female is occupied with incubation, the male brings her food, which consists almost entirely of herring and sprats. In the bag under their bill they are able to fetch four or five herring at a time, and a great number of sprats, which the young bird extracts from the mouth of the old one with its bill, as with pincers. The young begin to be taken in August, and by some are re-lifed as an exquisite morcel; but the old ones are tough and rancid. The fowler, who feizes the young, is let down by a rope from the top of a cliff, and is sometimes flationed on the slippery projection of a rock, with the perpendicular precipice of four hundred feet or more beneath him. The young are of a dark grey colour, and continue so for a year or more, when they gradually become white, except the tips of their wings, which are always black. In September and October the old birds leave their breeding places, and migrate southward, following, as is alleged, the shoals of herrings. In December they are often seen off Lisbon, plunging for furminze; but after that period, it is not well known what becomes of them till March. They are common on the coasts of Norway and Iceland, and are said to be met with in great numbers in the coasts of New Holland and New Zealand. They also breed on the coast of Newfoundland, and migrate southward along the American shores, as far as South Carolina. Of this species there are two varieties: the first is brown, spotted with white, and white beneath, with naked and blackish. The second is brown, with triangular white spots, whitish, and spotted with brown beneath; the bill, wings, tail, and legs brown.

**Piscator, or Lefler Gannet.** Tail wedged; body whitish; all the quill-feathers black; face red. It inhabits the Chiffew Indian, and American seas; and is about thirty inches long.

**Sula;** Booby. Tail wedged; body whitish; primary quill-feathers tipt with blackish; face red. It inhabits South America, and the neighbouring islands, and is about thirty inches long.

**Fiscer;** Brown Booby. Tail wedged; body brownish; all the quill-feathers blackish; face red. It inhabits America and Africa, and is rather more than two feet in length.

**Sinenis;** Fishing Cormorant. Tail rounded; body brown, whitish, and spotted with brown beneath; throat white; bill yellow; irides blue. It inhabits China, where
it is named for the purpose of catching fish. The bill of this bird is yellow, and the irides blue.

PAHUS; Letter Booby. This species is black, beneath it is white; the face downy. It inhabits Cayenne, and is about eighteen inches long.

PELECANUS, a name given by some authors to the plaitage, or spoon-bill; a bird very different from the pelican, being of the flork or horn kind. See PLATEAUS.

PELECHURO, in Geography, a town of Peru, in the diocese of Cuzco; 36 miles N.N.W. of Caravaya.

PELECHUSIN, in Biology, a kind of veteh, or leguminous plant, mentioned by Pliny, book 21, ch. 12, l. 45, as "growing in corn-fields, and having small shrubby stalks, with leaves like Cicer." It bears its seeds in pods (or legumes), which terminate in a hooked point, and grow three or four together, &c." This description accords well with the Linnæan Corollina Securidaca, which is certainly the P. discolor of Dioscorides, and Gelseum, as well as Bauhin, rightly so understood it. Pliny says "the seeds are bitter, and good for the stomach." It is remarkable that the modern Greeks, at this day, know the plant by the name of P. discolor, or, bitter pod. The seeds of a very similar plant, Trigonella Fumagrum, always enter into the pepper powders in Hindoos, and are supposed to possess a medicinal quality. Such a near coincidence is frequent between the medical opinions of the most ancient nations.

This being the true Pelecanus, we cannot account for Tournefort's having adopted the word as the name of the Linnæan Biserrula, see that article; to which it is certainly applied, nor does he give any reason or explanation concerning it. This, however, led Linnæus, as it seems, to retain it for the specific name of that curious plant.

PELECOID ANGLE, in Geometry. See ANGLE.

PELECOIDES, from πελεκοιδ, hatchet, and ἀεί, form, a figure in form of a hatchet.

Such is the figure B C D A, (Plate X. Geometry, fig. 16.) contained under the inverted quadrilateral arcs A B and A D, and the femicircle B C D.

The area of the pelecoides is demonstrated to be equal to the square A C; and that, again, to the rectangle E B. It is equal to the square A C, because it wants of the square on the left hand, the two segments A B and A D, which are equal to the two segments B C and C D, by which it exceeds on the right hand.

PELEE, in Geography, a small illand in the English channel, near the coast of France; three miles N.E. of Cherbourg. N. lat. 49° 41′. W. long. 1° 28′.

PELEGRINI, VALERIO, in Biography, an eminent finger, was in the service of Spain in 1700.

PELEGRINI, Pietro, a native of Brescia, and some time organist of the Jesuits' church in that city. He was a very neat player on the harpsichord, and a lively compositor for that instrument. Bremner published a book of lessons of his composition, and several books were published at Paris, where, in 1742, he set a drama to music, translated from Stampiglia, called Circere.

We heard him perform at Calais in 1706, at a concert for his own benefit. He was then in years, and in the last stage of a consumption; but the Duc de Monpensier, then governor of Calais, coming into the room during the performance, the poor man was obliged to rise and finish his concerted standing. We saw with uneasiness the difficulty with which he supported himself, and executed difficult passages; but no performer was ever more to the presence of the ducal governor, any more than in that of any of the royal family.

PELEGRINI, FERDINANDO, a Neapolitan compositor and performer on the harpsichord. According to M. Gerber, the

P E L

continuator of Walter's Musical Lexicon, he published a Paris and in London several works for the harpsichord. There is some mistake in the christians names of these two harpsichord-composers, and the works of one are indifferently ascribed to the other; nor are we certain of there having been two composers of the same time, of the same name, and in the same places, of similar professional shilities.

PELEGRINO, in Geography, an illand in the Pacific ocean, discovered by Quiros in 1606. S. lat. 14°. W. long. 162°. Also, a mountain on the N. coast of the illand of Sicily, near Palermo, in which is a celebrated sanctuary dedicated to St. Rosalia.

PELENGON, or CELERON, a town of Peru, in the province of Larítan; 66 miles N.E. of Lar.

PELES, a town of Sweden, in the province of Savolax; 48 miles E. of Nyfölt.

PELEW ISLANDS, or PALOAS, a group of illands in the wester part of the Pacific ocean, or in that extensive division of the globe, called Polynesia, situated between the Philippine illands and the Caroline illands. The first discovery of these illands has been attributed to some Jesuits of the Philippine, viz. the fathers Duberon and Cortil, who left the Philippines for this purpose on the 14th of Nov. 1710. Before this time, it was only known, that the largest illand, which is the most northerly, was called Panlog, and that the royal residence was in Fahn or Pelew. After a voyage of fifteen days these fathers discovered land towards the north-east, and the two illands that were seen were called those of St. Andrew, as having been discovered on the day of that apostle. From some Pelewans, whom they accosted, they received information that the true name of these illands was Sonforol; that Panlog was to the N. N.E. and Pulo to the S.S.E. Panlog was afterwards discovered about fifty leagues from Sonforol, in lat. 7° 14'. This seems to be the illand now called Babelthorup, and the largest of the group, the S. extremity of which in Arrow-smith's maps is about lat. 7° 25'. Father Cantova's letter, dated 1722, and contained in the collection, entitled "Lettres Edituantes," gives a brief account of the Pelewos, and very unjustly repreffes the natives as cannibals. By his account, the group called the Peleus, or Pelewos, consisted of seven principal illands, situated from N. to S. Their names were Pelihien, Coengal, Tagateuen, Cogcal, Yalap, Mogulibe, and Nagarlo; the king was called Yayre, and reformed in Yalap. The natives were described by the Jesuits as naked cannibals, who were regarded with horror by the people of the Carolines. It was not till the year 1783, that we were able to obtain a just account of these illands, and of their inhabitants. When captain Wilton, commander of the Antelope packet, in the service of the East India Company, was wrecked on Oorlooog, one of these illands, he derived that information which was communicated on his return to Mr. Keate; and this ingenious writer, indulging perhaps in some degree the glow of his feelings and imagination, drew up that very pleasing and interesting account, which, from its first publication, has passed through several editions. The whole group is said to contain eighteen illands; but those which Mr. Keate mentions are Oorlooog, Artingall, Pelelew, Emilligne, Emunga, Aramalooeo, Arraguy, Caragaba, and Pethouli: but the names of all were not discovered: and it was but lately known that Pelew was only the name of the capital of the illand called Coororoa; and the residence of the king. From Mr. Keate we learn that the natives of these illands, so far from being savage cannibals, were remarkably mild, hospitable, and humane. These illands are in general of a moderate height, and covered with wood; and encircled on the W. side by a reef of coral, from two to six leagues from the shore, and of

4 C 2 great
PELEW ISLANDS.

great length. Coorooraa, the capital of which is Pelew, bears
the marks of industry and good cultivation. All the islands
which the English saw were covered with trees of various
kinds, and some of them of large size, which appeared from
their canoes, made of their trunks, and capable of carry-
ing twenty-eight or thirty men. Among the trees in the
forest, they observed the ebony, and also a tree which
when pierced with a gimblet, yielded a juice of the confi-
dence of cream; a species of the machinel tree; a tree in
fiz and its branches resembling the cherry-tree, and in its
leaves the myrtle, and having, instead of bark, an outward
coat of the thickness of a card, darker than the infide,
though equally cloie in texture: the colour of the interior
part being nearly that of mahogany, and so extremely hard,
that few of the tools which the English had could work it
without breaking their edges. Here were also the cabbage-
tree, and a tree whose fruit resembled an almond: the eca-
rambula, and the wild bread-fruit, called by the natives
"rational." Yams and cocoa-nuts being the chief means
of subsistence, are objects of particular attention. Of the
beetle-nut, which abounds, the natives make great use: and
their islands also afford plantains and bananas, Seville
oranges, and lemons. They furnish some sugar canes, great
abundance of the bamboo, and likewise the turmeric, used
as a dye, and employed by the women for staining their
skins. None of the islands which the English visited afforded
any kind of grain, nor any sort of quadrupeds, except some
rats which were found in the woods, and three or four
megre cats, found in the house, and which were probably
driffed ashore from some wreck. Of birds, pigeons were
the most numerous; and they had plenty of cocks and
hens, undomesticated and running wild in the woods, of
which they had made no use as articles of food till they were
instructed by the English to eat them. Several birds of
beautiful plumage were observed to fly about, and some
of a small size, whose notes were very melodious, and par-
ticularly one, which used to sing every morning and evening,
with a pipe as sweet as a flageolet. Of fish they had
great variety.

These islands, when seen from the sea, exhibit high rugged
land, covered with wood; the interior parts were in many
places mountainous, but the valleys were extensive and beau-
tiful, and presented many agreeable prospects. The soil
was in general rich; the grass, as no cattle ate it down, grew
high, and was burnt up with the heat of the sun. The
English saw no river in these islands; their supplies of fresh
water were derived from small streams and ponds of which
there were many. They had no salt, or any kind of seafon-
ing with their food, which consisted chiefly of fish, and
they had also a kind of sweet-meats, which they prepared
from the sugar-cane, which seemed to be indigenous. The
milk of the cocoa-nut was their usual beverage. As soon
as they rife, which is common at day-light, they immediately
go to bathe in fresh water. They had no method of
measuring time, but by the height of the sun; and they
divided their feasons, like the inhabitants of other tropical
countries, into wet and dry. They appeared to have some
knowledge of the stars, to feveral of which they gave
names. Those islands that werevisited by the English ap-
ppeared to be populous, but the account of their popula-
tion was not ascertained. Their houses were placed upon
large flones, and raised about three feet from the ground;
being constructed of planks and bamboos, and having the
fire-place in the middle, secured with hard rubbish. For
public meetings they had large mansions. Their fishing-
hooks were of tortoise-shell: their twine, cord, and fishing-
ets, were well manufactured from the husks of the coco-
nuts. The mats on which they slept, and which they threw
over them at rest, were formed of plantain-leaf. At their
meals they used a plantain-leaf instead of a plate, and the
shell of a cocoa-nut served them as a cup, which they some-
times finely polished. Their belt knives were of mother-of-
pearl, and others of a large muscel-shell, or sfruit bamboo.
They had also vefels of an oval shape and reddish-brown
colour, which were a kind of earthen ware, and which they
used for heating their water, and for boiling their yams, &c.
The principal weapons used in their battles were spears,
about twelve feet long, formed of the bamboo, hav-
ing its pointed end of very hard wood: these were barbed
transfixingly, nor could they be drawn from the body with-
out tearing the flesh. Another weapon was the dart
and fling; the ding was a piece of wood about two feet
long, with a notch made in it, wherein the head of the
dart was fixed. The dart was of bamboo, pointed with ex-
tremely hard wood. Their canoes were formed of the
trunks of trees, and neatly ornamented. The natives of
these islands are a stout, well-made people, rather above the
middling stature; their complexions are of a far deeper
colour than what is understood by the Indian copper, but not
black. They are mild, affable, and indolent, and, like
the inhabitants of Otaheite, they form an exception to the
general rule of savage existence. Their hair is long and
flowing, rather dispoed to curl, which they moly form
into large knots, and wind round their heads. Some of the
dr women, who wore remarkably long hair, let it hang look-
down their backs. The men were entirely naked; the
women wore only two little aprons, or rather thick fringes,
one before and one behind, about ten inches deep and seven
wide: these were made of the husks of the cocoa-nut flippred
into narrow slips, which they dyed with different shades of
yellow: this, which was their only drefs, they tied round
their waists, commonly with a piece of line, though such as
were of higher rank used a ftring of some kind of beads.
Both men and women were tattooed, or as they called it
"melothed;" an operation which is supposed to have
taken place at a certain period of youth, children of either
sex not being marked by it. The men had their left ear
bored, and the women both; a few of the firft wore beads
in the perforated ear; the latter put either some leaf through,
or an ear-ring of tortoise-shell inlaid. The earligage be-
tween the noifills was also bored in both sexes, through
which they frequently put a little fprig or blossom of some
plant or shrub that accidentally caught their fancy. When
the men and women grew up, their teeth were blacked,
which was done by means of some dye; and the opera-
tion was tedious and painful. For this purpose they used
groundfl, with four other herbs, bruited together, and
mixed with a little chaffin into a pafle, which was applied
to the teeth every morning, in order to dye them black:
the patients lyes with their heads upon the floor, and let-
ting the saliva run out of their mouths. At night the
pafle was taken away, and they were permitted to eat a
little. The fame proces was repeated the day following,
and five days were necessary to complete the operation. This
occasioned great trouble, and made them extremely fitck.
Perfons of both sexes were very expert at swimming, and
appeared to be as perfectly at ease in the water as on land.
The men were admirable divers. Their marriages were
probably no more than a civil contract, but at the same
time the contract was regarded as inviolable. They al-
lowed a plurality of wives, but in general had not more
than two: the king had five, though not living together.
They did not appear to be in any degree jealous of them,
permitting them to partake of all their diversions. When
a woman was pregnant, she always separated from her husband
at night; and it was observed that the utmost attention was
paid
pel

paid to women in that situation. Their children are named
soon after they are born; and probably without any cere-
mony. Some peculiar circumstances attended their funerals.
At the place of interment, an elderly woman was observed
to get out of the new made grave, who was supposed by
those who attended to be the mother, or some near relation,
who had been drawn by affection to the melancholy frame,
in order to be satisfied that every thing was duly prepared.
When the corpse was laid in the earth, the lamentation of
the women that attended was very great. These last sad offices
seemed to be wholly left to the tendernefs of the weaker
sex; the men only assembled round the body, before it was
carried to the grave, where they preferred a solemn silence.
They had places appropriated to sepulture. Their graves
were made like ours in country church-yards; having the
mould raifed up in a ridge, over the place where the body
was deposited, some flat stones raifed above them, with a
flat one laid horizontally over, and surrounded by a kind of
hurdle-work, to prevent any one from treading over them.
There seemed to be no religion of any kind among these
indians, though they have an idea that the soul furvives
the body. The government is in the hands of a king,
under whom there are "rupaks," or chiefs, who also con-
stitute a kind of nobles. The property of all the land is
supposed to be vested in the sovereign, while that of the
people is only personal, as a canoe, weapons, or rude arti-
cles of furniture. The king of Pelcow entertained to great
an eddem for captain Wilfon, that he enthrilled his second
son, prince Lee Boc, to his care, to accompany him to
England. This young man was of a most amiable dispo-
sition, difposed of information, and possessed a capacity for
receiving it; he died of the small-pox at captain Wilfon's house
in London in the year 1784, at about twenty years of age.
N. lat. between 6° 54' and 8° 12'. E. long. between 134°
and 134° 40'.

Pelham, a township of America, in Hampshire county,
Massachusetts; 12 miles N.E. of Northampton; incor-
porated in 1742, and containing 1144 inhabitants.—Allo,
a poll-town of Rockingham county, in New Hampshire, on
the S. rate line, which separates it from Dracut, in Mas-
sachusetts; 30 miles S.W. of Exeter; incorporated in 1736,
and containing 918 inhabitants.—Allo, a township in West
Chester county, New York, on the acid S. and E. by the
South River, New York, and Appleby's island; containing
493 inhabitants.—Allo, a township of Lincoln county,
Upper Canada, S. of Louth, watered by the
Chippewa or Welland.

Pelhestre, Peter, in Biography, a confiderable
French writer, who flourished in the 17th and early part of
the 18th centuries, was a native of Rouen, where he was
born about the year 1645. At an early age he was in-
spired with the love of learning, and from thenceforward he
developed his life to Roudous purpofes. At the age of sev-
eteen or eighteen he came to Paris, when the archibishop
of that city fent for him, and said, "I am informed, sir, that
you read the works of heretics; are you sufficiently learned
to venture on fuch a dangerous practice?" To which the
young man replied, "Your quetion, my lord, embarrasses me;
for were I to anfwer in the affirmative, you might charge
me with preumpitous vanity; and should I fay that
I have not fufficient learning, you would prohibit me from
reading fuch books." Pleated with the ingenuousness of
the anfwer, the prelate laid him under no reftriCtion.
For some time M. Pelhef tre officiated in the clerical charaCter,
and was zealous as a miffionary for the converfion of
Protestants to Catholifm: he afterwards refumed the habit
of a layman, which he did not change upon his appoint-
ment to the place of sub-librarian in the great convent of
the Cordeliers at Paris. His motive for accepting of this
poff, was the unrestrained acces which it gave him to a
valuable library. He became intimately acquainted with
father Mabilion, and feveral other of the moll learned perfon:
ths of his time. He visited most of the religious focieties
in France, and faw, if he were to indulge himfelf from the
d, he fhould make choice of one of the principal monaf-
teries on mount Athos, for the advantage of confulting the
numerous Greek MSS. which they pofted. When he
had any particular object in view, it was usual for him to
fhut himfelf up in a room from which day-light was ex-
cluded, where he applied himfelf night and day, excepting
when nature called for refiefement. Father Le Long was
told that he had been feen frequently in this fituition. He
was fuddenly in 1710, when he was fifty-five years of age.
He was a man of prodigious reading, and particularly con-
verfant in theological controversy, and the knowledge of
eccclfifical authors. He wrote a fewe criticism on va-
rious paflages in M. Dupin's "Bibliotheque des Auteurs
Ecclefaftiques," and filled all the margins of Cave's "His-
toria Literaria" with notes. The manuscripts of these
performances are faved to have fallen into the hands of the
Benedictines, to whom they would prove ufeful in their
critical refearches. He was the author of the numerous
additions and valuable notes to the fecound effoification of
father Bonaventure's "Treatife on the belt Method of
reading the Fathers of the Church," in 1697. Moreri.

Peliala, in Ancient Geography, a town of Alia, in
Meleagris, between Rhefana and Alvanis. Ptolomy.

Pelias, an island on the coafl of Sicily, in the vicinity of
the promontory of Drepanum.

Pelias, in Zoology, a fpecies of Caluber; which fee.

Pelican, in Chemistry. See Pelican.

Pelican, in Ornithology. See Pelicanus.

Pelican Island, in Geography, a small ifland near the S.
coafl of Weft Florida. N. lat. 35° 14'. W. long. 33° 6'.
—Allo, a small ifland near the N.E. coafl of Antigua.
N. lat. 17° 14'. W. long. 61° 24'.—Allo, a small ifland
near the S.W. coafl of Antigua. N. lat. 17° 10'. W.
long. 61° 35'.

Pelican Islands, a clufter of small islaunds near the coafl
of Weft Florida. N. lat. 29° 49'. W. long. 88° 55'.

Pelican Key, Great, a small ifland near the S. coafl of
Jamaica. N. lat. 17° 49'. W. long. 76° 49'.

Pelican Key, Little, a small ifland near the S. coafl of
Antigua, a little N. of the former ifland.

Pelican Rocks, rocks on the N.W. coafl of Antigua,
lying under water, and dangerous.

Pelican Shoals, fand-banks about half a mile from the
shore, on the S.W. coafl of the ifland of Barbadoes.

Pelicare, a town of Cochin; 50 miles E. of
Cochin.

Pelicaro, a town of Naples, in the Basilicata, at
the mouth of a river that runs into the Adriatic; 10
miles E.N.E. of Tarf.

Peliconda, a town of Hindoollan, in the ciear of
Cicace; 25 miles N.W. of Cicace.

Peligini, in Ancient Geography, a people of Italy,
between the Marmeni and the Marth; sometimes com-
prehended under the name of Marth. They were immedi-
ately defended from the Samnites, but owed their firft origin to
the Sabines. They are mentioned by Ovid, Fast. i. iii.
v. 95. As they inhabited the high mounfains which formed
a part of the Apenines, it is probable that they derived
their name from the primitive pat, elevated. They are faid
to have conftucted a temple to Jupiter Palenus. Their
chief town was Corflium; Salmo also was within their
dominion.
PEL

PELIARVI, in Geography, a town of Sweden, in the government of Kopio; 100 miles S.E. of Kopio.

PELIKANI, a town of Lithuania, in the patinate of Wilna; 16 miles S.S.W. of Breslaw.

PELIM, a town of Russia, in the government of Tobolfo, on a lake of the same name; 72 miles N. of Turink. The lake is about 56 miles in circumference. N. lat. 59° 10'. E. long. 65° 36'. This lake receives a river, called alfo Pelim.

PELING, an island near the coast of Corea, in the Hoang-Hai, or Yellow sea; ten miles long, and four broad. N. lat. 38° 24'. E. long. 124° 28'.—Allo, a small island in the E. Indian sea, near the E. coast of Celebes; 56 miles long, and 14 broad. S. lat. 1° 45'. E. long. 125° 10'.

PELION, Mount, in Ancient Geography, a portion of that long chain of mountains which lay on the eastern coast of Thessaly, and which extended from the peninsula, inclining towards the south the greatest part of the country called Magnesia, as far as the mountains that separated it from Macedonia. The portion which bore the name of Pelion commenced at the summit of Rhamus, and reached almost from the sea in advancing towards the N.W. In a kind of angle which this mountain formed in its return towards the E. at the bottom of the mountain flowed the small river Amyrus. The coast, in the direction of the mountain, formed in this place a small gulf, in which was Melion. From Melion to the right bank of the mouth of the Penius, the chain of mountains, which approached very near to the sea, was called Olla. On the other side of the Penius, in ascending towards the north, it formed two chains of mountains, one of which took the course of the sea very exactly, and the other inclined a little from the S.E. to the N.W. These two mountains were connected with the mountains which separated Thessaly from Macedonia. They were these two chains of mountains which the ancients comprehended under the name of Olympus. When the giants are said to have piled Olla upon Pelion, the meaning seems to be, that they had fortified these two mountains, whither they retired after their excursions, and kept Jupiter's garrison upon mount Olympus in awe.

PELIOSANTHES, in Botany, from ρηιος, Reid or lurid, and ανθη, a flower, a recently established East Indian genus, so named by the late Mr. George Jackson, in Andrews's Repository, in allusion to the pale lead-colour, for which the flowers are remarkable. Andr. Repof. v. 9. 605. Ker in Curt. Mag. v. 32. 1302.—Clas and order, Hexandra Moneymia. Nat. Ord. Sarrantecles, Linn. Apafrgi, Jull.

Gen. Ch. Cal. none, unless the corolla be taken for such.

Cor. inferior, of one petal, permanent; tube cylindrical; limb wheel-shaped, in fix equal, obovate segments. Nectary of one leaf, globular, contracted at the mouth, one-third the length of the petal. Stam. Filaments very short, equal, inserted into theinside of the nectary; anthers oblong, of two lobes and two cells, projecting just beyond the nectary. Pfl. German superior, enveloped in the nectary, globose; style scarcely any; stigma of three obtuse furrowed lobes. Peric. Berry ovate, of three cells. Seeds in each cell, some of them frequently abortive.

Eff. Ch. Corolla tubular; limb wheel-shaped, in fix segments. Stamens inserted into the globular nectary. Berry with three cells, and fix seeds.

Corolla oblong. Gathered by Dr. Roxburgh in Bengal. Living plants were sent by him to the late Lady Amella Hume in whose bower they flowered in the following spring, for the first time in England. Root fibrous, perennial. Stem none. Leaves several, radical, erect, a foot or more in height, on channelled flalks, elliptical, pointed at each end, entire, rather rigid, evergreen, smooth, plaited, with many longitudinal ribs, and fine transverse veins. Flower-flalks several, taller than the leaves, erect, round, simple, smooth, somewhat glaucous, each bearing an upright cluster of numerous inodorous small flowers, scattered or in tufts, of a livid purplish lead-colour, intermixed with dull green. Bracteac scattered, ovate, pointed, concave, membranous, pale. The flowers fall off even before they wither, without producing any fruit in this country. The natives of Bengal know this plant by the name of Teta, but we find nothing recorded of its qualities or virtues.

2. P. humilis. Dwarf Teta. Andr. Repof. t. 634. Curt. Mag. t. 1532.—Flower-flalks shorter than the leaves. Clutter simple. Corolla acute.—Introduced from Prince of Wales's island, about the year 1808, by Mr. Evans of Stepney, in whose hot-house it bloomed in November. This differs from the former in its much humbler stature, the leaves being not more than three inches high, and the flower-flalk hardly two inches, bearing an ovate, dense, simple cluster of flowers, whose segments are acute, green with a white edge.

Mr. Jackson has recorded, in Andr. Repof. v. 9. 605, that he had seen two species in Mr. Evans's collection just imported from Prince of Wales's island, one of which had the leaves nearly of a blue colour. The other probably was our lumi. Mr. Evans's collector declared that he had found five or fix distinctive species of this genus, growing wild in the island just named, though he did not succeed in his attempt to bring them alive to England.

PELL, JOHN, in Biography, a divine of the church of England, was born at Southwic, in Suffix, in the year 1610. He was educated in grammar-learning at the free-school of Bening, in the same county, and made so rapid a proficiency in the Latin and Greek languages, that at the early age of thirteen he was fully qualified for entering upon academic studies, and was sent to Trinity college, Cambridge. Here he exhibited a wonderful facility in acquiring languages, and at the same time shewed a peculiar turn for mathematical learning; so that, in 1629, when he was only eighteen years of age, he drew up "A Description and Ufe of the Quadrant, in Two Books." In the same year, he held a correspondence with the celebrated Mr. Henry Briggs upon the subject of logarithms, and in the following year he wrote "Modus fupp芦andi Ephefferes Albramonefis (quantum ad motum Solis attinet), paradeigimate ad annum 1630, accommodato;" and "A Key to unlock the Meaning of Johannis Trithemius, in his Discours of Steganography," which he communicated to Mr. Samuel Hartlib and others. He had been admitted to the degree of B. A. at the usual period, and in the present year he proceeded M. A. During this year he wrote "A Letter to Mr. Edmund Wingate, on the Subject of Logarithms." In 1634, he finished his "Albramonomical History of Observations of Heavenly Motions and Appearances," and soon after his "Ecliptica Prognostica, teaching how, by Calculation, to foreknow and forecast all Sorts of Eclipses of the Heavenly Lights." By these and other works, it which is not unnecessary to enumerate, Mr. Pell's reputation for mathematic knowledge was so well estallished, that he was considered to be deserving of a professor's chair in that science. When, therefore, a vacancy took place in one at Amsterdam in 1652, a sensation was made to procure Mr. Pell the appointment. The vacancy was not, however, filled up before the latter end of the year 1643, when Mr. Pell was chosen to it. Of the estimation in
in which he was held in Holland, a good opinion may be formed from what was said of him by his colleague, Gerard John Vossius, who ryles him a person of various erudition, and a most acute mathematician, and he greatly applauds his lectures upon Diophantus.

In 1661, Mr. Pell published at Amsterdam, in two pages, a refutation of Longomontanus's pretended quadrature of the circle, which obtained for him a high degree of credit among the most learned mathematicians in Europe. Two years afterwards, Mr. Pell was called to the display of his talents on a new scene; for the prince of Orange, having founded a Schola illustris at Breda, invited him to be professor of philosophy and mathematicks in the new institution, with an annual salary of a thousand guilders. This offer he accepted, and he filled the mathematical chair at Breda with the same reputation and success which attended him at Amsterdam, having, among his pupils, several who were afterwards distinguished as eminent algebraists.

In 1662 he returned to England, and in 1664 Cromwell appointed him agent to the Protestant cantons in Switzerland, which character he retained till the death of the protector. After the restoration, he was encouraged to enter into holy orders; and, having been ordained deacon and priest in 1661, he was immediately instituted to the rectory of Fobbing, in Essex, with the chapel of Battleden annexed, on the presentation of the king.

In 1663 he was presented by Dr. Sheldon, then bishop of London, to the rectory of Langdon, in Essex, and about the same time he was created doctor of divinity. Scarcely had he been honoured with this degree, before his patron was translated to the see of Canterbury, and Dr. Pell became bishop of his diocese. Such an appointment is generally considered to be a step to higher preferment, but Dr. Pell was so intent on his studies as to neglect his own interest, and it is said he was so imprudent, with respect to the management of his worldly affairs, that he would have disgraced the station of a dignitary. Anthony Wood says, "that he was a shiftless man, and his tenants and relations dealt so unkindly with him, that they cozened him of the profits of his parsonages, and kept him so indigent, that he wanted necessaries, and even paper and ink to his dying day."

In the mean time he distinguished himself as a fellow of the Royal Society, to which he had been elected in the year 1663. He gained few matters of work in that body, and was the inventor of some algebraical signs, of which a few have obtained a general reception, viz. \(\div\) for division; \(\div\) for involution, and \(\div\) for ergo, or therefore. In the midst of his incessant application to his studies, owing to the neglect of his pecuniary affairs, his embarrassments increased, and he contracted debts which occasioned him more than once to be thrown into the king's bench prison. He died in 1685, in the 74th year of his age. Besides the various labours already noticed of this gentleman, he wrote a demonstration of the second and tenth books of Euclid, and also of Archimedes' Arenarius, and the greatest part of Diophantus' Arithmetic. He left behind him a great number of manuscripts, which were, after a considerable time, obtained for the Royal Society; the collection contains not only Dr. Pell's mathematical papers, letters to him, and copies of those sent by him, but also several manuscripts of Mr. Walter Warner, an eminent philosopher and mathematician in the reigns of James I. and Charles I.

PELLA, in Ancient Geography, a town of Macedonia, near the sea, on the confines of Emathia. This city became the capital of the kingdom when Edessa was annihilated according to Ptolemy, and owed its grandeur to Philip, who had been educated there, and to his son Alexander, who was born in this place. Livy describes it as situated on an eminence surrounded by marshes, in the midst of which was a fortress, appearing like an island, and at a distance seeming to be joined to the city; it was, however, separated from it by a river which ran between their walls, and over which there was a bridge of communication. This river was called Litas, Loidias, and Lydus. Pella became a Roman colony. Alexander derives from this city the appellation of Pellaeus.—Alfo, a town of Greece, in Thessaly.—Alfo, a town of Judea, in the half tribe of Manasheh, on the other side of Jordan; situated on the torrent of Hircananaeas, and forming one of the boundaries of Phœna. This town is placed in Codex by St. Bon. Byz. and in the Decapolea by Piny.—Alfo, a town of Greece, in Achaia.—Alfo, a town, and a mountain of Ethiopia.

PELLA, in Geography, a town of Ruffia, at the junction of the Tofina and Neva; 20 miles S.E. of Peterburg.
Pella, in Ortnithology, a species of Trachius; which see.
PELLACK, in Zoology, the name of a young spout whale, often found in Zetland; where they run into creeks, and fo entangle themselves among the rocks, that they are cast on shore, or easily taken. Phil. Trans. No. 743, sect. 8.
Pellaconta, in Ancient Geography, a river of Aafia, in Meopotamia. Piny.
Pellacopas, a river of Aafia, in Meopotamia. Arrian de Exped. Alex.
Pellaeuspagus, a name which Alexander gave to the district in which was situated the town of Alexandria, which he built at the mouth of the Tigris.
Pellage, in our Old Writers, a custom or duty paid for fkins or leather.
Pellagra, in Medicine, probably from pella, the \(\beta\)in, and \(\alpha\)gracia, \(\varepsilon\)nervia, a sort of cutaneous disease, which was first described about the year 1771 by some Italian physicians, as occurring in many persons in the neighbourhood of Milan and Venice.

The disease appears to have been a species of lepra or \(\phi\)orissia; since, in common with those diseases, it commenced about the head and on the extremities with small red patches, upon which scales were afterwards formed, and sometimes chaps and ulcers succeeded. This eruption is said to appear first in the spring or summer, and to disappear with the return of cold weather; but it recurs with renewed violence in the following spring. Subsequently, it is affirmed, though the cutaneous affection ceases to be very troublesome the nervous system becomes greatly deranged; languor, dyspepsia, depression of spirits, and ultimately melancholy, and actual insanity, in which the patients have a particular tendency to drown themselves, ensue, and they sink under a failure both of the mental and corporeal powers.

There is something bordering upon the marvellous in this history of the pellagra; and as we have heard nothing of the disease in later times, when credulity is diminished and observation improved, it may perhaps be concluded, that the disease, to which this new name has been given, is nothing more than the common lepra or the \(\phi\)orissia, and that the nervous affections, said to be connected with it, were in reality accidental and independent of it. A full account of the disease may be found in Frapolli, "Animadversiones in Morbus, vulgo Pellagrum dictum," Milan 1771, (the first writer who noticed it); and in an essay by W. X. Janken, "De Pellagra, Morbo in Mediolanensi Ducatu endemico," Leyden 1787. (This essay was reprinted in Dr. Frank's "Delectus Opificorum Medicorum," vol. ix. art. 9.) See also

PELLANA or PELLANE, in Ancient Geography, a town of Laconia, S.E. of Belemina. It was washed by the Eurotas; and is thought to have been very ancient. In the time of Pausanias it had a temple of Eiculapius and a fountain called "Pellandia."—Alfo, a town of the Peloponnesus, in Arcadia.

PELLERGIN, Simon Joseph, in Biography, a French poet and ecclefaiftic, was born at Marseilles. He obtained, in 1704, the prizes of the academy for his "Epitile to the King on the Success of his Arms." He entered into the religious order of the Servites, but afterwards he obtained leave to remove into that of Cluny. He wrote several pieces for the theatres, and dramatized the history of the Old and New Testament, the Psalms of David, &c. He is also known as the translator of the works of Horace into the French language. He died in 1745.

PELLERGINI, Camillo, a learned historian and antiquarian, was born in 1508 at Capua. He was educated at the Jefuits' school at Naples, where, besides the usual studies, he acquired an accurate knowledge of civil and ecclefaifical law and theology. He entered into the clerical order, and having been sent to Rome, he diligently consulted the archives and libraries of that capital, and formed the defign of collecting all the ancient documents relating to his native place, and to the whole kingdom of Naples. For this purpose he made many journeys, and was at great ex pense in procuring copies of records and manuscripts, and in forming a collection of antiquities. The firft fruit of his labours was "L'Apparato alle Antichita di Capua," printed in 1651, in which he minutely defcribes all the parts of Campana Felice, and relates its history and feveral revolutions. He afterwards published a work entitled "Hiftoria Principum Langobardorum," containing the chronicle of the Anonymus Salernitanus, and several other historical pieces which had not yet been feen the light, illuftrated with learned annotations and diffarations. This publication was of great fervice in elucidating the history not only of those provinces of Naples which were under the fway of the Lombard kings, but of Italy; it was therefore republished in the collections of Burmann and Muratorius, and has been re-edited, with various additions, at Naples, 1749, by Sig. Fr. Mofia Prattii. This learned writer published other works on different subjedts, and had a great collection of MSS., as well of his own writing as others, which were unfortunately loft to the world by the following incident. Being in a bad ilate of health, he had given orders to a female domestic, that when he fhould be near his end, he fhould burn a large bundle of papers which he pointed out. One day overhearing the physicians prognosficate that he had not many hours to live, he too faithfully executed his command, to his own great regret, after he was somewhat recovered. He died at Naples in 1660, at the age of 65.

PELLERGRUE, in Geography, a town of France, in the department of the Gironde, and chief place of a canton, in the district of Le Réole; 12 miles N.N.E. of Réole. The place contains 1882, and the canton 4676 inhabitants, on a territory of 145 kilometres, in 17 communes.

PELLER, a town of Prussia, in the circle of Natan gen; 16 miles S. of Brandenberg.

PELLENA, in Ancient Geography, a town of the Peloponnesus, in the Argolid.

PELLENDORF, in Geography, a town of Austria; 10 miles W. of Zisterdorf.—Alfo, a town of Austria; 8 miles S.E. of Vienna.

PELLENE, in Ancient Geography, a town of the Peloponnese, in Achaea, S. of Ariontaurus. It was built round a mountain, and formed a beautiful amphitheatr. The inhabitants pretended that it took the name from Pallene, one of the Titans; but the Argians with greater probability ascribe its name to Pellené, the son of Phorbas, and grand-son of Triopas, who came from Argos to this place. Water was conveyed to this city by a beautiful acqueduct; and at a small distance was a gymnium. In this city were the statues of some famous athletes. Charon was one of them, and he, seduced by Alexander, affumed the sovereign authority, so that his country detefled him as a tyrant, whilst they honoured and crowned him as a victorious athlete. Near this town was a temple, on a spot consecrated to Neptune. About two leagues towards the S.E. from Pellené was a famous temple of Ceres the Myfian. In its vicinity feasts were celebrated for seven days, and after the third day no male could be found within the precincts of the temple. During the night the remaining females offered facrifices, and performed other ceremonies. The men afterwards turned and associated with high satisfaction after this separa tion. Pellené was defended by a fortrefs called Olorus to wards the S.E., and by the valour of its inhabitants long maintained its liberty; at length it became a part of Sicily, retaining its liberty to the time when the Romans took possession of Greece.

PELLENE, in Mythology, an epithet of Diana, given to her by the inhabitants of Pellené; and upon this occasion Piutarch tells us (in the life of Aratus), when her flature was carried in the processions, her aspect became so terrible that no one durft look upon it.

PELLENINKEN, in Geography, a town of Prussian Lithuania; 9 miles N.E. of Insterburz.

PELLERIN, Joseph, in Biography, an eminent medaliSt, born at Paris in 1683, was Parnellary-general and firft clerk of the French marine. Having obtained his demiffion after forty years' service, he devoted the remainder of his life to the study of antiquity. His collection of medals was the richest and moft valuable that was ever made by a private individual. It was purchased by the king in 1776. He contributed to the promotion of the numismatic science by a publication in nine volumes 4to. enriched with a great number of plates. It consists of a collection of medals of kings hitherto meditated or little known; a collection of medals of people and towns, inedit or little known; miscellaneous medals, supplements to the above, and letters on medallic subjedts. It is reckoned a very valuable work, not only on account of the beauty of the engravings, but of the learned and judicious explanations subjoined. The author died at Paris in 1782, in the 59th year of his age.

PELLERIN, Le. in Geography, a town of France, in the department of the Lower Loire, and chief place of a canton, in the district of Painbez; 12 miles S.E. of Paim bez. The place contains 1456, and the canton 839 inhabitants, on a territory of 1521 kilometres, in 7 communes.

PELLETS, in Heraldry, a name given to those roundlets which are black, called also aggeries and gun stones.

PELLICAN, or PELICAN, among the Cbreuf, a kind of double vefsel, ordinarily of gluf: used in working on leuis, by circulation. It has a tubulated capital, from which two opposite and crooked beaks pas ou-, and enter again at the belly of the cucurbit. Two matefasses, the mouth of one of which is infected into the mouth of the other, anfwer the fame purpofe with this vefsel. PELICAN also denotes an infliction used by furgeons, &c. to draw teeth.

Pellican.
PELLICAN, again, is the name of an ancient piece of ordinance, carrying a ball of six pounds; by the French made eight feet and a half, and by the Dutch nine feet long. See BEAR.

PELLICER, JOSEF DE OSSAU, SALAS Y TOBAR, in Biography, a man of considerable eminence in the literary history of Spain, was born at Saragossa April 22, 1603, and inherited a disposition to letters from his father D. Antonio Pellicer de Oliau, who left in MS. an epitome of Guribay's Great History, and a poem, entitled "Batavia Rebelde." He took an honorary degree at Alcalá, and from thence removed to Salamanca, and at the age of 22 took up his residence at Madrid, and in 1629 he was made chronicler or historiographer of Castile. The states of Arragon named him to the same office for their kingdom; but as it was already held by Francisco Ximinez de Urruce, it was decided that the reverion could not be granted: Philip IV. made him amends by creating him arch-historiographer for the kingdoms of the crown of Arragon; the duty attached to this office was to revile and correct the works of the chroniclers of the particular kingdoms. As a farther token of respect, the habit of the order of Montesa was given him, and afterwards exchanged for that of Santiago. These honours were far from profitable to the wearer, and Pelllicer was all his life poor. He died at the age of 77, worn out, according to the reports of his biographers, by incessant literary application. He was author of a great number of works, the titles of which, some time previously to his death, filled five folio pages. His learning is generally acknowledged, and his learned works are still consulted by the literati of different countries. Gen. Biog.

PELLICULA, in Vegetable Physiology, is a fine skin, which closely adheres to the proper tela, or skin, of some seeds, constituting an additional integument, concealing their proper colour and naturally polished surface. Gærtner improperly calls it epidermis; a name appropriated to the whole cuticle of the vegetable, as well as animal, body. This part is either membranous, and often downy, as in caryocarbus; or mucilaginous, and not perceptible till the seed is moistened, as in Salvia verbenaca. The latter is a curious influence of such a pellicle; and the seed is, in consequence, endowed with the, often very useful, property of extracting any small irritating body from the human eye. One seed, introduced under the closed eyelids, soon becomes, by the abstraction of moisture into the pellicle, enveloped with a mass of jelly, that usually entangles and sheaths the obnoxious substance. We cannot but consider the urticales of Gærtner, which covers the seed of Gneumopodium and some of its allies, as no other than a pellicula.

PELLISSON, FONTANIER PAUL, in Biography, an eminent French writer, born at Beziers in 1634, was descended from a family of great respectability in the profession of the law. The subject of this article loft his father at an early age, and he was left to the care of his mother, who educated him in the principles of the Protestant religion. He studied successively at Caïares, Montauban, and Toulouse, and acquired an intimate knowledge of the best authors in the ancient and modern languages. He applied himself profeSSIONALLY to the study of the law, and had already appeared with distinction at the bar, when he was feized with the small-pox. This cruel disease left a permanent weakness in his eyes, and so disfigured him, that he became a model of ugliness. He quitted the bar and retired into the country for some time afterwards; he came to Paris, and made himself known as a man of letters. In 1652 he obtained the place of a king's secretary, and applied with diligence to the affairs of the council, with which he became intimately acquainted. In the same year he read before the French academy an history which he had composed of that institution, and which was so much approved that a resolution was made to admit him a member on the first vacancy, and in the meantime to give him the privilege of being present and speaking at the meetings of the academy. His history was printed in 1653, and many successive editions of it were given. It is upon the whole a curious and interesting performance. M. Pellisson was brought into a conspicuous situation in the year 1657, by being appointed first clerk to the celebrated intendant Fouquet. The financial business into which he was now plunged did not impair either the diffinterestedness of his character, or the amenity of his disposition. His services were recompensed in 1660 by admission into the council of state, but in the following year he was involved in the fall of his patron, and, as having been one of his principal confidants, was committed to the Bastille. As it was found impossible to corrupt his fidelity to his former master, attempts were made to worm out his secrets by means of a German, a suppos'd fellow prisoner, who concealed craft under a gross and simple exterior. Pellisson was soon aware of his artifices, and treated him with so much politeness, that he converted him into a friend, and by his means kept up a constant correspondence with mademoiselle de Scudéry. During his imprisonment, he composed three memoirs in favour of Fouquet, which are reckoned among the most eloquent and best-written pieces of the kind in any language, and have conferred a lasting honour on his memory. They were, however, the immediate cause of increased rigour in his confinement. He was prohibited the use of pen, ink, and paper, and was reduced to write with the lead of his cæment upon the margins of books, or to use a kind of ink which he made with burnt crust tempered with wine. His whole company was a Baliqez, whole only talent was playing on the bagpipe. With vaft pains he trained a spider to come out of his hole at the sound of this instrument, and take flies from his hand. Books of controversy were another employment of his solitary hours, and he received in the Bastille those impreSSIONS which afterwards produced a change of religious profession. He preferred many friends in this forlorn situation; and Tannegui le Fevre had the courage to dedicate to him, while in his dungeon, his "Lucretius," and his translation of Plutarch's treatise on "Superflition." At length, after a confinement of four years and a half, he obtained his liberty, and thenceforth passed his life in lavishing praises upon the sovereign who had previously deprived him of it. He was taken into favour, obtained a royal pension and a brevet of entrance, and was made king's historiographer. His public recantation of the Protestant religion is supposed to have been one of the conditions of this favour. He soon after took the order of sub-deacon, and was preferred to an abbacy and a rich priory. It was with some reason, therefore, that he annually celebrated his reconciliation with the church of Rome. He gave a more interfering proof of the excellence of his disputation by commemorating the anniversary of his liberation from the Bastille with the annual release of some of the prisoners.

In 1671, Pellisson delivered at the French academy a "Panegyric on Lewis XIV." which was translated into several languages, and even into the Arabic, by a patriarch of mount Lebanon. He accompanied his royal master in his campaigns, and for some time was the only man of letters engaged in writing his history; but some offence which he gave to Monsieur de Montespan induced the king to transfer the appointment of historiographer royal to Boileau and Racine. Although Pellisson was thus deprived of his office,

Vol. XXVI.

he
he was ordered to proceed in his own historical labours; and he produced a "History of Lewis XIV., from the Death of Cardinal Mazarin in 1661, to the Peace of Nimoghen in 1678," in three vols. 12mo. It is more the work of a courtier than that of a faithful historian, yet it has been spoken of with applause by Voltaire and others. He totally disapproved of the dogmatizing system of projelyting, and he seems to have relied much more on the judicious distribution of the third of the savings delegated by the king for rewards to such as should conform to the established religion. He also employed his pen in controversy, and wrote "Réflexions pour les Différences de la Religion," and "Traité de l'Enchablable," which were composed with much art, and in a laudable tone of moderation.

After this Pellisson was made master of requêtes, and passed all the latter part of his life in great credit and prosperity. He died in February 1693. Besides the works above-mentioned, he wrote several pieces in verse and prose, among which were an "Abridgment of the Life of Anne of Austria;" "Lettres Historiques," being a journal of the king's journeys and encampments; "Recueil des Pieces galantes;" "Poëies Christiennes et Morales." Moret. Bayle.

PELLITORY of Spain, in Botany. See Anthemis. Pellitory, Bajard. See Achillea. Pellitory, Double. See Achillea, and Yarrow. Pellitory of the Wall. See Parlatoria. Pellonia, in Mythology, a goddes invoked at Rome, when her votaries wished to be delivered from their enemies, or from any thing that annoyed them.

PELLOUTIER, Simon, in Biography, pastor of the French Protestant church at Berlin, member and librarian of the academy in that capital, and ecclesiastical counsellor, was born at Lepic in the year 1694. He filled with high reputation the polls confided to him, and obtained a high character for erudition by his work entitled "Histoire des Celtes, et particulièrement des Gaulois et des Germanes, depuis les temps fabuleux jusqu'à la Prise de Rome par les Gaulois." Of this work, which is replete with learned and curious research, the best edition is that of M. de la Baydine, in eight vols. 12mo. and two vols. 4to. Pelloutier likewise enriched the Memoirs of the Berlin academy with a number of valuable papers. He died in 1757, highly respected and beloved for his learning and beneficence.

PELONIUM, a town of Spain, in the Taragonensis, and country of the Ligurians. Ptol.

PELOGE, a town of Asia Minor, in Lydia, on the confines of Phrygia. Steph. Byz.

PELOPIA, ΠΕΛΟΠΙΑ, in Antiquity, a festival celebrated by the Eleans, in honour of Pelops, for whom that nation had more veneration than for any other hero.

PELOPIDAS, in Biography, an illustrious Theban leader, was the son of Hippocles, of a distinguished family in Thebes. Though brought up in affluence, he adopted a frugal and simple mode of living, and emulated, in private and public virtue, his noble friend Epaminondas, though he had less mental cultivation than that hero. He married and had several children, but was more intent upon serving the state than improving his fortune. He made a campaign with the Theban auxiliaries, who marched to the aid of the Spartans in the Peloponnesian war, and in a battle fought at Mantinea, he received several wounds, and would have been killed, had he not been protected by Epaminondas. After this period, the citadel of Thebes being betrayed to the Spartans, Pelopidas with many of his friends fated their lives by flight. They took refuge in Athens, where they kept up a correspondence with those of their friends who remained at Thebes. Pelopidas, animated with the love of liberty and his country, was continually urging his fellow exiles to attempt the recovery of their native city out of the hands of foreign and domentic tyrants, and at length a plan was formed to collect the exiles, and to endeavour to effect a revolution. Pelopidas undertook to be the leader of this bold enterprise; and accordingly, with only eleven associates, he left Athens on a certain day in the middle of winter, and proceeded to Thebes. The party were in the habits of peacocks, with dogs and hunting poles, as if they were from the country on an hunting expedition. Thus disguised, they entered Thebes in the midst of a heavy fall of snow, which kept the doors of the people shut; but they were immediately joined by about thirty or forty others, who were apprized of their approach. The two Theban rulers were at an entertainment given purpossly by Phylldas; and although they received an intimation of the entrance of some exiles they paid little or no regard to the fact. A letter disclosing the whole conspiracy was received by Archias, one of the rulers, from an Athenian friend; but although he was told that it contained matter of great importance, he threw it under the bolster of his couch, exclaiming: "Bufinis to-morrow!" which afterwards became a proverbial saying. Whilst these perfons, half intoxicated, were easily dispatched by some of the conspirators, who entered the room in female habits, Pelopidas and his party had the more difficult task of breaking into the houses of two others of the supporters of tyranny and overpowering them. When this was effected, they fellied out into the streets, proclaiming liberty to all the Thebans, and arming all who joined them out of the shops of the armourers. On the next morning, they were joined by the body of exiles from Athens, and Epaminondas, who had abainted from the bloody scenes of the night, having collected all the most respectable citizens, put an end to the confussion and avowed the common cause. Pelopidas, who was universally hailed as the deliverer of Thebes, was placed at the head of affairs, and at his instigation measures were taken to recover the citadel from the Macedonian garrison. The fortess was surrounded, and compelled to surrender for want of provisions. The date of this revolution, which was the commencement of the Theban glory, is fixed at the first year of the 1oth Olympiad, or the year B.C. 380. In the subsequent war with Sparta, Pelopidas excercised all the talents of a brave and able general. He defeated the enemy at Tanagra, in which he flew their general with his own hand. Pelopidas is considered as the first who inspired the Thebans with the ambitious desire of ruling to distinction among the Iates of Greece, and extending their power by conquest. His military fame was of an earlier date than that of Epaminondas, though the latter came in time to be superior. It is, however, to the honour of both, that they lived in perfect amity, and concurred in every measure for the advancement of their country. Before the battle of Leuctra he supported with his voice the advice of Epaminondas for an immediate engagement, and at the head of the faced band he greatly contributed to the success of the day. He was joint-commander with that chief
in the expedition into the Peloponnesus, in which the city of Messene was restored, and partook with him the danger of a charge made against them on their return, for having illegally prolonged their command.

The Thebans, having requested the aid of the Thebans against the tyrant Alexander of Phere, Pelopidas was sent with an army into that country, and brought the king to terms. He afterwards marched into Macedonia, as arbitrator of a dispute in the royal family of that country, and the opinion entertained of his equity was such, that he was entrusted with a number of noble hostages for the purpose of securing tranquillity, among whom was Philip, father of Alexander the Great. He went a second time into Macedonia, where new tumults had arisen; and obliged Ptolemy, the usurper of the throne, to give his own son, with fifty others, as hostages for performing the conditions enjoined him. Returning through Thessaly with a small escort, he met with Alexander the Pherean at the head of his army, and with his colleague Iomenas went to him unarmed, trusting to the fairness of their character as ambassadors. The tyrant, however, feized their persons, and took them with him as prisoners to Phere. The spirit of Pelopidas supported him under this misfortune, and he even sent messages of defiance to Alexander, telling him that he acted very absurdly in putting to death so many of his own innocent subjects, and at the same time sparing him, who, he might be sure, would severely punish him for his perfidy, should he ever get out of his hands. Alexander, in return, asked, "Why is Pelopidas in such haste to die?" "In order," the hero replied, "that by my death thou mayest become the fonder hateful both to gods and men, and thus brought to destruction." Soon after this, Epaminonas was placed at the head of an army, with orders to invade Thessaly, and proceed against the tyrant. It was the object nearest his heart to extricate his friend from the peril that threatened him; therefore he forbore pursuing the Pherean to extremities, and by alternately acting upon his hopes and fears, brought him to consent to a truce, with the condition of releasing Pelopidas and Iomenas; after this was performed, he marched with them back to Thebes. The Thebans having discovered that the Athenians and Lacedemonians were negotiating a treaty against them with the king of Perus, sent Pelopidas to counteract it. He was received with great honour at the Perrhian court, and completely succeeded in confirming the former friendship between it and the Thebans, and in obtaining a declaration in favour of the liberty and independence of Greece.

Alexander continuing to oppose his neighbours, deputies were again sent to Thebes, requesting that forces might be sent to their aid, with Pelopidas to command them. An army was levied for the purpose; but as it was about to march, an eclipse of the sun struck a superstitious terror into the minds of the Thebans; and Pelopidas, not choosing to proceed with a disheartened army, took with him only 300 volunteer cavalry, and entered Thessaly, disregarding the warnings of the footslogers. When he arrived at Phalarus, he assembled all the Thebians who were the opposers of the tyrant, and marched in quest of Alexander. The latter, knowing that he had few Thebans with him, did not hesitate to meet him with a very superior force. The battle commenced, and while the event was still dubious, Pelopidas saw Alexander at some distance, rushed forwards, and loudly challenged him to single combat. The tyrant, however, thought it more prudent to flatter himself among the thickets of his troops, than to risk the trial. The noble-minded Theban, hurried away by an inconsiderate thirst of revenge, followed him almost alone, and beat down a number of his opposers; at length, covered with darts, and pierced through with spears, he fell dead, a victim to unrestrained ardour. The Thebans lamented him as their father, favour, and instructor, and the Thebians and allies joined in their expressions of sorrow. They, however, revenged his death by a total and bloody defeat of the enemy. His body was met in procession by the magistrates of the towns, the priests and young people bearing trophies and garlands; and the Thebians made an urgent request to be allowed to give it a funeral in their own country, which was granted, and performed with great solemnity and splendour. This event took place B.C. 364. Plutarch. Univer. Hist.

PELOPIS, in Ancient Geography, a name given to seven small islands, situated on the coast of the Peloponnesus, over-against Methana, according to Pausanias.

PELOPONNESUS, a peninsula in the south part of Greece, joined to the continent by an isthmus, formerly denominated the isthmus of Corinth, and in later times Examili. The peninsula now bears the name of Morea. The ancients called it by different names, of which the most known are Aphi, the Argolid, and Pella. The Peloponnesus was divided into several parts, which formed separate states; there were Laconia, Messenia, the Argolid, the Elide, Achaea, Sicinion, Corinth, and Arcadia in the centre; all the others were washed by the sea. Its form was very irregular; its length from N. to S. was about 125 geographical miles; and its breadth about 150 miles. The ancients compared it to a plantain leaf, and some of its inhabitants have represented it under this form on their coins. The medals of the Peloponnesus had for their type a tortoise. The name of Peloponnesus is of uncertain origin; and accordingly the Greeks ascribed its origin to a hero named Pelops, who migrating from Asia took possession of this part of Greece, and gave it his name.

The Greeks were divided into two nations, viz. the Dorians and Ionians. In the heit days of Greece, the Dorians had under their dominion the greatest part of the Peloponnesus, and a column was erected in the midst of the isthmus, upon which was engraved, towards the side of Athens, "this is not the Peloponnesus, but Ionia," and on the side towards Corinth, "this is Peloponnesus, and not Ionia." Notwithstanding its small extent, the Peloponnesus was, for a long time, the most considerable portion of Greece. The principal gulfs in its circuit were, the "Sinus Golichi," or gulf of Lacedaemon; the "Sinus Acti," or gulf of Corinth; the "Sinus Melisseni," or bay of Corone; the "Sinus Lacoicus," or gulf of Colochina; the "Sinus Argolicus," or gulf of Naples; and the "Sinus Saronicus," or gulf of Engia. The chief promontories were, the "Promontorium Scyllaeum," or cape Skilae; the "Promontorium Malea," or cape Malo; and the "Promontorium Tamarium," or cape Motapana. See the article GRAECIA.

PELOPS, in Ancient History, the son of Tantalus, king of Lydia, who is said to have been the last foreigner who arrived in Greece before the destruction of Troy. This prince, forced to fly from his country on account of the war which Troy had waged with him, to revenge the rape of Ganymede, retired into Greece, where he married in marriage, the daughter of Oenomaus, king of Pisa, ascended the throne, after the death of his father-in-law, and communicated his name to that part of the peninsula, which was from that time called Peloponnesus (which fee.). But his dominion extended also to Aetolia, and by his immense wealth he became one of the most powerful kings of Greece. The era of Pelop's arrival in Greece must have been about the 11th or 12th year before the Trojan war. Among other
fatalities of Troy, it is said that it could not be taken by the Greeks, unless they had the bones of Pelops; and they therefore sent for them to Pisa where he had been interred. The vessel was shipwrecked in its return, and some time after a peasant found upon the shore the shoulder of that prince, and hid it under the sand. The Plataeans went to consult the oracle, in order to be delivered from the plague; the priests ordered them to go and dig up the bones of Pelops; and perhaps, in memory of this event, they made an ivory shoulder, which they consecrated to Ceres, and the Pelopidae bore it afterwards upon their ensigns. Some of the ancient fathers contend that the palla- 
dium of Troy was made of Pelops's bones. The fable says, that the horses which drew Pelops's chariot had wings, and that they had been given to him by Neptune, the meaning of which is, if we believe Pindar and Palæphatus, that Pelops made use of a ship with sails to carry off Hippodamia.

PELORIA, in Antiquity, feals instituted by Pelorus, and celebrated by the Thesalians. They had a considerable affin- 
ity with the Satyraxis; for in thefe the maiffers served while their servants fat at table, as in the Chronia celebrated in Athens, in honour of Chrones or Saturn. At the festival of the Peloria, public entertainements were made for 
strangers and even for slaves, who were served by their 
maiffers; and it is said, that the practife, as well as the feaft, 
originated from this circumstance, that Pelorus was the per-
son who first gave imitation to Pelagius, that by means of 
an opening in the valley of Tempé the waters of Deuc-
lion's deluge were removed, which intelligence gave that 
prince so much joy, that he regaled Pelorius in a magnificent 
manneer, and infulted upon feizing him at table.

Peloria, in Botany, fo named by Linnaeus, from πηλός, a monifer, is a remarkable variety of the common Yellow 
Toadflax, Antirrhium Linaria, in which the flowers, na-
turally rinfent, with two long and two short flaments, and 
one fimple nectariferous fpur, become regularly five-cleft, 
with five fpurs, and five equal flaments. Linnaeus publifhed 
a difcourfe on the fpur, reprinted in Am. Acad. v. 1: 55, 
with a plate. He gives an interefting history of the 
first discovery of this flower, by a young infentent of botany 
little aware of its cuftom, who gave it to Olaus Cæfius; 
and by the latter it was fent to Linnaeus, who at first 
thought a trick had been played, by affixing flowers of some 
other plant to the Toadflax. But when these flowers them-
elves could not be referred to any thing, his cuftom was 
strongly awakened. This monifer, in short, overthrow not 
only his own furyim, but that of every other teacher, if we 
except the fober frutufith; who, no doubt, had they seen 
such a prodigy, would thence have deduced no fmall matter 
of triumph over their adverfaries, who contended for the 
importance of the flower in clasfification, above other plants; 
for the pilafl and fruit are not affe&ed by the above meta-
morphofs. How mighty Linnaeus in his turn have exul 
ted, in exhibiting the latter parts changed to a real leaf, in 
the double-blofomed cherry!—Exultation, however, does not 
justly belong to thofe who attempt to meafure their own 
powers with the wisdom of Nature. A little further en-
quiry discovered other fpieces of Antirrhinum fpurut to 
the fame change; nor are fimilar infances wanting in different 
genera of the Didynamia Anglofermica, which by this means 
are transferred to the Pentandra Monogyynia. Both arts of 
flowers are often found on the fame plant of Bignonia radia-
ts, and have likewife been obfferved, for many succifive 
feasons, by the writer of this, on the Antirrhinum in que-
tion, an approach towards which is drawn from the life, 
in Engl. Bot. v. 10. t. 658. The feeds from fuch altered 
flowers, nevertheless, do not appear more disposed to pro-
duce the Peloria than others. Indeed if all their progeny 
be not caufefully rooted out, the garden will soon be overrun 
with genuine A. Linaria, to the exclusion of the lefs vigo-
rous plants that bear monoftrous flowers, though the latter, 
if kept clean from weeds, continue in general true to their 
original metamorphofy, and increafe confiderably by root.

PELORIDES, in Natural History, a name given by 
tome to a peculiar species of chama. Bellonius, who firft 
used the word, never gives it alone as the name of the 
flhall, but only uscs it as an epithet derived from Peloro, the 
name of the place where a particular species of chama was 
very frequent.

PELORUM, in Ancient Geography, a river of Afia, in 
Iberia. Dion Cæfius.—Alfo, a promontory in the N.W. 
of Sicily, near the cape of Faro.

PELOS, in Geography, a town of Italy, in the Cadorin; 
cen feet miles N.E. of Cadoro.

PELOW, a town of Ava, on the left branch of the river 
Ava; 15 miles from Prome.

PELT-Root, in Agriculture, a difeafe in feep, which 
is often very destractive. See Ror.

PELT-roof, wool tripped of the skin or pelt of a dead 
seep.

PELTA, πέλτη, in Antiquity, a kind of buckler, used 
among the ancients.

The pelta was small, light, and more manageable than 
the para.

It appears from Virgil, and other authors, that the pelta 
was the buckler ufed by the Amazons: and Xenophon ob-
erves, that the pelta of the Amazons was shaped like a 
leaf of ivy. Pliny, speaking of the Indian fig-tree, fays 
it leaves are of the width of the Amazonian pelta. Ser-
vius on the Hæned fays, the pelta resembled the moon in 
her firft quarter.

PELTA, in Botany, a name happily adopted by Dillenius 
from the Latin language, (in which it means a flort, some-
what crescent-like, shield or buckler,) for the peculiar 
shields of one tribe of Lichens, firft separated as a genus 
by Hoffmann, under the appellation of Feltigera, and now 
retained by that of Pelidea; fee that article, and Lichenela.

Pelta, or targets, are almost always situated towards the 
margin or extremity of the frond, either on the upper or 
der under fide, being clofly attached to its furface, and each 
confifing of a fliatifh, or flightly convex, brown smooth 
dift; the border being acceflory, and hardly diftinguifhable, 
originating from the frond.

PELTÆ, in Ancient Geography, a town of Afia, in 
Phrygia. This town was well peopled, and situated at the 
dilatance of 10 parafangs from Celenes. Cyprus fecourned 
here three days, and was a fpectator of the Lupercalia 
which Xenias of Arcadia celebrated by facrifices and games, 
at which the prizes were curvycomb of gold. This town 
is not mentioned by Xenophon, Strabo, Ptolemy, and Ste-
phanus of Byzantium.

PELTÂN, Theodore Anthony, in Biography, a 
learned Jewift in the 16th century, was born at Pelts, in 
the diocafe of Liege, whence he derived his furname. He 
became a member of the Society of Jefus in the year 1552, 
and acquired celebfity by his profeffion in the Latin, Greek, 
and Hebrew languages, and his knowledge of philofophy 
and divinity. When Albert, duke of Bavaria, founded the 
university of Ingolftadt in 1556, he was appointed pro-
feffor of Greek and Hebrew literature in that feminary, 
and discharged the duties of his office with unceafing 
affiduity and fecuace. He was admitted, at different periods, 
to the several degrees, and in 1565 he proceeded doctor. 
Immediately afterwards he was called to the theological 
chair,
chair, which he filled with great reputation until the year 1754, when he retired to the college belonging to his order at Augsburg, where he spent his time in laborious study and writing till his death, which took place in the year 1784. He was the author of a work entitled "Theologia Naturalis, et Theologia myrtica." He was also author of many other works, chiefly on moral and theological subjects.

Gen. Ch. Cal. Perianth inferior, of four ovate, concave, erect, coloured deciduous leaves. Cor. cruciform, of four obovate, entire, flat petals, whose claws are shorter than the calyx. Stam. Filaments fixed, awl-shaped, the two opposite ones shortly, and equal to the calyx; authors simple. Pet. German roundish, compressed; style short; stigma simple, obtuse. Peric. Pouch roundish, compressed almost flat, entire. of one cell, not burbling. Seeds from one to three, roundish, compressed, emarginate.

Eff. Ch. Pouch nearly orbicular, entire, compressed, of one cell, not burbling, with from one to three seeds.

Obst. Juvenile reduces this genus to Clypeola, and he is followed by Lamarche; but the only genuine species of the latter, which is Lounhiasia, has toothed lamens, like Aflatum; and Gartner observes, that the valves of its pouch are really distinct and separable, which is not the case in Peltaria. He therefore retains the latter, for this particular reason more especially. In affiniting to this however we can only inftit upon the original species, P. Garinii, Wild. n. 2, appears by Burman's figure, Fl. Ind. t. 45. f. 1. to be, as Mr. Brown has suggested to us, probably an Isatis. P. cornes, Linn. Suppl. 296. has, as Willdenow observes, a pouch of two cells, with distinct valves and a membranous partition. Its habit is like a Heliotrope. Whatever it may be, it is so Peltaria.

1. P. alliacea. Garlick-scented Peltaria. Linn. Sp. Pl. 910. Jacq. Aufr. t. 125. (Bohdhscha; Crautz Stirp. Aufr. 121. t. 2. t. 1. t. 1.) Clypeola pereisius; Arcn. Spec. 1. 16. 6. Thalpsis montanae primum; Cluf. Hilt. v. 2. 130. P. pannonicum Clusii; Ger. Em. 266.) - Native of Rocky mountainous places in Austria, near the lofty Schneeberg. It was introduced into our gardens in the time of Clusius, as he himself mentions, and is still preserved, as a楷ual of connoisseurs, in botanical collections. flowering in May, and ripening a seed a month or six weeks later. The root is perennial. Plants like some species of Thalpsis, as perfoliata and alpestris, but larger. The leaves are ovate, entire, smooth, of a light glaucous hue, clasping the stem with their arrow-shaped base. Flowers white, rather small, in several terminal slender-flaked corymb, which at length become racemose. Pouches orbicular, but very irregular in their outline, about a quarter of an inch broad, reticulated with prominent veins, the calyx of much less diameter than the whole pouch. The herb when bruised has an unpleasant garlick scent, somewhat like that of Ery- fium Allaria. The seeds are bitter and acrid.

PELTASTEBES, sub-rugulis, among the Ancients, one who used the back and called pelta.

PELTATUM FOLIUM, in Botany, a peltate leaf, is so called from the infection of the footstalk into some part of its disk, whether towards the centre or near the margin, which mode of attachment is compared to a shield prefixed at arm's length. Such is the leaf of the Tropaeolum, whole infection is nearly central, and that of Pelargonium peltatum, in which it is nearer the base, sometimes, if we mistake not, gradually disappearing, or varying, into the common mode of attachment. See Pelargonium.

PELTIDEA, in Botany, so named by Acharius, from pelta, a target, in Pelata, and ἰδέα, an idea or thought; a genus of the natural order of Lichenes, for whole characters, with mention of some principal species, we refer the reader to that article, n. 18. The genus is divided, in the Method of Acharius, into four sections.

Section 1. EMPONTEA. Targets nearly marginal, on the upper surface of the frond. This section consists of ten species, of which venosa, Engl. Bot. t. 887, and the common canina, t. 2299, are examples; and from which is now excluded by its author the chlorophyllus, n. 7, as being a variety of Centaria sepincola. To this point we cannot speak; but collina, Engl. Bot. t. 1834, is now admitted by Dr. Acharius, as possibly distinct from rufescens, t. 2306, so that the number of species in this division remains unaltered.

Section 2. OPISTERIA. Targets nearly marginal, at the back of the frond. Two, which Acharius considered as certain species, form this section; polaris, (Jacq. Milc. v. 2. t. 10. f. 1.) and rufipinata, Engl. Bot. t. 305. To these are subjoined as doubtful, what we can aver to be no lefs certain and distinct than the others, parisiis, Engl. Bot. t. 2360, and cellulosa, a curious species brought by Mr. Menzies from the fruits of Magellan.

Section 3. PLEUROTHEA. Targets lateral, scattered over the upper surface of the frond. The beautiful croce, Engl. Bot. t. 498, is the only example.

Section 4. PEROPHORA. Targets lateral, sunk in hol- lows in the upper surfaces. The only certain species is faciata, ibid. t. 288. Two doubtful others, unknown to us, are efculenta and vellosiformis; the former described in Pallis's Travels, t. 1. f. 4: the latter by Bellardi, in his Appendix to the Flora Pedemontana.—The plants of these two sections are now referred by Acharius to his genus Arboniis, a measure from which we have already, under the article above referred to, presumed to express our dissent.

PELTUINUM, in Ancient Geography, a town of Italy, in theterritory of Samnium.

PELUA, a town of Illyria, on the route from Sirmium to Solone, between Salva and Asinum, according to the Itinerary of Antonine.

PELUS, in Anatomy, is a large irregular bony cavity, open above and below, and forming the inferior end of the trunk. At the upper and back part its parietes support the vertebral column, and they are fullaned below and towards the front by the thighs, to which they transmit the weight of the body; thus a well-marked space, which measures the immediate base of support of the trunk, is left between the plane of the limbs and of the spine. In a well-formed individual the pelvis divides the body into two equal halves: that is, if a line be drawn across it's middle, the upper and lower portions of the body have the same length. This rule, however, is subject to some exceptions: the lower limbs are imperfectly developed in the fetus; and, in unusually tall or short adult individuals, the lower extremities or the trunk exceed the just proportion.

The pelvis is symmetrical, but of a figure not easily defined. It forms, by its upper portion, a cavity nearly oval in the transverse direction, expanded at the sides, and hollowed out in front, communicating by an elliptic opening, called the superior aperture (détruit supérieure), with its lower portion, which is much smaller in size, and ends be-
PELVIS.

low by an opening called the inferior aperture (détroit inférieur).

Lines drawn from one side of the pelvis to the other are horizontal, because, on account of the symmetry, the parts on the two sides are exactly on the same level.

The position of the pelvis is oblique, the back part being considerably higher than the front: this obliquity is well seen in the superior aperture, which slants very manifestly from above downwards and forwards: the inferior aperture looks downwards and backwards. S-semierring plates, that in the erect attitude, the last bone of the coccyx is an inch higher than the inferior edge of the symphyysis pubis; and that the promontory of the sacrum is higher than the same point, by the whole depth of the facrum and coccyx. (Osteologia, § 432.) The symphyysis pubis is oblique, from before backwards and downwards; and the upper part of the facrum slants in the same direction. The axis of the upper or broad part of the pelvis (the greater pelvis) is nearly perpendicular: that of the smaller or lower division (the lesser pelvis) slants from above downwards, and from before backwards. It is said to correspond to a line drawn from the apex of the os coccygis to the umbilicus. This line would cut the level of the pelvis nearly at a right angle: that is, the meeting of the two lines would form an angle of 75 degrees in front, and of 105 behind. The weight of the trunk being obliquely transmitted to the thighs, in consequence of this inclination of the pelvis, it follows, says Bishop, that the latter is the result of a decomposition of motion in this transmission, proportioned to the degree of inclination, which is about thirty-five or forty degrees at the upper part, where we can easily estimate it by the line, which extends from the sacro-vertebral articulation to the upper edge of the symphyysis pubis.

The capacity of the pelvis differs remarkably in man and woman. It is manifestly larger in the latter in every direction: thus the two iliac cribles, the two anterior, and the two posterior spines, the cotyloid cavities, the tuberosities of the ischium, &c. &c. are further apart. These are all transverse measurements, and those from before backwards are greater, as we may see in measuring from the facrum to the pubes, from the anterior to the posterior spine, from the sacro-iliac articulation to the foramen ovale, &c. The oblique measurements, from one side to the other, are also larger in the female. The superior aperture often exhibits deviations from the accustomed arrangement, in the diminution of its diameters subsequently to birth; and these are generally caused by rachitis, which exerts its effects more on the antero-posterior, than on the transverse or oblique diameters, because the weight of the upper parts, transmitted by the spine, is the principal exciting circumstance.

The breadth of the pelvis in the female produces some difficulties in progressio; but the passage of the child in parturition is facilitated. It performs an important part in this function, besides having the same offices as in man, even those of forming the basis of support to the trunk, and of containing and protecting the viscera.

The comparative height of the pelvis in the male and female is exactly the inverse of the breadth. The measurement from the crista of the ilium to the tuberosity of the ischium, the depth of the symphyysis pubis, and the length of the canal formed by the smaller pelvis, are considerably greater in men than in women.

There are some individual varieties in the dimensions of the pelvis, but they depend very little on stature. Parturition is as easy in small as in large women, although the former frequently produce very large children.

The pelvis is formed of few but very broad bones, united in such a manner, as not to admit of motion on each other: it can be moved therefore only altogether, and not partially. Four bones enter into its composition; two posterior, symmetrical, and placed on the middle line, are the facrum and coccyx; two anterior and irregular, transmit to the thighs the weight of the trunk, which they have received from the facrum; they are the os innominata. The facrum and coccyx, placed at the back of the pelvis, form a continuation of the vertebrae, and are constructed in a mode similar to that of the vertebrae. In most quadrupeds this prolongation of the spine is much more extensive, and forms the tail, which goes considerably beyond the anus, while in man, that opening is situated a little farther than the end of the coccyx. The facrum and coccyx are described under the article Spine; the os innominata under Extremities.

Articulations of the Pelvis.—The relations of the vertebral column to the pelvis are maintained by the articulation of the last vertebra to the facrum, and to the os innominatum. The coccyx is articulated to the facrum. The two os innominata are joined to the sides of the facrum, and to each other in front.

1. Sacro-vertebral Articulation.—It is formed by two articular surfaces, belonging to the lumbar vertebra and the facrum, and resembling, in every respect, those by which the vertebrae correspond to each other. The uniting media are also the same with those described in the account of the vertebral column; viz. anterior and posterior vertebral ligaments, which are prolonged to the facrum, a fibro-cartilage between the latter and the body of the vertebra, a yellow ligament between the laminae of the latter and the back of the orifice of the sacral canal, an interspinal ligament uniting the middle ridge of the facrum to the spinous processes of the vertebra; and the supraspinal ligament, which ends here upon the facrum. The disposition and structure of all these, as well as of the synovial membranes belonging to the articular proceses, are exactly the same as those of the corresponding parts in the spine. (See Spine.) This articulation has however one ligament peculiar to itself, extending from the lower and anterior part of the transverse processes of the vertebra, obliquely outwards and downwards to the facrum, decollating the anterior fibres of the sacro-ilac articulation. It is short and strong, covered by the pia in front, by cellular tissue and ligaments behind.

2. Facro-coccygeal Articulation.—This is analogous to the joints of the spine: it is formed by two oval surfaces of the facrum and coccyx, strengthened by a fibro-cartilage, and by an anterior and posterior fibrous band.

The fibro-cartilage is analogous to those of the spine, but much thinner, and allows much freer motion of the connected parts. The three smaller pieces are connected to each other and to the first piece by fibro cartilages analogous to this. The little tendency of these fibro-cartilages to ossification explains why the four pieces of the coccyx remain so long separate.

The anterior ligament is very thin, and often scarcely perceptible. It consists of some parallel fibres, varying in length, connected from the pelvic surface of the facrum to that of the coccyx. Sometimes there are two more strongly marked lateral fasciculi.

The posterior is a much more considerable ligament, and, besides strengthening the articulation, has the office of completing the end of the vertebral canal. It is fixed above to the edges of the excavation, which terminates the canal, and descends perpendicularly to the spinal surface of the coccyx, on which it is expanded. It is covered by the skin behind, and has a few fibres of the glutus maximus adhering to it. In front it corresponds, first, to the end of the
the facral canal, then to the surface of the facrum within the excavation at the end of the canal, and lastly to the coccyx.

3. Connection of the last lumbar vertebra to the os innominatum: (vertebro-iliac articulation).

A ligament, called ilio-lumbar (lig. pelvis anterior superior et inferior) is the medium of connection. It is fixed to the point of the transverse procès of the last vertebra, and sometimes of the fourth also, goes horizontally outwards, and is fixed to the posterior and superior spine, and to the crista of the os innominatum.

Its fibres are often divided into several fasciculi, separated by cellular tissue, of which the superior are longer than the inferior ones. It is a strong ligament, covered in front by the psoas, behind by the vertebral muscles, corresponding above to the quadratus lumborum, and below to the facro-iliac ligaments.

4. Sacro-iliac articulation.—sacro-iliac symphysis, or posterior symphysis of the pelvis.

The broad and irregular opposed surfaces of the facrum and os innominatum are covered by a crust of cartilage, which has been generally represented as single, and common to the two bones. Bichat considers that each surface has its own covering, and that the involution of the facrum is rather the thickest. When the bones are torn asunder, the two surfaces are rough, and Bichat describes a soft whitish substance between them, which he regards as analogous to synovia. In the child this is white and really fluid, and the cartilaginous surfaces are much smoother and more distinct. The bones are tied together by the following ligaments.

The posterior or great sciatic ligament (ligamentum tuberofacrum) is thin, flattened, nearly triangular, and situated at the lower and back part of the pelvis. It arises from the end of the crista ilii, and from the sides and back part of the facrum and coccyx, being at first very broad: it becomes narrower and thicker, and pales obliquely outwards and downwards to the tuberosity of the ischium; in which it is inserted, growing again a little broader. A little prolongation runs beyond the tuberosity, and is fixed to the edge of the bone in front. This ligament is composed of fibres more oblique in their direction in proportion as they are higher, converging from the facrum to the os innominatum, and often separated by intervals occupied by a fatty cellular substance and vessels. It is covered behind by the gluteus magnus, of which the fibres are inserted in it. In front it corresponds, on the inside, to the keeler facro-sciatic ligament, to which it is united; on the outside to a triangular aperture separating it from that ligament, and traversed by the obturator internus, and the pudic vessels and nerve.

The anterior or small facro-sciatic ligament (lig. spinofo-facrum) is placed in front of the former, and resembles it in form, but is less oblique. Its attachments to the sides of the facrum and of the coccyx are confounded with those of the former. Thus it passes outwards and forwards, becoming narrower and thicker, and is fixed to the apex of the spinofo procès of the ischium. Its fibres are more nearly transverse in proportion as they are higher, separate into distinct fasciculi, and leaving cellular and vascular intervals between them. It corresponds behind to the former ligament, and to the pudic vessels and nerve. In front it contributes, as well as the posterior ligament, to complete the sides of the pelvis, of which the bony parietes are here interrupted. Its fibres are mixed with those of the coccygeous muscle.

A very strong flattened perpendicular ligament (ligamentum pofticum longum offis coxe, lig. facro-hippilux) pales from the pofterior and superior spine of the os innominatum to the lateral and back part of the facrum. The superficial fibres are the longest, and they become shorter as they are more deeply seated. It is a very strong compact ligament, and holds the two bones together nearly motionless in the natural state. A facriculus, situated more deeply than the former, (lig. pofticum breve,) goes obliquely from the posterior inferior spine to the facrum, and rather deviates from the former, to which it is much inferior in length and strength.

The facro-fciatic ligament is a large assemblage of dense, short, and close fibres, occupying the irregular space left between the facrum and os innominatum, behind their articular surfaces. It passes transversely from one bone to the other, and is attached to the rough unequal part behind the point of contact of the two bones. Its form is irregular, like that of the space which it occupies. The posterior fibres are the longest, whitest, and most distinct, and form a particular layer: in front they are shorter, in proportion as they are nearer to the articulation. Their resilience is so considerable, either in consequence of their number or shortness, that, when the facrum is forcibly detached from the os innominatum, the ligamentous fibres are not torn, but detached from one or the other bone, leaving the surface bare.

Besides the two ligaments just described, several fibres of different length and direction pass over the facro-fciatic symphysis, from one side to the other, on its upper and anterior parts. They strengthen the joint, but do not require a particular description.

5. Symphysis Pubis.—Before we describe it, we shall notice a ligament, not belonging to it, but requiring, from its situation, to be considered in this place.

The obturator ligament occupies the foramen ovale, which it fills up almost entirely. It is a thin plate, fixed to the circumference of the foramen, except at the upper part, where a groove is left, comprising the channel through which the obturator veisels and nerve pass. Its fibres are interwoven in every direction, and form in many parts prominent fasciculi, which are particularly distinct near the groove. It corresponds, by its two surfaces, to the two obturator muscles, which are inserted in it.

The os innominata are joined in front by two opposed oval surfaces. Numerous fibres pass from one to the other: they are transverse, and more dense and close in the male than in the female. They may be seen by tearing the bones apart from behind. When they are ruptured in the middle, and not detached from the surfaces, as in the facro-fciatic symphysis. They form concentric laminae, which decussate, and the most superficial of which extend round the joint, while the others occupy only the upper or lower portion. In some subjects the fibrous laminae arise from the whole breadth of the articular surfaces; and in others, particularly in women, these surfaces present behind two small cartilaginous incrustations, contiguous to each other, moistened by a whitish or yellowish fluid, but not furnished with a distinct synovial membrane. Sometimes these cartilaginous incrustations occupy nearly the whole breadth of the surfaces in women, and then the fibres are in smaller quantity. The latter and the cartilaginous incrustations are in an inverse ratio to each other, and the proportions are very variable. According to these varieties the bones are more or less strongly tied together.

This and the facro-fciatic symphysis form a kind of connection intermediate between the moveable and immovable articulations.

The following ligaments strengthen this articulation.

A thick and distinct facriculus of triangular shape (lig. four-pubien) occupies the upper part of the arch of the
pubes, which it completes, being fixed to the oblique ramus of each bone at its upper and internal part. Its fibres are long below, and correspond to the cellular tissue about the urethra; they are shorter above, and continuous with the interarticular fibres.

The anterior ligament is not so distinct as the last. It is decubitated and covered in front by the aponeurosis of the abdominal muscles, under which it forms several frata. The most superficial consists of oblique fibres, which arise at the upper part of the articulation, separate from each other as they descend, and form two faciculi, which are loft on the front of the two branches of the arch. The others have an oblique or transverse direction, are much stronger, and go from one bone to the other, confused below with the interarticular lamina.

The articulation is surmounted above by various fibres, which strengthen it; the interarticular laminae project behind towards the pelvis, and this prominence, which is most considerable in the female, marks the middle of the junction.

General Description of the Pelvis.—The pelvis, taken altogether, is a cavity of conical form, of which the base is formed upwards and the apex downwards. We have to consider in it the external and internal surfaces, and the superior and inferior circumferences.

The external surface comprehends four regions: an anterior or pubic, a posterior or sacral, and two lateral or iliac.

The anterior is the least extensive, and exhibits, if, on the median line, the symphysis pubis, which is longer in men than in women, and covered by ligamentous fibres; adly, on each side, and from within outwards, the quadrilateral surface, to which the adductors are fixed, the foramen ovale, and the cotyloid cavity.

The posterior region, longer but feebly narrower than the preceding, offers, if, on the middle line, the series of fascial sinuous procresses, or the continued ridge, which supplies their place; the triangular excavation, which terminates the sacral canal; a future indicating the union of the facrum and coccyx; and the spinal surface of the latter. adly. On each side, and from within outwards, the fascial channels, and their foramina; a deep depression corresponding to the facro-iliac symphysis, which is covered by a thick layer of ligamentous fibres; and the posterior prominent tuberosity of the os innominatum.

The lateral regions are formed by the broad external surfaces of the os innominata, bounded below by the ifchiatric notches.

The internal surface is manifestly divided into two portions: a superior broader one, or the great pelvis; an inferior, which is narrower, and forms a kind of canal, called the smaller pelvis, or simply the pelvis.

The great pelvis presents, behind, the facro-vertebral articulation; and on the sides the internal iliac fosse. The superior portions of the os innominata are expanded horizontally, and sustain the principal weight of the abdominal contents. This arrangement is connected with the erect attitude of the human subject. For a further explanation of the differences between the pelvis of man and animals, see the article Man. The bony parieties are not continued towards the front, where there is a large excavation, filled by the abdominal muscles.

The inferior aperture of the pelvis is the more or less prominent line, beginning from the sides of the facrum, extending obliquely downwards and forwards along the middle of the os innominatum, where it is called linea ili-pectinea, to the upper and front part of the pubes, and forming the communication between the great and the small pelvis. It describes an oval, with the long axis placed laterally, and is much more strongly marked in front than behind.

The small pelvis, much narrower, but longer than the great, forms a kind of canal, wider in the middle than at the ends, and filled by the bladder and rectum in man; and by the same parts, with the addition of the uterus and vagina in women. We observe, in front of it, two surfaces corresponding to the bladder, separated by the symphysis pubis, and bounded by the thyroid foramina; behind, the concavity of the facrum, with its foramina, terminated by the lines which mark the facro-iliac symphysis; on the sides, the sciatic notch completed by the ligaments of the same name, and the quadrilateral surface, which separates the notch from the foramen ovale.

The superior circumference forms a very irregular line, slightly inclined forwards, and very much expanded in the female. It presents, behind, the facro-vertebral articulation, bounded on each side by a marked depression, in which we observe the trace of the facro-iliac symphysis; in front, the large excavations already noticed, formed by the anterior portions of the upper edges of the os innominata; on the sides, the two iliac crura. The inferior circumference, called also the inferior aperture, is directed downwards and backwards, and is remarkable for three eminences separated by three notches. The two anterior prominences are the tuberosities of the ifchia: the posterior and middle one is formed by the coccyx, which does not descend fo far as the tuberosities; so that, in the fitting attitude, the latter alone support the weight of the body. The notches have an arrangement exactly in reverse of that of the prominences: two are posterior, and one anterior. The latter is called the arch of the pubes. The oblique and oblong portion, which bounds the foramen ovale in front, contributes on each side to its formation. It is terminated above by an angle, nearly acute in man, rounded in women, occupied almost entirely by the generative organs and urethra in both sexes. The posterior notches lie between the facrum and the tuberosities of the ifchia. The facro-sciatic ligaments divide each into three portions: the superior is a large hole, through which the pyramidalis muscle, the sciatic nerve, and the glutæal, sciatic, and pudendal vessels pass. The second is a less extensive hole than the former, giving passage to the obturator internus, and the pudendal vessels. The third is the general opening, placed in front of the coccyx, and between the facro-sciatic ligaments, in which the termination of the rectum is placed, surrounded by much cellular tissue.

We have flated already, in general terms, that there are great differences between the male and female pelvis; that the latter is wider in all its dimensions, and deeper from before backwards, while the former measures the most in the perpendicular direction. Hence the cavity of the pelvis is more capacious, and fitted to receive the uterus and vagina, in addition to the parts which it contains in the male, and to give passage to the child in parturition. The distinctions of the two sexes, in this respect, are to be traced through all parts of the pelvis. The ilia are more horizontally expanded, the facrum more convex, the arch of the pubes much wider and more rounded above in the female than in the male. The superior aperture in the latter has a contracted triangular figure, with the base turned backwards, and the apex forwards; the inferior aperture is remarkably small, when compared to that of the female. In consequence of this great width of the pelvis in women, that is the broadest part of their trunk, while in man the shoulders are the broadest, and the pelvis the narrowest.
The following is a comparative view of the dimensions of the male and female pelvis, taken from Soemerring's Osteology, § 246. The measure is probably Rhenish, of which the foot is to the English as 1033 to 1000.

Progressive Development of the Pelvis.—The foetus, the adult, and the old subject, present essential differences in this part.

In the foetus it is small in proportion to the rest of the body; it follows, in its growth, nearly the same laws as the lower limbs. This disproportion contributes to the marked prominence which the abdomen of the foetus presents. The smaller parts of the pelvic cavity leave no room for the intestines in that part; even the urinary bladder is in the abdomen, which is moreover dilated in consequence of the great bulk of the liver. The size of the abdomen, which is very considerable from the causes above-mentioned, becomes more striking in consequence of the pelvis being so very small.

The upper part, or great pelvis, which belongs to the abdomen, is more developed than the lower, which contains the generative organs, and affords the point of support to the lower limbs. The iliac fossae are not so much expanded horizontally, nor so deep. All the dimensions of the pelvis are very small at this time; but the transverse measurements are particularly contracted. The direction of the cavity is more inclined.

The middle of the facrum, which is concerned in forming the vertebral canal, is already much advanced, but the lateral portions are more backwards; since the foramina are proportionally nearer to the facro-iliac synphysis. The posterior prominences hardly exit. The spaces corresponding to the bodies of the vertebrae, like those bodies, are rounded and imperfect in front, more developed behind, where they form the canal. The coccyx is small, and contains only ossaceous rudiments.

The three portions composing the osa innominate are developed towards their middle; but the circumference, and all the prominences, are cartilaginous. The cotyloid cavities are almost entirely in this state, and not capable of affording to the thighs a degree of resistence sufficient for the purposes of standing and walking.

As age advances, the pelvis is more developed to fulfill the important functions, which it has to execute in locomotion and standing, as well as in regard to the generative functions. It becomes lefs inclined in its position, and gradually acquires those proportions and dimensions which we have already indicated in the general description. Its development is earlier in the female than in the male, so that in many individuals the cavity is so far formed as to answer the purposes of parturition at the age of nine or ten years. The pieces which compose the facrum and os innominatum, are consolidated about the age of puberty. The cartilage between the rami of the pubes and ischium disappears sooner. The critic, and the tuberofities of the osa innominate, remain to a later period, and the former are the last in their completion.

The pelvis experiences very little change in old persons; its bones are very seldom ankylosed, except the facro-coccygeal articulation. Their unions, however, are more dense and solid. The general direction of the cavity is altered, the obliquity being lessened.

Mechanism of the Pelvis.—We must consider it as it is concerned in four principal functions: first, as the support of the trunk in standing and sitting; 2dly, as the point on which the thighs are moved; 3dly, as executing itself various motions; and 4thly, as forming a large cavity, lodging various important visera.

In standing, the pelvis is placed between two opposite forces; viz. the weight of the body transmitted to it by the vertebral column, and the resistence opposed by the thighs; hence it would be carried backwards on the thighs, if the powerful muscles extending from the latter to the front of the vertebral column, did not maintain it in the horizontal position. The bafis of support of the trunk then occupies the space included between the line of the spine, and of the hips. This space is narrower in the foetus and child, because the greater obliquity of the pelvis brings the thighs nearer to the line of the facrum; hence standing is more difficult, and becomes easier in proportion as the elevation of the pubes widens the base of support. The figure of the facrum, which is received like a wedge between the osa innominate, is well calculated for the office which it serves, of transmitting to the latter the weight of the trunk, and for preventing it from being depressed between them.

The pelvis rests on the tuberofities of the ischium in the fitting attitude; so that the bafis of support is rather enlarged towards the front, the line of these tuberofities being rather anterior to that of the cotyloid cavities. The horizontal extension of the lower limbs, either in whole or in part, according as we sit on the ground, or on a more elevated seat, is another circumstance contributing very greatly to extend the bases of support towards the front, in the fitting attitude.

In considering the pelvis as the point on which the lower limbs are moved, its mechanism belongs particularly to progression. The separation of the two cotyloid cavities produces an analogous separation of the thighs, and thus increases the extent of their motions. The pubes may be regarded in the lower extremity as having the same use with the clavicle in the upper; with this difference, that the latter is movable, and accompanies all the motions of the humerus, while the former is fixed. The interval between the acetabula is more considerable in the female, because all the transverse measurements of the pelvis are greater. Hence the progression of females has in it something peculiar, arising from...
from the greater portion of a circle which the pelvis has to
describe at each step. In the child, where the thigh bones
are nearer together, the motions are easier but less secure.
At this time the thigh-bones are equally approximated in
both sexes. The pelvis of the male and female hardly differ
in the facts; the dilatative characters are produced at a
subsequent age.

The pelvis may be moved on the spine, or on one or both
thighs. It cannot be moved on the vertebral column with-
out the whole body being prostrate; in that attitude it may
be bent, extended, or inclined laterally. These motions do
not take place entirely in the sacro-vertebral articulation, but
in the whole of the joints of the lumbar vertebrae; as the
more extensive motions of the head are effected by a general
movement in the whole neck.

Flexion of the pelvis upon the two thighs is not so easily
performed, as might at first be supposed. For, if the trunk
is much inclined forwards, the centre of gravity is no longer
fulfilled, and the body very quickly falls. The trunk has
two points of support; the cotylloid cavities above, and the
feet below, the slit of which is on a line posterior to that
of the pelvis. Hence, when the trunk is bent, the pelvis
remaining immovable, the centre of gravity must pass
beyond both in succedaneum, before a fall can occur. But, if
the pelvis is moved with the trunk, the centre of gravity
has a single base of support, and soon goes beyond it; con-
sequently the pelvis in general parts but little in these
motions; yet it is sometimes Oncentered, and then the hip-
joints are the centres of motion. In the latter case, the legs,
thighs, and pelvis, are carried backwards, so that the lower
limbs describe an oblique line, the upper part being thrown
much farther back than the lower. This inclination visibly
enlarges the basin of support, which would have been too
narrow, formed by the feet alone.

Extension of the pelvis on the thighs is not more marked
than flexion; indeed the ligamentous fibres on the front of
the joint prevent the thigh-bone from being carried back-
wards on the pelvis beyond a straight line, and must equally
prevent the corresponding motion of the pelvis on the thigh.
In inclinations of the trunk backwards, the loins are the seat
of motion, and not the hip-joints; when we extend this
motion as far as possible, the pelvis and thigh are both in-
clined. When the trunk is carried in this direction, the
knees are bent forwards, so as to give the legs an oblique
direction, calculated to support the line of gravity of the
trunk, because there is no basis of support behind, analo-
gous to what the feet offer in front. If we incline the trunk
backwards in any feasible degree, the lower limbs remaining
straight; a fall is inevitable.

Lateral inclination on the two thighs can hardly be said
to take place; in fact it cannot be deprected on one side,
without being raised on the other; and as the two limbs rest
at the same time on the ground, this motion cannot take
place.

The motions of the pelvis on one limb are quite different
from those which it performs on the two. It can be moved
with facility in every direction; lateral inclination and rota-
tion are easily executed. The latter movement is seen in the
pirouettes of dancers. It is very partial, the structure of the
hip being such that the pelvis can describe only a small
portion of a circle on the thigh.

The particular bones of the pelvis have scarcely any mo-
tion in the natural state, except the coccyx, which can be
moved forwards and backwards.

The osa innominata are entirely incapable of motion at
both their articulations; yet, if the lymphaticus pubis be cut,
there is a degree of mobility in the sacro-iliac joint. At the
time of pregnancy, or after several utero-foetalations, there
is a relaxation of these connections, allowing a visible mo-
tion between the two osa innominata at the pubes. This
phenomenon however is not confidant.

The organs contained in the cavity of the pelvis are ex-
cellently protected from shocks. The kind of arch formed by the osa pubis in front, the thick mufcles, the hip-joints, and the trochanter at the sides, and the muf-
cular masses of the spine behind, constitute an effectual pro-
tection for the resilience of injury. The projection of the osa
innominata beyond the fcarcnum behind, protects the
latter bone in cafes of blows or falls on this part of the pelvis.

PELVIS OF BIRDS. See Anatomy of Birds.

PELUS, in Ancient Geography, the name of an iland,
spatuated in the vicinity of that of Chios.—Allo, a mountain
of Italy, in Etruria.—Allo, a torrent of Sicily.

PELUS, in Geography, a town of Perisia, in the province
of Mecran; 54 miles N.N.E. of Rich.

PELUS ARMENA, in the Materia Medica, a name given by
some of the old writers to the drug that we at present call
bole armonica. This was the original name, and the term
boles armena is not to be found, but in the later writers.

PELUSIUM, in Ancient Geography, a town of Egypt,
at the eastern extremity of the lake Menzale, near one of the
mouths of the Nile, and, according to Strabo, about two
miles from the sea. Its name, which in Greek signifies mud,
proves its sitution to be in the midlt of lakes and marshes;
as does also the Hebrew term Sim, by which the prophet
Ezekiel denominates it; and also the Thamgh of the Arabs.
The period of its foundation, as well as that of the other
ancient cities of Egypt, is lost in the obscurity of time. It
flourished long before Herodotus. As it commanded the
entrance of the country on the side of Asia, the Pharaohs
rendered it a considerable fortress; one of them raised a
rampart 30 leagues in length, from the walls of this town to
Heliopolis. This rampart, which covered Pelusium, did not,
however, stop Cambyses, who attacked it with a formidable
army. Cambyses, after a bloody battle, in which he
slaughtered his enemies, entered Pelusium in triumph.

Pelusium, in Ancient Geography, a town of Egypt,
at the eastern extremity of the lake Menzale, near one of the
mouths of the Nile, and, according to Strabo, about two
miles from the sea. Its name, which in Greek signifies mud,
proves its sitution to be in the midlt of lakes and marshes;
as does also the Hebrew term Sim, by which the prophet
Ezekiel denominates it; and also the Thamgh of the Arabs.
The period of its foundation, as well as that of the other
ancient cities of Egypt, is lost in the obscurity of time. It
flourished long before Herodotus. As it commanded the
entrance of the country on the side of Asia, the Pharaohs
rendered it a considerable fortress; one of them raised a
rampart 30 leagues in length, from the walls of this town to
Heliopolis. This rampart, which covered Pelusium, did not,
however, stop Cambyses, who attacked it with a formidable
army. Cambyses, after a bloody battle, in which he
slaughtered his enemies, entered Pelusium in triumph.

Herodotus, who visited Pelusium some years after the
conquest of Cambyses, says that he surveyed the plain where
the two armies had fought, and found it covered with human
bones collected in heaps; those of the Persians on one side,
and those of the Egyptians on the other. Pelusium, after
passing under the dominion of Persia, was taken by Alex-
ander. The brave Antony, general of cavalry under Gu-
binius, took it from his successors; and Rome restored it to
Ptolemy Anuletus. Pompey, after the fatal battle of Phar-
alia, took refuge at Pelusium; but he had scarcely landed
on the shore, when Theodore, the rhetorician of the isle of
Chio, Septinius the courtier, and Achillius the enuch, who
commanded his troops, wishing for a victim to present to his
conqueror, flabbled him with their swords. At the fight of
the alifainfs, Pompey covered his face with a mantle, and died
like a Roman. They cut off his head, and embalmed it, to
offer it to Cesar, and left his body naked on the shore.

Pelusium was often taken and pillaged, during the wars
of the Romans, the Greeks, and the Arabs; but in spite
of her dilatlers, the preserved, to the time of the crusades,
her military and her commerce. The Christian princes, having
it by storm, sacked it. It never again rule from its
ruins, and the inhabitants went to Damietta. Farama,

Pelusium
Pelusium gave name to the Pelusian branch of the Nile, but nothing now remains of it but ruins. This canal has now no communication with lake Menzalé, except that which is merely temporary, on the dwelling of the Nile; but at other times it is dry.

Pelusium, a port of Thebais. Steph. Byz.

Pelusino, in Geography, a small island in the Mediterranean, near the coast of Natalia. N. lat. 36° 45'. E. long. 28° 12'.

Pelusin, or Pelusinum, a town of France, in the department of the Loire, and chief place of a canton, in the district of St. Etienne; 13 miles E. of it. The place contains 3,200, and the canton 11,716 inhabitants, on a territory of 140 kilometres, in 13 communes.

Pemaquid, a bay of America, on the sea-coast of Lincoln county, in the state of Maine. It lies eait of Sheepscot river, and contains a number of islands, many of which are under cultivation. N. lat. 43° 43'. W. long. 69° 30'.

Pemaquid Point, a cape on the west side of the above bay, two miles E. of Booth bay, and about four leagues N.W. of Menhagen island. N. lat. 44° 5'. W. long. 69° 56'.

Pemar, a town of Sweden, in the province of Finland; 12 miles E. of Abo.

Pemaro, a town of Etruria; 15 miles E.S.E. of Leghorn.

Pemba, or Pendia, an island in the Indian sea, near the coast of Africa, about 100 miles in circuit, and governed by a king, who is tributary to the Portuguese. S. lat. 5° 55'. E. long. 42'.

Pemba, a province of Congo, bounded on the north by the province of Sundi, on the eait by Batta, on the south by Bamba, and on the west by Songo. It is divided into the province of St. Salvador, and the marquise of Bamba, from its chief towns. It is generally fertile, more especially towards the eait—Alfo, a town of Congo, and capital of a marquise; 75 miles S. of St. Salvador. S. lat. 7° 30'. E. long. 12° 52'.—Alfo, a bay of the Indian sea, on the coast of Africa. S. lat. 13°.

Pembroke Point, a cape on the east coast of the Isle of Wight. N. lat. 50° 42'. W. long. 1° 56'.

Pembroke, or Pembrooch, a borough and market-town in the hundred of Caillé-Martyn, and county of Pembroke, South Wales, is situated on a singular neck of land, dividing the small estuary of Dowa-Pool, which flows from Milford haven. It is the county town, and, next to Caermarthen, is one of the largest and richest towns in the southern division of the principality. The period of its foundation is unknown, but it is certainly of great antiquity, and is supposed to have derived its name from the British word Penbro, signifying a cape, or promontory. It was anciently fortified, and protected by a most magnificent castle, the vaft ruins of which still give it an appearance of uncommon grandeur; and was likewise defended by a strong wall, still nearly entire, on the northern side, where it is flanked by numerous ballions of great thickness and strength. Through this wall were formerly three gates, on the eait, north, and west sides; besides a small gateway on the north side, leading to the marsh. Of these gates, that facing the north is the only one now standing; the other two having been long since destroyed. The eait gate, which remained in Leland's time, is described by him as consisting of solid iron, and as being highly ornamental, and the mount on it built of stone. The corporation of Pembroke is composed of a mayor and council, two bailiffs and ferjeants at law, and about 1,500 burgesses. The mayor holds a court every four-
kind in Great Britain. Its figure approaches that of a circle, the diameter from north and south being 76 feet 8 inches, and from east to west 57 feet 4 inches. The natural opening, which was of great width, is built up, and contracted into a small door-way, that appears to have been once strongly barricaded. Above are the marks of four loop-hole windows, and of another door-way, now flopped up. Of the cist to which this vault was applied there is no account upon record, but it was most likely a deposit for stores of every kind, "the larder of the garnishment." At its south-east corner is an adit, traditionally said to communicate with Tenby; and under the south-east balcony of the castle is another very curious passageway, in some parts spacious, and in others extremely narrow, which has been explored to a considerable distance, but its termination is not known. This last is doublet, however, in a great measure a natural duct; apertures of a similar kind frequently appearing in most limestone rocks. It is supposed byfone to penetrate under the keep that rears its proud head in the centre of this magnificent ruin, terminating, as Leland observes, "with a roof of stone, almost in conus, the toppe whereof is keverid with a flat mill-stone." This building is 75 feet in height to the dome, and in girth 165 feet 7 inches at the base, the mean thickness of the wall being about 14 feet. It is divided into four stories.

The vicinity of the town presents many objects worthy of attention. Close to its south-eastern side is the village of Monkton, so called from its having been the seat of an ancient priory, founded by William Marshall, about the year 1120, as a cell to the Benedictine abbey of St. Martin at Sayes, in Normandy. Part of the priory church is still entire, as is likewise the prior's mansion; but the other buildings are in a state of great decay. From the varied style of the church, it has evidently been erected at different periods. That portion of it which is now appropriated to public worship, is completely modernized within, and scarcely a vestige of its former ornaments remains. This structure has long been the burying-place of the Owens of Orielton, and probably also of their predecessors the Wyre-riots, as some early monuments of the latter family still appear here.

The village of Castle-Martyn is situated about three miles to the westward of Pembroke. This place was formerly adorned with a magnificent castle, erected by some Norman chieftain of the name of Martyn, on the site of an extensive Britishearthwork. Few vestiges of that pile now remain, but they appear to have been pretty considerable in the time of Leland. Between this village and the county town is a curious moor, called Dry-Burrow, which is covered with tumuli, similar to those on the downs of Wiltshire. Northwards from the moor stands Orielton, the seat of the Wyrirods and Owen families; and beyond it is the village of Pellcrocho, memorable for a skirmish between the royal and parliamentary forces, in March 1648. In the church are several ancient monuments, in honour of the Benegers of Bagenlow. In the adjoining parish of Rhôferother is Jellington, the residence of a branch of the royal family of Wales, previous to the conquest: it is now the property of the family of Meares. Further to the westward is the village of Nantlle, which was formerly a place of very considerable consequence, and had a castle attached to it, some vestiges of which are still visible near the extreme point of the curved promontory, which forms the bay of Nantlle.

Crefwell, the seat of John Allen, esq., is situated about two miles and a half to the west of Pembroke. The house occupies an elevated site, overlooking the river Crefwell. Beyond this, on the same road, stands Carew-castle, one of the most conspicuous features of this county, and celebrated as the residence of characters of great distinction at different eras. It was a royal residence, and formed part of the dowry of Nell, daughter of Rhys ap Tudur, who married Gerald de Windsor, lieutenant to Henry I., after the outlawry of Armlph de Montgomery. The defenders of this lady took the name of Carew, and continued to profit the castle till the reign of Henry VII., when it reverted to the crown, and was granted to Sir John Perrot. In the time of the great rebellion, it was garrisoned for the king, and withstood a long siege; but after the ill success of the royalists at Tenby, it surrendered upon quarter. Subsequent to that period it has been suffered to go to decay, and now constitutes a most magnificent and picturesque ruin. Its form is that of a quadrangle, with a court in the centre, and an immense bailey at each exterior angle. The architecture of this pile belongs to various ages, but a great part of it is undoubtedly coeval with the original structure. The north front is peculiarly grand and majestic, and can boast of windows "than which nothing more nobly magnificent is known in the kingdom." On the south-west side appear a number of old towers, all differing from each other in height, diameter and form. On three sides this castle is bounded by water, but to the south was formerly a very extensive deer-park, the outer wall of which is yet apparent in many places, though it is divided into several distinct enclosures, in one of which Sir Rhys ap Thomas held a tilt and tournament, which was the first flow of the kind recorded to have been exhibited in Wales. Near this is Nantlle stands one of the early croftes, richly ornamented with true-love knots, &c. and having an inscription upon it, which, though often copied, and submitted to the examination of the curious, has never yet been accurately deciphered. The church here contains several ancient monuments, with effigies and inscriptions in memory of various members of the Carew family.

The other places of note situated in this part of the county are Lawrenny, the seat of Hugh Barlow, esq.; Upton, a castellated mansion, anciently the residence of the Malefants; and Lamphey, or Lanfey-court, a noble ruin, once the favourite palace of the bishops of St. David's. A chapel, adjoining this palace, exhibits the remains of a very finished piece of masonry. Stackpool-court, the seat of Lord Cawdor, also deserves mention. It is built on the site of a former castellated structure, and is certainly one of the most splendid modern mansions in Wales. It has two fronts, and is surrounded by very extensive and well-wooded pleasure-grounds, which are further adorned by a beautiful lake, and most luxuriant gardens. The edifice of Stackpool being the only safe and commodious landing-place on this coast, it was much frequented by the predatory chieftains of ancient times, and particularly by Earl Harold, some of whose successeys are supposed to have been commemorated by three large upright stones, which are fixed here at the distance of about a mile from each other. A Historical Tour through Pembrokeshire, by Richard Fenton, Esq., F.S.A., 1811. The Scenery, Antiquities, and Biography of South Wales, &c. by Benjamin Heath Makin, Esq., M.A., F.S.A., 2d edit. 2 vols. 8vo., 1807. The Itinerary of Archibald Baldwin through Wales, A.D. 1187, by Giral- dus de Barri, translated, &c. by Sir Richard Colt Hoare, Bart., F.R.S., F.S.A., 2 vols. 4to., 1806.

Pembroke, a township of America, in Plymouth county, Massachussetts; 30 miles S. by E. from Boston; incorporated in 1752, and containing 1945 inhabitants. Some welfells have been built here. — Alto, the Suncook of the Indians, a township of Rockingham county, New Hampshire,
on the east side of Merrimack river, opposite to Concord; incorporated in 1750, and containing 982 inhabitants.

PEMBROKE, or PEMBROKESHIRE, one of the southern counties of Wales, is bounded on the south by the Bristol channel, on the west and north by St. George's channel, and on the north-east and east by the counties of Cardigan and Caermarthens. It is irregular in its form, and deeply interfefted throughout its extensive coast by bays and havens. Its extreme length north from south is about 35 miles, and its greatest breadth from east to west 29. According to the most accurate surveys, its superficial content amount to 335,600 acres. According to the population report of 1811, this county is divided into the hundreds of Caftle-Martyn, Dewifland, Dungleddy, Kemefs, Kilgerron, Narberth, and Roafe; and contains the city of St. David, and three towns, i.e. Pembroke, Haverford-weft, and Tenby: it also comprises 142 parishes, and 3 hamlets. The number of houses is flated to be 15,024, inhabited by 60,615 persons, of whom 27,453 are males, and 33,162 females.

At a very remote period this county formed part of the kingdom of Demetia, or Dyvet, which inhabited as an independent monarchy till conquered by Ethelwoif, king of England. Brogmlaen, king of Demetia, is mentioned as one of the princes who affifted Caflibracans in compelling Julius Caesar to evacuate Britaff. How far this ancient kingdom extended is uncertain; some supposing it to have comprised the three counties of Cardigan, Caermarthens, and Pembroke; and others, that it was confined to the last mentioned county only. In the time of the Danifh invasions, this county suffered more injury than perhaps any other in the principality. Among the chieftains who commanded in these depredations were Hubba and Ivar, or Inguar, both of whom are described by the old writers as men of the "moll dreadful ferocity and unheard-of courage."

The name of Pembroke, or rather Pembroch, first given to this county shortly after the Norman conquest, and was evidently derived from that of the town which forms the subject of a former article. This district is not unusually called by the old writers, and even vulgarly at the present day, Little England beyond Wales, from the circumstance of the inhabitants in the hundred of Rhos being descendants of Flemings and English, and its courts being formerly subject to the king's writs, as appears by several inftances of removed pleas, as late as the reign of Henry VI. Concerning the settlement of the Anglo-Flemifh colony here, considerable uncertainty prevails in the writings of historians; some afferting that the Flemings, who had previously settled in England, were driven out of that county by Henry I., and feized upon Rhos as depredators; but others, with more probability, contend, that they came hither under the fignation of the English prince. That they eventually obtained his protection is undoubted, for he placed among them a great number of his own subjefts, to teach them the English language, and attach them to English interests. This object he seems to have fully succeeded in; for we find that the English inhabitants of Pembroke were afterwards chief officers in the subjugation of the remaining portions of Wales. Many attempts were made by the Welsh to extirpate them from the country, but the most determined efforts proved wholly availavable. At Llandilovery the decisive battle was fought between Edward I. and Llewellyn, which ensured the final conquest of Wales, and its annexation to the English crown.

In later times, Milford, a port in this county, is remark-
harbours and great extent of coast. Haverford-west is the only town within its limits which has a cotton manufactory of any consequence; and all the attempts hitherto made for the introduction of the linen business have completely failed. Milford and Fishguard alone can justly claim the appellation of trading ports, and even in the towns the imports and exports are extremely limited; but they are certainly suf-

ficiently large to augment, with a very little exertion and expense. Indeed we have no doubt, but that the spirit of manufacturing and commercial enterprise was once properly excited and fostered, Pembrokeshire would, from its natural advantages of situation, soon become the trading emporium of Wales. At Milford has lately been established a South sea whale-fishery, which is in a flourishing condi-
tion; and we are happy to observe, that the fame thing may be affirmed of the herring-fishery at Fishguard, though it might be improved to an almost unlimited extent.

Pembrokeshire abounds with objects of antiquarian curiosity and interest, of almost every kind and era. Druidical circles and cromlechs are frequent, of which the principal are those near Caflle-Hendrev, Drefwon, Trellys, Longhouse, Lch-y-dribedd, Pentre-Evan, and Caflle-Martyr.

Single stone monuments are also numerous, particularly along the coast, where they are conjectured to have been raised as memorials of predatory battles. The great Roman road to Menapia, St. David's, enters the county near Llan-
dewi-Velfry, and proceeds by Haverford-west and Roch-Caflle, almost on the same line with the present turnpike-
road from Caernarthen, which it crosses at different points. Another Roman road led from the great road to the itation, called Ad-Vicidum. But the most important antiquities are its castles, of which there are nineteen mentioned as belonging to princes and great barons. Some of the churches in this county are likewise objects worthy the attention of the antiquary. The cathedral and palace of St. David's are particularly entitled to attention. See St. David's; also Norris's Architectural Antiquities of Wales, 4to. Fenton's Historical Tour in Pembrokehire, 4to, 1811. Cambrian Register for 1796. Camden's Britannia, vol. ii.

PEMIGEWASSET, a river of America, in New Hampshire; one branch of it proceeds from Moufe-hi lock mountain, another from the four-west extremity of White mountains, and a third from the township of Franconia. It's course of about 50 miles is generally south, and it receives its fource by a number of fires. After the union of the Winnipocée river, at the lower end of Sanborn town, it bears the name of Merrimack for the sea.

PENMANUR, a fort of Hindoostan, in Bahar; 31 miles N.W. of Durbungah. N. lat. 26° 29' E. long. 83° 45'.

PEMPHIGUS, in Medicine, from μηδεις, bulla, a bubble or blister, has been variously called the vesicular fever, febris vesicularis, amputella, and bullula, by the continental physicians, who have mentioned the disease.

From the descriptions of a few of these writers, Sauvages constituted this disease a distinct genus, in his system of no-
tology, and gave it the appellation of pemphigus, which has been adopted by subsequent authors, with the exception of Linneaus, who designated it by the barbarous term moria, conceiving it to be a mortal mortal pestilence. Febris diaria, maligna, functuflima. (See his Genera Morb., clafs i. gen. 1.) Upon the authority of Sauvages, and the authors whom he quotes, the pemphigus has been defined an idopathic, contagious, and malignant fever, in the course of which, phlyctene or vesications, of the size of a filbert, with an inflamed base, appear in succession on different parts of the surface of the body, and sometimes in the mouth. See Sauvages, Nofoi. Method., clafs iii. gen. 3. Cullen, Nofoi. Meth., gen. xxxiv.

Nevertheless, it is pretty clear, from an examination of the imperfect histories of the subject, that there is no such idopathic and contagious disease as has been defined a critical eruption of bullae, as has been thus defined, under the appellation of pemphigus. Dr. Cullen justly expressed his doubts of the accuracy of the original writers; and, after giving his definition of the disease, he says, "From the opinion of others, rather than my own, this character is taken; because I have seldom seen such a disease, and never have observed it epidemic, or purifying a regular course, as is here described." And in respect to the species, he observes again, "Since I have never seen a pemphigus, which I could consider as an exanthematos fever, and have found only very few observations in the writings of physicians concerning a disease of this kind, almost every thing inferred in my nomenclature must necessarily be taken from Sauvages; therefore, I have followed him, though I would willingly have omitted this malady, since almost all that has been said about it appears to me doubtful, obscure, and am-

biguous."

Dr. Willan has examined the matter more minutely, and pointed out the fallacious foundation, upon which the notion of such an epidemic contagion has been built. Sau-
vages has enumerated three species of pemphigus, not from his own observation, but merely from the descriptiion of three writers. The first species, pemphigus major, which is taken from a little cafe, related by Scalliger, (Ephem. Acad. Nat. Curios. Dec. 1. ann. vii. obi. 56.) which is worthy of little attention, was perhaps, as Dr. Willan fug-
gest, a mere erythema, with some incidental variation in

The account of the epidemic at Prague, mentioned by Thierry, (see his Medicine Experimentale, p. 134,) which is the prototype of the second species (pemphigus cafrensis) of Sauvages, is not entitled to credit, as Dr. Cullen remarked, in several of its circumstances: the bullae are supposed by Dr. Willan to have been symptomatic of severe typhus, or of phlebitic fever, in the same manner as they appeared in the plague of 1665 in Lon-
don, as described by Dr. Hodges, and as they are occasion-
ally seen, intermixed with petechiae and vires, or with patches of erythema, in typhoid fevers. Again, as to the third species (pemphigus helveticus) of Sauvages, which was borrowed by him from the description of Dr. Langhans, (in the Acta Helvetica, vol. ii. p. 26.) Dr. Cullen gives of his opinion, that the disease was in fact, cymanche maligna; and Dr. Frank viewed it in the same light; for he considered it as a variety of sciarlatina, accompanied with ulceration. Dr. Willan, who points out the unsatisfactory nature of the history given by Langhans, and the contradictions which it involves, proposes a query, whether the disease was not rather endemic, than epidemic or contagious, and referrible to death, or some other local cause, like the ergot, mal des ardens, &c. See his Treatise on Cutaneous Diseases, part iv.; and Bateman's Synopsis of Cutaneous Diseafes, p. 135.

In short, it is evident, that the description of an idio-
pathic contagious fever, terminating in a critical eruption of bullae, after the manner of the small-pox, and other exan-
thematos fevers, which Sauvages and the nofoiogists have
given us, has been founded in misconception; and that no such disease exists. Yet many cafes of bullous disease have been recorded, under the appellation of pemphigus, by medical men of considerable discernment. Those who are curious, and disposed to investigate the matter, will find such cases described by Mr. Gattfeill and Mr. Upston, in the
the Memoirs of the Medical Society of London, vol. iv. art. 1, and vol. iii. Appendix; by Mr. Chirat, in the Lond. Med. Journal, vol. x. p. 385; by Dr. Stewart, in the Edin. Med. Comment., vol. vi. p. 79; by Dr. Hall, in Duncan's Annals of Med., vol. iii. art. ix; by Mr. King, in the Lond. Med. Journal, vol. xi. p. 235; by Dr. Dickson, in the Trans. of the Royal Irish Acad. for 1787; and in the Lond. Med. Journ., vol. ix. p. 309. By Bangor in the Acta Reg. Soc. Med. Hanriest. vol. i. p. 8, &c.; by Withers, in his Treatise on Athana; and by Frank, De Curand. Hom. Morb., lib. iii. p. 263. The reader will find, however, that, in these cases, the eruption of bulbe has either been chronic, and altogether unconnected with fever; or it has occurred in connection with common fever, dysentery, &c. in which it was merely accidental and symptomatic, and by no means the result of any particular contagion, or indicative of a distinct and peculiar species of fever.

The more common eruptions of these water-bulls, or bulbe, is unconnected with any acute fever; and for the sake of distinguishing them from this suppoxiditons pemphigus, Dr. Willan arranged them under a new genus, POMPILLOX; which see.

PEMPHINGODES, or PEMPHIGODES, from the same root with the preceding, was an epithet applied by the ancients to certain fevers, said to be distinguished by flatulences and inflations, in which they supposing some aeral effluvium passed through the skin of the patient, and was sensible to the finger of a person applied to it. (Galen, Comment. on 6. Epidem., sect. 1. app. 17.) It is not easy to refer such a description to any known disease.

Poélus says, the febris pemphigodes was supposed to be a fynoeus, in which the blood-vessels were inflated, and consequently it was called an inflamed fever. Both the term and the absurd hypothesis have been long obsolete.

PEMPHIS in Botany, so named by Forster, from παμφίς, a globular, in allusion to the globular protuberance of the germen above the calyx, or of what, in Linnaean language, is the receptacle of the flower. Forl. Gen. t. 34. Juff. 331. Venten. v. 3. 299. (Lythrum; Lamarck Il. l. l. 3. p. 408. f. 2.)—Clas and order, Dodecandria Mono- gymia. Nat. Ord. Calycanthemis, Linn. Salticarias, Juff.

Gen. Ch. Cal. Perianth inferior, of one leaf, turbinate, permanent, fritiated, regular, with twelve teeth, the intermediate ones smaller. Cor. Petals six, obovate, obtuse, spreading, inferted by their claws into the throat of the calyx, at the base of each leaflet segment. Stam. Filaments twelve, awl-shaped, shorter than the corolla, inferted into the middle of the calyx, the fix adhering to it short; anthers ovate, two-lobed, incumbent. Pfi. Germani globofæ; stylo short, cylindrical, erect; stigma capitato, deprefse. Peric. Capsule turbinate, inferted with the permanent calyx, of one cell, opening by a hemispherical deciduous lid. Seeds numerous, wedge-shaped, abrupt, compressed, with a fumgous angular border. Receptacle central, short, triangular, muricated.

Obs. This genus is effentially different from Lythrum, in having a capsule which burits horizontally, and which contains of one cell instead of two. In an earl flate, we folped the Linnean Soc. of the Royal Irish Acad. for 1787. The hemispherical lid of the capsule is obliquely marked with fix concentric lines, which, it seems, Forster midlook, in an Unripe flate perhaps, for fix valves. We readily affix to the maxim of the younger Linnaeus, Suppl. 250, that a natural genus ought not to be divided on account of a single peculiarity in any one species; but where the habit is so different, and the technical character so important, as in the present cafe, besides both being supported by several secondary dispositions, there can no longer be room for hesitation, though only a solitary species of Pemphis has hitherto been discovered.

P. acidula. Forl. Gen. 34. (Lythrum Pemphis; Linn. Suppl. 249. Forl. Prodr. 36. Mangium porcellinum. Rumph. Amherb. i. 3. p. 344.)—Rumphius mentions this as growing in the muddy shores of some parts of Ambonya, or its neighbourhood. The late Mr. Chirtofer Smith sent us specimens, gathered in April 1797, in flower and fruit, at Nufalou. Koenig's, in the Linnean herbarium, were found on the sea coast of Ceylon. Forlter obtained his in the island of Teanta.—The them is thrubby, decumbent, with many hoary, rigid, leafy branches. Leaves crowded, opposite, on short flalks, obovate, entire, about an inch long, coriaceous or flabby, filky on both sides, especially when young. Rumphius, whose figure represents them rather too much pointed, says they have an agreeable falt flavour, and are eaten raw as a sauce to some kinds of fish. The flowers are axillary, solitary, on simple flalks rather shorter than the leaves; the calyx, as the calys, which is the lize of a pea. The petals are wavy, and described by Koenig as of a pale blueflue hue. Lamarrck, in his t. 408. f. 2, gives a sufficiently good, and apparently original, representation, of the whole plant in fower. Rumphius exhibits it in fruit only. We have never seen a specimen from Forlter, but there surely can be no doubt as to the identity of his plant.

PEMPPTÆUS, a word used by medical writers, as the name of an ague, the fits of which return always on the fifth day.

PÆN, according to Camden, originally signifies a high mountain, which was thus called among the ancient Britons, and even the Gauls. And hence, that tall range which parts Italy and France is called pæniæs.

PÆN is often used for a pound, or head of water, artificially kept up.

PÆNS, Dutch, are those made of quills which have been paffed through hot ashes, to take off the groffer fat and moisture thereof.

PÆN, Fountain. See FOUNTAIN-PÆN.

PÆN, Sea, penstatula, in Natural History, a genus of zoonophytes, which, though it swims about freely in the sea, approaches near to the gorgonia. This genus hath a bone along the middle of the inside, which is its chief support; and this bone receives the supply of its offensive matter by the fame polype mouths that furnish it with nourishment. Linnaeus reckons seven species. See PÆNATULA.

PÆN Stock, a sort of fluce or flood-gate placed in the water of a mill-pond, or a canal, to retain or let it go at pleasure.

PÆN UNGLASS, in Geography, a cape of South Wales, on the N. coast of the county of Pembroke. N. lat. 51° 57'. W. long. 4° 59'.

PÆN D WITH, a cape of Wales, on the N. coast of St. Bride's bay. N. lat. 51° 48'. W. long. 5° 10'.

PÆNA. See PÆNE.

PÆNA COVA. See PEGNA COVA.

PÆNA JOHN, in Biography, an able French mathematician in the 17th century, was descended from a noble family at Aix in Provence, and born at Moufliers, in the diocese of Riez, about the year 1530. He distinguished himself in early life by his proficiency in the Latin and Greek languages, and philosophy; but the best of his genius particularly
cularly directed him to the study of the mathematical sciences. About the year 1556, he was appointed professor of mathematics in the College Royal; and, according to some writers, his poetism professorship-extraordinary, created out of compliment to his great merit, and supped after his death. He published a Latin version of the Catoptrics of Euclid, with a curious preface, explaining and illustrating the uses of the cylindrical mirror, the “Optics” of the fame geometrician; “Euclidis Elementa Muñuces; Scicio Regulae Harmonicæ,” in Greek and Latin; and a Latin version accompanying the Greek text of “The Spheres of Theodorus.” He composed some papers on the “Mechanics of Hero,” and the “Geometry of Euclid,” which have not been published. This young mathematician was prematurely cut off by a violent fever in 1562, when only thirty years of age. Morei.

PENAC, in Geography, a town of Naples, in Abruzzo Citra; nine miles E.S.E. of Civita Borella.

PENEA, in Botany, received that appellation from Linnaeus, in memory of the learned Peter Pena, a native of Joques, near Aix, in Provence; who afforded great assistance to Lobel, in the composition of his “Adversaria;” not only by his general botanical learning, but by the communication of many rare plants of the south of France; see Lobel. Pluemer had already communicated a plant to his honours, which Linnaeus reduced to Polygonum; see that article.—Linn. Gen. 66. Schreb. 76. Willd. Sp. Pl. v. 1. 626. Mart. Mill. Dict. v. 3. Thub. Prodr. 35. Ait. Hort. Kew. ed. 2. v. 1. 248. Juff. 419. Lamarck Illust. t. 78.—Clas and order, Tetradiaia Monogynia. Nat. Ord. uncertain.

Gen. Ob. Cal. Perianth inferior, of two equal, opposite, lanceolate, concave, coloured, lax, deciduous leaves, half the length of the corolla. Cor. of one petal, bell-shaped; limb in four acute spreading segments, very much shorter than the tube. Stam. Filaments four, extremely short, erect, naked, inserted into the corolla between its segments; anthers erect, flat-topped, notched at each end. Pet. Germin superior, ovate, quadrangular; style with four membranous, dilated, longitudinal angles; stigma cruciform, obtuse, permanent. Peric. Capsule quadrangular, crowned with the style, of four cells and four valves. Seeds in pairs, rather oblong, obtuse.

The species of this genus are singularly confounded by Linnaeus. We shall attempt, by the help of his own specimen, to reduce their characters and synonims to order. They are all natives of the Cape of Good Hope, or the adjacent regions of southern Africa. Their habit is shrubby. Leaves crowded, opposite, nearly or quite sessile, rather thick, undivided, entire, in almost every instance perfectly smooth. Flowers terminal or axillary, solitary or aggregate, generally handkerchiefed, red, white, or yellow. Nobody has settled the natural order of Penaca, nor have we a conjecture to offer on the subject. Jussieu merely hints at its possible affinity to his Aconithi, which we see little to countenance. Its habit, but not its characters, bears some resemblance to Boronia, Sm. Tracts, one of the Rutaceae.

1. P. Sarcocolla. Linn. Sp. Pl. 162. Berg. Cap. 35. (P. fucata | Linn. Mant. 199. Lamarck f. 1. Willd. n. 6. P. n. 48; Linn. Mat. Med. 16, character and synonym erroneous. P. mucronata | Berg. Mat. Med. v. 1. 68 ?; Thymaliae myrtinae specie, arbucula aethiopica, subrotundis foliis, floebus labiis caucati capitato duro lachrymam fundens; Pluk. Mant. 193. t. 446. f. 6.)—Leaves ovate, somewhat rhomboid, acute. Bracteas wedge-shaped, pointed, coloured. Calyx-leaves linear.—Native of hills at the Cape. A humble, much-branched, bushy shrub. Leaves about half an inch long, of a pale tawny glaucous hue in the dried plant, their mid-rib rather convex. Flowers few together, at the tops of the branches, rather longer than the leaves. Bracteas but half the size of the leaves, entire, smooth, red, as well as the calyx. Segments of the corolla rounded, obtuse, slightly spreading. There is no appearance of gum about the flowers, and whether this, or any other species of Penaca, really yields the gum-rein called, from its reputed healing or conglutinating virtues, Sarcocolla, or flesh-glue, appears to be very doubtful and very unimportant. Modern surgery disclaims such aids, and has long ceased to confide in them.—Pluckenet’s imperfect figure is evidently done from this species, though his definition rather points at squamosa hereafter mentioned.

2. P. mucronata. Linn. Sp. Pl. 162. Berg. Cap. 37. Willd. n. 2. Att. n. 1. Vent. Malm. t. 87. (Thymaliae myrtinae specie, arbucula aethiopica, folio parvo late belii in acutifolium mucronum subrotundis, capitato oblongo; Pluk. Mant. 193.)—Leaves heart-shaped, pointed, horizontal. Flowers in dense terminal spikes. Bracteas somewhat lunate, pointed. The numerous, small, horizontal flowers in each other in pairs, and the copious dense spikes of yellow flowers. Whole corolla is not very unlike in size and figure to Arbustus Unedo, characterize this species. Pluckenet’s comparison of the heads of Origanum is strikingly opposite, as to the dried plant. Linnaeus, in Syfl. Veg. says the flowers are red, having been misled perhaps by the dried specimen. This species was sent to Kew by Mr. Maffon in 1878, but has not flowered there.

3. P. marginata. Linn. Mant. 199. Willd. n. 3.—Leaves heart-shaped, rather concave, thick-edged, shining. Flowers lateral, axillary.—Found near rivers at the Cape. The branches are straight and wand-like, often tertiary. Leaves three quarters of an inch long; dark green and shining above; paler and yellowish beneath, remembering some kind of Celastrus or Buxus; their edges remarkably thickened. Flowers not quite so long as the leaves, sessile, reddish in the dry state, but Linnaeus says they are white.

4. P. lateriflora. Linn. Suppl. 122. Willd. n. 4.—Leaves ovate, flat-topped, opaque. Flowers lateral, axillary. Very distinct from the last, notwithstanding the doubt expressed by Willdenow. The leaves are rather larger, not heart-shaped, nor thickened at the edges. Flowers also larger, extending a little beyond their corresponding leaves.

5. P. tomentosæ. Thub. Prodr. 30. Willd. n. 5.—“Flowers lateral. Leaves ovate, downy.”—Of this we have seen no specimen, but the downy leaves are peculiar to it.

6. P. squamosa. Linn. Mant. 331. Willd. n. 7. Linn. Sp. Pl. 162 ? the observation at the end certainly misapplied. (P. Sarcocolla | Willd. n. 1. Lamarck f. 2. P. tetragona | Berg. Cap. 36.)—Leaves ovate, somewhat wedge-shaped, flatly. Bracteas fringed, glutinous, larger than the leaves. Segments of the corolla reflexed.—Distinguished by its large terminal flowers, enveloped in dark red, glutinous, broad, densely fringed bracteae. The leaves most resemble the first species, but their mid-rib is depressed, not prominent, and their colour in a dried state very dark. Linnaeus at first marked his specimine Sarcocolla, then refusæ, and finally squamosa, under which last appellation he described this fine plant. It may, perhaps, yield a gum, as well as the first species. The corolla seems to be white or yellowish; its tube is above an inch long; the segments of the limb ovate,
Penal Action. See Action.

Penal Statutes. See Statutes.

Penalties Negative. See Negative.

Penalva, in Geography, a town of Portugal, in the province of Beira; nine miles N. of Coimbra.

Penamously, a town of Hindoostan, in the cir-
car of Rajamundry; 42 miles E. of Rajamundry.

Penance, Penitentia, is properly the exercise of penitence; and may be defined a punish-ment, either voluntary, or imposed by legal authority, for the faults a perforn has committed.

The Romans define penitence, a sacrament wherein a person, who has the requisite dispositions, receives absolution at the hand of the priest, of all sins committed since baptism.

To a legitimate penance they require three things, contri-
bution, absolution, and satisfaction.

Their priests receive a power of administering the sacra-
ment of penance, when they receive the priesthood; but to
exercise this power, it is required they have the jurisdic-
tion of an ordinary, i.e., that they have a benefice, either original or delegated; with the approbation of the bishop to hear confessions. See Poverry.

Penance is particularly used in the Roman church, for the penalty which a confessor imposes for the satisfaction of the sins of which a person is abjured.

The ancient discipline, Du Pin observes, was very severe on the head of penance: for great crimes people were exclud-
ed the communion of the church, expelled the assemblies of the faithful, obliged to fast, and to mortify themselves publicly, even at the church-door, cut their hair, go always on foot, &c.

He adds, that those who had done public penance were never admitted into the clergy; and that public penance was never granted more than once. There, who fell a second time, were never to be reconciled to the church, and were to look for pardon only at the hands of God.

Penances, in our Common Law, is an ecclesiastical punish-
ment, used in the discipline of the church, and affecting the body of the penitent; by which he is obliged to give a public satisfaction to the church, for the scandal he hath given by his evil example. In the case of incest, or incontinency, the offender is usually enjoined to do a public penance in the cathedral, or parish church, or public market, bare-legged and bareheaded in a white sheet, and to make an open confession of his crime in a prescribed form of words, which is augmented or moderated according to the quality of the fault, and the discretion of the judge. So in smaller faults and scandals, a public satisfaction or penance, as the judge shall decree, is to be enforced before the minister, churchwardens, or some of the parishioners, respecting being had to the quality of the offence, and circumstances of the fact, as in the case of defamation or laying violent hands on a minister or the like. And as these cenfures may be moderated by the judge's discretion, according to the nature of the offence: so also they may be totally altered by a commutation of penance: and this hath been the ancient privilege of the ecclesiastical judge to admit that an obligation of a sum of money for pious uses shall be accepted in satisfaction of public penance. But penance must be first enjoined, before there can be a commutation; or, or her wife it is a commutation for nothing. Linwood and other canons mention three forms of penance, viz. private, enjoined by any priest in hearing confession; public, enjoined by the priest for any notorious crime, either with or without the bishop's licence, according to the custom of the country; and solemn, the particulars of which are prescribed by the constitution of arch-
bishop Peckham. By the statute of "Circumspicte agatis" (13 Edw. I. fl. 4.) the king to his judges senteth gree-
ing: use yourselves circumspectly concerning the bishops and their clergy, not punishing them if they hold plea in court Christian of such things as be mere spiritual, that is to acts of penance enjoined by prelates for deadly sin, as fornication, adultery, and such like; for which sometimes corporal penance, and sometimes penitential is enjoined (2 Rol. Rep. 384) in which case the spiritual judge shall have power to take knowledge, notwithstanding the king's prohibitions. By the statute of "Articulicet," (9 Edw. II. fl. c. 2.) if a prelate enジョes a penance corporal to a man for his offence, and he is demanded; the king's pro-
hibition shall hold place; but if prelates enjoin a penance corporal, and they which be so punished will redeem upon their own accord such penance by money; if money be demanded before a spiritual judge, the king's prohibition shall hold no place. And by the same statute (c. 3.) if any lay violent hands on a clerk, the amends for the peace broken shall be before the king, and for the excommuni-
cation before a prelate, that corporal penance may be enjoined; which if the offender will redeem of his own good will by giving money to the prelate, or to the party grieved, it shall be required before the prelate, and the king's prohibition shall not lie.

Penat, in Geography, a town of Hindoostan; 30 miles S.S.E. of Agra.

Penates, in the Ancient Mythology, a term applied to all the domestic gods, whom the ancients adored in their houses: whence they are ordinarily confounded with the lares. See Lares.

Authors are not all agreed about the origin of the dii penates, who were properly the tutelary gods of the Trojans, and were only adopted by the Romans, who gave them the title of penates.

De Meziriac, in his notes on Dido's Epistle to Aeneas, relates at large what he has met with in the ancient writers.
on the subject: Dionyfius Halicarnassus tells us, that Æneas first lodged these gods in the city Lavinium; and that his son Æneas, afterwards, upon building the city Alba, translated them thither; but that they returned twice miraculously to Lavinium. The same author adds, that in Rome there is still seen a dark temple, shaded by the adjacent buildings, wherein are the images of the Trojan gods, with the inscription DEXIA, which signifies penates. These were the public penates of the city and empire, and their temple was near the circus Maximus. A light was continually burning before them, and libations and incense were offered upon almost all occasions. Lucan observes, that in time of peace, the Romans used to hang up their arms, in the place belonging to their household gods, as intrusting them to their custody; and that it was esteemed an abominable sacrilege to commit murder in the presence of Vesta, that is, in the entry, and before the perpetual fire of the household gods.

The images above-mentioned represent two young men sitting, each of which holds a lance. I have seen, adds Dionysius, several other statues of the same gods in ancient temples; who all appear like young men drest in habits of war. Varro vouches these penates from Samothrace to Phrygia, to be afterwards transported by Æneas into Italy. Macrobius, who relates this from Varro, adds also, that they were called penates, from the Latin words per quos penitus spiramus, which seems a mere subtilty. But the real etymology must be sought in the Phrygian, not the Latin tongue.

Cicero, in Anulus Gellius, derives the name hence, quod penes nos nati sunt. Yet in his book de Nat. Deor. he says, it is formed from penus, provision; or, perhaps, adds he, quod penitus infident; others say, quia coluntur in penetralibus.

Rutilius distinguishes among the penates: he makes an order of penates of the heavens, such as Pallas in the ethereal region, Jupiter in the middle region, and Juno in the lowest; besides penates of cities, penates of private families, &c. On which footing the divi penates were the guardians or tutelary gods of every thing.

Nigidius, an ancient author cited by Arnobius (Adv. Gent.) distinguishes four forts of penates: those of the clas of Jupiter, or chosen from among the celestial gods; those of Neptune, from the sea-gods; those of Pluto's clas from among the infernal gods; and those taken indiscriminately from the clas of all the deified men.

It is a popular question among the learned, who were the penates of Rome? Some say, Veia; others Neptune and Apollo; Vives says, Castor and Pollux; with whom agrees Volusius, who adds, that the reason of their choosing Castor and Pollux in quality of penates, might be the important service they did the Romans in the war against the Latins.

Nor are authors more unanimous on the subject of the penates which Æneas brought into Italy. Some say they were Neptune and Apollo, who built the walls of Troy; others, Jupiter, Juno, and Minerva; and others Cælus and Terra.

Dionyfius Halicarnassus, lib. i. speaking of the divi penates, tells us, that the historian Timæus has written, that the figure, statue, or effigy of the penates, or penates, was nothing but a crooked iron, or copper rod, and a Trojan vessel from potters' ware: and that this was all Æneas brought to Troy. But, for himself, he affures us, he had seen a temple at Rome, near the forum, where those gods were represented sitting, under the form of two young men, having each of them a dart in his hand: he adds, that the inscription was DENATES, for that the ancients, before the invention of the letter P, used a D instead of it: But Dionyfius might be mistaken: for the bottom of the P is frequently to fo very small on medals, that there is no sensible difference between a P and a D; which might be the case in the inscription that author mentions; for that the ancient inhabitants of Italy had no P, is a mistake sufficiently refuted by many proper names still remaining of the most early ages, e. g. Cupys, Captus, Picos, Pallas. Nor were the Trojans without the fame, with the name Palmarus, Paris, Priamus, &c.

The penates seem to have originated in a vulgar opinion which prevailed very generally amongst mankind, that the manes of their ancestors took pleasure after death to dwell in their houses, where indeed they were frequently interred, and where their pictures used to be preferred in the places that were most respected. After having been accustomed to consider them under the character of illustrious personages, they by degrees paid them respect and homage, they then implored their assistance, and lastly they succeeded to the worship and religious ceremonies. The penates were therefore the manes of their ancestors, which St. Augustine (de Civ. Dei. i. ix. c. 11.) maintains, on the authority of Appuleius and Photinus; and in process of time they were associated with all the other gods without distinction.

The statues of these gods were made not only of wax, as some authors pretend, but indifferently of all sorts of materials, even of silver itself: they were consecrated in the most secret places; altars were erected to them, lamps kept burning, and symbols added, all of them expressive of vigilance. Anciently children were offered to them in sacrifice, but Brutus, who expelled the Tarquins, discontinued this barbarous practice, and from that time nothing was offered to them but wine, incense, fruits, and sometimes bloody victims, lambs, sheep, &c. : their statues were likewise crowned with platters of garlic and poppy. In the public sacrifices offered to the penates, they sacrificed to them a fow. It was in the time of the Saturnalia, that they celebrated the festival of the lares and penates, and there was a day besides in each month set apart for the worship of those domestic gods. At the temple consecrated to these gods in Rome, there was yet apart for them a holiday, which was observed with much solemnity; and this was the second of the kalends of January, or the last day of December. To this were added the games called "Compitales." Indeed, the respect paid to the penates was so great that no important enterprise was undertaken without consulting them: their figures were even sometimes carried about in journeys, as we learn from Appuleius: "Wherever I go," says he, "I always carry with me in my journey the figure of some god.

The figure of the gods penates was sometimes the single representation of some god, genius, hero, or demi-god, or lastly of some famous ancestor: frequently they were pantheons, that is such as were charged with the symbols of several divinities. It is probable that some of the penates delivered oracles.

Authors have conjectured, that the idols which Jacob brought from the house of Laban his father-in-law, and which the scripture denominates "theraphim," were gods penates, whose worship was propagated afterwards into Phrygia, and transmitted from thence into Greece and Italy. This, it is confidently asserted, was their true original.

Penatolen, in Geography, a town of Chili; 20 miles E. of St. Yago de la Nueva Eftramadura.

Penatoor, a town of Hindooftan, in the Carnatic; eight miles W. of Gingee.
PENDRAY, a cape on the S. coast of Wales, in the British channel; 3 miles S. of Kidwelly.

PENBROUGH HEAD, a cape of South Wales, on the N. coast of the county of Pembroke. N. lat. 51° 56'. W. long. 5° 15'.

PENCARROW, a cape in the English channel, on the S. coast of Cornwall; two miles E. from the river Fowey.

PENCE, Peter-pence. See Peter-pence.

PENCE, Pitching. See Pitching-pence.

PENCIL, in architecture, penicillus, or penilium, which signify the same, formed by diminution of pennis, an instrument used by painters for the application of their colours. There are pencils of various kinds, and made of various matters: the most usual are of badgers' and squirrels' hair, those of swans' down, and those of boars' bristles; which last are bound to a flick bigger, or less, according to the uses they are designed for; and, when large, are called brushes. The others are included in the barrel of a quill. The ancients, M. Felibien observes, had pencils made of little pieces of sponge; whence, doubtless, the story of the painter, who, not able to express the form of a horse, succeeded in throwing the sponge at the picture.

PENCIL, Black-lead. See Black-lead.

PENCIL, of Electricity. See Brush, and Electricity.

PENCIL, of Rays, in Optics, is a double cone, or pyramid of rays, joined together at the base; one of which hath its vertex in some part of the object, and has the crystalline humour, or the glass GLS (Plate XVII. Optics, fig. 10.) for its base; and the other has its base in the same glass, or crystalline, but its vertex in the point of convergence; as at C. Thus BGSC is a pencil of rays; and the line BL'C is called the axis of that pencil.

PENCIL, in Ancient Armour, a small frame fixed to the end of a lance, and adorned with the coat-armour of the effigies, by whom it was carried, and which served to point him out in the day of battle.

PENCK, in Geography, a town of Germany, in the principality of Cullum; 4 miles N.E. of Bayreuth.

PENCKUM, a town of Anterior Pomerania; 13 miles S.W. of Old Stettin. N. lat. 53° 15'. E. long. 14° 20'.

PENDANT, EAR-RING, an ornament of gold, or some precious stone, worn by the ladies; hung by a hole made for that purpose through the ear; and frequently enriched with diamonds, pearls, and other precious stones.

The pendants of the European ladies are nothing in comparison to those worn by the East Indians, both men and women; among whom it is the fashion to lengthen out the ears, and to enlarge the hole, by putting in pendants of the size of fankeys, set with stones.

In the West Indies, Columbus named a certain coast Orea, because he found people with holes in their ears big enough to pass an egg through.

They make holes too in their lips and nostrils, and hang pendants at them: which is also practised by the Mexicans, and other nations.

PENDANT, in Heraldry, a term applied to the parts hanging down from the label, to the number of three, four, five, or fix at most. These must be specified in blazoning, when there are more than three. They resemble the drops at the bottom of the triglyphs in the Doric frieze.

PENDANT Barometer. See BAROMETER.

PENDANT Capital, a mass of sculptured stone, or other material, in the form of the capital of a column, with ribs and arches springing from it, which seems to support the general vaulting, but which, in fact, being distinct of a supporting column, is infected into and hangs from that vaulting. This piece of mechanism belongs to the third order of painted architecture, and may be seen to advantage in the chapel of King's college, Cambridge, Henry VIIth's chapel, Welf-miller, &c. See Gothic Architecture.

PENDANT Feathers, in Falconry, are those feathers which grow behind the thighs of a hawk.

PENDANT Gardens, in Antiquity. See PENDLES Horti.

PENDANTS, among Florists, a kind of globules, growing on flaminia, or chives. Such are those in the middle of tulips, lilies, &c. See Apices, and Staminia.

PENDANTS of a Ship, are those long colours, or streamers, cut pointing towards the end, and there divided into two parts; hung out at the head of masts, or at the yard arm ends.

The pendants are chiefly used for show, though sometimes for distinction of squadrons, and for signals.

PENDANTS, (Rigging,) large, but short, ropes which go over the masts, or a mast, or a derrick, spliced into the lower ends for tackles, all of which serve to transmit the effort of their tackles to some distant object: such are the bitt-pendant, brace-pendants, preventer-brace-pendants, burton-pendants, flax-pendants, gny-pendants, main-flay-tackle-pendant, pendants of tackles, quarter-tackle-pendants, reef-tackle-pendants, rudder-pendants, fall-tackle-pendants, top-rope-pendants, trusfl-pendants, van-pendants, winking-tackle-pendants, and yard tackle-pendants.

PENDARRY, in Geography, a town of Hindoostan, in Oude; 17 miles N.W. of Kairabad.

PENDARTY, a town of Hindoostan, in the Carnatic; eight miles E. of Ongole.

PENDENNIS CASTLE, a fortress of England, in the county of Cornwall, situated at the mouth of Falmouth haven, built by Henry VIII., and fortified by queen Elizabeth. N. lat. 50° 9'. W. long. 5° 15'.

PENDENTIVE, in Architecture, the whole body of a vault, supfended out of the perpendicular of the walls, and bearing against the arches of the vaults.

Daviler defines it, a portion of a vault between the arches of a dome, usuall enriched with sculpture: Felibien, the plane of the vault contained between the double arches, the forming arches, and the ogives.

The pendentives are usuall of brick, or soft stone; and care must be taken, that the joints of the masonry be always laid level, and in right lines proceeding from the sweep whence the rise is taken.

The joints too must be made as small as possible, to save the necessity of filling them up with slips of wood, or of using much mortar.

PENDILHO, in Geography, a town of Portugal, in the province of Beira; 12 miles S.E. of Lamego.

PENDLETON, a township of Lancashire; 2 miles W. of Manchester.

PENDLETON, a county of Virginia, in America; bounded N.W. by Randolph, and S. by Rockingham, counties; watered by the S. branch of the Patowmack. It contains 36,542 free inhabitants, and 12,482 slaves. Its chief town is Frankfort.—Also, a district of South Carolina, on the Coowe and Savannah rivers; containing 20,050 inhabitants, of whom 2204 are slaves; 52 miles W. of Cambridge.—
Also, a county of Kentucky, containing 1573 people, of whom 239 are slaves.

PENDOUN, a town of Birmah; 12 miles S. of Raynangong.

PENDULOUS, Hanging down; a name which Botanists give to those heads of flowers which hang downwards; the stalk not being able to sustain them upright.

PENDULOUS Roots, such as are fixed to the ends of fibres, whence they seem to hang.

PENDULUM, in Dynamics, is a simple ponderous body, so suspend from a flexible cord from an axis of suspension, that it is liable to vibrate by the action of its own gravity alone, when it is once raised, by any external force, to the right or left of its quiescent position; and in demonstrating the theory of its motion, mathematicians are obliged to assume, that there is no rigidity in the cord; no friction at the axis of suspension; no reftility to motion opposed by the air; and no variation in the total length of the cord, arising from the variable temperature or moisture of the atmosphere; and if these assumptions were strictly correct, a pendulum, once put into motion, would continue to move forever, without the further accession of any external force; but when the pendulum is applied as the regulator of a clock, for which purpose it is admirably adapted, the assumptions we have named require an equal number of mechanical corrections, of which the theory, simply considered, takes no notice. In Horology, therefore, the pendulum must be considered, not simply as a self-moving ponderous body, without any tendency to come to a state of rest, or to have its dimensions altered by the circumstances in which it is placed; but as a body, whose motion is perpetuated by repeated accelsions of force, in aid of its own gravity, and whose vibrations are rendered isochronal by a nice adaptation of mechanical contrivances, that prevent or remedy the prejudicial influences of all natural impediments to uniform and uninterrupted motion. It seemed necessary, in the first place, to establish the distinction that thus exists between the free or detached and attached pendulum; and having done this, which we must beg the reader to bear in mind, we propose to divide our article into three heads, namely, 1st, the history of the pendulum; 2dly, its theory in its detached state; and 3dly, its various constructions, when used in its attached state, as the regulator of an horological machine.

1. We have already given an historical account, under our article Clock, (see History of the Successive Improvements in Clocks,) of the first notion that was taken by Galileo of the vibrations of bodies suspended by long chains, and also of the application that was made soon after, by various persons, of the isochronal property of the detached pendulum, particularly in astronomy, as well as of its introduction, in its attached state, into horological machines as a regulator of their motions, after the balance had been applied for the same purpose: we beg leave, therefore, to refer the reader to the article already named, for the particulars that would have fallen under this head, had not this part of the subject been anticipated.

2. The second head of this article which we proposed to consider, was the theory of the simple pendulum vibrating in its detached state. When Galileo discovered that ponderous bodies, whether large or small, suspended by cords of equal length, perform their vibrations apparently in equal times, he was led into the contemplation of the laws of uniformly accelerated motion, produced by the centripetal force of gravity, and soon found that the theory of the detached pendulum was derivable from the same laws by which bodies, left to descend in free space, were found to be accelerated, and that gravity was the sole cause of such acceleration. We have already treated of these laws at some length, under our articles Acceleration, Descent, and Motion, which render unnecessary a repetition of this part of our subject, except so far as the vibration of the pendulum is concerned. It was, however, soon perceived, that a pendulum, vibrating in long arcs of a circle, requires a somewhat longer time for the performance of each of those vibrations, than when it vibrates in small arcs, all other circumstances remaining the same; it thence became a question among mathematicians what the nature of that curve might be, in which, substitutd for the arc of a circle, both long and short vibrations would be performed in the same time. Though Galileo is acknowledged to have been the first who discovered and described the curve first called by him the cycloid, yet it remained for the celebrated Huygens to point out not only the isochronal property peculiar to this curve, but also that the involute of a cycloid is itself a cycloid, which latter discovery enabled him to make the attached pendulum actually vibrate in a cycloidal curve. Under our article Cycloid, we have given at considerable length both the geometrical and mechanical properties of this remarkable curve, which we recommend to the reader's notice, as preparatory to our doctrine of vibrations performed in cycloidal, and also in circular curves; for he will there fee that short arcs of vibration, at each side of the lowest or quiescent point of the curve, are very nearly small, both as to coincidence in position, and also to the consequent isochronal property. He will fee, not only that arcs of all lengths, when cycloidal, are performed in equal times, but that small circular arcs approximate fo nearly to their correspondents in the cycloid, that they may be substituted in practice for each other, the former for the latter, without sensible deviation.

Prefusing, now, that our reader has made himself acquainted with the laws of uniformly accelerated motion, agreeably to our references, and that he has perused with attention also the article Cycloid, we will proceed to lay before him the fluxional method of determining the actual times of a detached vibration both in cycloidal and in circular arcs. This part of our subject has been recently treated so ably by professor Bridge of the East India college, that we beg leave to avail ourselves of his labours, at the same time that we recommend to general notice his "Introduction to the Study of the Mathematical Principles of Natural Philosophy, 1813."

On the Times of Vibration in Cycloidal Arcs.—In fig. 1. of Plate XXXIX. of Horology, "let A V B be a cycloid, in which a body, P, suspended from the point S, performs its vibrations between the two semi-cyliorh S A, S B, and let it begin its vibrations from the point E; also let p p be any very small arc, describ'd in the deficient from E to the lowest point V; draw E F, P N, p n, parallel to the base, A B, of the cycloid, and join C M, C m, M V, m V. Let C V, the diameter of the generating circle, and F V = a, N V = x; then F N = a - x, M V = $\sqrt{C V \times N V}$ = $\sqrt{x}$. Now the cycloidal arc P V being = twice the chord M V = $2 \sqrt{x}$; let E P = z, then E V = z + P V; and since E V is a constant quantity, z + P V = o, z = $-\sqrt{x}$. The velocity down E P (v) = the velocity down F N = $\sqrt{4 m \times FN} = \sqrt{x}$. "
\[ t = \sqrt{\frac{1}{4}} \sqrt{4m \cdot a - \frac{x}{a}} \] if therefore \( t \) is the time down \( EP \), we shall have \( i = \frac{\sqrt{d}}{\sqrt{a} \cdot x} \times \frac{1}{4} m \) and \( t = -\sqrt{\frac{d}{4m}} \times \frac{x}{a} - x \); and \( t = -\sqrt{\frac{d}{4m}} \times \frac{x}{a} \) circular arc, rad. = 1, ver. fin. \( \frac{x}{a} \); but when \( t = 0 \), \( x = a \), \( \pi = -\sqrt{\frac{d}{4m}} \times \text{cic.} \text{rad.} = 1, \text{ver.} \text{fin.} = 2, + \text{cor.} = -\sqrt{\frac{d}{4m}} \times \text{cemicircle, rad.} = 1. + \text{cor.} = (\text{if } \pi = 3.1416, \&c.) - \sqrt{\frac{d}{4m}} \times \pi + C, \text{or } C = \sqrt{\frac{d}{4m}} \times \pi.

The fluent properly corrected therefore is \( t = \sqrt{\frac{d}{4m}} \times \pi - \text{cic. arc, radius } 1, \text{ver. fin. } \frac{x}{a} = (\text{when } x = 0) \)

\[ \sqrt{\frac{d}{4m}} \times \pi = \text{the time of descent through the cycloidal arc } EV; \text{ consequently the whole time of vibration} = \sqrt{\frac{d}{4m}} \times 2 \pi = \sqrt{\frac{d}{4m}} \times \pi. \] Since the quantity \( a \) does not enter into this value of \( t \), it is evident that the times of vibration will be the same, from whatever point of the cycloid the body \( P \) begins to vibrate. Moreover, since the time down the axis \( CV = \sqrt{\frac{d}{4m}} \), we have the time of a vibration : the time down the axis \( = \sqrt{\frac{d}{4m}} \times \pi = \sqrt{\frac{d}{4m}} \times \pi \); the circumference of a circle ; its diameter ;' which conclusion coincides with our former determination under the article Cycloid.

On the Times of Vibration in circular Arcs. — In fig. 2. of the same plate, let the small body \( P \), vibrating in the circular arc \( EVG \), begin its vibrations from the point \( E \); let \( PV = z \), \( NV = x \), \( PV = a \), \( \rho = z \).

\( SP \text{ or } SV = r \), then \( z = \sqrt{2r \cdot x - x^2} \). Let \( t \) be the time through \( EP \), \( v \) be the velocity in the point \( P \), then \( v = \sqrt{4m \cdot x} \times F N = \sqrt{4m \cdot a - x} \), and \( t = \frac{-z}{v} = \frac{r \cdot x}{\sqrt{2r \cdot x - x^2}} \times \frac{1}{\sqrt{4m \cdot a - x}} = -\frac{r \cdot x}{\sqrt{4m \cdot a - x}} \times \frac{1}{\sqrt{2r \cdot x - x^2}} \times \frac{1}{\sqrt{2r \cdot x - x^2}} \) \( = \frac{1}{\sqrt{2r \cdot x - x^2}} \times \sqrt{4m \cdot a - x} \) \( \times \text{for } \sqrt{2r \cdot x - x^2} = x \sqrt{2r \cdot x - x} \), hence \( t = -\frac{x}{\sqrt{4m \cdot a - x^2}} \times \frac{1}{\sqrt{2r \cdot x - x^2}} \times \frac{1}{\sqrt{2r \cdot x - x^2}} \times \frac{\pi}{1 + \frac{x}{4r - 32r^2}} \) \( \&c. \) by expanding \( \frac{1}{\sqrt{2r \cdot x - x^2}} \) into a series.

Again, let \( \frac{1}{\sqrt{a \cdot x - x^2}} = A \); then since \( \frac{1}{\sqrt{4m \cdot a - x}} \times \frac{A}{4m \cdot a - x} \)
two first may be rejected, then the time of a vibration
\[ \frac{\sqrt{r \times 2\pi \times 1 + \frac{a}{8r}}}{8} \text{; and, consequently, the time of a vibration in a circular arc (whose radius is \( r \)) \text{; the time of a vibration in a cycloid (whose axis is \( \frac{1}{r} \))} = 1 + \frac{a}{8r} \]

: 1. For instance, let the arc of semi-vibration be \( a \) at each side of the lowest point, then \( a = \text{versed sine of} \, \alpha = \frac{6r}{10000} \) nearly; \( \frac{a}{8r} = \frac{1}{13333} \). In arcs which are less than \( 2^\circ \), this difference will be still less; so that if the whole arc through which a pendulum vibrates does not exceed \( 4^\circ \), it may, without any material error, be considered as oscillating in a cycloid; and consequently all its oscillations will be performed in the same time, whether it vibrate in a greater or a lesser arc within this limit.

Lastly, let \( A = \) the arc, whose versed sine is \( a \), then (supposing the arc to be very small) \( a = \frac{A}{2r} \); and if \( n = \) the number of degrees in this arc, then \( A = 2 \pi r = n : 360 \), or \( A = \frac{2 \pi r}{360} \cdot a = \frac{A}{n} = \frac{2 \pi r}{360} \cdot \frac{a}{r} = \frac{\pi a}{180} \) = (for \( \pi = \frac{3.1416, \text{ &c.}}{6565} \) very nearly; hence \( \frac{a}{8r} = \frac{n^2}{5520} \); consequently the variation for \( N - n \) degrees is \( \frac{n^2}{5520} \); if therefore the pendulum keeps true time, when it oscillates through \( n \) degrees, the error arising from its vibrating through \( N \) degrees will be \( \frac{N^2 - n^2}{5520} \) of the time of one vibration. For instance, if a pendulum which vibrates \( 2^\circ \), on each side of the vertical line; then if it vibrate through an arc of \( \alpha \), it will lose \[ \frac{3^\circ - 2^\circ}{5520} = \frac{5}{5520} = \frac{1}{10504} \] every second, or \[ \frac{60 \times 60 \times 24}{10504} = \frac{10504}{10504} \text{, or } \frac{10504}{10504} \text{, or } \frac{10504}{10504} \text{, or } \frac{10504}{10504} \text{, or } \frac{10504}{10504} \text{, or } \frac{10504}{10504} \text{, or } \frac{10504}{10504} \] per day,.

Nearly the same results will be the consequence of this still more simple process; vis. “Take \( \frac{1}{3} \) of the difference of the squares of the arcs for the seconds, gained or lost by a decreased or increased arc;” thus \( 3^\circ \times 3^\circ \times 2^\circ \times 2^\circ \times \frac{1}{3} = \overline{7.5} \) nearly as before.

When two pendulums of different lengths are made to vibrate in a detached state, at the same time, the times of their respective vibrations will be in the subduplicate ratio of their lengths; and the respective lengths of different pendulums, vibrating at the same time in similar arcs, will be in the duplicate ratio of the times of a vibration directly; or in the reciprocal duplicate ratio of the number of vibrations so made in any one and the same time. Let the length of a second’s pendulum be taken in a given latitude at 39½ inches = \( r \), let \( g \) be 16½ feet, or the space that a heavy body falls in free space in the first second of time, and let \( p = 3.1416, \text{ &c.} \) the diameter of a circle, whose radius is \( r \); then \( t \), the time of vibration in a circular arc, being as \( \sqrt{\frac{r}{2g}} \), where \( p \) and \( g \) are constant or given, \( t \) will be as \( \sqrt{r} \), and \( r \) as \( r \). Hence the length of a half-seconds pendulum will be \( \frac{1}{2} r \), or \( \frac{39}{4} = 9.781 \) inches; and the length of a quarter seconds pendulum will be \( \frac{1}{4} r = \frac{39}{16} = 2.445 \) inches; and in this manner a table of square roots may be readily constructed of the various lengths of a pendulum, that are required to correspond to any number of seconds, or portions of a second, in each vibration.

The action of gravity, however, is not the same in all latitudes; nor yet at all heights above the earth’s surface in the same latitude; for instance, the vibrations are slower at the equator than at the poles, and increase in quickness with the latitudes, north or south, as the centrifugal force decreases. Hence, \( \frac{p \times A}{r} \), the force of gravity being counteracted, in a certain degree, by the centrifugal force, which increases with the distance from the earth’s axis of rotation, and the times of a vibration being reciprocally proportional to \( \sqrt{r} \).

By an experiment made on the pendulum that vibrated seconds at Paris, Richter found that at the island Cayenna, 4º from the equator, it required to be shortened a line and a quarter, to perform a vibration in a second; and Mr. Campbell, in 1731, by an experiment made in Jamaica in 18º north latitude, determined that if a seconds pendulum is 39.126 English inches long, agreeably to Graham’s determination, the length at the equator would be required to be 39.00, and at the pole 39.206 inches. (Phil. Trans. N° 343.) These experiments led Mr. Emerson to compute a table for the length of the pendulum to swing seconds for every five degrees of latitude, together with the length of a degree of latitude in each of those parallels, in English miles, which table we shall here subjoin.

</table>

The
The numbers in this table of course suppose the pendulum vibrating close to the Earth's surface in each parallel of latitude.

Professor Bridge has also calculated a little table, on a supposition that the length of a seconds pendulum is 39.2 inches in latitude 59°, which is taken as his standard, and he has given the lengths corresponding not only to six different latitudes, but to four different heights, six at the Earth's surface, and at one, two, and three miles of elevation respectively. We shall take the liberty of giving this table also.

</table>

The greatest variation in the length of a pendulum vibrating at three miles above the equator, and on the Earth's surface at the pole, is only 0.284 of an inch, which affords but a small scale for determining either altitudes or the figure of the Earth, to both which purposes the observed variations in the lengths of the pendulum have been proposed as a measure.

When a pendulum of a given length has been observed to gain or lose a certain quantity daily, it is convenient, in making the adjustment for exact time, to have some concise theorem as a guide to bring it to the point defired, at one trial in all cases, which theorem professor Bridge has given in these words: "Multiply twice the length of the pendulum by the number of seconds gained or lost, and divide the result by the number of seconds in a day; the quotient will give the number of inches, or parts of an inch, by which the pendulum is to be lengthened or shortened."

Suppose the gain of a seconds pendulum to be three minutes, or 180" in a solar day, then \( \frac{39.2 \times 2 \times 180}{86400} = .163 \) parts of an inch, is the quantity, in this case, by which the pendulum must be lengthened to measure mean time; but if the three minutes had been lost with a half-seconds pendulum, then \( \frac{9.8 \times 2 \times 180}{86400} = .041 \) of an inch, or the fourth part of the former gain, will be the quantity by which the said pendulum will require to be shortened. This rule is not only short in its application, but easy to be remembered.

Under the title Cycloid, we have shown that if \( l \) be the length of a seconds pendulum, and \( x \) the periphery of a circle, or 3.1416, &c. the expression \( \frac{\pi l}{2} \) will be the measure of the velocity of a falling body acquired in one second of time, and also that the expression \( \frac{\pi l}{2} \) will denote the space fallen through in a vertical line in the same time; if we would apply these expressions to experiments in any given latitude, instead of the length of the pendulum determined in our own latitude, we must substitute the length given in one of the preceding tables, agreeably to the latitude proposed, and then the result arising from such length, as determined by the said expressions, will be corresponding; and the scale of acceleration will be accommodated to the increased or decreased force of gravity in that particular latitude; for instance, agreeably to Mr. Bridge's Table, the spaces fallen through in one second of time at the equator and at the pole will be respectively 192.663 and 193.753, the difference between which is only 1.092 inches; which is the greatest difference that exists between the spaces fallen through in one second on any two points of the Earth's surface.

If it should be required to know what the height of a mountain is, on which a seconds pendulum, that measured mean time truly at its base, lost a given quantity; let \( r \) = radius of the Earth, \( x \) = the height of the mountain, \( T \) = the number of seconds in an hour, or the number of vibrations in an hour at the base, and \( t \) = the seconds lost on the mountain; then \( T - t \) will be the number of vibrations in an hour at the top of the mountain. When the length of the pendulum is given, it is known that the number of vibrations in a given time are directly as the square roots of the forces, which act upon the pendulum; hence \( T \cdot T - t = \sqrt{\frac{1}{r}} : \sqrt{\frac{1}{r + x}} :: \frac{1}{r} : \frac{1}{r + x} :: r + x : r \), or \( x = \frac{t^2}{T^2 - t} \).

If \( t \) be very small with respect to \( T \), then \( x \) may be considered as equal to \( \frac{t^2}{T} \). Let \( T \) now be taken equal 3600", and let \( t \) be taken successively at 1, 2, 3, &c. seconds, then \( x \) will be equal to \( \frac{r}{3000}, \frac{2r}{3000}, \frac{3r}{3000}, \) &c.; and supposing \( r \) to be equal to 4000 miles, the heights of mountains upon which a pendulum, that vibrates seconds at their bases, loses 1, 2, 3, &c. seconds in an hour, will be \( \frac{1}{2}, \frac{2}{2}, \frac{3}{2}, \) &c. miles respectively. Hence, if the pendulum should gain \( t \) seconds in an hour before it is carried up the mountain, and it should be required to find that point in the ascent, where it would keep true time, we have \( T + t = T : \frac{r + x : r}{T} \); or \( x = \frac{t^2}{T} \); that is, if we multiply the gain by the Earth's radius, and divide the product by the number of vibrations performed in the hour, the quotient will be the height of that part of the mountain, where the pendulum must be fixed to keep true time.

Hitherto we have considered the matter that constitutes the whole pendulum as collected into one point, and that the centres of gravity and of oscillation coincide in that point, which cannot be strictly the case with any shape of the body; however slender the cord, wire, or rod of suspension. For instance, if a small ball of lead, or other ponderous body, were suspeded by a filken thread; suppose the ball to be divided into two equal semi-balls by a horizontal line, as it is suspeded by the vertical thread, then the lower semi-ball would move with a greater velocity than the upper one, though vibrating together, in consequence of its greater radius of motion, consequently the momentum of the lower semi-ball
femi-ball would exceed that of the upper one, and considering the two semi-balls as again united, it is clear that the common point of oscillation will be somewhere in the line of division, even if the silk thread be assumed as having no tenable weight. As we have given the methods of determining the centres both of gravity and of oscillation of bodies of different figures, with much minuteness, under our article CENTER, it is not necessary to pursue this part of our subject here, but to beg of the reader to recollect that the centre of gravity of any single pendulum is always above the centre of its oscillation, and that the distance from the point of suspension to the centre of oscillation is always to be taken as the true length of the pendulum, however suspended, or whatever may be the shape or size of the bob or ball. This observation is indeed equally true, however complex the construction of the pendulum may be, for we have shown, (see CENTER,) that whatever be the number of particles composing a pendulum, the products of the particles lying at 0 of side of the centre of oscillation, when multiplied both by their respective distances from the point of suspension, and also from the centre of oscillation, will make an amount, always equal to the amount of the products obtained from the particles so multiplied, lying at the other side of the centre of oscillation, without regard to shape or size. In a common seconds pendulum of 39.2 inches length, with a heavy lenticular bob, and a slender verge or rod of suspension, the centre of gravity is very nearly 8\text{th} of an inch above the centre of oscillation; and in all our preceding deductions the length of the pendulum must be considered as measured from the point of suspension at the vertex, to the centre of oscillation. But we have seen a pendulum so applied for the regulation of a portable clock, that the point of suspension was not at the vertex, but in a point somewhere between the vertex and the centre of gravity; by which application, the centres of gravity and of oscillation were farther removed from each other, than they would have been with the point of suspension at the vertex. A pendulum of this description, of a short length, may be made to vibrate in times of different lengths, which will depend on the respective distances between the centres of gravity and of oscillation; but the scale of adjustment for time being very short, and liable to be altered by variable temperature, this construction may be considered as an object of curiosity rather than of utility. If it were required, however, to find the distance between the centre of oscillation and point of suspension in any pendulum of this sort, where the time of vibration is given, it may be thus determined: Let T be the time given, L = length of a simple or common pendulum that will vibrate in that time, \(\pi = 3.1416\), \(m = 16\frac{1}{2}\) feet, and \(F = \) the force of gravity constantly acting; then since \(T = \sqrt{\frac{\pi^2 L}{2 m F}}\), we shall have \(L = \frac{2 m F T^2}{\pi^2}\) for the distance from the point of suspension to the centre of oscillation. Again, in fig. 3, Plate XXXIX. of Horology, let \(A a\) be a solid uniform rod, and \(G\) its centre of gravity; then if \(A\) be taken as the point of suspension in the vertex, the centre of oscillation will be at \(O\), at two-thirds of its length from \(A\). But let \(S\) be put as the point of suspension below \(A\), then \(L = S G + A G \times G O\). Let \(S G = s\), \(A G = D\), \(G O = d\); then \(L = x + \frac{D d}{x}\), or \(x^2 = L x + D d = 0\), from which

\[
x = \frac{L \pm \sqrt{L^2 - 4 D d}}{2}
\]

substitute \(\frac{2 m F T^2}{\pi^2}\) for \(L\) in this equation, and it determines the distance of the point \((S)\) of suspension to \((G)\) the centre of gravity of the rod; through which point \((S)\), if the axis of suspension be made to pass, the rod will vibrate in the given time. But as \(x\) has two values, it seems that there are two points at different distances from \(G\), the centre of gravity; from which it will be suspended, it will oscillate in the given time. By similar reasoning it may be proved, that the rod will vibrate in the least possible time, when \(S G\) is a mean proportional between \(A G\) and \(G O\); likewise, that if \(e\) be the centre of oscillation to the point of suspension \(S\), the point, \(G\), of the centre of gravity will be in the middle between \(S\) and \(e\); and, lastly, that a rod so circumflexed will vibrate in the least time possible, when its point of suspension, \(S\), is \(\frac{2}{3}\) of the whole length of the rod from its vertex \(A\).

3. We come, in the third and last place, to treat of the various constrictions of the attached pendulum, when used as the regulator of an horological machine, as we at first proposed. It has been usual, when treating of the pendulum, to call what we have denominated the free or detached pendulum, vibrating by the action of its own gravity, the simple pendulum; and what we call the attached pendulum, where external force is introduced in aid of gravity, the compound pendulum. But as the attached pendulum is constructed sometimes with a simple rod or verge, and sometimes with a compound one, we propose to apply these two terms, simple and compound, exclusively to the different constrictions of the attached pendulum, agreeably to the signification in which they are used by clock-makers.
