1819.
P

A labial consonant, formed by a slight compression of the anterior part of the lips, and retaining an uniform sound, and the fifteenth letter in the English alphabet.

When the P is followed with an H in the same word, it has the sound of an F; thus Philosophy is pronounced Philo-fy: and this is generally the case in words derived from the Greek.

P and B are fo like each other, that Quintilian declares, that in the word obelix, his reason required him to put a b, but that his ears could hear nothing but a p, optimus: hence in ancient inscriptions, and old glossaries, it appears, that these two letters have often been confounded.

Several nations still pronounce one for the other, the Welsh and Germans particularly, who say, ponum vinum for bonum vinum.

Plutarch observes, it was usual for those of Delphi to say ράδιν for πάδιν, διστερ for πιτερ; and among the Latins, as often as an s followed, the b was changed into a p, as scriba, scripsi.

P is sometimes mute before t, as accept; but in modern orthography it is usually omitted.

P, in Music, is the initial of piano, soft, for which it stands; and p p, by abridgment, for pianissimo, very soft.

P. M. among Astronomers is frequently used for post meridiun, or afternoon; and sometimes for post mane, after the morning, i.e. after midnight.

P was also used among the ancients as a numeral letter, signifying the same with the G, viz. a hundred; according to the verse of Ughtio.

"P fimilem cum G numerum monstrarum habere."

Though Baronius thinks, it rather flood for feven.

When a dath was added a-top of P, it flood for four hundred thousand.

St. Jerom observes, on Daniel, that the Hebrews had no P; but that the Phe served them instead of it; adding, Vol. XXVI.

that there is but one word in the whole bible read with a P, viz. apadno.

The Greek ß signifies 8o. The Latins used P as an abbreviation. Thus P. florid for Publius, pondo, &c. in S. P. Q. R. or Senatus populus Romanus, for populus; R. P. denoted república: P. C. patres conscripti: PR. S. praetoris fenticia, &c. On the French coins, P denotes thofe that were struck at Dijon.

P. in Medicinal Prescriptions, is used for pugil, or the eighth part of a handful.

P. AE signifies partes equalis, equal parts of any ingredient: otherwise denoted by a or an.

P P. signifies pulvis patrum, i.e. Jesuit's powder, or the cortex Peruvianus in powder; which is so called, because first brought into Europe by those fathers; and P p i. preparatus, prepared.

P. L. in Geography, a town of Thibet, 450 miles E. of Laffé. N. lat. 28° 18'. E. long. 98° 34'.

PAA, a town of the island of Ceram, and capital of a district abounding in fago.

PAAKOLA, a town of Sweden, in the government of Ulea; six miles N. of Kemi.

PAALAVANKA, a town of Hindooftan, in Colonda; 30 miles N.W. of Damapetta.

PAARDEBERG, o. the Hoofe Mountain, so called from the number of wild horfes or zebras, that formerly frequented it, a mountain of the Drakenfein district, in Southern Africa, which is a continuation of Paarl mountain to the northward. The produce of the farms is chiefly confined to wheat, which, with a sprinkling of manure, or a couple of years' ret, or by fowing, will yield from 15 to 20 fold. They cultivate, also, barley and pulse, but have few horfes or cattle beyond what is necessary for the purposes of hufbandry.

PAARL, a village in the district of Drakenfein, in Southern Africa, situated at the foot of a hill that fluts in
the valley of Drakenstein on the west side. It consists of about 90 habitations, diffused in a line, but so far detached from each other, with intermediate orchards, gardens, and vineyards, as to form a direct from half a mile to a mile in length. About the middle of this street, on the east side, stands the church, a neat octagonal building, covered with thatch; and at the upper end is a parsonage-house, with garden, vineyard, and fruit groves; and a large tract of very fine land. The village is overhung by blocks of granite, the pearl, and the diamond. Barrow's Africa, vol. ii.

PAATTS, a town of Sweden, in the government of Abo; 10 miles N. of Abo.

PAATPASSER, a small circular of Bengal, watered by the Ganges, between Dacca and Bodosnah.

PAAVOLA, a town of Sweden, in the government of Ules; 20 miles E. of Brahefeld.

PAW, Peter, in Biography, a physician and anatomist, was born at Amsterdam in 1564. When he had finished his scholastic education, he went to Leyden at the age of sixteen, where he attended the medical courses for the space of four years, and thence proceeded to Paris for further improvement. He afterwards commenced his travels for the purpose of visiting other celebrated schools; and after spending some time in Denmark, and at Rostock, where he received the degree of doctor in 1587, he repaired to Padua, and attended the dissections of Fabricius ab Aquapendente. Paw was naturally of a grave and serious disposition, and possessed a acute and retentive memory; and was therefore well able to profit by these advantages of education; and accordingly his great acquisitions were soon acknowledged, on his return to Leyden, by an appointment to a medical professorship in that university in 1589.

His whole ambition was centered in the prospect of supporting the dignity and utility of this professorship, and he obtained the approbation and esteem both of the public and his colleagues. He died, universally regretted, in August 1617, at the age of fifty-four. Anatomy and botany were the departments which he most ardently cultivated, and Leyden owes to him the establishment of its botanical garden.

PABBAY, or PAPAY, in Geography, one of the Bishop's islands, among the Hebrides. N. lat. 56° 50', W. long. 7° 32'.—Alfo, one of the small Hebrides, near the W. coast of Lewis. N. lat. 58° 11', W. long. 6° 59'.—Alfo, one of the western islands of Scotland, about nine miles in circumference, and five miles N. from North Uist. N. lat. 57° 55', W. long. 7° 12'.

PABIANICE, a town of the duchy of Warsaw; 32 miles E.N.E. of Siradza.

PABLON, St., a lake in the jurisdiction of Otabalo, in the province of Quito, three leagues in length, and about half a league broad. Its waters are discharged into Rio Blanco.—Alfo, a town of Mexico, in New Navarre; 170 miles W. of Cafa Grande.—Alfo, a town of New Mexico; 70 miles E. of Sumas.—Alfo, a town of South America, in the province of Mexico; 450 miles N.W. of Trinidad.—Alfo, a town of Mexico, in the province of New Bexar; 130 miles S.W. of Piaral.—Alfo, a town of Mexico, in the province of Veraguas; 22 miles S.W. of Remedios.

PABNEIKIRCHEN, a town of Austria; four miles N.W. of Grein.

PABOIS, in Botany. See CAAMINTH.

PABOU, in Geography, a town of Canada, on the N. coast of Chaleur bay; 20 miles S.W. of Cape Goope.

PABULUM is sometimes used among naturalists for fuel, or that part in combustible bodies which the fire immediately feeds on, or is supported by.

PABULUM of Plants, in Agriculture, a term applied to that substance which nourishes them. See FOOD OF PLANTS.

PACA, the Spotted Cavy, in Zoology. See CAVIA PACHUS.

PACAJES, or PACAXES, in Geography, a town of Peru, and capital of a jurisdiction in the diocese of La Paz, containing some rich silver mines, which are not much wrought. Here are also emeralds. The air is variable, sometimes cold, sometimes hot, and occasionally temperate. The pastures are good: and its principal source of commerce and wealth is cattle; 80 miles S.W. of La Paz.

PACALIA, a feast held among the ancient Romans, in honour of the goddess Pacis, Peace.

Alhelminus, de Laud. Virgin, speaking of the impure festivals and ceremonies of the heathens, calls one of them Penatia; which pottage Gronovius charges as faulty, alleging, that there was no feast of that name, but that it should have been Pacalia, or perhaps Puthia.

The ancients, who perfanifed, and even defiled every thing, were not forgetful of Peace: she had an altar at Rome, and a flately temple; and religious rites were paid her with great solemnity.

PACAMARES, in Geography, a district of Peru, where the air is temperate, and which is said to abound with gold.—Alfo, an Indian nation occupying the banks of Amazon river.

PACATIANUS, Titus Julius Marinus, in Biography, an usurer, who excited the Gauls to revolt in his favour, in the reign of the emperor Philip; but he was defeated and put to death in the year 240 by the troops which raised Decius to the throne. There are medals of Pactianus still existing. Moreri.

PACATUS, Latinus Drepanius, who flourished in the fourth century, was a native of Drepanum, in Aquitania, and celebrated as a poet and orator. He was in habits of intimacy with Ausonius, who confulted him on his own writings, and has addressed several pieces to him. When
When Theodofius the Great visited Rome in the year 388, after the defeat of Maximus, Pacatus was despatched from Gaul to congratulate him on his victory. On this occasion he pronounced a panegyric oration before the emperor and senate, which is extant, and in the course of which he said, if the elder Brutus could be permitted to revisit the earth, the Roman republic would abjure, at the feet of Theodofus, his hatred of kings, and ingenuously confess that such a monarch was the most faithful guardian of the happiness and dignity of the Roman people. "Yet," says the historian of Rome, "the piercing eye of the founder of the republic must have discerned two essential imperfections, which, perhaps, have abated his recent love of deputamen. The virtuous mind of Theodofus was often relaxed by indolence, and it was sometimes inflamed by passion:" see Theodorus. Pacatus was afterwards created a proconful, and in 393 was appointed superintendant of the imperial domain. The orator Symmachus addressed several letters to him, and Sidonius Apollinaris mentioned him with applause. He was probably a Pagan. None of his poems remain: his panegyric on Theodofus was printed in 1651, separately, and it is contained in the "Panegyrici Veteres." It is reckoned eloquent for the age in which it was written, "more characterized by force of expression and imagination than by tact and purity of style, and, in its first passages bearing some resemblance to the manner of Tacitus," Moore-Gibbon.

PACAUDIERE, I.A., in Geography, a town of France, in the department of the Loire, and chief place of a canton, in the district of Roanne; 12 miles N.W. of Roanne. The place contains 1,426, and the canton 7,326 inhabitants, on a territory of 245 kilometres, in eight communes.

PACCHIEROTTI, GASPARE, in Biography, one of the most scientific, expressive, and finishing figures, which Italy ever produced, was born in the Roman state, and began his career in 1770, at Palemo in Sicily, where he continued during 1771. In 1772, he was the principal figure in the great theatre of San Carlo at Naples, with the De Amicis. In 1773, at Bologna; in 1774, at Naples again. In 1775, at Milan, with the Taiber; in 1776, at Forli; in 1777, at Genoa and Milan; and in 1778, at Lucca and Turin, previously to his arrival in England, where his reputation had penetrated a considerable time, and where Signor Piozzi, who had heard him at Milan, sung several airs after his manner, in a style that excited great ideas of his pathetic powers. The travels of Captain Brydone had likewise contributed to raise public expectation; indeed our own was excited so much, that we eagerly attended the first general rehearsal, in which, though he sung fatti voce, under a bad cold in extreme severity, and did not feem to exert himself, our pleasure was such as we had never before experienced. The natural tone of his voice was so interesting, sweet, and pathetic, that when he had a misf d'io voc, or long note to swell, we never wished him to change it, or to do any thing but swell diminish, or prolong it in whatever way he pleased, to the utmost limits of his lungs. A great compass of voice downwards, with an ascent up to B flat, and sometimes to C flat, with an abundant fancy, and a power not only of executing the most refined and difficult passages of other figures, but of inventing new embellishments, which, as far as our musical reading and experience extended, had never then been on paper, made him, during his long residence here, a new figure every time we heard him. If the different degrees of sweetness in musical tones to the ear might be compared to the effects of different flavors on the palate, it would perhaps convey our idea of its perfection, by saying that it is as superior to the generality of vocal sweetnefs, as that of the pine apple is, not only to other fruits, but to figgar or trelace. Many voices, though clear and well in tune, are yet infipid and uninteresting, for want of luminancy and flavour. The voice of Pacchierotti, when at its best, was the dolce piaceo. A more perfect shade on short notice, and in every degree of velocity, we never heard. His execution of rapid divisions was so true and distinct, that, with a loud and vulgar-toned voice, he would have been admired as a bravura finger; but the natural tone, and, if we may so call it, sentimental expression and character of his voice, is such, as to make many hearers lament his condescending to rival the lark, or ever, even in pathetic songs, quitting simplicity in order to change or embellish a passage in the most new, artful, or ingenious manner possible. But to lovers and judges of music, who constantly attend the opera, it seems desirable that the performers, during the run of a musical drama, should have the power of stimulating attention to an air often repeated, by a variety of new graces and ornaments, which, in some measure, renovate a long every time it is performed; yet, though Pacchierotti polished this power far beyond any finger we had heard, the public, frequently poissoned by the shafts of envious profciours, and perhaps diletant, was always more inclined to confide than duly commend this talent; for which we can neither ays account, unless this seeming injustice still proceeds from the wishes of an audience to hear more of the sweet tones of his natural voice, undisturbed by art or science.

That Pacchierotti's feeling and sensibility are uncommon, is not only discoverable by his voice and performance, but countenance, in which, through a benign and benevolent general expression, there is a constant play of features, which manifests the sudden workings and agitations of his soul. He is an enthusiast in his art, and feels the merit of a composition and performance with true Italian energy. Nice and fastidious in criticizing himself, he consequently does not gratify frivolous and doubtful claims upon his admiration or applause; but to real and intrinsic merit, we never met with more candour, or heard more judicious and zealous panegyric bestowed from one profciour to another.

To hearers not accustomed to the refinements of singing, his extemporeaneous flights and divisions were in new, that they at first were doubtful whether to blame or commend. But as the true criterion of merit in the arts, is to improve on examination, all perfections of knowledge and feeling constantly experienced increasing pleasure at each performance, however frequent the opportunities may have been of gratifying their wish to hear him.

He is not gifted with a very robust constitution, nor was his chesl proof against the rude and sudden attacks of our climate; so that though he was never obliged by indisposition to be absent from the stage when his duty called him thither, above once or twice during four years residence among us, yet his voice was sometimes affected by flight colds, from which the stoutest natives are not exempt; but when he was quite in order and obedient to his will, there was a perfection so exquisite in tone, tale, knowledge, sensibility, and expression, that our conceptions in the art could not imagine it possible to be surpassed.

The low notes of his voice were so full and flexible, that in private, among his particular friends and admirers, we have often heard him sing Anlani's and David's tender songs in their original pitch, in a most perfect and admirable manner, going down sometimes as low as B flat on the second line in the base.

It appears that in his youth, when his chest was strong, while stimulated by a love of perfection and a determination to
and, which connection He and year, our and "an Olimpiade, funk however, and biography, which have yet"

"but many fluidsorum," 1785. particular the

"lirmnefs read dered he had long perused and prepared them for public performance. This we have often seen him do in original scores, that it was impossible for him ever to have seen before. He was the only modern finger that of late years we had found able to enter into the style of composers and performers of past times; but being an excellent musician, he seems never to have heard a finger of great abilities without remembering the particular traits, inflections, tone of voice, and expressions, which rendered him or her famous. Though he seemed to have a particular zeal for the success of his friend Bertoni's composition at the opera; yet we never perceived a want of ardour in his performance of Sacchi's music, particularly in "Rinaldo," where he sung with as much energy, taste, and expression, as ever it was possible for him to manifeft on any occasion. And in concerts he treated the audience with a greater variety of matters, in the songs he selected, than any finger of our time had ever done. At the Haymarket he was usually obliged to lower his performance, particularly duets, to the level of a first woman of very moderate abilities; we except madame Le Brun, who was however so cold and instrumental in her manner of singing, that they did not well accord together.

We know there were, many frequenters of concerts, who called themselves lovers of music and judges of singing, and yet disliked both his voice and manner, and did not scruple to say, that he had never sung a note in tune during his residence in this country; which was such an insult upon the ears and feelings of his admirers, that they, in revenge, flatly denied their claims to superior knowledge, taste, or experience in such matters.

Almost every great finger unites himself in interest and friendship with some particular composer, who writes to his peculiar compass of voice, talents, and style of singing. Thus Manzoli and Pefcetti, Guarducci and Sacchini, Millico and Gluck, the Agujari and Colla, and Pacchierotti and Bertoni, were closely connected.

In the summer of 1779, Pacchierotti returned to Italy for a year, when he was succeeded by Rongheau, but returned again in 1780, and remained here till after the Commemoration in 1784.

The airs in which the natural sweetness of his voice, taste, expression, and general powers of pleasing, seem to have made the deepest impression, were, "Miferi pargolotto," by Monza, in Demoisonne; "Non temer," by Bertoni, in the fame opera; "Dolce sperme," by Sacchini, in Rinaldo; and "Ti fuggirò todele," in Olimpiade, by Pacchietto.

After retiring from England, Pacchierotti seldom sung in public, except at Venice, in which state, at Padua, he established himself in an elegant house, wholly fitted up with English furniture, and an excellent library of well-chozen English books, of which he was very fond, and was able to read with fluency and taste.

During the Revolution he was much harassed and plundered both by the French and Autrians; and, we fear, was a great lover by the breaking of the bank of Venice, and by other failures where he had invested or lent his property. He is, however, said still to retain the low notes of his voice, which is sunk into a full and rich counter-tenor, and in which he still sings to his friends with more strength and firmness than ever.

PACCHIONI, ANTONIO, a learned physician and anatomist, was born at Reggio in 1664. His early education he obtained in his native place, but he repaired to Rome for the purpose of completing his medical studies, and attended the celebrated Malpighi, who subsequently introduced him into practice at Tivoli, where he resided six years, and obtained considerable reputation. He was therefore invited to return to Rome, where he obtained the friendship of Lancisi, who united him as an associate with himself in the work which he was prosecuting, an explanation of the plates of Eulachius. Pacchioni, from his connection with these two able anatomists, was led into similar pursuits, and now devoted himself to anatomical researches, occupying much of his time in dissection, particularly in the examination of the membranes of the brain. His first work, which obtained some temporary celebrity, was entitled "De Dura Matris Fabrica et Utrum Disquisitio Anatomica," Rome, 1705; but his observations were not confirmed by other anatomists. In this treatise, he advanced an opinion concerning the muscular and contractile nature of the dura mater, which he supported, by means of its connection with the tentorium, to act by alternate compression upon the brain and cerebellum. This doctrine, however, was confuted by Baglivi, Fantoni, and some other anatomists. His second publication was upon a similar subject, and entitled "Differtatio Epistolaris de Glandulis conglobatis Durae Meningae humanae, indeque orbiti Lymphatici ad Piam Menagem productis, ad clariss. Virum Lucum Schroccchemium," Rome, 1705. The alerted discovery of glands in the neighbourhood of the longitudinal fins, involved him in controversies with other anatomists, which produced other publications of his own. In his "Differtiones binse ad spectatìllimum Virum Joannem Fantonii datas; &c," Rome, 1713, he defended this hypothesis of the glandular structure of those parts; and in his "Differtiones Physico-Anatomicae de Dura Meninge humana, novis experimentis et Lâebrationibus auctæ et illustréte," ibid, 1721, he published his final notions on his favourite subject, and continued to maintain the muscular nature and action of the dura mater. Although his opinions have not been received by later anatomists, they were supported with ingenuity, and the investigations, to which the controversy led, contributed to a more accurate knowledge of the parts concerned. Pacchioni died at Rome in 1726. He was a member of the academies of Bologna and Sienna, and of the Society Natura Curiorum. An edition of all his works, with figures, was published at Rome in 4to, in 1741; in which, among other additions, were the following papers, viz. "Epîstola ad Ludovicum Tefli de novis circa foildorum et fluidorum Vim in viventibus, ac Durae Meningis Structurarum et Utrum Observationibus;" "Vécnitantian damnis in Multis Morbis;" and "Propiapi Cordis Historia." Eloy Déité. Hift. Gen. Biog.

PACCHIONI Glandula, in Anatomy, small white and rounded bodies, connected with the membranes of the brain, and named after an Italian anatomist, who described and delineated them. Bichat calls them granulations cérébrales. See Brain, and Nervous System.

PACCIAUDI, PAOLO MARIA, in Biography, an historian and antiquary, was born at Turin in the early part of the eighteenth century. He entered into the order of Theatines, and became librarian to Philip, duke of Parma. He died in 1785. He had passed a studious and retired life, almost entirely occupied in the duties of his station. His principal works are, "De cultu S. Ioanni Bapt. Antiquitates Christianse," 1755; "Monumenta Peloponnesiae," in two vols. 4to; "Memorie de Gran Maestri dell' ordine Gerosolimitano," three vols. 4to; and several dissertations on particular objects of antiquity.

PACE,
PACE, or PACE, RICHARD, a learned priest and considerable statesman, who flourished in the sixteenth century, was probably born at or near the city of Winchester, about the year 1482. He was educated at the university of Padua, at that time the most famous seminary of learning in Europe, with a handsome allowance to defray his expenses. Here he was afflicted in his studies by Cathubert Tonfill, afterwards bishop of Durham, and William Latimer. On his return to England he entered himself of Queen's college, Oxford, of which his patron, bishop Langton, who was now dead, had been provost. He was almost immediately taken into the service of Dr. Bainbridge, the new provost, who was soon promoted to the archbishopric of York, and afterwards being made a cardinal, Pace accompanied him to Italy. In this land of aff villainy Bainbridge was poisons by a priest, out of revenge for having received a blow from him in the moment of passion. Of the manner of the cardinal's death, of the circumstances attending it, and the measures taken to discover those concerned in it, Pace transmitted an account to king Henry VIII. Upon his return home he was sent for to court, where his talents and accomplishments recommended him so powerfully to the king, that he appointed him secretary of state, and employed him in several important negociations. His political character did not prevent him from entering into holy orders; and in the year 1514 he was made prebendary of the cathedral of York, and afterwards an archdeacon. In 1515, Henry VIII. being alarmed at the progrees which the arms of Francis I., king of France, were making in Italy, sent the archdeacon on an embassy to the court of Vienna, for the purpose of engaging the emperor Maximilian to attempt the expulsion of the French from the duchy of Milan. Having succeeded in his mission, he next went into Switzerland, where he induced some of the cantons to furnish Maximilian with troops. In the year 1519, upon the death of the emperor, when the kings of France and Spain declared themselves candidates for the imperial throne, Henry determined to become their competitor, and sent Pace his ambassador into Germany, to watch over his interests at the diet of the empire. His services on this occasion, though not successful, were rewarded, in the same year, with the deanship of St. Paul's, London, as successor to Dr. Colet, and very soon after he was made dean of Exeter. In 1521 he was presented to a prebendal stall in the church of Sarum, and on the death of pope Leo X., in the same year, cardinal Wolsey sent him with proper instructions to Rome, for the express purpose of endeavouring to obtain for the cardinal the papal chair. The election had, however, taken place before he could arrive at Rome, and Adrian, bishop of Tortosa, had been chosen pope. On the death of Adrian, in 1522, Pace was employed a second time to negotiate on Wolsey's behalf, but with no better success than before. Unable to obtain the grand object of his ambition, the cardinal employed Pace in soliciting from the pope an enlargement of his powers as his holiness's legate, which he obtained. After this he was sent ambassador to Venice, where he acquitted himself with much talent: but notwithstanding the abilities by which he fullfilled his character as ambassador, Wolsey conceived a prejudice against him, of which he experienced the dire effects. For two years he received no instructions relative to the object of his appointment, nor any remittances for the support of his expenses, notwithstanding the almost incessant applications which he made to England. At the same time intelligence was imparted to him, that the cardinal, who had been his friend, had become ineradimately hostile to his interests. This usage had such an effect upon Pace, that he fell sick and lost his intellects. Information of his condition having been brought to the king, he infantly gave directions for his return home, where he was so carefully attended by physicians, at the king's command, that his faculties and health were so far restored, as to be able to direct his attention to literary pursuits. Soon after this, Pace was introduced to the presence of the king, who expressed much satisfaction and pleasure at his recovery, and admitted him to a private audience, in which he took the opportunity of remonstrating against the cardinal's unjust treatment. Wolsey was called upon by the king to vindicate himself against this charge: this he found no difficulty in performing, and in his turn attacked the complainant with such vigour, as to get him sent to the Tower, where he was detained a prisoner for the space of two years, till he was at length discharged by the king's command. The rigour of this treatment was more than Pace could sustin; he was again bereaved of his fences, and never recovered the use of them, except at short intervals, when he was able to read and to enjoy the conversation of his friends. He resigned his church preferments a little before his death, and retiring to Stepney, he died in 1532, before he had completed his fiftieth year. He had passed an active life, and devoted all his leisure from public busines to study, the fruit of which he published in several learned works. Of these the first was entitled "De Fructu qui ex Doctrina percipitur Liber;" which was written while Mr. Pace was at Conftance, and in the course of which the author took an opportunity of inveighing against drunkenness, a vice very general at that place. The inhabitants considered the attack as levelled against themselves, and an anwer was written, apologizing for themselves, and their customs in drinking. Pace's next printed work was "Oratio Pace suprimei composita et Pecore percutie inter Henricum Anglie Regem, et Francorum Regem Christiamillium in Aed piculi Londinii habita." He was author also of "De lapfo Hebraicorum Interpretum," of "Epistles," and of several other pieces; and of some translations, one of which was a sermon of Fisher, bishop of Rochefelor, of which he gave a Latin version, which had been preached on the day when the writings of Luther were publicly burnt. Pace was held in high esteem by the learned men of his time. Erasmus denominates him "uiriusque literaturn caletanillimum," and addressed to him more letters than to any one of his correspondents. He had an extraordinary facility in learning languages, and not only spoke several modern tongues, but understood the Latin, Greek, Hebrew, Chaldee, and Arabic. Erasmus was attached to him on account of his candour, the mildness of his temper, and his literary acquisitions, and could never forgive the perfons who had been the cause of his misfortunes.

PACE, POFFUS, STEP, a measure taken from the space between the two feet of a man in walking.

The ordinary pace of a man is two feet and a half; though many reckon it a yard; the geometrical or German pace, called also the greater pace, is five feet.

The ancient Roman and modern Italian mile consists of a thousand paces, miles poftus. The French league is 3000 paces, and the German 4000.

PACE of the Horse, in the Mange, a term signifying the particular manner of his going on the road, or when at work. It is also applied to the lep or progression of other animals of different kind. The most common paces, and those which are natural to the horse, are the walk, the trot, and the
the gallop. There is likewise another pace which is acquired by horses, called the amble, but which, in some appears to be almost natural to them. In some cases it is not uncommon for horses to mix their different paces, and by this means to go in a sort of shuffle between the walk, trot, amble, and gallop; but horses which make use of this kind of motion are rarely of any great utility or value to their owners.

This bad mode in the progression of the horse may proceed from different circumstances, as habit, a fretful disposition; and perhaps, in some instances, from debility in the back or loins, as well as in the legs or other parts.

Where the horse has a good and proper pace, he moves with readiness in these several modes of progression without mixing them in any degree whatever.

PACES, in Surgery. See TOOTH-DRAWING.

PACHA. See BASHAW.

PACHACAMA, or PACHACAMAC, in Geography, a pleasant and fruitful valley in the audience and jurisdiction of Lima, about 12 miles S. from Lima, and celebrated for the conquest of Peru, on account of a famous temple dedicated to the creator of the universe, called by the Incas "Pachacamae.

PACHACAMAC, in Mythology, the name which the idolaters of Peru gave to the Sovereign Being whom they worshipped, together with the sun and other imaginary deities. The principal temple of this deity was situated in the valley above-mentioned, and was founded by the Incas of Peru. This idol was held in the greatest veneration; and it is said that kings and priests entered this temple with their backs towards this altar, and came out again without daring to turn about. Pizarro derived great riches from the temple of Pachacamac, to the amount of 9,000,000 ducats, although 400 Indians had taken away as much as they could carry, and the Spanish soldiers had pillaged it before he came. The ruins that still remain furnish a very high notion of its magnificence.

PACHAMAQLI, in Geography, a town of European Turkey, in Romania; 40 miles S. of Filippopolii.

PACHAMAMA, in Mythology, the name of a Peruvian goddes.

PACHEA, in Geography, a small island in the bay of Panama. This is one of the Pearl or King's islands, low and woody, about 12 leagues from Panama.

PACHECO, John de, in Biography, marquis Villena, the favourite and prime minister of Henry IV., king of Castile. By his inimitating manners and talents he obtained to great an authority, that he dispensed, at pleasure, of all places in the kingdom. Lewis XI. of France corrupted him by a pension, and he perfidiously betrayed his master's interests in the peace of 1443, by agreeing to many articles prejudicial to the kingdom of Castile. Henry, having discovered his treachery, reproached him with it, which so provoked Pacheco, that he actually confounded against the power of his sovereign, and proclaimed prince Alphonso king of Castile in 1465. Shortly after this, Alphonso displeased his minister, and fell a victim to his treachery. Pacheco caused the young king to be poisoned, and was reconciled to Henry, who continued him in his authority and favour till his death, in 1473.

Pacheco, Francisco, a painter, who owes his celebrity more to the ingenuity and talents of his scholars Caneo and Velada, and to his theory and writing, than to his superiority as an artist. He was the pupil of Luis Fernandez, but though partial to the great style, does not appear to have studied it in Italy. With sufficient correctness of outline, judgment in composition, dignity of characters, propriety of costume, observance of chiaro-Scuro, and perspective, Pacheco displays by want of colour, timidity of execution, and dryness of style. Seville possesses the best of his historic performances; of his numerous portraits, those of his wife and Miguel Cervantes were the most praised. As a man of literature, he possesses consider-able erudition; and wit and humour as a writer of epi-

PAC HELBET. At the latter end of the last century there were several famous organists of this name in Germany; of these, John of Nuremberg, born 1671, is said to have been the first who introduced the overture style into Germany. He was successively organist of the principal cities of the empire, and greatly improved both vocal and instrumental church music, by his numerous compositions; all which were still held in great esteem, according to Walther, in 1732, when he published his dictionary.

PACHQUE, in Geography, a small island on the S.W. side of the bay of Panama, on the coast of the N. Pacific ocean, and one of the beautiful islands within the femail-

PACHERRY, a town of Meckley; 90 miles S.E. of Mynnypour.

PACHETE, a circuit of Bengal, bounded on the N. by Currackdsagh, on the E. by Buruan and Biflanpour, on the S. by Midnapour, and on the W. by Silkee, Tamar, and Rangur; about 70 miles long and from 12 to 40 broad. The capital is Rogonatpur. It derives its name from a fort, six miles N.E. from the capital.

PACHI, or PAGHOOUTOC, a town of Thibet; 70 miles S.E. of Hami.

PACHICA, a town of Peru, in the government of Buenos Ayres, seated on this coast, S. lat. 22°.

PACHIRA, in Botany, Asbelt's name for the Cayenne tree which the French call Cacao savage, or Wild Chocolate. Nothing is to be discovered of its etymology or meaning.

PACHIRA, in Geography, a town of Peru, in the diocese of Truxillo; six miles N. of Payta.

PACHITEA, a river of South America, which joins the Maranon at 8° 26', and is esteemed the most beautiful of all its tributary streams. It rises in 10° 46', first running E., then N., and in the early part of its progress it is called the Perubos, especially at its confluence with the Mayro, where it forms a noted haven, from which there is an open navigation to the Maranon.

PACHODECARHOMBIS, in Natural History, the name of a genus of foilis, of the class of the felicetis. The word is derived from the Greek Ναόννης, thick, dowl-

PACHOMIUS, in Biography, a saint and calendar of the Greek and Latin churches, who flourished in the fourth century, was a native of Thebais or Upper Egypt, and born of Gentile parents, who brought him up in their religion. When he was twenty years of age, he was forced to bear arms in the war of Comitante against Maxenius, by which
which means he had the first opportunity of meeting with any Christians who showed him hospitality and kindness, and to whose faith he avowed himself a convert, as soon as he was reduced from military service. He immediately began to practice all the austerity of that perfection which St. Anthony had lately proved himself the parent. He now formed the design of establishing a community of persons subject to the same rules of an ascetic life, and fixed his abode at Tabenna in Upper Egypt, on the banks of the Nile, where he built a monastery, and established rules of discipline, which was reported had been dictated to him by an angel. In a short time the fame of his sanctity drew to him such numbers of disciples, that his house overflowed, and he was obliged to erect new ones, from time to time, till the Upper Thebais was almost filled with monks of his order. He died in the year 350, or, according to others, in 360. In his life, written by a ancient Greek author, and translated into Latin by Dennis le Peir, many miracles are ascribed to him; and in Benedict of Aniana’s “Codex Regularum,” there are preserved eleven of his letters, written with great simplicity, and addressed to the superiors of the monasteries founded by him. In the life already referred to, are preserved the rules of discipline, pretended to have been divinely communicated to him, and in the fourth volume of the “Bibl. Patr.” a larger collection of rules, concerning the diet, the habits, the employments, and the discipline of monks, which is said to have been translated from Pachomin’s original in the Egyptian language into the Greek, and from Greek, into Latin by St. Jerome. Moreri.

PACHORE, in Geography, a town of Hindoostan, in the circuit of Gobud; 10 miles N.E. of Ahar.

PACHUCO, a town of Mexico, famous for the silver mines in its vicinity. It is said, that of these there are not less than 2000. One of them, called Trinity, is supposed to be as rich as any in Mexico; 45 miles N.N.E. of Mexico. N. lat 20° 45′; W. long, 100° 42′.

PACHUNTICA, a genus of Pachysandra, I inrofate, a term used by some medical writers to express incarnating medicines.

PACHYMERUS, or PACHYMENOR, GEORGE, in Biography, a Greek historian, born at Nicea, of a Constantinopolitan family, in the middle of the 13th century. He entered into the church, and was likewise employed in offices of importance in the state under Michael Palaeologus and Andronicus. At the age of nineteen he accompanied the emperor, when he took possession of Constantinople in 1261. He died in the year 1310. He was author of a valuable portion of the history of the East, which is inserted in the collection of the Byzantine historians, and published at Rome in 1668. It consisted of thirteen books, and contained an account of the reign of Michael, and that of Andronicus, down to his twenty-third year. The style is said to be harsh and offensive, yet it is not wholly deficient in eloquence, and the author displays a more free and enlightened spirit than most of his countrymen. This history was translated into French by the presbret Cousin. To Pachymer is attributed a paraphrase on the epistles of Dionysius the Areopagite, and a treatise on the procession of the Holy Ghost; a compendium of the Arian school philosophy was published by him from his MS. at Oxford in 1666. Moreri.

PACHYSANDRA, in Botany, a genus of Michaux, was thus named from pachys, thick or clumsy, and andros, a man, in allusion to the thickened of the filaments. Michaux Boreali-amer. v. 2. 177. Wildl. Sp. Pl. v. 4. 339.—Cliffs and order, Monocot Tetradiace. Nat. Ord. Triacone, Linn. Euphorbia, Joff.
PACIFIC, peaceful, or free from troubles, tumults, &c.
PACIFIC AGE is a denomination given to that period in which our Saviour was born, on account of the general peace which then prevailed through the Roman empire.
PACIFIC Letters, Literae Pacificae, in the Anti-ant Church, was a denomination given to all sorts of letters testifying, given by the bishop or choripiscopus to their priests, when they had occasion to travel abroad; certifying that the bearer was a Catholic, and in communion with the church.
The life of pope Sixtus I. taken from the postcul of pope Damasus mentions that pope as the first who introduced those letters called Formato. Canonica, Communieat, Communicatoria. Ecclesiastica, &c. Pacificae.
PACIFIC Ocean, or South Sea, in Geography, that vast ocean which separates Asia from America: it is called Pacific, from the moderate weather which the first mariners, who failed in it, met with, between the tropics; and it was called the South Sea because the Spaniards crossed the Ilimus of Darien from north to south. It is properly the western ocean, with regard to America.

Geographers call the South sea, Mare Pacificum, the Pacifc Ocean, as being less infested with storms than the Atlantic. Mr. Frezier affirms, it does not defer any that appear.

Separately considered, this immense concavity receives but few rivers; the chief being the Amur from Tartary, and the Huang-ho and Kian-kh from China, while the principal American rivers run towards the east. This ocean, considered as the boundary of the Russian empire, washes the shores of the government of Irkutsk, from Tschukotkoy Nosof, or Cook's Straits, to the frontiers of China; or, in other words, from the south of the river Amakau, that is, from 65' to 45' N. lat. It is divided into two great parts. That lying eastwards from Kamtchatka, between Siberia and America, is eminently the Ealch, or the Pacific ocean; that on the W. side from Kamtchatka, between Siberia, the Chimen Mongolie, and the Kurillic islands, is called the Sea of Okhotk. From the different places it touches, it affumes different names: e. g. from the place where the river Anadyr falls into it, it is called the Sea of Anadyr; about Kamtchatka, the Sea of Okhotk; and the bay between the ditches of Okhotk and Kamtchatka, is called the Sea of Okhotk, the upper part of which is termed Penjikoye mare, that is, the Penjikayan sea, as it approaches the mouth of the river Penjina.
PACIFICATION, the act of restoring or re-establishing the public peace and tranquility.
The word is applied to many ordinances of the kings of France, designed to pacify the troubles that occurred in the kingdom, with regard to religion, during the 16th century, and particularly appropriated to the periods put to the religious broils roused in France in the year 1598, by the edict of Nantz, and the civil commotions, between the English and Scots, ending in 1638.
PACIFICATOR is commonly undergound in the fame sense with mediator; viz. one who endeavours to reconcile princes or powers at variance.

Wicquefort makes a difference between mediator and pacificator. The peace being concluded between France and England in 1621, the instruments on each side were put in the hands of certain ambassadors, who had been employed as pacificators, not as mediators, to be kept till such time as the ratification had been exchanged. So the archbishop of Pisa, the duke of Tuscany's ambassador at Madrid, was never offered a mediator, though the French ambassadors allowed him to be present at the conferences held with the commissioners of Spain, to act as a pacificator of the differences between them. The grand duke had not offered his mediation, nor would France have accepted it. Wicquefort, part ii. feft. 11.
PACIFICATORS, in Church History, a name given to those who, in the sixteenth century, followed the Henoticm of Zeno.
PACIFICUS, in Mythology, an epithet of Jupiter, synonomous with Salamis, among the Syrians, derived from the Hebrew "Salman," which generally signifies pacatus fuit.
PACIFICUS MAXIMUS, in Biography, a Latin poet, was born at Ascol, of a noble family, in 1439; the time of his death is not known, but his poems were printed at Florence in 1489, under the title of "Heccatyglium fives Elegies:" this edition is now very scarce. That of Parma, with his other works, in 1631, is purged of many licentious passages that occur in the former. He mentions the venereal disease in his poems before the discovery of the new world by Columbus.
PACINISCO, in Geography, a town of Naples, in Lavora; 11 miles E.S.E. of Sora.
PACIO, GIOVIO, in Biography, a distinguished jurist and philogopher, was born at Vicenza in the year 1550. From an early age he was distinguished for his proficiency in letters, and being divined for the study of the law, he was sent to Padua, where he studied under the ablest masters that could be obtained. On his return to Vicenza, his propensity to enquiry led him to pursue the writings of the Reformers, for which he was accused to the bishop, who gave orders for his apprehension. He accordingly took refuge at Geneva, where, being delirite of other means of support, he opened a school for children. In 1578 he was chosen professor of jurisprudence in that city. He married a lady of Lucca, who was also a refugee, by whom he had ten children. In 1583 he was invited to a professorship at Heidelberg, and on his acceptance of that office he delivered an oration, "De jure civilis difficultate ac doceendi Methodo," which he afterwards printed, signing himself Beriga, from a country-house belonging to his family. He remained at Heidelberg till 1597, when he quitted it for Sedan, where the duke of Bourbon had established a new academy. In this he held the logical chair till the war broke out, which obliged him to return to Geneva. Soon after he was elected principal of the college of Nifins, whence he removed to the professorship of civil law at Montpelier, where he had as a dilettante pupil the celebrated Pierefe. It was the great object of the pupil to bring back his master to the Catholic faith; and for this purpose he wished to fix him, with a large stipend, at the university of Paris. But Pacio's wife, more zealous than himself for the new principles, could not be brought to reside in a Catholic city. At length, however, he refused a flattering invitation from the university of Leyden, because he had again become a Catholic. In 1616 he removed to Valence...
in Dauphiné, where he occupied the chair of the celebrated Cujas, with a very high salary. About the year 1619, he published a work concerning the dominion of the Adriatic sea, on account of which he was honoured by the republic of Venice with the order of St. Mark; it also procured him a preceding invitation to a professorship at Padua, which he accepted for a very short time; after this, in 1621, he returned to Valence, where he continued his professorial labours till his death, in 1635. The works of this writer are numerous, and chiefly on legal or philosophical topics, in both of which sciences he was profoundly versed. He published new and accurate versions of several of Aristotle's works, which have ranked as models of translations. The great honours and emoluments which he received, and the contends which fulfilled among the most famous universities to obtain possession of him, sufficiently prove that he was one of the most considerable scholars of that period. The titles of his most important works are, "De Contractibus;" "Synopsis Juris;" "De Jure Maris Adriatici;" "Corpus Juris Civilis." He wrote a treatise on arithmetic at the age of thirteen.

PACK, in Commerce, denotes a quantity of goods, made up in loads, or bales, for carriage. A pack of wool is a horse's load, containing seventeen stone and two pounds, or 240 pounds weight. See Wool.

PACKAGE, a duty set and rated in a table taken of goods and merchandize; and all goods not specified in the table are to pay for package duties, after the rate of one penny in the pound, according as they are valued in the book of rates.

PACKERS are really, what their title expresse, packers as well as prefellers of all sorts of bale goods (intended for exportation); for the great trading companies and merchants, for which they are an answerable, if they should happen to receive any damage through bad package; besides this, severall of them are confiderable dealers.

PACKSFIELD, in Geography, a townehip of New Hampshire, Cheffire County, E. of Keene, on the head branches of Ahuebt river, containing 977 inhabitants; 86 miles W. of Portsmouth.

PACKET, or Packet-boat, a vessel appointed by government to carry the mails of letters, packets, and expresss, from one kingdom to another, by sea, in the most expeditious manner. Thus, the packet-boats under the direction of the master-miller general of Great Britain carry the mails from Dover to Calais, in time of peace; from Famouth to Lisbon, Gibraltar, Malta, the Weel Indies, and America; from Harwich to Helvotlayes, or Gottenburgh and Heligoland; from Weymouth to Guernsey and Jersey; from Parkgate and Holyhead to Dublin; and from Milford to Waterford. See Post.

PACK-HORSE, in Agriculture, such a horse as is employed in carrying heavy loads on the back in the manner of a pack.

For this use, horses should be close, well made, and strong.

PACKMOTSE RAY, in Geography, a bay on the eutt coast of the ifland of Martinico.

PACO CAATINGA, in Botany, a coniferous species of Brazilian canna. Margr.

There is a second species of this plant, which is distinguished by the sweetnefs of its leaves underneath, and by its red flowers; and a third species, known by its ceruleous tetrapetalous flowers. Ray.

Paco Sereca, Marg. 750, a species of Brazilian canna, which bears its fruit in clusters at the bottom of the flalk. The freth leaves, as well as the flalk and fruit, before it is ripe, being rubbed, give a smell like ginger, which is very grateful, and therefore serves instead of spices. They are also used in hot-baths. Ray.

PACOLET, in Geography, a small river of America, in South Carolina, which unites with Broad river, 30 miles above Tyger river, and 24 S. of North Carolina line. On this river are the famous Pacolet springs; 17 miles above its confluence with Broad river.

PACORUS, in Biography, son of Orodres, king of Parthia, signalized himself by the defeat of Crafus, whose army he nearly cut to pieces, in the year 52 B.C., and whom made prisoner. He took Syria from the Romans, the republican party of Pompey, and that of the murderers of Julius. After ravaging Syria and Judea, Ventidius defeated him, and Pacorus was slain in battle in the year 39 B.C.

PACOS, in Zoology. See CAMELUS Paco.

PACOURINE, in Botany, a genus in Aublet, t. 105, who names it thus from the Caribbean appellation Packourina. Jussieu retains it, Gen. 148, expressing a doubt of its being distinct from Ambelania of the fame author, t. 104. Both are united by Schreber and Willdenow, under the name of Willughbeiana; see that article.

PACOURI, De Laet, a small tree growing in the island of Maragnan, belonging to Brasil; it bears leaves like those of the apple-tree, a white flower, and a fruit of the bignefs of two fballs. The rind or peel of this fruit, which is about an inch thick, being boiled or preferred in fugar, is reckoned a delicacy. Ray.

PACOURINA, one of Aublet's unexplained names. See HAYNEA.

PACQUING, in Ornithology, a name given by the people of the Philippine iflands, to a small bird of the sparrow kind, but very beautifully variegated. It feeds on the seeds of grasls.

PACK-RAG DAY, in Rural Economy, a provincial term, signifying the day after Martinmas-day, the time of changing farm-ervants.

PACK-SADDLE, a faddle adapted to the carriage of heavy packs or burdens.

PACK-WAY, in Rural Economy, a provincial word, signifying a bridle-road, or horfe-path.

PACT, Pactum, or Paetion, in Law, a covenant or convention between two or more parties.

Ulpian derives the word from the Latin verb pactae, to bargain, agree, contrait; others, with more probability, from pactum, propofal, or pacto, or from pango, I fix, embellish.

The civil lawyers, after Ulpian, define the word pact, the content of two or more parties to the fame thing. "Duorum aut plurium in idem confessus," lib. iii. fct. 2. 77. de paetis.

There are two species of conventions, viz. the pat and contract. A pact against good manners, against public or natural equity, is null. It is a maxim in law, Ex nudo pacto non oritur lex.

PACTA CONVENTA, in Poland, are the articles agreed on between the king and the republic, and which they mutually oblige each other to obserue.

These stipulations were introduced after the demife of Sigismund Augustus, in 1572, when all title to the crown, from hereditary right, was formally abrogated, and absolute freedom of election establifhed. At this era a charter of immunities was drawn up at a general diet, to be ratified by the new sovereign before his election. The groundwork of this charter, termed in the Polish law " pacta conventa," was the whole body of privileges obtained from Louis and his succifors, with these additions: 1. The king to be elective, and his succifor never to be appointed during his life: C 2. The
2. The diets to be assembled every two years: 3. Every noble or gentleman in the whole realm to have a vote in the diet of election: 4. Should the king infringe the laws and privileges of the nation, his subjects be absolved from their oaths of allegiance. From this period, the “pacta conventa,” occasionally enlarged, have been confirmed by every sovereign at his coronation.

PACTOLUS, in Ancient Geography, a river of Asia, which had its rise on mount Emolus, in Lydia, watered the plain adjoining to Sardis, traversed that town, and ran into the Hermus, which discharged itself into the gulf of Smyrna. This river is said to have contained a quantity of gold. As to the table related concerning it, we refer to Midas. The kings of Persia obtained possession of the Pactolus and its treasuries, by Cyrus’s conquest of Lydia. Xerxes I. drew gold from the Pactolus, and this valuable metal was furnished by it in the time of Herodotus; but it afterwards failed long before the time of Strabo. The gold of the Pactolus was derived from the mines of mount Emolus; and when these were exhausted, the supply of the river was discontinued. This river was, according to Varro and Chryfotom, the chief source of the wealth of Crete.

PACUVIUS, Marcus, in Biography, a Latin tragic poet, was a native of Brundusium, and is said to have been the father’s son of Ennius. He flourished about the year 154 B.C., and is renowned as the friend and poet of C. Lewis. In the rude state of the Roman theatre, he obtained a high reputation; and his tragedy of Orestes is mentioned by Cicero in his “De Amicitia,” as having been heard with thunders of applause. He was the author of some fates, and had a talent for painting. In advanced life he retired from Rome to Tarentum, where he died, having nearly reached his ninetieth year. The fragments of his work, which still remain, have been published in the “Corpus Poetarum Latinorum” of Mattei. Morei.

PACY, in Geography, a town of France, in the department of the Eure, and chief place of a canton, in the district of Evreux, seated on the Eure, and formerly surrounded with walls; 11 miles E. of Evreux. The place contains 4750, and the canton 9930 inhabitants, on a territory of 195 square kilometers, in 32 communes.

PACZANOW, a town of Poland, in the palatinate of Sandomirz; 28 miles E.S.E. of Sandomirz.

P.D., in Rural Economy, a term applied to a fort of stuffed cushion, a foot-path, and also to an easy paced horse.

PAD-Saddle. See Saddle.

PADA, in Geography, a town of Hindoostan, in the circuit of Genganpour; 30 miles E. of Ganganpour. N. lat. 21° 56′. E. long. 84° 59′.

PADDANG, a sea-port town on the W. coast of the island of Sumatra. This was the principal settlement of the Dutch, who established themselves here because it was in the vicinity of Menaycabo, the richest seat of gold; and it was under the government of a director and council. The fort is situated within 40 yards of the north bank of the river, and is of a square form, having four bastions of stone, and walls about nine feet high. On the south side of the river are high mountains, which extend to the sea-coast. The water is very good; and both cattle and fruit are plentiful and cheap. Padang, before its capture by the English, in 1781, used to draw to itself about a third part of the whole quantity of gold procured at the several ports on the W. coast of Sumatra, which has been estimated at about 10,000 ounces annually. In this place there has been a considerable manufacture of ilangree. (See Filigrane.) S. lat. 0° 40′. E. long. 99° 48′.

PADDANG, a small island in the East Indian sea, near the W. coast of Borneo. S. lat. 0° 33′. E. long. 109° 21′.

PADDANG-Goodie, a river of Sumatra, which divides the Lampoon country, or a portion of the southern extremity of the island, from Pallumah, near the sea-coast.

PADASJOKI, a town of Sweden, in Tavalland; 36 miles N.E. of Tavallhus.

PADATO, a town of Mexico, in the province of Cuilcan; 40 miles N.W. of Cuilcan.

PADBERG, a town with a citadel, in the kingdom of Wolphalia; 5 miles E. of Brilon.

PADDA, of Rice-Bird, in Ornithology. See Lonix Orzyvora.

PADDA. See Rice.

PADDINGTON, in Geography, a parish and village in the hundred of Stoodle, and county of Middlesex, England, is situated at the north-western extremity of London. The parish, which extends about two miles in length, is bounded by Kennington, St. Margaret’s, Wolwich, and St. George’s, Hanover-square, on the south; by Wilton on the north; by Mary-le-Bone on the east; and by Kennington, and a detached part of Chelsea, on the west. According to a survey, its area comprises 1197 acres, 3 roods, and 30 perches, of which about one hundred acres are laid out as garden-ground, and the remainder is occupied by houses, and appropriated to pasture.

The village of Paddington stands about a mile to the north of Tyburn turnpike. Like most of the other villages connected with the metropolis, it has increased greatly in extent of late years, and, since the opening of the canal in 1801, has become a place of considerable commercial importance. This canal, which derives its name from the parish, branches off from the Grand Junction canal near Norwood, and passing through the parishes of Ealing, Northall, Greenford, Perivale, Harrow, Acton, Fulham, Twyford, and Wilton, as well as the detached parts of Chelsea and Kennington, terminates at this village in a large basin, on the sides of which are convenient wharfs and warehouses, belonging to the Paddington canal company. The advantages of this cut must be obvious to every one at all acquainted with the inland navigation of this country. By entering the Grand Junction canal, it affords to Paddington, directly or indirectly, a navigable communication with almost every trading or manufacturing town in the kingdom. The New, or Regent’s canal, which is to connect the Paddington canal with the river Lea, and consequently with the Thames below London, is now in rapid progress of execution; and this may likewise be regarded as a measure which promises much commercial benefit, not only to the capital but to the country at large.

Paddington manor in ancient times constituted part of the possessions of Wolwich Abbey; at the dissolution it was annexed to the bipsip of Wolwich; and when that see was abolished, soon after its establishment, Edward VI. transferred it to Ridley, bishop of London, and his successors, along with the advowson of the church, which is supposed to have first become parochial about the same time. The church, since that period, has been twice erected; first by Sir Joseph Sheldon, lecturer of the manor, little more than a century ago, and again in 1791, by the parson, under the authority of an act of parliament. It is a square building, with a projecting wing on each side, and a portico of the Doric order, fronting the south. Several persons of note are buried, both in the church and in the surrounding cemetery, among whom are John-Henry, marquis of Lansdown, Dr. Geddes, and the celebrated Itinerary Banks. In Lyforn-Green is a small chapel of ease, called the “Bentinck-chapel;"
chapel;" and close to the Mary-le-Bone turnpike is another place of worship, erected within the last few months, and denominated the “Paddington chapel.”

In this parish are the hamlets of Baywater, and Tyburn. Contiguous to the former are large public tea-gardens, formerly appropriated as physic-gardens by the late Sir John Hill. Here is also the Queen’s Lying-in hospital, originally instituted in 1752, in St. George’s Row, near Tyburn turnpike, but removed hither in 1791. It is an excellent establishment, and is much indebted for its present prosperity to the active exertions of their royal highnesses the dukes of Suffer and Cambridge. Tyburn is noted for having been the place of execution for the malefactors of London and Middlesex, till the year 1783. Here were likewise nine of the city conduits, and a banqueting-house, belonging to the lord mayor, which was demolished in 1737. None of the conduits now remain, but there is a large reservoir newly constructed, at a short distance from the westward of the canal basin, whence a considerable division of the west end of the town is supplied with water.

Paddington parish, according to the late parliamentary returns of 1811, contains 935 houses, and a population of 4,609 persons. A charity-school, established here in 1802, for thirty boys and the same number of girls, is supported by voluntary contributions; and there are several almshouses for the accommodation of the poor, the gifts of various benefactors. Lyfons’s Environs of London, &c. vol. iii. edit. 1795. Supplement by the same author, 4to. 1811.

PADELE, a term used for a small flaxen; such are those that fill and empty the locks of a canal. See Lock.

PADELE-hale is the crooked arch e e (Plate V. Canals, fig. 36.) which gives a passage for the water from the upper pound to fill the lock.

PADELE-WIR. See Lock-Wir.

PADEL, a fort of oak used by the natives of Africa, America, and some of the islands in the South Sea. They are made of light wood of various shapes, but oddly shorter and broader in the blade than our oars, and instead of rowing with them horizontally like an oar, they manage them very dextrously, in a perpendicular manner, either for rowing or steering.

PADELE in Glass-making, a name of an instrument with which the workman flits about the fawd and ashe in the calker.

PADEL, in Agriculture, an implement used by ploughmen to free the share from flubble, earth, clay, &c. which impedes its action.

PADDOCK, or Paddock Courte, a piece of ground, generally taken out of a park, ordinarily a mile long, and a quarter of a mile broad, encompassed with pales or a wall, for the exhibiting of races with greyhounds, for wagers, plates, or the like.

At one end of the paddock was a little house, where the dogs were to be entered; and whence they were flipped; near which were pens to enclose two or three deer for the sport.

The deer, when turned loose, ran all along by the pale; and the spectators were placed on the other side.

Along the course were several polls; viz. the law-poll, 160 yards from the dog-house and pens; the quarter of a mile poll; half-mile poll; and pinpoint poll; beside the ditch, a place made to receive the deer, and prefer them from farther pursuit. Near the ditch were placed judges, or triers. For further particulars, see the article COURTING.

PADELL, in Agriculture, a small field or inclosure. It also signifies a large road.

PADENS, in Commerce, a sort of bitter almonds from Persia, which are used at Surat for money, about 60 of which pass for one piece.

PADEPATNAM, in Geography, a town of Hindostan, in the Carnatic; 35 miles S.S.E. of Tanjore.

PADER, a river of Wetphalia, which rises near Paderborn, and about three miles from the town is joined by two other streams, and forms the Lippe.

PADERBORN, a city of Wetphalia, and capital of a bishopric of the same name. The bishopric or principality is bounded on the N. by the county of Lippe, on the E. by Helff and Calenberg, on the S. by the duchy of Wetphalia and the principality of Waldeck; and on the W., by the counties of Reitberg and Lippe, in the duchy of Wetphalia; its greatest length being about 44 miles, and its greatest breadth 36. The greater part of it is fertile, and produces a great breed of cattle; but some part of it is an extensive heath. It has some good iron-mines, salt and medicinal springs, and several rivers that abound in fish: the principal of which are the Wefer, Dimel, Nette, Lippe, Alm, and Pader. In 1802 this bishopric was given to the king of Prussia, and by the peace of Tilsit, it became a province of the new kingdom of Wetphalia.

The city was chosen by Charlemagne as a place of abode, when he willed to put an end to the Saxon war of 30 years’ duration; accordingly he fixed his camp here, and erected it into a bishopric, which was confirmed by pope Leo. Hence the town became considerable, and several diets were assembled here. It enjoyed imperial privileges, carried on a great trade, and was reckoned one of the Hanse-towns. At present it has much declined, and its trade is become insignificant. Besides the cathedral, it has a collegiate and two paroch churches; 42 miles S. of Minden. N. lat. 52° 40’. E. long. 8° 54’.

PADERNAL, a town of Portugal, in the province of Algarve; 9 miles N. of Silves.

PADEW, a town of Poland, in the palatinate of Sandomierz; 32 miles W. of Sandomierz.

PADDON, Don Juan de, in Biography, the leader of a popular insurrection in Cadiz against the ministers of Charles V., was the eldest son of the commissary of Cadiz. When the cortes, or parliament of Spain, assembled in Galicia, and had voted the emperor a free gift, without obtaining the redemptions of grievances under which the nation laboured, the citizens took up arms, gained possession of the calle, established a popular form of government, and chose Padilla as their leader. He was well qualified for the duties imposed upon him, and his zeal was animad by that of his wife, Maria de Pacheco, a lady of noble birth, great abilities, and unbounded ambition. The regent, cardinal Adrian, having sent a body of troops under Ronquillo for the reduction of the revolted citizens, Padilla came to their assistance with a considerable reinforcement, and gave Ronquillo a defeat. He then, in concurrence with the other leaders, appointed a general convention of the malcontents, to be held at Avila. In this assembly, deputies appeared from almost all the cities entitled to representation in the cortes, and formed a solemn league of mutual defence, under the title of the junta. They placed the dowager queen Joanna, who was almost in a state of mental debility, at the head of the government, renounced the authority of the regent, and confined on all their operations in her name. Padilla next proceeded to Valladolid, where he reduced Adrian to the condition of a private person, and seized upon the archives and seals of the kingdom. The junta then drew up a remonstrance, containing a statement of grievances, with demands for redemptions, which struck no less at the privileges of the nobility than at the prerogatives of the crown; and thereby
PAD

thereby produced an union of the nobles with the royals. The junta, at first, jealous of the popularity of Padilla, substituted at the head of a large army Don Pedro de Giron, a nobleman high in rank, but wholly unequal to the trust committed to him. Through his unskillfulness the person of the queen was recovered by the royals, together with the seals and public archives, and several of the members of the junta were made prisoners. Padilla was now raised to the chief command, and to procure the necessary supplies of money, Donna Maria went with her train to the cathedral of Toledo, in which was contained a vast treasure of ecclesiastical wealth. She entered it in solemn procession, with all the marks of the deepest sorrow and contrition, and her train, after much ceremony, proceeded to the pillage which afforded a rich booty. Padilla was for a time successful in various small encounters, but at length the royal army advanced upon them, in April 1521, and put them to flight almost without resistance. Padilla attempted, but in vain, to rally them, and resolved not to survive the ruin of his party. He rushed among the thickets of the foe, was wounded and made prisoner, together with his principal officers. On the next day, without the form of trial, he was led to execution. He viewed the instruments of death without terror or dismay, and having written two moving and eloquent letters to his wife, and to the city of Toledo, he quietly submitted to his fate. When the sentence was read proclaiming them as traitors, one of his fellow sufferers betrayed emotions of indignation, but Padilla restrained him, observing, "that yesterday was the time to have acted with the spirit of gentlemen; to day that of dying with the meekness of Christians." After his death, his widow Donna Maria supported the sinking cause, and to revenge his fate, she raised new forces, and used every art to animate the citizens of Toledo to a vigorous resistance. She marched through the streets with her train, in deep mourning, seated on a mule, before whom a standard was borne representing his father's execution. At length, however, the city was invested by the victors, and though they defended the citadel, to which in an early period of the siege he retired, with great resolution for four months, she was at last under the necessity of escaping in disguise, and fled to her relations in Portugal, where she ended her days. Robertson's Hist. of Charles V.

PADILLA, LORENZO DE, one of the historiographers of Charles V. is celebrated on account of his great eminence as a Spanish antiquarian. He took great pains in preferring Roman inscriptions, and ascertaining the classical geography of Spain. Among other works, he left a general history of Spain, in four parts, a few sheets of which have been preserved, a proof that it had been committed to the press, though the impression was probably never completed. The manuscript is still in the Dominican library of St. Paul's at Cordova. Padilla was one of the earliest genealogical writers among the Spaniards. Gen. Biog.

PAD.2EE, in Geography, a town of Hindoostan, in Guzerat; 10 miles S. of Durrampour.

PADMA, or PAGNA, in Mythology, is an attribute of the Hindoo deity of Vishnu, and in pictures and statues is generally seen in one of his four hands, in the form of a lotus or lotus, for which lovely aquatic padma, or padma, is a Sanscrit name. (See LOTOS.) As there noticed, Padma is a name of Lakshmi, confort of Vishnu, as is also Pedma, and Pedmalaya. Pedma-devi, meaning goddess of the lotos, or perhaps queen of beauty, is a name likewise given to Lakshmi, and sometimes to Parvati, the confort of Siva. Pedma-nabha, and Pedmaksha, denoting lord or possessor of the Padma, or of Lakshmi, are other names of Vishnu. Ramala is another Sanscrit word for the lotos, and for the goddess named after it, similar to Pedma. (See KAMALA and LAKSHMI.) One of the eighteen sacred mythological poems is named Padma Purana. See PURANA.

PADOBÉ, of Senegal, in Ornithology. See TURDUS Erythropterus.

PADOGI, a species of punishment used in Russia. In this punishment the body of the criminal is flapped to the waist, and then laid upon the ground; one flake holds the head between his knees, and another the lower part of the body; then rods are applied to the back, till some person gives notice to desist, by crying out enough.—This punishment is considered in Russia merely as a correction of the police, exercised on the soldier by military discipline, by the nobility on their servants, and by persons in authority over all such as are under their command.

Ever since the accession of Elizabeth to the throne of Russia, the punishments were reduced to two kinds, viz. the padagi and knout.

PADOLA, in Geography, a town of Italy, in the Cadon; 13 miles N.N.E. of Cadara.

PADOINGEWE, a town of the Birman empire, on the Irrawaddy; 6 miles S.W. of Prone.

PADOR, a town of Africa, in Danel, on the Senegal. N. lat. 14° 30'. W. long. 14° 20'.

PADOCAS, a western branch of the river Misifour. The inhabitants of its banks are called Padousas, and are said to have been of Welsh origin.

PADRAMA, a small island near the coast of Sardinia. N. lat. 40° 38'. E. long. 9° 53'.

PADRÁN BAY, a bay on the S.E. coast of Cochinchina. N. lat. 11° 24'. E. long. 102° 40'.

PADREAH, a town of Hindoostan, in Guzerat; 10 miles N. of Barouch.

PADROENS, a town of Portugal, in the province of Alentejo; 13 miles W. of Mertola.

PADRON, EL, a town of Spain, in Galicia, situated on the Ulla; anciently called "Iriss Fluvia;" 15 miles S. of Santiago.

PADRON, Cape, a cape on the W. coast of Africa. S. lat. 6'. E. long. 12° 20'.

PADSHAWPOUR, a town of Hindoostan; 30 miles S. of Delhi.

PADSTOW, or PENCOSTOW, a market and sea-port town in the hundred of Pyder, and county of Cornwall, England, is situated on the west side of Padstow haven, near the mouth of the river Camel or Allan, which falls into the Bristol channel. It is distant 243 miles W.S.W. from London, and 30 miles W. by S. from Launceston. This town is of considerable antiquity, and is said to be the spot where St. Patrick founded the first religious house in Cornwall, when he arrived from Ireland in the year 432. It was first called Lodenick, and afterwards Adellfow, from king Athelthain, who, according to tradition, conferred many privileges on the inhabitants. The market-day here is on Saturday, weekly, and here are two fairs during the year. The harbour is amongst the best on the north coast, though much obstructed by sand, except in the middle channel, by which vessels of large burden may enter, and find a commodious anchorage. Padstow is governed by a portreeve, assisted by a certain number of the most respectable inhabitants. Its chief support is derived from the trade it possesses in the pilchard fishery, and the custom of the numerous small vessels which resort to the harbour in the event of contrary winds, or storms of weather. Humphrey Prideaux, the learned dean of Norwich, author of the "Connection of the Old and New Testament," was a native of this town. According to the parliamentary elections of 1811, the parish of Padstow contains 237 houses, and a population of
PADUAN, in Geography, a country of Italy, bounded on the N. by the Trevisan, on the E. by the Dogado of Venice, on the S. by the Polifino, and on the W. by the Vicentia; about 35 miles from N. to S., and 28 from E. to W.; being formerly a part of Lombardy. The air is fabulous, except in a few places situated near the salt marshes. The land is flat, and the eminences are hilly rather than mountains, and produce grapes of excellent flavour, oranges, and other fruit, exclusively of corn, hemp, rice, and all kinds of vegetables. The aspect of the country presents plantations of vines. Here are also commons for the grazing of cattle, and mulberries for the culture of silk, which yields a considerable trade. Upon the whole, we may observe, that this country has been denominated a second paradise, and the garden of Europe. The number of inhabitants has been estimated at 300,000. The rivers Adige, Brenta, Bagnolo, and Maffi, though they sometimes do injury by overflowing their banks, contribute to the enrichment of the country, particularly by promoting navigation and commerce, and by giving motion to a number of mills. This country, which in 1405 became subject to the dominion of Venice, followed its fate, under the new arrangement of the French revolution, in being annexed to the kingdom of Italy. The principal places are Padua, Vicenza, Arqua, Campi S. Pietro, Padua, and Monfeluco.

PADUAN, among Medallists, a modern medal made in imitation of the antique; or a new medal struck with all the marks and characters of antiquity.

The name is taken from Paduan, Paduanus, a famous Italian painter, who succeeded so well in the impotence, if it may be so called, that the bell judges are at a loss to distinguish his medals from the genuine ones. This Paduan was thus called from the place of his birth, Padua; his proper name was Giovanni Cavino; others say, Lewis Lee; he flourished in the seventeenth century. Goethe Rink adds, that he had an associate in this forgery, called Alexander Bassianus. His son Octavian, though born at Rome, was also called the Paduan.

PADUAN is properly applicable to those medals only, which are struck on the matrices of the elder Paduan; which are still preferred. Though it is frequently used in the general for all medals of this kind.

Joubert observes, that there have been a Paduan and Parmelian in Italy, and a Carteron in Holland, who had the knack of imitating the antique in perfection. The Parmelian was Laurentius Parmelianus. We may also add another Italian who excelled in this way, viz. Valerius Bellus of Ventimia; but his medals are not so common as those of the rest.

PADUANINO, Dario, in Biography. His real name was Dario Varotti, but he is better known under the one by which we have designatc him. He was born at Verona in 1539, and at first attached himself to the study of archi-
tecture; but afterwards received instructions in painting from Paul Veronese, and became a very skilful artist. His fame rests principally upon the pictures he painted for the churches in Padua and in Venice, but there are many very graceful and agreeable productions of his upon a smaller scale scattered about, and some few are found in this country. They indicate a lively and brilliant, though not a profound genius, and exhibit the gay effect of the Venetian style, which he adopted in a pleasing manner.

He was renowned for his piety as well as for his ingenuity; and in the act of returning thanks at the shrine of the Virgin, in Padua, for having been miraculously preserved when a scaffolding had broken and fell with him, he was smitten with apoplexy, and died at the age of 37, anno 1596. He left a son, Alexander Varotti, called also Paduano, who was so successful as his father, though he was not without merit. He died in 1650, at the age of 60.

A daughter also of Dario's excelled in portraiture. Her name was Chiari, and she is highly praised by Rodolfi.

PADULA, in Geography, a town of Naples, in the province of Otranto; 4 miles N. of Nardò.—Alto, a town of Naples, in Principato Città; 14 miles N. of Policastro.

PADUS, in Botany, a name borrowed from Theophrastus, who gives no other account of his padus, than that it greatly delights in a shady situation, like the Yew, and another plant which he denominates thepandora, and which some have judged to be the Quellerâ, Viburnum Opulus. Padus is now applied to the Bird cherry, Prunus Padus of Linnaeus; a tree to which the above account is hardly suitable, but which is nevertheless considered as the plant of Theophrastus by his recent commentator Mr. Stackhouse.

PADUS, in Ancient Geography, the Po, a river of Gallia Transpadana, commencing towards the W., at mount Vefal, and running eastwards, so as to discharge itself into the Adriatic gulf by many mouths, in which case the Egyptians called it "Eridanos" or "Eridan." The origin of the name has been traced by etymologists to a corruption of the Celtic "bodes," whose root is "bod" or "pot," and refers to its height and depth. According to Pliney the Po received 30 rivers; but Cluver reckons as many as 40; under which number they must have comprehended many torrents, which become dry in summer.

PADUTI, in Geography, a town of Naples, in Calabria Città; 4 miles E. of Rofano.

P.EAN, padus, in Antiquity, a hymn in honour of Apollo, or some other of the gods; chiefly used on occasion of victory and triumph. They were sung in the procession at the Panathenaia.

Feilus derives the word παδος, παδον, παιρης, to finite, shoot; but Hefychius rather takes Apollo to have been denomi-
nated Pan, from παν, πάντος, I heal; in allusion to his being the deity of medicine.
The Pean took its name from Apollo himself; who was denominated Peon; because in his combat with the serpent Python, his mother Latona encouraged him to make use of his arrows, by crying frequently, in εἰς, in εἰς, do boy bravely.

Pean, or Peon is also a name of a foot in the ancient poetry; so called, as commonly suppos’d, because appropriated to the hymn Pean; though Quinquilian derives the name from its inventor Peon, a physician. There were four kinds of feet called Peans.

The first Pean consists of four syllables, one of which is long, and the rest short, as colligere; the second is composed of a short, a long, and two short, as resolvere; the third of two long, a short, and a long, as communicant; and the fourth of three short and one long, as ternereus.

P. CECILIA, in Ichthyology, a name given by Schoneveld, and some others, to the fish called by most authors the Mytilis foliis. It is properly a species of cobitis, and is called by Astrid the bluefin cobitis, with five longitudinal black lines on the body. See Corbis Foliis.

P. DARTHRACACE, from παι, a child, ἀγερος, a joint, and υπαντ, an evil, in Surgery, a scrofulous swelling of a joint; a disease to which children are particularly subject.

1. P. fatida. Stinking Opa1-berry. Linn. Mant. 52. Banks Icon. Kæmpf. t. 9. Lamarck f.t. (Convolvulus fartoidus; Rumph. Amboin. v. 6. 456. t. 160.)—Leaves ovato-lanceolate, or somewhat heart-shaped. Panicles cy-mose. Germs smooth. Corolla externally downy.—Native of China, the East Indies, and the island of Mauritius. A climbing shrub, with long, smooth, twining, compound, leafy branches, spreading to a great extent over the neighbouring bushes and trees. Leaves opposite, on long roughish stalks, lanceolate, pointed, entire, various in breadth, more or less ovate or rounded at the base, sometimes heart-shaped. Stipulas within the flower tablets, short, triangular, deciduous. Panicles axillary, compound, forked, cy-mose, twining, more or less downy. Bracteas small, membranous, jagged. Germs and calyx smooth and shining, small. Corolla about half an inch long; externally downy and greyish, internally of a deep purplish brown, lined with hairs. Berry the size of a currant, globose or oblong, crowned with the calyx, smooth, shining, very brittle, pale green and feminipient, finally yellowish. Rumphius says the leaves are very feto3 when rubbed, or when the fun shines upon them, infomuch that those who pass by where the plant grows, are greatly annoyed with the smell. This odour is of a fierceraceous kind, like that of another plant of the same natural order, Ermodoe montana, Sm. Prodr. Fl. Grec. Sibth. v. 1. 98. (See Erinacea.) We have seen the Pedaria in the faves at Paris in 1786, and have per-ceived this smell. This plant is said to have been brought to Kew in 1806, but has not yet flowered. One of Linnaeus’s specimens from China, on which the shining berries, though dried are very beautiful, has heart-shaped leaves, exactly like Kæmpf’s plate, with very downy flaks both to the leaves and flower. Most specimens accord with the figures of Rumphius and Lamarck; yet we do not see sufficient grounds to distinguish theirs as a species, from that of Kæmpf.

2. P. fragrans. Fragrant Opa1-berry. Lamarck Dict. v. 2. 160. Illustr. t. 166. f. 2. Willd. n. 2. Leaves elliptical. Panicles Corymbose. Germs downy. Tube of the corolla smooth. Gathered in woods in the island of Mauritius, by Commeron, who taking it for a new genus, named it Danais. In allusion to the history of the Danaides who murdered their husbands, “because,” says he, “where the flowers of this plant are luxuriant, the male or the female organs are rendered abortive.” This is abundantly diffused from the first species, in its more elliptical and brighter-coloured leaves; but more especially in its corymbose downy panicles, downy germs and calyxes, and longer, more flender, corolla, whose tube is quite smooth, even though the limb be sometimes slightly hairy at the back. The flowers are said to have the scent of a Narcissus, but even more delightful; their colour is red. Commeron describes the fruit as globular.

P. PEDEROTA. See Hemmeris and Wulfenia. The name is ancient, and has been applied by some to a species of Tenoria. by others to the Acanthus fpinosus.

P. PEDO-BAPTISM, a compound of παις, υπαντ, infant, and βapist, baptism, infant baptism, or that conferred on children. See Baptism.

P. PEDO-BAPTISTS, formed of παις, υπαντ, infant, and βapist, baptizos, those who maintain that baptism should be administered to infants. In support of this opinion, they plead, that if infants, under the Christian dispensation, were excluded from the privilege of baptism, the Christian institution must appear, in this respect, to be less complete and perfect than that of the Jews; and it is not likely, by arguing a priori, that God would appoint an external sign of peculiar distinction and benefit for children under the patriarchal and Jewish constitution, without any similar appointment under the Christian dispensation; more especially as the first prophets to Christianness, and those in particular who were converted from among the Jews, would naturally expect some token of distinction and privilege, comprehending their children, and refembling in its design, though milder in its nature, that which Christianness had abrogated. This expectation was farther encouraged by the very condescending and affectionate manner in which our Lord expressed himself concerning infants; particularly when he says, Mark x. 14. “Of such is the kingdom of God;” which some understand to signify, that the rights and privileges of the Christian church belong to such. With these views, it is easy to conceive to what subjects they would apply the general charge to baptize profestes, unless they had been directed and restricted by some express order.

An order of limitation was absolutely necessary to prevent their mistaking the proper subjects of baptism, and misaplying this ordinance, if infants were to be excluded. This would be the more likely, as they would explain the precepts of Christ, concerning baptism, by the custom prevailing among the Jews, in his time: and as it was the practice, when profestes came over to the Jewish religion, to baptize the children with the parents, the apolies would naturally conclude, that children were included in the general comission. Matt. xxviii. 19.
Mr. Wall has endeavoured to shew, from the books of the Jews themselves, and those of others, that understanded the Jewish customs, and have written concerning them, that it was the custom of the Jews before our Saviour's time, and, as they affirm, from the beginning of their law, to baptize as well as circumcise any profylete that joined them from other nations, and with him, at his defence, his infant children likewise.

Moreover, the advocates for infant baptism urge more directly the argument from circumcision after this manner: the covenant made with Abraham was a covenant of grace, by which spiritual and eternal blessings were promised to him (see Matt. xxii. 31, 32. Heb. xi. 6. Rom. iv. 11-17. Gal. iii. 6.-18. 29.) and as such comprehended both Jews and Gentiles, and their seed. Circumcision was instituted by God as a token of that covenant, and as such, he commanded that it should be administered to the infant offspring of his covenant people. Gen. xvii. 1-4. And yet, though the covenant endureth, that ancient token of it is abolished; nor is there any external sign or seal of it, under the Christian dispensation, except baptism. We have, therefore, reason to think, that this ordinance was intended to succeed circumcision, as it resembless it in many respects, and seems to be called the circumcision of Christ, by the apostle Paul, Col. ii. 11, 12. And inasmuch as circumcision was administered to infants, in token of this covenant, baptism, being its substitute and antitype, ought to be administered to infants likewise. Consult Acts, ii. 39. Rom. xi. 17, 18.

Another argument for infant baptism is deduced from the words of the apostle, 1 Cor. vii. 14. which are supposed to have a direct reference to infant baptism; because holy often signifies those that might be admitted to sacred rites, and unclean such as were to be excluded from them. Daddr. in loc.

The Pædo-baptists acknowledge that there is no direct and express command to baptize infants; but appealing to the history of the administration of baptism, they argue, that the apostles are said to have baptized whole families, (Acts, xvi. 15, 33. 1 Cor. i. 16.), and, therefore, probably infants, comprehended under this general denomination. And they apprehend, that they have been able to trace such intimations at least of infant baptism, in the earliest ages of the church, as may, to a high degree of probability, prove it to be an apostolic, and consequently divine institution.

Irenæus, who was born about the time of St. John's death, and probably of Christian parents, mentions infants among the regenerate, i.e. the baptized, as the word generally signifies in his writings.

Justin Martyr, about forty years after the apostles, speaks of some who had been made disciples from their infancy.

Tertullian, about one hundred years after the apostles, though he advises parents to defer baptizing their children, except when their lives were in danger, speaks of the practice as generally received and observed in his time.

Cyprian, about one hundred and fifty years after the apostles, is allowed by all to speak expressly of infant baptism, as generally used in the church; and we learn, that, in his time, A.D. 253, a question being agitated among sixty-bishops, in the council of Carthage, Whether an infant must be kept till he was eight days old before he be baptized, all unanimously gave their opinion to the contrary.

There are many passages that expressly refer to infant baptism in the works of Origens, who was born of Christian parents; and as his father was martyred in the year 202, when he was seventeen years old, the remoter Christians of his family must have been nearly contemporary with the apostles.

In the Apostolic Constitutions, which are allowed to be very ancient, express mention occurs of infant baptism, as commanded by Christ. Matth. xix. 14.

The learned Wall, who took great pains in this inquiry, informs us, that, in the firr four hundred years after the apostles, there appears to be only one, viz. Tertullian, who, in some cases, advised the delay of infant baptism; and another, viz. Gregory, who practised such delay in the case of his own children; but no society of men adopted this opinion, nor did any one person pretend to say it was unlawful to baptize infants: and in the next four hundred years, there is not so much as one man to be found, that either spoke for or practised any such delay; and, if truth were to be determined by numbers, the general and uniform practice of the Christian church is very much in favour of infant baptism.

On the other hand, the Baptists plead, that infants are incapable of complying with the terms required in order to baptism, i.e. repentance and faith, and of receiving those instructions which Christ directed, as previous to v. Matt. xxviii. 19. compared with 1 Peter. iii. 21. But the Pædo-baptists reply, that those instructions and conditions were required only of those who were capable of them. Besides, the word υἱοὶ, which some understand of teaching, previous to baptism, may signify make disciples: and that infants may be comprehended under that name, some have argued from Acts, xv. 10. The words used by Justin, Martyr, in the passage above cited, and applied to infants, is ἑτορόφιοι. And it has been farther alleged, that the penmen of scripture, and other Christian writers, have commonly used the word to signify the reception of any one to the number and degree of disciples, as preparatory to subsequent instruction; so that persons, thus received in order to be taught, were, before the instruction itself, denominat ed disciples. Compare Luke, ix. 57, and Matt. viii. 19, 20, 21. Eusebius Evang. Dem. lib. iii. fecl. 7. where he styles those who were distrums of learning of Christ, his disciples.

It is farther objected, that infants are incapable of receiving any benefit from baptism; and that, in this case, the ordinance is exposed to contempt. The Pædo-baptists reply to this objection, by maintaining, on the contrary, that there are many advantages resulting from baptism administered to infants, both to them and principally to their parents, whose immediate act it is; that an ordinance, as in the case of Christ, who was himself baptized, may sometimes be administered to those who are not capable of all the purposes for which it was originally instituted, and which it may subserve with regard to others; and still farther, that this argument against baptizing infants, by proving too much, proves nothing: for if infants are incapable of the ends of baptism, under the Christian dispensation, infants under former dispensations were equally incapable of the ends of circumcision; and, therefore, such an institution was useless and improperly enjoined.

The objection founded on the silence of the New Testament, with regard to infants as the subjects of baptism, is already answered, in the beginning of this article, and the objection retorted against the Baptists themselves. The history of the practice of baptizing infants has been already stated; and though it is urged, that Justin Martyr contends for a profession of faith as necessary in order to baptism, whence was derived the use of sponsors, in the case of infants, it is answered by the Pædo-baptists, that Justin speaks of the adult, or may consider the confession of the sponsor.
as the child's, being made in his name: and this is the more probable, as the subsequent fathers use the same language long after infant baptism was the prevailing practice.

The Pædo-baptists also differ from the Baptists as to the mode of administering the Christian ordinance. The former perform it by sprinkling or pouring on water; the latter, by the immersion of the whole body, which they contend to be an essential circumstance. In favour of immersion it is pleaded, that the word βαπτισμὸς, being derived from βάπτω, properly signifies to plunge: on the other hand it is urged, that in this diminutive and derivative form it may signify any method of washing, and is sometimes used in scripture for washing things which were not dipped in water, but on which it was poured. Compare Luke, xi. 38. Mark, vii. 4. and those passages in which the pouring out of the spirit is called baptism, Acts, i. 5. ch. xi. 15, 16; to which some add, 1 Cor. x. 2. observing that βάπτομαι is never used for baptism.

Farther, the Baptists argue, that John performed his baptism by immersion, and that his practice is obligatory upon all Christians. To this some have replied, that John's baptism is distinguished from Christian baptism, and that some, who had received his baptism, were again baptized in the name of Christ. (Acts, xix. 3. 4. 5.) And, therefore, that his example does not bind Christians. However, it is at least doubtful whether John, who was of the line of the priests that had been always used to perform their purifications by sprinkling, did really baptize by immersion. On the affirmative it is urged, that we read of his baptizing (υ) in Jordan: but this is answered, that it signifies by, at, or with, and consequently furnishes no proof that John plunged his disciples into the river of Jordan. It is further pleaded, that he chose a place for this purpose, where there was much water; and this might have done, for the convenience of sprinkling as well as of plunging, considering the numbers that reorted to his baptism, Matt. iii. 5. It is improbable, that such multitudes of both sexes, and at a distance from their own habitations, should be baptized in any other mode.

Another argument, in favour of immersion, is drawn from the account of Philip and the eunuch, Acts, viii. 38. 39. who went down (υ) into the water; and, after the baptism, they are both said to come up (υ) out of the water. But many passages might be cited, where υ signifies to or unto, and in, from, Matt. xiv. 24. chap. xvii. 27. chap. iii. 11. John, i. x. 2 Cor. v. 1. Rev. xi. 9.

It is farther argued, that plunging alone represents our being buried with Christ in baptism, and consequently that this ceremony is essential. Compare Rom. vi. 4. Col. ii. 2. The Pædo-baptists, though they allow that there are in these passages an allusion to the mode of baptism which then generally prevailed, maintain, that in the institution of the ordinance, there is no declaration that it was chiefly designed to represent this; and, if it was, it was performed before it was generally known that Christ should die and arise from the dead. Our being cleansed from sin seems to be the thing primarily intended, which may well be represented by pouring on water; and this more naturally represents the pouring out of the spirit, the sprinkling us with it, and the sprinkling of the blood of Jesus, it may answer as valuable purposes as that mode, which, more directly, represents death and a resurrection.

The most considerable argument in favour of immersion is, that it was practised in the primitive ages. Several texts in the New Testament, say the Baptists, plainly declare this. (Matt. iii. 6. 16. John, iii. 23. Acts, viii. 36—39.) But from these passages, the Pædo-baptists reply, that no certain conclusion in favour of immersion can be drawn; nor from the subsequent history of the Christian church. Though they allow that immersion might be used, there are some cases in which it is more probable that the mode of baptism was sprinkling; partly on account of the number baptized at once, and partly because many of them were strangers, and far from their own habitations, and therefore desirous of that change of raiment which decency, convenience, and safety, would have required. We might add farther, that baptism by sprinkling is, in its nature and the circumstances attending it, more suitable to the mild and benevolent genius of Christianity, and to the designed extent of its spread through all the various climates of the earth, than baptism by immersion. See, on this subject, Wall's History of Infant Baptism, 340. 1707. Wall's Defence of the History against Gale, &c. Svo. 1702. Towgood's Baptism of Infants a reasonable Service. Fleming's Plea for Infants, &c. &c.

For a summary of the principal arguments in favour of baptizing adults, and by immersion, see BAPTISTS.

PÆDOPHLEBOTOMIA, from παιδις and φλεβομαι, veneporation, in Surgery, the operation of veneporation practised on a child.

PÆDOTHYSIA, παιδοθυσία, in Antiquity, an inhuman custom, that prevailed amongst the ancient heathens, of sacrificing their children. Thus it is related in the scriptures, that the king of Moab, being besieged by the Israelites in his capital, and reduced to great straits, took his eldest son, that should have reigned in his stead, and offered him for a burnt offering upon the wall, on which the siege was raised. 2 Kings, iii. 27.

From Phoenicia this cruel practice passed into Europe and Africa, and spread itself far and wide; and it is reported, that the Mexicans are, at present, guilty of it.

PÆNA, in Ancient Geography, an island of the Atlantic ocean, west of the province of Tingitan, Ptolemy.

PÆNOE, in Botany, the name of a very large tree, which grows in Malabar.

The resin, discharged from the root, bark, fruit, and other parts of this tree, when boiled with oil, is used either for a hard or liquid pitch; and is, in the Indian sacrifices, sometimes burnt instead of incense.

The kernels of the fruit when bruised, and, in conjunction with warm water, levigated on a marble, corroborate the stomach, remove a nausea and vomiting, slay rackings of the belly, and cure the cholera. The resin of this fruit, when melted with the oleum fesami, is an excellent vulnerary balsam; when reduced to a powder, and exhibited, it also powerfully cures a gonorrhoea, and other vulnerary symptoms. Ray.

PÆNULA, or PENULA, among the Romans, a thick short, clothe-bodied garment, fit for a defence against cold and rain.

PÆONES, in Ancient Geography, a people who inhabited the coast of Macedonia and mount Rhodope, according to Dion Cassius. Herodotus places them on the banks of the Strymon; and Ptolemy assigns to them for their habitation Macedonia, towards the sources of the river Haliaeum.

PÆOMIA, a country of Macedonia, which, according to Paufanias, took its name from Peon, the son of Endymion. Herodotus speaks of this country, as subject to Darius, son of Hytaipes. It was situated east of the Axios, and west of the Strymon.

PÆONIA, in Botany, the Peony, so named by the ancients, in memory of Peon the physician, whom Homer records as having cured Pluto with this herb, when he was wounded by
by Hercules. We premise its virtues are altogether re-
ferred for such august occasions, they having never been
made manifest on any other, as far as we can learn. The

\[ \text{Paeonia} \]

by the gratins account of male and female, are now
acknowledged to be two species; though Linnaeus
considered them as varieties of one, by the name of \( \text{P. officinalis} \).

and order, Polyandra Pentagna. Nat. Ord. Multiflæque,

Gen. Ch. Cal. Perianth inferior, of five small, roundish,
concave, reflexed, permanent leaves, unequal both in size
and infcrion. Cor. Petals five, roundish, concave, con-
tracted at the base, spreading, very large. Stem. Filaments
very numerous. (about three hundred), capillary, short;
whether erect, large, oblong, quadrangular, of four cells.

Pith. Germs two or more, ovate, erect; styles none;

Petals compressed, oblong, obtuse, coloured. Peric. Fol-
licles as many as the germs, ovate-oblong, spreading
widely, often downy, coriaceous, burrowing lengthwise at
their inner edge. Seeds numerous, oval, polished, coloured,
ranged along each margin of the future.

Follicles superior, with many marginal seeds.

Ob. Linnaeus remarks, that though the most natural
number of the germs is, in his opinion at least, two, they
are often more numerous; but he thinks they scarcely ever
amount to five. Some newly discovered species however
contradict this, and indeed much of the old ones afford rea-
sons, at one time or other, for the union of the Linnean
orders from Dicynia to Pentagna, in the class Polyandra,
into one; which is functioned also by Delphinium, Aconitum,
and others. See Sm. Intro. to Bot. 

n. 1. Sims in Curt. Mag. t. 1154. (P. suffruticosa;

Andr. Repof. t. 373 and t. 448.) —Stem woody, perennial.
Leaflets oblong-ovate; glaucous and somewhat hairy be-
neath; the terminal one three-lobed. Germs numerous,
distinct. —Native of China, where it is one of the most fa-
avourite objects of horticulture, as may be seen by the paper-
hangings, fences, porcelain, and other ornamental produc-
tions of art, brought from that country. It is depicted on
such with double blossoms, either of a role-colour, crimped,
crimson, purple, white, or even of a golden yellow. The first only
has been introduced into this country, by Sir Joseph Banks,
in 1780. Collectors who have had means of communication
with China, particularly the late Right Hon. Charles Gre-
ville, and Sir Abraham Hume, have anxiously endeavoured
to obtain some of the other varieties, but in vain; except
that the gentleman last mentioned has procured a shrubby
Peony with a single flower, more beautiful than the double,
of which we shall presently speak as a distinct species. The
Moutan proves tolerably hardy in England, though, like
many other plants from the same country, which blossom
early in our spring, it requires the protection of a glass
frame at that season. The shrubby flen is peculiar to this
and the next species, among all those hitherto known, and
forms a large bush, spreading several feet in diameter.

Leaves on long stalks, alternate, large and spreading, twice
or thrice serrate in an opposite manner, deciduous; their
leaflets tapering at the base, acute, entire, occasionally
lobed, veiny; glaucous and very sparingly hairy beneath;

\[ \text{VOL. XXVI.} \]
and dangerous, which we can readily believe. Bulliard’s plate seems intended for this, though he did not distinguish it from the following very distinct species.

4. P. corallina. Entire-leaved Peony. Wild. n. 2. Ait. n. 3. Retzi. Obs. fac. 3. 34. Engl. Bot. t. 1513. (P. officinalis; Linn. Sp. Pl. 6747. Mill. Illufr. t. 47. P. mas; Ger. em. 980. Lob. IC. 683. Matth. Valgr. v. 2. 265) — Leaves twice ternate; leaflets ovate, undivided. Follicles downy, recurved. — Native of the south of Europe. Dr. Sibthorp had wild specimens communicated to him by an apothecary of Zante. It was also discovered, in a wild state, by Francis Bowcher Wright, eqq. in the rocky cliffs of the island called Steep Holms, in the Severn, in August 1805, whence this species has found a place in English Botany. Gerard says he found it at Southfleet, Kent, which his editor Johnston rudely denies. Ruftic gardens often abound with this flower, in its proper angle state; the feed vesels being admired, and long preferred for the decoration of the cottage chimney-piece, on account of their fining pink inside, and black polished feed, contrasted with the red remains of numerous abortive ones, ranged along the edges. This is the Paeonia rubra, or male Peony, of Dinecorides, whose leaves he compares to those of a Walnut-tree, a sufficient indication of their ovate, undivided, filmy pinnate form, by which the species is clearly distinguished from the last. The qualities of the two plants probably differ but little. We find the leaves of the present sometimes downy beneath.

5. P. peregrina. Crimson-flowered Small Peony. Ait. n. 4. Sims in Curt. Mag. t. 1850. (P. promicacea; Ger. em. 982. Lob. IC. 683. P. byzantina; Ger. em. 982.) — Leaves twice ternate; leaflets elliptic-oblong, decurrent, lobed; glaucous and hairy beneath. Follicles erect, downy. — Native, probably, of the south of Europe. It is a plant of much humbler growth, and smaller dimensions, than any of this genus that we have hitherto mentioned, and is essentially distinguished, if we mistake not, by its deciduous leaflets, whole main ribs unite far above the base. The flowers are of an elegant, but not very deep or bright, crimson, scarcely three or four inches in diameter, often double, with linear internal petals, like a double anemone. Such is the plant we had from Mr. Lodge by the name of P. humilis, with whose figure and description it, as Dr. Sims well remarks, does not at all agree. But neither, in our judgment, does it accord with the P. peregrina, flore caeleste, Bell. Hort. Eyth. Vern. (not Aeliv.) ord. 6. t. 9, nor with P. byzantina of Gerard, Parkinson and others, which is described by Parkinson as larger than the Male Peony, P. corallina; whereas our peregrina is a great deal smaller, and exactly answers to the promicacea of old books. It appears to be rather of recent introduction among us, and we have some suspicion of its having been brought from Siberia. The flowers are produced in May or early in June, and the roots are quite hardy.

6. P. daurica. Glaucous Daurian Peony. Ait. n. 10. Andr. Repof. t. 436. — Leaves pinnate; leaflets elliptical, obtuse, glaucous, somewhat wavy. Stem herbaceous. — Native of Siberia, from whence it was procured, in 1790, by the late Mr. Bell. This, like the red, is a Hardy perennial, flowering in May or June. Stem about two feet high. Leaves apparently all simply pinnate, glaucous on both sides, paler beneath; leaflets broadly elliptical, obtuse, concave, velvety, rather wavy at the edge. Flowers large and handsome, of a purplish roe-colour, with copious yellow stamens, and two pistils. Follicles ovate, divaricated, downy, about one inch and a half long. We know this species, which seems well worthy of general cultivation, from Mr. Andrews’s work only. Its affinity to the three preceding, has made us here ferwe from the arrangement in the Hortus Kewensis.

7. P. alboflora. White-flowered Peony. Pall. Roff. v. 2. 92. t. 84. Wild. n. 3. Ait. n. 5. Andr. Repof. t. 64. and t. 612. — Leaves twice ternate; leaflets elliptic-lanceolate, acute, entire, smooth. Capsules recurved, smooth. Calyx bracteated. — Native of Mongol Tartary, on graily hills, and introduced into the British gardens by Pallis, its celebrated discoverer, in 1784. This flower of May or June, and is hardy, but we do not find this species so easy of culture, nor so free in flowering, as some others. The inhabitants of its native country are said to eat the roots boiled in soups, and to mix the powdered seeds with the infusion or decoction of their tea. The stem is herbaceous, usually dark brown, smooth and polished. Leaves twice ternate, of a dark bluing green above, paler beneath, quite smooth and naked. Flowers comparatively small, but peculiarly elegant in their native simplicitie and glossy white nefs, with concave, partly cloved, petals, and a brown calyx, accompanied by three green, leafy, filiform bracteae. Germs three or four, brown and smooth. These flowers have a sweet aromatic scent. There is a double variety, with a blufh-coloured tint, and yellowish inner petals, figured in Andrews’s t. 612, which makes a very splendid appearance; but we have always admired the original plant, as one of the most desirable of its genus, or as we are usually in this opinion.

8. P. humilis. Dwarf Spanish Peony. Retzi. Obs. fac. 3. 35. Wild. n. 4. Ait. n. 6. (P. pamula xifentina; Lob. IC. 683. Ger. em. 982.) — Leaves twice ternate; leaflets in three deep linear segment, downy beneath. Follicles hairy, nearly erect. Chifius records this as a native of Spain. Gerard speaks of it as known in the English gardens in his time. We have never met with a specimen, and should be very glad to see it well figured. Retzius describes the stem a foot and half high, simple, smooth, angular and green. Leaves in very narrow segments, acute; glaucous above; white and downy beneath. Petals of a deeper red than those of P. corallina. n. 4. Germs greenish, slightly hairy, as are also the short, nearly upright, follicles.

9. P. anoma. Jagged-leaved Siberian Peony. Linn. Mant. 247. Wild. n. 5. Ait. n. 7. Andr. Repof. t. 514. (P. lacinata; Pall. Roff. v. 2. 93. t. 55; biflorda. P. n. 14. Gmcl. Sib. v. 4. 84. t. 72.) — Leaves twice ternate; leaflets with many lanceolate segments, smooth. Follicles depressed, smooth. Calyx bracteated. Frequent throughout most parts of Siberia, in graily, shady, rather hilly spots. Mr. Bell introduced this into England, and it flowered with him in July 1807. The calyx is accompanied with leafy bracteae, like those of P. alboflora, but longer and narrower, like the numerous lanceolate segments of the foliage, by which this species is distinguished at first sight from all we have hitherto described, except the last, but that has downy leaves, glaucous above, and hairy upright feed Vesels. The corolla of P. anomala is concave, of a full roe-colour. Germs usually five, spreading, smooth, as well as the follicles.

10. P. hybrida. Mule Peony. Pall. Roff. v. 2. 94. t. 86. Wild. n. 6. Ait. n. 8. — Leaves twice ternate; leaflets with numerous linear segments, smooth. Germs downy. Pallis mentions this as occurring now and then wild, in valleys on the banks of some of the larger Siberian rivers, but much smaller than the specimen delineated in his plate, which he says originated in the garden at Peterburgh, and was supposed to be a hybrid production between the preceding species and the following, as it never produced seeds. Mr. Bell is recorded as having introduced P. hybrida into England,
England, in 1788. Like the lafl it is perennial, flowering in May, and like that, has the leaflets much divided, but with full narrower segments. The parts of fruitification however more agree with *tenifolia*, hereafter defcried. The *bracteas* are partly lacinated, as in that, not all undivided, as in *annula* and *altiflorus*. The *corolla* is of a deeper red, and the *germin* instead of being smooth, are downy. It is very likely, though occasionally found wild, to be a mule plant, rather than a permanent intermediate species.

11. *P. tenifolia*. Finc-leaved Peony. Linn. fil. Pl. 748. Linn. fil. Pl. Rar. fæce. t. 9. t. 5. Pall. Roff. v. 2. 975. t. 5. Wildn. n. 7. Alt. n. 9. Meerb. 9. t. 25. Curt. Mag. t. 526. (P. n. 15; Gmel. Sib. v. 4. 185. t. 73)—Leaves thrice terete; leaflets in numerous linear-ovate shaped segments and smooth. Follicles hairy. Native of Siberia, from whence the late Mr. Malcolm is said first to have obtained it alive in 1765. This is one of the most elegant species, and a highly delectable hardy herbaceous plant, flowering readily in the open border, about the end of May. The root creeps moderately. In a wild 1 rate the *florum* is said to be about a foot high; in a garden it is full two feet, erect, simple, or slightly branched, clothed with numerous, very compound and finely divided, dark-green, smooth leaves, spreading in a recurved direction. Flowers terminal, solitary, concave, rather above two inches wide, of a most vivid, deep, rich, shining blood-colour, with copious yellow filaments. The bracteas are partly divided like the leaves, partiely furled. Germes denfoy covered with ereth, close- fet, plough-like, shining, brown, rigid hairs. We seldom see the *fruits* perfected in England, though they are said to ripen in Sweden. No wonder that Linnaeus, who, when he first became acquainted with this beautiful Peony, was full of his newly conceived ideas of hybrid generation in plants, immediately guessed it to be a mule between the common *Paeonia* and *Adonis autumnalis*. It does indeed look like a magnified *Adonis autumnalis*. Such resemblances are, nevertheless, fallacious, and there is no real foundation for believing the *P. tenifolia* any other than a mott distinct and permanent original species.

*Paenonia*, in Gardening, comprises plants of the large, herbaceous, flowers, perennial kind, of which the species are, the common *Paeonia* (*P. officinalis*), and the slender-leaved *Paeonia* (*P. tenifolia*).

There are two principal varieties of the first species; the common female, and male *Paeonia*.

The former of these has the roots composed of several roundish thick knobs or tubers, which hang below each other, flattened with firings; the flanks are green, about two feet and a half high; the leaves are composed of several unequal lobes, which are variously cut into many segments; they are of a paler green than those of the latter fort, and hairy on their under side; the flowers are smaller, and of a deeper purple colour.

The latter has the roots composed of several obovate knobs hanging by firings flattened to the main head; the items the same height with the preceding; the leaves are composed of several ovate lobes, some of which are cut into two or three segments; they are of a lucid green on their upper side, but are hoary on their under; the items are terminated by large single flowers, composed of five or six large, roundish, red petals.

The flowers in both sorts appear in May, and are natives of several parts of Europe.

And Miller suggefts, that it is fearcely necessary to ob serve that the old names of male and female have nothing to do here with sexes, the flowers of both being hermaphrodite. Besides, there are several sub-varieties of the female *Paeonia*, as with double flowers, differing in size and colour, cultivated in gardens. The male *Paeonia* also varies, with pale and white flowers, and with larger lobes to the leaves; they also vary much in different countries.

As there is the Foreign *Paeonia*, with a deep red flower; the roots are composed of roundish knobs, like those of the female *Paeonia*; the leaves are also the same, but of a thicker substance; the flanks do not rise so high; the flowers have a greater number of petals, and appear a little later. This is a native of the Levant. The large double purple *Paeonia* is probably a sub-variety of this.

The Hairy *Paeonia*, with a larger double red flower; the roots like the common female *Paeonia*; but the flanks taller, and of a purplish colour; the leaves much longer, with spear-shaped entire lobes; the flowers large, and of a deep red colour.

The Tartarian *Paeonia*, with roots composed of obovate lobed tubers of a pale colour; the flanks about two feet high, pale green; the leaves composed of several lobes, irregular in shape and size, some having fixed, others eight or ten spear-shaped lobes, some cut into two or three segments, and others entire; of a pale green, and downward on their under side; the flanks are terminated by one flower of a bright red colour, a little less than that of the common male *Paeonia*, having fewer petals.

The Portugal *Paeonia*, with a single sweet flower, has not roots composed of roundish tubers, but has two or three long taper-forked flags like fingers; the flanks rises little more than a foot high; the leaves are composed of three or four oval lobes, of a pale colour on their upper side, and hoary underneath; the flanks is terminated by a single flower, which is of a bright red colour, smaller than the above, and of an agreeable sweet scent.

Method of Culture.—The single sorts are easily raised by Genetic, and the double by parting the roots. The seed should be sown in autumn, soon after it is perfectly ripened, or very early in the spring (but the former is the better season), on a bed or border in the open ground, where the soil is rather light, raking it in lightly. It may also be sown in small drills.

The plants should afterwards be properly thinned, kept perfectly free from weeds, and be occasionally watered when the weather is hot and dry.

As they should remain two seasons in the bed, it is nece ary, in the second autumn, to spread some light mould over them, to the depth of an inch; and in the autumn following they may be removed where they are to remain. Plants of the double-flowered kinds are often produced from these.

The roots of the old double-flowered plants may be taken up in the beginning of the autumn, and divided so as to have one bud or eye, or more, to each part or crown, as without care in this respect, they never form good plants. And where regard is had to the flowering, they should not be too much divided, or the offsets made too small, as when that is the case they do not flower strong. But where a great increase is wanted, they may be divided more, being left longer in the nursery-beds.

They should be planted out as soon as possible after they are separated, though, when necessary, they may be kept some time out of the earth. The large offsets may be set out at once where they are to remain; but the small ones are best set in nursery-beds for a year, or till of proper strength for planting out.

The plants may afterwards be suffered to remain several years unremoved, till the roots are increased to very large branches, and then be taken up when the flanks decay, in autumn,
autumn, divided, and replanted in their allotted places in the manner directed above.

All the fowls are hardy plants, that are capable of flourishing in any common soil in almost any situation, either in open exposures, or under the shade of trees.

The Portual variety, however, should have a warmer situation and lighter soil than the others.

They are proper ornamental flowerly plants for large borders, and may be had at all the public nurseries. In planting, one should be put here and there in different parts, placing them with the crowns of the roots a little within the surface of the earth, and at a yard at least distant from other plants, as they extend themselves widely every way, affumting a large bushy growth; and, together with their conspicuous large flowers, exhibit a fine appearance, and are often planted at the terminating corners of large borders adjoining principal walls, displaying a bushy growth in their foliage and flowers. When the flowers are gone, the capsules opening lengthways discover their coloured seeds very ornamental, especially in that called the male peony and varieties. And to forward this, the capsules may be flit open on the inside at the proper valve; whereby they will expand much sooner, and display their beautiful red seed more conspicuously than would otherwise be the case.

PÆONIES, in Natural History, a name given by some writers to the flower called by others peonies, and esteemed of great use to women in labour. It seems to have been called paeonies, from Paeonia, in Macedonia, where it was found.

PAES. in Geography, a river of Lapland, which runs into the North Sea. N. lat. 70°.

PÆSIELLO, GIOVANNI. in Biography, a Neapolitan, and gifted with so much fertility of invention for dramatic compositions as nature ever bestowed on an Italian opera composer. He was thought, at the beginning of his career, not to have labour'd sufficiently at the drer parts of counterpoint, upon which many great masters of Italy have established their fame.

From his early youth he gave way to the fire of his invention, which art could hardly restrain, much less confine to rule. His wildness, however, was never grotesque, ungraceful, crude, wild, or offensive to cultivated ears; but confin'd to the most happy flights of fancy, pleasing melodies, and new effects of accompaniment. He at first worked at little dramas in the Neapolitan jargon, so different from good Italian, that it is totally unintelligible to the rest of Italy. This language, however, is allowed to be very poetical, and capable of receiving all the grace and refinements of melody.

He composed for the burletta a comic opera in Italian, as early as 1765, "Amore in Ballo," and in 1766, "Le Nozze Turbata." In 1770 we heard at Naples his comic opera called "Le Trame per Amore," in which, though the singing was but indifferent, and out of nine characters there was not one good voice, yet the music pleased us extremely. The symphony, consisting of only one movement, was truly comic, and contained a perpetual succession of pleasing passages. The airs were full of fire and fancy, the ritornelles abounding with new passages, and the vocal parts in elegant and simple melody, such as might be remembered and carried away after the first hearing, or be performed in private by a small band, or even without any other instrument than a harpsichord or pianoforte. The airs of this drama were much applauded when we heard it performed, though it was the first performance of its kind.

But since that time he has continued improving in his style, both in serious and comic operas, and the public all over Europe has not been insensitive to his transcendent merit, as he has justly been regarded at the head of vocal composition of the present time, as Haydn of instrumental. In 1770 he was the only composer in Naples who could make head against the high favour in which Piccini then stood, after his "Buona Figliuola." We were so happy as to hear him improvire in music at sir William Hamilton's, where, having dined, he was begged to sing a scene of an opera; but there being none at hand which he liked to perform, he said "date mi un librettino," and the words of the first opera which could be found having been put on the harpsichord desk, he composed and sung extempore three or four scenes in so exquisit a manner to his own ingenious accompaniment, that no studied music and singing we ever heard of the greatest composers or performers ever pleased us so much. It was not written music, it was inspiration.

He passed three years at Petersburg in the service of the empress Catherine II., whose court was constantly in possession of the best composers and vocal performers of Italy, and there he established a great reputation, which since his return has been constantly increasing in his own country. He is now (1804) at Paris, and though a modern, is as much revered and respected as any of the most invaluable antiquities among the spoils of Italy. A lift of his works would astonish by the number, as much as they have delighted by their performance, every judge of feeling, who is able to discriminate good music from bad, or perfection from mediocrity.

PÆEZ, PEDRO, a man deferredly celebrated in the history of the Jesuits, and of Abyssinia, was a Castilian, born at Toledo of a noble family. Having completed his studies in the company, he was sent to India in the year 1588. The Portugueze in Abyssinia were at this time without a patriarch, or any spiritual affidiant, so difficult was it to introduce them into that kingdom, every entrance into which was in possession of the Turks or Moors. To this million Paez and P. Antonio de Monteferrat were appointed. They were made prisoners on their way, and sent to the court of the king of Sax, by whom they were kindly treated; but being himself tributary to the pacha of Yemen, and bound by treaty to send him all the Portugueze who might fall into his hands, they were sent to Cearea, the capital where the pacha resided. At first their captivity was easy; but afterwards they were treated with great barbarity, in hopes that he might obtain a very large ransom for their liberty. At length the vicerey of India obtained their deliverance, upon the payment of a thousand crowns: they returned to India, where Monteferrat soon afterwards died. Paez was more successful in his second attempt; he entered Abyssinia very safely in 1603, and instead of buffeting himself with court intrigues, and seeking court favour, he remained quietly among his flock, translating into Abyssinian a compendium of the Christian doctrine, which had been written by Marcos George. He instructed some children in the dialogues of this work. The king of the country, hearing of their proficiency, sent for the master and his scholars to exhibit before him. He was delighted with their performance, and became himself a thorough convert to the Roman Catholic faith; but the zeal which he threw in behalf of the new system of faith led to his deposition and untimely death. Other revolutions followed; when things, however, were become quiet, Paez undertook to build a palace at Gorgora, a rocky peninsula, on the south side of the lake of Dambza. He was himself architect, mason, smith, and carpenter, and produced a building which was the adornment of those who beheld it. A spring-lock, which he fixed upon one of the doors, faced the king's life, when an attempt was made to assassinate him. The last triumph which Paez enjoyed was
that of feecing the king put away all his wives but one, and
receiving his general confession. He died in May 1622.

PAG. In Ancient Geography, a town of the territory of
Megara, situated towards the north, on a small gulf
formed by an extention of the gulf of Corinth, and called
"Mare Alevonium."

PAGAHM, in Geography, once a magnificent city of
the Birman empire, on the Trawaddy, but now its remains
are merely numerous mouldering temples, and the veltiges
of an old brick fort, the ramparts of which are still to be traced.
The town of Necundah, about four miles to the north,
which may be called a continuation of Pagahm, has flourished
in proportion as the latter has decayed. Pagahm is said to
have been the residence of forty-five successive monarchs,
and was abandoned 500 years ago, in consequence, as it is said,
of a divine admonition; but whatever may be its true history
it was certainly once a place of no ordinary splendour.
The temple of Pagahm rises upwards with a heavy breadth almost
to the top, and then terminates abruptly in a point, which
give to the buildings a clumsy appearance. Many of the
most ancient temples at this place are not solid at the bottom;
a well arched dome supports a ponderous superstructure; and
within, an image of Gaudma sits enshrined; four Gothic
door-ways open into the dome, in one of which was a human
figure flanding erect, said to have been Gaudma, and an-
other of the same personage, lying on his right side asleep,
both of gigantic structure. These, however, are not the
usual attiptes of the divinity; as he is generally depicted
fitting cros-legged on a pedestaL, adorned with representa-
tions of the leaf of the sacred lotus carved upon the base; the
left hand of the image rests upon his lap, and the right is
pended. Beyond the suburbs there is a part where the
inhabitants are employed in expressing oil from the Sefa-
num seed; the grain is put into a deep wooden trough, in
which it is prefixed by an upright timber fixed in a frame;
the force is increased by a long lever, on the extremity of
which a man fits and guides a bullock that moves in a
circle, thus turning and pressing the feed at the same time:
the machine was simple, and effectually answered the pur-
pose. Of these mills, there were not less than 200 within
a very narrow compass. From the circumstance of the
cattle being in good order, it was concluded that they were
fed on the feed after the oil was extracted. The land about
Pagahm favourably yields sufficient vegetation to nourish goats.

Syennes' Embrary to Ava, v. II.
PAGALOAN, a town in the N.W. coast of Mindanao.

PAGAMEA, in Botany, Aubl. Guian. v. 1. 112. 1 44.
Juhl. 209. Lamarck Illstr. 1. 88. A genus consisting
of only one freecise, whose fruit was judged by Jullieu
to be not sufficiently ascertained. It appears next akin to
Faramea of the same authors. (see that article,) and like-
wise belongs to the Rubifae of Jullieu. Aublet describes
the berry as of two cells, with two seeds, convex on one
side, flat on the other, one of them frequently abortive.
Each of these seeds, when cut across, is found to have two
cells, with a kernel in each cell.—The Pagamea guianensis is a
shrub feven or eight feet high, growing on the top of the
Serpent mountain, in Guiana, and bearing flowers, as well as
fruit, in August. The branches spread every way, and are
knotty, leafy at the extremities. Leaves opposite, in pairs
crossing each other, lilac, lanceolate, pointed, entire, about
three inches long, fingle-ribbed and veiny, smooth and pliant.
Stipulas leafing, short, with two small points. Flowers
in short-tube, auxiliary, thalloed spikes. Corolla white, funnel-
shaped, equally four-clit, downy within. — No reason is given
for the name, nor any thing said about the qualities or uces
of the plant, except that the wood is hard, and of a yellowish
colour. — "The truck is only five inches in diameter."
PAGAN, PAGANUS, a heathen, gentile, or idolater, one
who adores false gods.

Baronius derives the word paganus, a pagis, villages, becauce,
when Christians became matters of the cities, the heathens
were obliged, by the edicts of Constanctine and his sons, to
go and live in the country villages, &c. Salmansius will
have the word come from pagus, considered as originally
signifying gens, or nation: whence he observes, we say
indifferently, pagans, or gentiles.
The abbot de Fleury gives another origin of pagan: he
observes, that the emperor Constanctine, going from Antioch,
against Maxentius, in 350, assembled all his troops, and
advised such as had not received baptism to receive it im-
mediately; declaring withal, that such as should be found
unbaptized should quit the service, and go home.

Hence, perhaps, says the abbot, the name pagan might
be given to those who chose the latter; the Latin word
paganus properly signifies a person who does not bear arms,
in opposition to miles, a folder.

And hence it might, in time, extend to all heathens; or,
continues he, the word might come from pagus, village, in
regard the peasants were those who adhered longest to the
idolatry of the heathens.

Pagan, Blaise François, Compte de, in Biography, an
eminent military engineer, was born at Avignon in the year
1604. He entered into the army at twelve years of age, and
distinguished himself in a variety of actions. He was patro-
nized by his near relation, the constable de Luyres, whom he
had the misfortune to lose at the siege of Montauban, at which
he was also deprived of the sight of an eye by a musket-shot.
At the passage of the Alps, and the barricades of Susa, he
placed himself at the head of a determined band, and having
gained the summit of a steep mountain, he cried out "This
is the road to glory," and instantly slid down the mountain;
and being imitated by his men, they arrived first at the bar-
icades and carried them. When the king, Lewis XII.,
laid siege to Nauzi in 1633, Pagan had the honour to attend
him in drawing the lines and forts of circumvallation. In
1642 he was sent to the service of Portugal, in the post of
field-marshall, and there he had the misfortune to lose his
eye. Though disabled from serving his country in the active
duties of a warrior, he was intent upon augmenting its
glory, by extending the boundaries of military science.
Having from his youth closely applied to mathematical
studies, with a particular view to the science of fortification,
he now employed the whole force of his active mind in
speculations of this kind, and in 1645 published his "Traité
des Fortifications:" this was regarded as the best work that
had ever been written on the subject, and it is said that
whatever improvements have been made since, have been
derived chiefly from this treatise, as conclusions from its
principles. In 1651 he published his "Theoremes Geom-
étriques," which flew an extensive and deep knowledge of
all the parts of the mathematics. In 1655 he published an
"Historical and Geographical Account of the River
Amazons, extracted from different Writers," and we are
affired, that though blind, he drew the chart of that river
and the parts adjacent. His other works, published in 1657
and 1658, were "Théorie des Planetes:" and "Tables
Astronomiques:" by the former he cleared the sytem from
that multitude of eccentric circles and epicycles, which
astronomers had invented to explain their motions. His
astronomical tables are reckoned fortunate, and very plain.
Pagan died at Paris, November 18, 1685. He was devoted
to judicial astrology; but what he wrote on this subject is the only thing which detracts from his high character. He had an universal genius, and having applied himself entirely to the art of war, and particularly to the branch of fortification, he made much progress in it. He understood the deeper branches of the mathematics, and had so fine a genius for these abstruse speculations, that he read but little on the subject, his own fertile mind supplying him with almost everything that he wanted. Lewis XIII. regarded him as one of the most adroit, and most valiant men in his kingdom. That branch of his family which removed from Naples to France in 1552, became extinct at his decease. All his works were collected and printed in 12mo. in the year 1669. Moreri.

PAGAN, Peter, a distinguished poet of the 16th century, was born at Wanfried, in Hesse, and being educated with great care, he exhibited at an early age much literary talent, and a particular turn for poetry. In the year 1550 he received the degree of bachelor in philosophy, and he became poet to the emperor Ferdinand. To the study of poetry he joined that of history, and was elected professor of both in the university of Marburg. He died at Wanfried, on the 29th of May, 1576. Besides many pieces in poetry on miscellaneous subjects, he left "Historia tergeminarum Romanorum et Albaniarum fratrum," in verse, which contained the history of the three Horatii, and the three Curtiati. Moreri.

PAGAN Creek, in Geography, a river of Virginia, which runs into James river, N. lat. 37° 5'. W. long. 76° 37'.

PAGANALIA, an ancient rural feast thus called, because celebrated in the village, in pagis.

In the paganalia, the peasants went in solemn procession all round the village, making lustrations to purify it. They had also their facrimcs, wherein they offered cakes on the altars of the gods.

Halicarnassus and St. Jerm refer to the institution of the paganalia to Servius Tullius. They were held in the month of February.

PAGANELLUS, in Ichthyology, a species of Gobius; which see.

PAGANICA, in Geography, a town of Naples, in Abruzzo Ultra; 8 miles N. N. W. of Aquila.

PAGANINA, an Italian word, used by some authors to denote the first excrement of children; these, dried and reduced to powder, are esteemed by some a very great and powerful medicine against epilepsies. It is to be taken in small doses, every day, for some time.

PAGANINI, La, in Biography, an admirable singer and actor in the character of "Il Mondo della Luna," and "Il Filosofo di Campagna," composed by Galuppi, when his genius was in full flower. The airs "Si l'Uominí stirpiràno," and "Donne, donne, fanno Nata," were sung in a way so piquant and agreeable by the Paganini, that the applause which they acquired by them amounted almost to acclamation. This last opera had an uninterrupted run of fifteen nights; and the Paganini, though not young when she came hither from Berlin, in 1760, increased in reputation so much during the run of this opera, that when it was her turn to have a benefit, such a crowd assembled as we never remember to have seen on a like occasion, before or since; indeed, not one-third of the company that presented themselves at the opera-houses were able to obtain admission. Caps were lost, and gowns torn to pieces, without number or mercy, in the struggle to get in. Ladies in full dresses, who had lent away their servants and carriages, were obliged to appear in the streets and walk home in great numbers without caps or attendants. Luckily the weather was fine, and did not add to their distress by rain or wind; though their confusion was greatly augmented by its being broad daylight, and the streets full of spectators, who could neither refrain from looking or laughing at such splendid and uncommon street-walkers.

PAGANISM, the religious worship and discipline of pagans; or the adoration of idols and false gods.

The gods of paganism were either men, as Jupiter, Hercules, Bacchus, &c. or fictitious perions, as Victory, Fame, Fever, &c. or beasts, as in Egypt, crocodiles, cats, &c. or finally inanimate things, as omens, fire, and water, &c.

PAGE, in Botany, Somnerat Guian. t. 10, 11. See Sonneratia.

PAGARCHUS, Formalis et village, and | command, among the ancients, a petty magistrate of a pagus, or little district, in the country.

PAGASA, or PAGAST, in Ancient Geography, a town of Magnesia, formerly a part of the town of Phere.

PAGE, from wauu, child, boy; a youth of flate, retained in the family of a prince, or great personage, as an honourable servant to attend in visit of ceremony, carry messages, bear up trans, robes, &c. and at the same time to have a gentle education, and learn his exercises.

The pages in the king's household are various, and have various provinces assigned them: as pages of honour, pages of the preference-chamber, pages of the back flairs, &c.

Pages were anciently distinguished from the other servants in livery, by their wearing drawers in lieu of breeches; and sleeves turned up with velvet.

Cujas and Godofred observe, that pages in the emperor's families were called pedagogiani pueri. Fauchet says, the word page was first given to the little boys who attend tilters, to bring them their tiles, &c. that till the time of Charles IV. or VII. the name was common to the baflë servants; and it is since then, that page is become a term of honour; and the meaner servants are distinguished from them by the name of lacqueys, valets, &c.

Page is particularly used in the Turkish seraglio, for the children of tribute, or slaves who wait on the grand signior. They are commanded by the first sga, and constitute four classes, called odas.

Page of a Book. See Printing.

PAGEANS, in Mythology. See Pygmies.

PAGEANT, a triumphal car, chariot, arch, or other like pompous decoration, variously adorned with colours, flags, &c. carried about in public shows, processions, &c.

PAGEL, in Ichthyology, a name given by the Spaniards to that fish which authors in general call the crythinus, or rubello, and some the xatabus and pagrus. It is properly a species of the sparus, and is distinguished by Artedi from the rest of that genus, by the name of the yellow-eyed red-bolied sparus, which see.

PAGET'S PORT, in Geography, a small harbour within the great found in Bahama islands, and in the most easterly part of the sound.

PAGHATAKAN, a town of New Jersey, on the Pagachton. N. lat. 42° 8'. W. long. 74° 40'.

PAGI, Anthony, in Biography, a celebrated Cordelier, and one of the ablest critics of his time, was born at Rognac, in Provence, in the year 1624. He embraced the monastic life, in the convent of Arles, in the year 1641, and obtained to high a reputation, that he became four times provincial of his order; but his religious duties did not prevent his application to the study of chronology and ecclesiastical history, in which he excelled. His most considerable work is a critic
critique upon the "Annales" of Baronius, in which, following the learned author year by year, he has rectified an infinite number of mistakes, both in chronology, and in the representation of facts. The first volume was published in Paris in 1680, and dedicated to the clergy of France, who allowed him a pension; the other three were not printed till after the death of the author: the publication of them was superintended by his nephew Francis. A new edition of the whole was published at Geneva in the year 1727. Father Paggi died at Aix in 1699. His nephew, already referred to, having finished the publication of his uncle, employed himself in writing a work of his own, which he published under the title of "Breviarium Historico-Chronologico-Criticus, Illustrissimi Pontificii Romanorum Geita, Conciliorum Generalium Acta, &c. complectens," forming in the whole four volumes, 4to. This work is said to display much curious research, and is drawn up in a correct and neat style. Francis Paggi died in 1721, in the sixty-seventh year of his age. He left a nephew, Anthony, on whom devolved the care of publishing the last volume of his uncle's "Breviarium." Moreri.

PAGIETTA, in Geography, a town of Naples, in Abruzzo Citta; 3 miles S. Langiano.

PAGIN, M., in Biography, a violinist at Paris in the year 1770, much admired for his tette, nailefies, and delency, by judges of the violin, not of the French school. He was a disciple of Tartini, and regarded by many at Paris as his last scholar. Having had the honour of being hired at the Concert Spirituel for daring to play in the Italian style, he quitted music as a profession, and had a place conferred upon him under the count de Clermont, of about 2500 a year.

PAGLIA, in Geography, a river of Italy, which runs into the Tiber, a few miles below Orvieto;

PAGLIANELLO, a town of Naples, in Lavora; 14 miles N.E. of Capua.

PAGLIANO, a town of Naples, in Abruzzo Ultra; 15 miles E.S.E. of Aquila.

PAGLIAPIOLI, a town of Naples, in Calabria Ultra; 4 miles of Gierace.

PAGLION, a river of France, which runs into the Mediterranean, a little to the E. of Nice.

PAGNINUS, Sanctus, in Biography, an Italian Dominican monk in the fifteenth century, eminent for his skill in the oriental languages and biblical learning, was born at Lucca in 1436, but according to others, in the year 1470. At the age of sixteen he took the habit in a convent of the Dominican order, and applied with extraordinary diligence to the study of the learned languages, and of divinity. He became deeply and accurately skilled in Latin, Greek, Hebrew, Chaldee, and Arabic, but he was particularly celebrated for his knowledge of the Hebrew language. He spent the greater part of his life in a monastery at Lyons, was distinguished by his zeal in defending the Catholic church against the attacks of the reformers, and laboured to prevent the numerous Italian families which had settled in this city from being converted by the emiaries of the Waldenfes and Lutherans. Pagninus is, however, chiefly known by his making the first modern translation into Latin of the Old Testament from the original Hebrew, and of the New Testament from the Greek. To this design he was led from a firm conviction that the Vulgate translation, as it has descended to modern times, is greatly corrupted from the Latine in which it was left by St. Jerome. It was his object, therefore, to produce a new translation, in which the Vulgate should be followed wherever fidelity to the originals permitted. Being patronized by Leo X. he began his great work in 1493, and having employed himself in it with the greatest affiduity twenty-five years, finished it in 1518. He then applied to the translation of the apocryphal books and the New Testament, both of which he rendered from the original Greek before the year 1521. The work was published at Lyons in 1528, under the title of "The naked of Telle-ament Nova Translatio, per Sanctum Pagninum super sanctum approbante Clemente VII." Many high commendations have been bestowed upon this work by the most learned rabbis, who have given it the preference to all other translations of the sacred Hebrew writings, and likewise by many eminent Christian critics, Catholic and Protestant, and among others, by Leufden, Erpenius, Buxtorf, and Huet. But father Simon and others, though they admit that Pagninus has shown great learning and talents, contend its claims to the superior excellence which the former attribute to it. Simon says it is obscure, barbarous, and full of folcisms, and he maintains that it sometimes changes the sense of the text. The version has gone through many editions. Huet, though he gives Simon credit for the general truth of his criticism, yet proposes his manner as a model for all translators of the sacred books; "Scripture interpretandae rationis utile nobis exemplar propoefuit Sanctus Pagninus." This author published "Theaurus Linguarum," in folio, which was reprinted by Robert Stephens, under the title of "Theaerus Linguarum," and Praefatio. Pagninus published many other works; he died at Lyons in 1536. Buxtorf, who made much use of his Theaurus, in forming one of his own, calls him "Vir linguarum Orientalium perfeffus." Luther spoke of him with great applause.

PAGO, in Geography, an island in the Adriatic, near the coast of Dalmatia, or Morlachia, about 26 miles long and 6 broad containing several villages. It is subject to a stormy sea, so that neither wood, nor pallure, nor corn lands are found upon that part which is opposite to the continent, except in few places. The air is darkened by the salt mift that is raised by the collision of the waves in the narrow channel of Morlachia. The large lake itself is not calm in the stormy season, and so far from being a harbour, it is tempestuous and unsafe. The inhabitants of the city are not secure in their houses, without defending the roofs by large tiles, nor can they leave them with safety during the violence of the wind. This island in winter is no less inhospitable than Siberia, always covered with snow and fire, and exposed to the cold north wind. The rocks which form the surface of almost the whole island, the narrowness of the valleys, the reversioner of the water of the lake, which is generally quite calm in summer, increase the heat to such a degree among the tiles, that the vines which are planted round the lake ripen the grapes before the beginning of August, and the few other productions of the spot anticipate the usual time of maturity. The part of the island under the jurisdiction of Pagó, produces about 40,000 barrels of good wine, and about 2000 of Rakia, one year with another. The island is covered with sage and odoriferous herbs; which furnish food for the bees, inasmuch that honey forms no incomparable branch of trade. The pallure among barren rocks maintains also a large number of sheep and goats, so that the wool, which is very bad, and coarse, furnishes small articles of export. The northern part of the island, called "Novaglia," and depending on the government of Arba, is well supplied with water, and has good pastures on its low grounds, by which its black cattle are larger and better than those on the lower island, or of their Dalmatia. The produce of corn and oil is very scanty, and not sufficient for two months sustenance of the inhabitants. The most considerable produc;
deal, from the island is fall: the falt-works belonging partly to the government, and partly to private proprietors. The northern extreme of the island, called "Punta di Lomi," is abundantly supplied with wood for various purposes, though other parts are wholly defirite. The roots and trunks of all olives trees afford excellent materials for the cabinet-makers and sculptors. The soil of the island, that is, of the land lying on the declivity and at the bottom of the hill, is very gravelly and light; but on the northern extremity, where are plains, though oily, the land is better, and stronger, and might be cultivated for all sorts of corn. The whole number of inhabitants amounts only to 3500, most of whom live in the city of Pag, which is supposed to contain 3000. N. lat. 44 40'. E. long. 15 10'.

Pogo, a town of the above island, built by the Venetians in the year 1468. This city has undergone various revolutions. The difficulty of access to it, and the bad accommodation it affords to strangers, render the intercourse with it very unprofitable; and to this circumstance it is owing that the inhabitants are as wild and unpolished as if they were ever so remote from the sea, and the commerce of people and nations. Even the gentry exhibit grotesque figures, both in their dress and behaviour; and the ignorance of the clergy is incredible.

PAGOD, or Pagoda, a name which the Portuguese have given to all the temples of the Indians, and all the idolaters of the East.

These pagods, or pagodas, are mostiy square; they are stone buildings, which are not very lofty, and are crowned with a cupola. Within, they are very dark; for they have no windows, and only receive their light through the entrance. The image of the idol stands in the deepest and darkest recess of the temple; it is of a monstrous shape, and of uncouth dimensions, having many arms and hands. Some of these idols have eight, and others sixteen arms; with a human body, and the head of a dog, with drawn bows and instruments of war in their hands. Some of them are black, others of a yellowish hue. In some pagodas there are no images, but only a single black, polished stone, lying upon a round altar, covered with flowers and sandal-wood, which were spread upon it. Greater veneration is manifested for these stones than for the idol's themselves. Their worship of these divinities consists in throwing themselves upon the ground, and making their falbs, or folution, with their hands, and ejaculating their prayers in fionence. In this profeffion. The offerings which they are accustomed to present to the gods consist of flowers, rice, pieces of silk and cotton, and sometimes gold and silver. Everything is laid before the idols, and is taken care of by the Brahmins, who profit the most by it. They guard the pagodas both by day and night. The pagodas of China are lofty towers, which sometimes rise to the height of three stories, of more than 20 feet each.

In order to give such an idea of these buildings as may enable the reader to judge with respect to the early state of arts in India, we shall briefly describe two of which we have the most accurate accounts. The entry to the pagoda of Chillaubum near Porto Novo, on the Coromandel coast, held in high veneration on account of its antiquity, is by a lofty gate under a pyramid, 122 feet in height, built with large stones above forty feet long, and more than five feet square, and all covered with plates of copper, adorned with an immense variety of figures, neatly executed. The whole structure extends 1332 feet in one direction, and 936 in another. Some of the ornamental parts are finished with an elegance entitled to the admiration of the most ingenious artists. The pagoda of Seringham, superior in finery to that of Chillambrum, surpasses it as much in grandeur; and, fortunately, we can convey a more perfect idea of it by adopting the words of an elegant and accurate historian. This pagoda is situated about a mile from the western extremity of the island of Seringham, formed by the division of the great river Caveri into two channels. It is composed of seven square inclosures, one within the other, the walls of which are twenty-five feet high, and four thick. These inclosures are 350 feet distant from one another, and each has four large gates with a high tower; which are placed, one in the middle of each side of the enclosures, and opposite to the four cardinal points. The outward wall is near four miles in circumference, and its gateway to the south is ornamented with pillars, several of which are single stories, thirty-three feet long, and nearly five in diameter; and those which form the roof are still larger; in the inmno inclosures are the chapels. About half a mile to the east of Seringham and nearer to the Caveri than the Coiboom, is another large pagoda, called Jembikifma; but this has only one inclosure. The extreme veneration in which Seringham is held, arises from a belief that it contains that identical image of the god Vishnou, which ufed to be worshiped by the god Brahma. Pilgrims from all parts of the peninsula come here to obtain absolution, and none come without an offering of money; and a large part of the revenue of the island is allotted for the maintenance of the Brahmins who inhabit the pagoda, and thefhe, with their families, formerly composed a multitude not less than 40,000 souls, maintained, without labour, by the liberality of superfluity. Here in all the other great pagodas of India, the Brahmins live in a subordination which knows no refistant, and are some in a voluptuousness which knows no wants."

The pagodas of the Chinefe and Siamefe are exceedingly magnificent.

The revenues of the pagoda of Janugrade are fo great, as to luxuriate, every day, from fifteen to twenty thousand pilgrims.

Pagod is also used for the idol adored in the temple.

Hence many give the same name pagod to those little porcelain images brought from China.

Pagod, or Pagoda, is also the name of a gold coin, current in several parts of the Indies, on the footing of the piece of eight.

There are also silver pagodas, struck at Narifung, Binafour, &c. which usually bear the figure of some monstrous idol: whence their names. They are of various values.

Accounts are kept at Madras, or Fort St. George, on the Coromandel coast, in pagodas, fanams, and cash; 80 cash = 1 fanam, and 42 fanams = 1 pagoda. Such is the mode of reckoning used by the East India company, and other European merchants. But among the natives, the value of the pagoda varies from 44 to 46 fanams. The gold coins are far or current pagodas; and the silver coins, Arcot rupees. Double and single fanams are current here, and copper pieces of 20 cash, called pice. Also pieces of five and ten cash, called doodees, and single cash pieces; these copper coins are struck in England, bearing the date of 1803, and the value is marked upon each. The far pagoda weighs 52.56 English grains, and the gold is 19½ carats fine; it therefore contains 42.048 grains of fine gold, and is worth 7s. 5½d. sterling; but it is commonly valued at 8s. In the company's books, 100 far pagodas are valued at 425 current rupees; and 10 far pagodas at 16 Spanish dollars. Many other coins circulate on the Coromandel coast, of which the most generally current are the following; viz. the old pagoda, with three swamy, or figures, coined at Madras and Negapatam, which is about 20½ carats fine, and which generally
generally bears a batta, *i.e.* an agio or discount of 10 per cent. against the new coins of the same places: the old pagoda of Negapatam and Tutocorin, which is of the same value as the ōlar pagoda: the new pagoda of Negapatam and Tutocorin, which is 18½ carats fine; and is reckoned about 4 per cent. worse than the ōlar pagoda: the Porto Nova pagoda, which is 17½ carats fine; and is about 20 per cent. worse than the ōlar pagoda: the Pondicherry pagoda, originally equal in value to the ōlar pagoda, but its standard has been lowered to 17 carats, and even less. All these different pagodas are nearly of the same weight. Mohurs, or gold rupees of Bengal, occasionally pass here for four ōlar pagodas. There are also gold fanams, which are only 7½ carats fine, and are allowed chiefly with silver; 24 of these are reckoned for an old Negapatam pagoda.

Gold and silver are weighed by the current or ōlar pagoda weight, as above stated. At Mangalore, on the Malabar coast, accounts are kept in Sultannee pagodas, rupees, and annas; the pagoda being four rupees, and the rupee, 16 annas: others divide the pagoda into 10 hunas, and the huna into 16 parts, called likewise annas. At Madras, on the Coromandel coast, accounts are kept in pagodas, rupees, and annas; the pagoda being 3½ silver rupees, and the rupee 16 annas. The coins, besides gold and silver rupees, are pagodas of nearly the value of the ōlar pagoda of Madras.

* N. B. The fineness of the ōlar pagodas varies from W. 2 car. 5 gr. to W. 3 car. 0½ gr.

*PAGOYUM,* a word used by Paracelius and his followers, to express an imaginary being, which prefigures, or is the occasion of disasters, whose causes are left known, and which have been supposed to arise from enchantment. Such is the doctrine of this strange writer, and on this subject he has written a treatise called Pagouis.

*PAGRUS,* in *Ichthyology,* a species of *Sparus,* which see. See also *Sparus Dentex,* and *Sparus Erythrinus.*

*PAGUL,* in *Geography,* a town of Africa, in Whidah; formerly N.W. of Sibi.

*PAHACACHON,* a town of Thibet; 100 miles S.W. of Hara-Toubé.

*PAHANG,* Paham, or Pão, a sea-port town on the E. coast of Malacca, called by the Portuguese "Paon," and by the Arabs "Íhan." It is situated about four leagues from the sea, and inhabited only by nobility, the people dwelling in the suburbs. It is inclosed by a wall, made of the trunks of trees joined close together, and about 24 feet in height, strengthened with a bastion. The streets are fenced on both sides with hedges of reeds, and planted with cocoa

---

**NOTES:**

In the Myore country, and particularly at the capital, Seringapatam, accounts are kept in Canterv's pagodas, and palams, called by the English Cantery pagodas and fanams. This pagoda is an imaginary money, and the fanam, which is a real coin, is the 10th part of the pagoda. The coins are gold Mohurs, which pass for four pagodas; sultany pagodas, coined by Tipoo Sultan, and other pagodas, coined by Hyder Ali, and by the rajahs of Myore, all paying for 13 fanams; also, sultany rupees, and rajah rupees, 26 of which pass for 7 sultany pagodas; copper dudus, called by the English dubs, 260 of which are the market price for a sultany pagoda. The sultany, when they exchange copper for gold or silver, pay at the rate of 234 dudus for a pagoda; but when they change gold and silver for copper, they receive 240; whilst the price fixed by government is 182 dudus per pagoda: and the other coins exchange in proportion. At Pondicherry, the coins are gold pagodas, and silver rupees and fanams. Gold and silver are weighed by the hoon, pagoda, rupee, and fanum. A pagoda weighs 9 fanams, or 14½ nelloes; so that three rupees are equal in weight to 10 pagodas; 7½ pagodas weigh a French mark, or 3778 English grains.

The following table shows the affray, &c. of the several pagodas which it specifies. W. every where denoting worse than English standard, and the mint price of gold in England, that is 3l. 17s. 10½d. per ounce, being standard.
and other trees; so that Pahang appears more like an assemblage of gardens than a regular town. The houses are constructed of reeds and straw, the king's palace only being of wood: for Pahang was formerly the capital of a kingdom, but it is now part of Johor. The adjacent country is low, but fertile, producing pepper, eagle and calabac woods, coarfe gold, nutmegs, Sapan wood, diamonds, and hog-stones, deemed of superior efficacy to bezoar-stones. In the interior of the country the inhabitants are numerous. N. lat. 3° 40'. E. long. 103° 36'.

Pahang, or Pulo-Pahang, a small island near the coast of Malacca; five miles E. from the town of Pahang.

PAHARGUNE, a town of Bengal; ten miles S.W. of Beyhar.

PAHAVENS, a town of Peria, in the province of Irak; 30 miles W. of Jefd.

PAHICH, a town of Arabia, in the province of Hedsjas; 60 miles S.E. of Medina.

PAHIE is one of the clusses of canoes or boats used by the inhabitants of the islands in the South sea. The pahie is of different sorts, from sixty to thirty feet long, but very narrow; a transverse flection of it reflebles the shape of cards, the whole being much wider in proportion to its length. The largest pahies are used for fighting, in which case they are fitted with a flag or platform; but principally for long voyages. Hawksworth's Voy. vol. ii. p. 222, &c. See Boat (Pahie.)

PAHO, in Geography, a river on the W. coast of the island of Celebes, which runs into the straits of Macassar. S. lat. 3° 10'. E. long. 119° 52'.

PAHVA, a small island on the coast of Finland, with a town upon it. N. lat. 60° 29'. E. long. 21° 30'.

PAHVITRAM, a town of Hindooftan, in the Carpathian; 14 miles E.S.E. of Coverporeum.

PAJACK, in Commerce, a corn measure in Russua; thus, the chetwert or cool of corn is 2 olimins, 4 pajaks, 8 chetwericks, or 64 garatzy. A cool of flour is 9 poos, and a fack 5 poos. The chetwerick is 1 1/2 English inches in diameter, and 1 1/2 in depth; it therefore measures 1555 92 cubic inches, and contains 52 Winchester gallons nearly. In business the usual calculation is, that 100 chetwerts produce 72 quarters, and 1 chetwert 3 1/2 bushels, Winchester measure.

PAJANA, in Geography, a lake of Sweden, in the province of Tavalland, about 100 miles in length.

PAJAS, a town of Asiatic Turkey, in the government of Maraich and bay of Alexandria; five miles W. of Alexandretta.

PAJAUNNY, a town of Hindooftan, in Ouide; 30 miles W. of Kairabad.

PAICHAM, a town of Chinefe Tartary. N. lat. 42° 42'. E. long. 120° 22'.

PAIDORFF, a town of the duchy of Stiria; six miles N. of Monehau.

PAIGLES, in Botany. See Primula.

PAJA LA, in Geography, a town of Sweden, in Weft Bothnia; 86 miles N. of Tornca.

PAIL, in Rural Economy, a wooden vessel in which milk, water, or other fluids are commonly carried.

PAIL-Braths, in Agriculture, a sort of hard brush furnished with bristles at the end to clean out the angles of the vessels more fully. These ought to be in every dairy, though in many districts their use is scarcely known.

PAIL-Stroke, in Rural Economy, a simple contrivance for drying dairy utensils upon, being merely a bough of a tree furnished with different small branches, which is fixed with its thick end into the ground in the dairy-yard. The several small branches being lopped of proper lengths, the stumps afford pegs for hanging the pails upon, or for other utensils, by which they are not liable to be blown down and thereby burst or injured.

PAILLY, in Geography, a town of Hindooftan, in Visapur; five miles S.S.W. of Sassarah.

PAIMPEUF, or PAIMBEUF, a town of France, and principal place of a district, in the department of the Lower Loire, situated at the mouth of the Loire, 21 miles W. of Nantes. The place contains 4220, and the canton 6047 inhabitants, on a territory of 724 kilometres, in three communes. N. lat. 47° 17'. W. long. 1° 97'.

PAIMPOL, a town of France, in the department of the North Coasts, and chief place of a canton, in the district of St Brienc; seven miles E. of Treguier. The place contains 1679, and the canton 16,319 inhabitants, on a territory of 127 5/6 kilometres, in 11 communes.

PAIN, Dolor, &c., in Medicine, an uneasy and distressing sensation, which is connected with various forms of disease, and with various species of injury, inflicted upon the living body.

As we are altogether unable to explain the nature of sensation, and the agency of the nervous system, as the organ of that faculty; so it is impossible to give any satisfactory account of the proximate cause of pain. As in all similar cases, we must content ourselves with considering it as an ultimate fact, and with observing the various circumstances under which it occurs, and the different phenomena which accompany it. All the attempts which have been made to explain its nature, being founded entirely upon hypothetical speculations that have been altogether gratuitous, are justly exploded.

The varieties of pain can only be described by referring to the common agents by which they are excited to the parts of the body in which they are felt, or to the degree and duration of their occurrence. The external agents, which produce painful sensations, operate variously upon the living body; some by mechanical, and some by chemical action upon the animal fibre; while others act by a peculiar influence upon the nervous system, without deranging the structure of the sentient parts. The mechanical agents are all such as tend to produce a solution of continuity in the solid parts, to interrupt the circulation of the blood in them, and to produce an extravasation of the fluids from their proper vessels: whence pain is a consequence of blows, bruises, and continued pressure, of laceration from the bites of animals, of abrasion, of the cutting and rasping of sharp instruments, &c. The chemical agents produce a solution of continuity, by inducing the parts of the living body, like dead matter, to enter into new combinations: whence pain is the consequence of the action of fire, or intense heat from any source, and of a number of acid substances, which corrode the substance of the body, such as the strong mineral acids, the pure alkalies, &c. A gain, the third clas of external causes of pain consists of those agents, which act speedily upon the sentient system, inflicting its functions, without injury to any organic structure; namely, the venemous and narcotic excitations of animals and vegetables, which are called poisons. As the operation of these various exciting causes occasions many modifications of pain, which are probably very similar in different individuals, we are thus furnished with a language, by which the various painful sensations may be described to those who feel them not. Thus we speak of a burning, ringing, prickling, gnawing, cutting, or lacerating pain. Pains are also distinguished by other
PAIN.

other concomitant sensations, such as by being connected with a sense of weight, of throbbing or pulsation, of rawness or excoriation, of tension or contraction, of formation or the creeping of infest, of shooting or darting through particular parts, of coldness, of torpor or numbness, and so forth. Some pains, again, are characterized by remaining fixed and immovable; while others are flying or wandering pains, leaving one part and being upon others in succession; and others are periodic or intermittent, ceasing altogether for a certain number of days or hours, and recurring with great regularity, like the paroxysms of an ague.

Many of the causes above-mentioned, however, do not immediately excite pain, but indirectly, by producing one or two morbid conditions, which are invariably accompanied by pain; we mean inflammation, or &sfrin: whence pain frequently occurs, as a symptom of these diseases, arising from internal causes, and independently of the violent operation of the external agents above enumerated. The diagnosis between these two sources of pain, in many maladies, is of the utmost practical importance, as the indications of cure are nearly of an opposite nature in the two cases.

Before we come to these practical points, it may be proper to notice some pathological facts, which are worthy of observation. It is obvious, that the nervous system is the medium of sensation, or the communicating link between the parts receiving the impression, and the common fen torium, the brain, where the perception is produced. For if the nervous trunks are divided, and the communication cut off, the parts of the body, so insulated, may be cut or otherwise injured without pain, and even without the cognizance of the individual. Hence the pain cannot be said strictly to be seated in the part to which the sensation is referred. This is illustrated in a remarkable manner in cases of the loss of limbs by amputation or accident. The patients, in these instances, often complain of pain in the fingers or toes of their lost arm or leg; a sensation, which can only arise from the impression which the wounded nerve makes upon the brain, being similar to that which it had been accustomed to convey from the extremity of its branches, while the limb remained perfect. In other cases, again, the pain is not even referred by the mind to the actual seat of the irritation which induces it, but to some other point, at a distance from it. Thus the part which is the seat of unequal pain, when the cells of the lungs are loaded with mucus, blood, or other matters, is the top of the larynx, or wind-pipe, which excites the effort of coughing, to expel the offending substance, and which subsides when the cells are unloaded. In a similar manner, in inflammation of the liver, the pain which is most complained of is not always seated in that organ, but is often referred to a small space at the top of the shoulder. And in all cases of irritation in the urinary bladder, whether from the presence of a stone or gravel in that sac, of acrid urine, of blood, pus, or other foreign matter, the most poignant irritation is often seated at the extremity of the urethra. The facts are not easily explained, but are necessarily referred to some peculiar communication of sympathy through the distribution of the nerves.

It is a curious fact, which has been attempted to be explained in various ways, that pain is much alleviated by certain exertions of the voluntary muscles; whence, in all cafes of violent pain, persons are observed to refer to some species of exertion, such as grasping anything strongly, fixing the teeth, exerting the voice in screams or moanings, &c. Dr. Darwin, with his accustomed acutenes, generalizes this observation to a great length. "The reliefness in some fevers," he says, "is an almost perpetual exertion of this kind, excited to relieve some disagreeable sensations; the reciprocal opposite exertions of a wounded worm, the alternate emphysema and opisthophora of some spasmodic diseases; and the intervals of all convulsions, from whatever cause, seem to be owing to this circumstance of the laws of animation; that great or universal exertion cannot exist at the same time with great or universal sensation, though they can exist reciprocally; which is probably resoluble into the more general law, that the whole sensorial power being expended in one mode of exertion, there is none to spare for any other." Zoology, vol. i. lect. xxxiv. 1, 2.

This idea of the two great powers of motion, sensitation and volition, in the animal machine, is, Dr. Darwin thinks, confirmed by the observation, that they never exist in a great degree or univerally at the same time; and hence he would account for the fact, stated above, that we in finitively exert our voluntary motions, when suffering severe pain or uneasiness, and thus procure ourselves relief. The ingenuity with which he illustrates the mode of exertion, in cases of bodily suffering, is peculiarly his own.

"When any violent pain afflicts us, of which we can neither avoid nor remove the cause, we soon learn to endeavour to alleviate it, by exerting some violent voluntary effort, as mentioned above; and are naturally induced to use those muscles for this purpose, which have been in the early part of our lives most frequently, or most powerfully exerted. Now the first muscles, which infants use most frequently, are those of respiration; and on this account we gain a habit of holding our breath, at the same time that we use great efforts to exclude it, for the purpose of alleviating unavoidable pain; or we press out our breath through a small aperture of the larynx, and scream violently, when the pain is greater than is relieved by the former mode of exertion. Thus children scream to relieve any pain either of body or mind, as from anger, or fear of being beaten. Hence it is curious to observe, that those animals, who have more frequently exerted their muscles of respiration violently, as in talking, barking, or grunting, as children, dogs, hogs, scream much more, when they are in pain, than those other animals, who use little or no language in their common modes of life, and hares, sheep, and cows.

"The next most frequent or most powerful efforts, which infants are first tempted to produce, are those with the muscles in biting hard substances. Hence when a person is in great pain, the cause of which he cannot remove, he feds his teeth firmly together, or bites some substance between them with great vehemence, as another mode of violent exertion to produce a temporary relief. Thus we have a proverb, where no help can be had in pain, "to grin and abide;" and the tortures of hell are said to be attended with "gnashing of teeth." Hence in violent spasmodic pains, I have seen people bite not only their tongues, but their arms, or fingers, or any object which was near them, &c.

"If the efforts of our voluntary motions are exerted with still greater energy for the relief of some disagreeable sensation, convulsions are produced; as the various kinds of epilepsy, and some hysteric paroxysms. In all these diseases, a pain or disagreeable sensation is produced, frequently by worms, or acidity in the bowels, or by a diseased nerve in the fide, or head, or by the pain of a diseased liver." Loc. cit.

"To this view of the subject it might perhaps be objected, that the exertions and convulsive motions, if they were excited by the pain, should be proportionate to the violence of the pain; which is not the case. This objection, however,
PAIN.

is entirely obviated by the consideration, that the nervous system suffers a greater degree of irritation from many feintitions, that are even in some degree pleasurable, than from intense pain. This is exemplified in respect to tickling. Children have been tickled into convulsions; and perhaps no pain is so intolerable as that of tickling, if the violent efforts of laughing and of moving the limbs were to be restrained. The writer of this article has been informed by a very intelligent gentleman, who is subject to contant and severe convulsive actions, of the nature of St. Vitus's dance, that they are clearly the result of disagreeable feintitions, not always amounting to what may be called pain. In this way, it seems to happen, that the most violent and fatal convulsive malady with which we are acquainted, the tetanus, or locked jaw, is produced from the irritation of a wound, but not from a deep and open wound, but from a slight abrasion of the skin, or from a wound that is just healed.

Independently, then, of the suffering which pain occasions, its effects on the animal economy are sufficiently severe to induce one to search for the means of relieving it. It never exists long without exciting some degree of fever, and disturbing the functions of life, especially that of digestion; whereas debility and emacation ultimately follow: frequently it brings on delirium, syncope, or fainting, and convulsions of every species, besides those already mentioned, and even occasions death itself. In many diseases, therefore, it is an important object to alleviate pain, even where such alleviation has no remedial effect upon the disease, of which it is a symptom.

With a view to the successful alleviation of painful diseases, it is necessary to establish a clear diagnosis with respect to the origin of the pain; for the treatment, which will cure one variety, will aggravate another, and even accelerate the fatal termination of the disease which it accompanies.

Violent or acute pain originates, in general, from acute inflammation of some organ, or from spasm in a muscular part. The former species of pain accompanies inflammation of all the viscera; occurring in the head, in phrenitis, or inflammation of the brain; in the chest, in pleurisy, and inflammation of the heart, or of the diaphragm; in the right shoulder in inflammation of the liver; in the abdomen, in enteritis and peritonitis; in the joints, in neuralgia, and so on. The spasmatic pain occurs in the muscles of the limbs, in cramp; in the bowels, in colic; in the stomach, in gall-stones; in the uterus, during the time of parturition; and in the muscles of the jaw and of the spine, in locked jaw and tetanus, &c. In some of these cases, the obvious appearance of rigid contraction, or spasm, in the muscles of the parted parts, as in the cramp, locked jaw, and tetanus, is sufficient to point out the nature of the pain. But in regard to the internal pains, the principal source of diagnosis is the presence or absence of a state of fever. Acute inflammation cannot exist, without an increased velocity of pulse, which is also commonly strong, or at least hard, and vary, and not easily compressible under the finger: there will also be thirst, heat of skin, a dry and foul tongue, with failure of appetite, and some prostration of strength. When the pain arises from spasm, the symptoms of fever are generally absent; the pulse is often not altered in its beats, but remains moderate, soft, and compressible; the tongue continues moist, and without fur; there is no particular thrill, nor any pulse of heat, exceeding chillness; and the animal functions are not much disturbed. It is principally from these circumstances that the nature of pain, in any one part, is ascertained: thus in inflammation of the bowels, and in spasmatic colic, the heat and the degree of feverity of the pain are often precisely similar, and can only be thus decided distinguished. Some other circumstances, however, require attention as auxiliary to the diagnosis: for instance, in inflammation, pressure upon the part injured aggravates the evil, and a feint of forness is felt under the touch; while, in spasm, the parts are not generally tender, but the pain is often relieved by pressure, and even by friction. In inflammatory affections, again, the pain remains fixed in one spot, and regular in the degree of its intensity; whereas, in spasmatic affections, the pain is commonly movable, wandering from one point to another, as the spasm suddenly relaxes in one part of muscular fibres, and recurs in others; and it is commonly sudden it its attack, and remittent in its degree, being aggravated and alleviated by fits or paroxysms.

The progress of an internal inflammatory disease may often be ascertained, and the nature and period of its termination anticipated, by an attention to the variation of the pain, together with other symptoms. Thus it, after some continuance, an acute inflammatory pain gradually becomes less intense, is accompanied with a feint of weight and tenderness, and at length with a sensation of throbbing or pulsation; it is much more likely that suppuration has commenced, and that the disease must terminate in abscess; and there will be no doubt of this, if at the same time the fever begins to remit, and paroxysms of pyre, followed by flushes of heat, come on daily: in other words, if the fever persists on a hectic type. Again, if, during the continued severity of the pain and fever, the farmer should suddenly cease altogether, the practitioner is not to suppose his patient recovering; it is probably an indication that gangrene has come on, and that the life of his patient is near its close. This will be placed beyond a doubt, if, at the time of the cessation of pain, the pulse loses its sharpness, and becomes small and feeble, with a tendency to coldness in the extremities, and a sinking of strength.

Another material consideration, in estimating the probable event of a painful disease, is the importance of the organ in which it is situated. An inflammation in any of the viscera, immediately subserous to the great functions of the living body, is always attended with danger, especially in the brain, stomach, or bowels; because the functions of these organs cannot be interrupted with safety to the vital machine. But an inflammation, however violent, may occur in the external muscular or ligamentous parts, as in the joints and limbs, without much risk to the safety of the system. It is never to be forgotten, however, that what is called a metastasis of such external inflammation to an internal organ, (of which both gout and acute rheumatism afford many examples,) that is, the occurrence of inflammation in some internal viscus, immediately upon the spontaneous disapperance of external inflammation, is always an alarming circumstance, and leads to an unfavourable prognosis.

Of the more chronic varieties of pain, it is not necessary to treat at any length, as they are commonly accompanied by other symptoms of disease, which are equal objects of medical attention, and which contribute to point out the nature of the malady. The diseases being once established, in cases of acute pain, according to the principles above stated, the selection of the proper mode of cure will be perfectly easy: but if a mistake is committed in determining the first point, the misapplication of the remedies will be of serious injury. For if the expedients, which will preferably alleviate spasmatic pain, be administered for the removal of that which is inflammatory, it is scarcely possible that aggravation should not follow; and
and in many cases, on the contrary, when the proper remedies for inflammation are applied for the relief of spastmodic pain, an injurious effect, slightly less severe, may be expected to result. Yet in the popular practice, no mistake is to common as the forms of these errors.

For the cure of violent inflammatory pain, such as occurs in phreny, pleurisy, and inflammation of the stomach or bowels, evacuations by blood-letting, both general and local, by external application, and by the use of cathartics, are the means which must be adopted, and executed with expedition; while every fluxus, in the way of food, drink, and medicine, must be cautiously interdicted, and the whole anti
diphlogistic system rigidly pursued. But in the febile and debilitated constitutions, in which spastmodic diseases often occur, such a plan might aggravate the malady, and reduce the constitutional powers to a dangerous state of imbecility. On the other hand, in the constitutions just described, and in most cases of spastmodic pain, the most effectual remedies are opiates, combined with stimulants of the most powerful and diftinguishable kind, such as alcohol, flagging the flamin
gum and eflential oils, ammonia, preparations of ether, &c.
Yet it is scarcely necessary to remark, how directly adverse to inflammatory affections such medicines must prove. It is, therefore, lamentable to reflect upon the indiscriminate resort, which is popularly made to spirituous and hot liquors, under all internal pains, especially in their commencement, and the recklessness of attending to the marks of distinction above pointed out, or of delaying all remedies until proper medical assistance be procured, in cases of the attacks of such diseases, cannot be too strongly enforced.

PAINS, After, in Mutilation. See After Three or Four Days.
Pain-de-abeilles, a word used by force to express what the ancients called ambrosia, or the yellow substan
ced found concre
ted in lumps on the legs of bees, and supposed by the gen
erality of the world to be real wax.

Experiments made by Mr. Reaumur and others, have suf
ciently proved that this substan
cce is not wax, nor has it
any of the properties of wax; but it has been conjec
tured, that this is the matter out of which wax is finally made.

In tracing this substan
cce up to its origin, we find that
the bees collect the farina of flowers, which, when moulded by their feet into a lump, makes this matter. It is very probable, that they feed on this matter, and, as some ima

gine, after passing through certain changes in their bodies, it becomes wax. This was an opinion so old as the days of Phry; some of the authors he quotes calling this substan
cce ambrosia, or the food of the little deities; but later ob
ervations overthrew this opinion, till it again got credi

t under the more accurate examinations made by Mr. Rea

um, on the structure and parts of the bee. This is a food
not only eaten occasionally by the bees, but necessary to
their support, and is found stored up in their hives against a
bad feast. The combs have their different cells made for differ
ent purposes; and, before that, some are destined for receiv
ing honey, and some for the young worms which are hereafter to become bees; there are some alto which serve to
contain this yellow matter, collected on the legs of these in
fects. In fine weather, when more of this matter is col
lected than is eaten for immediate nourishment, the bees
ferage off the lumps of it from their legs into some of the
holes, or cells of the combs, where, others following their
example, there finally become large reserves of it; which
are eaten on such days when they cannot go out in search of
more.

The bee collects this yellow matter, which, according to

Reaumur, is the prime conqunent of the wax, from what
ever flowers happen to be most plentiful about the hives;
and though generally yellow, as the farina of most plants is so,
yet it is sometimes seen in red or green lumps on their thighs;
but whatever be its natural colour, it is always turned yellow
before it is discharged from the body of the animal; and
when the farinac of any of them is effected, after feeding
on a red substancc collected from flowers, the farinac of which
is that colour, the change is gradual to be made as to colour
is this part, for the whole is found there in form of a
yellow jelly. This matter, taken out of the hones of sev
eral plants, and dried, it found to be of a disagreeable
smell, like fermented matter, and of a putridy somewhat
resembling that of the volatile salts. Mr. Reaumur was
hence induced to try the effect of the volatile salts in making
the bees bread, or rough wax, into perfect wax by digestion,
continued a long time, but in vain. If we may give credit,
however, to the German Ephemerides, there is a much
more easy way of reducing this matter, while yet contained
in the apes of the plant, into true wax; and that without
the asilence of the work of the bees. Mr. David Maja

gives an account, in those papers, that the perfumes he
employed in beating roxes into confere, always observed in the
pounding of the roxes, before the fugar was put to them,
that a piece of solid but wet matter was found adhering to
the pellets of the mortar, which, on a strict examination,
proved to be true and genuine wax. It appeared from this
experiment that the juice of the petals or leaves of the roxes,
was able, by the asilence of beating, to convert into true
wax the farinac contained in the apes of that flower. Mr.
Reaumur tried what effect the juice of roxes would have on
the yellow matter collected on the legs of the bees; and on the farina of plants, but no treatment he could give this substan
cce was ever able to produce wax. Mr. Reaumur al
leges as an absolute proof, that the bees eat the rough wax
or bees bread; that, by obsering the bees of a certain hive
to come home loaded with it every day, under the influence
of the sun, during the month of April, and a great part of May;
and after this, opening and examining the hive they belonged to,
there were found no new combs, nor were the old bees en
larged in size; it is true, that there were some cells found
filled with magazines of this matter, but as the far greater
part was brought to no fort of account, it seems very plain
that they had eat it. It is to be obsered, that the bees
have their several periods of going out in search of this mat
ter and of honey; it would be too fatiguing for them to be
always thus at work; and to avoid this there is always a very
large part of them, even more than half the hive, found at
rest within it; these are such as have worked till they are
tired, and the others in turn take this manner of resting, and
send them out to work again. Reaumur's Hist. Inf. vol. x.

p. 68. But it is necessary to add, that Butler, Purchas, Rul
den, and Thorley, very accurate obervers of the various opera
tions of bees, have urged several arguments to disprove the
identity of the substancc now described, and wax. When
the hives, they say, have been for a year or more filled with
combs down to the floor, and there is no more room to build,
the bees carry in this matter in the greatest plenty; and even
when no more wax is wanting, besides the small quantity
which is required for sealing up the honey and the breeding
cells. They also urge, that this substancc is very different
from wax; as the particles of the former will separate from
each other, and be crumbled to powder when examined
between the fingers, whereas that of the latter will adhere,
and cleave together; and if the one be carried to the fire, it
will melt and disolve, whereas the other will be converted
into
Paine Fort, 3 Durs, in Law, an espedal punishment, formerly inflicted on one, who, being arraigned of felony, refused to put himself upon the ordinary trial of God and his country, and thereby flood mute by the interpretation of law.

This is vulgarly called pressing to death. The process whereof is thus described:

"He shall be bent back to the prison, whence he came; and he laid in some low dark room, where he shall lie naked on the earth, without any litter, rufhes, or other clothing, and without any raiment about him, but only something to cover his privy members; and he shall lie upon his back with his head covered, and his feet; and one arm shall be drawn to one quarter of the room, with a cord, and the other arm to another quarter, and his legs in the same manner; then let there be laid upon his body iron, or stone, as much as he may bear, or more; and the next day following, he shall have three morfels of barley-bread without drink; and the second day he shall have drink three times, as much at each time as he can drink, of the water next unto the prison, except it be running water, without any bread; and this shall be his diet, till he dies."

This species of punishment is now discontinued by 12 G. 111. cap. 20. See Mute.

PAINIM, the name with Pagan.

PAINOM JEUNG, in Geography, a town of Thibet, on the Painom-tcheiu; 122 miles S.S.W. of Laffa. N. lat. 29°. E. long. 89° 8'.

PAINOM-TCHIEU, a river of Thibet, which runs into the Burhampooter; 15 miles S. of Sigaigchee-Jeung.

PAINOUC, a town of Chinefe Tartary. N. lat. 41° 56'. E. long. 119° 49'.

PAINSWICK, a small market-town in the hundred of Bisley, and county of Glocefter, England, is seated on the southern declivity of Spooned-hill, at the distance of six miles S.S.E. from the city of Glocefter, and 101 miles W. by N. from London. It is a town of considerable antiquity, being mentioned in Domedday book under the name of Wicce. The manor then belonged to Roger de Laci, who, in the rebellion excited by Robert Curthofe against his father, was deprived of all his possessions. On this event Painwicke became the lordship of Pain Fitz-John, from whom it derived the former part of its present designation. Since that period it has been inherited by several noble personages, and among others by the lords Talbot, one of whom obtained a grant, in the year 1400, to recompense the widows of those persons who were slain in foreign wars, "it having been represented that eleven married men out of sixteen had lost their lives beyond the sea; and the widows were allowed to marry with whom they list."

- Painwicke conflits of several streets, very irregularly built. The church, dedicated to St. Mary, is the only edifice worthy of notice. This building has a nave, a chancel, and a north and south aisle, with a tower and spire at the west end, rising to the height of one hundred and seventy-four feet. Its style of architecture is mixed and incongruous; the south aisle, which is modern, is supported by Doric pillars, and the entrance is beneath an Ionic portico, while the body of the church is in the pointed style. The spouts under the battlements of the north aisle, represent singularly grotesque heads of demons. In the chancel are several monuments of the Jertrshen family.

According to the parliamentary returns of 1811, this town and parish contains 674 houses, and a population of 3321 persons, a great proportion of whom are employed in the woollen trade.

Above the town, on the summit of Sponebed hill, is an ancient entrenchment, designated by the different appellations of Kimbury-castle, King's-Barrow, and Castle-Gedwin. This fortification is of a square shape, and has a double ditch and vallum. The inner rampart includes an area of about three acres, and as well as the outer one is till of considerable height, though both have of late years suffered great dilapidation for the sake of the stones employed in constructing them. This encampment is supposed to have been of Roman origin, as coins of that people are frequently dug up within its area. It was afterwards, however, occupied by ear Godwin during the insurrection made for the expulsion of all foreigners from the kingdom; and again by the royalist army after the siege of Glocefter, in the time of the grand rebellion. The position of this entrenchment, in a military view, is excellent, as from its loftiness it overlooks a large tract of the adjacent country.

Haresfield parish, to the westward of Painwicke, contains some villas of antiquity. On the high ridge of hills, which shelter the village, is a very singular entrenchment, conjectured to have been a flation of the Romanized Britons. It extends on one side 600 yards in length, and is defended by a single vallum fifteen feet high. Connected with this work is another, (partly in the parish of Standish,) which includes the bold promontory, called Beacon-hill, by a "transverse vallation fifty feet deep, and containing fifteen acres." At Harescomb is the site of an ancient castle of the Bohuns. Beauties of England and Wales, vol. v. by E. W. Brayley and John Britton, F.S.A. Bigland's History of Gloceftershire, vol. ii.

PAINT, BLACK OIL, in the Arts, is prepared by grinding, with a proper quantity of oil, the charcoal or foot blacks, or the natural black earths, or the pit-coal, till they are united into a smooth, uniform, thick compound, which is occasionally diluted with more oil to a due consistence for being worked freely with the brush or pencil. The fine black colour is made with ivory black, ground before the addition of the oil, into an impalpable powder. The material most commonly made use of is lamp-black, the uneasiness of which dispenses it to mix more easily and perfectly with other pigments; but it derives hence the imperfection and disadvantage of drying slowly, which may be remedied by a due preparation of the oil; as by setting it on fire and boiling it, as in the method of making printing-ink. An opaque deep black paint with water, is made by grinding ivory-black with gun water, or with the liquid which settles from white of eggs, after they have been beaten up and suffered to stand a little. Some use gum-water and the white of eggs together; and observe that a small addition of
PAI

of the latter makes the mixture flow more freely from the pencil, and improves its glossiness. Lewis's Com. Phil. Tech. p. 356, &c.

PAINTED LADY, among the Flora, a term for a particular fort of carnations, the flowers of which have all their petals red or purple on the outside, and white underneath.

PAINTED Lady Pea, in Gardening, the common name of an ornamental pea. See LATHYRUS.

PAINTED Po fo, in Geography, a township of America, in Steuben county, New York, on Tioga river, between Bath and Newtown; containing 262 inhabitants.

PAINTEN, a town of Bavaria, in the principality of Neuburg; 11 miles W. of Ratibon.

PAINTER, in Naval Language, a rope employed to fallen a boat either alongside of the ship to which it belongs, or to some wharf, key, &c. as occasion requires. See SHANK-PAINTER.

PAINTER, in the History of the Arts, one who possesses and practises the art of painting.

PAINTER's Harbour, in Geography, a port on the W. coast of Cape Breton. N. lat. 46° 32'. W. long. 61° 16'.

PAINTERS, Hands. The price of painters work is limited by statute, and they shall not take above 16d. a-day, for laying any flat colour, mingled with oil or size, upon timber, stone, &c. and plasterers are forbid using the trade of a painter in London, or to lay any colours of painting, unless they are servants to painters, &c. on pain of 5l. But they may use whitening, blacking, red lead, ochre, &c. mixed with size only, &c. 1 Jac. I. cap. 23.

Painting is measured by the square yard in the same manner as wainscoting, the mouldings being measured by a thread; the lattice of windows are paid for by the piece; and it is usual to allow double measure for carved mouldings, &c.

PAINTING, the Art of, is the art of imitating the appearances of natural objects, by means of artificial colours spread over a surface; the colouring substances being used either dry, as in crayon painting; or compounded with some fluid vehicle, as oil, water, or solutions of different gums and resins in oil or spirits, &c.

The theory and practice of this ingenious and delightful art, are divided by its professors into five principal parts; viz. invention, or the power of conceiving the materials proper to be introduced into a picture; composition, that of arranging those materials; design, that of delineating them; chiaro-Scuro, or the arrangement and management of the lights and shades, and of light and dark colours; and colouring, whose name sufficiently designates its end.

Each of these principles we have already amply discussed in separate articles; and our readers will also find the more minute, though not less useful, subdivisions of them explained and illustrated under their respective designations (See EFFECT, ELEGANCE, EXPRESSION, &c.) We shall in this place, therefore, confine ourselves to the treatment of the subject generally, rather than technically; and trace its history from its first application as an arbitrary means employed to relate or record a mere fact, in a rude and formal manner, such as it was found practised among the Mexicans (see Robertson's America,) to that high state of cultivation, when it was employed to soften and mould the heart, by impressing it with sentiments at once moral, lovely, and energetic.

Nature has denied to few the passions and feelings which are the bals of the imitative art; and most men delight in beholding their productions. The desire of imitation appears to be so congenial to the mind, that one can scarcely imagine there could have been any lengthened period of time when it was not called into action, as an agent, either of amusement, of information, or of instruction. Of drawing or painting more particularly, it appears reasonable to suppose, that it must have been adopted for either or all of these purposes, in the earliest stages of human society; though in its very simplest and rudest form.

It will be therefore a vain attempt, if we endeavour to trace the period when the art began its original effays, as an anvil towards communication between man and man; as a means of adorning their perons, or amusing their minds.

A state of indolence and ignorance, such as that of savage nations whose sole occupation, dictated by necessity, confin'd to procuring the necessaries of life, by becoming acquainted with the productions of nature, never appears to have prevented the practice of the ruder elements of it; and it is not improbable that the waste of time between the active periods of exertion in the chase, might itself have been the cause of the first step towards imitation. In pure indolence of thought, or by accident, the first trace of form might have been made in the sand, or on the body; or resemblances observed in sticks or stones, have given rise to the idea of imitating by lines and colours the appearances of natural objects. Among the rudest, most uncultivated nations which our circumnavigators have within the two last centuries discovered, nulhs it the natives of New Holland, and that may admit of a doubt, some are without the rudiments of art. Some exhibit it by carving what they consider as ornamental forms, &c. on their instruments of war, their idols, or their utensils. Others, in more refined attempts, adorn their persons by coloured lines and figures; puncturing their skins, and rubbing in powders of various colours, which become by that means indelible. All display the influence of natural principle in this particular; and from these rude employments of the inventive and imitative faculty, the progress appears neither unnatural nor difficult, till we find it adopted as a subtilty for language; transmitting an image and record of events before the invention of writing, and even in a more universal, though in one view more confined manner, than that later invention is capable of.

Although thus early the art of painting may be supposed to have allured the attention of men, to have excited their inherent taste for imitation, and to this find the basis of a durable principle for itself whilst mankind exists; yet, when the mere object of conveying ideas was once completed, its advance towards that cultivation of which we now know it to be capable, was extremely slow. Being more an adjunct to the pleasures than the necessities of human life, it could not experience that attention which alone carries it forward, when time was occupied almost exclusively in procuring necessary food; and before intellectual education had made men acquainted with its true value. Painting may exist in a state of ignorance, but has never been known to flourish, except at the periods wherein human cultivation was most affluently encouraged, and ardently pursued; and even in the highest states of mental acquirement, and when that art was most devotedly admired, and indulgently practised, it struggled with difficulties proportioned to its value, and the delight it is calculated to afford; and few have been the happy mortals who have enjoyed the blessing of having pre-eminent in the exercise of it.

Such are the uncertainties attending the traditional history of the progress of the arts of design in the countries to the east of Syria, which relate to the probability of their having been first practised there, and thence travelled through Persia
Persepolis, as its chief city, and in which the arts were first introduced. Greece, and is supposed to have been that time when the art of painting was first introduced, and to have been attended with great success. In the reign of Minos and Semiramis, and about 20,000 years before the commencement of the Christian era. The art of painting at this period, we have but a glimpse, and are then immersed in the fame obscurity as before, where doubt but conjectures and arguments drawn from subsequent events are the guides.

Diodorus Siculus relates, lib. ii. "that Semiramis having thrown a bridge over the Tigris at Babylon, erected a temple to her at the end of it, and enclosed them by three walls of considerable height, with towers upon them;" these were built of brick, painted and burnt. These paintings exhibit a very great advance in the arts for that early period; for he says, "the bricks were painted before they underwent the fire," (so that, if this account be correct, here was enamel as well as painting), and that not only there were single figures of animals represented in colours, but they were also combined in groups; one, a hunting-piece of considerable length, wherein the queen herself was represented on horseback, throwing her dart at a panther; and near her Minos striking a lion to the earth with his spear.

They were of great extent, covering walls and towers attached to them. One other mention of painting is found in the same author, concerning the fame period, and under the guidance of Semiramis; and that is, of paintings in the temple dedicated to Belus, and founded by her. In them were represented monstrous figures, exhibiting hermaphrodites and centaurs; or unnatural combinations, probably alchemical, to the idolatry of the time. Diodorus also mentions the situation of the arts in Egypt at about the same period, where probably they had attained nearly the same degree of cultivation: sculpture, as belting serving religious purposes, being in both countries carried much farther than the finer art of painting.

From Egypt the arts were supposed to have been transplanted to Greece, where a more genial climate awaited them; where they had not to struggle with such impediments as arose from the government and habits of Egypt; and where alone, in the more early period of the world, they are found to have been fully brought into action. In other countries, where any trace is visible of them, wrought before the Greeks had exhibited their power, the rudest examples are little better than hieroglyphics; and most probably they never far exceeded the efforts of youthful leamers of the present day.

It is, doubtless, to the Greeks alone we are indebted for the highest cultivation which the imitative arts have known. In sculpture they attained so high a pitch of excellence, as to remain univalued to this moment; and it is probable, that as far as relates to the perfect imitation of a single figure, in taste, in expression, and in execution, the fame may be said of their painting: but there is much reason to conclude, that in many branches of that art they were surpassed by the age among the Greeks. In Egypt, the knowledge of what is most desirable in art, execution, never appears to have operated far. When a specific character was once adopted, there it remained, and was repeated unchanged for generations. Little action was given to figures, and no attempt at all at expression. Piny says, "that the figures of the Egyptians in his time, differed in no respect from those made by them 1600 years before. Of their painting, a few figures remain to us, but their date is by no means clear. Two of them, seen at Thebes, and described by Bruce, are supposed to have been of the time of Scotores (about 700 B.C.), who is said to have beautified and refounded the city; but this is mere conjecture. Of these paintings, he remarks, that they may be compared with good sign-paintings of his day."

It appears very probable that the practice of improved art, improved in comparison with the very rudest periods, was very widely diffused. Pliny, besides mentioning the culture of it in Egypt, speaks of paintings at Ardea in Italy, older than the foundation of Rome. Unfortunately we cannot follow this author presciently, in his account of the rite of the art in that country, any more than in Greece. By his own statement, the only guides he had, except tradition, viz. the Greek writers, were extremely incorrect. But though we may not trust our judgments with him on the era of the rite of painting, yet the plan he offers us of its progress, the imperfection of its first essays, the gradual advance towards perfection by the addition of new and more valuable qualities, and the retrograde steps it fell into after it had reached its acme, present an order of things so precisely following the sytem of nature in every part, that we cannot hesitate to give complete faith to it.

After singling at the claims of the Egyptians, who said that the art had been known and practised in Egypt 6000 years before it was introduced into Greece, he says, that it was not practised in Greece till after the siege of Troy; a circumstance certainly not credible, if the story above related of Semiramis be true; and if Homer be correct in imputing so much of sculpture as he does to the artificers of that period; or the amusements of Penelope, of Andromache, and of Helen, at their boards, be at all founded in fact. It is not probable that so much of other arts, particularly of weaving, of coloured design, should exist, without some advancement being made at the only source whence it is natural to imagine they could arise. It is vain to discuss the point; nor is it of much consequence whether it were at Corinth or at Scicamous in the practice of drawing first attracted particular notice.

But, as Mr. Fuseli has beautifully observed in his first lecture, "if ever legend deferred our belief, the amorous tale of the Corinthian maid, who traced the shadow of her departing lover by the secret lamp, appeals to our sympathy to grant it." The first essays, then, of this delightful art were merely outlines of a shade, such as are still made use of in that agent of the science of physiognomy, termed a "signet;" with no line within, no shade, or colour; and they were therefore called "sketograms." The next step was to the monogram, or lines within the outline; and afterwards to the monochrome, or outlines filled up with one single colour. This, by study, and a more scientific mode of proceeding, advanced to the polychrome, or picture of many colours; and at length was perfected by that harmony of tone, so exalted in the hands of Apelles and his contemporaries.

Pliny mentions the name of Sarius, as one who practised the earhest stage of the art, and of his drawings the figure of a horse; and of Phileas the Egyptian, the Chaldeas of Corinth, Arians of the same place, and Telephanes of ScYLON, who advanced to the monographic. Cleophas of Corinth is said to have been the first who practised the monochromatic, and his colour to have been that of a rounded tine. In concurrence with him, or after him, wrought Hygemos, Damos, and Charlos; and probably one of these improved the monochromatic style; so as not to make a whole picture, containing many figures, of one colour in every part; but varied the colours, so as to characterize the different objects introduced. According to Quintianus (lib. ii. c. 3.), "they could so manage the single colour, which they used in the monochro-
monochromatic style, as to give every appearance of relief to parts;[1] but by what means, as light and shade appears not to have been observed, he does not say. After these came Eumæus the Athenian, and Cymon of Cleonea; to the latter of whom, Pliny gives the praise of having greatly advanced the art, by giving variety of attitudes to his figures, attending to the folds of draperies, and more discerningly marking the joints and veins of the body, than had been done by his predecessor.

To the existence of none of the above-mentioned artists does Pliny, or any other author, affix a date; but he contends, and with reason, for that of an estabished and important fact in the history of the art, viz. that about the 10th Olympiad, or little better than 700 years before the Christian era, Candaules, king of Lydia, purchased a picture, painted by Buralcês, called the battle of the Magnetes, and gave for it its weight in gold: a tolerably sufficient proof of the high esteem the art was held in at that time; though we ought by no means to deduce from it, that Buralcês had arrived at any other degree of perfection, than what placed him among the best of his day; and it tells but very little as to the actual state of the art at the time: since, in its infancy, the patron could only be guided in his judgment, by what he had preceded; and the bell, though moderate, has always received the highest eulogiums from those who, of necessity, are ignorant of superior exertions.

Whatever was the degree of excellence to which the immediate successors of this fortunate painter carried the art, we must be content to remain entirely ignorant of it. Possibly the confusion of civil anarchy and of foreign wars, which followed this period, and brought Athens, and indeed all Greece, near to destruction, prevented, in a great degree, the exercise of an art, which requires the fostering aid of peace, of science, and of patronage flowing from the hand of power.

When intellec:ation had subsided, and Xerxes had been driven out of Greece, then the depression under which her inhabitants had groaned was removed, and her spirit exalted by a sense of its own dignity and importance. Genius then stepped forth from its retreat, encouraged and rewarded. The liberal arts, aided by the general cultivation of mind which then took place, were fomented to afflile in erecting monuments to the heroic deeds of the national heroes; and again we are enabled to trace the steps of painting, still weak and tottering in her gait at first, but soon advancing with amazin: rapidity towards the highest point she is supposed ever to have reached.

Sculpture was most probably practised with continued success, even during the times of distress and warfare. The necessities of the idolatrous religion, which so powerfully controlled the Greeks, might alone have required the exertion of all the talents the country could produce. We can no otherwise account for the immense advance which that art found to have made before painting, at the period of which we are speaking. Phidas, who was the most renowned among sculptors, guided the hand of his brother Panæus, (the first painter whose name occurs after the reappearance of the art.) in adorning the walls of the portico, called Pecile, at Athens; where he painted the battle of Marathon, and introduced into it the portraits of the principal commanders, both Greek and Pers. But how great was the difference between their powers! The former, among other works, had produced thefe in the temple of Minerva, called the Parthenon, which to this day remain a source of admiration and of envy; while that of the latter, as described by Pausanias (Attics, lib. 4. c. 16.) exhibit

Vol. XXVI.
of record as artists; and that no picture had till then been produced, which a man might take pleasure in observing for any length of time."

The fyllem of Apollodorus, to whatever height he bore it, was eagerly embraced by his pupil and succesor Zeusx of Heraclea; of whom his master did not deem it derogatory to himself to say, (in some verses which he wrote,) that "the art of painting had been stolen from its profefleurs, and practifed by Zeusx alone." Uniting the fimple but energetic fyle of Polygonthus, with the peculiar felection and taste of his master, he certainly appears to have fufpended both. It is the remark of Quintilian, that he considered the poetic unity of character adopted by Homer, in the defcriptions of his heroes, as his model; and gave to each individual he painted, the defcription of different materials, at leat in the picture of Juno, which he painted for her temple at Agrigentum, according to a vow which the inhabitants of that place had made. For before he began the picture, he defired to fee all the moft beautiful maidens of the city naked, and from them he chose five, whose form he moft admired; intending to exhibit the moft perfect combination of female forms, by felecting and adopting the moft beautiful parts of each.

Timanthes, Eupompos, Androcycles, and Parrhafius the Ephefian, all flourifhed and were renowned together with Zeusx; the firft, and the two laft, however, bore the fway of skill and of public favour. Among the principal productions of Zeusx, are enumerated, a figure of Penelope, wherein he is faid not only to have given her a becoming perfon, but also to have expreffed the qualities and affections of her mind. Another of Jupiter on his throne, accompanied by the gods. Heracles slaying the Serpents in his cradle, in the presence of Aecma and Amphictyon: and of a wrestler, or champion, with which he himfelf was greatly delighted, and which under the refcription of "This would be more eafily envied than imitated." Having acquired great riches, he refused to paint any longer for money, and gave away his pictures; declaring they were above all price. Of him and his rival Parrhafius, it is difficult to fay which carried the art to the greateft extent, or was moft vain-glorious. The story which Pliny relates of their conteft, by no means settles the former; as both their pictures were mere matters of imitation, and could have little to do with their real excellencies, except in colouring. But if the fect be true, it is a wonderful iflance of their perfection in that point; and totally excludes the poffibility of belief in what he fays concerning the colouring materials with which they were acquainted, and used, viz. only four; and thofe were impure and imperfect in themselves. A curtain might, indeed, be of a dull colour, and poibly fuch an one Parrhafius might have imitated, with fuch materials, and fo perfectly, as to have deceived Zeusx; but it is to be prefumed the lufious tranfparentness, colour, and brilliancy of the grape in thofe days, were not very widely different from what it now exhibits: and the pure qualities can only be imitated by the pureft and moft perfect of colours. Zeusx, indeed, having himfelf miftaken the painted curtain of Parrhafius for a real one, was obliged to acknowledge himfelf furpaffed; or muff have submitted to the inference, that his penetration was not superior to that of the birds whom he had deceived. It was remarked, in favour of Parrhafius, that he had a purer eye to proportion and fymmetry, which he is faid to have reduced to rule; that he rounded the boundaries of his figures into their grounds, better than thofe who had preceded him; and that he superadded the charms of grace in the action of the body and features, and in the disposal of

hair and draperies. With these qualifications, if juftly given him, he claims the pre-eminence; though perhaps in the compliment which Pliny pays him concerning the softnefs of his outline, he himfelf might have been deluded by the agreeable effect of fuch a procedure; whilft it may have been carried to a fault by Parrhafius. Such an inference may certainly be fairly drawn from the obervation of Euphranor upon his picture of Thoefus, which, in comparifon with his own, he faid, appeared to have been fed on roles: implying, probably, that it wanted finelnefs as well as colour. As the vanity of Zeusx led him to have his name embroidered in gold upon the border of his robe, when he attended at the Olympian games; that of Parrhafius induced him to wear a purple robe and a golden garland; to bear a staff wound round with tendrils of gold; and to have sandals tied to his feet and ankles with golden fraps. He fyled himfelf Abru- diatus, the dainty or delicate, and declared he was defcended of Apollo; and that he had nightly visits by Hercules, while he was painting a picture of that divinity. The emperor Tiberius was fo delighted with a picture of his, of an Archigallus, or chief priet of Cybele, that he kept it conflantly in his own room, and valued it at 60,000 sicles, 484. 10s. Pliny mentions many of his works, and alfo that though he was thus fiklful, he was exceded, according to the opinion of the Samians, by Timanthes, in a picture of Ajax at the award of the arment of Achilles to Ulyfles; whereon he fimpfly remarked, that his regret was only, that fuch a hero as Ajax fould have been overcome a second time, by a man unworthy of the honour.

The quality for which Timanthes is renowned, is vigour of imagination. This aided him to fill the decided corporeal forms, now fixed as characterifical, with passion; and it is sufficiently illuftrated by that well-known circumance of the peculiar action given by him to his figure of Agamenon, in the picture representing the facrefceion of Iphigenia; and by the mode in which he embodied the idea of grandeur in fature, in a fmall picture of a Cyclops; viz. by introduing fome fatory, supposed to be of the usual fize of man, measuring the length of the giant's thumb with a thyrus. One of his pictures remained at the time Pliny wrote, about 400 years afterwards, in the temple of Peace, at Rome. He calls it the portrait of a prince; and fays, "it is fo perfect, and fo full of majesty, that it appears to comprife every thing defirable in the art of painting."

The art continued advancing by rapid degrees at this period. Nature, in form, in colour, and exprefion, was the guide; and to develop her beauties the fole object of the artifts. Eupompos fufficiently displayed this fballs, in his advice to Lyfippus, the sculptor, who enquired of him, whom among his predecessors he should make the objeets of his imitation. "Behold," faid the painter, flewing his friend a multitude of characters paffing by, "belott my models! From nature, not from art, by whomsoever wrought, muff the artift labour, who hopes to attain honour and ex- tend the boundary of his art." (Pliny, lib. xxxiv. c. 8.) To such a pitch of excellence was painting at this time advanced among the Greeks, that it became highly eileemed; was thought worthy of being ranked at the head of the liberal arts; was ordered to be taught to the fons of the higher classes, in preference to all other things, according to Pliny, and forbidden to be prafticed by flares. Such was the honour done to it, by the influence which the painter Pamphilus of Amphipolis had acquired. Of him it is remarked, that he was the firft who proved the value which the art acquired, by an union with science and literature; and to
PAINTING.

him, Apelles, the unrivalled hero of Grecian painting, was indebted for his initiation to its mysteries.

This extraordinary man (Apelles) appears, if we give full credit to the traditions concerning him, to have been endowed with a more perfect combination of rare talent and excellent qualities, than has, either before or since, fallen to the lot of any other. He had, besides, the peculiar felicity of being born at that period when his country was at its highest pinnacle of cultivation; so that mankind saw in him the happy union of a perfect mind, strengthened and guided by the best assistance education could possibly afford. Not only as an artist is he extolled above all others, but equally so as a man; for his gentleness, his amiability, generosity, and magnanimity. Pliny places the time when he flourished, in the 112th Olympiad, (518 years B.C.); and adds, that he became so conficlurmed in the art, that he alone enriched it more than all his predecessors had done; and compiled several books upon it, wherein he illustrated its principles. It is agreed by all writers, who speak of him, that in him, the art of painting reached its acme. He himself indeed acknowledged, that he was surpassed by several artists in different branches of its practice; by Amphion in disposition, by Aeclepiodorus in proportion, &c. but that in the combination of the whole, he excelled them all.

Yet it is not without some grains of indulgence, this most liberal praise is to be received. It is extremely difficult to know how far to attach real value to the language of praise, as given to works of art; so much depends upon the taste and judgment of him who bestows it. The highest terms of praise will always be given to the best works of their time: and therefore we find, that at all periods contemporary authors have expressed the same degrees of approbation, and in nearly the same terms, of the pictures they have seen produced; whilst we know, that in art was flow in its progress towards perfection, that in all its varying stages, it would have merited equal praise. No doubt, however, can remain, but that Apelles was a most powerful and agreeable painter; and that he must have given a degree of taste, of grace, of life and effect to his figures, which had never till then been equalled in their union, is evident, since it is the general unvarying opinion of all writers who have mentioned him; and they are neither few nor weak. As many of his pictures were preferred at Rome in the time of Pliny, he had an opportunity of judging for himself; as far as at least as their condition after such a lapse of time (nearly 400 years) would allow him: but the tribute which he pays to the excellence of his mind is of course deduced from the reports of others. There appears in the latter no extravagant hyperbole which leads to disbelieve; and his generous conduct towards his powerful rival as Protogenes, well deserves the honourable mention made of it. Being highly delighted with a picture of Jalyfus, painted by that artist, he failed to Rhodes on purpose to visit him; where finding him neglected and in poverty, he purchased some of his works, and declared, that he intended to sell them as his own. Roused to a recognition of the talents of their fellow citizen by such powerful testimony as that of Apelles, they raised him from his humble situation to rank and fortune.

The well-known conteft of these two friendly artists, in the lines they drew as significants of themselves, exhibiting that taste and skill which they knew none but themselves possessed, flands upon well founded testimony as a fact. The tablet whereon they were drawn remained untouched, was taken to Rome, and was there seen by Pliny himself; who speaks of it, as having the appearance of a large blank surface; the extreme delicacy of the lines rendering them invisible, except on a close inspection. They were drawn with different colours, one upon, or rather within, the other. To judge from his account of it, it might be supponed, that all the beauty lay in the extreme delicacy of the points which had been used, and of the hands which had applied them; but it is reasonable to suppose, that the first direction of the line might have some principle of beauty for its guide, by which, as well as by the neatness of its execution, Protogenes was instantly moved to the declaration, that none but Apelles could have drawn it!

Beloved, honoured, and employed by Alexander, Apelles had the privileges of enjoying that fullness of renown, to which he was so justly entitled. Alexander, the envy and admiration of the world, treated the painter with the familiarity of a friend; ordained that none other should presume to paint his likeness; frequently visited him; and crowned his favours by a facrifice to friendship of a most uncommon nature among men; depriving himself of a beloved object, his favourite Campafse; and giving her to gratify the affection of one whom he so much esteemed.

The pictures produced by this exalted artist were numerous, and are mentioned pretty much at length by Pliny, lib. xxxv. cap. 10. But perhaps the best comment upon his talents as a painter, will be found in the character Mr. Fuseli has given of him. He places him in that rank where every thinking mind will be gratified to find him. "The name," he observes, "of Apelles in Pliny, is the synonyme of unrivalled and unattainable excellence; but the enumeration of his works points out the modification which we ought to apply to that superiority: it neither comprizes exclusive fublimity of invention, the most acute discrimination of character, the widest sphere of comprehension, the most judicious and best balanced composition, nor the deepest pathos of expression: his great prerogative consisted more in the union than the extent of his powers; he knew better what he could do, what ought to be done; at what point he could arrive, and what lay beyond his reach, than any other artist. Grace of conception, and refinement of taste, were his elements, and he went hand in hand with grace of execution, and taste in finish: powerful, and seldom possessed singly, irresistible when united."

That our readers may judge for themselves of the propriety of these remarks, we will enumerate from Pliny the pictures of which he speaks, and which of course may be supposed to convey a very just idea of the class of subjects generally chosen by Apelles. Of Alexander the Great, and his father Philip, the portraits he painted were very numerous; some single, and some accompanied by other figures. One in the temple of Diana at Ephesus, of Alexander launching thunder, is highly extolled for its effect; and the boldness of its relief; "the hand which was raised appearing to come forward, and the lightning to be out of the picture;" in another of the same king, he was represented in a triumphal chariot, near him the figure of war, with his hands tied behind his back. This, and another Alexander, accompanied by Caius and Pollux, and a figure of Victory, were preferred by Augustus in the forum. Many other portraits are mentioned; viz. of Antiochus, King of Syria; of Antigonus; Archelaus with his wife and daughter; Abraun, an effeminate debauchee; Clytus on horseback, armed, except his head, with an attendant delivering his helmet to him; and of Megabyus, a priest of the temple of Diana at Ephesus, sacrificing, in his pontifical vestments. In subjects of fancy, are, a Diana surrounded by her nymphs, attending at a sacrifice; Neptolemus, son of Achilles, on horseback, contending with Persians; Hercules with his
PAINTING.

back towards the observer, and his head turned round so as to shew his face; a horse painted in competition with other painters, and said to have excited living horses to neigh; and lastly, his renowned picture of Venus rising from the sea; which being taken to Rome was dedicated by Augustus in the temple of Cæsar; and several Greek epigrams upon it, are preferred in the Anthologia. So great was its perfection, that no artiff could be found who would undertake to reduce the lower part of it, when by accident it had been injured: and of another of the same subject, begun for the inhabitants of his native island, (Cor.) and of which he had only finished the head, and the breath which the first Pliny says, that no painter would set his hand to complete it; through a fearful acknowledgment of this great master's superiority. Other pictures and designs of his are mentioned by different authors, but these are sufficient to shew the general tendency of the subjects on which he employed the extraordinary powers of imitation he was endowed with. The bare mention of them is sufficient to prove the critical acumen of our learned professor of painting; but doubtless they are fully capable of admitting, indeed they require, all that grace and taste in conception and execution, for which he was renowned, to compensate for their want of pathos.

What was omitted by Apelles, was supplied by his contemporary, Ariilides of Thebes. Unable to rival him in harmony and grace of colour and execution, and qualified by nature to display the influence of the passions, Ariilides followed in the steps of Timanthes. His was the power of impressing form with soul, of fixing upon, and representing with effect, those impassioned actions of the body, which are the result of the more amiable or violent emotions of the mind. So effective was the earnesthed of a furnace poured by him, that “his voice seemed to escape from the picture,” and not only was he capable of representing the more simple emotions of the passions; but their most complex unions were also subject to his skil. An expression, in which are discoverable maternal affection, anxious for the benefit of its offspring, amissed the pangs of certain and approaching death, was produced in his picture of a woman who had received a mortal wound upon her breast, endeavouring to prevent her infant, eager for its nourishment, from suckling her blood instead of milk. (Pliny, lib. xxxv. c. 10.) The mind dwells with apprehensive commiseration on the bare relation of the image; and great, indeed, must have been the discriminative power of mind, and of hand, to execute, so difficult a task. Although Ariilides appears to have most delighted in subjects which afforded him an opportunity of displaying his knowledge of the human mind, and its pathognomic influence upon the body; such are pictures above mentioned, and those of a father dying for love of his brother, and of one suffering under the languishment of illnes; yet he sometimes ventured upon a more extended field, and in one instance painted a picture of a battle between the Greeks and Persians, in which were introduced 100 figures, and was paid by Mnason, king of Elataes, tolbs. of silver for each of them. In another he represented a race of chariots with four horses; of which, Pliny observes, “you would almost think the wheels were in motion, such was the energy of action in the picture.”

At this time, the art of painting was upheld in Greece by a great number of ingenious men renowned for their distinctive excellencies. Alciphidorus for the beauty of symmetry; Protogenes, for exquisite skil in execution and finish; and in him the art received one of the highest tokens of regard it was ever favoured with; for when Demetrius Poliocetes was besieging the city of Rhodes, and might have taken it by assaulting it on the part where Protogenes resided, he forbore, lest he should do an injury to his works; and when the Rhodians delivered the place to him, and requested him to spare the pictures of their admired artist, he replied, “that he would sooner destroy the images of his forefathers, than the productions of Protogenes.”

With these artists, and a few others, as Nicias, Nicomachus, Mnason, Arilodemos, &c. nearly contemporaries, this delightful art arrived at its utmost height; and though it continued to be practised by a fuscfillion of ingenious men, many of whose names are handed down to us, and who contended against the formidable difficulties presented by the scenes of luxury and confusion which opposed them, yet their efforts to uphold its dignity were in vain. When the country, weakened by domestic broils, became subjugated by the Romans, its arts and its energies expired with its liberties; the spirit which animated the arts in Greece being removed, they fell to rife no more, at least for ages. But the cycle of nature will have its course in the arts, as well as in governments, and in man himself. All sublunary things have within them the seeds of their own destruction; and having reached the acme of excellence in their kinds, their further progrès in exaltation can only be retrograde.

In the means left us for tracing the history of painting in Greece, many are the deficiencies we have to deplore; but in nothing more than the want of pictures, and the entire loss of the treatises written on the principles of the art, by Apelles, Parhafius, Protogenes, and Perseus, a pupil of the former, to whom he dedicated his work. If, happily, there had been preserved, we might have been able to decide upon the state of the art and the merits of its professors, with much greater accuracy than from the remarks of mere critics, however acute and judicious; who are now our only resource. The liability to error and misguidance of such, none can be as a lot to determine, who have perused the extended labours of Winkelman, Du Bos, and others upon subjects of this nature; where, though surrounded with great ingenuity in antiquarian research, ignorance of the technical parts of the art is made apparent by affected allusions and frequent misapprehensions, which the mere tyro in practice would detect; and where a display of classical learning appears to have been more an object of the authors, and for which they were better qualified, than a just extension of the principles of art, or instruction in the practice of it.

From the information we still possess upon this subject, it is extremely difficult to decide upon the exact degree of cultivation the Greeks attained, in many branches of the art of painting, as now understood. We have sufficient data to ground a satisfactory belief, that in the most essential points, as fullness of invention, expression, grace, character, and design, they rivalled the sculptors of the best periods; and that they carried colouring to an equal degree of perfection, (though by some doubted,) appears to us not improbable. But whether they ever understood and employed composition, as it is now scientifically practised, as far as relates to the union or separation of groups, and effecting the distance of given objects according to the rules of linear or aerial perspective; or whether they at all comprehended, and practised the science of chiaro-furo, as employed by subsequent schools of art, we have yet to learn. On these points the descriptions of their productions afford no conclusive evidence.

It must be observed, that the criticisms employed by the ancient writers partake very little of scientific information; nor appear to have arisen from any thing like technical knowledge;
the only source from which any very satisfactory information was likely to ensue. Left, as we are, to deduce principles from imperfect materials, we are led to conclude, that the ancient painters of Greece never contemplated their art in many points of view, at which the moderns have successively aimed: but that their prime object was, even in the most cultivated periods, to impress, undisturbed upon the mind, the whole force of one image; and for that purpose apportioning, rather than composition, is the most effective mode; especially when aided by a peculiar style of representation. It may, therefore, have been the effect rather of a peculiar scientific principle, than a want of intelligence, that we find, or conceive we do, an imperfection in the mode engaging, though not the most useful part of the art. It may rationally be doubted, whether, as applied by this polished nation to the worship of imaginary deities, or the exaltation of heroes, it would not have been deprived of a great portion of its influence, if more artifice had been introduced into their pictures; though there is no doubt at all, of the improvement, the minor qualities produce in the art, as it is now employed; being an agent of pleasure rather than of instruction or emulation.

We occasionally meet in authors who speak of ancient art, with descriptions of pictures containing many figures, but in general its efforts were confined to subjects in which two or three only were required; and it is worthy of remark, that in none of them is there any observation on the contrasts employed in lines, in light and shade, or in colour: nor is there any mention of what is now understood by the term back-ground. To guess from these attempts at criticism, we should, at least we might conclude, that all pictures painted by the Greeks were similar in principle to those found at Herculaneum, of which the belt have entirely plain grounds, and others very little variety; which evidently shews, that the writers were unacquainted with the art. Their remarks are too vague, too undetermined, appear not to flow from any feeling or knowledge of what art is, but only from common perceptions, alike felt by all of equal understanding. Yet every painter knows, that without some ingenious management of the ground, quite sufficient to form an object of particular remark, the hand of Alexander would have still adhered to the canvas; and not, as Pliny remarks, have appeared to project before it, or out of it.

That they discovered to a certain extent the effect of contrasting lights and shades, is evident from Plutarch's observation, that "painters increase the brilliancy of light colours by opposing them to dark ones, or to shades;" and Pliny has this remarkable general expression, when, having spoken of the painters in the monochromatic style, he adds, "in process of time the art attained new powers, and discovered (or invented) light and shadow; by grading which, the colours are alternately heightened or kept down. Afterwards splendour was added, which was different from light, and which, because it was a mean between light and shade, they called tuman; and the union of the colours, and the transition from one to another, they called harmone," lib. xxxv. c. 5. Although we see in these passages, that the three grand requisites for the science of colouring and of chiaro-fouro, viz. contrast, tone, and harmony, were felt by the Greeks; that the degrees of light and shade in their own force, and in their approach towards each other, were fully understood; with the value of middle tume; the most difficult and important object of the painter's attention; and that one general hue in the whole work was considered and effected; yet we cannot agree with M. Du Bos and others, that we ought hence to conclude, that chiaro-fouro was scientifically understood and practised by them to any extent, at all approaching that of which it has sufficiently been carried by Rembrandt and the Flemish school, or the best among the Italians. All, which Pliny affirms, they knew upon this head, is requisite for the due execution of a single figure, upon a plain ground, and offered to view in the most simple style of composition. Unhappily very few of their pictures have remained to us, and those we have, we must suppose are the works of inferior artists. Among the twelve pictures, the best of those found at Herculanum, and all possessed of infinite beauties in taste, in grace, and feeling; there is exhibited in one of them a more compound management of chiaro-fouro, in the reduction of tone on parts of the flesh and drapery, than is to be found in any other monument of ancient art; but it is not sufficient to prove that it proceeded from any thing like principle. We have, therefore, no satisfactory proof upon this subject; and it is most rational to conclude with sir Jos. Reynolds, that this, which makes so material a part of modern art, was unknown to the Greeks (as a science) "If," he observes, and justly, "the great painters had possessed this excellence, some portion of it would infallibly have been diffused, and have been discovered in the works of inferior artists handed down to us.

The fame may be said of their knowledge of perspective, at least of the application they made of it in pictures; notwithstanding Vitruvius says, that it was practised by Agatharchus, a contemporary of Archilochus and Polygnotus, in the theatre at Athens; and was soon afterwards reduced to principles, and treated as a science, by Anaxagoras and Democritus. The reposing upon this subject stands precisely upon the same ground as that concerning their knowledge of chiaro-fouro. and we are naturally led to the fame conclusion; though it is difficult to conceive, that when the general principles of a science so necessary to just delineation were understood, that they should not be put into practice. Perhaps, as we have before observed, it is possible that back-grounds were more simple than we are accustomed to see them in modern times; and therefore less of perspective would be required in them.

It certainly is not a little remarkable, that no mention of confluence, of any thing like a ground of relief, should be made in describing pictures, of whose beauties in the principal parts we have such enthusiastic encou-
actual progress there; and that little, partaking more of antiquarian curiosity, conjecture, and doubt, than of utility, or certainty. Pliny, indeed, says, that there were paintings existing at Ardea in his time, executed before the foundation of Rome. But after a lapse of 800 years, how much of this may not be attributed to error in the tradition he recorded? The earliest traceable and satisfactory account of the art being practiced in Rome, is in the year 450 of the city; or 303 years before our era; when Fabius, a noble patrician, painted the temple of Salus; and he and his family thence obtained the surname of Pictor. It is not improbable that Fabius had travelled in Greece, and there had the happiness to see the elevated imitation of the art at that time; he might even have seen Apelles himself, employed upon those works which brought honour upon his country, and secured immortality for himself. Yet the city does not appear to have much profited by this example; nor to have obtained renown for its artists, either in number or in quality. Pliny mentions none other after Fabius till, on the lapse of 150 years, Pacuvius, the poet, amused his declining years with painting the temple of Hercules in the Forum Boarium. Although it is evident, that about this time Greek paintings were introduced into Rome, either to gratify curiosity, or adorn the triumphs of generals who had been engaged in Sicily, or Greece; yet no emulation to cope with the artists of those countries was exhibited by the Romans. That warlike people were too much occupied in schemes of aggrandizement and military fame, to devote much attention to the arts; and it was not till the time of the emperors, that they experienced any thing like encouragement in Italy.

After the reduction of Greece to the Roman power, the city of the conquerors became the emporium of honour, employment, and consequent profit to artists; but that only in a gradual advance. First of all, the plunder of the ancient residence of taste, (that country, where, of all the world, it had alone found a secure and honoured establishment and due regard for a great length of time; where its utility was proved, and its delights enjoyed;) fattiated, as well as abonished, the uncultivated, comparatively uncivilized, inhabitants of Italy; and no employment might be found for domestic artists, when the views of all admirers of art, were directed to another country for a supply of their wants. Afterwards the men themselves, who had in vain laboured to continue the arts in that once favoured, but now unhappy country, quitted it, to ensure their own existence; till, by degrees, Rome, become the metropolis of the world in policy, assumed the control of the arts. Still its own native citizens were content to allow themselves an inferior share in its praise; first the principal part of the artists, either in painting or sculpture, who practiced in Italy, are supposed to have been Greeks.

Antiquaries, under the influence of varying circumstances, have at different times attached priority of cultivation to different countries. Such is the case with the regions of Italy. Etruria has been, and is still, most generally considered as the nurse of the arts in that country; but the discovery of painted vases in the southern parts of Italy, and in Sicily, being more frequent than in Etruria, has led many to imagine, of late, that painting was practiced in those countries previous to its cultivation in the more northern provinces. But very little argument can be derived from this circumstance; as it appears to us, that the designs and execution of those curious monuments of art, only testify the previous existence of some superior powers in the art; as the extension of taste in our own manufactories, or the attempts at it, proves the existence of the art of painting, and its higher, or more direct cultivation in this country. The paintings upon those vases are, in truth, so inferior, as to the extent of art they exhibit, that they merit only to be classed among the productions of the earliest periods; but that perhaps is more owing to the artists who executed them, being deficient of proceeding only so far as would answer a specific purpose; and by no means aiming to attain the degree of perfection at which the art had actually arrived at the time. The flight degree of difference in point of excellence and the superiority of the ancients as argued to prove, that it was not painting, or the cultivation of it, which was the object of those who supplied the imitated with these vases. Some few of them, in invention indeed, indicate a mental power superior to the system upon which they are executed; and the artists who painted them, only appear to have employed, in an imperfect manner, materials offered to their hands by others. For whatever purpose they pursued their labours, it was probably sufficient for them, that the hieroglyphics they marked were understood; that being effected, their object was completed. Some of them being rather more ingenious artificers than others, and guided by the learned or artful, multiplied combinations of figures, in order to create or explain deeper mysteries, and excite the zeal of the superstitious and enthusiastic. If these opinions are correct, there is no arguing concerning the state, or antiquity, of the art of painting from Etruscan vases. The use of their hieroglyphics, for so the figures employed upon them may be termed, like those of the Egyptians, or like letters, admit of little improvement, or indeed of alteration, in themselves; and allow only of being changed in effect, by new combinations. They may, therefore, or they may not, have been executed at a period comparatively late, when confidered with regard to the history of painting properly so called; and certainly may be regarded, rather as an offset, than as attached to the main items in its growth; or as an extraneous application of part of the art, rather than the art itself.

Where the Greeks first settled in Italy, or where the most free communication was held with the mother country, there it most likely the arts transplanted, would be first cultivated; but they do not appear to have arrived at any great degree of excellence in any part of that country, previous to the conquest of Greece by the Romans; and it must still remain a doubt, whether Etruria or Calabria was the parental abode of the arts of Italy. They appear certainly to have received more cultivation in the former of those districts than in the latter, particularly sculpture; at least, there is something like evidence of the culture of it in Pliny, who mentions, "that the little brazen image, disfigured all over the country, were wrought in Tuscany in very ancient times."

Whenceever it were that Rome acquired the little taste she felt for art, or rather the flight degree of emulation which animated her citizens to enter the paths of tasteful cultivation, it is certain, that during the period of her existence as a republic, the impetus was very weak, and the progress of course of little or no extent. The practice of painting after the days of Pacuvius, before mentioned, was held to be effeminate and disgraceful; and it was not subsequently engaged in by any respectable men. The result, of course, was a testimony to the wisdom of the Greeks; who, in order to enhance the merit of the art, ordained, that none but such as Roman pride excluded, should presume to practice it. From being regarded as contemptible, it actually became so; whereas in Greece, being raised in rank and esteem, it became vastly worthy of both. But what this powerful city could not acquire by her own genius, she endeavoured, after her
her generals became acquainted with the riches of Greece and Sicily, to treasure up from the spoils of those countries. Some of those generals, to increase the splendour of their triumphs, and others, for private or for public ornament, carried pictures as well as statues to Rome, and exhibited them to the people; and others again cauied pictures to be painted of their successful battles, to stimulate the admiration and applause of the people; and thus tacitly acknowledging the value of the art, upbraided their fellow citizens, for neglecting the cultivation of it.

It would be natural to suppose that when the fierceness and severity of republican independence gave way to the frivolity and more refined manners of a court devoted to one person; when literature and science were highly cultivated, and the example of Greece was before them; that the Romans would not fail to blend the pursuit of the elegant arts, with the refined luxuries in which they indulged. But that does not appear to have been the case, to any great degree. Had it been so, Phiny, who does not easily lose sight of the honour of his country, would not have failed to mention it; particularly as it came so near the time in which he lived. He gives only the names of a few painters then practising, or who had practised, being native artists; and accompanies it with a lamentation, “that the art was dying.” Lib. xxxv. cap. 5.

Even in the practice of the Greek painters of that period employed in Italy, the certain mark of decaying art is constantly referred to by contemporary authors; viz. brilliancy, rather than purity and truth in colouring; and ornament, adding affected beauty to forms, and taking place of simplicity, elegance, and expression.

As no preparation of art had previously taken place, powerful enough to aid the plans of the state, when Augustus underfood the system of the Grecian leaders, and saw the noble to be made of painting by a monarch; he very wisely endeavoured to adopt what was ready to his hands; and caused two pictures, painted by Apelles, of Alexander victorious, and triumphant, to be carried to Rome, and placed conspicuously in the forum. Images of his own power and exaltation, which Claudius Cæsar more openly proclaimed, when he ordered the heads of both pictures to be cut out, and Augustus’s portrait placed in their stead. But the Romans, and Roman emperors, whatever subjects they may have created for the pencil, found little native talent able, or sufficiently interested, to convey to posterity in an honourable manner by painting; and even in sculpture their best artists were low indeed in comparison with the Greeks, at least no Roman artists’ names of great repute are handed down to us. Both arts were diverted to unworthy objects; they continued to fall in every valuable quality; and painting most of all; till at length the irritations of the northern nations put an end to both Grecian and Roman efforts; and barbarism, from which Greece is not yet redeemed, usurped the flations of luxury and refinement. For near 1000 years, did the glorious title of the cultivator of intellectual power in the leader among nations, in whatever was most adapted to do honour to human nature, appertain to that highly favoured country; for a period approaching 2000, has suffered degradation and deprefion, even almost to annihilation. Yet her present inhabitants are represented by travellers as if the fame animated and ardent race, although bending to the strong hand of power, and unhappily under the influence of a government and religion, whose tenets forbid the extension of human knowledge; and whose power is upheld by ignorance.

Italy, overcome by the fame wild anarchy with Greece, groaned not under the weight of the despotic spoiler who had subdued her energies, more than half the time which her predecessor in the race of nations has bowed. The dawning of science beamed upon her, and roufed her from the slæt of torpor to which she had been reduced.

Even then, Greeks had the honour of stimulatings her to the cultivation of her native powers; till at length that flame was kindled, which, by a gradual accumulation of strength, warmed Italian breasts, and excited them to emulate in arts, those whom their forefathers had subdued in arms. But the country being then under the control of a fyllem of religion which forbade the introduction of images into her temples, the course and application of study was necessarily changed, and the art of painting became the principal object of attention: whereas that art, highly as it was prized and cultivated by the Grecians, in the latter period of their excellence as a ruling power, had remained, as we have seen, for a great length of time, nearly unemployed; whilst the finer art of sculpture, being most subservient to the purposes of an idolatrous religion, was cultivated in so extraordinary a manner, that the accumulation of its productions in statues, bas reliefs, &c. both in bronze and marble, became prodigious; and not to be imagined by thofe unacquainted with the fact. Paufanias speaks of 2827 entire statues in the places which he travelled through, as remaining in his time, besides numerous other works of sculpture; and this was only in a part of Greece, and not till after the Romans had, for 300 years, been plundering the country of innumerable useful productions. Rhodes, it is said, could boast of 3000 statues of brafs; and Nero took, from Delphi alone, 500 statues. The cause of this vast accumulation of sculpture is apparent; in the patronage that art derived from the government and the priesthood; who found it an useful instrument in moulding the people to their wishes. They were well acquainted with its influence upon the minds of men, when skillfully applied in exciting their sympathies, stimulating their emulation, or affailing in compelling their devotion. The foundation, therefore, of the superexcellence of this art among the Greeks, does not lie very deep for our research. What else could be the result of so much, and so constant an employment for a connected series of hundreds of years, the consequent emulation which must ensue, where so many competitors entered the field, and when, in addition to the influence of government, so many establishments of a religious order were anxious to become conspicuous by employing them? By its means the priesthood were enriched, and exalted in the eyes of their countrymen; adorers were drawn to their shrines; and their favourite divinities more generally worshipped.

The same sentiments and principles, always present to the ambitious and powerful, and which, under happy auspices, re-act for the benefit of the people, operated near 1000 years afterwards upon the government and church of Rome; when, by the revival of science and of art, thefe salutary means of strengthening themselves fell into their hands. But, as the second commandment, which enjoins to worship God in the only manner by which they were, or rather ought to have been, controulcd, prohibited the worship of images; their attention was directed to the use which might be made of painting, and sculpture was confined to monumental and ornamental purposes; or nearly so. Thus circumstanced, the result was precisely the reverse of what occurred in Greece. Sculpture, except in a few inftances, made a progress only to mediocrity; whilst painting rofe and expanded its beauty to the utmost perfection; and soon followed that period, when, as we have before observed, notwithstanding the high flown panegyrics of ancient authors upon Grecian art, the doubt
doubt is justified, whether its painters were not surpassed by those of Italy and Flanders, who flourished in this latter age of the world.

It was not at once, and by miracle, that painting re-appeared. Cherished, amidst the terrors of war and bigotry, by the Greek monks, in their silent seclusions, it was occasionally exhibited; and for two centuries at least before the acknowledged era of its rise, according to Malvasia, and perhaps more early, had been publicly practised, though humbly, in fresco, and in mosaic. He says that from 1115 to 1140, Guido, Ventura, and Orson, were employed as painters in several churches at Bologna; and doubtless these practices prevailed in other places; for now the ecclesiastical power of the church of Rome was completely established in Italy, and felt the advantages to be derived from adding splendour to the buildings erected to its honour, and excelling the zeal of its devotees. The character, however, of the art, as exhibited in the works of the Greek agents universally employed at this time, was but ill calculated to answer the higher views of those who promoted the exercise of it; for it was now at its lowest ebb.

Pié, Lucca, Florence, and other petty republics into which the kingdom of Italy was divided, began, about this period, to shake off the barbarism which had so long abased and controlled them, and to exhibit a taste for improvement. Artificers were summoned from Greece to adorn in adorning Pifa and Florence; and amongst other things to paint the chapel of the Gondi family, at the church of Sts. Maria Novella, in the latter place; whilst the Venetians employed Apollonius and others of the same country, on mosaics, in the church of St. Mark.

To the gratification enjoyed by Giovanni Cimabue at seeing the productions of the former of these artists, is Europe indebted, in a great measure, for whatever she has since beheld in the art. He, Andrea Tafi, who learned the art of working in mosaic from Apollonius; and Nicolo Pifano, instructed first in sculpture by Greeks, and afterwards by study from ancient bas reliefs, brought by his countryman from Greece; were the first Italians reported to have entered the lists with their masters; whole tale is allowed to have been hard and poor, and devoid of all spirit of imitation; either of nature or of ancient art. A state of debasement we might deem impossible to have occurred, after the extraordinary display of talents which those countries had witnessed; did we not know the rapidity with which the arts fall into decay, if not upheld by a constant succession of practice; and how slow their growth is in advance. And yet, doubtless, notwithstanding the horrors of destructive war, and the mad superstitious zeal of the Iconoclasts of the 8th century, many noble examples of sculpture, and architecture, more particularly, must have remained to guide their taste. So it was, however, and Valari and others speak of the art at this period, as being utterly unworthy of the name. Such was their situation in Italy, when Cimabue, who was born at Florence, of a noble family, in 1240, having been initiated into the miserable practice of the Greek artists, conceived the desire of improving upon it; and succeeded so well in his attempt, that a picture of the Virgin, which he painted as large as life, for the church dedicated to her at Florence, excited enthusiastic delight in his fellow citizens. They treated the painter with almost divine honours; the picture was carried in procession, with the sound of trumpet, to the place of its dedication; and the day was celebrated as a public feast. Encouraged by this applause and admiration, Cimabue pursued the art with ardour; and though the utmost of his efforts were weak and inefficient, yet he made a very great advance beyond his teachers. Valari, 200 years afterwards, could not help expressing his surprise, that he had seen his way so far through the obscurity of the age he lived in; yet such was the Gothic barbarity in his picture of Christ encircled, in the cloister of St. Francis, at Pié, that written labels are employed to convey the sentiments of the Saviour to his mother and St. John.

His pupil Giotto, whom from a shepherd he raised to be a painter, relieved the art infinitely more from the fetters of Greek imperfection. The extreme rapidity with which he advanced in design, we can only account for by supposing, that he left the trammels of the art, as then practised; and studied attentively the productions of the ancients which were to be found in Florence; and which then, doubtless, began to be in repute. Giotto left off the use of labels; aimed at real expression, and obtained it; and, even in his own age, was acknowledged to be the pupil of nature. He may be said to have performed for the Italians what Polygnotus had done for the Grecians, by marking the line in which the art ought to be pursued; and though in both it was accompanied with great deficiencies, yet it was just in its object and direction.

To Giotto the world was indebted for the portraits of Dante, Brunetti, and others, amongst those who at that time shone conspicuous in literature, and with whom he lived upon terms of intimacy and friendship. His abilities procured him the patronage of pope Benedict IX, according to Valari, (though Balducci says he was mistaken, and that it was Boniface VIII.), who employed him in St. Peter's; and highly honoured and remunerated him. Henceforth the art of painting became attached to the papal dignity, and few succeeding pontiffs dis-regarded the use of it.

An inclination to encourage the practice of painting in all the countries attached to, or dependent upon, the church, at this time became apparent; and the fame of Giotto having spread very widely, the advantage attending the exhibition of his powers was extended to numerous places where he was called to employ them. The king of Naples required him for a time of the pope; received him with honours, and employed him largely. At Avignon, where he attended the pope, at Milan, Lucca, Arezzo, and many other places, besides his own native city, Florence, was he engaged to adorn the churches, &c. with his paintings; and his great work at Assis remains, though in a ruined state, to this day. (See the article Giotto.) The principal benefit the art gained by him was his having again returned to nature for the actions and expressions of his figures; and been very successful in attempting to imitate her effects.

The skill of this ingenious artist excited the emulation of many among his contemporaries throughout Italy; and the arts having now acquired an earthen of employment and reputation, of emolument and of honour, no longer wanted skilful professed, or illustrious patrons. A grand epoch of their establishment took place at Florence in 1350, fourteen years after the death of Giotto; when a disciple of his, Jacopo Caffentino, and nine other artists, founded the academy of St. Luke in that city: an institution from whence arose a large display of talent, increasing in worth, till at length, near 150 years after its foundation, it gave to the world three of the greatest luminaries in art which it has ever known: Lionardo da Vinci, Michael Angelo Bonarotti, and Raphael; besides Malfaccin, and others of great repute.

About the same time, considerable advance was made in painting at Venice and Bologna. In the latter place, Franco Bolognese had practised, with great reputation, as a miniaturist and illuminator of books. He enjoyed with Giotto the friendship of Dante; and the language which that poet employed
employed in praise of their talents, is at once an argument and
proof, how little reliance is to be placed upon the praises
which authors so freely bestow upon the works of contempo-
rary painters. For though in their time they were granted
the rank they gave them, of being at the utmost height
in the practice of art; yet we know for certain, that
they were very far indeed from having reached the extent of
its possible career; and instead of being found to have of-
fered a perfect sacrifice at the altar of taste, they had scarcely
passed the threshold of her temple.

What they had done, however, was of sufficient excellence
to operate powerfully in the establishment of the art, par-
sially by Giotto. But, unhappily, the taste of the time
and of the country, was not in favour of that kind of study,
by which the Greeks had obtained their exalted rank. The
attempts of the art were confined, almost exclusively, to sub-
jects drawn from the history of Christianity; or more fre-
quently, from the legends of saints, and the sufferings of mar-
tyrs. The latter, indeed, required some knowledge of anat-
omy and form; but those drawn from the former sources
however engaging they might be to the heart, presented a
field of exercise to the artist, comparatively narrow and con-
 fined, when placed in competition with the variety afforded
from the wide irregularities of heathenism. Not well the-
known series of the Bible fails in presenting to the pencil scenes
engaging and poetical, of the highest moral culture, and of
sublime imagery; and not less delightful by their simplicity,
than interesting and important in their consequences; but
there is an alloy attached to them, which renders them
not so engaging in vogue, as in description; and, therefore,
less fit subjects for the painter, than the poet. In the
scenes of the New Testament, more particularly; the al-
most entire exclusion of the nude, or, when introduced, its
being devoted to the exhibition of deformity or common life,
confining the exertions of the artist to heads and draperies
alone; would operate strongly to delay the progress of the
art towards its legitimate object, when exclusively employed.

And the general feelings of a superfluous age, but just
emerging from barbarism, and under subjugation to a priest-
hood bigoted in the extreme; by no means gave room for
that latitude of exertion, without which it is in vain to look
for very high attainments. In such a period, whatever tend-
end to make the pleasures of the world inviting, and to render
man happy and contented with himself; counteracted the
principles of those who hoped, by exciting his apprehen-
sions, to keep him in subjection. Terror, therefore, the most
powerful agent of superstition, was more employed than the
sentiments of humanity, as the guide of those who selected
subjects for the painters; to whom they offered scenes of mar-
yrdom, of infernal punishments, or of hardships and fe-
verities to which devotees submitted themselves, in their
mistranslated zeal for purity and truth. We cannot wonder,
therefore, if, under such trammels, the art languished in its
progress; and if the ill direction given to the great employ-
ment it enjoyed, for a while withheld it from that perfection,
to which, under more free indulgence, it aspired; when
civil policy united her influence to that of religion, or rather
of superstition, in its support.

After a lapse of near 100 years from the death of Giotto,
Toscano da San Giovanni, better known by the name of
Mafaccio, (from his total neglect of personal appearance),
exhibited a more exalted taste, and a grander style of execu-
tion than his contemporaries. The art under his hands may
be said to have advanced from the weaknesses of infancy to
the station of youth, verging towards the vigour of perfect
manhood. He first complied with an eye to the whole;
managed his groups and single figures upon the principles

Vo. XXVI.
PAINTING.

judgment of artists was thus itself justified; and by Vafary is declared to have been regarded, as manifesting not only foundness of sense, but also freedom from every unworthy feeling.

When such care was taken to select in sculpture, it is not probable that the art more immediately applicable to the purposes of the church, which participated in the governments, or rather controll'd the sentiments of the whole community, should be neglected in cultivation, or studied vaguely. Accordingly we find, that painting advanced in rapid progress; and circumstances now combined, to render that advance just in its course. The general increase of mental civilization, of literature, and of science; the same causes which operated in the establishment of the first grand era of the arts among the Greeks; now again began to prevail in the world; and the country where they were found, by natural progres, in its turn became the nurce of art; and in time was remunerated in the honour and renown of supporting them, till they established a second epoch, scarcely less illustrious than the former.

The exillence of Lionardo da Vinci was the immediate precursor of that exaltation; and the examples he left, and the lessons he inculcated in his writings, had no small share in producing it. (See VINCI DA.) In him, as we have seen in Pamphilus, the master of Apelles, the art enjoyed the advantage of an union with science and general cultivation; and the effect of that combination is evident in the history of both. It enabled Lionardo to embellish and diversify the general impression of character drawn by Masaccio; and to exhibit, with more variety and fullness, the latent feelings of the human heart. Of this, his picture of the last supper, at Milan, is a sufficient proof. And that this perfection was the reult of deep reflection, is evident, by his having refrained from painting the head of the Saviour, till he could completely satisfy his mind, with what features and expression he ought to compose a representation of his divine charactar. By him the theory of design was perfected to a considerable degree. His book upon its principles is well known, and though confused, ill digested, and unequal in its parts; yet it is, beyond a doubt, the most scientific and useful, of all elementary books on the subject; and will alone testify the extraordinary power of his mind, and his activity in research. Many others of his writings are unfortunately lost; and some confined to libraries, where they are very rarely visible.

About the beginning of the century in which Lionardo was born, the use of oil was adopted as a vehicle for painting; and afforded the means of most extenfive improvement; particularly in colour and effect. Differing, or colours mixed with fize and water, &c. appears to have been the first adopted practice; and afterwards, fresco; as more durable and better adapted to larger purposes. (See DISTEMPER and FRESCO.) But both of these modes are limited in the execution, more particularly the latter, in which no means being given to change or retouch the colours without evident disparagement of the work, the art was oblig'd to adopt as simple a plan of conduct as possible in the management of its design. But when a vehicle was discovered, or applied, the use of which permitted frequent changes in effect, and in arrangement of colours, with the assurance of perfect uniformity at the conclusion; no means were wanting which he could devise for the indulgence of the utmost stretch of his imagination.

The event which gave rise to the exercize of painting with colours ground and mixed with oil, is suppos'd, with great reason, to have been varnishing over pictures painted with water-colours; which, as they were wrought up to the full resemblance of natural objects when the colours were dry, were rendered by the varnish as deep in hue as when the materials were wetted to be employed; and thus a tone of effect was superadded to the natural and ordinary one, purely artificial, but very engaging; and the more so, when placed in opposition to the comparatively dull and tame effect of the former modes; which of necessity lacked luster, as they always dried with a deadened surface.

The discovery of this very essentinal advantage to the art of painting, which so readily enabled it to outstrip whatever had been previously done; has been, by most authors who have written upon the subject, ascribed to Lionardo di Eyck, of Brussells, in 1410. Though many doubt concerning the accuracy of this opinion, yet one thing remains clear, that till after the time in which he lived, oil, as a vehicle for colours, was not in general use. No doubt can remain, that if he did not actually first apply it to the purpose of his art, at least he first used it effentially and effectually. His application of it would not otherwise have made, as Vanmander says, "as much noise in the world as the discovery of gunpowder by Bertoldo Schwartz had done, near a century before;" nor would a native of Italy have taken the trouble of journeying to Flanders, and soliciting the friendship and instructions of Van Eyck, as, Vafary says, Antonello da Messina did, could he have obtained the knowledge he fought at the cost of loyal trouble and time.

Painting, according to Vanmander, the historian of the Flemish artists, had been carried into Flanders about the time of Giotto, by some Flemings who went for the express purpose of learning it; and he says that "the mode of painting brought from Italy was with gum and eggs; having been so practis'd at Florence, at its first commencement by Cimabue." It spread in practice among the Germans about the same time, and each of these countries established a mode of art, or style, for themselves. It was in Italy alone, however, that any true perception of what was the proper object of art appears to have been felt, and there it was first exhibited; and even there, it dates its principal exertions from one city and its dependencies, viz. Florence. In this place alone it remained pure in its object, the delineation of character and expression, with the concert of form, and simplicity, and unmixed purity of effect. A style of design, which purifying the first impulse of the art, viz. the representation of events at their most impressive moments, leaves minor particulars out of consideration; and aims solely at fulfilling its purposes in an intuitive manner, upon the mind of an observer. That style, Giotto had founded; it was improved in effect by Masaccio, strengthened by Bartolomeo della Porta, and Lionardo da Vinci, and finally perfected by Raphael and Michael Angelo.

To this most important aim of the art, the introduction of oil in painting brought no efficient aid. What has been said of its benefits, applies only to the ornamental, or less important applications of it. The objections of the grand style, viz. beauty of design, and purity of expression, the weakest materials are capable of presenting to the imagination; and, therefore, notwithstanding the brilliancy of colour and effect, which was afforded by the use of oil, it was in great measure disregarded by the Florentines; or if employed by them, they carried it into its practice, the defective hues of fresco; to the exception of Lionardo da Vinci, and Fra. Bartolomeo della Porta, (born at Florence in 1479,) who followed closely the line of colouring laid down by the former, his immediate predecessor. To him, the art is indebted for the first conception of the union of true grandeur of style in design, with a suitable dignity and depth of colouring. The subjects he chose were generally of a religious kind, which nearly ex-
clad naked figures; but he amply compensated for that, by the mode in which he composed his draperies, and arranged his groups. Of him Raphael is supposed to have acquired more information than from any other source, till he had seen the works of M. Angelo in the Sifilini chapel. It was Bartolomeo who changed the table he had inhabited from his master Pietro Perugino, and directed it in the course wherein he afterwards surpassed all that the modern art of painting had effected.

This delightful art, supported by an illustrious patronage, derived, from its acknowledged ability to aid the purposes of state, the increase of riches and of intellectual cultivation; but most materially from religion, now attained its second era of glorious successes. A constellation of ingenious men, endowed with uncommon talents, appeared to spread its light once more through the world; and painting was perfected, as far perhaps as human nature can carry it, in the works of Michael Angelo, Raphael, Titian, and Correggio.

Although no one of these four great men appear to have made the Grecian principles of ideal beauty a precise object of attention; yet in those branches of the art which they more immediately cultivated, they must be considered as having attained the very highest rank. The almost miraculous facility of invention, grandeur of design, and breadth of manner, with which the series of pictures adorning the chapel of Sixtus IV. in the Vatican, are planned and executed; sufficiently attest the power of the former. The truth, simplicity, grace, and propriety, exhibited in the historic and poetic compositions, which cover the walls of the pontifical palace itself, and which are also exhibited in the cartoons at Hampton Court; justify the praise bestowed on Raphael. The renown of Titian would be supported by the grandeur of conception, richness and truth of colour, and vigour of effect, which characterizes his St. Peter Martyr, did no other work of his masterly hand exist. And Correggio will ever live in estimation, while the suavity and grace of arrangement, the perfect harmony of colour, and the concentrated and brilliant effects of chiaro-undo, exhibited in the Domo of Parma, the Notte at Dresden, and the St. Jerome at Paris, are preferred to the world. (See lives of M. Angelo, Titian, Raphael, and Correggio.) To behold the various excellencies of the great men united in one, is full "a confirmation devoutly to be wished."

At the time in which they flourished, namely, about the end of the fifteenth and beginning of the sixteenth century, the immense patronage which the art was enjoying throughout Italy, stimulated numbers to the profission of it. In Rome, Naples, Florence, Bologna, Parma, Venice, Lucca, &c., abundance of artists were found ready to fulfill the commissions which individuals, convents, and churches, heaped upon them.

Whilst it was pursued at Florence in its higher principles, and thence transplanted pure to Rome, to adorn the pontifical palaces, &c. of the imperial city; its more alluring, though less solid charms, were cultivated at Venice; where colour occupied the attention of the artists, and repaid it with her most engaging fascinations. Among those artists, Giorgione del Castel Franco, born in 1477, has the reputation of having begun that fylem of colouring, which his early death alone prevented him from carrying to perfection. Had the period of his existence been lengthened, it is probable that Titian, who adopted his fyle, would not have flowed so completely alone, as he now does, at the head of the Venetian school. In character, and in grace, Giorgione, in some of the few works which he has left, has evidently surpassed him. Except in the adaptations of it to exalted subjects, and an admixture of a certain degree of grandeur and purity in design, which was effected by Titian, the Venetian style of art has an equal supporter in Giacomo Robusti, called il Tintoretto; who too free to be correct, and too daring to be chaste, held the pencil with a vigour of colour and execution, worthy of being added to the sublimity of Michael Angelo in design. Unfortunately, to the delights of execution and surface, he sacrificed character, expression, and propriety; and the world ought to regard him as the founder of the ornamental fyle, rather than Titian; whose best works hold a middle rank between Tintoretto and Michael Angelo, and are of too serious a character to merit that appellation. It was, however, his procés of colouring, which guided the hand of Tintoretto, and also that of Paolo Veronese, in establishing the fucces of the Venetian school. Badusino, the elder and younger Palma, Pordenone, the Bassano, and many others, upheld the fylem for a time, but not with equal powers.

Another aberration from the grander aim, and more solid original principles of the art, was effected at Parma by the talents of Correggio. Whether he had ever seen the works of Leonardo da Vinci, must remain a doubt. Certainly, the same feeling of arrangement in light and shade, and in the tones, or approaching tones, of colour, seems to have governed both; but Correggio first exhibited it in large works, with brilliancy, with richness, and with consummate harmony. To his principal object, grace of effect, he sacrificed forms and characters; but made amends for the treason, by the perfection to which he carried his own principles. Yet the peculiar grace which accompanied his designs, was too frequently of an artificial nature, and dangerous to follow; as it approaches the verge of accident, and sometimes justly detested that appellation.

That peculiar practice of the art, of which Correggio was the inventor, acquired from the district wherein he and his imitators refeid, the title of the Lombard syle; having chiaro-undo, rather than colour, for its basis. So that we find the three great schools, into which the Italian practice of painting has been divided, were founded separately upon the three great principles of the art. The Florentine, upon design; the Venetian, upon colour; and the Lombard, upon the union of colour and chiaro-undo, but principally upon the latter. The colouring of the Lombard school differs from that of the Venetian, in being less positive, or less pictorial; and more like the reduced effect of colours seen by twilight; their hues being rendered subseuent to the principal which more immediately characterizes that school. Whereas, in the Venetian style, the colours themselves form a part of the chiaro-undo, and are wrought up to the highest degree of purity and brilliancy of which they are capable. The styles of both are completely artificial; and the refult of science, deviating from the general appearances of nature; and are in great danger of becoming unnatural, except in the most skilful hands.

There are, indeed, two other schools spoken of in Italy, viz. the Roman and the Bolognese. But we can hardly separate the former from the Florentine; for the principal works done at Rome were by Florentines, or those educated amongst them, who of course brought the style of that school with them to Rome, and executed their pictures in it; and that of the Bolognese, being an attempt at combining the excellencies of the three principal ones, cannot be claimd with those original fylies; founded as they are on original principles of art. The Carracci, nearly 100 years after the time of Raphael, were the principal promoters of
this system of combination; which in no slight degree afflicted in the ruin of the art, by detracting the attention of its professors. Agostino Carracci wrote a sonnet upon it, in which he inculcated his own ideas, of the qualities necessary to form a perfect painter; wherein he says, "whoever would be a great painter, must take the design of Rome; the shade and motion of Venice; the dignified tone of Lombardy's colour; the terrible manner of Michael Angelo; the just symmetry of Raphael; Titian's truth of nature; and the sovereign purity of Correggio's style: add to these, the decorum and solidity of Tibaldi; the learned invention of Primaticcio; and a little of Parmigiano's grace." However laudable the attempt to unite these various excellencies may be, the difficulty has hitherto been found too great for any one successfully to combine; and the labours of its great founders, even of Annibale and Ludovico Carracci, powerful and able as they were, by no means sufficed to prove the certainty of the system, in conducting the practice of art to perfection. Notwithstanding the plausible theory it held out, it was too vague in principle, and admitted of too much uncertainty and variety in practice; as each one who adopted it, was at liberty to take, or reject, as much of the peculiar qualities of the masters recommended, as his own taste might direct.

The exercise of painting, as pursued by the Florentine school, being founded upon the most original, most simple, and most valuable principle of the art, is, no doubt, most worthy of esteem. Its grand object, at its happiest period, was an undigested address to the understanding; and its means, were grandeur of style and truth in design, and a simple unaffected colouring. In its practice there was an uniformity of pursuit, and the fame ideas which governed and directed the attention of the earlier artists, were eminently and steadily cultivated; till at length, after a lapse of more than 300 years, from the time of Cimabue, if he may be called the founder, its triumph was completed by the talents of Michael Angelo Buonarroti, who has been styled the Homer of modern painting. Raphael, however, must not be deprived of the share of applause due to him in tracing the line of its success; for though he was not briefly Florentine, yet the better part of his means were drawn from that school, whose principles he adopted as soon as he was acquainted with them. The praise, however, which is his due, does not arise from any extension of improvement upon the principles of the Florentine school, but from a more perfect application of them than had before been known. He therefore, in this respect, stands upon much lower ground than his great contemporary, who increased considerably the importance of its aims, and grandeur of style in which they were displayed; and after whose death it gradually declined, till it was at length overpowered by the more ingenious attractions of the two other schools we have mentioned, the Venetian and the Lombard. In this elevation of the Florentine school, we would not be thought to fail in due respect for the others; from whence have proceeded so many men of great abilities, and so many works of superior excellence. The combination of the three, forms a mass of excellence, the productions of which, the world yet beholds with wonder and delight; but of which, the eclectic principle of the Bolognese school has failed to exhibit one highly effective instance. For further illustration of the peculiar varieties of these schools, see the articles COLOURING and COMPOSITION, most of the principal ones concerning the different parts of painting, and the lives of the painters most conspicuous in them.

At the time when the great masters of these schools were assiduously cultivating the art, and almost simultaneously bringing it to perfection in all its various branches; it fortunately occurred, that there existed men possessed of affluence and power, conscious of its value, and sensible to its beauties; willing to aid the exertions of its professors, and to employ their talents in an exalted manner. Long held benumbed by the rigid severities of neglect, the germ of its growth, at first, had scarcely felt the genial warmth of encouragement applied to it; by degrees it slowly spread forth its leaves to catch the inspiring gale; then eagerly enjoyed the kind atmosphere which surrounded it; at length its beauties burst suddenly on the view with delightful perfection, and by the enchanting pleasure it afforded, more than repaid the hands which had cherished it. Even in its decay, it left a blest odour upon the countries that had fostered it: a memento of their excellence in the great scale of nations, far more estimable, than the melancholy details of artifice, (under the name of policy,) and of war with its attendant miseries, which so perpetually blacken the page of history.

If the circumstances which attended its progress in ancient Greece, be compared with those accompanying its more recent one in Italy, of which we now speak, they will be found most singularly to correspond; even to the periods of time occupied in its several stages. In both countries, it had risen under the influence of devotional feelings, to various degrees of improvement, as possessed by different masters. It had been enlarged, enlightened, and rendered more estimable by the elements of learning and science infused into its studies; in Greece by Pammphilus, and in Italy by Lionardo da Vinci; and during the latter periods of its progressive improvement, it was employed in both countries as an agent of late policy.

The patronage which we have seen the art enjoying in Italy from the commencement of its career, kept pace with its progress, till it was perfected by the family of the Medici at Florence, and by Julius II. and Leo X. at Rome. Cosimo di Medici in his superintendence over the political affairs of the former place, during the first part of the fifteenth century, did not neglect the interests of its academy, and of the arts in general. A great mass of relics of ancient art, recovered from oblivion by industrious research throughout the country, of which they had once been the most conspicuous ornaments, adorned his magnificent mansion in that city. These he exhibited for the improvement of taste, and took under his peculiar care the academy of St. Luke, which had been formed in the preceding century. His grandson, Lorenzo, furthered the Magnificent, who in 1465 succeeded to his power and influence, and was endowed with a far greater predilection for art, for science, and for literary pursuits; increased the collection in a very considerable degree. Being laudably desirous of exciting his countrymen to a successful rivalry with these treasures of beauty, or rather of encouraging the spirit and ability already exhibited by them, he opened his gardens where they were deposited as a school of study; and honouring the abilities of Michael Angelo, appointed him to the management of it. By his influence, and that of Piero Soderini, then Gonfalonier, the council hall of the republic, which had been recently rebuilt, was ordered to be adorned with paintings by Lionardo da Vinci and Michael Angelo; each having one side of the hall appointed for the exertion of his abilities. This was the first example of any confluence, of public civil employment being given to the painters of Italy; for hitherto their greater exertions had been confined to religious subjects, and devoted to the service and benefit of religious establishments. The subjects chosen for these great competitors were of an heroic nature; and selected from the history of
PAINTING.

of the wars of the republic. Unfortunately neither of them proceeded so far as to complete their pictures, although their preparatory cartoons were the theme of universal approbation; and whilst they were preferred, succeeding artists rushed with caiism to study their excellencies.

The political disturbances which took place soon after prevented the further attention of the Florentines to the arts for some time. In the mean while the skilful, great, and ambitious successor to the papal chair, Julius II., informed of the high perfection in which painting was then practised, would not allow so useful an instrument to lie unemployed in his service. He summoned both Angelo and Raphael to attend him; and under his auspices those great works were begun in the Vatican, of which we have before spoken. His successor, Leo X., elevating the magnificence of his father, Lorenzo di Medici, and that of his immediate predecessor in the papal chair, continued to perfect the plans which the latter had laid down; and directed the efforts of the pencil, to the honour and service of the church over which he presided, the elevation which he more immediately held, and his own peculiar glory.

The recent discoveries of some of the most beautiful antique statues with which we are acquainted, and which were brought by the popes to adorn the pontifical palace; together with the splendid and admirable works produced by the two great artists and others of lesser note; completely transferred the seat of the arts from Florence to that imperial residence of power, which had hitherto acted but a secondary part, or hardly that, in their cultivation. To this alluring mass of talent, the powers of Titian were also ultimately added; and to important and instructive an affemblage of excellencies was thus combined, that Rome became a kind of university of art, and the resort of all those who aspired at eminence in the practice of it; and more particularly in its most exalted qualities. Thus the second grand epoch of the art was completed in the age of Leo X.

It might have been expected that the effects of these brilliant examples of art would produce still greater excellencies; but, as if there were a boundary set to the intellectual exertions of man, beyond which he is not permitted to pass; the patronage of the highest powers, and the ardent ambition of ingenious artists failed, even to prolong these days of superficident success. The splendour of the talents exhibited by these great luminaries of the art, seem to have dazzled, whilst it illuminated, those who approached the hemisphere wherein it shone; and all attempts to reach its exaltation were in vain. After this favoured period, in which it appears that both patrons and artists, had arrived at the ultimatum of their greatness, the hand of destiny once more conducted the art of painting to its decline in Italy. Yet, as before, lingered in its fall; and like a meteor approaching to dissolution, call many brilliant eminences around.

Among the most skilful of those who continued to uphold the practice of art with ability, were Julio Romano, Francesco Parmigianino, Pellegrino Tibaldi, and Tintoretto. The former was the most successful of the pupils of Raphael; but though, like Raphael, struck with the grand aims and style of Michael Angelo, he had not his judgment and taste to guide him in the application of it. Endowed with a poetical imagination, and devious of being original, he swerved from the course pointed out by his master, and lost sight of his purity and truth. Yet if there ever were one painter in the world, whose taste, whose feeling, and whose style, might be adopted with impunity, and imitated without apprehension of misguidance, it certainly was Raphael. Founded as it was upon nature, his taste in composition seems to bid defiance to perversion. His invention was sublervent to his subject, and was dictated by it; and yet, in his successors it not unfrequently took the lead; and the subject, gave way to the bewitching delights of contrast, grouping, and all the systematic arrangements of the art. The grandeur of style, and imposing power of Michael Angelo, was the milled source of this destroying evil. That style, emanating from a peculiar sympathetic feeling of his exalted mind, and correspondent to the poetic favour which inspired it, though strong and boldly marked, was still under the guidance of nature; and by his perfect knowledge of her forms, was prevented from swerving to deformity. After him, men unable to fathom his principles of action, did not venture to tread on the ground which he had hallowed; Pellegrino Tibaldi alone traced his steps with successful energy; and displayed his power in the frescoes which adorn the hall of the Institute at Bologna. But in the hands of most of his imitators, it became only a fopiduous mode of imposing upon the unlearned; and contortion and grimace, under the appellation of il Guelfo Grande, took place of style and character.

The principle of the Venetian style, being more loosely founded than those of the former two, and capable of application to all kinds of subjects, though not with equal propriety, was of course less likely to be soon destroyed; and having the natural charm of colour for its support, it was practised with considerable success for a long time. That of Correggio being altogether imaginary, or arising from more abstruse research, found no successful imitator. His expansive breadth of light, conducted with fullness of colour, perfect harmony, and depth of tone, has certainly never been repeated by any one, or but partially. Parmigiano, who probably saw him paint, and doubtless studied his works with great attention, imbibed more of his peculiar excellencies than any other; and in his best works adopted as much of the tone and style of Correggio, as he could blend with his more exalted attempts to reach the lofty design of Michael Angelo. One work, such as his picture of the vision of St. Jerome, now in England, makes more than ample amends for his mistaken adoption of the grace of Correggio; and its too frequent perversion to affectation, visible in his smaller designs. He, unfortunately, like Giorgione, was cut off in the early part of his career, (at the age of 37,) and perhaps before the fullness of his power had time, or opportunity, completely to develop itself. Had he been longer spared to the world, and his progress been equal to the promise afforded by the works he has left, it is more than probable, that we should have seen a more perfect combination of the superior excellencies of the art, than has hitherto been effected. See Parmigiano.

About the end of the 16th century, the Ecclesiastical school of Bologna, of which we have before spoken, was founded under the auspices of the Carracci; and certainly, though they did not effectually complete the object they proposed, yet their exertions and abilities were reftored, for a while, the retrograde progress of the art. Ludovico the senior, and teacher of the others, in a great measure restored the art once more to nature; and by the purity and simplicity of his taste in form and in colour, preferred his superiority over his nephews, Annibale and Agostino. The former of these, however, strongly contested that point, by his powerful and free execution, and his great academical acquirements; but his mistaken application of them, more than counterbalanced their value; and of this, his great work, the gallery of the Farnese palace is an abundant proof.

The school which they formed for the improvement of their art, and which was entitled l'Academia degli Desiderati, but
PAINTING.

but is now better known as the Academy of the Carracci, proved a fource of information whence sprung many artists
deprecatedly renowned. Among them were Guido Reni, Domenichino, Lanfranco, Albano, and Guercino. Amid
the varied works of these able men, may be seen the imper-
fection of the plan adopted by their master. Each following
the dictates of his inclination, differed from his fellow student
in the objects of imitation, as well as in manner; and yet the
school attached in measure to all, inasmuch as the art, in
preference to nature, was the main object of attention with them
generally. In some few instances, indeed, the reverse
took place; and Domenichino, in his pictures of the Commu-
nion of St. Jerome, and the Cure of the Demoniac, rivalled,
in feeling and expression, the fame of Raphael; qualities
which had languished, and been neglected after the death of
that renowned artist. See lives of the artists mentioned.

After this period the art continued to decline in Italy.
The great talents of Pietro da Cortona, and Luca Giordano,
were abused by the too great facility with which they satisfied
the perverted minds of their employers. Nicholas Poupin
alone endeavoured to stem the torrent of corruption in taste,
which now flowed over the classic ground of former ages;
but though he reverted to the pure fource of Grecian art for
his models, yet in severe criticism, he is justly laid "rather
to have copied its reliques, than adopted its spirit." He
indeed is by some denied to the Italian school; but as the
chief part of his life was spent in that country, and all the
valuable information he possessed derived from his residence
there, we have attached him to the history of its art; and
with him cloes all record concerning it, worthy of parti-
cular distinction.

To Germany the art travelled from Italy; at what pe-
riod is not exactly to be ascertained; but it is not improbable
that it was soon after the time of Giotto. It was not, how-
ever, till towards the end of the 15th century, that its pro-
gress there claims our attention. At that time Albert Durer
relieved it from little better than obscurity, by his ingenuity,
his fertile invention, and his skilful attention to minute imita-
tion of individual forms. He carefully studied the human
figure, but waited his time in fanciful schemes for regulating
proportion; and never attained the air of selection, or a
flair in the rank of exalted artists. Yet sometimes his com-
positions are well worthy to have been treated in the
greatest style in design, and the colour with which he exe-
cuted them, often rivals the best among the Venetians.
The banes of the style, if it may be called so, are meagreness
and poverty of forms, mean expression, and capricious and
often vulgar invention. Lucas Van Leyden was the bane
of those who attempted to rival the name of Albert Durer,
unkless we except Holbein; who, though he never equalled
him in composition, infinitely surpassed him in portraiture.
The taste of the Germans totally changed after they pos-
essed the knowledge of the works of Michael Angelo;
when, with the constant effect of the sudden transition of
extremes, the newly imbued principles burnt all reason-
able bond; and were employed, only to be abused. Un-
able to penetrate the depth of its mysteries, its surface was
extravagantly imitated by Goltzius, by Spranger, and a
holl of ambitious contemporaries; but the folly of this mis-
application soon acted to its destruction; and in its decay
bore down with it the character of the German school of
painting.

The history of the art in the neighbouring countries of
Flanders and Holland, is merely the fame with that of its
progres in Germany, till about the middle of the 16th cen-
tury. The ultimate riches of colouring which had been
effected by John Van Eyck, was maintained entire; and
seems almost exclusively to have occupied the attention of
the Flemish artists. Their distance from Italy, and the con-
sequent want of intercourse with that country, precluded
any precise acquaintance with the peculiar beauties of ancient
art; and having no model to guide them, or rival to contend
with, they were at liberty to follow the suggestions of their
own inclinations. It conducted them to as precise an imita-
tion of the effects of natural objects immediately presented
to their eyes, as lay in their power to produce. The system
of religion here, as in Italy, found occupation for the artists
in a considerable degree; but its exercise soon deviated into
common life, and reached its ultimatum in the days of Ru-
bens and Rembrandt. The former of these "meteors of the
art" shining in a sphere completely his own, irradiated the
world with a brilliant and uncommon lustre. Possessed of
a mind as full of genius as of energy; he appears without dif-
ficulty to have embraced from contemporary artists, and the
great masters of Italy, whose works he visited, those ele-
ments of which he composed his own system. The prin-
cipal features of which are, an union of the splendours of
the Venetian school, with a grandeur of outline drawn from
the Florentine, without its corruptions, yet untinged with the
natural imperfections of his countrymen, and guided by his
own individual brilliancy of imagination, and a total disre-
gard of the beauty of the antique. But whenever he drew
the first rudiments of his style, his application of it was im-
mediately to nature, with all her varieties. Never man was
left the slave of a style than Rubens: although it does
not cease to appear in all his productions yet it was moulded
to his subject, of whatever nature it were, with the greatest
facility; and he certainly added a gradation to the scale of
the art by a manner peculiarly his own, and totally diversified
from all others. Its great object was to captivate, and no man
more completely succeeded in his design, in spite of the num-
berless defects with which his works abound. To use the words
of Sir J. Reynolds, "such is the fascination of his pencil, that
it is only when we are removed from its influence, we are
willing to acknowledge any inferiority in Rubens, to any
other painter whatever." (See Rubens.) He was truly
the father of the Flemish art; and under the influence of
his example and subsequently to his decease, fo perfect a
cultivation of the means of imitation, both in drawing and
colouuring, and alo in arrangement, took place in Flanders
and in Holland, that a new species of art was produced, un-
known to any other part of the world; and during the course
of the 17th century, furnished those countries wherein it
arose, with innumerable works of the greatest perfection in
their kind.

At the beginning of the century, that most extraordinary
and original luminary of the art, Rembrandt, appeared;
and aided the power of Rubens in completing the perfec-
tions of the Dutch and Flemish schools. In him the world pos-
essed another of those men of powerful genius, who created
an atmosphere of art for themselves, and moved within it un-
controlled, with a security that sets imitation at defiance.
What Correggio had given to the Italians, Rembrandt
bestowed upon the Dutch; chiaro-uro, concentrated, or
expanded; rivalling the purity and brilliancy of nature.
That, and colour, were his immediate agents; with which he
played at will, in all the varieties which a vivid imagination
and close observation of the more striking effects of nature,
could possibly supply him; and not unfrequently by their
means gave beauty even to deformity, at least robbed it of
dignity, and rendered it engaging to the eye.

The characteristic features of the schools, at the head of
which these two extraordinary men are duly placed, are, a
perfect skill in combination and arrangement of chiaro-
uro,
fevour; great strength of natural and local character; and a
precise truth of imitation, even almost to perfect deception
in form, colour, and effect. These powerful qualities are,
evertheless, too constantly degraded by a low and vulgar
application of them, particularly among the painters of the
Dutch school. Among the Flemings, many of the pupils
of Rubens adhered to his chief of subjects, and exhibited a
brilliance of imagination, and power of execution, worthy
of the source whence they proceeded. Vandyke more espe-
cially; who, in point of chaffery of design, and purity of col-
ouring, excelled even the power of his master, though he
had not his capacious genius, to whom the representation of
all things seemed equally facile, and whose abilities seem to
have been enlarged according to the sphere he was called to
act in, or the canvas he was employed to cover.

It would be useless to enter into a minute detail of the pro-
gress of the art in those countries: The lives of the various
artists who maintained it for a time, supply the necessary
information; and their names are, in general, familiar to our
readers; we therefore refer to them for further information.
See Jordaens, Chaver, Lieffeneck, Koninck, Metzu,
Teniers, Netscheir, &c.

The history of the patronage of the art in Holland and
Flanders, lies within a very short compass: as it rested
almost entirely with the church, who called for altarpieces,
(and their chapels were filled with them,) and the munificence
and taste of private individuals. Very few, indeed, of their
public establishments were adorned with pictures, notwith-
standing the immense fund of abilities the countries pos-
sessed; and it was left to find its own interest, by gratifying
the taste for portraiture, among the rich merchants and
burghers; or the execution of small pictures, within the
scale of admission to private rooms, on subjects of ordinary
interest, of landscape, or of vulgar amusement. Its practice
in those countries failed completely soon after the commence-
ment of the 18th century.

Very little of the progress of the art in Spain is known
previously to the year 1500; though it is scarcely probable,
considering the intercourse between that country and Italy,
that it should have been so slight, that it had not much previous
employment there. Soon after that time, the renown of Titian,
and the favour in which he stood with the emperor Charles V.
the example offered by the portraits he drew of that mon-
arch, with the high honour he received from that son of
Philip II., and his own residence for a few years (according
to Palomino Velasco) in the country, roused a spirit of
 emulation among her natives. And as far as an excellent
power of individual imitation, and of gentle, amiable
feeling, in composition and expression, will bear a rank
among the higher qualities of the art of painting, the
Spanish nation may justly claim their share. But the
beaut works of their best painters, give them no just
title to any proportion of the homage due to the great
masters of Italy, who exercised successfully the grand style.
Nevertheless, the style of the best Spanish artists is of no
mean quality. Spagroletto certainly selected for himself an
original one; the principal foundation of which he had
gathered in his studies from the Italian masters; and which,
when properly adapted to subject, presented an air of
grandeur, forcible, yet severe. But he found alone in it.
A milder and more amiable feeling characterises the manner
of the historic painters of his country, as is testified in
the works of Coello, Morales, (El Divino,) Murillo, Carrero,
Herrera, and others; whilst the bold freedom, and mastery
of hand acknowledged to have been poissied by Velatges,
with the singular reality of his portraits, places him upon
a level with Titian and Vandyke in that peculiar branch of
the art. The gay luxuriancy of the pencil, in the hands of
Luca Jordan, employed to cover the ceilings and flaircases
of the Eficuri, and other royal palaces; and the very high
honours and emoluments bestowed upon him, and others of
the like taste, attested, no doubt, to halen the downfall of the
art in Spain; in which country it disappeared, as to any
effective prosecution of it, about the same time that it did
in Italy and in Flanders. The late turn of events in the
Peninopila, has made us better acquainted with the produc-
tions of Spanish painting than we formerly were; and more
intimate acquaintance serves to increase respect for the simplici-
ity and purity of the general taste of their best artists.
But their productions were not very numerous, and are
difficult to be obtained.

In France the adoption of Leonardo da Vinci by Francis I.
after he had left Italy, (and in whose arms he died,) together
with the powerful talents of Primaticcio, of Roffo, and of
Nicolo Abbati, employed by the same monarch to paint in
fresco the chambers of the royal palace of Fontainbleau;
it might have been imagined, would have had for a long
foundation of exalted taste in the country, where it came with
all the charm of novelty, that it could not but have been
purified by a people eminent for their ingenuity, with a degree
of success rivaling the neighbouring country of Italy; more
especially as they had perpetual intercourse with it, and were
under the influence of the same system of religion, which
had there adopted painting as a portion of itself. Yet very
little arose from these admirable examples; and the only
French painters whose names have come down to us of any
pretensions to excellence for the next 150 years, are Jean
Conin and Jacques Blanchard. The former lived towards the
end of the sixteenth century, and was a skilful designer, though
in a meagre taste. He painted principally on glass. (See
Cousin.) The latter was of somewhat later date; and hav-
ing, by study at Venice, acquired a taste for Venetian design
and colouring, he obtained the name of the French Titian,
and his works were much esteemed. After thes, the art did
not rise in France, till Poussin, having imbibed a taste for its
excellencies in Italy, returned to his native country, but
with reluctance, at the invitation of Louis XIII. Although
the treatment he received was handsome, and becoming both
patron and painter, yet he found the taste of his country
not formed to relish the simplicity of his style. The facile
mediocrity of Simon Vouet received more admiration; and
Poussin, disgusted, returned to his tranquil life at Rome;
leaving the field to a competitor, who laid the foundation
of that butter and frivolity, which characterized the style of
the French school previous to the revolution. Le Sueur,
indeed, felt like a man of a pure and elevated mind; and
spurned the trammels imposed by the style of Vouet.
The chaitly, the feeling, and purity of the soul of Raph-
el, seem to have been infused into his mind, and exhibited
itself in the series of pictures painted for the convent of
the Chartreux at Paris, and known as the life of St. Bruno;
in the burning of the books of magic at Epheus, &c. &c.
But no preparation had been made to receive so pure a taste as
Le Sueur's; and in a court where ostentation took place of
magnificence, its vulgarity and gentleness were ill capable of
withstanding the brilliant, but falfe glitter, which accompanied
the exertions of his fellow student under Vouet, Charles le
Brun. He sunk under the unjuft abatement, and fell a
victim to mortality at the early age of 37; not without leav-
ing caufe for a fulpicion of his having been poisoned.

His fortunate competitor, Le Brun, formed, by the great
extent of his ability, an era in the history of the art in
France; and stands unrivalled in his style, as the acknow-
ledged head of the French school; the deity of its succe-

5
ing artists; and the theme of their eternal adoration, to the utter exclusion of all the real great painters of Italy, of Flanders, or of Spain. And if a vigorous imagination, and powerful execution of rich combinations, in forms, and colour; with an eye and a hand, which arranged with facility the various parts of extended compositions, and united them as a whole; will effectively weigh against the want of simplicity, natural expression, and purity in design; then he well merited the distinction given him by his countrymen. The splendid arrangement of the gallery of Versailles (now in danger of perishing by the neglect that palace experienced during the days of republican France) is a satisfactory proof of the extent of his abilities; and when his battles of Alexander are placed in conjunction with it, we can no longer wonder that such a display of talent, so congenial to the mind of that vain ambitious monarch, Louis XIV., completely overpowered all competitors. During his long reign, talent of all kinds (one conspicuous round his throne, and painting was consequently elevated and encouraged; the splendour of the court, and the dignity of the king, being made the principal objects of attention by its professors. An academy of painting, &c., was formed at Paris, under the immediate patronage of his majesty; and another at Rome, for the benefit of French students. Vander Meulen accompanied him in his campaigns, and painted the principal events that occurred, to perpetuate his renown. But a more classificable tribute of homage was required of the art, in that age of learning. In imitation therefore of Cæsar, who had perverted the pictures of Alexander, painted by Apelles, to his own exaltation, by adopting them as symbolic of that power which he had created for himself; so, by the instrumentality of Le Brun, Louis XIV. contrived to make the victories of that immortal conqueror emblematic of his own refulgent ambition, and his love of false glory, on which he prided himself, but for which no real hero lights, when it must be purchased at the dread price of suffering humanity. The grand monarch, however, in this mistaken application of the art, acknowledged the utility of it, as an agent of glory to himself, through the medium of a more magnanimous prince, who conquering but to conquer, lightened a weight of execution by exhibiting many traits of real heroism. And the result has been, another proof added to the testimony of former ages, of the sanctified renown which may be acquired by a monarch and a country, from a cultivation of the arts which adorn human nature, above that derived from political causes.

If even the firm basis of nature, upon which the style of Michael Angelo was founded, did not prefer it from perversion by his imitators; it was not likely that Le Brun’s, built as it was upon the sandy foundation of artifice, should share a happier fate. As it led the way in subtilizing theatrical for natural taite, in gefulure and in expression, and had obtained such a commanding influence by its successes; those who adopted it appeared to have imagined that the former was the real prototype of the two; and accordingly the stage, and its artificial airs and graces, which were ready made to their hands, and prevented the difficulty and trouble of searching and selecting from the coy haunts of nature what was necessary for their works, was made the subject of their imitation. But no want of ability appears in the men who immediately succeeded Le Brun. The wonder is that men endowed with so much talent, could have submitted their understandings to so false a taste. Sébastien Bourdon, indeed, ruffled from it, and with true poetic feeling endeavored to imitate, and did very successfully imitate, the pure taste of Poussin; but Pierre Mignard, Jouvenet, Champagne, and Rigaud, ruffled into the stylen, till it became reduced to pomposo no-meaning flutter; and in the hands of Van Loo, Bouchet, &c. lost all trace of its masterly origin, and sunk into contempt, even in the country where it originated. In a more minute detail of the progress of the art than our limits will admit, the names of Watteau and of Vernet ought not to be overlooked, the former, particularly, who created a pleasing style of execution and colour, and exhibited it in sportive scenes of imagination drawn principally from the amusements of the higher circles; and the latter introduced a taste for landscape and views of sea-ports which had been unknown till his time, but was too artificial in his colouring.

When the terrors of the recent revolution had subsided, and in measure even during its course, it was thought proper in France to revolutionize the taste of its arts. But whether the fervour of hatred to royalty, the determination to exterminate all remnants of it, even to its bounties, or a real feeling of the indirect course which the taste of their school of art had taken, guided them in the choice of their present style of design, and was the cause or not of the change, certain it is, that in its vibration, it has gone as far beyond the true line of propriety on the one side, as it had before done on the other. In place of the pompous display of figures in affected attitudes, overloaded with draperies of rich trifles flowing in all the parade of unmeaning magnificence, a dry and inipid imitation of Greek sculpture is adopted; and in spite of the immense mass of perfect exemplars, in the works of Raphael, of Titian, of Domenichino, and almost all the renowned masters of Italy and of Flanders, &c. with which the gallery of the Louvre abounds, and which, with a superior judgment, the government leave free to their study; the present rulers of taste in France have marked a line of conduct for the students, imitative of the condition of painting before those masters were born. Rejecting the efforts of the happy period of its maturity, they prefer referring to the infancy of the art, with about as much propriety as a man who is devious of walking might tie up his legs, and throw himself into the arms of his nurse. Whether the minute attention now given by the French school to drawing, and the peculiar taste in which it is directed, viz. to the adoption, in painting, of the forms which appear to belong exclusively to sculpture, be likely to produce, in any length of time, the end proposed, is extremely problematical. We rather suspect the stylen must be changed ere they will reach the object of their wishes; and then perhaps this preparatory attention to simple forms may have its due effect.

It has remained to our time, that it should be said of England, she had a school of art appropriately her own. So very little is known of what occurred concerning the art of painting in this country; it was a period to the time when Henry VIII. encouraged the abilities of Holbein in portraiture, and invited Titian to come here; that it would be useless to endeavour to trace its history. Enough, however, is known to satisfy us that it was at a very low standard. It was but little before his time, that the people of England began to throw off the yoke of ignorance and barbarism; and to cultivate literature and science. The ambition of Henry to be renowned, and his spirit of rivalry to his great neighbour Francis I. of France, were quite sufficient motives to stimulate him to the proud aim of becoming a patron of the liberal arts; had not his theological discussions with Luther, and afterwards his more fabulous quarrel with the pope, so powerfully diverted his attention from them, and produced him to active employment in deciding the course of the reformation in religion which consequently ensued. But however great be the cause that England has to rejoice in the general fruits of that change in religious principles and government; its effects were fatal to the cultivation of the
PAINTING.

Of the natives of England, few caught the flame of desire to imitate them even in portraiture, not one in history. Of the former, W. Dobson took the lead, and succeeded in painting a head with great skill; but there his abilities flagged. His exertions, and those of his contemporaries, were arrested, almost entirely, by the Gothic barbarity of the puritanical style which followed; and the taste of Charles II., whatever he might have acquired from his father, was only merged in impurity and frivolity, by his long residence at the French court; where he acquired a taste for that parade and pompous display of magnificence which was the ruin of the French art.

Verrio, and Benedetto Gennaro, were the protectors of this monarch. The former was employed by him to decorate the ceilings and walls of the royal palace of Windfor; and received for the extravagant load of ingenious absurdities with which he covered them, to the amount (according to Walpole) of 5,500l. and upwards. Of the latter, there are several pictures at Windfor, in a florid and droll imitation of Guercino, of whom he was a nephew. In portrait, Sir Peter Lely filled with very great ability the place which Vandyke had held; and in an original and very agreeable manner, he often rose to a station very nearly approaching that of his great predecessor. In the expression of beauty he frequently surpassed him; and was a far more agreeable painter to the ladies. Sir Godfrey Kneller, likewife, in this reign began his long career of portrait painting; he succeeded to Lely's fame upon his decease in 1680; and as an artist was utterly ruined by success. Had he been under the necessity of labouring with care to support the great name he enjoyed and abused, he had talents sufficient to the purpose. Witnesses for him, the converted Chinesse at Windfor, the portrait of Newton at Petworth, of Dr. Meade at Oxford, and many others. But he lived and practised painting for five successive reigns, almost without a rival, making gain rather than fame the object of his desire. Dahl, who was a Swede, was the only one who interfered with his practice, to any extent.

Willing, his countryman, threatened, by his carefulness in finishing, to have more effectually counteracted him; but he, unfortunately for Kneller, died young.

In historical painting, no English artist had appeared to rival the productions of foreigners introduced here, in any degree, till at length Sir James Thornhill, born in 1677, arose to contend the honours of the palette with La Guerre, who had been employed to adorn the halls and salons of many among our nobility. The style he adopted, that of his rival, was but a lower imitation than Verrio's of the French school; and by no means served to elevate the taste of the country. However, the state did him the justice to employ him in the decorations of St. Paul's and at Greenwich, in which he was most materially assisted by a German of the name of Andre; but such was the humbling nature of his engagement, that he was paid at the rate of 40s. per square yard. With him properly commences the history of English art, though portraiture, as we have noticed, had been practised by Dobson after Vandyke, also by Riley, and by Cooper, who was a very ingenious artist, in miniature. But after them, it sank lower and lower, in the hands of Greenhill, Jervas, Richard- son, (who, notwithstanding, has taken admirable works upon the canvas, and exhibited in his efts a true feeling for those excellencies which he could never exemplify by manner;) and hundreds of others whose names it would be cruel to refuse from oblivion; for the mania for portraiture did not cease, though the ability of the artists was fast verging to utter decay. What Sir James Thornhill had done in historical, or rather decorative art, found no very successful imitator; so that to use the words of Horace Walpole, "in the com-

Vol. XXVI.
mencement of the reign of George I, the arts of England were funk almost to the lowest ebb; and with the still greater authority of Sir Joshua Reynolds we may add, "lower they could not well be."

That such should be our degraded condition in the art of painting, which from its value and importance, when properly applied, has been so justly considered as essentially useful in promoting the dignity of a state; and that, at a time when, in political importance, in science, in poetry, and philosophy, we held so high a litation among the kingdoms of Europe, where it had been cultivated with success, mult, at first light, appear somewhat paradoxical.

A little consideration upon the circumstances which have counteracted its growth among us, will, however, at once satisfactorily dispel the surrifice it necessarily occurs.

No nation has the art been known to achieve spontaneously to perfection. We have been in Greece and Italy gradually gaining strength through accumulated years, growing as it were with the people. "The artist and the age," Mr. Barry has observed, "were so fitted to the weaknesses of each other, that admiration was kept constantly alive during the whole successful progress from barbarism to perfection."

When it was first introduced from the earliest sources of cultivation on the continent, this was the time to have encouraged it, and taught the nation to imbibe a taste for its beauties; and then, by degrees, it might also have reasonably been expected to have improved among us. Whereas the circumstances related above, exhibit it, on the contrary, rebufsed, before it had taken sufficient root, and what lighter branches had attached themselves to the foil, torn with violence from its nourishment.

The earlier works of the artists, whether British or foreign, being expunged from the churches, and the seal of authority placed against their future admission; together with the breaking up of the monasteries, and the consequent dispersion of those bodies of men, to whom in leal mankind are indebted for the maintenance of literature, and the arts during the dark ages, settled completely the fate of historical painting in England.

The favourable moment for employing it in any other than a religious course elapsed; and the general tone of education among the people, not having fitted them to receive its influence, except as attached to religion, what little had been adopted was lost in its growth. In the mean time an accumulation of pictures gradually took place; the produce of other countries, where the art had been more regularly attended to, and the habit of referring to the continent for information gaining strength, the acquired ideas of our nobility and gentry rose above the power of the unenlightened artists of the country, which those who guided public taste upon too jut grounds decreed; and thus an evil which to this day operates to depref our artists, commenced its preponderating influence.

The circumstance apparently most surprising in this matter, is, that when the powers of Vandyke were so long and so widey displayed in England, and portraiture so much encouraged, that so few of her artists should have followed in his track, or that taste should have swerved so completely from it.

But the fact is, that British students were inclined to pursue, without Dobson and Riley; and Jamieson in Scotland; and they succeeded to a very considerable degree. It could not, however, be expected that when there had been so little food for nourishment offered to artists, that they should at once spring to perfection, unless endowed with genius in a higher degree than even the renowned master whom they emulated.

No one was immediately found equal to that, and the allusion created by his exquisite abilities, had scarcely subsided into regular study, when Lely appeared to usurp his station, and spread the peculiar beauties of his own ready pencil in the way; gratifying the court, and, consequently, guiding the taste of the country. Kneller succeeded rapidly to him; the English artists had not time to rise; and imitation of the reigning influence was alone left for them; as no one advanced with sufficient power of mind to flies successfully in a track of his own.

The period at length arrived, when England, exerting her native energy, advanced in her turn to enjoy a share of renown among the cultivators of the art of painting.

The principal difficulty in the outset of this event, was to rescue the art from the degrading influence of a vicious taste, to retrace the steps of our predecessors, or rather, to burst the bondage in which they had enthralled us, and reform at once to the original principle of imitation; which, when pure and select, is the only found basis of the art. The first step towards it was the establishment of a school for drawing from the living figure. This had been begun by Sir James Thornhill, in most inexplicable conjunction with Sir Godfrey Kneller, who one would imagine, from his latter works, had left all consideration of the value of such a thing far behind. Thus, however, he affiliated in laying the foundation of a remedy for the evil, which he more than any other had occasioned. This school, Sir James continued at his own house in the Piazza for some years. His death, in 1734, obliged the artists to procure another situation, which was not effected without some difficulty; for the people were so unprepared to confer the study from the naked figure as necessary to the artists, that their meetings were even suspected to be held for immoral purposes.

Another school was at length formed by Michael Mofer, a native of Schaffhausen, and a charier by profession, and fix other artists, principally foreigners, the management reposing with Holler. After a while they were visited by Hogarth and others, and a larger body was formed in consequence, who established themselves in Peter's-court, St. Martin's-lane, in the year 1739.

Having acquired some property by combined exhibitions of their works, they solicited a charter of incorporation, and the scheme being sanctioned by the king, their charter was granted in 1765. But disaffections arising in the body, a feccion of many of its principal members took place, and the result was the establishment of the Royal Academy in 1768, under the more immediate patronage of his majesty; Sir Joshua Reynolds being nominated its first president. Edwards's Anecdotes of Painters. Introduction.

In conjunction with these more active exertions of the artists, there did also arise in the minds of many gentlemen of improved understanding, a wish to see the art of the country emancipated from the shackles of the artificial taste which was imposed upon it, and sociceties were formed, which made it an object of attention, and excited a more general regard for it. But this was not till after the time when the artists had forced their way into notice; more especially Reynolds, Hogarth, and Wilton.

Richardson, who died in 1745; at the advanced age of 80, unable by his pencil to rival the real beauties of Vandyke, of Raphael, or others whose names stood on high record, endeavoured to make amends by his pen, and in 1715, published a book full of high encomiums of the merits of those masters, and of useful observations on the theory of the art of painting; and in 1719 another, on criticism, and the science of a connoisseur; works of which nobody will be inclined to dispute the merit, who knows the value which Sir Joshua Reynolds placed upon them; and particularly the former, which he declared contained him in his love of the art, and elevated his ideas of 15 professors. In it, Richardson contended for the propriety of painting portraits in the colurine of their time; a dangerous symptom of feel-
ing for the continuation of the system of loose robes introduced by Kneller, when common sense began to resume her influence in the minds of artists. Hudfon, the son-in-law of Richardson, with the help of Van Alken, (a Fleming,) and in rivalry with Van Loo, (a Frenchman and brother to Carlo Van Loo,) profited by the suggestion, and ventured to reject the non-sensical draperies in use at the time; and instead of loose unmeaning pieces of varied stuffs thrown in artificial folds over the shoulders of the gentlemen; and the affectation of grace and grandeur in which the ladies were represented en chemises, half exposed and half enveloped in one ill-contrived piece of silk, as if they had carelessly thrown on a mantle when rising from their beds, he dressed them in their formality of the day; and his Flemish assistant painted their figs and lashes with great care and exactness. Hayman also, who had succeeded Sir James Thornhill as an historical painter, upon the principle of what was truly admirable in art, at liberty to preserve the uniforms proper to those whom he introduced into his pictures; and no longer by a few feeble magic converted them into Roman centurions or Grecian heroes.

Thus, by the aid of the schools we have mentioned, and their own good sense, the attention of English painters was at last steadily attached to the first principle of their art, imitation, from whence they might rise; instead of being distracted by that which properly belongs only to its decay, ornament, from whence to proceed must be to fall. It was comparatively of no import, that the materials which they had to imitate were detectable in themselves; and nothing could be more repugnent to good taste than the toguees and stuff skirts of the men, and the ruffled ruffles, high heads, and hoop petticoats of the women. Attention to actual representation in the first instance, appears to have been the only means by which the vile spell that controlled them could be effectually dissolved. That once broken, and a cultivation of taste taking place on better grounds; and when a real knowledge of what was truly admirable in art, and attainable in its practice, had been assiduously cultivated by our artists in Italy, unshackled by any extraneous trammels, and exerting their judgments in a right unbiased direction; it no longer appeared problematic, whether England might, or not, produce painters, as she had done poets and philosophers. The chains which had prevented her native exertions, had been forged imperceptibly by foreigners, who reviled her, aided by unfortunate political circumstances; and it is not a little striking, that when the rejected their influence, when all pretensions to art were sinking upon the continent, and those countries where it had most flourished, ceased to produce painters of eminence; that, at that very time, England should step at once from her obscurity, and illumine the darkened atmosphere of art, with an irradiation of no common lustre.

It were uselefs to trace the progress of the art in the hands of those who in minor degree assisted in this enfranchisement of it in our country; "or recount the hammering and babbling of its infancy," for as such, its condition at the time of which we are speaking may be regarded. It feebly enjoyed the period of youth, for when Reynolds and Wilfon returned from Rome, they rushed at once with it to maturity in portraiture and in landscape. And when Weft, having by his British connections in America impunity a true taste for its beauties, had also cultivated it in Italy, and came here to devote his life in its service, all that had been done in history, by Hayman, by Pine, by Wale, and others, was instantly sunk in oblivion.

Hogarth, however, demands a rescue from the mafs of our earlier artists. With a marked originality of feeling, he pursued the art as his own taste, or rather fortune, guided him; and traced a line for himself totally unknown to any other, though more in the application of the art than in itself. Yet in his latter pictures, particularly in his Rake's Progress, and the Marriage-a-la-Mode, he exhibited a thorough feeling for the beauties of the Dutch school; executed in a broad style of his own, and proving, that if his youth had been employed in painting pictures, instead of engraving silver tankards, he might have rivalled the best among them.

In landscape, Lambert had advanced beyond the steps of his contemporaries; and produced with some talent, a kind of union of the peculiarities of Gaper Double, and Claude. But when Wilson expanded his brilliant, chaste, and glowing tints, in ample mafles of light and shade, over the canvas; the art seemed to leap at once ages in advance; too far rapid, indeed, for the taste of the public; or the benefit of its (subsequently) adored professor. See Life of Wilson.

Whatever had been done here in portraiture, from the time of Vandyke and Lely till 1752, when Reynolds returned from Italy, was then utterly annihilated by the display of his splendid talents; the foundation of all, which this branch of the art builds in the English school. Not but that there have been and are exhibited various deviations with original feeling, from his peculiar taste; but his is the acknowledged and undoubted claim of superiority, as of priority. His best portraits are inferior to none, for truth of character, and style of treatment; in many points they are superior to those of all the portrait painters who ever lived; and to his talents, exhibited in the various works collected by the British Institution, and opened to the public during this last summer, (1813,) the nation has, by acclamation, declared its homage, and acknowledged its obligations. See Sir Joshua Reynolds.

With respect to the practice of the higher style of historical painting in this country, the rank it merits is so much the almost exclusive privilege of artists now living, that it is not easy to know how to state the sentiments which liberal and candid criticism dictates concerning it. Partiality may blind, or true criticism, if given, may be misconstrued to flattery, or some principle of a meaner kind. It must be left, therefore, to posterity, to give the due meed of praise to those, who have exerted themselves against innumerable difficulties, and endeavoured to uphold the true spirit of the art in this, its most arduous application; and perverted, till at length something like an inclination to encourage their efforts appears to arise, where alone it can be effectual. No one can for an instant hesitate to declare their feue of the exalted abilities with which it has been, and is supported; or safe to wish to see them duly engaged.

Of those who have professed in this branch of the art, and are departed, Reynolds, Romney, Opie, and Barry, require to be particularly mentioned. The former with all the splendour of chiaro-vero and colour, which no one since Rembrandt has wielded with so much authority, exhibited in his pictures of Hercules flattering the serpents, Magdeth, cardinal Beaufort, and Ugolino, a fund of historic power. Romney also had poetic imagination, feeling and expression; and in the little leisure allowed by his general practice of portraiture, indulged in the delights ideal subjects afforded him; while Opie presented "images new and striking, drawn directly from nature," and "what he wanted of academical or classical information, he compensated for, in great measure, by character, by force, and by a just and bold imitation." But of the four, Barry was the only one who had regularly educated himself for its practice, and undoubtedly had the highest
highest and most enthusiastic feeling for its best qualities. With a generous zeal worthy of the highest encomium, he broke entirely from all consideration of the ordinary style of subject, or design; and contemplating his art in the most exalted manner, attempted to embody the elevated ideas he entertained. His most sincere admirers must, however, regret, that those excellent sentiments, which he so ably incalculable by his pen, were not more completely supported by his pencil; yet, his productions of the series of pictures upon the culture of man, in the great room of the society in the Adelphi, notwithstanding their imperfections in the executive part, must ever remain a marked event in the annals of historical painting in England.

For further illustrations on this subject, see Picture.

Colours employed by the Romans in Painting, in the time of Pliny. See Pliny, lib. xxxv. caps 6 and 7.

**WHITES.**

**Melium.**

A native white earth, from the island of Melos, used by Apelles before white lead prepared with vinegar was invented.

**Paragonium.**

An Egyptian white earth, used in diftemper; and similar probably to the white now called Creemntz white, from Hungary. Pliny complains that paragonium was frequently adulterated with Cimolian earth, which was used by the fullers at Rome.

**Eretria.**

An alfly white. It is named from a town of Eretria, now Trocce.

**Cerufla.**

White lead.

**Anagora.**

Gypsum.

**Creta.**

Chalk.

**YELLOWs.**

**Sil.**

Ochre of four kinds: named Atticum, Lucidum, Syricum, and Marmorofum.

**Aurigsmium.**

Orpiment.

**Arsenatum.**

Mallicot, first discovered by the fire at the Piraeus.

**REDs.**

**Minium.**

Red lead, both natural and artificial. The best native minium was found in a quicksilver mine near Ephesus; and in endeavouring to extract gold from it, Callias, the Athenian, discovered vermilion.

**Vermilion.**

The name as now used.

**Sinaeptis.**

A red earth. The best was found near Lemnos, and was so valuable, as to be sold sealed up. It approached near in colour to minium.

**Rubrica.**

A red earth.

**Cinnabar.**

Native Indian name for dragon’s blood.

**Sandaracha.**

A red orpiment.

**Sandyx.**

By some thought to be vegetable red, and obtained somewhat after the manner of our lakes, viz. absorbing the colouring matter of a decoction of the vegetable matter in chalk.

**Purpripissum.**

A lake made from the ingredient used in dyeing purple, being absorbed in tripoli.

**Syracum.**

A mixture of finyx and sandyx

**BLUES.**

Armenium, or Azur, also called Cerulium.

**Indicum.**

Verd’azur, or blue verditer. Pliny calls it a sand, and says there were three kinds, viz. the Egyptian, the Scythian, and the Cyprian.

**INDIGO.**

Greens.

Cibyrlicollia.

Malachite, or mountain green. Another of the same nature.

**BLACKS.**

A common name for all black colours. Pliny speaks of one kind, as oozing from the earth; and it may possibly have been some kind of bitumen. Of another, as being made from smoke of rosin and pitch. Burnt lees of wine, or husks of grapes, produced another, used under the name of Traginon, by Polygnatus and Micon; and another was invented and used by Apelles, by burning ivory. That being made thin by some vehicle, was probably the atramentum or varnish, which he is said to have laid over the surface of his pictures. What the vehicle was is unknown; perhaps, as the mode of painting with wax by heat was practised, it might have been some modification of that material.

According to Pliny, “Apelles and other ancient artists used only four of the colouring substances mentioned above. But if we are to give him credit for the propriety of the praises he belabors upon their productions, we are under the necessity of denying it to him in this matter. Had he not specified the substances themselves, and we had been left to imagine that they poifled others more perfect in quality, the allusion might have been admitted; because, philosophically speaking, four perfect colours, with all their tints, are certainly adequate to every purpose the art of colouring could require. Unfortunately for him, the substances he has mentioned are not in their nature equal to the power of those we now possess: and the practice of art, even with our present advantages, denies the knowledge of any four pigments, equal to the production of a work worthy of being denominated a fine piece of colouring. He says, lib. xxxv. c. 7. that “they used only Melos for white; Sil, Attic ochre, for yellow; Sinos, red; and Atramentum, black.” He has before observed, that “Polygnatus and Micon used a black made of grape husks,” which is a blue-black; and probably the greytely they had; but this is no substitute for blue, worth mentioning. The mere enumeration of them must suggel to every artist, the utter impossibility of producing any work of fine colouring from them, unless in a very confined scale.

The pigments in present use are very numerous. Those employed in fresco, have been mentioned under that head. The principal ones fitted for the general purposes of oil painting, are, Cremnitz white, white lead of different kinds, a fine yellow lately discovered from chrome of iron, King’s yellow or orpiment, Naples yellow, patent yellow, ochre, Dutch pink, terra di Siena, yellow lake, red lead, vermilion, red ochre, Indian red, Venetian red, lakes of various kinds, bowron pink, Van Dyke’s brown, umber, burnt and unburnt, terra di Siena, burnt, Prussian and Antwerp blue, ultramarine, ivory-black, blue-black, opalatum. These are
are the principal colours for the palette, but there are a variety of others, which are employed for particular purposes, such as verdigris, &c. &c. The natures of these colours may be known by reference to their particular specifications.

The oils best adapted to the purpose of painting, are poppy, nut, and linseed oils; and in this climate a preparation of the latter, by boiling it with some fixative, is in very common use. See Oils.

The varnishes most employed are made from gum mastic and gum copal, the former dissolved in spirit of turpentine, the latter in oil, &c. (See Varnish.) To those who desire more minute information on the subject of colours and vehicles, we recommend the perusal of P. F. Tingry’s Painter’s and Varnisher’s Guide.

The preparations of grounds for painting upon, is matter worthy of particular attention. The mode now most in use is of absorbent ones; by which the oil being taken up, is of course prevented from coming to the surface of the painting, and giving its own yellow hue to the work. Absorbent grounds are made of different materials. Some employ plaster of Paris, others pipe-clay, whiting, and fize, &c. The former are apt to take up the oil too quick, and render the colour too stiff to work agreeably; and the latter are always liable to be affected by damp. A better one than either is produced, by grinding the colour in water, and then mixing a little oil with it. This does not cause the disagreeable effect above-mentioned, and is always firm. One great object in laying on the ground, is not to give too much of it; but just sufficient to cover the threads and interstices of the canvas, or the grain of the wood: if too much be laid on, it is in danger of chipping off, or of cracking.

For the practice of the art of painting, it is very difficult to give many efficient rules. The principal objects which require attention, are to let the preparatory colours be lighter and cleaner, (that is rather more grey,) than those with which it is intended to finish, and to take care that the full form be made out with the under colour, before any proceeding is made with the finishing ones; which ought not to be disturbed in their hues; and to be employed only to strengthen those prepared, and give lightness and delicacy of execution. It is also desirable in painting, that the colours be disturbed as little as possible with the brush; and not be too much blended, or softened; but rather laid on with touches, beside each other; as that tends to keep them pure; whilst too much fretting causes them to become muddy, and to change in drying. The first part of the process of a picture, after the artist has fixed in his own mind a full idea of his composition in all its material parts, is, for him to draw correctly the general forms, and then begin to paint in his chiaro-ucuro, with as simple a scale of colour as possible; and fully to satisfy himself on that head before he proceeds with his positive colours. This is the readiest mode of avoiding confusion and the necessity of frequent repetition; but there are almost as many modes of processes as there are painters; each varying in some respect from the other, and every man’s practice, either by accident or principle, furnishing him with varieties. Too great an adherence to system, is certainly not favourable to advancement; yet without a system, much time is necessarily lost; and it seems most reasonable, that every artist should commence with one, however he may find it necessary to vary from it in his progress. Rubens, and most of the Flemish school, evidently exhibit theirs, by leaving so much of the coloured ground of the picture to act among the shades, and under the half taint; as is always seen in their productions. In order to do this effectually, a finished sketch ought to be prepared; and indeed, in any mode of art, such an one is very useful; particularly where the work is of any great extent.

For the great principles which guide and govern the practice of the art, see the respective articles Composition, Colouring, Design, &c. &c.

Painting. Economical, is that application of artificial colours, compounded either with oils, or water, which is employed in preferving or embellishing houses, ships, furniture, &c. &c. The term, economical, applies more immediately to the power which oil and varnish possess, of preventing the action of the atmosphere upon wood, iron, and flueco, by interposing an artificial surface; but it is here intended to use the term more generally, in allusion to the decorative part, as applied to buildings; as well as to its more essential ones; and as it is employed by the architect, throughout every part of his work, both externally and internally.

In every branch of painting in oil, as applicable either to churches, theatres, houses, or any other public or private buildings, or edifices, the general processes will be found very similar; or with such variations, as will easily be suggested by the judicious artist, or workman.

The first coatings, or layers, if on wood or iron, ought always to be of ceruse or white lead; the very best that can be obtained; which should have been previously ground very fine in nut or linseed oil, either over a floor with a muller, or, as that mode is too tedious for large quantities, it may be passed through a mill. If used on wood, as shutters, doors, or wainscoting made of fir or deal, it is highly requisite to destroy the effects of the knots; which are generally so completely saturated with turpentine, as to render it, perhaps, one of the most difficult processes in the business to conquer. The best mode in common cafes, is to pass over the knots with ceruse ground in water; bound by a size made of parchment, or some other animal substance. When that is dry, paint the knots with white lead ground in oil, to which add some powerful fixative, or dryer; as red lead, or litharge of lead, about one-fourth of the latter. These preparations should be done carefully, and laid very smoothly with the grain of the wood. When the last coat is dry, which will be in twelve or twenty-four hours, then smooth it with pumice-flour, or give the work the first coat of paint, prepared, or diluted with nut or linseed oil. When that is dry, all the nail holes or other irregularities on the surface should be carefully stopped, with a composition of oil and Spanish white, a whitening commonly known by the name of putty; but which is frequently made and fold at the flops of very inferior articles. When that is done, let the work be painted over again, with the same mixture of white lead and oil, somewhat diluted with the essence of oil of turpentine, which processes should be repeated not less than three or four times, if the work is intended to be left, when finished, of a plain white or white colour; if of the latter, the last coat should have a small quantity of ivory or lamp black added, to reduce its whiteness a little; and this
PAINTING.

This is also of service in preserving the colour from changing; a circumstance which the oil is apt to produce. But if the work is to be finished of any other colour, either grey, green, &c. it will be requisite to provide for such colour, after the third operation, particularly if it is to be finished flat, or, as the painters style it, deaf-white, grey, fawn, &c. &c. In order to finish the work flatted, or dead, (which is a mode much to be preferred for all superior works; not only for its appearance, but also for preserving the colour, and purity of the tint,) after the work, supposing it to be wood, has been painted four times in oil colour, as directed in general cafes, one coat of the flatted colour, or colour mixed up with a considerable quantity of turpentine, will be found sufficient; although in large surfaces it will frequently be requisite to give two coats of the flating colour to make it quite complete. Indeed, on fluco it will be almost a general rule; but as that will be hereafter treated, we shall at present lay no more concerning it.

It must be observed, that in all the foregoing operations, it will be requisite to add some sort of fixative. A very general and useful one is made by grinding in linseed, or, perhaps, prepared oils, boiled, are better, about two parts of the whole of copperas, which must be well dried, with one part of litharge of lead: the quantity to be added, will much depend on the dryness, or humidity, of the atmosphere at the time of painting, as well as the local situation of the building.

It is highly proper here to observe, that there is a kind of copperas made in England, and said to be used for some purposes in medicine, that not only does affix the operation of drying in the colours, but absolutely prevents those colours drying, which would otherwise have done so by themselves. The bell dryer for all fine whites, and other delicate tints, is sacharum fumari, or sugar of lead, ground in nut oil; but which being very active, a small quantity, about the size of a walnut, will be sufficient for twenty pounds of colours, where the basis is ceruse. It will be always worthy to be observed, that the greatest care should be taken to keep all the utensils, brushes, &c. particularly clean; or the colours will soon become very foul, so as to destroy the surface of the work. If this should happen, the colour should be laid through a fine sieve, or canvas; and the surface of the work be carefully rubbed down with sand-paper, or pumice-flour, and the latter should be prepared by being ground in water, if the paint be tender, or recently laid on.

The above may suffice as to painting on wood, either on outside or inside w-rks; the former being seldom finished otherwise than in oil, four or five coats are generally quite sufficient.

We shall now proceed to note what is requisite for the painting of new walls, or fluco, not painted before, and prepared for oil colours.

It does not appear that any painting in oil can be done to any good or serviceable effect in fluco, unless not merely the surface appear dry, but that the walls have been erected a sufficient time to permit the mafs of brick-work to have acquired a sufficient degree of dryness; when fluco is on batttered work, it may be painted over much sooner than when prepared as brick. Indeed, the greatest part of the mystery of painting fluco, so as to stand or wear well, certainly needs in attending to these observations; for whoever has observed the expansive power of water, not only in congelation, but also in evaporation, must be well aware that when it meets with any foreign body obstructing its escape, as oil painting for instance, it immediately refills it; forming a number of vehicles, or particles containing an acid lime water, which forces off the layers of plaster, and frequently causes large defective patches, extremely difficult to get the better of.

Perhaps in general cafes, where persons are building on their own estate, or for themselves, two or three years are not too long to fuller the fluco to remain unpainted; though frequently, in speculative works, as many weeks are scarcely allowed. Indeed there are some nostrums set forth, in favour of which it is flatted, in spite of all the natural properties of bonding that fluco may, after having been washed over with these liquids, be painted immediately with oil colours. It is true there may be initatives, and in many experiments some will be found, that appear to counteract the general laws of nature; but on following them up to their causes, it will be found otherwise.

Supposing the foregoing precautions to have been attended to, there can be no better mode adopted for priming or laying on the first coat on fluco, than by linseed or nut oil, boiled with dryers, as before mentioned, with a proper bruft; taking care, in all cafes, not to lay on too much, so as to render the surface rough and irregular, and not more than the fluco will absorb. It should then be covered with three or four coats of ceruse, or white lead, prepared as described for painting on wainscoting; letting each coat have sufficient time to dry hard. If time will permit, two or three days betwixt each layer will not be too long.

If the fluco be intended to be finisht of any given tint, as grey, light grey, apricot, &c. it will then be proper, about the third coat of painting, to prepare the ground for each tint, by a slight advance towards it.

Grey is made with ceruse; Prussian blue, ivory black, and lake, fage green, pea, and sea-greens, with white; Prussian blue and fine yellows, apricot and peach, with lake; white, Chinese vermilion, and fine yellow, fawn colour, with burn: terra Siena, or umber and white; olive greens, with fine Prussian blue and Oxfordshire ochre.

Painting in ditterem, or water colours mixed with size, fluco, or plaister, which is intended to be painted in oil when finisht; but not being sufficiently dry to receive the oil, may have a coating in water colours, of any given tint required, in order to give a more finisht appearance to that part of the building.

Straw colours may be made with French white, a ceruse, and mafficot or Dutch pink. Greys, fine, with some whites, and refiners' verditer. An inferior grey may be made with blue-black, or bone-black, and indigo. Pca greens, with French green, Olympian green, &c. Fawn colour, with burnt terra de Siena, or burnt umber and white; and so of any intermediate tint. The colours all should be ground very fine, and incorporated with white, and a size made of parchment, or some similar substance; ifinglafs being too expensive for common works.

It will not require less than two coats of any of the foregoing colours in order to cover the plaister, and bear out with an uniform appearance. It must be recollected, that when the fluco is sufficiently dry, and it is desirable to have it painted in oil, the whole of the water colour ought to be removed; which may be easily done by washing; and when quite dry, proceed with it after the directions given in oil painting of fluco.

When old plaistering has become discoloured by flains, and it be defir'd to have it painted in ditterem; it is then advisable to give the old plaister, when properly cleaned off and prepared, one coat of fair lead ground in oil, and used with spirits of turpentine, which will generally fix old flains; and when quite dry, will take the water colours very kindly.

The above processes will also apply to old wainscoting.
in cafes where temporary painting is only required; but cannot be recommended for durability.

PAINTLICK, in Geography, a town of America, in the state of Kentucky; 14 miles E.N.E. of Stamford.

PAINTLICK Creek, a river of Kentucky, which runs into the river Kentucky, N. lat. 37° 37' W. long. 84° 43'.

PAINVILLE, a town of America, in Amelia county, Virginia, with a post office; 197 miles W. of Washington.

PAJOT, Lewis Leo, Count d'Ansembourg, in Biography, a French nobleman, was born at Paris in the year 1678. He received the advantages of a liberal education, and having discovered an inclination for mathematical pursuits while he was very young, he was instructed in the philosophy of Descartes. After this he took a tour to Holland, where he formed an acquaintance with Huigens, Rayth, Boerhaave, and other person distinguished by their profound knowledge in literature and the sciences. He was appointed director-general of the arts in France, and conducted the business of that department in such a manner as entitled him to the esteem of the public, and the confidence and favour of his sovereign. Upon the death of his father, the count came into possession of a country-seat at Bercy, where he determined to establish a scientific museum; and he spared neither trouble nor expense to furnish it with rarities of nature and art, and with philosophical and mechanical instruments, and machines of every description. In a short time his cabinet was enriched with a great number of curiosities, particularly in mechanics and natural history, on which account it was visited by Peter the Great, the emperor of Germany, and by other princes. It was thought to be the most valuable museum in Europe, and was unrivalled in articles connected with the doctrine of mechanics. In the Transactions of the Academy of Sciences, of which he was a member, there are several of his papers; among which is a description of an "Instrument for the Measurement of Liquids"—of "An Arceometer, or Wind Gage"—of a "Machine for heating regular Time in a Clock." He died in 1752, bequeathing his museum to the academy.

PAIR, Pan, a collective term, used for two equal or similar things ordinarily joined together; though more frequently for artificial things than for natural ones. As, a pair of gloves, of stockings, of shoes, &c.

PAIR is also used in compound things, for two parts alike or each other, though they only make one whole. As, a pair of scissors, &c.

PAIR is also used for a set or syllable of several things joined to make another complete: as a pair of bagpipes, &c.

PAIR, again, is used, by extension, for a thing that is single, as a pair of tables, &c.

PAIR of Nerves, in Anatomy, the right and left corresponding nerves, which are almost everywhere alike in the body. See Nervous System.

PAIR, in Geography, a river of Peru, which loses itself in a lake near Tadou, in the province of Farfian.

PAIRAN, a town of Siuh, one of the Philippine islands; inhabited chiefly by Chinese merchants and artificers.

PAIRUMBAUCUM, a town of Hindostan, in the Carnatic; 30 miles W. of Madras.

PAISHAWUR, or PEISHWAR, a city of Candahar, and capital of a district, in Cabulistan, on the Kameh. In 1738 this town was taken by Nadir Shah; 125 miles S.E. of Cabul. N. lat. 33° 18'. E. long. 70° 36'.

PAISLEY, a large town and borough of barony, in the county of Renfrew, Scotland, is situated at the distance of six miles and half a mile westward from the city of Glagow, on the banks of the White-Cart river. It probably owes its origin to an abbey, which was founded here in the year 1160. It did not, however, rise to be a place of much importance till after the union in 1707. From this period, the inhabitants began to direct their attention to manufactures, which have ever since been gradually on the increase, and have rendered Paisley at present, second only to Edinburgh and Glagow, among the towns of North Britain. According to the parliamentary returns of 1811, it contains 2951 houses, and a population of 36,785 persons, including the two suburb parishes of Abbey, East and West.

James IV. king of Scotland, granted to Paisley the first charter, constituting it a borough, in 1488, at the intercession of George Shaw, then abbot of the monastery. Under this grant it enjoys all the privileges of a royal borough, except the right of being represented in parliament, and of sending delegates to the general convention at Edinburgh. The corporation or magistracy consists of three bailies, and fourteen councillors, who are elected annually, besides a treasurer, town clerk, and other inferior magistrates. The bailies are invested with the full powers of justices of the peace, and take cognizance, in the first instance, of all offences committed within their jurisdiction.

At the commencement of the last century, Paisley is described as consisting only of one principal street, about half a mile in length, with a few narrow lanes branching out on either side. Now, however, it is an extensive and well built town, and contains many excellent public and private edifices, especially in that part called the New Town, which stands on the eastern bank of the Cart, and is laid out with great regularity. Over the river are three bridges, placed at convenient distances, and connecting with each other the buildings on its opposite sides, that is, the New and Old Town, with their respective suburbs. The streets are in general well paved and lighted, and exhibit all the marks of opulence and industry, some of them being crowded with warehouses and manufactories, occupied by the merchants and tradesmen. The whole town is built of stone, and in all the modern streets the houses have squared and smooth freestone fronts, in the same manner as those of Edinburgh and Glasgow.

Paisley contains three parish churches, and several chapels of ease and dissenting meeting houses, but none of them are peculiarly remarkable as buildings, except the abbey church, which will be described in the sequel of this article. The edifices appropriated to public business, charity, or amusement, are all of modern erection. The hospital or poor-house was built in 1752, and is under the management of fifteen directors. It is a large structure, with an extensive garden attached, and is supported by a small assessment on the inhabitants at large. The town-hall is a handsome building of cut stone. The butcher market is probably the nearest and most commodious range of stalls in Great Britain. The front is of hewn stone. No public theatre has yet been erected here, but there are rooms appropriated to concerts and assemblies. A large subcription room, on the plan of the Glasgow tontine, has been erected within the last five years.

Paisley has attained its present rank and importance from its manufactures; and hence it seems proper to give a flight sketch of the rise, and of the progressive changes which have undergone at different periods since their first establishment. At the time of the union, and for some years after, fearlessly any other goods were produced here, but coarse linen checks, and a kind of striped cloth, called Bengal; and even these were manufactured only on a very limited scale. When a free trade, however, was opened with England, the spirit of manufacture began to display a

K 2
itself in Paisley, with a vigour seldom paralleled. This effect resulted in a great measure from the exertions of pedlars, or, as they are called in Scotland, packmen, many of whom, having accumulated a small capital, settled in this town and its vicinity, and became resident manufacturers. The experience of what would suit the taste of the people, and the connections they had established in the course of their travelling career, afforded many advantages in their new occupation, of which they did not fail to avail themselves. They first improved the quality of the linen cloths above-mentioned; but these in a few years gave way entirely to articles of a lighter and more fanciful design; such as linen gauze and lawns; both plain and ornamented. The manufacture of thread was introduced about the year 1750, and still continues to afford employment to a large portion of the inhabitants. In 1760 the manufacture of silk gauze was begun by Mr. McKerral of Hillhouse, and soon displaced the linen cloths as the staple produce of Paisley. Before that period, the patterns and designs of all fancy goods were made at Paris; but the Paisley manufacturers disdaining the servility of imitation, established their own forms of their own, whose productions were thought not only to rival, but to excel those of the French artists. Hence such a variety of elegant and richly ornamented gauzes was issued from this town, as surpassed every thing that had hitherto appeared. Spitalfields was compelled almost to abandon the manufacture; and several companies came down from London to carry it on, on the banks of the Dart, where it flourished beyond any manufacture which any town in Scotland could boast of till the invention of Arkwright's machinery for spinning cotton, by rendering fabrics of that material both cheap and elegant, almost excluded filks from any share in female drabs, when it of course declined, and is now almost abandoned. Following the tide of fashion, the manufacturers of Paisley turned their exertions into the new channel, and soon brought their cottons into competition with those of Manchester itself. The whole neighbouring waters were speedily occupied with spinning mills and bleach-fields, and many thousand persons took up the employment of weaving cottons here and in the surrounding villages.

Besides these principal manufactures, Paisley has some others of a more local description, likewise conducted on an extensive scale; tan works, and soap and candle works are numerous, and there is also a calico printing work, a copperas work, and several manufactories for tape and ribbons.

The most important remain of antiquity in Paisley, or indeed in the county of Renfrew, is the monastery already mentioned, as having probably been the nucleus which determined the origin of the town. It was first bounded as a priory by Walter lord high steward of Scotland, and filled by him with monks of the order of Cluny; but afterwards attained the rank of an abbacy. The lands belonging to it were further erected by Robert II. into a regality under the jurisdiction of the abbot. At the reformation this abbey was secularized; and towards the close of the sixteenth century, it was constituted a temporal lordship in favour of Lord Claude Hamilton, who was created lord Paisley in 1591. His son James, earl of Abercorn, afterwards sold it to the earl of Angus, by whom it was alienated, in 1653, to William, earl of Dundonald, and continued in his possession till the year 1704, when it was repurchased by the late earl of Abercorn. The monks here are supposed to have been the authors of the "Chronicon Cluniacensium," or "The Black Book of Paisley," as it is usually called, from the colour of its boards. This curious monument of antiquity is a chronicle of the public affairs of Scotland during several centuries, and is frequently quoted by Buchanan. It was long in the possession of the president Spottiswood; after his death it was carried into England by general Lambert, and was subsequently deposited in the king's library at St. James. Many additions have been made to the buildings of this abbey at different eras since its original erection. Abbot Shaw, in particular, enlarged and beautified the whole monastery, and indeed may properly be regarded as a second founder. He built the refectory and other offices necessary for the monks, the church and the precinct of the convent; and inclosed the gardens and orchards by a wall of hewn stone, which measured about a mile in circuit. This wall, observes Mr. Pennant, (Tour in Scotland; "is a very noble and extensive one, and indicates the ancient grandeur of the place." On a stone at the north-west corner is this very singular inscription.

"Thy call it the Abbot George of Shaw
About my Abbey gart mak this saww;
An hundred four hundredth zeir
Eighty-four the date, but weir
Pray for his saluie
'That laid this noble foundation."

All the buildings of this abbey are much dilapidated, excepting the chancel of the church, which is still entire, and has of late years been fitted up for parochial service. Judging from this member, and some additional ruins, the church appears to have been, when complete, a very grand and magnificent structure. It was in the form of a cross, but the only part of the transept standing is the great north window, the arch of which is uncommonly lofty and elegant. The chancel is separated into a middle and two side aisles, by two ranges of columns, supporting pointed arches, and having their capitals ornamented with grotesque figures. The exterior of this building displays much sculptural embellishment, especially the north and south doors.

Near the abbey church is an old chapel, which is appropriated as the burying place of the Abercorn family. It is remarkable for its echo, which is probably the finest in Europe, as its effects are said to surpass those of the whispering gallery at St. Paul's. "When the end door (the only one it has) is shut, the noise is equal to a loud and very distant clap of thunder; if you strike a single note of mufic, you hear the sound gradually ascending till it dies away, as if at an immense distance, and all the while distilling itself through the circumambient air; if a good voice sings, or a musical instrument is well played upon, the effect is inexpressibly agreeable." In this chapel is the monument of Marjory Bruce, daughter of Robert I. king of Scotland, and mother of Robert II. Here were likewise interred Elizabeth Muir, and Euphemia Rofs, both conforts to the monarch last mentioned. The former died previous to his accession to the Scottish throne.

Of the Roman camp mentioned by Camden, as situated close to Paisley, very few vestiges remain; the valis are nearly levelled, and the ditches filled up. Of the outworks to distinct marks are now visible, excepting one which was constructed at a spot near bearing the name of Caille Head. A military road led to this entrenchment, which is supposed to have been the Vanduara of Ptolemy.

Elderlie, in the vicinity of this town, is noted, in the annals of Scotland, as the birthplace of the illustrious Sir William Wallace. (See Wallace.) Pennant's Tour in Scotland. Beauties of Scotland, vol. iii.

PAIT, a provincial term applied to a badger.

PAITA, GIOVANNI, of Genoa, in Biography, flourished early in the last century, and was called by all the great masters,
maiters, king of tenors; they speak still in Italy of the
erit of this admirable singer, who was likewise an ex-
cellent actor, and a fine performer on the harpsichord.

PATA, in Geography. See PAYTA.

PAITAN, a town on the N. coast of the island of Born-
eo. N. lat. 6° 32'. E. long. 117° 28'.

PAITLEY, or PATELEY-BRIDGE, a small market town
in the parish and liberty of Rippon, lower division of the
wapeake of Claro, and well riding of Yorkshire, England,
is situated on the river Nidd, at the distance of twelve
miles W.S.W. from Rippon. The market is held on Sat-
urday, and here are four fairs annually. Neither the town nor its
vicinity present anything remarkable. It is somewhat
ingular that it should not be mentioned in the late population
reports, though several townships in the same parish are there
noted. Beauties of England and Wales, vol. xvi. by
J. Bigland.

PAITSEPOO, a town of Little Buccharia; 50 miles
E.N.E. of Cashgar.

PAKA, a town of Bohemia, in the circle of Konig-
gratz; 18 miles N.W. of Koniggratz. N. lat. 50° 25'.
E. long. 15° 22'.

PAKANG-YAY, a town of the Birman empire, situ-
ated on the Irrawaddy, containing several neat temples, and
surrounded by lofty palmry, tamarind, and banyan trees;
25 miles S. of Pagahm.

PAKASHASANA, a name of the Hindu deity Indra,
regent of the visible heavens.

PAKIR, or PACIR, in Geography, a sea-port town
of Arabia, in the province of Oman, the inhabitants which
carry on a considerable trade to India. Its environs abound
in cattle, grain, dates, raisins, and other fruits; 25 miles
E. of Dofar.

PAKOLTSZ, a town of the duchy of Warsaw; 34
miles N. of Gnefna.

PAKOLTSZ, a town of Scavonia; 20 miles N.W. of
Pozega.

PAKUPZKI, a town of Croatia, on the Kupa; 20
miles E. of Carlstadt.

PALA, in Botany, a name by which some authors have
called the nutmeg-tree.

PALA, in Geography, a town on the W. coast of the island
of Celebes. S. lat. 2° 32'. E. long. 119° 9'.

PALA, in Ichthyology, a name used by some authors for a
fish of the truttaeatus kind, more usually known by the
dame of serra. See GUINIAD.

PALACE, PALATIUM, a name generally given to the
dwelling houses of kings and princes.

Procopius derives the word from a Grecian called Pallas,
who gave his own name to a magnificent house he had built;
adding that Augustus, after him, gave the name palatium to
the house of the Roman emperors on the hill which for that
reason was called the Palatine mount. Others take it the
contrary way; and say that Romulus's house, in which Au-
gustus lived, was properly called palatium, because situate
on the Palatine mount. Be this as it will, it is certain, palatium,
from a proper name, in time became common to all houses
of kings.

And as the kings usually heard and determined causes in
their houses, in what part of the realm they were
situate; hence also palatium became a name for a court of
justice, which usage is still retained, especially in France.

In course of time the name palace has also been applied
to the houses of other perons; taking different epithets,
according to the quality of the inhabitants; as imperial pa-
lace, royal palace, pontifical, cardinal, episcopal, duca-
lace, &c.

PALACIOS, Los, in Geography, a town of Spain, in
the province of Seville; 10 miles S.E. of Seville.

PALACIOS, a town of Spain, in the province of Leon;
eight miles S. of Astorga.

PALADIA, a town of Hindostan, in the circuit of Aun-
rungabad; 48 miles S.E. of Aurungabad.

PALEMON, Quintus Remmius, in Biography, a ce-
lebrated Roman grammarian in the reigns of Tiberius and
Claudius, was a native of Vicenza, and domestic slave to a
woman of that place, but by attending her son to the aca-
demy he acquired so much knowledge, that she gave him
his freedom, and he opened a grammar school at Rome.
He gained great reputation as a rhetorician and poet, but
his morals were so loose, as to be considered a very improper
preceptor for young people. His income, however, as
teacher was very considerable, but quite inadequate to his
luxurious mode of living. The remains of this writer, who
was so arrogant as to say that letters were born, and would
die with him, are "Ars grammatic," printed among the
"Grammatici Antiqui," of which the best edition is that of
1605; and a treatise "De Ponderibus et Menfuris," printed at
Leyden in 1587, which has been ascribed to another
writer of the same name.

PALEPHATUS, a Greek philosopher of whom a
tratise "πέιρας ἰωτίως Αὐτίων" remains; its subject is the explica-
tion of ancient fables. It has been several times reprinted
in the Greek and Latin; but the best edition is that of Ficher,
Lipf. 1761. It must be observed that there are several an-
cient writers of this name; one an Athenian, placed by
the poets before the time of Homer; one a native of Paros, who
lived under Artaxerxes Memon; and one, a grammarian
and philosopher, born at Athens or in Egypt, posterior to
Aristotle. Which of these is the author of the work already
noticed, is not at all certain.

PALESTE, the name of a Greek measure of length,
being the same as andere, and consisting of four finger-
breadths, or digits.

PALESTRA, παλαίητρα, among the ancient Greeks,
a public building, where the youth exercised themselves in
wrestling, running, playing at quoits, &c.

Some say, the palestra conformed both of a college, and an
academy; the one for exercises of the mind, the other for
those of the body. But most authors rather take palestra to be
a xylus, or mere academy for bodily exercises, according
to the etymology of the word, which comes from παλάσ, a
wrestling, one of the chief exercises among the ancients.
See Pale.'

The length of the palestra was marked out by flapis,
each equal to one hundred and twenty-five geometrical paces;
and hence the name fladium was given to the arena, whereon
they ran.

PALÆSTROPHYLAX, formed from παλαίητρα, and
φυλαξ, guardian, or keeper, among the Ancient, was the di-
rector of a palestra; and of the exercices performed therein.

This officer was also called xylarcha and gymnaarcha.

PALEFOX v MEXDEZ, D. JUAN DE, in Biography,
a Spanish prelate, was born of a noble family at Arragon,
in the year 1600. He studied at Salamanca, after which he
was appointed a member of the council of war, and next
of that of the Indies; but he renounced civil distinctions for
the ecclesiastical state, and was made a bishop in Spanish
America, with the title of judge of the administration of
the three viceroyes of the Indies. Zeal for the interests of
the church involved him in some difficulties, and he was com-
pelled to recite himself to save his life. His conduct was,
however, in every respect approved by the king, and he was
appointed to the bishopric of Olma in 1653, in which he
continued
continued till his death, in 1659. He was a voluminous writer, but the works by which he is chiefly known are the "History of the Siege of Fontarabia," and "The History of the Conquest of China by the Tartars." PALAFUGELL, in Geography, a town of Spain, in Catalonia; 20 miles S.E. of Gerona.

PALAIS, L'E, a sea-port town of France, and capital of the island of Belle Île, situated on the E. coast, and defended by a citadel, with good anchorage in the road; containing two churches, and about 200 houses; 24 miles S.E. of L'Orient, N. lat. 47° 17', W. long. 13° 41'.

PALAIS, St., a town of France, in the department of the Lower Pyrénées, and chief place of a canton, in the district of Maulèon, seated on the Bidouze; 21 miles S.E. of Bayonne. The town contains 1000, and the canton 14,673 inhabitants, on a territory of 530 kilometres, in 42 communes. N. lat. 43° 15', W. long. o° 50'.

PALAIZEAU, a town of France, in the department of the Seine and Oise, and chief place of a canton, in the district of Verfailles; seven miles S.E. of Verfailles. The place contains 1750, and the canton 9560 inhabitants, on a territory of 150 kilometres, in 17 communes.

PALAKA, a town of Turkish Armenia, in the government of Kars; 60 miles N.N.E. of Kars.

PALALACA, in Natural History, the name given by the people of the Philippine islands to a bird common among them, and somewhat resembling the upupa, or hoopoe. From the description which father Camili gives of this bird, it seems very plainly to be a species of woodpecker, of a very large and beautiful kind. See Picus Bengalensis.

PALAMADA, in Geography, a town of Bengal; 28 miles S.E. of Doega.

PALAMBANG, or PALAMBANG, a river of Sumatra, which takes its rise in the country of Moosfe, near the W. coast, and within a day or two's journey from that of Beng- coolen, and is the most advantageous for navigation of any in the island. High up, on its banks, the pepper is cultivated, and purchased at the natives at a very cheap rate — Alto, a town and kingdom of Sumatra. The town is situated on the above mentioned river, and is the capital of the kingdom, which is very extensive, and comprehends the island of Banca. Palambang is peopled mostly by Javans, in consequence of that part of the island being formerly under the jurisdiction of the Bantam empire, whence its sovereigns derived their appointment. It has been since under the immediate protection of the Dutch government at Batavia, who have had a chief and factory there, and procure from it pepper and tin. It has likewise been an useful mart to them, for rendering opium and other commodities from the west of India. The inhabitants of Palammah are mostly supplied with opium, salt, and piece goods from Palambang. The king's agent comes up the river in large boats, which are towed against the stream. Thus the goods are conveyed to a place called "Mooarro Moulang," from whence they are transported on men's backs to that country. The voyage by the river is said to take up 14 days; but the journey from Mooarro Moulang, where they disembark, to Palammah, is performed in one. Their returns are mostly in a species of twine called rope, silk in its roughest state, and elephants' teeth. The tin, though exported from Palambang, is dug up in the island of Banca, which covers the mouth of the river, and constitutes a trade of considerable importance. The king of Palambang, whose dominions are very extensive, receives as far as the hills of Lampoon to the southward, and comprehending the island of Banca, accumulates immense riches. It is said that the quantity of pepper brought annually from Palambang is about 2,000,000 lbs, which is purchased at the rate of two rivers per lb. The Dutch company likewise take about 1000 carats of rough diamonds, and a considerable quantity of canes and rattans. For these commodities a large sum in specie is yearly required to balance with the king. In 1774 the Dutch company rebuilt there an old ruined fort in a pentagonal form, at the charge of about 7320l. flooring. S. lat. 2° 50'; E. long. 104° 39'. Maridens Sumatra. Stavorinus's Voyage, vol. 1.

PALAMBUAN. See PALAMBUAN.

PALAMCOTTA, a town of Cavite.

PALAMEDEA, the Screamer, in Ornithology, a genus of birds of the order Grallæ, of which the generic character is: bill conic, the upper mandible hooked; nostrils oval; feet four-toed, cleft, a very small membrane connecting the toes at the root. There are only two species of this genus.

Species.

CORNUTA; Horned Screamer. Wings with two spines at the head; the front is horned; hence its specific name. The birds of this species are about as large as a turkey; they have on the crown of their head a flight horn rising perpendicularly, about three inches in length. They feed on herbs and seeds, and perhaps on reptiles. They are found in Guiana and other neighboring territories of South America, chiefly in the low and marshy grounds. These birds are never observed but in pairs, and so faithful, tender, and constant is their attachment, that the death of one is generally attended with a degree of distress and grief which destroys the other. While young they are eaten, but their flesh is of very dark color, though not ill tasted. The legs are black, and so is the bill; the irides golden; body above blackish, beneath white; wing reddish beneath; spines strong, sharp, horny, triangular, yellow; horn on the front recurved, round, whitish, three inches long; the hind toe is straight. They lay two eggs, which are about the size of those of a goose.

CRISTATA; Crested Screamer. Wings unarmed; front crested. It inhabits Brazil, and is about the size of a heron. The bill and legs are yellowish; the irides golden; crest black variegated with cinereous, erect; the body is mixed with Rufous and brown; the hind toe is placed so high as not to touch the ground in walking. The birds of both species, on hearing the leafy noise, or seeing any person, though at a distance, rise from the ground, and make a loud screaming noise.

PALAMEDES, in Biography, a distinguished Greek, was the son of Nauplius, king of the isle of Eubæa. At the time of the Greco-Roman confederacy for the expedition against Troy, Palamedes is said to have contrived the counterfeited infantry of Ulysses, who had acted the madman, in order that he might be excused from accompanying the other princes. In reparation for this exploit, Ulysses contrived to bury a sum of money in the tent of Palamedes, and then to charge him with having received a bribe from Priam. The discovery of the treasure was deemed evidence of the fact, and Palamedes was floned to death for the crime of treason. To him are attributed the invention of weights and measures; the art of drawing up a bateau; the regulation of the year by the course of the sun, and of the month by that of the moon; likewise the games of dice and even ends are ascribed to him. Pliny confirms that during the siege of Troy he invented the four letters in the Greek alphabet θ, ε, ζ, ξ; but Philostratus ascribes to him only the ζ and ξ. He has been mentioned as a poet, and Suidas says his poems were suppressed by Agamemnon, or by Homer.

PALAMOS, in Geography, a sea-port town of Spain, in
PAL

in Catalonia, on the coast of the Mediterranean, fortified and defended with a castle; 22 miles S.E. of Gerona. N. lat. 41° 50'. E. long. 2° 58'.

PALMOW, a town of Bengal, and capital of a circuit to which it gives a name. The circuit is bounded on the N. by Bahar, on the E. by Kosumbah, Corea, and Nagpur, on the S.E. by Burahah, on the S.W. by Sirgojoo, and on the W. by Bittoume, about 80 miles long and 40 in its greatest breadth. The capital is 120 miles S.S.W. of Patna. N. lat. 23° 48'. E. long. 84° 20'.

PALAMPONG, a town on the W. coast of the island of Leyte. N. lat. 10° 58'. E. long. 124° 14'.

PALANA, a town of Peru, in the audience of Quito; 50 miles S. of Lima. - Also, a town on the W. coast of the island of Lecuon, at the entrance of Calgaran bay. N. lat. 16° 45'. E. long. 122° 14'.

PALANDO, a town of South America, in the province of Quito; 45 miles S. of Lima.

PALANE, a river of Africa, which runs into the Indian sea, near Mozambique.

PALANKA, a town of European Turkey, in Bulgaria; 40 miles S. of Sophia. - Also, a town of European Turkey, in Paffarabah, on the Diclef; 32 miles N.W. of Akerman.

PALANQUIN, or PALANKEEN, a kind of caife, chair, or litter, borne by men on their shoulders; much used by the people of China, and the Easfs, as a vehicle for their easy conveyance from place to place.

PALANTONE, in Geography, a town of Italy, in the department of the Lower Po; 13 miles N.W. of Terrara.

PALANY, a town of Hindostan, in Bahar; 7 miles S.E. of Bahar.

PALANZA, a town of Italy, on the W. side of lake Maggiore; 15 miles S.E. of domo d'OCoelho.

PALAOOS. See New Philippines.

PALAPARIJA, in Zoology, the name of a species of East India serpent, found in the island of Ceylon. It is a large kind, and beautifully variegated in colour, with a great deal of red about it. It is one of those species which naturally live underground.

PALAPETY, in Geography, a town of Hindostan, in the province of Dindigul; 18 miles N. of Dindigul.

PALAPOUR, a town of Bengal; 22 miles E. of Bogilpoor.

PALAPRAT, JOHN, in Biography, a poet and dramatic writer, was born at Toulouse in the year 1650. He distinguished himself from his youth by a talent for poetry, and obtained several prizes at the Floral games of that city. He was brought up to the legal profession, and obtained some offices of consideration, in which he conducted himself with great credit. At length an attachment to literature, and a natural simplicity of character, gave him a dislike for business; and after a visit to the wits of Paris, he went to Rome in 1686 for the purpose of being introduced to the celebrated queen Chirtilina, then resident in that metropolis. Thence he returned to Paris, which afterwards became his principal abode. In 1691 the duke of Vendome attached him to his person in quality of secretary. He employed himself, at Paris, chiefly in theatrical compositions, and he contracted an intimacy with the abbe Brueys, in concert with whom he wrote several pieces for the stage. Of their conjoint performances, three have kept their place on the stage, with one of his sole composition. He also wrote eight diffcouries on different subjects, and published a volume of poems. He died at Paris in 1714, in the seventy-second year of his age. The character of his works is gaiety and vivacity, with an air of simplicity, but with little regard to correctness. His dramatic pieces are contained in the collection of those of Brueys.

PALARIA, among the Romans, a kind of exercise performed at a lake by the soldiers.

The lake being fixed immovable in the ground, and fixed feet close up to it, the young undisciplined soldiers advanced against it armed with a hurdle and cudgel, i. e. a hedge of a shield and sword, and went through all the rules of attack and defence, as if actually engaged with an adversary. Sometimes they stood at a distance, and attacked it with miffive weapons, at the same time using all the requisit motions for defending themselves, and warding off what might be thrown against them.

PALASBARY, in Geography, a town of Bengal; 6 miles N.N.E. of Goragot.

PALASBONA, a town of Bengal; 16 miles S. of Buxton.

PALASCO, a town of Corsica; 14 miles N. of Corte.

PALAZJ, a town of European Turkey, in Servia; 15 miles S.W. of Belgrade.

PALATCA, or PALATAS, a town of Asian Turkey, in Natalia, near the coast of the Archipelago; 8 miles N. of Milet. N. lat. 37° 31'. E. long. 27° 12'.

PALATCHY, a town of Hindostan; 15 miles S. of Combetore.

PALATE, the upper part or roof of the mouth in animals of different kinds.

In a horse it should be lean, for if it be full and high, so as to be nearly level with the extremities of the upper teeth, the leaf height in the liberty of the bit will be troublesome, and make him either check in the bridle, and be always throwing up his head, or otherwise carry it too low, which, besides the unfightliness, much annoys the rider's hand.

PALATE, in Anatomy, the roof of the mouth. It is the arched superior boundary of that cavity, and, at the same time, the inferior surface or floor of the nose. The anterior two-thirds of it are made up of the palatine plates of the superior maxillary and palatine bones, surrounded by the teeth and covered by a firm membrane: the posterior third is a movable membranous and muscular organ, called the soft palate, velum palatini or palate molle. These parts are more minutely described in the article Dgglutation.

PALATE, Discause of. See Tonsils and Vclula. A description of the defective state of the palate, frequently accompanying the bare-lip, is noticed in the article Hare-lip.

PALATI OSSA, in Anatomy, two small bones of the upper jaw. See Cflanix.

PALATINATE, PALATINATUS, a province or fignory, possessed by a palatine, and from which he takes his title and dignity.

The palatinates now subsisting, are either those of Germany or Poland. Those of Germany are the principalities of the Upper and Lower Rhine, d. e. of Bavaria, and the Rhine.

The palatinates in Poland are the provinces and districts of the Polish grandees or senators, who are the governors thereof.

PALATINATE of the Rhine, or Lower Palatinate, in Geography, a country of Germany, in the circle of the Lower Rhine; bounded on the N. by the electorate of Mentz and Catzemibogen, on the E. by Catzenelboigen, the electorate of Mentz, the bishopric of Worms, and a part of Franconia, on the S. by Wurttemberg and the bishopric of Spire, and on the W. by France, the duchies of Deux Ponts and Simmern, and the county of Sponheim. Its greatest extent is about 80 miles. Although the country
PAL

is mountainous, it is uncommonly fertile, and produces plenty of corn, pulse, fruit, chestnuts and walnuts, and its pasturage seems to yield a good breed of cattle. It has plantations of tobacco, particularly between Heidelberg and Mannheim, and also good Nectar and Rheinhof wines (See Bergstrasse). The Rhine traverses this electorate palatine; and out of the lands near Germerheim and Veltz is washed the best Rheinhof gold, to which the Rheinhof gold flowers over their origin. The electorate palatine contains 41 towns and several boroughs. The ecclesiastical state has undergone many changes, as the doctrines of Calvin and Luther have alternately prevailed ever since the reformation was first introduced in the year 1518. The name and origin of the "Palatines" are deduced from the palatia, or palaces, which the old Frankish and German kings and emperors possessed in various places, and over which they appointed stewards and judges, who were styled "Pfalzgraves" or "Pfalzgraves." The addition of y or on the Rhine first occurs in the year 1092. The electoral palatinate, ever since the reformation of the Upper Palatinate to the electors of Bavaria, paid only one-half of the electoral evaluation. All that part of the palatinate which lay on the left side of the Rhine was by the peace of Lunéville ceded to France, and forms the department of Mont Tonnerre.

PALATINE, Upper, a part of Bavaria, bounded on the W. and N.W. by Franconia, on the E. and N.E. by Bohemia, and on the S. by the duchy of Neuburg and Lower Bavaria. In the 12th century this country belonged to the dukes of Swabia: it was afterwards annexed to the palatinate of the Rhine. By the peace of Baden, in 1714, it was ceded, after some previous changes of masters, to the electors of Bavaria. The capital is Amberg.

PALATINE, Palatinus, in Anatomy, an epithet applied to many parts about the roof of the mouth: as the palate artery, a branch of the internal maxillary, fee Artery; the palate glands, fee Deglutition; the palate ducts, which were supposed communications between the nose and mouth through the anterior palate holes or foramina incilvia; the palate nerves, branches of the superior maxillary, fee Nerve; the palate processes, of the face, on the maxillary and palate bones. See Cranium.

PALATINE, Count Palatine, Comes Palatinus, in Ancient Cylones, was a title given to all persons who had any office or employment in the prince's palace.

The appellation is derived hence, that anciently the emperors sent the judges of their palaces, whom they called comites palatini, or pales-graves, to correct the abuses of the other judges in the provinces of Saxony, Bavaria, Franconia, and the Rhine.

Matthieu says, that the palatines were originally those who had the superintendence of the palace, the fame with what the Greeks called epipelaios, and the French maistres du palais; though in time the name became more general.

The title of count palatine is now appropriated to the princes of Sulzbach, Deuponts, and Berkenfeld, who are three branches of the same family. The elector palatine is a prince of the first of these branches, i.e. the prince palatine of the Rhine.

Palatine was afterwards a title conferred on those delegated by princes to hold courts of justice in the provinces; and on such among the lords as had a palace, i.e. a court of justice in their own houses.

The French writers make the palatines of Champagne to be the first who bore that title; which, they will have it, the Germans and other people borrowed from them, not they from the Germans.

At present the word palatine is restricted to a prince of Germany, or a lord of Poland, possessor of a palatinate. In the code we find a title "De palatinis facrum turris.

PALATINE, in Geography, a port-town of America, in Montgomery county, New York, on the N. side of Mohawk river and W. of Caghawaga; containing 3517 inhabitants. The compact part contains a reformed Dutch church, and 20 or 30 houses; 36 miles above Scheneectady.

PALATINE Bridge, a bridge of ancient Rome, now called St. Mary's bridge, which crosses over from the present church of St. Mary the Egyptian, at the lower end of the forum basilicum to the via Transiberina. This bridge was supposed to be that which Livy speaks of (Decad. 4. 1. 10), built by M. Fulvius, washed down by the Tiber, and afterwards rebuilt by the cenfors Sepicio Africano and L. Mumius. Another inundation having damaged it, pope Gregory XIII. repaired it, partly upon the old piles, in the year 1575. But another inundation sweeping away some of it in 1598, it has never since been repaired, so as to be serviceable.

PALATINE, County. See County.

PALATINE Mount, one of the seven principal hills inclosed within the walls of ancient Rome. Whether the Palatine hill received its name, from a people called Palantes or Palatini, or from the hooting and thrbling of cattle, in Latin balare and palare; or from Pales, the pastoral goddess; or from the burying place of Pallas, is disputed among the learned, and undetermined. Here, however, Romulus laid the foundation of his city, in a quadrangular form; and here the fame king and Tullus Hostilius kept their courts; as did afterwards Augustus and all the succeeding emperors; on which account the word "palatium" came to signify a royal seat. To the E. of this hill is Mons Celius, to the S. Mons Aventinus, to the W. Mons Capitolinus, and to the N. the forum. Its compass is 1200 paces. Romulus's house, preferred for several ages by the care of the senate, was on this hill, near the spot where the church of St. Anacalia now stands; as was also that of his foster-father Fafulius, near the place now occupied by the church of Santa Maria Liberatrice.

PALATINE Games, ludii Palatini, among the Romans, were games instituted in honour of Julius Caesar, as Rome will have it, or, as others say, of Augustus, and celebrated in his palace during eight days, from the sixth calendar of January. Suetonius informs us, that Caligula attended these games when he was affaiphined. "Cum placeretur palatinis luidis spectaculo egressum meridie aggregi:

It is pretended, that Dion calls them Augufaltia; which should seem to confirm the second opinion. Indeed, it is certain, that he says Livia instituted particular games in the Palatine Mount, in honour of that prince, but he apparently distinguishes them from the called Augiftalia. The Romans had also their Apollo Palatins, a name of that deity, given him in respect to the temple erected to him by Augustus on the Palatine Mount, in consequence of a report of the arufpices, which required it to be done; Augustus enriched it also with a noble library; as is intended by Horace, lib. i. epift. iii. ver. 17.

PALATINE Tribe, was one of the four tribes into which Rome was anciently divided by Servius Tullius.

Servius Tullius added a fourth tribe to the three tribes into which Rome was divided by Romulus; and having inclosed the seven hills within the city, and divided it into four quarters, which he named from the principal hills they contained, he assigned to each tribe its appropriate district. Thus, the inhabitants of the Capitoline mount, the Palatine mount, and the space between these two hills, composed the
PAL

the first tribe, called "Tribus Palatina." They who dwelt in the quarter called Suburra, containing mount Caelian, formed the second tribe, which retained the name of "Tribus Suburranus." The inhabitants of the Equilone mount were called "Tribus Equilina." And they who lived on the mounts Vinimalis and Quirinalis, bore the name of the hills on which they were placed, and were called "Tribus Collina" or "Collatina."

PALATINI. See ACOLYTHI.

PALATO-PHARYNGEUS, in Anatomy, a muscle of the palate. See DEGLUTITION.

PALATO-STAPHYLINUS, a synonym of the azygus uvulae.

PALATULUNGA, in Geography, a town of Hindooflan, in Coimbatore; 15 miles S.W. of Errood.

PALATUM MOLLIS, in Anatomy. See PALATE.

PALAVAI, in Geography, a town of the island of Ceylon; 48 miles W.N.W. of Candy.

PALAVASOURY, a town of Hindooflan, in the circuit of Jodhpur; 15 miles E. of Jodhpur.

PALAVIA, in Botany, so named in honour of Don Antonio Palau y Verdera, professor of Botany in the royal garden at Madrid, who translated the Philobiblum Botanicum of Linnaeus into Spanish, and who, according to Cavanilles (see his Diff. fac. 1. 5.), has given much attention to the genera and species of plants. This gentleman is the author of several botanical or economical treatises in his native tongue. His name appears, with that of Ortega, (see ORTEGA,) in the title-page of a Curto elemental de botanica, published at Madrid, in 1785, which is perhaps the translation of Linnaeus above-mentioned; but it contains, moreover, a Spanish version of the essential generic characters of that author. Cavanilles wrote the name of this genus Palavus, which Schreber has properly corrected. Schreb. 404. Wild. Sp. Pl. v. 3. 1737. Mart. Mill. Dict. v. 3. (Palava; Cavan. Diff. i. 140. Jaffa. 271. Lamarck Illusr. t. 577.)—Cliffs and order, MONANDRIA Polyandra. Nat. Ord. Columnifere. Linn. MALVACEAE. Jaffa.

Gen. Ch. Cal. Perianth simple, inferior, of one leaf, each half way down into five segments, permanent. Cor. Petals five, roundish, inserted in the base of the tube of the filaments. Stam. Filaments numerous, united below into a tube, separate above; anthers roundish. Pfl. Germin superior, globose; style short, divided in the upper part into many segments; stigmas capitare. Peric. Capsule roundish, of many cells, which do not burst, and are clothed about an elevated central receptacle. Seeds solitary, roundish, angular.

Obs. This genus differs from Malope, merely in having a simple calyx. We have already (see MALOPE) mentioned professor Martyn's remark concerning it, and now adopt it on the authority of the above authors.

2. P. rosiiflora. Wild. n. 2. Cavan. Diff. 1. 41. t. 11. f. 5. Leaves downy. Flower-flasks longer than the foot-flasks. Stem erect. —Native of sandy ground about the town of Lima, where it was gathered by the celebrated and unfortunate Dombey, flowering in September. The root is annual, long and fibrous. Whole plant clothed with soft short down, and smelling of musk. Stem erect, branched, Vol. XXVI.

leafy, two feet high. Leaves on short thick stalks, alternate roundish-heart-shaped, obtuse, waved and crenate, about two inches long. Stipulas small, lanceolate, dark-coloured, Flowers solitary, on simple axillary stalks, longer than the leaves. Calyx bell-shaped. Petals yellowish-purple, about an inch long.

PALAWAN, in Geography. See PARAGUAY.

PALAZOL, a small island in the Adriatic. N. lat. 45° 46'. E. long. 14° 47'.

PALAZZOLO, a town of Italy, in Friuli; 14 miles S.W. of Palma la Nuova.—Alfo, a town of Italy, in the department of the Mela; 15 miles W. of Brescia.—Alfo, a town of the island of Sicily, in the valley of Noto; 20 miles W. of Syracuse.

PALCATU, a lake of Tartary, in the country of the Eulths, called also "Tchoi." 30 miles W. of Barcas.

PALARIFS, a town of South America, in the province of Wucuman; 50 miles W.N.W. of St. Fernando.

PALLAS, in Geography, a town of Hindooflan; 30 miles S. of Tinevelly.

PALTOS, a town of Italy, in the province of Caiana; 5 miles N. of Cusabang.

PALINDANO, a town of Italy, in the Campagna di Roma; 5 miles E.S.E. of Palestrina.

PALÉ, Pales, a little pointed stake, or piece of wood, used in making inclosures, separations, &c.

The pole was an instrument of punishment and execution among the ancient Romans; and still continues so among the Turks. Hence empalgement; the passing a sharp pale through the fundament up the body.

PALE, in Heraldry, is one of the honourable ordinaries of an escutcheon; being the representation of a pale or stake, placed upright; consisting of two perpendicular lines, drawn from the top of the base to the escutcheon, and continuing the third middle part of the field.

When there are several, more properly called pales, they are proportioned so as that two take up two-fifths of the field; and three take up three-sevenths; and, in those cases, the number of species are specified, as well as that of those they are charged with, &c.

Pales are borne various ways, as wavy, crested, faulx, indented, ingrailed, &c. There are also the comet, and flaming pale, which are pointed, sometimes waved, &c.

Pales, in heraldry, is applied to things borne one above another, in manner of a pale.

Pales, Party per, is where the shield is divided by a single line through the middle, from top to bottom. See Pales.

Pales, Wrestling, in Antiquity, one of the exercises of the Olympic stadium, first introduced into it in the 18th Olympiad; and Eurybalus, a Spartan, was the first who received the wrestler's crown. Thoth, according to Plutarch, is reported to have been the first who reduced wrestling into a science; and in processes of time, though the rules which he laid down are unknown, it was much cultivated by the ancients.
cient. The most remarkable difference between the ancient
and modern practice of this art is, that the ancient wrestlers
contended naked, and that their bodies were rubbed all over
with oil, and with a certain ointment, composed of a due pro-
portion of oil, wax, and dust, mixed up together, which
they called "ceroma." These ointions, as some say, were pe-
cular to the wrestlers, or pancratists, whose combats were thus
rendered more toilsome and various; while each combatant
endeavoured to seize upon the other, whose efforts to escape
or break the hold of his antagonist were allayed by the
slipperines, as well as the force and agility of his body.
In order, however, to qualify this extreme lubricity of the skin,
occasionally by this ointion, the athletes were accoutumed,
before they came to an engagement, either to roll themselves
in the mud of the palestra, (from which some persons derive the
words pale and palestra, παλαιστρα, signifying mud,) or in the
sand kept for that purpose, in a place called χῶρα, or that
with which the place of combat seems to have been covered.
It is certain, whatever was the mode of doing it, that the ath-
letae, who were anointed, were always, before they engaged,
sprinkled with dust or sand; so that to lay an athlete gained
a victory, κόμποι, and without being fo sprinkled, was the
same thing as to lay he gained a victory without en-
gaging; which, indeed, sometimes happened, when, either
from the great reputation of the champion, or other reasons,
one appeared to encounter him. This office of anointing
and sprinkling the combatants was sometimes performed by
themselves to one another, and sometimes by the officers of
the palestra, called from thence αλίπτα, or anointers.

After the wrestlers were thus prepared for the engagement,
they were matched by the judges or presidents of the games
in the following manner. Into a silver urn, consecrated to
Jupiter, and brought forth upon this occasion, were cast so
many lots or dice, about the bigness of a bean, as answered
to the number of the competitors. These lots were all marked
with letters; as for example, upon two of them was written
the letter Α, upon two others, and so on in an alphabetical
order; if the number of combatants required more,
there were always two lots marked with the same letter. This
being done, the athletes approached in order, and invoking
Jupiter, put their hands into the urn, and drew out each his
lot; to prevent all fraud, an officer appointed for that pur-
pose attended upon every one as he came to draw, and held
up his hand before him, to hinder his seeing the letters writ-
ten upon the lot. When every one had drawn, the Al
tarches, or one of the presidents of the games, going round
to every athlete in order as they flood, inspected the lots.
And thus the two, whose lots were both marked with the
same letter, as with Α or Β, were by him matched and ap-
pointed to engage with each other. This was the case
when the number of the combatants was even, as four, eight,
twelve; but when the number was odd, as five, seven, nine,
&c. there was put into the urn, together with the duplicate
lots, an odd one, marked with a letter to which there was
none that corresponded. The athlete who was fortunate
enough to obtain this lot, was named ephedrus, was to wait
till the others had contended, and was then to take up one of
the conquerors. This, as Lucian observes, was a very con-
 siderable advantage; as the champion, who by virtue of his
lot was to wait till the others had contended, and then engage
with one of the conquerors, came fresh and vigorous to the
encounter, against an adversary, animated indeed and flushed
with conquest, but shattered and exhausted in obtaining it.

The wrestlers, being thus matched, proceeded to the comb-
bats, in which the victory was adjudged to him who gave his
adversary three falls; as seems to be evident, from the famous
epigram upon Milo, which will be produced in the sequel
of this article.

If one of the combatants in falling drew his antagonist with
him, the contest began afresh, or was rather continued upon
the ground, until one getting uppermost, constrained his
adversary to yield the victory. This combat was called
amelingapel, and seems not so much to be a dillinct species
from, as a modification of the pale; or an accidental, or
perhaps artificial variation of the battle: for he who found
himself in danger of being thrown, had sometimes recourse
to this irrationing of dragging his adversary with him, and
trying upon the ground a combat in which he thought himself
better qualified to succeed. However, those authors who
have written upon the pale, have made this a distinct ex-
cercice; and it is not unlikely but it may have been treated as
such in the gymnalia, or schools of exercise; where there
were masters whose business it was to give their scholars dif-
tinct lessons in every branch of the science they professed to
teach: from which custom one may very well account for
the many divisions and subdivisions of the pale, and other
gymnastic exercises, of which modern writers have made fo
many distinct species. Of this kind is all likelihood was the
acrocheirias; so named, because the combatants, during this
part of their engagement, held one another only by the
fingers, without seizing on any part of the body. This has
been reckoned a distinct exercice, and another division of the
pale; though, as Montf. Buretts very well observes, it seems
rather to have been the prelude of the combat, in which the
antagonists made trial of each other's strength, or endeavoured,
perhaps, by feizing each other's hands, mutually to prevent
one another from taking a firmer and more advantageous
hold.

The champion who distinguished himself the most in this
exercice, was Milo of Crotone, who gained no less than nine
Olympic, and as many Pythian crowns. There are so many
influences of the prodigious strength of this famous wrestler,
and most of them to well known, that it would be endless
and impertinent to cite them all: but we cannot forbear pro-
ducing one, as remarkable for the singularity, as the ifue
of the experiment.

This Milo, to give a proof of his astonifhing force, was
wont to take a pomegranate, which, without squeezing or
breaking it, he held fo fast by the mere strength of his fin-
gers, that nobody was able to take it from him; nobody
but his mistres, says Ελία. But however weak he may
have been with regard to the fair sex, his superior force was
universally acknowledged by the men, as will appear by the
following epigram:

When none adventur'd, in th' Olympic band
The might of boil'rous Milo to withstand;
Th' unrival'd chief advance'd to seize the crown,
But 'mid his triumph he'd unwar'd down.
The people shun'd, and forbade below
The wreath on him, who fell without a foe.
But rising, in the midst he flood, and cry'd,
Do not these falls the victory decide?
Fate indeed hath giv'n me one, but who
Will undertake to throw me th' other too?
Well's Pindar.

PALEARIUS, Aonius, in Biography, an elegant and
liberal scholar, and martyr to the cause of the reformation,
was born about the beginning of the sixteenth century, at
Verul. in the Campagna of Rome. The name of his family
was Della Pagha, and his baptismal name was Antonius,
both which he changed to the classical form under which he
PAL is known. Having studied six years at Rome, he quitted it on the approach of the imperial army in 1527, and took up his abode at Perugia, Sienna, Padua, and other places, improving himself by attendance on the most celebrated professors. He fixed at length at Sienna, where he married in 1536, and opened a private school for some young men of rank. Here he passed some years tranquilly in the bosom of his family, till the freedom of his opinions began to excite against him many enemies. The suspicion into which he fell, as being a favourer of the new opinions, gave the monks a handle, and they publicly accused him of heresy. He was brought before the archbishop and governor. On this occasion he wrote an oration, in which, though he did not avow the opinions imputed to him, he spoke of them in a way that showed what he thought upon those points. He was acquitted, but was successfully opposed in his attempts to obtain a professorship in the university. In 1544 he published a work "On the Merits of Chiril," which was written on the principles of the reformers. He received an invitation, in 1546, to take the professorship of eloquence at Lucca, with which he complied, and exercised that office for several years. In 1555 he was invited to Milan, to succeed Majorino in the chair of eloquence. He resided quietly in that city till the accession of pope Pius V., who having been a Dominican and Inquisitor, began his reign with the severe persecution of heresy. Palearius was one of the first victims to his cruelty; the charges exhibited against him were very serious, and of these he was found guilty, and condemned to the flames. The sentence was executed in July 1570. Such was the lamentable fate of one who was universally admitted to be moral, pious, and learned. Of the writings of Palearius, the best known is his poem "De Immortalitate Animorum," in three books, first printed at Lyons in 1536. Its verification is formed upon that of Lucretius, rather than that of Virgil. It has been reprinted in several collections of select Latin poetry by Italians. His other works are fourteen orations on different subjects, letters, and poems, all written in a pure Latin style. After his death was printed a work entitled "Actio in Pontifices Romanos et eorum Asseclas," which he had composed a short time before the meeting of the council of Trent, with an intention of getting it presented by the embassadors of the emperor. It is said to be an eloquent plea in favour of the reformed religion.

PALECKE, in Geography, a town of Prussia, in the province of Oberland; 14 miles S.E. of Muehringen.

PALED FLOWERS, in Botany, are those which have thin leaves set about, or surrounding a head, or thum; as marguolds, &c.

PALEE, in Geography, a town of Hindoostan, in Oude; 45 miles W. of Kairabad.

PALEMON, in Mythology, a deity so called by the Greeks, the same with the Melicartus of the Phocians, and Portumnus among the Romans. See PORTUMNUS.

PALENCIA, in Geography, a city of Spain, in the province of Leon, which has a very ancient bishopric, suffragan to Burgos; the bishop enjoys a revenue of 2500l. to 2900l. and bears the title of count. This town is situated in a fertile territory, watered by the little river Carrion, on the banks of which it stands. Most of the edifices of this town are in the Gothic style; and the most remarkable is the church built and dedicated to that saint by king Sancho, after having escaped great danger in hunting wild boars. At the beginning of the 13th century, this town had an university, established by Rodrigo the bishop, and the first founded in Spain after the invasion of the Moors. In 1239, this university was removed to Salamanca. Its district, called the Tierra de Campos, is remarkable for its fertility. It contains 5 churches, 11 convents, and 2 hospitals; 57 miles S.E. of Leon. Lat. 41° 59'. Long. 4° 34'.

PALENO, a town of Naples, in Abruzzo Citala; 9 miles E. of Sulmona. Lat. 43° 3'. Long. 14° 2'.

PALENEQUE, a town of Mexico, in the province of Chiapa; 60 miles S.E. of Chiapa de los Espagnoles.—Alfo, a small island in the Spanish main. N. lat. 9° 30'. W. long. 79° 5'.

PALENSEN, a town of Welfphalia, in the principality of Calenberg; 6 miles S. of Hanover.

PALENZUELA, a town of Spain, in Old Castile; 25 miles S.W. of Burgos.

PALEO-CASTRO. See POLICASTRO.

PALEOCASTRO, a town on the N. coast of the island of Lemno. Lat. 40°. Long. 43° 55'.

PALEOTTI, Gabriel, in Biography, a learned Italian cardinal, descended from an illustrious family, was born at Bologna in the year 1524. He was intended for the profession of the civil and canon law, and made a rapid and very successful proficiency in the study of literature and jurisprudence, at the university in his native city. He was in early life appointed to the canonry of Bologna; after which he was appointed professor at the university. Here he acquired high fame by his lectures and publications, and was distinguished by the accuracy of his judgment and the goodness of his taste. Being led to visit Rome, he was appointed by cardinal Alexander Farnefe, who had been his fellow-student at Bologna, and who was just appointed perpetual legate of Avignon, governor of Vaflion, in the county of Venafin, which he was led to decline, on account of some family concerns which he was obliged to attend to at Bologna, where he remained the professor's chair. The Farnefe family were, however, resolved to make him a favour, and obtained for him the post of auditor of the rota, when he was only thirty-three years of age. When pope Pius IV. opened the council of Trent, he sent Paleotti thither in the capacity of procuror and counsellor to his legates, who took no step of importance without his advice. Of this council Paleotti wrote a history, which still remains in MS. In 1565 he was raised to the dignity of the purple by Pius IV. and by Pius V. he was created bishop of Bologna, and that see was erected into an archbishopric by the same pope, to do honour both to Paleotti and his native country. So exemplary was Paleotti in his diocese, that it was with the greatest reluctance that the pope summoned him to attend the consultations and other business at Rome. He died at Rome in the year 1597, when about the age of seventy-three. He was author of several works of considerable merit, on subjects in antiquities, jurisprudence, and morals. Of these the most considerable are the following, "Archipeiopale Bononienfis;" "De imaginibus Sacris, et Profanis;" "De Sacri Confiniori Confulationibus;" "De Nothiis. Spuriisque Fabulis;" "De Bono Senectu;" "Pastoral Letters, &c. Moreri.

PALEPATO, in Geography, a town of Naples, in Calabria Citala; 10 miles S. of Raffano.

PALEPOLI, a sea-port of Asiatic Turkey, in Carmania, on the S. coast; 220 miles S. of Cogni.

PALERMO, an ancient city of Sicily, in the valley of Mazzara, the seat of the viceroy, and the see of an archbishop, was built on the site of the ancient Panormus, (which see,) and situated on a bay to which it gives name, on the north coast, well fortified, with a harbour, the entrance of which is defended by two strong citadels. This bay, as well as Palermo, is at the bottom of a great gulf, formed to the eastward by cape Zofarano, and the mountain

L 2 of
of Catalfano, and to the westward by mount Pellegrino, the ancient Ertea. Under this hill, which is both high and steep, and the top of which affords a very beautiful and extensive prospect, and commands the most advantageous view of the situation of Palermo, a mole has been formed, where vessels of all sizes obtain a secure shelter. This city, according to Brydone’s account, is greatly superior to Naples in beauty and elegance. Although it is not so large, yet the regularity, the uniformity, and the neatness of its streets and buildings render it much more pleasing; it is full of people, who have mostly an air of affluence and gaiety. It stands near the extremity of a kind of natural amphitheatre, formed by very high and rocky mountains; and the country that lies between the city and these mountains is one of the richest and most beautiful spots in the world. The whole appears a magnificent garden, filled with fruit-trees of every species, and watered by clear fountains and rivulets, that form a variety of windings through this delightful plain. From the singularity of this situation, as well as from the richness of the soil, Palermo has had many flattering epithets bestowed upon it, particularly by the poets; who have denominated it “Conca d’Oro,” the golden shell, expressing both its situation and richness. It has likewise been styled “Aurea ballis,” “Hortus Sicilicus,” &c. and to include all these together, the lauding term of “Felix” has been added to its name, by which it is even distinguished in the maps. Palermo is built upon a very regular plan; its two great streets intersect each other in the centre of the city, where they form a beautiful and regular square called the Ottangolo, adorned with very handsome and uniform buildings. The centre of this square commands the whole of the noble streets and the four great gates of the city which terminate them, and which are at the distance of about half a mile; the diameter of the city being no more than a mile. These are elegant pieces of architecture richly adorned; particularly the Porta Nova and Porta Felice, that terminate the street called the Corfo, which runs S.W. and N.E. The lesser streets in general run parallel to these great ones. The Porta Felice (which is by much the handomest of the gates) opens to the Marinu, a delightful and much frequented walk; bounded on one side by the wall of the city, and on the other by the sea, from which there is, in the hottest weather, an agreeable breeze. In the centre of the Marinu there is an elegant kind of temple, which serves as an orchestra for music in the summer months. This city contains, besides an university, many churches, abbeys, seminaries, convents, and hospitals. Many of the churches are extremely rich and magnificent. The cathedral (Madre Chiesa) is a very venerable Gothic building, of a large size, supported within by 80 columns of oriental granite, and divided into many chapels, some of which are extremely rich, particularly that of St. Rosalia, the patroness of Palermo, who is held here in greater veneration than even the Virgin Mary herself. Her relics are preserved in a large silver box, curiously wrought and enriched with precious stones. These perform many miracles, and are looked upon as the greatest treasure of the city. The Sacristie too is very rich. The Jesuits church is singularly magnificent; and the Chiesa del Palazzo is entirely covered over with ancient Mofaic. The church of Monreale, about five miles distant from this city, is the next in dignity in the island, after the cathedral of Palermo. About a mile without the city is the famous convent of Capuchins, remarkable for its burial place. This is a vast subterraneous apartment, divided into large commodious galleries, in the walls of which are numerous niches filled with dead bodies, amounting to about 300, standing upright, and dressed in the clothes which they usually wore. The skin and muscles are rendered, by a cer-
to the N. it had the mountains of Libanus, or rather of Antilbanus, or the province of Phoenicia, and to the S. Edom, or Idumea, from which it was likewise parted by another ridge of high mountains. This was, strictly speaking, the "Land of Promise." Its extent has been variously assigned; some allowing it no more than 170 or 180 miles in length from N. to S., and 140 in breadth from E. to W where widest, as it is towards the S., and about 70, where it is narrowest, as it is towards the N. But of late it has been made to extend to nearly 200 miles in length, and about 80 in breadth, about the middle, and 10 or 15, more or less, where it widens or shrinks. In the ancient writings it is represented to have been exceedingly fertile, rich, populous, and powerful. Before the Israelites took possession of it, Moses has described its fertility and productive powers in Deut. viii. 7, &c. And it is said to have exceeded even the celebrated land of Egypt, in the number of cattle which it bred, and in the quantity and excellence of the oil, wine, corn, and various fruits which it yielded. To this wonderful fertility several circumstances are ascribed, such as the temperature of its climate, the regularity of its seasons, and the richness of its soil. In order to justify the scriptural accounts of this country, it ought to be considered that, in the times to which they refer, it was inhabited by an industrious people, who spared no pains to improve its natural fertility, and to render even its rocks, naturally barren, productive. The fertility of Palestine has been extolled even by Julian the apostate, the avowed enemy both of Jews and Christians, who frequently mentions the perpetuity, as well as excellence, and great abundance, of its fruits and products. The visible effects of divine displeasure, which this country has experienced, not only under Titus Vespasian, but much more since that emperor's time, in the inundations of the northern barbarians, of the Saracen, and of the more cruel and destructive Christians, during the holy war, and in the oppression it now suffers under the Turkish yoke, are causes more than sufficient to have reduced the far greater part of the country into a mere desert. If, indeed, we were to judge by its present appearance, nature itself is so greatly decayed and impoverished, that it is incapable of cultivation. The principal river of Palestine was the Jordan. Under the Romans, Palestine began to be divided into tetrarchies and toparchies; the larger were those of Judea, Samaria, and Galilee, Upper and Lower; the lesser those of Geraritca, Saron, and others of less note, which lay on this side of the Jordan. The rest, on the other side, were those of Gilead, Perea, Gaulonitis, Auranitis, Batanea, and Decapolis. In the reigns of the Chaldean emperors, it was divided into Palæstina prima, secunda, tertiary, or Salutaris, which last included the far greater part, if not the whole country.

Palestine, in its present state (says Volney), comprehends the whole country included between the Mediterranean to the west, the chain of mountains to the east, and two lines, one drawn to the south, by Kan Younes, and the other to the north, between Kaffaria and the rivulet of Yafa. This whole tract is almost entirely a level plain, without either river or rivulet in summer, but watered by several torrents in winter. Notwithstanding this dryness the soil is good, and may even be termed fertile, for when the winter rains do not fail, every thing springs, retains abundance; and the earth, which is black and fat, retains moisture sufficient for the growth of grain and vegetables during the summer. More eurra, famum, water-melons, and beans, are sown here than in any other part of the country. They also raise cotton, barley, and wheat; though the latter be most esteemed, it is lefs cultivated, for fear of too much inviting the avarice of the Turkish governors, and the rapacity of the Arabs. This country is indeed more frequented than any other in Syria, for it is very proper for cavalry, and adjacent to the desert, it lies open to the Arabs, who are far from satisfied with the mountains; they have long disputed it with every power established in it, and have succeeded so far as to obtain the concession of certain places, on paying a tribute, from whence they infelt the roads, so as to render it unsafe to travel from Gaza to Acre. They might have obtained the entire possession of it, had they known how to avail themselves of their strength; but, divided among themselves by jarring interests, and family quarrels, they turn those powers on each other which they should employ against the common enemy, and are at once enfeebled by their disregard of all good order and government, and impoverished by their spirit of rapacity.

Palestine, says Volney, is a district independent of every Pachalic. Sometimes it has governors of its own, who reside at Gaza under the title of Pachas; but it is usually, as at present, divided into three appanages, or Melkana, viz. Yafa, Lound, and Gaza. The former belongs to the Valida, or sultan mother. The captain of Gaza has received the other two as a remembrance for his services, and a reward for the head of Daher. He farms them to an age, who resides at Ramla, and pays him two hundred and fifteen pounds for them, viz. one hundred and eighty for Gaza and Ramla, and thirty-five for Lound.

PALESTRINA, Giovanni Pierluigi da, in Biography. It has been frequently observed, that the life of a studious man, whose mind is more active than his body, affords few materials for biography, even if every transference of his life were known; but at a remote period, when every lineament and trace of character is obliterated, it is with difficulty that the time and place, even of his excellence, can be established, or the works enumerated which his genius and diligence have produced. Palestrina, whose works have been so long justly admired, is of this class; for little more has been recorded of his life, than if it had been wholly spent in a hermitage. His birth, however, has been fixed, with some degree of certainty, in the year 1529, at Palestrina, the Frangete of the ancients. Italy being divided into many independent states, each of which has a diets, and separate honour to maintain, the nates are not only very careful in setting the place where a man of genius was born, but of recording the place where he was educated, with the name of his master; and as the painters of Italy are appropriated to different schools, so are the musicians; and a composer or performer of great abilities is seldom mentioned without his country, by which it is known, that he is of the Roman, Venetian, Nespeliot, Lombard, or Bolognese school, each of which has some peculiar characterisitic, that enables one intelligent musician of Italy immediately to discover the school of another, by his works, or performance. To these distinctions the natives of other countries so little attend, that when it is known that a musician comes from Italy, no further enquiry is made.

From this ancient custom of naming the master with the scholar and his country, all the writers of Italy, who have given any account of Palestrina, have thought it necessary to say, that he was a scholar of Gaudio Mell, Fleming, a Fleming; by whom they have been generally understood to mean Claude Goudimel, a native of Franche-Comté, and a Huguenot, who was one of the sixt that fet the translation of the Psalms, by Clement Marot and Theodore Beza, to music; and who was murdered at Lyons in 1572, on the fatal day of the massacre of Paris.

Who Mell was, if different from Goudmel, we know not; of his works or name we have met with no memorial. Indeed,
Indeed, as the fact is not of sufficient importance to merit a long discussion, we shall leave it as we found it; for who can be very solicitous to know of what matter Palestrina learned the mechanical rules of his art, which were established and very well known, at least a century before his superior genius turned them to so good an account.

However, the few circumstances and outlines of Palestrina's life that have been preferred from oblivion, and seem the most indisputable, are, that he was born in the year 1526; that having distinguished himself as a composer, about 1555, he was admitted into the Pope's chapel, at Rome; in 1562, at the age of thirty-three, he was elected maestro di capella of St. Maria Maggiore, in the same city; as upon the death of Giovanni Animaccia, in 1571, he was honoured with a similar appointment at St. Peter's; and lastly, having brought choral harmony to a degree of perfection, that has never since been exceeded, he died in the year 1594, at the age of sixty-five.

The following account of his death and burial was entered in the register of the Pontifical chapel by Ippolito Gamboce, Puntatore, who at that time had the care of the records.

"February the 26, 1594. This morning died the most excellent musician, signor Giovanni Pierloschi, our dear companion, and maestro di capella of St. Peter's church, the which his funeral was attended not only by all the musicians of Rome, but by an infinite concourse of people, when Libera me Domine was sung by the whole college." To this account Adami adds that of Torrigio, who says: "In St. Peter's church, near the altar of St. Simon and St. Jude, was interred, in consequence of his extraordinary abilities, Pierluigi da Palestrina, the great musical composer, and maestro di capella of this church. His funeral was attended by all the musicians of Rome, and Libera me Domine, as composed by himself, in five parts, was sung by three choirs. Upon his coffin was this inscription: Joannes Petrus Aloysius Præsellinus Musica Princeps.

It would be useless to transcribe all the eulogia that have been bestowed on Palestrina by musical writers, though he has seldom been mentioned by others; but it is left to artifles to take care of their own fame: none but painters have written the lives of painters, or musicians those of musicians. Heroes indeed are configned to historians; and the learned are seldom negligent of themselves.

Indeed very honourable mention was made of our great contrapuntist during his life-time by Giovanni Guidetto, chaplain to pope Gregory XIII. who being appointed to collate, correct, and regulate the choir service of St. Peter's church, 1582, says that he was unwilling to depend solely on his own judgment in this undertaking, and therefore had applied to that prince of musicians, Giovanni Pierluigi da Palestrina, to superintend and correct the whole work, an office which he was so obliging as to undertake; "and if," says he, "the compilation be found to have any merit, it must be chiefly ascribed to his kind assistance." Some judgment may be formed, says the learned author of the "Essay on Counterpoint," to often mentioned, of the great veneration in which he was held by the professors of his own time, from a collection of psalms, in five parts, that was published in 1592, and dedicated to Palestrina, by fourteen of the greatest masters of Italy at that time; among these were Pietro Pontio, already mentioned, and Costanzo Porta, who will be distinguished hereafter as a composer, whose abilities, in point of learning and contrivance, are truly wonderful.

By the assistance of signor Santarelli, we procured at Rome a complete catalogue of all the genuine productions of Palestrina, with the several dates and forms of their publication, title of each work, the name and residence of the printer, which the Italians never fail to record. These are chaffed in the following manner: Magnificats in four, five, and six parts, twelve books; of which lib. i. appeared at Rome in folio, 1554, when the author was in the twenty-fifth year of his age; and in that city only went through three several editions during his life. Lib. ii. of his masses, which includes the celebrated composition entitled "Missa Papæ Marcelli," was published likewise at Rome, in 1567. Of this production it has been related by Antonio Liberati, in the letter above cited, and after him by Adam Berardi, and other musical writers, that the pope and concave having been offended and scandalized at the light and injudicious manner in which the masses had been long set and performed, determined to banish music in parts entirely from the church; but that Palestrina, at the age of twenty-five, during the short pontificate of Marcellus Cervinus, intreated his holiness to suspend the execution of his design, till he had heard a mass, composed in what, according to his ideas, was the true ecclesiastical style. His request being granted, the composition, in six parts, was performed at Easter, 1565, before the pope and college of cardinals; who found it so grave, noble, elegant, learned, and pleasing, that music was restored to favour, and again established in the celebration of sacred rites. This mass was afterwards printed, and dedicated to the successor of Marcellus, pope Paul iv. by whom Palestrina was appointed maestro di capella to the pontifical chapel.

The rest of his masses appeared in the following order:

Lib. iii. Rome per Valerium Duricium, 1570, in folio. Ven. 1599. Lib. iv. Venet. per Ang. Gardanum, 1582, quarto. Lib. v. Rome, 1590. Lib. vi. Ven. 1596. Lib. vii. 1594, Lib. viii. and ix. Ven. 1599. Lib. x. and xi. Ven. 1600. And lib. xii. without date, or name of the printer. Besides the usual rule of publication, these masses were reprinted in different forms and collections, during the sixteenth and seventeenth centuries, in most of the principal cities of Italy; of which editions we are furnished with memoranda.

To the above ample list of the works of this great and fertile composer, are to be added, La Cantica di Salomone, a 5; two other books of Magnificats, a 4, 5, & 6 voc. One of Lamentations, a 5; and another of secular Madrigals. These have been printed in miscellaneous publications after the author's death; and there still remain in the Papal chapel, inedited, another mass, a 4, upon the hexachord, ut, re, mi, fa, sol, la; with his Missa Defunctorum, a 5; and upwards of twenty motets, chiefly for eight voices, a due core.

Nothing more interesting remains to be related of Palestrina, than that most of his admirable productions still subsist. Few of his admirers are indeed possessed of the first editions, or of all his works complete, in print or manuscript; yet curious and diligent collectors in Italy can still, with little difficulty, furnish themselves with a considerable number of these models of counterpoint and ecclesiastical gravity.
If we consider the oratorio and flow manner in which works of this kind are conducted, from the many real parts they contain, and of which some are generally moving in canon, and the rest always in fugue, we shall be as much astonished at the number of his productions, as pleased with their effects. Indeed the works of Aristotle, Cicero, or the elder Pliny, among the ancients, or of Fabricius, among the moderns, were hardly more numerous. With the union, indeed, of great erudition and great industry we are not surprized; but genius is not often so voluminous.

Paley having brought his style to such perfection, that the best compositions, which have been produced for the church since his time, are proverbially said to be alta Palestrina, it seems as if this were the place to discuss its merit.

Though good taste has bannish’d fugue, canon, and elaborate compositions from dramatic music, yet found judgment has still retained them in the church; to which, from the little use that is made of them elsewhere, they are now in a manner appropriated. Indeed there seems no more impropriety in their being occasionally used in the chamber, than private prayer or family devotion. It is the church and stage which we wish to be wholly separated; for it has long appeared to us, that whoever lightly brings the rites of the church to a theatre, or theatrical levity to the church, is guilty of want of taste, judgment, and due reverence for the religion of his country.

In the compositions of Palestrina there is, indeed, no unity of melody; but as all the parts have an equal share of importance, and as hardly a note appears in them without some peculiar intention and effect, they cannot, like the resplendence of a modern concerto or opera longo, be composed with as much rapidity as they could be transcribed; little invention and few flights of fancy are required; yet there is a degree of happiness and genius in finding a few uncommon notes that are favourable to fugue and canon, as well as in creating new and graceful passages in melody. Indeed both the choral and secular style have their peculiar difficulties, beauties, and defects.

Whoever is accustom’d to the vocal fugues of Palestrina, Carissimi, or Handel, will be faulch’d with respect to those of other composers of equal learning. Repeating upon a text has been called a Gothic contrivance; and yet what admirable lections of piety and virtue have been produced under the denomination of sermons! Fire, genius, and harmonious resources are discoverable in fugues, as well as in modern songs, folos, or concertos: a musical student, therefore, unacquainted with the laws of fugue, is advanced but a little way in composition; as the hearer, who receives no pleasure from ingenious contrivance and complicated harmony, is but a superficial judge. Our wish is to resolve the discords of contention, to augment the pleasure of both parties, and extend the compass of their views; that, like the music composed à due cori, the friends of harmony and melody may agree, though performing different parts, at a distance of each other, and to terminate this long article concerning the most venerable patriarch of choral music, of whole style it has always appeared to us, that notwithstanding its general gravity and elaboration, that genius glows in all his productions, in spite of the cram-mels of canto fermo, canon, fugue, inversions, diminutions, augmentations, double counterpoint, or whatever would chill or petrify any other than himself.

It is hoped, therefore, that no apology will be necessary for the length of this article, which "the reader can make as short as he pleases." In a general history of ancient poetry, Homer would doubtless occupy the most ample and honourable place; and Palestrina, the Homer of the most ancient music that has been preferred, merits all the reverence and attention, which it is in a musical writer’s power to give.

Paley, William, in Biography, a justly celebrated divine and philosopher, was born at Peterborough, in July 1743 of the cathedral church of which place his father was a minor canon. Soon after the birth of his son he was appointed head-master of Giggleswick school, in Yorkshire, to which place he removed. Young Paley was now educated under his father’s eye; at school he soon surpassed his contemporaries, and at length obtained a pre-eminence over them all. He was even at this period more attentive to things than to words, and was ardent in the pursuit of knowledge of every kind. He was very curious in his enquiries about mechanism, whenever he had an opportunity of conversing with any workmen, or others capable of affording him information. In his mind he was uncommonly active; in his body quite the reverse.

Soon after he had completed his fifteenth year he accompanied his father to Cambridge, and was admitted a fizar of Christ’s college, November 16th, 1758. Soon after his return, as the classics alone were taught at his father’s school, he went for mathematical instruction to Mr. William Howarth, a teacher of some eminence at Dilhorth, near Tepellif, three miles from Kppton, under whose care he laid an excellent foundation of knowledge in algebra and geometry. In October 1759, he became a member of Christ’s college, and his father, who retained his name Bony, and his name, who faintly appears as a mor(...)
church. In June 1766, he was elected a fellow on the foundation of Chrift's college, which was worth about 100l. per annum, in consequence of which he returned to a residence in the university, took his degree of master of arts, and engaged in the busines of private tuition, which was soon followed by his appointment to the office of one of the college tutors. On the 21st of December 1767, he was ordained a priest by bishop Terrick.

The duties of college tutor Mr. Paley discharged with uncommon affiduity and zeal. Not contented with following the usual method of college-lectures, by which the progress of a student is left to depend chiefly on his own industry, or private assistance, he endeavoured to introduce his pupils to an acquaintance with the most important truths, by arguments and illustrations, which were equally pleasing and forcible. His lectures on moral philosophy, and on the Greek Testament, contained the outlines of the works, by which he afterwards so much benefitted the world, and extended his own reputation; and those works may be said to have owed their origin to the situation, which imposed upon him the duty of delivering the lectures. Mr. Paley at this time acted in conjunction with Dr. John Law, the late bishop of Elphin, and son of the celebrated bishop of Carlisle. The exertions and talents of these kindred souls rendered Chrift's college extremely popular; and while they retained their offices, that society rose to a flourishing state, unequalled, perhaps, in the history of the university. Mr. Paley maintained an intimate acquaintance with almost every person of celebrity in the university. Among his most particular friends were Dr. Waring, and Dr. John Jebb, well known by his talents, his integrity, and his zeal in religious and political controversy. Through his friendship with Dr. Law, he became intimately acquainted with his father, Dr. Edmund Law, who was master of Peterhouse, and who continued chiefly to reside in the university, after he was created bishop of Carlisle. The learned prelate's theological opinions fell greatly below the established standard of orthodoxy, and Dr. Jebb's sentiments were equally objectionable to the zealous friends of the church; on the same account, of course the intimate friendship that subsisted between these learned men and Mr. Paley was viewed with a jealous eye by many, who were closely attached to the established systems. Because he was liberal, he was suspected to be a latitudinarian, and they were prepared to discover dangerous tendencies in his moral and political speculations, should they ever be given to the public. After Mr. Paley had spent about ten years as college tutor, he quitted the university in 1776, and married. His first benefice in the church was the rectory of Muifgrove, in Wiltmoreland, worth only about eighty pounds a-year: this was in the month of May 1775, and in December 1776, he was inducted into the vicarage of Dalston, in Cumberland, after which he was presented to the living of Appleby, in Wiltmoreland, worth about 300l. per annum. and in a short time he was promoted to a prebendal stall in the cathedral church of Carlisle.

While vicar of Appleby, he gave the world a small volume selected from the Book of Common Prayer, and the writings of some eminent divines, entitled The Clergyman's Companion in visiting the Sick. This was first published without his name, but it has passed through many editions, and is now printed among his works. The professional usefulness of this book to the clergy, is no small recommendation of its merits, but when considered as originating in Mr. Paley's personal attention to the spiritual wants of his own flock, it affords an additional proof of his value as a parochial minister.

In the year 1782, upon the resignation of Dr. John Law, who was created an Irish bishop, Mr. Paley was made archdeacon of the diocefe, and not long after he succeeded Dr. John Burn, author of "The Justice of Peace," in the chancellorship. For these different preferments he was indebted either to the venerable bishop of Carlisle, or to the dean and chapter of the cathedral church. While his residence was divided between Carlisle and Dalston, Mr. Paley engaged in the composition of his celebrated work, "The Elements of Moral and Political Philosophy." This production would probably have never seen the light, had it not been for the intigations of Dr. John Law urged him to the undertaking. Mr. Paley for a considerable time objected to the risk of publishing, imagining there would be but few readers for a work on that subject, and he was the more determined on this point after he had entered on the married state, thinking it a duty that he owed to his family, not to clip a book that would probably not find purchasers. To remove the objection, a living having become vacant, of which Dr. Law had the disposal, he presented it to Mr. Paley, on the promise that he would consider it as a compensation for the hazard of printing, and he immediately set about preparing his work for the press. When the MS. was completed, he offered it to Mr. Faulder for 300l. which he refused, proposing 250l. as the full value; in the mean time the author was offered by another person in the trade 1000l. for the copy-right; he felt it his duty to give Mr. Faulder the refual, rising however in his demands from 300l. to 1000l. which the publisher agreed to pay. In 1785 the work was brought out in 4to. with an excellent dedication to the bishop of Carlisle, bearing honourable testimony to the purity of the motives by which that prelate was actuated in his religious researches, and avowing sentiments which reflect the highest credit on the author's ingenuousness and liberality. "Virtue," says Mr. Paley, "is the good doing good to mankind, in obedience to the will of God, and for the fake of everlasting happiness." The good of mankind, therefore, is the subj ect, the will of God the rule, and everlasting happiness the motive of human virtue. All obligation consists in being urged by a violent motive resulting from the command of another. As the will of God, then, is the rule, to enquire what is his duty, or what man is obliged to do in any instance is, in effect, to enquire what is the will of God in that instance, which consequently becomes the whole business of morality. There are two methods of coming at the will of God, viz. by having recourse to the scriptures, or to the light of nature. The tendency of any action to promote or diminish the general happiness, is the criterion for ascertaining the will of God by the light of nature; since the many proofs of benevolence apparent in the works of creation warrant the conclusion, that He wills the happiness of his creatures, and that those actions are agreeable to him, or the contrary, which promote or frustrate that effect. Actions in the abstract, then, are right or wrong according to their tendency. Whatever is expedient is right. It is the utility of any moral rule alone that constitutes the obligation of it. The expediency of any action, however, must be estimated by general rules, and in reference to all its remote consequences, as well as those that are immediate and direct. Right and obligation are reciprocal, for whenever there is right in one person, there must be a corresponding obligation upon others; and since moral obligation depends upon the will of God, right, which is correlative to it, must depend upon the same. Right, therefore, signifies, conformity with the will of God. Such is the outline of our author's theory, which, from its great popularity, we have thought it right to state under the article of
of the author, who has given it to it such celebrity. Concerning
the merits of this work, we may say in the words of an
able critic, “those who are fond of novelty, of ingenious theo-
cries, curious speculations, abstract and metaphysical notions,
will find indeed little in it to amuse or entertain them; but
those who are solicitous to have their confidence properly
directed in the general conduct of human life, to see their
duties and obligations delineated with perspicuity and accu-
tracy, will be fully gratified.” His reasoning on subcription
to articles of religion; and on the British constitution,
in which he disputes the expediency of reform in the house
of commons, and vindicates the undue influence of the
crown in that branch of parliament, is liable to great objec-
tion, and has been attacked, deservedly and fiercely, by
persons of considerable reputation in the literary world. “It
may, however,” says Mr. Meadley, “be esteemed the left
of an ingenious mind to often by interpretation the
vigour of practice, which he could not seriously approve;
and to enlargethe pale of conformity to liberal and con-
scientious men.” Mr. Paley’s casuistry, in this instance,
on the nature and extent of obligation incurred, may be most
effectually answered by his own better reasoning on the pro-
piety of subscription, in his “Defence of Bishop Law’s Con-
iderations,” and in this chapter, “of religious estab-
lishments and of toleration, in the present work.” “In
the one case,” says Dr. Difiey in the works of Jebb, “he
seems to betray the yoke of bondage, in the display of a
very feeble apologetic; in the other, he refumes somewhat
more of his Christian liberty, and recollects the principles
of his Protestant faith.”

On the death of the venerable bishop of Carlisle in 1787,
Mr. Paley drew up a short memoir of him, which has been
injected in Hutton’s History of Cumberland, and in the
Encyclopaedia Britannica, and which, in 1802, was pre-
ixed, with notes supped to have been written by the Rev.
Dr. Difiey, to an edition of the bishop’s Reflections on the
Life and Character of Christ, intended for popular circu-
lations.

The next work which Mr. Paley pretended to the public,
places him in a high rank among the advocates for the truth
and authenticity of the Christian scriptures. It is entitled
“Horae Paulinae ; or, the Truth of the Scripture History
of St. Paul evinced, by a comparison of the Epistles which bear
his name, with the Acts of the Apostles, and with one another,”
which he dedicated to his friend Dr. Law, at that time bishop
of Killala. The grand object of this work is to show, that
by a comparison, of several indirect allusions and references
in the Acts and Epistles, independently of all collateral tes-
mimony, their unconfined coincidence affords the strongest
proof of their genuineness, and of the reality of the tran-
sactions to which they relate. Instead of requiring the truth
of any part of the apologetic history to be taken for granted,
he leaves the reader at liberty to suppose the writings to
behave lately discovered, and to have come to our hands
definite of any extrinsic or collateral evidence whatever.
The design was original, and the execution admirable. Not-
withstanding the title, the utility of the work is not confin-
ed to the learned; the “Horae Paulinae” will furnish the
common reader, as well as the biblical student, with ingenious
criticisms and remarks, which will afford valuable assistance
in the right understanding of St. Paul’s epistles. See Acts
of the Apostles.

Soon after the appearance of this work, Dr. Yorke,
bishop of Ely, made an offer to Mr. Paley of the mastership
of Jesus college, Cambridge, in which the worthy prelate
was solely influenced by the reputation of Mr. Paley’s ex-
traordinary talents, and by a wish to render them servicable
in a high academical situation. After deliberate considera-
tion he declined the honour intended him, but his sense of
gratitude for his lordship’s kindness he publicly expressed
in a dedication prefixed to his work, which he published in
1794, and which is entitled “A View of the Evidences of
Christianity, in three Parts; I. Of the direct historical Ev-
dence of Christianity, and wherein it is distinguished from
the Evidence alleged for other Miracles. II. Of the Aux-
iliary Evidences of Christianity; and, III. A brief Con-
fermation of some popular Objections. This work was
first published in three volumes, 12mo, but in a few months
it was republished in two volumes, 8vo, and has been con-
tinued in this form through many successive editions. It is
perhaps the most complete summary of the evidences of our
holy religion that has ever appeared. It also proffers a merit
of offering a defence of Christianity, which every Christian
may read without feeling the tenets, peculiar to the sect to
which he is attached, in the least dearth.

After the publication of the “Evidences of Christianity,”
the bishop of London, Dr. Porteus, inflircted him to the
prebend of St. Pancras, in the cathedral of St. Paul’s.
This was in August 1794, and in a very short time he was
promoted to the deanship of Lincoln, a preferment of 700l. per ann., by Dr. Prettyman, bishop of that diocese.
In January 1795 he proceeded to Cambridge to take his
degree of D.D. and before he left that place, he was fur-
prized by a letter from the bishop of Durham, Dr. Barring-
ton, with whom he had not the smallest acquaintance, offering
him the valuable rectory of Bishop-Wearmouth, estimated
at twelve hundred pounds a year. When he waited on his
new patron to express his gratitude, his lordship infantly in-
terrupted his acknowledgments; “Not a word,” said he,
“you cannot have greater pleasure in accepting the living
of Bishop-Wearmouth, than I have in offering it to you.”
After reading himself in, as a prebend, at St. Paul’s cathed-
ral, March 8th, Dr. Paley, for he now assumed that title,
immediately proceeded to Bishop-Wearmouth, took pos-
session of his valuable cure, and then returned to Cambridge
against the commencement to complete the Doctor’s de-
gree, and on Sunday July 5th, preached before the princi-
ality his sermon “On the Dangers incidental to the
clerical Character.” From this time he divided his residence
principally between Lincoln and Bishop-Wearmouth, spend-
ing his summers at the latter, and his winters at the former
of those places. At Bishop-Wearmouth the principal land-
owners, wishing to remove even the probability of future
dispute, offered him an annual compensation for the tythes.
He readily acquiesced, and granted them leaves for his
life, and thus, by sacrificing any eventual interest of his own in
the agricultural improvement of the parishes, avoided one
great source of dispute and vexation. In his writings
he had already reproved tythes as noxious to cultivation
and improvement, and recommended their conversion into
corn rents, as a practicable and beneficial alteration, in
which the interest of all parties might be equitably adjusted;
and he now acted in strict conformity to these principles,
leaving to the indulgence of his parishioners their full operation
and entire reward. He next undertook the composition of
his last work, entitled “Natural Theology; or Evi-
dences of the Existence and Attributes of the Deity,
collected from the Appearances of Nature.” In this he pro-
ceded very slowly, and was much interrupted by illness.

This work was published in the summer of 1802; it was
dedicated to the bishop of Durham, for the purpose of
making the most acceptable return he was able for a great
and important benefit conferred upon him. “A weak, and
of late, a painful state of health,” he says, in his dedication,
In this admirable work the author has traced and shewn
the marks of wisdom and design in various parts of the
creation; but he has dwelt principally on those which
may be discovered in the constitution of the human
body. From

Mr. Meadley, to whose work we are greatly indebted for
the facts in this article, says, he faw him for the last time
in December 1804. His valuable life was then drawing fall to-
wards a close; and the powers of nature, gradually ex-
haufted by repeated fufferings, were becoming daily lefsable
to refit the force of his disease. At length, on his return
from his annual refidence at Lincoln early in the month of
May 1805, he experienced a very violent attack, in which
the usual remedies were found ineffectual. He soon funk
under the accumulated influence of debility and dilafe.
He met the approach of death with firmness, comforted his
afflicted family with the consolation of that religion which
he had so successfully taught, and on Saturday May 25th
1805, he breathed his laft. His remains were conveyed to
Carlile, and were interred in one of the ailes of the ca-
thedral by the fide of his firft wife, by whom he had eight
children, wit. four fons and four daughters. His fecond
wife survived him.

In private life Dr. Paley had nothing of the philofopher
about him. He entered into little amufements with a degree
of aridity, which, when contrasted with the superiority of
his mind, had a pleafing effedt, and constituted a very
amiable trait of his character. He was fond of company,
which he had extraordinary powers of entertaining; nor was
he, at any time, more happy than when communicating the
pleafure he could give, by exerting his unrivalled talents of
wit and humour. "No man was ever more beloved by his par-
ticular friends, or returned their affection with greater
fincery and ardor. As a divine, the great aim of Dr. Paley's
labours was to maintain the authority of the gospel, as an
authentic revelation, and to enforce the practice of virtue by
the functions of a future life. His views of the Christian
fystem were at once cheerful and enlightened, and in total
union with the benevolent spirit of the founder. It is gen-

eraliy understood that Mr. Pitt did once recommend him to
his Majesty for a vacant bishopric, and that an opposition
was made from a very high quarter of the church, which ren-
dered the recommendation ineffectual. Mr. Meadley has
endeavoured to account for this obftruction to royal pa-
tronage, and he prefumes that the promotion of Mr. Paley
was impeded by "the freedom of his manner in the story of
The worship of the gods Palici is said to have been derived from Phœnicia, and their name, according to Bochart, comes from the Hebrew word "Palichin," of palac, colere or venerari, and signifies Venerable; which the poet Æschylus, from whom Macrobius has borrowed the tale of their origin, seems to imitate, when he said Jupiter ordered the gods Palici to have the title of venerable given to them. However this be, the Palici were very much honoured in Italy; and Diodorus affirms, that they had a temple near the city Erice, revered both for its antiquity, and for the wonderful things that happened in it. Accordingly we are told by Macrobius, after Æschylus and Diodorus, that near this temple were two small lakes of boiling and sulphurous water, always full without overflowing, which were called "Doli," and held in the highest veneration by the credulous people, who imagined that they were the brothers of the Palici, or rather that this was the place whence they themselves had sprung, when their mother delivered them. Ovid likewise describes them. (Met. i. 5. 405.) It was near these two pools: that solemn oaths used to be made, and controversies determined, which could not otherwise be easily decided. Those who were called to take this oath purified themselves; and after having given security to pay, if the gods condemned them, they approached the pools, and swore by the divinity who prefided over them. If this oath was sincere, they went off unhurt; but perjurers were punished upon the spot, as all authors, who have mentioned it, are agreed.

"Perque lacus altos et olienta sulphure fertur
Stagna Palicorum, rupta ferventia Terrâ."  
Ovid. Met.

"Et qui praestanti dominant perjura Palici
Peclora supplicio."  
Sil. Ital.

But they are not quite agreed as to the nature of the punishment. Macrobius affirms that they fell into one of the lakes, and were drowned; Polenon says, that they died suddenly; Aristotle and Stephanus say they were consumed by a secret fire; and according to Diodorus, some of them lost their lives. As the custom of these oaths came from the East, as well as the worship of the gods Palici, it is not improbable that it was an imitation of what is recorded in the book of Numbers, concerning the trials of the water that was given adulterous women to drink; and the punishments above mentioned were merely a tradition of what befell those who were guilty of the crime of which they were accused. The temple of the Palici was also venerable on account of the prophecies that were delivered there from time to time. Macrobius, after Xenagoras, tells us that Sicily being distressed with famine, they consulted the oracle of the Palici, and were answered, that if they sacrificed a certain hero, whom authors have not named, the famine would cease; which accordingly happened. The Sicilians, in acknowledgment of this blessing, heaped fruits and presents upon the altars of these propitious deities; and this, according to Macrobius, has induced Virgil to say,

"Pinguis ara Palici."

The superstition was afterwards carried to such an extreme, that human victims were offered to these gods; but this barbarous custom was afterwards abolished, and the Palici contented themselves with common offerings. To this the above-mentioned poet alludes, when he says,

"Placabilis ara Palici."

PALICONDA, in Geography, a town of Hindooftan, in the cannatic, 15 miles s. of Polore.

PALLBUS, in Geography, a town of Hindooftan, which runs into the bay of Bengal; four miles s. of Sadras.

PALLICUR, a town of the island of Crete, situated in a bay on the W. coast; 19 miles N. of Trincrima, N. lat. 9° 37'. E. long. 80° 14'.

PALLIAPADA, a town of Hindooftan, in the canmatic; 15 miles S. of Poore.

PALLIKAR, a river of Hindooftan, which runs into the bay of Bengal; four miles s. of Sadras.

PALLIBOTHA, in Ancient Geography, a very considerable town of India, both with regard to extent and wealth, situated on the right bank of the Ganges (intra Gangan) and at the confluence of a large river with it, which river Arrian calls "Erranobos," inferior to none but the Ganges and Indus, and which Pliny denotes Jumnaes (Jumnaeli). This ancient author says, in one place, that the Jumnaes entered the Ganges by Palibothra, between Methora and Chiloba or Caryobara, but in another place he mentions the confluence of the Ganges and Jumnaes, and in the next article says, that Palibothra is situated 425 miles below that point of confluence. Pliny's Palibothra, says major Rennell, is clearly Patna; and it is probable that Strabo meant the same place, by the distance from the mouth of the Ganges. Palibothra was the capital of the Pratii, and in dimensions 80 feet in length and 50 broad, or about ten miles long and nearly two wide.

PALLICAUDERY, in Geography, a town of Hindooftan, in the country of Calcute, taken from Hyder Ali, in 1783, by the British, afterwards evacuated, and at the peace ceded to the English; 26 miles S. of Coimbetore. N. lat. 10° 58'. E. long. 76° 45'.

PALLIC GREEN, incorrectly written Palice or Pallas Green, a small poit-town of the county of Limerick, Ireland. It is situated at the foot of Knock-Green, the hill of the fun, which is remarkable for its bafallic pillars, about a mile from the village, towards Limerick, near the house of Mr. Apsjohn. These pillars, though much inferior to those in the county of Antrim, are calculated to arrest the attention of the traveller, and have led to an examination of the hill, and of other parts of the county, which will probably be laid before the public. Palice Green is 123 miles E. of Limerick, and about 60 miles S. from Dablin.

PALLICI DIY, in Mythology, were the sons of Jupiter by the nymph Thalia. The inhabitants of Sicily adopted these for their deities, and in honour of them erected a magnificent temple at Palico. Their altar became the asylum of the unhappy, and particularly of fugitive slaves. In this temple, according to Diodorus, the most important affairs were transacted, and the most severe punishment was inflicted on perjury.
in the Carnatic; 24 miles W. of Arcot.—Alfo, a town of Hindooftan, in Travancore; 55 miles N. of Ajinga.—Allo, a town of Hindooftan, in the circur of Gooty; 30 miles W. of Gooty.

PALICOUREA, in Botany, Aublet. Guian. v. t. 172. t. 66, a shrub seven or eight feet high, whose wood is white, hard, and brittle, the branches opposite, forming a pyramidal head. The leaves are opposite, on short stalks, oval, entire, pointed, about a foot long and five inches wide, smooth, with a principal longitudinal rib, and numerous parallel transverse ones. Stipules ovate, in pairs, combined, with the base of each, footstalk, at its inner side, so as all together to embrace the branch. Panicules large, terminal, solitary, repeatedly branched, of numerous fragrant scarlet flowers, with orange tubes. Calyx superior, small, with five sharp teeth. Corolla of one petal, funnel-shaped, curved; its limb in five acute segments, the two lower ones smallest. Stamens five, their filaments capillary, inserted about the middle of the tube, and extending as far as its orifice; anthers incumbent, oblong, with a longitudinal furrow. Ger- men inferior, roundish, crowned with a glandular disk; style slender, as long as the corolla; stigmas two, spreading, linear, flat, acute. The young fruit appeared to consist of two cells, with one seed in each.

Such is Aublet's account of his P. guianensis, the only species, which he found in the woods of Guiana, in the district named Caus, flowering in February. No explanation is given of the name. Jullien supposes this plant to be of the same genus as the Simire of Aublet, t. 65, and his Mapouria, t. 67. Willdrow has, very properly in our opinion, referred them all to Psychotria. (See that article hereafter.) Schreber however has made a genus of the Pali- courae, by the name of Stephanium, from stigma, a garland or ornamental crown, on account, as it should seem, of the beauty and brilliancy of the flowers; Schreb. Gen. 124. He records, in his appendix S 22, that Dr. Solander had reduced this shrub to Meliandra; but the description of the fruit by no means countenances such a decision.

PALIFISCO, in Geography, a town of Naples, in Lavora; 5 miles N. of Sezza.

PALIGHERY, a town of Hindooftan, in the circur of Cuddapa; 24 miles W. of Cuddapa.

PALILLA, a feaunt among the ancient Romans in honour of the goddes Pales.

The Pallia, by name called Parilla, were celebrated by the hephers on the day of the foundation of Rome, which, according to Cat, was the 11th of the calends of May, that is, the 21st of April; to beeche that goddes to take care of their flocks, and preferve them from wolves and difeases. On that day the people purified themselves, and also their folds and flocks with water and brimstone, and burned the shrub, called Savine, whose smoke diffused felf all over the fold. After this, they offered in sacrifice to the goddes milk, boiled wine, and mille: then followed the feast.

Part of the ceremony confifted in lighting heaps of fraw, and jumping over them. Ovid (de Feft. l. iv. 271, &c.) describes this whole feomnity at full length. These ceremonies were accompanied with musical instruments, fuch as flutes, cymbals, and tabours, which played all the day long.

PALILICUM, in Afronomy, a fixed ftar of the fiirt magnitude in the Bull's eye; called also Aldebearan.

Pliny gives the name Pallicum to the Hyades, of which the Palicum is properly only one. See TAURUS.

PALIMERDI, in Geography, a town of Hindooftan, in Madura; 35 miles N.E. of Colpetta.

PALINCOTOS, a term used by Hippocrates to exprefs such difeases as are wont to return with all their violence upon the patient, after their seeming to have left him, whether for a longer or shorter period of time.

PALINDJI, in Geography, a town of Hindooftan; 45 miles N. of Travancore.

PALINDROMIA, a term used by Hippocrates, and many other writers, to express a preternatural running of the peccant matter of difeases to the more noble parts.

PALINDROMUS, retrocurrent, running backward, formed of palin, again, and dromos, course, a verfe, or fentence, which reads the fame, when read either backwards or forwards.

Such is the verfe,

" Roma tibi subito motibus ibit amor."

Some people of leasure have refined upon the palindromus, and composed verses, each word whereof is the fame backwards as forwards. As that infance in Camden:

"Odo tenet mulum, madidam mappam tenet Anna."

"Anna tenet mappam madidam, mulum tenet Odo."

PALING, or Paling, in Agriculture, &c. a kind of fence-work for fruit-trees, &c. planted in fields, &c.

It confifts of three small polls driven into the ground, at a foot and a half distance; with crofs bars nailed to each other, near the top.

In fixing the pales, in form of a triangle, room is to be left for the tree to play and bow by the high winds without galling. The trees are to be bound to a flake for a year or two; after which fern or flraw may be fluffed in between the tree and uppermost rails, to keep it upright.

If the place be open to deer, rabbits, or the like, a poft is to be nailed to the bar between every two pales.

PALING-Fence, that fort of fence which is confructed with pales. See FENCE.

PALINGENESIA, Pallescens, formed of palus, antrum, and generis; generation, a new birth, or regeneration.

Palingenensis is also used by some for the migration or passage of the soul of a deceased person into another body.

The palingenesis is almoft the fame thing with the metamorphosis taught by Pythagoras, and still believed by the Brahmans, Banjans, and other philosophers of the Eaft.

Palingenesis is used among chemifs for the repro- ducing a mixed body from its ashes.

This has been pretended to by many, as well as the philo- sophers's stone, and other wonderful powers; but as to the palingenesis, or refalification of plants, the infances produced are no more than fome of those artificial vegetations which the learned Moni. Homberg has obferved and described many times. See Homberg in Mem. Acad. Sciences, 1710; and Boyle's Works Abridg. vol. i. p. 69.

PALINGENIUS, Marcellus, in Biography, a mo- dern Latin poet of coniderable note, who flourished about the commencement of the 16th century, was probably a native of Stellata in the Ferrarefe; whence he assumed the addition of Stellatus to his name. Some persons have imagined that he was physician to Hercules II. duke of Fer- rara, to whom he incribed his poem, entitled "Zodiacus Vitae," i.e. "De Hominis Vita, Studio, ac Moribus op- time Inflituitendis," lib. xii. It is denominated the Zodiac of Life, from its division into twelve parts, each ineribed with one of the signs of the zodiac. Its professed object is to guide men in the road to present and future happines. From his invectives against the church of Rome, he is supposed to have been a convert to the reformation. The poem was placed in
P A L

in the first class of prohibited books in the Index Expurgatorius; and it has been asserted, that his body was dug up, and burned; but very little seems to be known with certainty about the circumstances of his life. The poem has been highly applauded by some, and treated with a good deal of disrespect by others; but it has gone through a great number of editions, of which the best is said to be that of Rotterdam, 1722. It has been translated into the French language.

PALINGMAN, in our Old Statutes, seems to be a merchant-denizen, one born within the English pale. Stat. 22 Edw. IV, cap. 23, and 11 Hen. VII, cap. 29.

PALINGUIR, in Geography, one of the Philippine islands, about 15 miles in circumference, situated on the north of Cape Engano, on the island of Lucon.

PALMISTRY, a word used by Hippocrates to express the hubbing of a tumour by the dispersion of the matter that occasioned it, without its breaking.

PALINODY, Παλινωδας, a discourse contrary to a preceding one.

Hence the phrase Palinody canours, to sing palinody, a d.

to make a recantation.

The word in the original Greek signifies singing again, or anew. Hence it has palled as a general name for any poem, or the like, which contains a recantation in favour of a person whom the poet before had offended.

The poet Stesichorus is said to be the first author of the palinody. The sixth ode of the first book of Horace, beginning, "O mater pulchra," is a true palinody.

PALINTOCA, Παλιντοκα, formed from τοκος, anew, and τοκα, of τοκα, I bring forth, in Antiquity, the birth or delivery of a child a second time.

Thus the second birth of Bacchus, proceeding out of his thigh, was a palintoica.

PALINTOCA is also used for the restitution of usury, or the refunding of interests.

The Megareans, having expelled their tyrant, ordained the palintonica; that is, they made a law, that all the creditors should return to their debtors the interests they had received for money lent.

PALNUM, Cape, in Geography, a cape on the coast of Naples. N. lat. 40° 2'. E. long. 15° 10'.

PALIRRHHEA, a word used by the old Greek authors to express the reflux or retrograde course of the humours, as in case of the cholera morbus, where people vomit up their fluids.

PALISADE, or PALISADO, in Fortification, an incoherence of stakes or piles driven into the ground, each six or seven inches square, and nine or ten feet long; three of which are laid underground. They are fixed about six inches auster, and braced together by pieces nailed across them near the tops, and secured by thick posts at the distance of every four or five yards.

Palisades are placed in the covert-way, at three feet from, and parallel to the parapet or ridge of the glacis, to secure it from being surprized. They are also used to fortify the avenues of open forts, gorges, half-moons, the bottoms of ditches, the parapets of covert-ways; and, in general, all posts liable to surprise, and to which the access is easy.

Palisades are usually planted perpendicularly; though some make an angle inclining towards the ground next the enemy, that the ropes cast over them, to tear them up, may slip.

PALISADES, Turning, are an invention of M. Coehorn, in order to preserve the palisades of the parapet of the covert-way from the beligerent's shot.

He orders them so, that as many of them as stand in the length of a rod, or in about ten feet, turn up and down like traps; so as not to be in fight of the enemy till they just bring on their attack; and yet are always ready to do the proper service of palisades.

PALISADE, in Gardening, denotes a fort of ornament; being a row of trees which bear branches and leaves from the bottom, cut and spread in manner of a wall, along the side of an alley, or the like; so as to appear like a wall covered with leaves.

Their palisades are made of jellamine, phillyrea, &c.

PALISSE, in Heraldry, a range of palisades before a fortification represented on a felle, rising up a considerable height, and pointed at top, with the field appearing through them.

PALISSY, Bernard de, in Biography, an ingenious artist and proficient in natural philosophy, was born at Agen, a city of France, situated on the Garonne, about the year 1524. He was brought up to the trade of a potter, which he carried on at Saintes, and he was also employed as a surveyor and draughtsman of plans. A thirst for information led him to travel, and having by accident got possession of a cup of enamelled pottery, his whole attention was turned upon endeavouring to imitate it. For this purpose he commenced a series of experiments that absolutely impoverished him; he even broke up his furniture to supply his furnaces with fuel, and fold his clothes to furnish his assistant operator with wages. At length his labours were crowned with success, and he perfected himself in the manufacture, that he was immediately raised to the head of his profession. He pursued the science of chemistry, and applied his knowledge to the improvement of agriculture. He was the first person who formed a collection of natural history at Paris, upon which he gave lectures at the rate of half a crown each person, a large sum for that period, but he entered into an obligation to return the money four-fold, provided it were found that he taught any thing that proved false. In 1563 he printed at Rochelle "Recepte veritable par laquelle tous les Hommes de la France pourront apprendre a augmenter leur Trefors, &c." which, after his death, was reprinted under the title of "Moyen de devenir riche," in two vols. 8vo. In 1580, he published "Discours admirable de la Nature des Eaux, en Fontaines, de Metaux, des Solx, des Salines, des Pierres, des Terres, &c." This work was exceedingly valuable in the then existing state of knowledge, and in it he first taught the true theory of springs, and asserted that scoffin-shells were real sea-shells deposited by the waters of the ocean. He also pointed out the use of marle, and of lime in agriculture. This excellent philosopher was sincerely and ardently attached, with regard to religion, to the principles of Calvinism, on account of which he was, in the reign of Henry III. in 1584, apprehended and committed to the Bastille. The monarch, who, it appears, had a true regard for him, plainly said, that if he did not comply with the prevailing religion, he should be constrained to leave him in the hands of his enemies, to which Palissy replied, with energy, "Your Majesty has often said that you pity me; for my part I pity you for pronouncing the words I shall be constrained. This is not speaking like a king; but let me inform you in royal language, that neither the Guifarts, your whole people, nor yourself, shall confine a potter to bend his knee before images." He used commonly to say, in allusion to his religion and his trade as a potter, "I have no other property than heaven and earth." Such are the only facts known of this estimable citizen; the time of his death is not ascertained.
A new and complete edition of his works was published at Paris in 1777, with notes, by Faujas de Saint-Fonds. Gen. Biog.

P. PALIURI, Cape, a cape on the coast of European Turkey, in the gulf of Salonic. N. lat. 39° 56'. E. long. 23° 46'.

P. PALIURUS, in Botany, a name adopted from Dio- forides, but certainly misapplied here. He speaks of his πάλιον, as a well-known prickly shrub, whose seed is fat, or oily, resembling that of flax, and good for coughs, calculous disorders, &c. Dr. Sibbald judged that plant to be possibly the Ziziphus vulgaris or Rhamnus Ziziphus of Linnaeus. The description of the third species of Rhamnus in Dioforides, so exactly accords with our Paliurus, that no doubt can exist of its being what he there described, and consequently not his πάλιον: "The fruit," says he, "is broad, white, thin, shaped like a pouch or box, and resembling a focket or vertebra (παλιον)."

Gen. Ch. Cal. Perianth inferior, of one leaf, in five equal, acute, spreading, deciduous segments, internally coloured; its base permanent. Cor. Petals five minute, with narrow claws, infurled under the glandular disk of the flower, between the segments of the calyx. Stam. Filaments five, short, opposite to the petals; anthers small, round. Pist. Germen superior, roundish, bordered; styles three, very short; stigmas spreading, flat, obtuse, deciduous. Peric. Capsule coriaceous, of three cells, not bursling, globular, surrounderd at the bottom with the permanent base of the calyx, and crowned at the top with a very broad, orbicular, membranous, inflated, notched, horizontally spreading border. Seeds solitary, hard, ovate, compressed, rather thick. Eff. Ch. Calyx tubular, five-cleft; its base permanent. Petals five, opposite to each filament. Capsule coriaceous, of three cells, not bursling, crowned with a flat dilated border. Seeds solitary.

Obg. We are at length induced to separate this genus from Rhamnus, as well as Ziziphus, the fruit affording full as good a distinctive character in one case as in the other. (See Rhamnus and Ziziphus.) The seed-vessel of Paliurus is very peculiar. It has nothing that designates a berry, nor is it a dry drupe, because it conflits of more than one cell, and the seeds can scarcely be termed nuts. Its texture and structure are most like what is observable in Fraxinus and Ulmus. The cells, naturally three, are occasionally but two.

1. P. aufraisii. Chirft. Thorn. Gen. v. 1. 203. (Paliurus; Dod. Pemt. 756. Ger. em. 1336.) Duham. Arb. v. 2. 96. (Rhamnus Paliurus; Linn. Sp. Pl. 281. Pall. Roff. v. 2. 27. t. 62. Rh. territus; Math. Valgr. v. 1. 142. Ziziphus Paliurus; Willd. Sp. Pl. v. 1. 1103. Ait. Hort. Kew. ed. 2. v. 2. 18. Sm. Fl. Græc. Sibth. v. 1. 159.)—Common in hedges and bushes places throughout the north of Europe, as well as in the Levant. Gerarde cultivated it in his garden, and it is sometimes preferred in old-time curios collections, for the sake of singularity, or rather perhaps for the reputation attached to it of having been the thorn with which our Saviour was crowned. This its plant and prickly nature seems to render probable. It is commonly delineated by Italian painters, and we verily believe that, if the facred depoits of superstition were ransacked, this thorn would be found treasured up in them; at least in Italy. Yet Haflelquint lent Linneus from the Holy Land a different thorn, which the latter named Rham-

Gen. Ch. Cal. Perianth inferior, of one leaf, funnel-shaped, coloured; tube short; limb in four obvate segments. Cor. of one petal, funnel-shaped; tube long, with eight plates; limb in four oblong segments. Stam. Fila
tments eight, rigid, permanent, united to the tube of the corolla for more than half its length; anthers ... Pyl. Germens two, superior; style simple, compreife, situated between the germs and parallel to them, connected with its base, its edges finely toothed; ligmas two, spreading. Peric. Capsules two, club-shaped, prismatic, eréct, parallel, close together, membranous, rigid, ubiquously angular at one side, marked with a deep furrow at the other, each of one cell and two finally spiral valves. Seeds very numerous, minute, roundish, somewhat angular. Receptacle spiggy, as long as the capsule, to the edges of whole valves, at the furrowed side, it is attached, being marked there by a simi
lar furrow, while its other side is convex, and its whole surface rough with extremely minute tubercles.

Eff. Ch. Calyx in four segments. Corolla of one petal, in eight segments. Capsules two, superior, parallel, each of one cell, with two valves, and many seeds.

1. P. antarctica. The only species was given to Gär
tner, as far as he could recollect, by Dr. J. Reinhold Forster, for a specimen of his own Sinmera, Forst. Gen. t. 29. From that it proved, on the slightest examination, totally
distinct, for Skinnera is the very same genus with Fuschia. But it may be questioned whether Forster, who studied the new plants of the Southern hemisphere, chiefly by the rules of the Linnaean artificial sytem, without regard to natural orders, might not, in the hurry of collecting, confound these two plants of the Otidia Monogynia, so as to lodge them together in his herbarium, and afterwards forget to distinguish them. Still no two plants can be more distinct, what little we know of the Palladia being too unlike every thing else, to leave a doubt in the mind of any botanist. Of its habit, herbage, or inflorescence nothing is recorded. The capsular are nearly two inches long. The figures above cited seem to represent the remains of the corolla, in four abrupt toothed segments only, which do not answer to the description of Gärtner, the only person who appears to have seen the plant. As Forster's specimens have been pretty generally distributed, it is much to be wished that some relics of this great botanical curiosity might be detected by one or other of their possessors.

PALLADIO, Andrea, in Biography, a famous Italian architect, was born at Vicenza in 1518. He obtained instructions from the poet Trifino, who discovering in him a genius for sculpture and the arts connected with it, taught him the elements of the mathematics, and explained to him the works of Vitruvius. He soon obtained distinction as an architect, and having an opportunity of accompanying his patron to Rome, he employed all his faculties in examining the remains of ancient edifices in that capital, and formed his taste upon them. On his return, the conduct of many works of importance was committed to him, which he managed with great skill, and obtained for himself a high reputation. He was now sent for to Venice, where he built the palace Foscarì in the style of pure antiquity. Several other Italian cities were afterwards decorated with magnificent edifices, public and private, of his construction, and he was invited to the court of Emanuel Philibert, duke of Savoy, who received him with distinguished honours. To Palladio is chiefly attributed the classic taste which reigns in so many of the buildings of Italy. His master-piece is reckoned the Olympic theatre at Vicenza, in imitation of that of Marcellus at Rome. He died in that city in 1580, having greatly improved his art, not only by his edifices, but by his writings, which are standard performances. Of these the following account is given; "His Treatise on Architecture, in four books, was first published at Venice in 1570, and several times reprinted. A magnificent edition in three volumes folio, was published at London in 1715, in Italian, French, and English. Another, equally splendid, has since been published at Venice, in four volumes folio, with the addition of his inedited buildings. Lord Burlington published in London, in 1730, a volume, entitled "Diligenze delle Terme Antiche di Andrea Palladio." He composed a small work, entitled "Le Antichità di Roma." not printed till after his death. He illustrated Cæsar's "Commentaries," by annexing to Bedell's translation of that work, a preface on the military system of the Romans, with copper plates, defigined, for the most part, by his two sons, Leonida and Orazio, who both died soon after." Palladio was modest in regard to his own merit, but he was the friend to all men of talents; his memory is highly honoured by the votaries of the fine arts; and the simplicity and purity of his taste have given him the appellation of the Raphael of architects.

PALLADIUM, in Antiquity, a statue of the goddess Pallas, three cubits high, holding a pike in the right hand, and a distaff and spindle in the left, preferred in Troy, in the temple of Minerva, on which the fate of that city is said to have depended.

The tradition is, that in building a citadel, in honour of Pallas, and a temple in the most elevated part of it, the palla
dium dropped from heaven, and marked out the place which the goddess was pleased to poll the. After this Apollo gave an oracle, importing, that Troy should never be taken while the palladium was found within its walls; which occasioned Diomedes and Ulysses, in the time of the Trojan war, to undertake the fleeing of it. For this purpose, having en
tered the citadel by night, or by means of secret intelligence, they stole away this valuable pledge of the security of the Trojans, and conveyed it into their camp; but they were scarcely arrived, when the goddess gave testimonies of her wrath. To which purpose Virgil makes Simon say:

"Scarce to the camp the sacred image came,
When from her eyes the fiery flame gave
A briny sweat bedew'd her limbs around,
And thrice she sprang indignant from the ground;
Three' she was leen with martial rage to wield.
Her ponderous spear, and shake her blaz'd shield."
It. The grains of platina, as they come from South America, are first to be roasted, to dilute the mercury, and then digested in weak nitromuriatic acid, to separate the gold, and other metals of easy fusibility. The remainder is now to be digested in a sand-bath, with strong nitromuriatic acid. The whole will be dissolved, with the exception of a black feathery powder, from which the metals iridium and osmium are obtained, and of which we have given an account under those articles. The solution contains platina, rhodium, and palladium, with perhaps other metals. The platina is first to be precipitated by a solution of muriat of ammonia. Into the remaining solution immerse a clean piece of zinc, which precipitates the palladium and rhodium in their metallic forms, with the other metals that may be present. This residuum is next to be digested, with weak nitric acid, in the cold, in order to diffuse any easily oxidizable metal that may be present. The remainder, being washed with distilled water, is now to be diffused in nitromuriatic acid. To this solution some muriat of soda is added, for the purpose of forming a triple salt with palladium, which is soluble in alcohol. The solution, with the common salt added, is now to be evaporated to dryness with moderate heat. This residuum is next to be washed with repeated additions of alcohol, till the liquor becomes colourless. The triple muriat of soda and palladium, and the name of platina, if that metal be present, are diffused in the alcohol. The fluid in which the alcohol leaves undifflused is of a red colour, and contains the rhodium in the state of triple muriat of foeda, and the latter metal. If the alcoholic solution fills contain platina, it may be separated by muriat of ammonia. To the remaining solution now add prufiul of potash, which causes an orange precipitate. This being washed and exposed to a tolerable heat, loses its water, and the acid assumes a grey metallic appearance. This substance is lastly to be heated with sulphur and borax in a crucible, when it will afford a metallic button which is pure palladium.

This metal is of a white colour, more of the appearance of platina than any other metal. It is something harder than the above metal, being about the flinthes of jewellers' gold. It is less malleable than silver or platina, owing probably to its greater hardness. Its specific gravity, according to Dr. Wollaston, varies from 11.3 to 11.8. When heated to about 30° of Wedgwood, it assumes a blue colour, owing to its combination with oxygen, in which property it has some resemblance to iron. If, however, the heat be increased, the oxygen flies off, and it re-assumes its original lustre. It does not fuse at the ordinary temperature of furnaces. Although its oxide seems to be formed at a certain temperature in the open air, it has not been procured by these means. An orange oxisy is procured by precipitation from the acids, but not sufficiently pure to get the proportion of oxygen; hence we are at present unacquainted with the oxids of palladium. It does not combine with carbon, nor is it known to combine with hydrogen, nitrogen, or phphorus.

It combines with sulphur, forming a compound, fusible at a low red heat. The sulphur gradually escapes, leaving the metal in a state of purity.

According to the experiments of Chenneix, it forms an alloy with gold of a grey colour; less ductile than other of the metals. Its fracture was crystallized. Its specific gravity was 11.079.

It forms an alloy with platina in equal parts. The alloy is as fusible as palladium. It is less malleable than that with gold. Its specific gravity was 15.141.

It forms an alloy with an equal part of silver, much harder than the latter metal, and winter than platina. Its specific gravity was 11.2. Its alloy with lead is very fusible, hard, and extremely brittle. Its specific gravity was 12. Equal parts of copper and this metal form an alloy of a yellow colour, harder than wrought iron. Its specific gravity was 10.392. Its alloys with tin, iron, bismuth, and arsine, were tried by the same chemist, but had not striking characters.

The oxidy of palladium combines with the acids forming saltine compounds, which have not been much attended to.

The sulphuric, nitric, and muriatic acids, when boiled upon palladium, oxidate and diffuse it; but the nitromuriatic acid acts upon it with the greatest energy. All the solutions are of a red colour. The oxidy is not precipitated from these solutions in a state of purity by the earths and alkalies, owing to its forming insoluble triple salts with most of these saltines. The weight of the atom of palladium is not yet known with precision. Sir Humphrey Davy has flatted it to be about 37 times the weight of the atom of oxygen.

PALLADIUS, in Biography, an eastern prelate and ecclesiastical writer, was a native of Galatia, and born about the year 368. While a very young man he began to travel in foreign countries, and coming to Alexandria, in Egypt, he determined to embrace the monastic life. He spent three years under the discipline of Dorotheus, a celebrated mechanic of Thebes, and in 391 he visited the monasteries, and most celebrated lubricated in the desert of Nitria. At length, having wandered over almost the whole of Egypt, he was obliged, by the inward state of his health, to quit that country, and retire to Palestine. In the year 409, or 410, he went into Bithynia, where he was ordained bishop of Hellenopolis. It is by no means certain whether Palladius, author of the "Lausiac History," and Palladius, author of a dialogue of the life of St. Chryfoltom, written in 408, were different persons, or one and the same. Dupin reckons these works to have been written by the same hand; Tillemont and Fabricius think them the productions of different persons. The facts already cited are taken from the "Lausiac History," so called from Lausius, a man of eminence in the imperial court at Constantinople, to whom it is ascribed. Upon the supposition that it was the same Palladius, the author of the history, who wrote the "Dialogue," the following particulars may be added. He was ordained by St. John Chryfoltom, to whose party he attached himself; and upon the banishment of Chryfoltom, in 404, Palladius fell under persecution, and being obliged to withdraw from his sect, retired into Italy, and took refuge at Rome. Some time after, venturing to return to the East, he was banished to Syene, at the southern extremity of Egypt. Having regained his liberty, he resigned the fee of Hellenopolis, and was appointed to the bishopric of Apfona in Galatia. It is not certain when he died, but it was probably some time before the year 421, since Eusebius, his successor at Apfona, presided at the council of Ephesus, which was held in that year. He wrote the "Lausiac History" about the year 421, which contains the lives of persons, who, at that time, were eminent for their extraordinary auctories in Egypt and Palestine. The style in which it is written is plain and simple; the first edition of it, in Greek, was published by Meursius at Leyden in 1616. In several manuscripts, there is subjouion to the "History" a book concerning the nations of India and the Brahmins, which has been attributed to Palladius, but without any proof of the fact. Cave says nothing can be affirmed of this work, only that it is the production of a Christian writer, who lived before the destruction of the Roman empire. Dupin. Moret. Lapadn. Cave.

PALLANDROS, in Geography, a town of the island of
of Cyprus, situated at the foot of the mountain of St. Croix, anciently called "Palaë," 24 miles N. of Limas-
fol.

PALLANTIA, in Ancient Geography, a town of Hither
Spain, in the country of the Vassiæ ; distinguished, accord-
ing to Appian, by the value of its inhabitants. See Pa-
lercia.

PALLANTHMA, a town of Arcadia, N.E. of Megali-
opolis, and at the extremity of a plain, which, being en-
feebled by a colony detached to Megalopolis, became a vil-
lage in the time of the emperor Antonine, who embellished
it with some fine edifices, in honour of Pallas, Ceres, and
Prorpernix, free from every kind of imposition, and gave
it entire liberty.

PALLAS, being in Astronomy, a small planet, called af-
teroid by Dr. Herchel, discovered 28th March 1802, by
Dr. Olbera, at Bremen, in Lower Saxony, and situated be-
tween Mars and Jupiter. It is so small that it does not
subtend an angle large enough to be measured by our best in-
struments. Its orbit is very eccentric, and it is much inclined
to the ecliptic; ascending above its plane at an angle of
about 35°. The light reflected by it is of a less reddy hue
than that of Ceres, and it is attended by more or less of a
nubulosity, proceeding, perhaps, from a copious atmosphere;
and extending 468 miles from the body of the planet, where
that of Ceres is 675 English miles high; and in this respect,
as well as in the great inclination of its orbit, it appears
to have some affinity to comets.

From Dr. Herchel's observations (Phil. Trans. for 1802.
vol. 91.) we may conclude that the apparent diameter of
Pallas is either o°.17 or o°.13: its mean distance from the
sun 2.8; its distance from the earth, at the time of observa-
tion, 1,8333; and its apparent diameter, at the mean distance,
from the earth from the sun, subtends an angle of o°.3399, so
that its real diameter, if the largest measure be taken, will
be 147 miles; and if the smallest, resulting from a more dif-
tinct observation, be taken, the angle under which it would
be seen from the sun will be only o°.3399, and its di-
ameter no more than 114 miles. (See Asteroid.) The ele-
ments of the orbit of Pallas, as others have stated them, are
as follow:

Tropical revolution                                4° 7' 11" 16'
Sidereal revolution, from Maskelyne's Table       17034 16° 48'
Annual motion                                     2° 18' 11" 16'
Mean longitude, Jan. 1, 1804                      9° 29' 52' 58
Place of ascending node in 1802, from Mask-
   kelyne's Table                                  5° 22' 28' 57
Place of ascending node in 1804, accord-
ing to La Lande                                  5° 22' 28' 0
Place of perihelion                                4° 1' 7' 0
Eccentricity, the mean distance being 1
Inclination of orbit in 1801, according to
   Maskelyne's Table                                3° 50' 40'
Ditto in 1804, according to La Lande              34° 39' 0
Greatest equation of centre                        28 25 0
Mean distance from the Sun, that of the
   Earth being 1                                    2.7910
Mean distance in English miles                     266,000,000
Diameter in English miles, according to
   Herchel                                          80
Ditto ditto, according to Schroeter                2099
Apparent mean diameter, as seen from the
   Earth                                           0.5'

See Planet and Solar System.

PALLANTIA is also a name given by some to the first satel-

PALLAS, in Mythology. See Minerva.

Vol. XXVI.
abounded, and was particularly charmed with the collection of Gronovius, which he repeatedly examined.

Having visited the principal cities of Holland, he directed his course to London, where he arrived in July 1761. The principal intention of his journey to England was to improve his knowledge in medicine and surgery, and to inspect the hospitals. He was now, however, so much engrossed in his passion for natural history, that he neglected every other pursuit, and gave himself totally up to this favourite branch of science. At this juncture, his zeal was so ardent, that after having passed the day in curiously examining the various collections in natural history, and perusing the principal books, he could procure on that subject, he would frequently employ the greater part of the night, and occasionally even whole nights together, whenever he met with new publications that either awakened his curiosity or interested his researches. With a view of extending his information in this department, he took several journeys to the sea-coasts, and particularly in Suffolk.

Being at length summoned by his father to return to Berlin, he quitted London with regret in the latter end of April 1762, and repaired to Harwich in order to embark for Holland. Being there fortunately detained some days by contrary winds, he embraced that opportunity of examining the sea-coast, and collecting a variety of marine productions. On the 13th of May he landed in Holland, and paddling through the Hague, Utrecht, and Amsterdam, he continued his route through the circle of Westphalia, and arrived at Berlin on the 12th of June.

Previously to his commencing the practice of his profession, his father sent him to Hanover for the purpose of procuring the post of surgeon in the allied army; but, as, upon his arrival in that city, in the month of July, peace was on the point of being concluded, he returned by Wolfenbuttel, Brunswick, and Helmstadt, to Berlin, there he passed a year, which he chiefly employed in preparing materials for a "Fauna Insectorum Marchica," or a description of the insects in the march of Brandenburg.

Animated by his predilection for natural history, and encouraged by the favour and patronage of Gaubius, he at length prevailed upon his father to let him go and settle in Holland. Thither accordingly he went, and resided at the Hague.

His reputation as a man of science was, by this time, so well established, that he was, the same year, elected fellow of the royal society of London; and in the following year member of the Académie des Sciences de la Nature; to both of which societies he had previously sent very interesting and ingenious papers.

The intimacy he now contracted with the most celebrated naturalists in Holland, and particularly with those of the Hague, who had just begun to form a literary society; the free access which he had to the museum of the prince of Orange, and other curious cabinets; the systematic catalogues of those collections that he drew up, and several of which he gave to the public; contributed to advance his knowledge of the productions of nature in the various parts of the globe, and to collect such materials as gave birth to those accurate compositions on zoology, which have deservedly delight ed him as the first zoologist of Europe. One of his earliest works in this branch of science, which rendered him eminently conspicuous, was his "Elenchus Zoophytorum."

The attention which Dr. Pallas had bestowed on the zoophytes, or animal plants, in the investigation of the worms which infest the human body, and particularly the uncommon nature of the tennis or tape-worm, as he acknowledges, seems to have led him into this line of natural science, and in which he has shown a great degree of accuracy, and surprising industry. In this work, after having treated on the nature of these ambiguous kinds of animals in a general method, and stated the various opinions of authors relating to the place they ought to hold in the system of nature, he describes from his own inspection more than 250 species of these worms and animalcules, known under the several generic apppellations of polypes, corals, madrepores, corallines, sea-pens, ténia or tape-worms, sponges, sea-fans, &c.

The free access which he had to the museum of the prince of Orange, and other curious collections in Holland, enabled him to enrich his work with the description of a great variety of these productions, brought from both the Indies. He has described each species at large, and given it a new name, characteristic of its real discrepancies; and, what especially increases the merit of his work, he has, with wonderful industry, extricated, as far as possible, the synonymy of former authors, both ancient and modern; thus rendering his book highly useful to such as are inquisitive in this branch of natural history.

In a dedication prefixed to his "Miscellanea Zoologica," published in the same year, the author lays before the prince of Orange a plan for a voyage to the Cape of Good Hope, and to the other Dutch settlements in the East Indies, impelled by his wonted ardour for scientific knowledge, he offered to undertake and superintend. This project was strongly recommended by Gaubius, and approved by the prince; but was prevented from being carried into execution by the author's father; who not only refused his consent to his taking such a distant expedition, but even recalled him to Berlin: in obedience to his father's wishes, but with great reluctance, he quitted Holland in November 1766.

On his return to Berlin (continues Mr. Coxe, from whose ingenious travels these particulars are extracted), his only consolation in being separated from his friends in Holland, and in having lost so many opportunities of improving himself in natural history, consisted in putting into order the numerous materials he had collected, and the observations he was incessantly making, and in giving them to the public. He had, however, barely begun to publish his "Speciologia Zoologica," before he was invited by the emperors Catherine II. to accept of the professorship of natural history in the Imperial Academy of Sciences at St. Petersburg. Although in this instance he remained resolutely adherent; yet the author's ardent zeal for his favourite science, joined to an irresistible desire to visit regions so little explored, induced him, without a moment's hesitation, to accede to the invitation, and to hasten his departure for a country, where his curiosity was so likely to be amply gratified. He accordingly quitted Berlin in June 1767, and arrived at Petersburg on the 30th of August.

He made his appearance among the Russians at a critical period. The empress had already ordered the Academy of Sciences to send astronomers into various parts of the Russian empire, to observe the transit of Venus over the sun's disk in 1769. Being just returned from a voyage down the Volga, and from visiting the interior provinces of European Russia, the enlightened sovereign had received the deficiencies of the topographical and geographical accounts, and anticipated the advantage of deputing learned and skilful men to visit the distant provinces of her extensive dominions; with a view to enlarge the bounds of science, and extend the knowledge of useful arts among the natives. For this purpose Catherine had directed the academy to send, in company with the astronomers, the most able naturalists and philosophers. Pallas instantly offered to accompany this expedition; and was as eagerly accepted. He was immediately charged
charged with drawing out general instructions for the naturalist, and was gratified with the choice of his associates. To him was submitted, at his own request, the conduct of the expedition to the call of the Volga, and towards the extreme parts of Siberia; and he was the most calculated for that expedition, as the elder Gmelin, who had been his preceptor in those regions, had almost entirely neglected the zoology of those remote districts. Pallas employed the winter previous to his departure in forming a systematic catalogue of the animals in the cabinet of the Academy of Sciences; in putting into order the celebrated collection of professor Broy of Dantzic, lately purchased by prince Orlof, in preparing for the press fix numbers of his "Spicilegia Zoologica," which were printed during his absence, under the direction of Dr. Martin; and in forming the necessary arrangements and notices for his intended expedition.

At length, in June 1768, he quitted Petersburg, in company with Meiffis, Falk, Lepekin, and Guldenlandt, as his associates; passing through Moscow, Vladimir, Kazan, Samara, and Astrakhan, and having explored that part of that province, wintered at Simbirsk. From thence he departed, in March of the following year; and penetrated through Samara and Orenburg, as far as Gursef, a small Russian fortress, situated at the mouth of the river Yaik or Ural. There he examined the confines of Kalmuc Tartary, and the neighbouring shores of the Caspian, and returning through the province of Orenburg, passed the second winter at Ufa. After several expeditions in the adjacent parts of that province, he left Ufa on the 16th of May 1770; proceeded his route through the Uralian mountains to Catharnenburgh; visited the mines of that district; proceeded to Tchelabinfl, a small fortress in the government of Orenburg; and in December made an excursion as far as Tobolik. The next year he was employed in traversing the Altai mountains, and in tracing the course of the Irtish up to Omsk and Kolyvan; where, having inspected the celebrated silver mines, he made for Tobolik, and finished that year's expedition at Krafnoyarck, a town upon the Yenisei. In that place, situated only in 66° north latitude, the cold was so intense, that the learned professor was restrained from the natural freezing of quicksilver; which curious phenomenon he has minutely described. From Krafnoyarck he issued on the 7th of March 1772; and proceeded by Irkurfsk, and across the lake Baikal, to Udinsk, Selenginsk, and Kiatka, where the trade between Russia and China is principally carried on. Having penetrated into that part of Dauria which is situated in the south-eastermost part of Siberia, he journeyed between the rivers Ingoda and Argoon, at no great distance from the Amoor; thence tracing the lines which separate the Russian empire from the Mongul hordes dependent upon China, he returned to Selenginsk, and again wintered at Krafnoyarfl. In the summer of 1773 he visited Tara, Yaitik, and Altarcan, and concluded his route for that year at Tsarzan, a town upon the Volga; from whence he continued his journey in the ensuing spring; and arrived at Petersburg on the 30th of July 1774, after an absence of fix years.

The account of this extensive and interminable tour was published by Dr. Pallas in five volumes, 4to, which greatly extended his fame, and established his character. The author, in this valuable work, has entered into a geographical and topographical description of the provinces, towns, and villages, which he visited in his tour, accompanied with an accurate detail of their antiquities, history, productions and commerce. He has discriminated many of the tribes who wander over the various districts, and near the confines of Siberia; and specified with peculiar precision their customs, manners, and languages; he has also rendered his travels invaluable to the naturalist, by the many important discoveries in the animal, vegetable, and mineral kingdoms, with which he has enriched the science of natural history.

Two years afterwards, in 1776, the professor published his collections relative to the political, physical, and civil history of the Mongul tribes; in which he throws new light on the annals of a people, whose ancestors conquered Russia, China, Persia, and Hindoostan; and, at more than one period, established perhaps a larger empire than ever was possessed by any single nation. Mr. Pallas here proves unquestionably that the Mongul tribes are a distinct race from the Tartars; that they differ from them in their features, language, and government; and resembie them in nothing except in a similar propensity to a roving life. He intended a second volume describing their religious establishment, confining in the worship of the Dalai Lama. It is the religion of Tibet and of the Mandshur sovereigns who now sit upon the throne of China. "A work," as Mr. Tooke, in his "Rusical Illustratus," Introd. p. cxi. judiciously observes, "that will enrich the stock of human knowledge with discoveries, the greatest part entirely new, and which no perfon but Mr. Pallas is able to communicate." Whether, however, this second volume ever made its appearance, we have our doubts.

In the same year in which Dr. Pallas printed his "Elenchus Zoophytorum," he also published a treatise under the title of "Miscellanea Zoologica quibus novae imprimit atque obfcurae animalium specieum defcribuntur et observationibus iconibusque illustrantur." This work is in a great measure incorporated into a subsequent publication made the next year on his return to Berlin, intitled "Spicilegia Zoologica," and was continued in numbers, or fasciculi, till 1780. The works of count Buffon, the illustrious French zoologist, amply attest the labours of Pallas, and our countryman Mr. Pennant makes frequent acknowledgments of his obligations to the same source, particularly for his history of quadrupeds and arctic zoology.

In June 1777, the learned professor read before the academy of Petersburg, in a meeting at which the king of Sweden was present, a dissertation on the formation of mountains, and the changes which this globe has undergone, more particularly as it appears in the Russian empire. The tentative appeared so curious to Mr. Tooke, who was also, as a member of the academy, present at that sitting, that he has given a translation of it in his "Russo Illustratus." In 1778 the doctor published "Novae specieum quadrupedum et Gitanorum ordine," describing numbers of the rat genus and their anatomy. In 1781 he brought out "Enumeratio plantarum que in horto Precipitii a Demidof Mofco vivent," or catalogue of the plants in M. Demidoff's gardens at Moscow. His new northern collections on various subjects in geography, natural history, and agriculture, came forth the same year, to which were afterwards added two more volumes.

In 1782 he put forth two fasciculi or numbers of "Icones infectorum printertim Russe Siberique peculiarum." In 1784 he published the first number of his "Flora Russica," a splendid work, executed at the expense of Catharine's expeditions. About this period her majesty conceived the idea of collecting from all quarters of the globe a universal vocabulary, the superintendence whereof the empress committed to our author, which necessarily for a time retarded his zoological researches. Exclusive of these separate publications, he printed in the acts of the imperial academy of sciences, various zoological and botanical dissertations.

Not long after this he was distinguished by a peculiar mark of imperial favour, in being appointed member of the board of mines, with an additional salary of 200l. per annum, and honoured with the order of St. Vladimir. The empress also purchased N 2
purchased his ample collection of natural history, in a manner highly flattering to the author, and honourable to herself. Being informed that professor Pallas was desirous to dispose of that collection, her majesty sent to let him know that her country should not be deprived of so exquisite a cabinet; that she would be the purchaser, and ordered him to make out the catalogue and fix the price. He accordingly named 15,000 rubles. Having examined the catalogue, the subjoined with her own hand: "Mr. Pallas understands natural history much better than figures: he ought to have charged 20,000 instead of 15,000 rubles for so many valuable articles. The empress, however, takes upon herself to correct the mistake; and hereby orders her treasurer to pay 20,000 rubles. At the same time Mr. Pallas shall not be deprived of his collection, which shall still continue to be in his own possession during his life, as he so well understands how to render it most useful to mankind."

In 1784 the care of putting in order and publishing the papers of Gmelin and professor Guldentädt was intrusted to Dr. Pallas, which he executed with great diligence and accuracy, though from some incidental cause to us unknown, only the first volume of Guldentädt's remains, containing his journal and the description of the districts of Mount Caucasia, ever came to the public eye.

In 1794 Dr. Pallas travelled to the Crimea, and on his return published an account of that delightful peninsula, under the title of "Physical and Topographical Picture of Taurida." On his return, finding his health, by long and incessant labours, upon the decline, he resolved to render it necessary for him to remove to a warmer climate, on preferring his return to the empress, he obtained not only immediate permission to chuse for himself a settlement in her dominions, but also on his pitching upon Taurida for that purpose, the grant of an estate in that province, and to the forming of his establishment a present of 20,000 rubles. Here it was that he was visited by Dr. Clarke on his travels in the year 1800; with whose account of his then situation we shall conclude these memoirs. "A kind and ingenious traveller," says that spirited and ingenious traveller, "will long be celebrated as the refidence of professor Pallas, so well known to the literary world. His name would have been sufficiently established if he had published no other work than that begun by him under such favourable auspices, the "Flora Ruffica;" yet the barbarity of the people with whom he is compelled to live is such, that they will not allow him to complete the undertaking. The drawings were all finished, and almost all the text. To the hospitable and humane attentions of this excellent man we were indebted for comforts, equal, if not superior, to those of our own country, and for every literary communication it was in his power to supply. When we delivered our letters of recommendation to him, he received us rather as a parent, than a stranger to whose protection we had been conformed. We refused to intrude by occupying apartments in his house: this had more the appearance of a palace, than the residence of a private gentleman; but one day when we were about upon an excursion, he caused all our things to be moved, and upon our return we found a suite of rooms prepared for our reception, with every convenience for study and repose. I consider myself indebted to him even for my life. The fatigue of travelling, added to the effect of hot air and unwholesome food, rendered a quartan fever so habitual to me, that had it not been for his care and skill, I should not have lived to make this grateful acknowledgment. He prescrib'd for me; administered every medicine with his own hands; carefully guarded my diet; and, after nursing me as his own son, at last restored me to health. When I recovered, he ransacked his museum for drawings, charts, maps, books, antiquities, minerals, and whatever else might gratify our curiosity or promote the object of our travels; he accompanied us upon the moft wearisome excursions, in search not only of the insects and plants of the country, but alfo of every document likely to illustrate either its ancient or its modern history. His decline of life has been embittered by a variety of unmerited afflictions; this he has borne even with floical philosophy. Splendid as his residence appeared, the air of the place was fo bad, that the most rigid abstinence from all farts of animal food was insufficient to prepare his family from fevers. We left him determined to pafs the remnant of his days in cultivating vineyards among the rocks upon the fouth coast of the peninsula. There was reason to hope, that by the death of Paul he would have been caled to honours and emoluments; but subsequent travellers in Ruflia do not fhew intelligence fo creditable to the administration of the new reign, as that of the late emperour Catharine. I fee him to refide in the Crimea, with a grant of lands in the peninsula, it was intended for the re-establishment of his health, and as a reward for his long services; neither of these purposes has, however, been accomplished. A magnificent establishment in the midit of unwholesome air, has been all the remcompce he has obtained. Thus it is that we find him, in the fixtieth year of a life devoted to science, opening his laft publication with an allusion to "the diquitude and hardships which opprefes him in his prefent refidence, and embitter his declining days."—"We ufed," says Dr. Clarke, "every endeavour to prevail upon him to quit the country, and accompany us to England; but the advanced period of his life, added to the certainty of losing all his property in Ruflia, prevented his acquiefcence. Our intreaties were to no effect; and perhaps before this meets the public eye, our friend and benefactor will be no more." Happily, however, Dr. Pallas survived the departure of our traveller upwards of ten years; when determining once more to fee his brother and his native city, he took a journey to Berlin, where he died Sept. 8th, 1811, in the 74th year of his age. See Cooke's Travels; Tooke's View of the Ruflian Empire; and Dr. Clarke's Travels. PALLASIA, in Botany, is defined to comprehend the very eminent scientific merit of the celebrated Peter Simon Pallas, knight of the Ruflian order of Wladimir, or Vlodiumir, the chofen naturalist of the late emperour Catharine of Ruflia. See PALLAS.

His Flora Ruflica, his splendid monograph on the Affragali, as well as his botanical travels, and other writings, richly entitle him to fuch commeration. His liberal communication of firely preferred fpecimens to Linnaeus, affiled greatly to enrich the herbarium, as well as the later publications, of that distinguifhed man and his fon; and the whole collection of dried plants, made by Pallas for his own ufe, having been purchased of him by Mr. Cripps, the companion of Dr. Clarke, now form a part of the valuable mu-}

P A L
PAL

Ddict. v. 2. 356. Illutr. t. 709. Cavan. Ic. v. 1. 44. 
(Ximenefia; Cavan. Ic. v. 2. 60. Wild. Sp. Pl. v. 3. 2116.) 
Composit, Linn. Corymbifer, Jull.

Gen. Ch. Common Calyx of numerous, oblong, imbricated, nearly equal scales. Cor. compound, radiated; florets of the disk numerous, tubular, five-leaflet, all perfect; those of the radius ligulate, spreading, oblong, somewhat wedge-shaped, with three or four obtuse terminal teeth. Stam. in the florets of the disk only, filaments five, capillary, very short; anthers united into a cylindrical tube with five teeth. Pift. in the florets of the disk, germin'obovate, compressed, fringed; style thread-shaped, the length of the filaments; stigmas two, spreading; in those of the radius, germin obfolete or abortive, smooth; style and stigmas imperfect or wanting. Peric. none, except the permanent calyx. Seeds in the florets of the disk solitary, obovate, compressed, notched at the top, bordered and fringed at the margin; those of the radius obfolete and smooth. Down. none. Recept. slightly convex, chaffy; its scales lanceolate, keeled, acute, marked along the margin of the florets of the disk.

Obfl. We cannot feruple to reduce the Ximenefia of Cavani
tiles to our Pallisia, their habits being so similar, and the structure and appearance of the parts of the flower so much the same, as to overbalance the artificial distinction founded on the florets of the radius in Ximenefia being rather less imperfect; though by no means so perfect as to justify its being referred to the order Polygama-superflua. This genus is sufficiently different from Coreopsis, with which Jacquin confounds it.

1. P. halimifolia. Downy Pallisia. L'Herit. Stirp. Nov. v. 2. t. 19, unpublished. Wild. n. 1. (Encelia canecens; Cavan. Ic. v. 1. 45. t. 61. Coreopsis limensis; Jacq. Ic. larr. t. 594. Collect. v. 2. 299.)—Leaves blunt, nearly entire, downy on both sides. Radiant florets deeply and unequally four-toothed, scarcely twice as long as those of the disk. Native of Mexico. It is with us in Europe a flower plant, though long from July to September, but not much cultivated. The floret is bristly, branched and downy, about two feet high; branches alternate, leafy. Leaves alternate, on downy flanks about an inch long, broadly ovate, obtuse, one and a half or two inches long, entire, occasionally rather wavy or obscurely toothed here and there, three-ribbed, of a pale glaucous green, densely clothed on both sides with dense, soft, fine, short down. Stipulas none, but a dense snow-white tuft of accumulated down is more or less remarkable. At the inception of each floret. Panielles terminal, corymbose, downy, rather leafy, of about five or five flowers, scarcely so large as a French Marigold (Tagetes patula), with a yellow radius whose florets are broad, short, unequally lobed, and a convex greenish disk.

Cavalielles. This has the habit of the foregoing, but the leaves are smooth, and the flowers larger, in consequence of the florets of the radius being much longer. Their colour is pale yellow; their apex obtuse, with only three very shallow teeth, instead of being deeply and irregularly lobed. The florets of the disk are of a reddish-white below, their limb dark brown. Such is the description in Cavalielles. We have been no specimen, nor ever heard of this species in England.

3. P. ferratisfolia. Serrated Pallisia. (Ximenefia eccentrici
dioides; Cavan. Ic. v. 2. 60. t. 178. Wild. Sp. Pl. v. 3. 156.)—Leaves pointed, ferrated, hoary beneath; with winged ferrated foot-filaments. Native of Mexico, from whence the seeds were sent to the Royal garden at Madrid. The plant flowered there in November. We have not heard of it in England, but are indebted to our late friend Cavalielles for a specimen. Root perennial. Stem three feet high, branched, leafy, downy, ribbed, pale, apparently somewhat shrubby, corymbose and many-flowered. Leaves mostly alternate, not opposite, except perhaps some of the lowest, ovate, pointed, three-toothed, with many lateral veins, strongly and sharply ferrated; their upper side bright green, besprinkled with small defrayed bristles; under densely downy, pale, or glaucous. Foot-filaments about a quarter the length of the leaves, bordered with a narrow wing, which is greatly dilated and toothed at the base, where it clasps the stem or branch. Flowers terminating each branch, solitary, larger than the leaf, their radiant florets spreading, bright yellow, each near an inch long; disk brownish. Scales of the calyx lanceolate, acute, roughish, in central rows, hardly imbricated. Border of the ferris pale, ribbed, hairy; their disk bifert with numerous, minute, sharp tubercles. Scales of the receptacle pale, finely fringed at the edges and keel.

Cavalielles named this suppos'd genus after Joseph Ximenes, an apothecary, who undertook a Flora of Catalania, in four volumes, in which he delineated more than 750 plants, besides native butterflies and birds of the fame neighbourhood. Whatever his merits might be, the generic appellation given by Cavalielles could scarcely be retained, as the Linnaean filum already contains a Ximenia, long ago consecrated to one of his countrymen of the same name, by Plummer. See Ximenia.

PALLAVICINO, FERRANTE, in Biography, a man of letters, was born at Placentia about the year 1615. He devoted himself to the church, and became a canon-regular of Augustines; but the turn which he had to satire, and which he could not restrain, was at length the cause of his ruin. During the contet between pope Urban VIII. of the Barberini family, and Edward Farnefe, duke of Parma and Placentia, Count Pallavicino supported the cause of his sovereign with his pen, and wrote some fierce and galling satires against the pontiff, and all his house. The papal court set a price upon his head, which obliged him to withdraw to Venice, where he lived in obscurity. A young Frenchman, by affecting to pity his situation, obtained his confidence, and betrayed him to his enemies, who first imprisoned, and then beheaded him. The wretch who betrayed him was hanged at Paris, some years afterwards, by a friend of Pallavicino. He was author of many works, which are distinguished by their severity and indecency. He also wrote a history of the public events in Italy in 1636. A collection of his works was published in two volumes 12mo, 1644, at Geneva, under the title of "Villa-franca." Moretii.

PALLAVICINO, SPORZA, a cardinal, born at Rome in 1667, was the eldest son of a marquis of that name, in Lombardy. He adopted the ecclesiastical profession in opposition to the inclination of his parents. He attainted, at a very early age, to high preferment in the church, and was admitted to the prelacy in the pontificate of Urban VIII. The prospects that opened before him did not, however, prevent his putting into execution a design of quitting the world, and in his thirtieth year he commenced a noviciate in the society of Jesuits at Rome. When this was completed, he was employed several years in giving lectures in philosophy and theology, and in preluding over the studies of the Roman college. He composed a history of the council of Trent in opposition
opposition to that of father Paul Sarpi, which labour was rewarded by pope Alexander VII. with a nomination to the cardinalate in 1657. After this elevation he continued to live in the cloister occupied in his studies, and in the concerns of the church, and affording an example of Christian virtue and piety till his death in 1658.

The cardinal was author of other works besides the "History of the Council of Trent," there were partly acetical, partly moral, and partly theological. He also published a tragedy, entitled "Ermenigildo," which he afterwards republished with a preliminary discourse, said to be more valuable than the tragedy itself.

To this ecclesiastic also belongs a grammatical work, entitled "Avvertimenti Grammaticali," published under the name of Fr. Raimondo. His "Letters," in Italian, were published two years after his death.

The "History of the Council of Trent" was also written in Italian, and was at first printed at Rome in two volumes folio, 1656, 1657. It was, in 1664, republished in three volumes, 4to, with various corrections and additions by the author. A translation of it in the Latin language was published at Antwerp, in 1672, by father Gazzinni. Moreri.

PALLEIROS, in Geography, a mountain of Arabia, in the province of Oman; 80 miles W.S.W. of Moscat.

PALLENE, in Ancient Geography, one of the three peninsulas, which, formed at its extremity a more considerable peninsula, between the Thermaic gulf and the Strymon. This peninsula lay to the S.W., and according to Steph. Byz. upon it was also a mountain under the fame appellation, of a triangular form, and had upon it, says Scylax, five towns; one of which was called by the same name. It belonged to Macedonia.

PALLETS, among Painters, a little oval table, or piece of wood, or ivory, very thin and smooth; on and round which the painters place the several colours they have occasion for, to be ready for the pencil.

The middle serves to mix the colours on, and to make the tints required in the work. It has no handle, but, in lieu thereof, a hole at one end, to put the thumb through to hold it up.

Pallet, among Pottery, Crucible-makers, &c., is a wooden instrument, almost the only one they use, for forming, beating, and rounding their works.

They have several kinds; the largest are oval, with a handle; others are round or hollowed triangularly; others, in fine, are in manner of large knives, serving to cut off what is superfluous on the moulds of their work.

Pallet, in Gilding, is an instrument made of a squirrel's tail; used to take up the gold leaves from the pillow, to apply and extend them on the matter to be gilt. See Gilding.

Pallet, in Herbaey, is the moist or half of the pale; or a small pale, half the breadth of the usual one.

The pallet must never be charged with any thing either quick or dead; neither can it be divided into two equal parts; but it may be into four; for one-fourth part of the pallet, or two-eighth parts of the pale, is called an endorse.

If the pale be upon any bead, they say, the bead is destrosten with the pale; but if the bead be upon the pale, they say it is supported by it.

Pallets, in Clock and Watch-work, are those pieces or levers, which are connected with the pendulum or balance, and receive the immediate impulse of the flying-wheel, or balance-wheel, so as to maintain the vibrations of the pendulum in clocks, and of the balance in watches. The pallets in all the ordinary contrivances of clocks and watches, are formed on the verge or axis of the pendulum or balance, and are of various lengths and shapes, according to the construction of the piece, or the fancy of the artifi. For the modern improvements, comparative advantages, and the manner of constructing pallets, see ESCAPEMENT.

Pallet, in Ship Building, is a room within the hold, closely parted from it, in which, by laying some pigs of lead, &c., may be sufficiently ballasted, without losing in the hold; which, therefore, will serve for stowing more goods.

PALLETING, a slight platform made over the bottom of the magazine, to prevent the powder from damp.

PALLI, in Geography, a town of Asiac Turkey, in the province of Diarbekir; 83 miles N.E. of Diarbekir.

PALLIANO, or PALLANG, a town of Campagna di Roma; 28 miles E. of Rome.

PALLIATION, in Medicine, signifies the act of alleviating the more violent symptoms of a disease, by those means which have no power of removing the disease radically. Whence also the terms

PALLIATIVE, medicines, palliative indications, palliative treatment, &c. are applied to those remedies which the physician adopts, and to the rules of practice to which he is directed by the symptoms, under such circumstances.

The palliative treatment is never referred to by a skilful practitioner, except under one of two conditions of his patient; namely, when the disease, under which he labours, is clearly of an incurable nature, or advanced to an incurable stage; or, on the other hand, when some of the symptoms of a disease, which is in itself curable, are so violent as to become themselves the source of extreme distress, or even of danger, to the patient. Both these conditions are of frequent occurrence. Every organic disease, in its advanced stage, affords an example of the first, especially when it is accompanied by fever pain; for in that case, it becomes necessary to diminish the sufferings of the patient, by a constant use of narcotic medicines. Although the fever will not contribute, in the smallest degree, to arrest the progress of the disease.

Of the second condition just mentioned, many examples might be adduced: but it may be sufficient to observe, that, in fevers, many symptoms occasionally occur, which materially aggravate the original disease, if not palliated; and the palliation, therefore, becomes an object of the first importance, although the means to be adopted for that purpose do not strike at the root of the fever.

Thus an intense heat of the surface will, by the painful irritation which it produces, occasion extreme restlessness, thirst, loss of sleep, and increased quickness of pulse; whereas if the heat be palliated by external coolness, and by cold drinks, all these secondary circumstances will be removed, and the ultimate chance of recovery greatly increased. In like manner, a febrile diarrhoea, great contipation, or a violent local pain, often require palliation, by means which have no direct influence upon the primary fever. There are but too many practitioners, however, who form an imperfect knowledge of the principles of physiology and pathology, cannot see beyond the most prominent symptoms of a disease, and whose whole practice is comprised in a succession of palliative measures; such men are often called experimental, because they have seen much disease, but being delirious of their principles, they never acquire a true experience.

PALLICODE, in Geography, a town of Hindoostan, in Myrtr, at the extremity of a pafs leading to the Barmaul country, called either the "Palls of Pallicode," or the "Palls of Oodeadurgum." Through this pafs the Myrtr armies were generally sent to invade the Carnatic; 25 miles N.W. of Darempoury.

PALLIER, or PAILLIER, in Building, a landing-place in
in a staircase; or a step, which, being broader than the rest, serves to rest upon. See Staircase.

The term is pure French, and is not much used in English. In persons, on large staircases, where there are sometimes several palliums in the same range, or line, they ought to have each at least the width of two steps. Those in the turns of staircases ought to be as broad as long. Vitruvius calls the pallium on landing-places of the theatres, diasomata.

PALLIFICATION, or Piling, in Architecture, denotes the piling of the ground-work, or strengthening it with piles, or timber driven into the ground; which is practised when people build upon a moist or marshy soil.

PALLIGRAME, in Geography, a town of Hindoostan, in Golconda; 25 miles S.E. of Hyderabad. PALLIO, a town of Hindoostan, in Bahar; 45 miles S.W. of Patna.
PALLIO COOPERITE. It was an ancient custom, where children were born out of lawful wedlock, and their parents afterwards intermarried, that those children, together with the father and mother, should fland pallio cooperis, under a cloth spread over them, while the marriage was solemnising; which was a kind of adoption, and had the effect of a legitimation.

Thus Robert Grosseteste, the famous bishop of Lincoln, in one of his letters, says; "In signum legitimacionis, nati ante matrimonium confpeuerant ponit pallio super parentes eorum extuto, in matrimonii belemzatione." Selden, in his notes on Peta, adds, that the children of John of Gaunt, duke of Lancaster, by Catharine Swinford, though legitimated by act of parliament, yet were covered with the pall at the time of the marriage of their parents.
PALLIOT, PETER, in Biography, was born at Paris in 1608. He settled at Dijon, where he married the daughter of a painter, and followed the fame profession. From an early age he had attached himself to the studies of genealogy and heraldry, which he continued to pursue with great avidity, publishing several works upon those subjects. He died at a very advanced age in the year 1688. His principal works are, "Le Parlement de Bougogne," 1649; to which another volume was added by Fr. Peronet in 1733. "Science des Armories de Geuillet, augmentée de plus de 6000 Ecussons." Besides these he published genealogical histories of particular families, and he left in MS. thirteen volumes folio, of memoirs concerning the families of Burgundy. He not only printed his own works, but engraved with his own hand all the numerous heraldic plates by which they were illustrated. Moreri.
PALLISADES. See PALLISADE.
PALLISADED CROWN. See Crown.
PALLISER, CAPE, in Geography, a cape on the E. coast of New Britain. S. lat. 4° 22'. E. long. 191° 25'.
PALLISER, CAPE, a cape on the S. coast of Etenemauwe, the northern islands of New Zealand, and N.E. point of Cook's Strait. S. lat. 41° 38'. E. long. 175° 23' 12".
PALLISER'S ISLANDS, a cluster of islands in the South Pacific ocean; the largest being about fifteen miles long and nine broad, connected together by a reef of coral rocks, and difficult of access. S. lat. 15° to 16°. W. long. 146° to 147°.
PALLIUM, or PALL, a pontifical ornament worn by popes, patriarchs, princes, and metropolitans of the Roman church, over their other garments, as a sign of their jurisdiction.
It is in form of a band, or fillet; three fingers broad, and encompasses the shoulders; whence, by some authors, it is called superhumeralis. It has pendants, or fimbriae, about a palm long, both before and behind; with little laminae of lead round the extremities, and covered with black silk, with four red crosses.
Some, with Enfeebius, will have the pallium to have been introduced by pope Linus; adding that the ephod was the mark of the pontifical authority in the Jewish synagogue, so is the pallium in the Romish church.
Others have observed, that there is no mention made of it before the year 336.
Lastly, others will have it to have been first granted by Constantine the Great, to pope Sylvester; from whence it passed to the other patriarchs and archbishops.
The pall, it is certain, was originally part of the imperial habit, being a rich robe of flate, very magnificent, and reaching quite to the ground; and it has been said, that the bishops of Rome were allowed to wear it by Constantine the Great, and that in process of time the same honour was granted by the emperors to the other patriarchs. Hence, when they were either driven from their fees, or voluntarily quit them, they returned their pallas to the emperors.
When the popes first took upon them to grant that honorary badge, which they did before the pontificate of Gregory the Great, chosen in 590, they did not presume so to do until they had obtained leave of the emperor. But the successors of Gregory, upon the decline of the empire, took upon them to bellow that mark of distinction independently of them, and as a gift of their own. However, that it might no longer be deemed part of the imperial habit, which it was trefonable to wear without leave from the emperors, they changed its ancient form to the present. At what time the popes affirmed the disposing of the pall, independently of the emperors, is not well known; but it is certain, that no bishop was obliged to apply to Rome for it till the year 742, when Boniface, bishop of Monte, persuaded the bishops of France and Germany to pass a decree, obliging their metropolitans to apply to the pope for that ornament, and to promise, upon their receiving it, a canonical obedience to the commands of St. Peter. This practice proving very favourable to the ambitious designs of the bishops of Rome, they spared no pains to impose it upon all metropolitans; insisting, with this view, various decrees concerning the nature, virtue, and necessity of the pall; till, at length, they proceeded to declare it unlawful for a metropolitan, archbishop, or primate, to exercise any branch of his power, till he had received his pall from Rome; nay, in several decrees, the metropolitan jurisdiction and power were to be conferred upon the pall; and thus they made the pope the fountain of all ecclesiastical power and authority.
This doctrine seems to have been first broached in the ninth century, though vigorously opposed by Hincmar, archbishop of Rheims, and several others. However, the doctrine prevailed; and the pall was declared by Innocent III. in the thirteenth century, to be an ensign or token of the plenitude of the apostolic power, and said to communicate a competent share of that power to those who received it from the hands of the popes. Till the time of Gregory VII. the new metropolitans were only required to send for their palls within the space of three months after their ordination; but this pall obliged all, unless prevented by some lawful impediment, to come for them in person to Rome; and the promise of canonical obedience, upon receiving their palls, was changed into an oath of allegiance, such as vassals by the feudal laws were obliged to take to their princes. Gregory the Great conferred the pall without fee or reward; and in a council held at Rome in 595, decreed, that it should be given gratis; but it is well known, that in succeeding times the grant of the pall became one of the chief hands of the popish fee. Exorbitant fees were exacted not only for the palls that were lent to prebendaries, or private bishops, when raised to the archiepiscopal dignity, but likewise for those that were lent
to archbishops on their translation from one see to another. For by the canons, an archbishop is not to carry away his pall with him, but to a new one; and his successor is not to make use of the pall, which his predecessor had left, but to apply to Rome for another. Bower's Hist. of the Popes, vol. iii. p. 6. note (c).

The pope pretends to the sole right of conferring the pallium; though some patriarchs have granted it to their suffragans, having first received it themselves from the Roman see.

Anciently, the pope used to send the pallium to certain of his diocesan bishops, on whom he laid a good part of his authority, and who were a kind of collaterals to him, as the patricians were to the emperors. The first who received it in France was Vigilius, archbishop of Arles: this was done, in order, as Pasquier observes, to give him the precedence over the other bishops.

Anciently they went to Rome to seek the pallium in person; afterwards it was sent by the pope's legates. At last the custom was introduced of sending persons express to demand it, with this form, Infantium, Infantis, Infantisfime.

By the popish canon laws, a metropolitan, till he have received the pallium, cannot consecrate bishops, or churches, and he may not be called archbishop, &c. Upon a translation, he must have the pallium afresh; and till then he cannot hold a synod, nor perform any of his archiepiscopal functions.

The pallium was anciently interred with the person. The use of the pallium is restrained to certain feasons and occasions; none but the pope having a right of wearing it, and in all places. The pope sometimes lends it to bishops of his own accord; and has sometimes given the right hereof to particular churches.

Among the Greeks all the bishops wear the pallium. In ancient records, we find mention made of another pallium, which was a long garment spread over with crolles, Tertullian says it was a dilinguishing garment of the Christians; that of the heathens being called toga.

PALLIUM Episcopal. See PALL.

Pallium Ducal, in Natural History, a name given by writers on shells to a kind of pebbles, or scalfop, of a large size and beautiful appearance, though simple colour. There are two species of this, a red and a yellow one.

Pallium purpureum, a name given by Basil Valentine, and other of the affected writers in chemistry, to a powder of a purple colour, prepared from gold. It is made by preparing an amalgam of gold and mercury; and after the mercury is driven off by the retort, the remaining matter is mixed with sulphur, and calcined by a well regulated fire till reduced to a purple powder. This is called also the solar powder, and has, like the other preparations of this metal, many imaginary virtues ascribed to it.

PALL'S, in Ship Building, strong short pieces of iron or wood, so placed near the capitan or windlass as to prevent its recoil or giving way, which may very much endanger the men at the bars, in the act of heaving up the anchor, or otherwise, when charged with any great effort.

PALLUAU, in Geography, a town of France, in the department of the Vendée, and chief place of a canton, in the district of Les Sables-d'Olonne, 16 miles E.E. of Challans. The place contains 328, and the canton 8,794 inhabitants, on a territory of 250 kilometres, in 10 communes.

PALM, PALMUS, an ancient long measure, taken from the extent of the hand.

The Roman palmus was of two kinds: the great palmus, taken from the length of the hand, answered to our span, and contained 12 fingers, digits, or fingers' breadths, or 9 Roman inches, equal to about 8½ English inches. See DIGIT, and SPANN.

The small palm, taken from the breadth of the hand, contained 4 digits or fingers, equal to about 2 English inches, 9 tenths.

The Greek palm or doron was of two kinds. The small contained 4 fingers, equal to little more than 3 inches. The great contained 5 fingers. The double Greek palm, called duchas, contained also in proportion. See Measure.

The modern palm is different in different places where it obtains. At Rome, the canna for woollens and filken stuffs = 7¾ English inches = 8 palms; but the builders' canna = 87½ English inches = 10 palms; at Naples, the palm, is the 8th part of the canna = 10¾ English inches; at Genoa, the palm is 9½ inches; at Oporto, it is 8 inches: the English palm is 3 inches.

At Leghorn there are two kinds of palms, the one for woollens, the other for silks; the first one-third shorter than the latter. See the Tables under Measure.

Palm, Palma, in Anatomy, denotes the inside of the hand; called also sola and metacarpus.

Palm, in Naval Language, is an implement used instead of a thimble, in making and mending sails. It is formed of a piece of leather, seal's skin, or canvas, on the middle of which is fixed a round plate of iron, of an inch in diameter, whose surface is pierced with a number of small holes, to catch the head of the tail-needle. The leather is formed so as to encircle the hand, and button on the back of it, while the iron remains in the palm; so that the whole strength of the hand may be exerted to thrust the needle through the canvas, when it is stiff, and difficult to be penetrated.

Falconer.

Palm, Dwarf, or Palmetto, in Botany. See CHAMELEONS.

Palm-Oil. See Oil.

Palm-Tree. See Palma.

Palm-Wine, called in the East toddy, is obtained by incision of the trunk of a species of palm-tree, whence issues a liquid much grateful to the palate, but liable, especially on account of the heat of the climate, soon to turn sour.

Palm Islands, in Geography, a chain of islands near the N.E. coast of New Holland; extending about 30 miles in length, at the entrance of Halifax bay. S. lat. 18° 53', W. long 21° 25'.

Palma, Filippo, in Biography, a Neapolitan singing-maister, totally without voice that could be called tuneful, yet he sung, or seemed to sing, with such exquisite taste, as to revive the miraculous powers of music equal to those ascribed to Orpheus, Amphion, and Linus. Besides his want of voice, he was so ignorant of counterpoint, that he could not make a base to the most simple melody. And though the air which he composed for his own singing were universally applauded, he was so humble as to condescend to ask a young apprentice to Dr. Arne to furnish a base; and yet he touched the harpsichord in so original and seemingly matterly a manner, that this apprentice would have given the world to exchange all his knowledge in counterpoint for signior Palma's "not catering." Gluck's celebrated air in Armide, "Rafforza il meo ciglio," admirably sung by Monticelli at the opera, and encored every night, when sung by Palma without voice in private, the fine voice, figure, action, and knowledge of Monticelli were annihilated and forgotten. A singer in a room may hazard embellishments, which, on a stage, accompanied by a powerful orchestra, would have no effect. Palma's manner of singing and varying
The author of "Tratté foi la Melodrame," (le chevalier de Chaffellux) relates an anecdote of Palma, which is perhaps as strong an instance of the power of song in a modern age, as can be found in the legends of ancient music. Palma was always in "loves and debts, though (being an Italian) seldom in drink." Having been caught at home by the police by one of his deepest and most enraged creditors, from whom he had been long seeking, in order to escape his gripe; and on the inexcusable creditor informing him of his business, and of the care that would be taken of his person by the gentleman whom he had brought with him, Palma made no other reply to his abuse and threats, than by sitting down to the harpsichord and finging two or three of his most pleasing and touching airs to his own accompaniment: when the fury of the creditor was so softened by degrees, that at length he was entirely appeased, and not only forgave him his debt, but lent him ten guineas to stop the mouth of other creditors, who threatened him with a gaol.

But this security was of short duration, for he was soon after thrown into the king's bench, where we visited him, and found him writing to his brother, then a prisoner likewise in York gaol; when finding that the male Siren was putting his letter into a cover, we informed him of the expence in which it would involve his brother, by a double letter, when he said—"Che fare? è capo di c lla, ci vaol ripetto. What can I do? He is my elder brother, and head of our house, we must thw him respect." Palma, Giaco, was born at Serrella, in the territory of Bergamo, and was a disciple of Titian. He had genius and judgment, and his manner much resembled that of his master. His colouring had extraordinary strength and brightness, and his pictures are wrought to great perfection, though the execution of them is free and not over labourd.

Valari describes, with great fervour, a composition of the elder Palma, at Venice; representing the ship in which the body of St. Mark was brought from Alexandria to Venice. "In that grand design," he says, "the veil was struggling against the fury of an impetuous tempest, and is exquisited with the utmost judgment; the diffuses of the mariners, the violent bursting of the waves against the sides of the ship, the horrid gloom only enlightened with flashes of lightning, and every part of the scene filled with images of terror, are so strong, so lively, and naturally represented, that it seems impossible for the power of colour or pencil to rise to a higher pitch of truth and perfection; and that performance very defervingly gained him the highest applause."

Notwithstanding this deferred praise, his pictures in general are not correct in design, and his latter works did not maintain his early reputation. He died, according to Vafari, at the age of 48; but in what year is not absolutely known.

Palma, in Geography, one of the Canary islands, about 60 miles in circumference, anciently called "Capraria," famed by some to have deriv'd this name from a volcano so called; though others ascribe it to the great number of goats that are fed here. The soil is fertile in corn, wine, and figuercans, as well as in fruits, quadrupeds, and birds of all kinds. This island has a handsome town and a safe harbour, much frequented for its wines, which are reckoned equal to Malmsey, and thought by some to be the best of any produced in the Canaries. (See CANARY ISLANDS.) N. lat. 28° 36'; W. long. 18°.

Palma, the capital of Grand Canary. (See CANARY.)—Vol. XXVI.

Alfo, a town of South America, in the province of New Granada; 36 miles N.W. of Santa Fé de Bogota.—Alfo, a town of Naples, in the province of Lavora; 14 miles E. of Capua.—Alfo, a town of Naples, in the province of Calabria, near the sea. which was a great mart for oil; destroyed by an earthquake; 11 miles W.N.W. of Oppido.—Alfo, a town of Sicily, in the valley of Mazara, in the vicinity of which is a rich sulphur mine; and on a lake near the sea, not far from it, are white partridges; 6 miles S of Naro.—Alfo, a town of Spain, in the province of Cordova, on the Guadalquivir; 27 miles S.W. of Cordova.—Alfo, a town of Portugal, in Estremadura, on the right side of the river Cadoon; 18 miles E. of Setuval.—Alfo, a river of Brazil, which runs into the Tocantins, S. lat. 14° 16'.—Alfo, the capital of the island of Majorca, the fee of a bishop, and the residence of the captain-general of the Balearic and Pityuse isles. The city is situated on the banks of a large bay formed by the sea, between the capes Blanco and Cala Figuera, which is said to be 34 leagues wide; the port, though small, is good and safe. The city is built on a declivity on the sea-shore, in the part where the port makes a bend. It is surrounded with walls, flanked by twelve bastions; here are a half-moon, horn-work, and several redoubts; on the land side there is a dry ditch; but all these fortifications could not sustain a well-conducted siege. It has eight gates, three of which are on the side of the sea. The streets in some parts of the city are narrow, and badly paved; those in the lower parts, as well as of the squares, are large and regular. The population of the city is reckoned at 33,000 inhabitants. The bishopric is a suffragan of Valencia; the diocese comprehends 40 parishes, and the revenue amounts to 45,500 piastras a-year. The chapter consists of six dignitaries, whose stipends amount to 10,000 piastras among them, and the prebends are estimated all together at 42,500 piastras. Here are five rich parish churches, twelve monasteries, eleven convents, besides one in the suburbs, a number of chapels or oratories, four hospitals, two religious houses, nine penitentaries, two colleges, and several remarkable public edifices. The administration is composed of a captain-general and royal audience, who have the entire government of the kingdom, and decide as a supreme court on civil, criminal, and military affairs. The cathedral church, which stands in the highest part of Palma, is handsome and large, of Gothic architecture, with three aisles and lofty vaulted roofs. The parish of St. Michael is one of the most ancient; it was a mosque in the time of the Moors. The other churches have been built since, and are all large, and ornamented with turrets or spires of different forms. The episcopal palace is large, adjoins the cathedral, and is built of beautiful stone. The palace royal of government, where the captain-general and intendent-general reside, is the most considerable, and commands the sea-shore. The house of Contraclation, built in the 14th century, is of Gothic architecture, and is the place where the merchants assemble, and where the public fêtes and masked balls are held; near it is the consolate, where the board of commerce holds its sittings, and which gives its audience gratuitously. The manifon-house has a quantity of sculpture on its entablature, and a number of Gothic ornaments. The clock of this building marks and strikes the different hours of the day and night, according to the progress of the sun, and the different festivals, and is generally allowed to be the only one of the kind in the world. The houses in the town of Palma are pleasant; some are even built of marble.

Palma la Nueva, a town of Italy, in the country of Friuli, on the borders of Goritz, situated on a canal, which...
communities with the Lizonzo. It is fortified and surrounded with nine bastions, which bear the names of nine Venetian noblemen; 55 miles N.E. of Venice. N. lat. 46° 21'. E. long. 13° 16'.

Palma di Solo, a sea-port town of the island of Sardinia, on the S. coast. N. lat. 39° 20'. E. long. 6° 24'.

Palma, Cape, a cape on the coast of Ancona. N. lat. 43° 3'. E. long. 13° 50'—Alfo, a cape on the W. coast of Africa, in the country of Angoy. S. lat. 5° 50'.

Palma Chirilli, in Botany, &c. See Ricinus and Castor Oil.

PALM. The Palm tribe, a most distinct and important, as well as flately and beautiful, natural order of plants, so named from Palma, the ancient appellation of the most valuable among them, the Date tree; whose foliage was confederated, first by the Greeks and then by the Romans, as an emblem of victory, and whose fruit has been a principal article of food in the East, from the remotest antiquity to the present day. The word Palma is supposed to have been applied to this tree, from the divisions of its leaves having some resemblance to the fingers and palm of the hand, whence, perhaps, by an association of ideas, the fruit came to be called dattyl, from δαττύλος, a finger, to which its likeness is, at first, not apparent. The Greeks named this kind of Palm 20^, which Linnaeus has retained. (See Phoenix.) That great botanist terms the natural order in question "Princes of the Vegetable kingdom, of Indian origin, distinguished by their sheathed and many-splitted flowers, their flowing habit, their lofty stature, the simple elegance of their unbranched long-enduring stem, the leafy evergreen garlands with which they are crowned, and their princely treasures of rich fruit. They are tributary to the first order, or Primates, amongst animals; more especially to the lord of the animal creation, who is defined, in a state of nature, to dwell among them."

Palma constitute the eleventh order in the system of Jussieu, the first of his three classes. The character of that class is a simple coryledon, with filaments inserted into the calyx or corolla. The class is thus defined at length by Jussieu:

 calam of one leaf, tubular or deeply divided, superior or inferior, sometimes naked, but mostly accompanied by a sheath, containing one or many flowers, rarely by an involucrum, resembling an outward calyx. Corolla none, for what is so termed by Tournefort, Linnæus and others, Jussieu seeks a true calyx, as above. Stamens definite in number, rarely indefinite, inserted into the lower or the upper part of the calyx, opposite to its segments; their filaments usually distinct, rarely combined, with distinct two-celled anthers. In a few cases the germen are more than one, superior, with the same number of styles and of stigmas, each germen becoming a capsule of one cell, either with a single seed or with several, in which latter case the capsule conflits internally of two valves, to whose margins the seeds are annexed. More frequently, however, the germen is solitary, either superior or inferior; the style solitary, rarely three, or wanting; stigma simple, or divided; fruit pulpy, or capsular, of three cells, containing three or many seeds; sometimes two of the cells prove abortive, and one fixed only of the whole is perfected. The seeds of the pulpy kind are attached to the internal angle of their cells; in those furnished with capsulae, usually of three valves, they are inserted here and there, upon the margin of an elevated receptacle, constituting the partition, in the middle of each valve, and separating along with it. The corolla is small, in a large horned albumen.

The orders of this class are eight, Palma, Asparagus, Juncus, Lilace, Branchea, Aphodel, Narcissi and Iris.

The same author thus characterizes the Palmae. Calyx in six deep segments, often permanent, the three outer segments often smallest. Stamens six, rarely more or fewer, inserted into the base of the segments of the calyx, or rather perhaps into a glandular body situated beneath the germen, their filaments often combined at the bottom. Germen superior, simple, rarely three-fold (in Chamerops); style one or three; stigma simple or three-cleft. Fruit a berry, or a drupa, in the latter case internally reticulated, each of one or three cells, and with one or three bony seeds. Corolla very small, in a cavity at the base of the leaf, rarely at the base, of a large albumen, which is at first soft and estable, but subsequently hardened and horny.

The stem is simple, cylindrical, like the trunk of a tree, shrubby or arborecent, either fealy with the permanent bases of the leaves, or rough with the circular scars where the bases of old leaves have been. Leaves terminal, crowded, alternate, sheathing at their base; the young ones folded, and either covered or surrounded with the reticulated sheaths of last year's leaves, remaining between their bases. Spadix central among the leaves, terminal, many-flowered, either simple, or more frequently branched, each branch accompanied by a pair of sheaths, and the whole enclosed in one very large common sheath, mostly simple, rarely of several leaves. Flowers either dioecious or monocious, but perhaps from the abortion of one or other of the organs of impregnation in each; the sexes situated on the same spadix or on a separate one; rarely hermaphrodite, each flower accompanied by two short sheaths.

Mr. Brown, Prodr. Nov. Holl. v. 1. 266, remarks that the flowers are hermaphrodite (or united), though often polygamous, and that the flowers in some of the polygamous palms are indefinite in number. The stem, when shrubby, is sometimes branched. The same author adds that Palmae are certainly widely removed from Gramina, having apparently more affinity to the Juncs, through the medium of Xerotes and Flagellaria.

This order is divided into two sections, according to the structure of the foliage.

1. Leaves piniate, contain Calamus, Phanan, Aregia, Elata, Oreas, Elata, Caryota, Nipa; to which Willdenow has added Gonioma, and Brown Saxonithia; see their articles.

2. Leaves palmate, or fan-fractured, comprehends Caryota, Licuala, Latania of Commerson, Barygus, which Jussieu is pleased to call Lontaria after the name of Rumphius, and Chamerops; to which are to be added Trianax of Swartz and Raphis of the younger Linnaeus, see All Hort. Kew. ed. 1. v. 3. 473; as well as Livistona, Brown Prodr. 267; see that article.

Of the internal structure of the Palmae we have already given some idea, in speaking of the great natural class to which they belong. (See Monotypyledones.) The following account of their vegetation, extracted from Desfontaines, is published in Lamarck's Dict. v. 4. 701.

When the seed of a Palm-tree is committed to the earth, the leaves unfold in succession, and increase in number, during four or five years. The crown of the root diaties in the fame proportion. The bulb, formed by the re-union of the footstalks of the leaves, swells insensibly, its solidity gradually segments, and at length the item rises above the surface of the ground, of the full diameter that it ever will acquire. The leaves, produced every spring, originate always from the funiculus. The flowers, standing below the others, gradually dry up, and, on separating from the item, leave behind them circular impressions, which furrow its surface, and mark the years of its age, as long as it continues
PA L

nanes to grow. The stem is exactly cylindrical from top to bottom, and if its surface be taken at different periods, no increase of diameter will ever be discovered. This fact did not escape Kämpfer.” The famous able writer remarks nevertheless, that Palm-trees are liable to accidental irregularities in their growth, either from a deficiency of nourishment, whence they become slender in that portion of their stems elongated under such circumstances; or from a super-abundance of food, whence the new part proves of a greater diameter than the old; for the latter retains, in both cases, its original dimensions. Such being the mode of increase in the plants of this natural order, and their duration very long, amounting sometimes to 800 years or more, no wonder that they attain an extraordinary degree of elevation, much exceeding the generality of trees, though scarcely equal to the Norfolk Island Pine. (See DOMBEY.) Yet, notwithstanding this great loftiness of growth, botanists have doubted whether they directly ought to be denominated trees or herbs. They certainly have not the proper trunk, gradually augmented by succeseive annual concentric layers, which is characteristic of a tree or shrub. Their annual circles of leaves all spring in reality from the root, or at least from its singularly protruded crown; but so little of any such protrusion is discernible in herbaceous plants, which die down to the surface of the earth every winter, that the difference between them and the Palm tribe is abundantly marked.

Limnæus, not knowing whether to call their foliage leaves, adopted the term frond, a frond or bough; but, as it seems to us, without any necessity. That they were, by the ancients, very improperly termed branches, we readily allow, but the objections that they have no bud for the following year, neither have they the fulness of leaves, nor do they, like leaves, all wither and fall off together, see Linn. Prod. Ed. in Ord. Nat. 23, appear to us very unsatisfactory. They have, in fact, a central bud, like trees of tropical countries, though not the scaly *hyperena* comparable to those of cold climates; their foliage is much like that of a variety of other leaves; and they fall off in succession, like the foliage of other evergreen plants. When their whole summit is cut off, the plant perishes, they having no power of producing lateral buds.

The botanical arrangement of Palæ was, in the early days of Limnæus, a work of considerable difficulty. Tournefort had distinguished no proper genera in this order, nor Plantier more than one. So imperfect were the accounts of their flowers in early botanical works, and so impossible was it for the author of the sexual system to procure access, in most instances, to the reality, that he could not ascertain enough of their structure to refer more than a very few to his classes and orders; hence he assemblé as many as he knew of the family, in an appendix to his system, except Calamus, of whose relationship to the rest he was not aware. Limnæus, on the other hand, confounded with the Palme Gypæ and Zanies, which are more nearly allied to the Ficus, though properly distinct from both. These genera are now referred by Pearson and Brown to a separate order, under the name of Cycadales. See Br. Prodrc. New. Hall. v. 1. 136.

Meats paid great attention to the Palæ of South America, but his remarks and descriptions have only in part reached us. Dr. Roxburgh’s work, on the plants of Coromandel, has thrown much light on the Eair Indian Palms. Thunberg has, long ago, acquitted so much of their fructification, as to refer most of the established genera to their places in the Limnæian artificial system, where they chiefly belong to the class Hesperandria, like their near relations the Liliées. The native country of the greater part of the Palæ is within the tropics. The requisite degree of heat, and the space, which they occupy in a hot-house, as well as their tardy growth, and backwardness in flowering, render them difficult of cultivation, and prevent their being general in collections. The flores of the late marchions of Rockingham at Hiltingdon were splendidly furnished with some of these Princes of the vegetable kingdom, as are those at New, and the long established ones of J. Blackburn, esq. at Oxford, Lancashire.

PALMAJOLA, in Geography, a small island in the Mediterranean, near the coast of Italy. N. lat. 42° 53’. E. long. 9° 35’.

PALMAR, a river of Africa, in Benin, which runs into the Atlantic, N. lat. 6° 25’. E. long. 5°.

PALMAR Point, a cape on the west coast of Africa. S. lat. 5° 30’.

PALMAR, a town of South America, in the audience of Quiro; 40 miles S.W. of Ribamba.

PALMARIA, a small island in the Mediterranean, about 45 miles from the coast of Naples; 3 miles W. from the island of Ponza. N. lat. 45° 58’. E. long. 15° 53’.

PALLARI, a small island in the Mediterranean, near the coast of Genoa, at the entrance of the gulf of Spezza; 8 miles S. of Spezza. N. lat. 44° 4’. E. long. 9° 45’.

PALMARIGI, a town of Naples, in the province of Otranto; 3 miles W.S.W. of Otranto.

PALMARIS Longus et Brevis, in Anatomy, two muscles of the fore-arm. See Fascia.

PALMARIS Fascia. See Fascia.

PALMAROLA, in Geography, a small island in the Mediterranean, near the coast of Naples, about three miles long from north to south, and very narrow; 4 miles W. of Ponza. N. lat. 41° 4’. E. long. 12° 55’.

PALMAS, a small island in the Pacific ocean, near the coast of Peru. N. lat. 4° 35’.—Allo, a town of South America, in the province of Tucuman; 30 miles S. of St. Miguel de Tucuman.—Allo, one of the Philippine islands, near the south-east coast of Mindanao.—Allo, a river of Mexico, which runs into the bay of Campeche, N. lat. 18° 20’. W. long. 92° 20’.—Allo, a town of North America, formed by the union of the rivers Nicas and Saucede, in New Bilcay, and which, thus united, traverses the province of New Leon, and then falls into the gulf of Mexico, N. lat. 25°. W. long. 98° 56’.

PALMAS, or Palmar, the chief town of Gomera, one of the Canary islands.

PALMAN, Cape, a cape of Africa, on the Grain coast. N. lat. 4° 30’. W. long. 7° 41’. PALMATED-Roots, in Botany, are tuberous roots of a flatish shape, and divided into several oblong and slender branches, resembling to many fingers. Of this sort are the roots of some of the orchis kind, called hence palminated.

PALMATED-Stones, Palmar Lapidés, in Natural History, a name given by the ancients to a sort of stones, which were always found of the shape of a hand with its fingers. They were frequent in Spain; and some, which were found of a fine black, were reputed to be a kind of marble. The greater number were white, and were composed of the matter of one of the softer and less beautiful quarries.

PALMATIAN Horses, in the Manze, Cappadocian horses, which, together with the Hermagenian, were reckoned the noblest and finest in merit. They were fo prized, that they were devoted to the sole use and pleasure of the emperors, and they were not allowed to be sold without express licence or permission. With the Palmatian and Hermagenian.
magenian horses it was usual to couple Phrygian mares; and the produce of this mixture, especially if derived from the horses of Argeus, a mountain in Cappadocia, were thought the finest and best for the labours of the circus, to which they were always pre-emminently devoted, both at Constantinople and at Rome. The Palatine horses owe their name to a person called Palamatus or Palamatius, who was rich in a most valuable breed of horses, whose positions being feized and confiscated, his horses were appropriated to the emperor, and formed the most valuable part of the great dominions, or imperial stables. Palamatius is said to have resided at Andibulis, a town of Cappadocia, not far from Mount Taurus; and living in a country productive of fine horses, by his knowledge and care he raised so generous a breed, that they have at the same time perpetuated his fame and their own. The Hermagenian horses were reckoned next, if not equal in repute, to the Palatine race. These were so denominated from Hermagenes Ponticus, who was a general of horse under the emperor Constantius, and is supposed to have been the founder of this distinguished kind of horses, whose praises have been extolled to these times. Be renger's History, &c. of Horsemanship, vol. i.

PALMATUM FOLIUM, in Botany, a Palmate Leaf, is, like those of the Common Fig, and the Althea fistifolia, with several of the Mallow tribe, deeply divided into oblong finger-like segments; but still so as to leave an entire portion, like the palm of the hand, of greater or less extent, at the base. See Leaf.

PALMAW, in Geography, a town of Bengal; 24 miles S.S.W. of Rognatpour. N. lat. 23° 13'. E. long. 86° 54'.

PALMEIRA, a small island in the Persian gulf, near cape Bardilian.

PAMELA, a town of Portugal, in Estremadura, with a castle on a rock; 6 miles N. of Setubal.

PALMER, in our Ancient Writers, is used for a pilgrim, and sometimtmes for a croise, on account of a leaf made of the palm-tree, which they ever afterwards bore as a badge of their devotion. See Pilgrim and Croise.

PALMER, in Geography, a township of America, in Hamp shire county, Massachusetts, on the fourth side of Chicka pape river, and bounded eastward by Weftero or Worcester county; incorporated in 1752, and containing 1039 inhabitants.

PALMOA, CAPE, a cape on the east coast of the island of Formentera. N. lat. 38° 42'. E. long. 1° 30'.

PALMERIN, a town of Africa, in Beol, where is a mart for hides and teeth. N. lat. 13° 50'. W. long. 16° 21'.

PALMERIO, CAPE, a cape on the east coast of the island of Sardinia. N. lat. 39° 40'. E. long. 9° 50'.

PALMERSTON, CAPE, a cape on the north-east coast of New Holland. S. lat. 21° 30'. W. long. 210° 54'.

PALMERSTON'S ISLAND, an island in the South Pacific ocean, discovered by Captain Cook in June 1774. In the "Millionary Voyage," it is described as a group of small islands, eight or nine in number, connected together by a reef of coral rocks, and lying in a direction nearly circular. Captain Wilson describes some of his companions landed upon one of these islands, which is not a mile in circuit, and which, at high water, is not more than four or five feet above the level of the sea. The soil is coral sand, with an upper stratum of blackish mould, produced from rotten vegetable matter. The inner area of the island is covered with coconut trees, which, decaying and falling, form a thick underwood. They faw a number of men of war birds, tropic birds, and boobies. Among the trees there was plenty of red crabs, dragging after them a shell in form of a periwinkle, but larger, being in diameter about two or three inches. When they ran along the ground, they only put their claws out; but being touched, they withdrew themselves wholly into their shell. Here they saw the submarine grotto, described in Cook's Third Voyage. At one part of the reef which bounds the lakes within, almost even with the surface, there is a large bed of coral, which affords a most enchanting prospect. Its bale, which is fixed to the shore, extends so far that it cannot be seen, so that it appears to be fupended in the water. The refugiance of the sun, when the sea is unruffled, exposed to view the various hues of coral in the most beautiful order; some parts luxuriously branching into the water, others appearing in a vast variety of figures, and the whole heightened by flanges of the richest colours, glowing from a number of large clams interposed in every part. This scene was much improved by the multitude of fishies that gently glided along, seemingly with the most perfect security: their colours were the most beautiful that can be imagined, blue, yellow, black, red, &c. far exceeding any thing that can be produced by art. Our navigators observe, that no traces appear of this island's ever having been inhabited. S. lat. 18° 4'. W. long. 163° 10'.

PALMETTO, in Botany. See Chamaechoa.

PALMETTO-ROYAL, a name given by Ligon to a tree of the palm kind. Its trunk is very tall and straight, and hollowed regularly in the centre; yet so tough, that it is never blown down, nor destroyed by storms. It is recommended for making long telescopes for celestial observations.

PALMETO, in Geography, a town of the island of St. Christopher, situated on a bay to which it gives name; 3 miles W. of Balfe-Terre.

PALMETTO POINT, a cape on the north coast of Jamaica. N. lat. 18° 18'. W. long. 76° 20'. Also, a cape on the south coast of Jamaica. N. lat. 18° 7'. W. long. 77° 57'.

PALLMARTI, Matteo, in Biography, an Italian man of letters, born at Florence about 1405, was descended from an ancient and illustrious family, and educated in the sciences and learned languages under the ablest masters. In 1437 he was present in the public assembly, and nearly the general council of Florence. He was several times entrusted by his fellow-citizens with offices of magistracy, and ree to the supreme dignity of gonfalonier of justice. He was likewise appointed several times to important embassies to the pope, the emperor Frederick III., Alphonso king of Naples, the republic of Sienna, and other states. He died in 1475, at the age of 70. As a literary man, his most considerable work was a Chronicle from the creation down to his own times. He also wrote "The Life of Niccolo Acciaioli," which has been published by Muratori: as likewise has his book, "De Captivitate Piforum," and a work in form of a dialogue, "Della Vita Civile," several times printed and translated into French. The Chronicle already mentioned, was continued to the year 1452, by a native of Pisa, very nearly his namesake, viz. Mattea Palmieri, who was apostolic secretary, and died in 1483.

PALLINOS, in Geography, a town of Spain, in New Castille: 25 miles N.W. of Cuenga.

PALMIPEDES, Web-footed, in Ornithology, the name of an order of birds living about waters, and furnished by nature with feet for swimming.

This order corresponds to the Aniferes of Linnaeus, and comprehends two divisions, viz. those with long legs, and those with short legs. The characters of the former are, that the body is conical and somewhat flattened; the thighs are naked on their lower halves: the legs are very long; the feet
feet are fitted for wading; and the toes are only connected together at their posterior parts by a membrane, so that they are "palmipeds." These birds mostly pair in breeding time, and build their nests on the ground. They feed in the water, on small fishes and various insects; and, especially when young, are good food. The second division comprehends those called "palmipeds," the characters of which are, that the bill is smooth, covered with a membranous skin, and increasing in size towards the point. The feet are fitted for wading, having short legs, which are thin, or compressed laterally; and the toes are all connected, to their ends, by an interjacent membrane. These birds are mostly polygamous, one male associating with many females. They build their nests chiefly on the ground, and the mother seldom takes any trouble in feeding the young, which are very soon able to provide for themselves. They live very much in the water, feeding on aquatic plants, fishes, and other substances; and their flesh has generally a rancid fishy flavour. To the former division belong the avocet, courier, and flamingo; and to the latter, the duck, merganser duck, pigeon, petrel, albatross, pelican, darter, tropiecker, guillemot, diver, gull, tern, and skimmer.

PALMIPES, among the Romans, a long measure, containing a foot and a palm, or five palms; and was less than the cubit by one palm.

PALMIRAS, Point, in Geography, a cape of Hindooftan, on the coast of Catbav, in the bay of Bengal, anciently called "Promontorium Calionian," N. lat. 20° 44'. E. long. 87° 5'.

PALISTRY, a kind of divination, performed by inspecting the lines and marks of the hands and fingers; called also chirognomy; which see.

PALMO, in Commerce, a long measure in Italy, Spain, and Portugal. At Genoa, the palmo corresponds to 10½ French lines, or 9¼ English inches. The canna is of three sorts; the canna piccola, used by tradesmen and manufacturers, = 9 palmi, or 87½ English inches; the canna grossa, used by merchants, = 12 palmi, or 116½ English inches; and the canna, used at the custom-house, = 10 palmi, or 97½ English inches.

In Portugal, the palmo is equal 8 pelleegas = 8.64 English inches; each pellega or inch is divided into 12 linhas or lines, and each linha into 10 pontos or points. This is called the "palmo de cravada," or standard span, being the legal measure of the kingdom; and all other measures, derived from it, are likewise distinguished by the same term. See VARA and PORTUGAL. For the palmo of Spain, see SPAIN. See also Tables of Weights and Measures.

PALMS, among Batavians, white buds shooting out of willows, or willows, before the leaf; of the expansions of which the flowers of that tree are formed.

PALS, Isle of, in Geography, a narrow isle on the coast of Africa, at the entrance of the river Senegal, about five miles in length.

PALM-SUNDAY, Dominica Palmarium, the Sunday next before East Sunday; or the last Sunday in Lent. It has been thus called from the primitive days, on account of a pious ceremony then in use, of bearing palms, in memory of the triumphant entry of Jesus Christ into Jerusalem, eight days before the feast of the pasover, described by St. Matthew, chap. xxi. St. Mark, chap. xi., and St. Luke, chap. xix.

The ancients had other names for this day. For, 1. They called it Dominica Compendiata, i.e. Sunday of the Compendia; because, on that day, the catechumens came to ask the bishop leave to be admitted to baptism, which was conferred the Sunday following.

They had also then given them the symbol, or credo, to get out by heart, to be repeated to the bishop in the ceremony of baptism.

2. They called it Capitulum, the Sunday of washing the head; because those who were to be baptized the following Sunday, were prepared by washing their heads on this day.

Some time afterwards they called it Indulgence Sunday, because the emperors and patriarchs used to distribute gifts on that day.

PAMULARII, more properly called PAMULARII, in Antiquity, a sort of gladiators, who fought armed with a fort of little buckler, called parma; which see.

PALMYRA, Ruins of, or Palmyrene Ruins, in Ancient and Modern Geography, are the ruins of a famous city of this name, situated in a desert of Syria, in the palaic of Damascus, about 48 leagues from Aleppo, and as far from Damascus, 85 leagues from the Euphrates, and about 117 miles from the Mediterranean, and in N. lat. 34° 20'. E. long. 38° 48'. This city appears to have been originally built by Solomon, and called Tadmor. (1 Kings, iv. 18. 2 Chron. viii. 4.) Josephus affirms us, that this was the same city which the Greeks and Romans afterwards called Palmyra; and it is still called Tadmor by the Arabs of the country. But many circumstances, besides the style of the buildings, render it probable that the present ruins are not those of the city built by Solomon, though neither history nor tradition mention the building of any other.

The site of Palmyra is one of those few cultivated spots, which rise in the deserts of Arabia and of Egypt, like islands out of the sandy ocean. (See Oasis.) The name of Tadmor, or Palmyra, by its signification in the Syrian, as well as in the Latin language, denoted the multitude of palm-trees which afforded shade and verdure to that temperate region. It is needless, therefore, to recur to the etymologies, suggested by Hevelius and Dr. Halley (ubi infra). The air on this spot was pure, and the soil, watered by some invaluable springs, was capable of producing fruits, as well as corn. A place possessed of such singular advantages, and situated at a convenient distance between the gulf of Periæ and the Mediterranean, was soon frequented by the caravans, which conveyed to the nations of Europe a considerable part of the rich commodities of India. Palmyra infully increased into an opulent and independent city, and, connecting the Roman and the Parthian monarchies by the mutual benefits of commerce, was suffered to observe an humble neutrality, till at length, after the victories of Trajan, the little republic sunk into the bosom of Rome, and flourished more than 150 years in the subordinate though honourable rank of a colony. It was during that peaceful period, if we may judge from a few remaining inscriptions, that the wealthy Palmyrenians constructed these temples, palaces, and porticos of Grecian architecture, whose ruins, scattered over an extent of several miles, have attracted the curiosity of our travellers.

History is silent as to the fate and circumstances of this city during the great revolutions in the several empires of the East; but it may well be supposed, that it advanced a garrison as this was, being above 300 miles from Jerusalem, continued not long in the possession of the Jews, who immediately after Solomon fell into civil dissension, and divided their force; so that, without doubt, it submitted to the Babylonian and Persian monarchies, and afterwards to the Macedonians, under Alexander and the Seleucides. But when the Romans advanced to these parts, and the Parthians...
PALMYRA.

seemed to put a stop to their farther conquests in the East, then was this city of Palmyra, by reason of its situation, being a frontier, and in the midst of a vast sandy desert, where armies could not well subsist to reduce it by force, courted and carefree by the contending princes, and permitted to continue a free state, a mart or staple for trade, for the convenience of both empires, as we learn from the information both of Appian and Pliny. Palmyra is first mentioned by the Roman historians as a place which Mark Antony, after his victory at Philippi, about 40 years B.C., attempted to plunder, pretending that it had not observed a just neutrality between the Romans and Parthians. When the Romans, under Trajan, had made it appear by his victories, as we have already said, that there was no comparison between their power and that of the Parthians (Trajan having taken Babylon and Ctesiphon, the seat, at that time, of the Parthian empire), the Palmyrenes were induced to declare for the Romans; which they did, by submitting themselves to the emperor Adrian. About the year of Christ 156, when Adrian made his progress through Syria into Egypt. This magnificent emperor, being highly delighted with the situation and native strength of the place, situated on an extensive plain, and surrounded on three sides by a long chain of mountains, determined to further it with various splendid edifices and ornaments; and at this time he probably conferred upon it the privileges of a "Colony Juris Italic," which, as we learn from Ulpius, it actually enjoyed, and the inhabitants of the city were induced by gratitude to call themselves "Hadriano-polites." Many of its marble pillars, particularly those of the long porticoes, were probably the gift of this emperor. In the time of Caracalla it was a Roman colony; and from Adrian to Aurelian, for about 140 years, it continued to flourish and increase in wealth and power to a very considerable degree; and the Palmyrenes, who assisted Alexander Severus against the Parthians, were again conspicuous in the reign of Gallienus, under Odenathus, who, when the emperor Valerian was taken prisoner by Sapor, king of Peria, brought a powerful army into the field, recovered Mesopotamia from the Parthians, and penetrated as far as their capital city of Ctesiphon, and who, for this service to the Roman state, was made the associate of Gallienus in the empire. He was succeeded by Zenobia his queen, who broke the alliance with Gallienus, and made herself sole mistress of Syria and Mesopotamia. (See the biographical article Zenobia.) At length Aurelian, having taken Palmyra, A.D. 273, after a long siege, by means of his light horse pursuad Zenobia, who had mounted the fleetest of her dromedaries, and had reached the banks of the Euphrates, about sixty miles from Palmyra, and having feized the princeps, carried her to Rome, to grace his triumphs, and with her, her secretary Longinus, known for his admirable work on the Sublime, who was put to death. Her capital was treated with unexpected lenity. The arms, horses, and camels, with an immense treasure of gold, silver, silk, and precious stones, were all delivered to the conqueror. The city revolting in her absence, Aurelian returned and destroyed it, putting to death most of the inhabitants, without regard either to age or sex. Little is known concerning the fate of Palmyra since the time of Maximus, except that it was considered as a place of strength, and that in the 12th century there were two thousand Jews in it. Aurelian himself had lamented the destruction to which he had condemned it; and he not only manifested a concern for the re-establishment of the temple of the Sun, but he granted to the few Palmyrenians, who had survived the slaughter which he had ordered, the permission of rebuilding and in-habiting their city. But it is easier to destroy than to restore. The seat of commerce, of arts, and of Zenobia, gradually sunk into an obscure town, a trifling fortresses, and at length a miserable village. The present citizens of Palmyra, confounded by the destruction of their church, have erected their mud-cottages within the spacious court of a magnificent temple.

With respect to the ruins, they appear to be of two different and distant periods; the oldest are so far decayed as not to admit of measurement, and seem to have been reduced to that state by the hand of time; the other appear to have been broken into fragments by violence. Of the inscriptions, none are earlier than the birth of Christ, and none are later than the destruction of the city by Aurelian, except one, which mentions Diocletian. It is scarcely less difficult to account for the situation of this city than for its magnificence; the most probable conjecture is, that as soon as the springs of Palmyra were discovered by those who first traversed the desert in which it is situated, a settlement was made there for the purpose of carrying on the trade of India, and preserving an intercourse between the Mediterranean and Red sea. This trade, which flourished long before the Christian era, accounts not only for its situation, but also for its wealth. As it lay between Egypt, Persia, and Greece, it was natural to expect, that traces of the manners and sciences of those nations should be discovered among the Palmyrenes; who, according to the account of the Egyptians in their funeral rites, the Persians in their luxury, and the Greeks in their buildings; and therefore the buildings, which now lie in ruins, were probably neither the works of Solomon, nor of the Seleucidae, nor, few excepted, of the Roman emperors, but of the Palmyrenes themselves.

Palmyra was formerly encompassed by palms and fig-trees, and covered an extent of ground, according to the Arabs, near ten miles in circumference; and might probably have been reduced to its present confined and ruined state by quantities of sand, driven over it by whirlwinds. The walls of the city are flanked square towers; and it is probably by their general direction, that they included the great temple, and are three miles in circumference. But of all the monuments of art and magnificence in this city, the most considerable is the temple of the Sun. The whole space containing its ruins, is a square of two hundred and twenty yards, encompassed with a flate wall, and adorned with pillars within and without, to the number of sixty-two on a side. Within the court are the remains of two rows of very noble marble pillars, thirty-seven feet high; the temple was encompassed with another row of pillars fifty feet high; but the temple itself was only thirty-three yards in length, and thirteen or fourteen in breadth. This is now converted into a mosque, and ornamented after the Turkish manner. North of this place is an obelisk, consisting of seven larger stones, besides its capital, and the wrought work about it, about fifty feet high, and just above the pedestal, twelve in circumference. Upon this there was probably a statue which the Turks have destroyed. At a small distance there are two others, and a fragment of a third, which gives reason for concluding that they were once a continued row. There is also a piazza forty feet broad, and more than half a mile in length, inclosed with two rows of marble pillars, twenty-six feet high, and eight or nine feet in compass; and the number of these, it is computed, could not have been less than five hundred and sixty. Near this piazza appear the ruins of a flately building, supposed to have been a banquet ing house, elegantly finished with the belt mortar. In the west side of the piazza there are several apertures for gates into the court of the palace, each adorned with four porphyry
porphyry pillars, thirty feet long, and nine in circumference. There are several other marble pillars differently arranged, on the pediments of which there appear to have been inscriptions, both in the Greek and Palmyrene languages, which are now altogether illegible. Among these ruins there are also many fountains, which are square towers, four or five stories high, and varying in size and splendour. We are indebted for an account of these very magnificent remains of antiquity, partly to some English merchants who visited them in 1678 and 1691, (Phil. Trans. N. 217, 218, or Lowthorp's Abr. vol. iii.,) but chiefly to M. Bouverie and Mr. Dawsins, accompanied by Mr. R. Wood, who travelled thither in 1751. The result of their observations was published in 1753, in the form of an Atlas, containing fifty-seven copper plates, admirably executed. Since this publication, it is universally acknowledged that antiquity has left nothing, either in Greece or Italy, to be compared with the magnificence of the ruins of Palmyra.

PALMYRA, in Geography, a port-town of America, and the only port of entry and delivery in the state of Tennesee; so constituted by a law of the United States in 1797; situated on the south bank of Cumberland river.

PAINAUDE, a country of Hindoozlan, which is a district belonging to the Carnatic, but situated towards the Kithnaii river, on the W. of Guntoor. The principal place in it is Timerycotta.

PALO, a town on the E. coast of the island of Leyta. N. lat. 14° 15'. E. long. 125° 55'.—Also, a cape on the coast of Albania; 6 miles N.W. of Durazzo.—Also, a town of Naples, in the province of Bari; 3 miles W. of Bitteto.—Also, a town in Patrimonio, on the sea-coast, defended by a strong castle; 13 miles W.N.W. of Rome.

PALO, Cape, a cape on the coast of Albania, in the Adriatic. N. lat. 41° 44'. E. long. 16° 10'.

PALOZZA, a town of Hungary; 11 miles E. of Széhen.

PALOMAR, a town of Spain, in Aragon; 22 miles N. of Teruel.

PALOMBARA, a town of Naples, in Lavora; 5 miles N.E. of Canaua.

PALOMERA, or PALUMARIA, a sea-port town on the N.E. coast of the island of Majorca. The port is covered by a rocky island, called by the ancients "Columbia." Some coral has been found on this coast, and in the rocks.

PALOMINOS, a small island on the coast of Peru, three miles W. of St. Lawrence island.

PALONGOLA, a town of Congo, on the Lelanda; 2 miles S. of St. Salvador.

PALONGONG, a town of Matamba; 70 miles S.E. of St. Maria de Matamba.

PALOS, a gulf in the straits of Mascalar, near the W. coast of Celebes. S. lat. 0° 24'. E. long. 119° 15'.—Also, a town on the W. coast of Celebes, in a bay to which it gives name. S. lat. 0° 56'. E. long. 119° 39'.—Also, a sea-port town of Spain, in the province of Seville, at the mouth of the Tinto, in which is a tolerable harbour formed by the tide. In the year 1492 Columbus failed from this port, on his first voyage for the discovery of the new world; 2 miles S. of Moguer. N. lat. 37° 10'. W. long. 6° 58'.

PALOS, Cape, a cape of Spain, on the coast of Murcia. N. lat. 37° 37'. W. long. 4° 48'.

PALOTT, a town of Hungary, with a castle, and fortified with a high wall and a moat; 8 miles W.S.W. of Stuhl-Weifenburg.

PALOTZA, a town of Hungary, on the river Poprat; 54 miles N. of Cafferan.

PALOU, a town of Asiatic Turkey, in the government of Diarbekir; 60 miles N. of Diarbekir. N. lat. 38° 52'. E. long. 39° 40'.

PALOUé, and PALOY, in Botany. See GINNIA.

PALPABLE, something that may be perceived by the senses, especially by the sense of feeling. Hence impalpable powder.

PALPEBRÆ, in Anatomy, the eyelids. See EYE.

PALPEBRIS SUPERIORIS LATERIS, a muscle belonging to the upper eyelid. See EYE.

PALPEBRALIS CONJUNCTIVA, that portion of the membrane which lines the eyelids. See EYE.

PALPEBRARUM ORIFICIALES, a circular muscle, surrounding the opening of the eyelids. See EYE.

PALPEETER, in Geography, a town of Candahar, in the Cabulistan; 50 miles E. of Ghuzni.

PALPITATION, in Medicine, a vehement and inordinate action of the heart. This affection is very various in respect to the degree of its violence, and of the diftrefs which accompanies it, as well as in regard to the actual morbid changes of which it is symptomatic, and therefore to the degree of impurity or danger with which it may occur. For it appears under all the gradations of severity, from the flight beating occasioned by active exercice, or a sudden emotion of the mind, to the most tremendous convulsions of the heart and arteries, which are not only perceptible to the touch of others, but are obvious to the sight, and even sometimes to the hearing of by-standers. It is, indeed, only to the more severe instances of the difafe to which the term is applied in a medical view, and such only which it is the object of this article to describe.

This morbid pulsation of the heart is seldom constant in its vehement degree, for that would be inconsistent with the continuance of the functions of life; it sometimes continues in a minor degree, i.e. the ordinary action of the heart is carried on with more force than is natural, and with a constant sense of oppression about the region of the precordium.

But, in general, the palpitation occurs in paroxysms, at uncertain intervals, and, after continuing with extreme violence for a short space of time, then ceases, the heart resuming its ordinary moderate and measured action.

The fit of palpitation is extremely distressing. It is usually sudden in its attack, beginning insensibly in all its violence, from the operation of very slight exercises, or frequently without any obvious excitement. The short, quick, and rapid pulsation of the body occasioned by a false step, or slip of the foot, in walking, — any emotion of the mind, — certain impressions upon the stomach, arising from flatulence, acidity, or particular food or drink, — or even the mere diffusion of the stomach by a meal, will give rise to the paroxysm in those who are subject to the disease. Sometimes it comes on in the night; and certain positions of the body, such as lying on the left side, and compressing the heart, will occasionally produce it; and, in other cases, it recurs at regular periods, like the paroxysm of an intermittent.

The diftress which accompanies the paroxysm is not occasioned by the mere violence of the contractions of the heart, and by its blows against the ribs; but arises also from the complicated sensations of oppression and disturbance, which are produced in the different organs of the body, especially in the brain and lungs, by the torrents of blood, rapidly and vehemently injected into them from the labouring heart. The spasmodic motions of this vices are commonly visible at a considerable distance from the sufferer, by the motion of his garments, by which his pulse may be counted; and if he is stripped, the successive projection and collapse, not only of the ribs, but even of the pit of the stomach and abdomen, are very visible. At the same time, the violent

palpitations

THE DURATION OF THE PAROXYSM, AS WELL AS OF THE INTERVAL OF REMISSION, IS VARIABLE AND UNCERTAIN, EVEN IN THE SAME INDIVIDUAL. WE HAVE SEEN THE PAROXYSM CONTINUE, IN DIFFERENT INSTANCES, FROM A FEW SECONDS TO A QUARTER OF AN HOUR; AND, AS TO THE INTERVAL, WHICH DEPENDS MUCH UPON THE ACCIDENTAL ABSENCE OR OCCURRENCE OF CRITICAL CAUSES, IT MAY VARY FROM A FEW MINUTES TO MANY WEEKS OR EVEN MONTHS.

1. THE MOST ALARMING AND DANGEROUS CASES OF PALPITATION, ARE THOSE WHICH ARE CONNECTED WITH ORGANIC DEGRADATION OF THE HEART, OR OF THE GREAT VEINS ARISING FROM IT. THESE DEGRADATIONS OCCASION PALPITATION IN THREE WAYS; FIRST, BY INCREASING THE IRREGULARITY OF THE HEART, BY EXCITING IRRITATION IN THAT ORGAN, OR BY OBSTRUCTING THE EXIT OF THE BLOOD FROM ITS VENTRICLES.

THE IRREGULARITY OF THE HEART IS INCREASED BY INFLAMMATION, OCCURRING IN ITS SUBSTANCE, OR IN ITS INVOLVING MEMBRANE; THE SYMPTOMS, HOWEVER, ARE NOT ALWAYS SUFFICIENTLY CLEAR TO BE ACCURATELY DISTINGUISHED IN PRACTICE.

2. PALPITATIONS OF A FEW MINUTES SOMETIMES OCCASIONED BY THE CONDITION OF ORGANS IN THE VICINITY OF THE HEART, IN
fume cafes irritating it, in others obstructing its action. When the circulation of the blood in the lungs is impeded, it necessarily follows, that the right ventricle of the heart will be oppressed and overcharged; whence palpitations sometimes occur in ahima, in peripneumony, in hydrothorax, and other obstructions in the chest. Diforder, or even mere dilatation of the stomach, will occasionally give rise to palpitations, especially where there is much irritability of the heart, or any actual difease of that organ or its valves. Thus after a full meal, or from the dilatation of the stomach by flatulence, this viseus preffes the diaphragm upwards, diminishing the cavity of the chest, and therefore obstructing the circulation, as well as comprefling the heart; it likewise somewhat comprefles the defcending aorta in the abdomen, and thus also tends to impede the emptying of the left ventricle of the heart. Such an obftruction, though unperceived in health, is fufficient to produce palpitation, in thofe in whom the heart is predisposed to it, as above flated.

Senac, who has collected feveral cafes illuftrative of this fact, remarks also, that dilatation of the intestines by flatulence, or the accumulation of feces, enlargement of the liver, the prevalence of worms, and some other abdominal irritations, occasionally give rise to palpitation in a fimilar manner.

3. The most frequent source of palpitations, next to the actual organie difeafe of the heart, is that general condition of the conftitution, which gives rise to the various affections, that are called nervous. Whene re, women, who are fubjeft to hypheria, and men labouring under hypochondria, are often difturbed by fome fewer paroxysms of pal pitation of the heart, infomuch that the uttern alarm is excited, left there should be organie difeafe of that important organ. Indeed, under alfo almost all circumstances of general debility, palpitation is liable to occur, as well as other ipa modic affections; as in the state of chlorosis in young women, during the convalescence from acute difeases, after great hemorrhages, or after long watching, fevere fluty, long continued fatigue, and other caufes of exhaustion to the animal frame. It is one of the common torments of extremely fendentary and ftransparent men, and especially of students of medicine, who reduce themfelves to a hypochondriacal frame, and are then ready to find a whole fystem of nofology in their own persons.

It is often extremely difficult to pronounce with decision, that palpitations arife from organie difeafes of the heart and great veins, or that they are merely sympathetic of some local irritation, or dependent on a general debilitated nervous condition. In order to form a fatisfactory diagnofe, it is neceffary to examine carefully, not only the feat, nature, and violence of the palpitation, but also the various concomitant affections, and to inquire into the previous state of health and difeafes of the patient, and to attend to the in fluence of medicine on the complaint.

In the inftances of palpitation, originating from organie derangement, the paroxysms are commonly more violent, and of longer duration,—they occur more frequently, and often without any obvious or adequate caufe,—and they are often accompanied with acute pain across the chest, from the flernum to the spine. In the intervals, too, between the paroxysms, the patient is not entirely free from all halfing in the breast, or from fome other diftructive fenfations, fuch as pain, a tenfe of fluffling, weight, and oppreffion, difficulty of breathing, &c. as in the mere sympathetic cafes of palpitation. The labouring action of the heart, even in the intervals, is often perceptible to the hand applied over the ribs; and the apex of the organ, instead of being felt between the fifth and fixth ribs, juft under the mamma of the left side, is perceived confiderably lower, as between the ninth and tenth ribs. The pertinacity and long duration of this flate of difeafe, with repeated paroxysms, will often afford a strong argument, in conjunction with the other circumstances, for deeming the caufe organie. And the previous occurrence of fome fever acute difeafe, efpecially the rheumatic fever, or acute rheumatism, which is known to leave a frequent disposition to difeafe of the heart, particularly to enlargement of it, will also tend to modify the judgment in these cafes.

It is still more difficult, of course, to distinguish by any symptoms the particular kinds of organie affion of the heart, than to difcriminate thefe from the other forms of palpitation; and, with a view to practieal purpofes, it is obviously of little importance; for once organie change is equally inac cessible to the influence of medicine as another. Never thelefs this has been attempted; and an attention to the minute differences of the symptoms, will doubtlefs, in many cafes, enable the experienced practitioner to form fhrewd approximations to the truth. For infance, the palpitation will probably be more palpable and obvious to the byfander, when the ventricles, and especially the left ventricle, are enlarged, than when the auriicles are dilated or aneurymatic, in which cafe, the beating is more obscure and diftant under the hand prefling the ribs; and the motions of the pulse and of the heart will be more distinctly synchronous. When the valves are offiified, a flitting or churrupping found is in cafe cafes distinctly heard, during the violent ipa modic pulsations of the heart. When the heart is much enlarged, the pullation is less circufcribed and pointed under the hand, applied to the fun of the heart, than is natural: in fact, it is broad and diffused; and Dr. Ferriar has remarked, that a certain jarring fenfation, which he conceives to be peculiar to this difeafe of the heart, is felt by the hand under thefe circumstances. (See Cardiogmus.) If there is a confiderable adhefion of the heart and pericardium with the contiguous parts, Senac is of opinion, that there is rather a tre mor than an actual palpitation of the organ. It is not to be overlooked, however, that none of these symptoms are sufficient to eflablih a certain diagnofe; for it is admitted by the ableft practitioners, that palpitations of the molt severe degree, and of different modifications, which had been pronounced the symptoms of organie difeafe, have, nevertheless, yielded to remedies. See Senac, Traité de la Structure du Cœur, liv. iv. chap. xi. § 11; and Ferriar, loc. cit. vol. ii.

Although, however, confiderable caution is required in deciding that palpitation is the refult of organie difeafe; yet, on the contrary, it may, with more confidence, be pronounced to be independent of such difeafe, if the paroxysms are fit, and speedily terminate, while the intervals are more completely free from any affection of the chest, and of longer duration. And this conclusion will be further confirmed, if at the fame time other symptoms are prefent, which indicate a morbid irritability of the habit; fuch as those of chlorosis, hypochondria, hypheria, &c.; or if it be known that the patient has been recently exposed to the operation of the debilitating caufes above enumerated. See Headlam. Diff. Mang. de Palpitatione, Edin. 1800, p. 23.

According to the decision which is made, as to the source of the diforder, the prognofe will be favourable or other wise. If it be very obvious that it is of the latter clafs, and unconnected with any organie lefion of the heart, it may be expected to be relieved or removed by medicine, according to the age, constitution, and manner of living of the patient, and to the mildness of the diforder of which it is a symptom. But if it appear to be clearly the refult of organie difeafe, a cure cannot be expected, and palpation must be the fole object of the practitioner, and the fole hope of the patient.
PALPITATION.

patient. In this case, the disease will continue, gradually augmenting, for an indefinite period; and as the obstruction to the circulation is increased, other distressing symptoms are apt to supervene, such as asthma, putting of blood, constant oppression of the respiration, dropsy of the pericardium, and of the thorax, and ultimately anasarca; and during the occurrence of any of these affections, or sometimes before any of them have supervened, the patient is not unfrequently cut off by a sudden death, when it was not expected.

In considering the proper methods of treating palpitation, two indications are to be kept in view; the one regards the measures to be adopted during the paroxysm; the other, those which are to be pursued during the intervals of remission.

1. The paroxysm is to be viewed in the same light as other convulsive actions, from whatever source it may originate; and, like others, it may be relieved by blood-letting, and by what are called antipsymtomic measures, the choice of which is a matter of some importance. Whether the palpitation be connected with organic lesion or not, if the patient be robust or plethoric, if he suffer from pain and a great lefse of suffocation, if the respiration be excessively laborious and difficult, if the pulse beat with a full and hard stroke, and if there are no obvious marks of great debility or of a dropical tendency, a free blood-letting, from an hourly to a diurnal rate, will be safe, and afford speedy relief; nay, it may probably ward off an apoplectic attack, or prevent a rupture of the heart or some great vessel, and thus preserve life. If the palpitation be not of long standing or habitual, and if it be accompanied with the symptoms that belong to carisis or inflammation of the heart, then copious blood-letting is the principal remedy upon which any dependance can be placed; and it must be repeated, either in the paroxysm, or during the intermission, as those symptoms may require. In the majority of cases, however, the paroxysm will not be of this kind, and the ablation of blood will not only be unnecessary, because useless during the paroxysms, but it will be prejudicial to the subsequent state of the patient.

For whether the disease be organic, and of considerable standing, or sympathetic of the hypochondriacal, hysterical, or nervous temperament, considerable debility is usually present, and the tendency of the disorder is to increase that debility. Whenever, therefore, the patient is obviously not plethoric or robust, when there is much disposition to syncope or fainting, when the pulse is small and weak, and when the palpitation appears to be the result of strong mental emotions, or to have followed the debilitating circumstances, before enumerated, then it will be proper to refer to antipsymptomics, for the purpose of alleviating and shortening the paroxysm. Of these it will be necessary, in many cases, to take any that may be at hand; as camphor, ammonia, aferotic, opium, aether, valerian, cafiot, &c.; but where the choice can be made, a mixture of ather and the tincture of opium is preferable, as productive of the most speedy and powerful sedative effects.

The patient should not be constrained to assume any particular posture, but should be retained as quietly as possible in that which he instinctively chooses, and which experience satisfies him is the safest. This is commonly a sitting posture, in which he reclines a little forwards; and sometimes gentle but steady pressure on the ribs of the left side, affords considerable relief.

2. The treatment required in the interval will be different, in those cases in which the palpitation results from organic disease, and in those in which it is merely a nervous symptom.

In the organic cases, as we have before observed, palliation is all that medicine and regimen can accomplish; and it is certain that much alleviation of the sufferings of the patient, and probably that a considerable prolongation of life, is often thus effected. For this purpose two indications are to be kept in view: namely, the one, to avoid everything that may hurry the circulation of the blood; and the other, to avoid every source of plethoric, or turgescent, of the vessels.

Both the frequency of the returns of the paroxysms, and the violence of them, may be materially diminished by avoiding all hurry of the circulation. This is effected by a series of minute attentions, in respect to which, although the physician may point them out, the patient must minister to himself. Constipation quietness both of body and mind must be studied; the patient should move carefully and slowly, whenever motion is necessary, and especially should cautiously avoid false steps in walking on uneven ground. He should avoid declivities, as stairs, as little as possible, and therefore sleep on the ground floor of his house. He should shun heated rooms, the influence of strong fires, and of close unventilated apartments. He should avoid entering into the discussion of subjects which are liable to excite any strong emotion, or to ruffle his temper. The regulation of his diet becomes of extreme importance in this point of view; for nothing tends more directly to hurry the circulation, and to produce partial turgescences, than a heating and stimulant regimen. He should, therefore, totally proscribe all spicy, vitious, and fermented liquors from his table, and shud use the lightest and most digestible food, and that in great moderation, avoiding condiments, and a variety of dishes.

This regulation of regimen affords, in fact, one of the most effectual means of fulfilling also the second indication, that of avoiding a plethoric condition of the system.

Medicine, however, though inadequate to accomplish these purposes alone, may be made to contribute materially to the same ends, when united with a proper conduct of regimen. The constinent and regular evacuation of the bowels, especially by means of saline and other cooling laxatives, conduces both to moderate the activity of the circulation, and to prevent plethora, and cannot be neglected with impunity, where there is organic disease producing palpitation of the heart. If there is actual plethora to any extent, even actual debility by the lancet may be necessary.

There is another class of medicines which appear to be indicated under these circumstances; namely, such as have the power of directly diminishing the action of the heart and arteries; of these the digitalis is the most effective. This medicine, when combined with the repeated use of saline laxatives, and with the cooling regimen, and system of quietude, above recommended, has, in several cases under the inspection of the writer of this article, appeared to procure a very valuable degree of eafe, and freedom from palpitation, when there were obvious signs of organic disease, and to retard the progress of that disease itself.

A very different practice is requisite in the interval of remission, in those cases of palpitation that are merely connected with a morbid irritability of the habit, or with some local irritation. If the palpitation is excited by over-dilution of the stomach, the meals should be moderate, and the cauas of flatulence particularly avoided, while, at the same time, the proper remedies for indigestion should be employed. If the irritation arise from the presence of worms in the intestines, the remedy will be equally obvious. And the use of laxatives, which we have recommended above with another view, will also obviate one source of irritation, which not unfrequently accompanies both indigestion and the hysterical and hypochondriacal habit, namely, an accumulation of feces in the bowels, or habitual constipation.
It is fearely necaey to dwell upon the treatment required in the intermiffions of palpitation, connected with chlorosis, hyphemia, hypochondriac, and other flates of debility and irritability of habit; since these diseases have been amply discoursed under their repective heads. The general indication is to employ medicines polihefed of a tonic power, and to avoid every cause of debility, moral and physical. Preparations of cinchona, gentian, calumba, ferpentaria, and other vegetable bitters, the mineral tonics, especially the preparations of iron, the chalybeate waters, &c. and the use of the cold bath, are among the most efficacious means of removing that morbid irritability which gives rise to the palpamodic actions of the heart. Moderate exercise, in the open air, taken in such a way as to avoid any extraordinary hurry of the circulation, which might bring on the paroxysm of palpitation, will be adovable. And every source of anxiety, or other fevere emotion of mind, should be avoided as much as possible; by fixing the attention upon intereting and agreeable pursuits, or by travelling.

PALREDGYUR, in Geography, a town of Hindooftan, in Palnaud; 16 miles W.S.W. of Timerycotta.

PALSCHAU, in Biography, born in Germany, who, before he was thirteen years old, travelled with his father to several parts of Europe, and astonished every auditor by his performance of Sebastian Bach's most difficult harpsichord lefions; and by running most rapid divisions in thirds and sixths, with both hands: eightths he could not reach; and indeed he astonished speculators with his dextrous use of pedas, particularly in our country, where, though there have been pedals in our very large old organs, particularly at St. Paul's, Exeter, and St. Michael's, Cornhill; yet they seem never, or but rarely, to have been used by our organists after Handel's first arrival here, who, as we are told, used to go with young Green, then an apprentice, to exercise himself on these feet keys in private; intending always, during the reign of his patron the elector (afterwards George I.), to return to Hanover; but young Palschau must have been here very early in our musical life, before we had ever seen or heard of pedals; as, when Mr. Boyce defired us to officiate for him at St. Michael's, Cornhill, we knew not of their existence. (See Pedals.) But soon after we had heard the young German, and seen him use pedals, we heard Miss Robinson, the father, daughter of Mr. Robinson, the organist of Welminten Abbey, perform wonders on a harpsichord with pedals; which instrument it is probable Palschau's father borrowed of Robinson; for wherever he stopped on the continent, he was sure to find pedals. But after this period, we had been many years surprized at hearing nothing further concerning Palschau; and supposing he was either dead, or that some accident had befallen him to stop the progress of his premature talent. And when we went to Germany, one of our first enquiries was after Palschau; but were told that he was at Riga; but was still regarded as a great player of the Bach school: yet finding on his return home, that his performance became less miraculous every day, as he grew up he acquired great reputation in instructing youths intended for the profession of music, in which he had acquainted himself with an intelligence and integrity fo superior to common organists, and masters who take apprentices, in thoroughly grounding his pupils in every branch of the art which they were purifying, that he was invited to Riga, where he continued to qualify young organists, not only in that city, but from all parts of Germany. He had himself been instructed by Mittel, who was an elevé and imitator of C. P. Emanuel Bach. He composed but little, except two harpsichord concertos, and some songs. But we have heard since that his fame became fo extensive as to produce an invitation to Peterburgh, where his good taste in playing, and manner of teaching, pleased so much, that he was appointed court-mater by the empress Catharine, and his salary in that office, and the many scholars he had in great families, made him so easy in his circumstances, that he would undertake no more boys on the chance of their becoming great musicians, unless, on examining their hands, he found them well formed by nature; and that every finger on both hands were equally strong. He likewise examined their heads, by putting questions to them, which, to answer, required intellect. He then affigned, for practice to them, as a first lesson, one of the most complicated and difficult compositions for keyed instruments that he could find. We are to suppose, before these students applied to him, they were well acquainted with the first elements of music; as the gamut, time-table, clefs, flats, sharps, and the usual characters for graces, &c. He informed these young candidates for his institutes, that he would not lay no limits to the time they should take in accomplishing this task; as, if they only learned one bar in a week, they must come to the end of their labour at last.

We were furnished with the character and singularities of this musician, by the Rev. Mr. Smernove, of the Greek church (the chaplain of count Worontzow) and his brother, John Smernove, a fine performer on the violin, and private secretary to the count, when ambassador from Russia.

PALSCHOV, in Geography, a town of Prufia, in the province of Pomelia; 11 miles N.W. of Marienburg.

PALSgrave, a term used among the Germans, of the fame import with palatine.

It is compounded of the Latin palatium, and the Dutch grave, governor, g. d. governor, or supefintendent of a prince's palace.

Palsy, in Medicine, a corruption of paralysis, from paralyses, paralytic, laxatio, resolutio or, as the Latins wrote, nervorum resolutio, (relaxation of the muscles,) signifies a loss of the power of voluntary motion.

The appellation of palsy is, therefore, not applicable to those cases of impaired mobility of muscular parts, which arise from mechanical failures, or from inflammation; but only to those which are occasioned by an inherent imbecility in the muscles themselves, or rather in the nerves with which they are furnished, and through the medium of which the moving power is communicated from the brain.

It will not be necessary, in this place, to enter into any detail respecting the nature and functions of the nervous system in the animal body, as the structure and properties of that system have been amply delineated under its proper head. (See Nervous System.) It is sufficient for our purpose to know, that a multitude of accidents and experiments have demonstrated the dependence of sensation and voluntary motion, in every part of the body, upon the uninterrupted communication of nerves between that part and the brain respectively; and that the interruption of this communication, either by the division of the trunks of the nerves, or of the great nerveous mains in the canal of the spine, (incorrectly called the spinal marces,) or by pressure on the face, or, lastly, by pressure or other mechanical injury to the brain itself,—is invariably followed by a loss of one or both these faculties in the parts beyond such injury.

Hence the term paralysis comprehends a great variety of sensitive and muscular incapacity, to which various appellation have been given, according to the general or partial loss of power, or to the nature of the sensaion so impaired. Where the whole power of motion and faculty of sensation...
are abolished, the term *palsy* is, indeed, seldom employed, but the disorder is called *apoplectic*. When one-half of the body, longitudinal, is paralyzed, *i.e.* when the leg, arm, &c., of one side only lose their powers, while those of the other remain unimpaired, (which is the most common form of palsy,) the disease is termed *hemiplegia*, or *hemiplegia*; and when one-half of the body is paralyzed transversely, *i.e.* when both the lower extremities are paralysed, while the arms and upper parts retain their power, the malady is called *paraplegia*, or *paraplegia*. Some writers have appropriated the term *paresis* to the palsy of individual parts or muscles, as of the arms or legs, of the tongue, eye-lids, bladder, &c. Originally, however, these appellations appear to have been employed as general terms, without much discrimination. Again, a paralytic condition of the different organs of sense has been designated by corresponding appellations. Thus the loss of feeling, or of the fenfe of touch, has been called *anesthesia*, that of vision, *amaurosis*, that of smell, *anosmia*, that of taste, *aguesia*, that of hearing, *dysacusis*, &c. These affections will be found described under their proper heads; and, in this place, our attention will be directed to the more general forms of palsy, especially to the *hemiplegia* and *paraplegia*, and to those partial kinds, which are the result of particular agents, such as of the poison of lead, mercury, &c.

1. Of the Hemiplegia.—The palsy, which is most frequently seen, and which consists in the loss or diminution of the power of motion of one side of the body, is sometimes the consequence of an attack of apoplectic, where that has not proved fatal; but it more commonly occurs insidiously, and without any actual apoplectic attack. In the latter case, however, the disease differs from the former only in the degree of injury which has taken place in the brain, the prejudice upon that organ being more partial than in apoplectic.

The symptoms of *hemiplegia* are distinct and obvious, and scarcely liable to be confounded with those of any other disease. The most manifest symptom is the want of command over the limbs of the side affected, which either remain total immovable by the will of the patient, or are poised of so little power, that the arm hangs dangling by the side, and the leg is dragged along the ground, rather than elevated in attempting to walk, and vibrates from want of firmness, whenever the foot is planted on the ground. At the same time, the limbs are perfectly flexible by any external impulse, to which they offer no resistance. As the muscles of one side of the head are also paralyzed, the features, especially the mouth, are commonly drawn away, giving a distorted appearance to the countenance; for, as the paralyzed muscles offer no resistance, so the confluence tendency to contraction in the healthy muscles of the opposite side necessarily operates in drawing the whole towards themselves. The face is contracted, therefore, not on the plicated, but on the sound side. The same paralytic condition exists also in one-half of the tongue, which, if it be attempted to be protruded, is thrown in a curved state, the point always turning towards the angle of the mouth on the paralytic side. This plicated state of the tongue and lips, and other organs subservient to the voice, is necessarily the cause of indistinct articulation; so that various degrees of defect of speech accompany *hemiplegia*. From the morbid state of the brain, which gives rise to palsy, the functions of the mind are frequently more or less injured; the memory especially is liable to be impaired, and, in many cases, every faculty is so debilitated, that a considerable degree of fatuity or childish imbecility is the consequence. Indeed, there are perhaps few instances, in which the intellectual functions escape entirely unimpaired from an attack of *hemiplegia*: so that, where the stroke of palsy has been severe, few persons are left in a condition fitted for the active and important duties of life subsequently.

Some other phenomena accompany the paralytic state, which vary in different cases, and of which our knowledge of the nature of the nervous system and its functions is insufficient to afford an explanation. Although the nerves are unalterably the medium, both of *motion* and *feeling*; yet these two faculties are seldom injured in the same proportion. In the majority of cases of *hemiplegia*, the sensation of the paralyzed limbs is unimpaired; in a few instances, it is considerably diminished, *i.e.* a degree of numbness and torpor exists throughout; whilst in others, the sensation of the affected parts is entirely abolished, *anesthesia* being combined with the *paralysis*. But, on the other hand, many cases of a total abolition of the power of sensation, in parts which retained the full power of motion, are recorded. Dr. Gregory used to mention an instance in his lectures at Edinburgh, in which there was a perfect *anesthesia* on one side of the body, and a *hemiplegia* on the other; *i.e.* the nerves, on one side, ceased to be the instruments of sensation, while, on the other, they ceased to be the instruments of motion. Afterwards the *hemiplegia* attacked the other side; so that there was palsy without feeling on one side, and palsy with the feeling perfect on the other: the patient recovered; and the side, in which both faculties were lost, was the first to regain its powers.

In some cases of palsy, too, the circulation is materially affected, and in others not. Thus, sometimes the pulse in the affected side is slower than in the other; sometimes it is not to be felt, and the temperature of the limb is much diminished. In some cases the sub stance of the muscles is partly absorbed, and the paralyzed limbs waste; and occasionally anaemic effusions take place in them; but in others no such changes occur. Sometimes the sensations of the paralyzed parts are depraved, such as feelings of prickling and tingling, or actual pain; and sometimes there is numbness, with a sense of weight and load, as if from an extraneous body. A patient under this state of feeling exclaimed, "will nobody own that arm?" and the sense was sufficiently characteristic of the helpless condition of the limb.

Although the attack of palsy is sudden, yet, in the majority of cases, various premonitory symptoms occur, sometimes for a long period before the attack, which indicate the approaches of the disease. These symptoms are the result of an increasing determination of blood to the head, and consist of head-ache, giddiness, a sense of weight, and diminution in the head; dimness of sight, or the appearance of spots floating before the eyes (called *nuisea volitans*); sometimes a degree of fainting, and even of double vision; noise in the ears; occasional hammering in the speech; transitory numbness or loss of motion in the extremities; failure of the memory; drowsiness, especially after eating, but disturbed sleep; flushing of the face and neck; throbbing of the temporal arteries; and bleeding from the nose. Some one or more of these signs frequently precede the actual change in the state of the brain, which gives rise to paralysis, and an attention to them is therefore of great practical importance. They will, however, more certainly lead to an apprehension of an impending apoplectic or palsy, when they occur in persons who are constitutionally predisposed to these diseases.

The predisposition to paralytic affections is connected with a particular habit of body, which is frequently hereditary, and is characterized by a large head, and a short neck, especially in persons with dark eyes and hair, and by a corpulent habit. The large head implies a considerable proportion of blood circulating in the brain, and the short neck, that
that it is carried thither with greater impetus. The corpulent flat both gives and indicates the predilection; for an over-proportion of fat generally impairs an over-proportion of blood, as both arise from the same causes. A great quantity of fat, too, precludes upon the organs and vessels of the body, and necessarily tends to produce an accumulation in the parts where no fat is secreted, as in the brain. A certain raised age also contributes to the predilection to palsy, as a degree of venous plethora is then often produced; so that palsy seldom takes place before the age of forty. The same effect is produced by an indolent and sedentary mode of life, by a full diet, and especially by a habit of intoxication, which produces a great determination of blood to the head. But any habitual excess in the use of wine and malt liquors, although inconsiderable, and not occasioning intoxication, will have a similar effect. A plethora, and therefore a predilection to palsy, is also induced by the flappage of cutaneous discharges, such as bleeding at the nose, a copious hemorrhoidal or catamenial flux, the drying of habitual ulcers, &c.

Where this predilection exists, various circumstances may operate as the exciting cause, and bring on the paralytic seizure; and these causes produce that effect, either by determining an extraordinary quantity of blood into the brain, or by preventing a free return of it from thence; whence a morbid degree of prejure is occasioned in that important organ, either from simple congestion and over-dilatation of the vessels, or from congestion, followed by an effusion of serum, or by a rupture of vessels and an extravasation of blood. Now, an unusual flow of blood to the head is occasioned by every stimulus to the general circulation; whence violent exercise, by which the pulsations of the heart are quickened and increased in force; great external heat, which produces a similar effect; paroxysms of anger, intoxication, or even a more moderate excitement by strong liquors, have, in different instances, produced the paralytic attack. On the other hand, the blood is impeded in its exit from the head in various ways: thus flooding, or any other situation in which the head is kept in a depending position, and in which therefore the gravity of the blood increases the efflux of it by the arteries, and opposes the return of it by the veins; tight ligatures round the neck, which compreß the veins more strongly than the arteries; impeded respiration, or a full and long continued inspiration, as in violent training, or a long inspiration, as in coughing, laughing, &c., which impede the circulation through the lungs for a time, and therefore interrupt the free return of the venous blood from the head; over-dilatation of the aneurysm by a full meal, which compreßes the great descending artery, and also prevents the descent of the diaphragm, and therefore impedes the pulmonary circulation; all these circumstances have occasionally given rise to apoplectic and paralytic fevers. Indeed the manifold redness and flushing of the face and eyes, and the general turgescence of the countenance, occasioned by flooding, by tight neckcloths, by long fits of coughing and laughing, by intoxication, by violent muscular exertions, and by a full hearty meal, sufficiently demonstrate the determination of blood to the head, which excite. With respect to the influence of a full meal, the common reports of the newspapers afford abundant evidence; since nothing is more frequent than the accounts of sudden death, just after persons had eaten a hearty dinner or supper, and enjoyed the company of their friends.

This view of the nature of the causes of palsy, is completely confirmed by the examination of the state of the brain, by dilution, where the disease has terminated fatally; appearances of congestion and accumulation of blood in the vessels of the brain, or of effusion of serum, or of actual rupture of the vessels and extravasation of blood, have always been observed, where the attack was sudden; and in cases of the gradual supervision of palsy, some morbid growth, producing a slowly increasing prejure, which gradually disturbed the functions of the cerebrum, has been commonly found. So that, in all these cases, the obvious cause of the palsy has been the interrupted circulation of the nervous influence, whatever that may be, from the brain to the parts which have become paralytic.

The palsy and the apoplexy, which are thus produced, in connection with an over-dilated condition of the vessels of the brain, and with a plethoric habit, a short neck and large head, have had the epithet of sanguineous given to them; because it has occasionally been observed, that the same diseases have occurred in habits of a very different character. For example, persons of tall and slender form, of spare habit, with small heads and long necks, and pallid complexion, in whom no external marks of plethora, or of determination of blood to the head, were visible, have nevertheless been now and then seized with palsy, or died from a sudden apoplectic stroke. It has been suppos'd, that these diseases in such persons, originated from prejure produced in the brain by an effusion of serum, which is occasioned, not by an over-dilatation of the blood-vessels, but by a state of relaxation in the exhalant artery, the capillary arteries, and the capillary diatherm, or by other cases of a dappled diatherm, diatherm, or of an over-proportion of the watery parts of the blood, which is therefore ready to run off by the exhalants. Whence, in contra-distinction from the ordinary forms of these diseases, the epithet, fexous, has been applied to this variety. (See Cullen, First Lines, par. 1112.) Dilution, however, does not seem to have confirmed this theoretical division of the forms of the disease; for, in several cases of fatal apoplexy, which occurred in thin and spare habits, the same convulsions and ruptures have been found to have taken place, as in those patients, whose large heads and plethoric condition implied a fullness of the blood-vessels. In fact, medical observation teaches us, in numerous other instances, that local determinations and partial congestions of blood are liable to occur in persons very far removed from a plethoric condition; and that a paucity of the circulating fluids is no infallible security against local fullness. In our practical considerations, therefore, the notion of fexous apoplexy or palsy should perhaps be altogether discarded.

It is a curious fact, which has been ascertained by anatomical investigation, that in most of the instances of hemiplegia, the cause of the paralytic fit is found on the side opposite to the paralytic affection. A few cases have occurred, in which the morbid cause is laid to have been on the same side as the palsy; but this is certainly an exception to the general fact, and therefore the matter may still be considered as liable to doubt. Nevertheless anatomy has not taught us a satisfactory explanation of the phenomenon, that the injury of the brain and the palsy of the body occur on opposite sides. Anatomists have supposed a certain decapsulation or crossing of fibres from one hemisphere of the brain to the other; but there has been no very satisfactory demonstration as to this point. M. M. Gall and Spurzheim, the most accurate investigators of the structure of the brain, maintain that there is no decapsulation, except for the space of four or five lines at the lower extremity of the medulla oblongata, and they therefore deny that injury to one side of the brain (with exception of injury to the anterior corpora pyramidalis) ever affects the opposite side of the body. The facts, however, are perhaps too numerous to be set aside by the mere hypothesis, suggested by a difficult examination of a very obscure structure. See Nervous System.
PALSY.

Neither has any anatomical investigation afforded the means of explaining the different phenomena above alluded to, respecting the various and disproportionate affections of the fenation and power of motion, in parts supplied by the same nerves. For a clear and copious detail of the researches and opinions of anatomists and pathologists on these topics, we shall refer the reader to a paper of Dr. Yelloly's, in the Medico-Chirurg. Trans., vol. i. p. 181.

Independently of mechanical prelms, produced in the manner above described, some other causes occasionally injure the functions of the brain, and render it incapable of evoking the nervous power to the limbs, and thus produce a species of palsy. Certain poisonous substances have that effect, such as lead, and perhaps mercury, and some of the narcotic vegetables, such as the belladonna. A fever and continued impression of cold, long continued grief, great terror, and other depressing passions, occasionally also give rise to paralytic affections, by their direct influence upon the state of the brain.

The prognosis is generally unfavourable in hemiplegia, more especially when the patient is in advanced life, or debilitated in constitution, or has been in habits of intemperance. For under such circumstances, the system seldom recovers its powers, and the patient remains enervated both in mind and body, and generally incapable of the ordinary functions of life. If, as the disease continues, the paralysed limbs gradually lose their sense of feeling, or if they are affected with coldness, and the felh walkes, the prospect is most unfavourable. But, if there is a frequent prickling fenation, or even some degree of pain, in the parts; if they are occasionally affected with flushings of heat, or with profanodic twitchings; or if rheumatic or inflammatory swelling take place in them, these appearances are to be deemed favourable, inasmuch as they imply a less complete interruption of the nervous power, or its returning influence.

The treatment of hemiplegia will necessarily be somewhat different in different instances, according to the age and constitution of the patient, and to the obvious exciting cause of the disease. Before we state the general indications of cure, however, and the methods of fulfilling them, it will be proper to observe that the prophylactic treatment is often the most effectually useful. It too often happens, that, when the attack has taken place, some irremediable injury has been inflicted on the delicate texture of the brain, which, had the warning symptoms, which we have enumerated above, been attended to and removed, might have been altogether averted.

As a plethora of the vessels, either general or topical, is indicated by those premonitory symptoms; so the means of obviating that plethora are equally obvious, and within our power. Whenever, therefore, we observe these symptoms in persons, whose form and habit evince a predisposition to the disease, and more especially in those who have suffered a previous attack, every means should be resorted to, which diet, regimen, and an evacuant plan of medicine, can afford, to reduce the plethoric condition. The diet should now be low, consisting of whey, butter-milk, fruits, and farinaceous food, animal matters being disreased, or a little plain meat taken once every other day, and all fermented liquors totally abstained from. Even filling and distending the ileum frequently with mere vegetable matters ought to be avoided, for the reasons above explained. If the symptoms of oppression about the head are very considerable and menacing, it may be advisable to take some blood from the vessels of the head or neck, either by the lancet, by leeches, or by cupping; and at the same time the bowels should be well evacuated by cathartic medicines.

If, however, the previous symptoms have been neglected, and the attack of hemiplegia have actually come on, the first indication that presents itself, will be to remove or diminish the cause of compression, which may exist in the brain, whether it may be mere vascular turbulence, the extravasation of blood, effusion of serum, &c.; and the second indication will be gradually to excite the torpid portion of the brain and nerves to a sensible and active state. How very little power we possess, however, to accomplish either of these purposes, except in the case of mere vascular congestion, medical experience too clearly demonstrates.

Whatever may be the nature of the compression in the brain, it cannot be doubted, that a diminution of the turbulence of the vessels will tend to diminish it, by removing some portion of the bulk of the fluids in the general mafs of the viscera. If the compression arise from mere congestion, it may be entirely removed by such a measure; and if it arise from actual rupture and extravasation, or from a serous effusion the result of plethora, the abstraction of some portion of the circulating fluids will tend to arrest the progress of the extravasation or effusion, and therefore at least prevent an increase of the evil. Under all circumstances, therefore, the local detraction of blood seems to be advisable at the onset of hemiplegia. The quantity of blood to be taken away, as well as the mode of taking it, will be determined by the severity of the attack, and by the strength and plethoric condition of the patient. If the patient be extremely full and florid, and has not passed the middle age, a free bleeding from the temporal artery, or the jugular vein, may be preferable; but, even in the pale and thin habit of body, cupping the neck or temples, or the application of leeches to those parts, should be resorted to. In the full and florid habits, general blood-letting from the arm is often employed; but the fame general depletion may be accomplished by the section of the temporal or jugular vessels, while at the same time a more effectual depletion of the vessels of the brain will be produced. And in order that the local effect may be still more complete, it is desirable to make the evacuation from the side of the head opposite to the hemiplegic affection.

At the same time, other means of diminishing the impetus of the circulation in the head must be resorted to, as auxiliaries. The bowels should be emptied by active cathartics, by which a considerable depletion of the vessels, and a determination of the fluids downwards, are produced. Some practitioners also recommend emetics; but the objection of Dr. Cullen against these medicines, that the action of vomiting might impel the blood with too much violence into the vessels of the head, seems to be well founded, and they are seldom now employed. Blister applied to the shaven scalp, or to the nape of the neck, by the counter-irritation which they occasion externally, tend to diminish the internal action of the vessels.

It is a practice, but too generally adopted by routine-practitioners, to begin immediately with the exhibition of strong stimulants, upon the superficial inference, it should seem, of a torpor of the nervous power. But if they were to penetrate a little below the surface of things, it would be evident that this torpor of the nerves depends entirely upon an oppressed state of their origin, the brain, in consequence of an over-action and turbulence of its vessels; and, therefore, that every measure, which tends to augment vascilar action, must necessarily be a source of aggravation to the disease. Upon the plausibl principles, the very opposite object is to be pursued; and until the symptoms of plethora, and the active state of the disease be subdued, the meafures, which we have recommended as proper with a preventive view, should still be adhered to.
PALSY.

The second indication, therefore, which is "gradually to restore the torpid portion of the brain and nerves to a sensible and active state," can only be followed, after the hemiplegia has subsisted for some time, and when the symptoms, indicating a considerable compriression of the origin of the nerves, are removed. But even under these circumstances, the use of stimulants would appear to be of very ambiguous advantage. For it may be doubted, whether any paralytic affection, originally produced by compriression of the brain, would continue after the compriression was removed, i.e., whether the very existence of the hemiplegia does not imply the continuance of a compriressing cause, or at least of some organic injury, which it had inflicted and left behind. And at all events, the multitude of patients, who have in vain swallowed, for a long period of time, all manner of volatile, fidal, and spirituous stimulants, who have submitted to electricity and friction, and stimulant liniments, and warm bathing, and who have moreover obtained a recovery of the power of their limbs, nor even prevented subsequent attacks, do not bear any very favourable testimony to the efficacy of these expeditious means; while, on the contrary, the small proportion of persons, who do recover the full use of their hemiplegic limbs, may justly ascribe their recovery to the lightsness of the original attack, to the absence of effusion, extravafation, or any other organic mischief, and to the self-adjudging powers of the constitution, as soon as the cause of disease is removed. In some cases, indeed, it may be supposed that, even where actual effusion or extravafation had taken place, without materially injuring the texture of the brain, the fluids may be ultimately removed by absorption, and the brain therefore be restored to health; but, even in such cases, the beneficial aid of stimulants is more than problematical. In a word, it appears, that stimulants are perhaps never advisable in true hemiplegia; and that the benefit of these remedies is limited to those species of general palsy which arise from the influence of cold or narcotic poisons on the brain and nerves, or to those local varieties of palsy which seem to depend upon disease affecting the branches and extremities of the nerves, while the brain remains uninjured; of which we shall have occasion to speak presently.

For the purpose, therefore, of aiding recovery from an attack of hemiplegia, the principal indication will be, to avoid every species of Intemperance; to restrict the diet to light and cooling articles, and to take these with great moderation; to employ regular but always gentle exercise, avoiding every extraordinary hurry of the circulation; to preserve a regular, and rather free, flate of the bowels; and to manage the clothing, so as to preserve a regular flate of the cutaneous exhalation, and to avoid the impreffions of vicifitudes of heat and cold. In a word, the object will be to free the constitution from all embarrassments, in which condition it will be the best enabled to reform its healthy actions. We may liberate and affiit, but we cannot command the powers of the vis medicatrix nature.

It may be observed, however, that where the attack has been slight, and the tendency to recovery obvious, the return of power in the paralyzed muscles seems to be considerably accelerated by a constant exertion of them, or at least by constant attempts at exertion by directing the volition to them. The advantages of this voluntary exertion are commonly obvious in the more speedy and complete recovery of the motion of the leg, when compared to that of the arm, in persons who have suffered hemiplegia: a circumstance to be ascribed solely to the necessity of using the leg in moving from place to place, while the arm is too commonly hung in a fling, and no attempt is made to employ it.

II. Of the Paraplegia, or Palsy of the lower Extremities.—Without referring to the original acceptance of the term paraplegia, respecting which there has been some difference of opinion, and no very determinate definition (see Van Swieten, Comment. Aph. 1018); we take it in its modern sense. A palsy of the lower extremities may perhaps sometimes arise from injury or disease in some part of the brain itself; but of this the evidence appears to be imperfect; and at all events the occurrence is rare. The ordinary influences of this palsy obviously originate from pressure on some part of the vertebral nerve, or spinal marrow, below which the palsy passes itself, while the parts supplied with nerves, that branch off above the seat of the pressure, continue to perform their power of motion unimpaired.

The paraplegia may occur at all ages, and in either sex, and is always productive of much distress: for if the patient is a child, it becomes an object of constant and unavailing anxiety to its parents; and if an adult, he is rendered perfectly helpless to himself, and useless to all others, which of all possible states is surely the worst.

When this palsy attacks an infant of only a year or two old, the true cause of it is seldom discovered, until some time after the effect has taken place, at least by parents and nurses, who know not where to look for it. The child is said to be uncommonly backward in the use of his legs, or it is thought to have received some hurt in its birth. When it affects a child, who is old enough to have already walked, and who has been able to walk, the loss of the use of the legs is gradual, though not very slow. He at first complains of being very soon tired, is languid, trifling, and unwilling to move much; or at all briskly: in a short time after this he may be observed frequently to trip, and stumble, although there be no impediment in his way; and whenever he attempts to move briskly, he finds that his legs involuntarily crofs each other, by which he is frequently thrown down, and that without stumbling; upon endeavouring to stand even and erect, without support, even for a few minutes, his knees give way and bend forward. When the diltemper is a little farther advanced, it will be found that he cannot, without much difficulty and deliberation, direct either of his feet precisely to any exact point; and very soon after this, both legs and thighs lose a good deal of their natural facility, and become perfectly useless for all the purposes of locomotion.

When the disease occurs in an adult person, its progress is much the same but rather quicker. He complains also, in the early part of its course, of a sense of numbness in the affected limbs, with transitory tremblings and twichings, and sometimes of rigors: and he finds, as the bladder and lower portion of the bowels are included in the disease, that the stools pass unconsciously, and the urine flows without his consent, at the same time that he has a difficulty of employing the bladder. Ultimately the legs become rigid, and the knees and ankles stiff, and the feet extended, so that they cannot be placed flat on the ground. This last circumstance is likewise observed in children.

When the back is examined, some prominence or curvatura of the spine is always found. This curvatura varies in situation, extent, and degree, being in the neck or back, and sometimes, though very rarely, in the upper part of the loins; sometimes comprehending two vertebrae only, sometimes three or more, by which the extent of the cure becomes necessarily more or less; but whatever may be the number of the vertebrae concerned, or whatever the degree or extent of the curvatura, the lower limbs only feel the effect, the arms never being affected.

The effect is also different in different subjects: some are rendered
rendered totally and absolutely incapable of walking in any manner, or with any help, and that very early in the course of the disease; others can make a shift to move about with the help of crutches, or by grasping their own thighs with their hands; some can sit in an erect posture, in a chair, without much trouble or fatigue, which others are incapable of, at least for any length of time: some have such a degree of motion in their legs and thighs, as to enable them to turn and move for their own convenience in bed; others have not that benefit, and are obliged to lie till moved by another.

The general health of the patient does not seem at first to be materially, if at all, affected; but when the disease has continued some time, and the curvature is much increased, many inconveniences and complaints come on; such as difficulty in breathing, indigestion, pain, and what they call a tightness at the stomach, and other symptoms as palpitations, parings, the involuntary flux of urine and feces before mentioned, together with what are called nervous complaints. Some of these are occasioned by the alterations made in the cavity of the thorax, and others seem to arise from impressions on the abdominal viscera, by the intortion of the ribs, as the spine is distorted. The confinement and inability for taking exercise, will account for the other symptoms, that are not the direct result of the paralysis.

The disease is commonly ascribed to some injury, such as a blow, fall, or violent strain, which had affected the spine; and probably this is actually the origin of it in many instances. But there is no doubt, that the spine and its ligaments often become disfigured, so as to produce paraplegia, independently of such violence. For it is not the mere distortion or curvature of the spine which gives rise to the palsy; since the most extensive crookednesses often occur, where no paralysis fails; but actual pressure upon the vertebral nerve, by the concomitant deformity of the spine.

This morbid change in the structure of the spine has been described by Mr. Pott as follows. By many deformities he ascertained, that in infants, in young children, and in those who have been afflicted with the disorder but a short space of time, the ligaments connecting the vertebrae of the curved part were altered from their natural state, being somewhat thickened and relaxed, and the bodies of these bones were placed in their position, just as in the joints of rickety children. In those who had laboured for a long time under the malady, and in whom the symptoms were consequentially aggravated, whatever might be their age, the ligaments were still more thickened, relaxed, and altered, the bodies of the bones more enlarged and spread, and more inclining to become carious, and the cartilages between the bodies of the vertebrae much compressed and lefleened in size: and in all those who had so long laboured under the disease as to be destroyed by it, or by its consequences, the corpora vertebrae were completely carious, the intervening cartilages totally destroyed, and a quantity of fancies lodged between the rotten bones and the membrane investing the spinal marrow.

The cure of paraplegia was seldom effected till the proper treatment was devised by Mr. Pott. While the curvature of the spine remained undiscovered or unattended to, the disease was generally considered as nervous, and medicines so called were most frequently preferred; together with warm fomentations, embrocations, and blisters, to the parts affected: and when the true cause was known, recourse was always had to steel days, the swinging, the screw-chair, and other pieces of machinery, in order to restore the spine to its true and natural figure. But these expedients did not confer any real or permanent good purpose: the patients usually became unhealthy, and, after languishing for some time under a variety of complaints, died in an exhausted and emaciated state; or, which was still worse, dragged on a miserable existence, confined to a great chair, or bed, totally deprived of the power of moving.

The sagacious mind of that eminent surgeon, Mr. Pott, partly from a consideration of the disfigured state of the ligaments and bones, which precedes and occasion the curvature, and partly on the suggestion of a learned physician, Dr. Cameron, of Worcester, who, in consequence of an observation of Hippocrates, that a paraplegia had been cured by an abdus in the back, had imitated that process with advantage; devised the plan of inflicting a free discharge, by means of a largeitemName, from both sides of the spine. Experience confirmed the utility of this practice, and many examples of the complete restoration of strength and motion, in those deplorable cases, have been subsequently recorded. (See "Select Cases of the Disorder, commonly termed, the Paralytic of the Lower Extremities," by John Jebl, M.D. &c. 1782.) Mr. Pott’s method of practice is related, in his own words on the subject, in these words.

"The remedy for this most dreadful disease, consists merely in procuring a large discharge of matter, by suppuration, from underneath the memranma adiposa on each side of the curvature, and in maintaining such discharge, until the patient shall have perfectly recovered the use of his legs. To accomplish this purpose, I have made use of different means, such as fets, infus made by incision, and infus made by cautery; and although there be no very material difference, I do upon the whole prefer the laft. A fett is a painful and a nasty thing; whereas which it frequently wears through the skin, before the end for which it was made can be accomplished. Infus made by cautery, if they be large enough for the intended purpose, are apt to become inflamed, and to be very troublesome before they come to suppurate. But openings made by cautery are not in general liable to any of the inconveniences, at least not so frequently, nor in the same degree; they are neither so troublesome to make nor to maintain. I make the scaffold about this fize and shape: " [here he inserts an ellipsis, of an area equal to that of a tulip,] on each side, to have a sufficient expanse of skin between them. In a few days, when the scaffold begins to loosen and separate, I cut out all the middle, and put into each a large kidney-bean. When the bottoms of the forses are become clean by suppuration, I sprinkle, every third or fourth day, a small quantity of finely powdered charcoal on them, by which the forses are prevented from contracting, the discharge is increased, and possibly other benefit obtained. The infus I keep open till the cure is complete, that is, until the patient recovers perfectly the use of his legs, or even for some time longer; and I should think that it would be more prudent to heal only one of them first, keeping the other open for some time, that is, not only until the patient can walk, but until he can walk firmly, briskly, and without the assistance of a flock; until he can stand quite upright, and has recovered all the weight, which the habit, or rather the necessity of flopping, occasioned by the dilatment, had made him lose.

Although this remedy is sufficient for the cure of the disease, Mr. Pott admits, that there is no reason why every affiant means should not be applied at the same time, in order to expedite it; such as cinchona, cold barbing, frictions, &c. See "Remarks on that kind of Palsy of the Lower Limbs, which is frequently found to accompany a curvature of the Spine, &c." By Percival Pott, Jurgeon to St. Barthol. Hosp. 1779.

111. Of Palsy, or local Palsy.—Under this head we shall...
include all the forms of paralysis which are partial, and seem rather to depend upon a disordered condition of the nervous cords, near their extremities, than upon any injury done to the common feniferum, or to the great trunk of the spinal nerve. The partial paralyses of this kind are chiefly those which are connected with long continued rheumatic inflammation, or with the long application of cold, or byly, with the operation of certain mineral poisons, especially lead and mercury.

After a limb has been for some time the seat of inveterate rheumatism, especially in debilitated habits, it sometimes becomes torpid, and benumbed as it were, losing its power of motion, and commonly some degree of its sensibility. A similar condition is more speedily produced by the direct application of cold to the parts; as, for example, in the legs and feet of persons who work with these parts in water. The extremities of the nerves appear to be no longer capable of receiving and conveying the nervous power from the brain, while the latter shows no symptom of any disease. The pain of lead, by whatever means it is introduced into the system, produces a species of palsy peculiar to itself: its first effect is the production of a severe colic, which from its being most frequently seen in painters, has been called the painter’s colic; and it has received also several other appellations, from certain districts in which it has been prevalent, as the Devonshire colic, colic of Poi ton, &c. (See Colica Pidionum.) After one or more attacks of this colic, the patient perceives that one of his hands grows weak, and at length he finds himself altogether unable to extend either the hand or the fingers, which hang down (nearly at a right angle to the arm, when it is held out horizontally,) torpid and moveless, except from external force. As this commonly succeeds the attacks of colic, it may be probably connected with irritation in the intestinal canal, which appears at times to produce other forms of partial palsy. The palsy from the influence of mercury is also of a peculiar nature; it seems indeed to be rather an extreme debility of the muscles of the limbs, combined with tremors, than an absolute paralysis. See the accounts given of this disease by Haraszzi de Morbis Artificiis; and by De Haen, in his Ratio Medicinae. See also Iones’ observations of Dr. Bateman, in the Edinburgh Med. and Surg. Journal for 1812.

It is to these varieties of palsy, in which there is no plethora, congestion, or preface upon the brain, that the employment of stimulant remedies alone is properly applicable, and that in fact any benefit is to be expected from them. For if a slight attack of hemiplegia is gradually removed during their exhibition, all that can be said is, that the stimulants did not prevent recovery; for assuredly the recovery would take place, the preface of the brain having ceased to exist, if no stimulants were employed; and where, as happens in the majority of cases, some preface still remains, no benefit can possibly be derived from stimulants; but the rift of injury is manifest. But in the local paralyses just described, the local torpor of the nerves may be often effectually removed by the use of stimulant remedies.

In the palsy that is occasioned by protracted rheumatism, or by cold, recovery has frequently followed a peroration in the use of the warm bath, of repeated and continued friction with the flinth-brush, or with various stimulating oils and liniments, of which camphor, turpentine, and the acrid gums, together with alcohol, constitute the principal ingredients. Internally, also, stimulant medicines of a similar nature have been at the same time administered, with a view to aid these effects; especially the ammoniacal salts, or tinctures of the stimulant gums in alcohol, and medicines which have been supposed to possess peculiar powers of exciting the nervous system, such as the arnicas, the rhus toxicodendron, &c. Electricity has also been extensively applied to paralytic limbs under these circumstances, and it is probable, both from its obvious influence in exciting spasmatic twitches in the muscles, and from the number of successful instances of its application which have been recorded, that it has been of material benefit. There is, however, great room for self-deception in these cafes, as we have shown at length under the article imagination, and the metallic tractors and animal magnetizers can adduce ample testimony of their powers in the same form of disease. For our own part, we have seen so little obvious advantage derived from electricity in any disease, as to have nearly relinquished the employment of it; and the use of galvanism, for the same purposes, seems to be finking also into discredit.

We have mentioned, among other stimulants that are really successful in the cure of these species of local palsy, the warm-bath, an expedient which is hazardous, in the early stages at least, of hemiplegia. Hence the Bath waters, and more especially the use of the hot pump, commonly succeed in removing the palsy from lead, as well as from cold and rheumatism, although dangerous in cafes of hemiplegia.

There is, indeed, no remedy that appears to possess an equal efficacy: in the palsy from lead, after the disease has resulted in all ordinary expedients, the hot-pumping seems to be almost a specific. We have in vain tried the pouring of hot water upon the palsied hand, from the front of a tea-kettle, held at some height, in those patients, who have afterwards speedily recovered under the pump at Bath. There appears no reason, however, to suppose that any water of the same temperature, poured upon the limb in the same quantity, and with the same impetus, could not equally affect the cure, as the water of Bath; since it is the quantity of the stimulation, and not any peculiar quality of the water, that produces that effect.

For the palsy, arising from the poison of lead, and affecting principally the extensor muscles of the hand and fingers, Dr. Pemberton recommended a simple contrivance, which appears to have contributed to accelerate the cure of this disease; namely, a sort of battle-dore of wood, of the length of the fore-arm and hand, which is tied to the former, and supports the latter extended at length. Under this support, he conceives the muscles sooner recover their tone, than when they are constantly stretched by the pendulous hand. See his Treatise on the Difases of the Abdom. Visera.

Under all the forms of palsy, a constant exercise of the palsied limb contributes materially to expedite its recovery. This principle is equally applicable to the hemiplegia, as to these partial forms of palsy. To the palsy, or tremors originating from the poison of mercury, neither this nor any of the preceding precepts very clearly apply. The brain, in this case, seems to be affected by the poison, and the whole system suffers from its deleterious influence. Many remedies have been recommended, but especially sulphur, which was suggested perhaps upon chemical notions, rather than from a proper emulative of its operation upon the living body. On the whole, the disease is very unmanageable, and we know not how it is to be cured. The manufacturers of alloys, (among whom it almost exclusively occurs,) viz. watch and button-gilders, silverers of mirrors, &c. have contrived means of preventing the mercury, especially when used in its most pernicious form, vapour, from entering into the body so fully as formerly; and, therefore, the disease becomes less frequent. But even now, as we are informed, the persons employed in what is called water-gilding, that is, in laying an amalgam of gold and mercury upon the articles to be
be gilded, and driving off the mercury by evaporation, are generally short-lived from this cause.

**Palsy, Eleutheria for The**, is made of powdered mustardseed and conserve of roses, of each an ounce, with as much syrup of ginger as is sufficient to make an eleutheria. A tea-spoonful of this may be taken three or four times a day.

**Palsy, Infusion for The. See Infusion.**

**Palsy Drops, in Botany. See Lavandula.**

**PALTE, in Geography. See Jambro.**

**PALTECAM, a town of Wetphalia, in the bishopric of Osnabruk; 14 miles S.E. of Osnabruk.**

**PALTZ, New, a township of America, on the west side of Hudson’s river, in Ulster county, New York, about 20 miles N.W. of Newburgh; containing 3255 inhabitants, including 308 slaves.**

**PALVARYA, a town of Hindooftan, in Oude; 32 miles E. of Kairabad.**

**PALUDAMENTUM, in Antiquity, a garment worn by the Romans in time of war; being the coat of arms of their principal men, especially the generals; who, for that reason, were distinguished by the appellation paludati.**

The soldiers only having short coats, were therefore named *sagati.*

This garment was open on the sides with short sleeves, by some resembled to angels’ wings; and came down no lower than the navel. It was either white or red. Valerius Maximus remarks, it was an ill omen to Caius. that they gave him a black paludamentum: *Pullum et traditum eff paludamentum, cum in praelium eunitbus album, aut purpureum, dari foleter.*

Cornutus says, the Romans wore the toga in peace, and the paludamentum in war. And hence the phrase, ’*Togam paludamento mutavit.*’ See CHALMYS.

**PALUDE, in Geography, a town of Turkish Armenia, in the government of Erzerum, the residence of a prince, partly independent of the grand signior. N. lat. 38° 35’, E. long. 30° 14’.**

**PALVERETO, a town of Naples, in Calabria Citra; 10 miles E.N.E. of Cofarza.**

**PALUM Sanctum, in Botany, a name by which some authors have called a species of the guaiacum-tree, called the lignum sanctum, or holy wood.**

**PALUMBARIUS ACQUITIUS, in Ornithology. See Falco Palmbarius.**

**PALUMBUS, or RING-DOVE. See Columba.**

**PALUS, in Antiquity, a military exercise among the Romans, by which the young men prepared, and qualified themselves for real combat. The palus was a pillar, about six feet high, fastened into the ground; against this the soldiers made an attack, assailing it in several different modes and attitudes; always taking care to manage their weapons, that, supposing it was a real enemy, they might not expose any part of their body to be hurt, while they were directing their adversary. Instead of a sword, they used a rod or fick. They likewise ran at the palus with lance, and throw javelins and darts at it, endeavouring to hit particular parts; and their success was a proof of their dexterity. See PAIL.**

**PALUS MEETIS, in Ancient Geography. See Sea of Azof.**

**PALWAL, in Geography, a town of Hindooftan; 35 miles S of Dehi.**

**PALLY, or PALLE, in Heraldry. When an escutcheon is divided into six, eight, or ten divisions, pale-wise, i.e. by perpendicular lines drawn from the top to the bottom, it is blazoned pally of six, eight, or ten, &c. pieces.**

If the number be odd, then the field is first named, and the number of the pales specified. See PALB.

The like is to be understood also of barry and bendy.

**PALLY-BENDY is, when a coat is divided, both pale and bend-wise; in pally-bendy, the field is divided by perpendicular lines, which is called pally; and then, again, by diagonals crossing the former, from the dexter side to the sinister, which is the bendy. The field is pally-bendy, topaz and diamond.**

**PALLYANGHA, in Hindoo Mythology, a name of the Hindoo goddess Bhavani, or Parvati, consort of Siva.**

**PAMADA, in Geography, a town of Birmah, on the Ay; 24 miles N. of Trone.**

**PAMAKASSAN, a town on the north coast of the island of Madura.**

**PAMALANG, a town on the north coast of the island of Java. S. lat. 6° 45’. E. long. 109° 28’.**

**PAMANDAKAN POINT, a cape on the north coast of Java. S. lat. 6° 12’. E. long. 107° 54’.**

**PAMANDOOR, a town of Hindooftan, on the coast of Timoeyl; 10 miles N. of Tutacorn.**

**PAMAMACA, a lofty mountain in the province of Quito, being one of the peaks of the eastern Cordilleras.**

**PAMBANGOTIA, παμβαγοτια, in Antiquity, a festival celebrated by all the Bactrians, who assembled near Coronea, at the temple of Minerva, surnamed Itonia.**

**PAMBU, in Geography, a town of Tibet; 20 miles E. of Tankia.**

**PAMEA, in Botany, a name which seems to have no meaning, Aulub. Guiana. 946. t. 359. Julf. 76. is applied by the former author to a tree of Guiana, of which he knew nothing but the calyx and the fruit. From these however he rightly deduced its affinity to the Linnean Terminalia, of which it appears to be, as Jaffue supposes, undoubtedly a species. Its trunk is thirty feet high, and two or more in diameter; the branches widely spreading, knotty. Leaves oblong, entire, stalked, many together at each joint, in a spreading, whorl-like cluster. Fruit racemose, each consisting of a triangular, oblong, brittle drupe, with an ovate-oblong, angular, furrowed nut, about an inch and a half long, whose kernel is very good eating; on which account the tree is cultivated in Guiana, and the isle of Bourbon. See TERMINALIA.**

**PAMENE, in Geography, a town of the island of Ceylon, on the east coast; 55 miles S. of Trinconi.**

**PAMEER, a lake of Prussia; 12 miles W. of Lick.**

**PAMERS, a town of France, in the department of the Arnoie, and chief place of a canton, in the district of Mirepois, near which is a medicinal spring; 12 miles W. of Mirepois. The place contains 5500, and the canton 16600 inhabitants, on a territory of 235 kilometres, in 22 communes. N. lat. 43° 6’. E. long. 1° 43’.**

**PAMISUS, in Ancient Geography, a river of Melfenia, which had its source in the mountains that lay towards the north between Melfenia and Arcadia, ran north-east, and discharged itself to the sea, at the extremity of the Melfenan gulf. Allo, a river of Greece, in Theffaly. Allo, a river of Lower Melfia, in the environs ofodesus, called by Ptolemy Panyus, and placed between Odesus and Mefambria.**

**PAMLICO SOUND, in Geography, a large bay on the east coast of North Carolina, which is a kind of lake or inland sea, from 10 to 20 miles broad, and nearly 100 miles in length. It is separated from the Atlantic ocean, in its whole length, by a beach of coral hardly a mile wide, generally covered with small trees or bushes. Through it are several small inlets, by which boats may pass; but Orecock...**
PAM

eock inlet is the only one that can admit vessels of burden into the districts of Edenton and Newburn. Pamlico found communicates with Albemarle and Core sounds; and other vessels enter Pamlico or Tar river, the river Neuse, and other small streams. The mouth of Pamlico river is in N. lat. 35° 24'. W. long. 76° 42'.

PAMACHON, Pamachon, a name by which the exercised power of the town is sometimes called, whence the combatants were likewise called Pamachon, Pamachon.

PAMMACHON, a name given to the first collection of canons, rounds, and catches, that was printed in England. The full title of these ingenious and exhilarating effusions for social purposes is curious, and runs thus: "Pamachon, or a word formed perhaps, from a word and an adverb. Mr. Muck's Miscellany; or, mixed variety of pleasant Roundelays and delightful Catches of a, b, c, d, e, f, g, h, i, j, k, l, m, n, o, p, q, r, s, t, u, v, w, x, y, z, 10 parts in one. None so ordinarie as musical, none so musical as not to all very pleasing and acceptable. London, printed by William Barley, for R. B. and H. W., and are to be sold at the Spread Eagle at the north door of Paul's," quarto, 1609. The names of none of the composers of these epigrammatic and painted effusions have been preserved; but many of them seem of great antiquity, which is discoverable both by the words and style of composition. Great musical science is manifested in the canons, and the harmony and contrivance of the rest are excellent. The words, indeed, except those of the canons, which consist of small portions of the psalms, and other parts of scripture, in Latin, (which seems to imply that they were set before the Reformation,) are, in general, devoid of wit, humour, poetry, and common sense. Our lyric poetry, during the 16th and part of the 17th century, was in a barbarous state; and far inferior to the music of the times. But the composers fo little fictitious word for the words they had to set, and frequently to alter the syllables of composition Ut re mi fa sol la; Hey down down, derry down; or merely Fa la, to songs of Spenser and Shakspere. In the same year was published another collection, entitled "Deuteromelia, or the second Part of Mr. Muck's Melodie, or melodious Musicke of pleasant Roundelays, &c. London, printed for Thomas Adams, dwelling in Paul's Church-yard, at the sign of the White Lyon, 1609." This publication was much inferior to the preceding, and chiefly consists of songs for three voices, in which different lanzas are sung to the same music, after the manner of what are now called glee.

PAMMENOCKE POINT, in Geography, a cape on the north coast of New Guinea. S. lat. 0° 24'. E. long. 133° 21'.

PAMNAGUR, a town of Hindoostan, in the circuit of Kitchwar; 13 miles N.W. of Burdwar.

PAMOCAN, a town of Borneo, on the east coast, near the south part of the island; 150 miles N.E. of Banjermasin.

PAMODURIE, a town of Hindoostan, in Myfore; 290 miles S. of Taderni.

PAMPA-HERMOSA, a town of Peru, in the diocese of Truxillo, and province of Pataz, on the west bank of the Guayana, inhabited by Indians.

PAMPANGAN, a town of the island of Luzon, capital of a province, which is both extensive and populous. The inhabitants have, in general, adopted the religion and manners of the Spaniards. The town is situated on the coast:

N. lat. 15° 7'.

PAMPARA, a town of Africa, in Bambarra; 156 miles W. of Sego.

PAMPAS, a province of South America, in the vice-royalty of Buenos-Ayres, consists of vast plains, which extend from the sea-coast on the east to that great chain, which forms the beginning of the Cordilleras of Chili, about 140 leagues west from the city of Buenos-Ayres. Towards the south, they stretch about 100 leagues to a chain proceeding W.N.W. from the Atlantic. The northern boundaries are not distinctly known, but the name of Pampas is chiefly applied to the territory on the south of Buenos-Ayres, Cordova, and Mendoza. These vast plains, like the Steppes of Ruffia, having scarcely any elevations: the view, as at sea, is terminated by the horizon. They are only diversified by paths and ditches, which collect the rain-waters, and which commonly end in lakes, as there is no declivity; yet there are wide tracts in which no water is found, nor is there element pure; and trees are extremely rare, except a few shrubs round the lakes. Hence this region is only inhabited by a few wandering savages. The soil is generally a black earth, of little depth, and is followed by a kind of coarse white chalk, so that it is difficult to form wells, as the water can scarcely pass so tenacious a substratum. The chief pasture is evergreen clover, and, in the belt parts, sometimes so strong as to refill the depth of a horse: it is much liked by the cattle, which, when there is water, multiply prodigiously in the Pampas. The savages who roam through these deserts sometimes surplice Spanish caravans, and small settlements. Pinkerton.

Pampas del Sacramento, immense plains in Peru, lying between the Guayana and the Maranon well and east, bounded by the Tunguragua on the north. The names "Montana Real" and Pampas del Sacramento have been confounded; whereas the former, in its strict original acceptation, implied a mountainous region of no great extent, to the east of the provinces of Tarma and Cutumo; whilst the latter has been carried to an immense extent, so as to include the valley territories on the north and south of the Maranon, as far as the line of demarcation with the Portuguese settlements. In this acceptation the median length from the country of the Majos, S. lat. 15°, to the river Guayari, N. lat. 3°, is 180, or 1880 geographical miles. The breadth depends upon the Portuguese frontier, but the medium may be 10°, or 600 geographical miles.

The name of Pampas del Sacramento, plains or steppes of the holy sacrament, was imposed by the pious fathers on an enormous territory, watered by the Ucayal and genuine Maranon, and which they fondly reprent as being as large as Europe; but they defer to greater credit when they inform us, that it is about 8000 leagues square, and capable of maintaining five millions of inhabitants. The recent discovery of the Pampas is chiefly owing to father Girval, who has navigated about 400 leagues south to north, and 70 west to east, on the grand and genuine Maranon, and has inspected and described the country with considerable care. He has discovered 25 nations, or rather tribes of Indians, of whom he pretends to have converted four, viz. the Panos, Cambos, Chipeos, and the Piros. The common deity of all the tribes he found to be the Moon; and they dread a demon, called the "Nugi," whom they regard as the author of all their calamities. In war, for the conduct of which they elect a chief of the greatest courage and cunning; and in the prosecution of their contests, the men are slain, and women and children only become captives. Some tribes are more courteous and humane; while others, as the Caivos and Carapachos, are anthropophagi. The Carapachos are about 8° S. lat., on the bank of the river Pachita; and the Chipeos, at 5° 37'. Among all the nations on this part of the genuine Maranon, circumcision is practised among the men, and excision among the women. The Capanaguas, a tribe on the river Mague, drefs and cut
their dead, and think this action meritorious; and yet they are one of the most humane tribes.

The Pampas del Sacramento are divided from the Sierra, or the hills of Peru, by a lofty chain, from which this vast country appears so level that it resembles the ocean. The perpetual verdure of its fields forms a delicious perspective; and for some hours in the day, there is so thick a fog on the tall trees, that the clouds seem to be under your feet. Rain and thunder are frequent. Insects and reptiles are abundant. Many of the vegetable products are rare and singular. Balsams, oils, gums, resins, incense, cinnamon, though inferior to that of Ceylon, cacao, caffirilla, and an excellent spice, called the puecheri, are very plentiful. But the warmth and humidity render a country, equal in size to an Asiatic empire, almost uninhabitable; to have even the few traders on the banks of the rivers rarely fee a man of the age of 50. Yet the missionaries have founded several villages. New entrances have been found to the Montana reale, Pampas, or rather great territory of Colonna, since the late missions were established. For further particulars, we refer to Pinkerton's account of recent discoveries, 1790-1800, in the 3d volume of his Geography.

PAMEL, a town of the duchy of Courland; 24 miles S. of Goldingen.

PAMELONNE, a town of France, in the department of the Tarn, and chief place of a canton, in the district of Alby; 12 miles N. of Alby. The place contains 1839, and the canton 5896 inhabitants, on a territory of 105 kilometres, in 10 communes.

PAMPHILIS, in Ancient Geography, a town of Asia Minor, on the confines of Pamphylia, near a mountain called "Cimon." Strabo says, that it was a considerable town, and that it had three ports and a lake.

PAMPHILUS, in Geography, a presbyter of Caesarea, in Palestine, is found to be a native of Berytos in Phoenicia, and a descendant from a good family. Having received the rudiments of an excellent education at his native place, he went to Alexandria in Egypt, where he completed his studies, and there settled at Caesarea. Here he became intimately acquainted with Eusebius, who has given many testimonies of his sincere respect for the memory of his friend, and added his name to his own. Pamphilus is supposed to have flourished about the close of the third century. He was puffed of such zeal for the interests of religion and sacred literature, that he founded, at a great expense, a library at Caesarea, which contained all the most celebrated writers of the church, collected from all quarters. He was concerned with Eusebius in publishing a correct edition of the Greek version of the Seventy, from Origen's Hexapla. He was jointly concerned with Eusebius, in writing five books of "An Apology for Origen," to whom Eusebius added a sixth. He is thought, by some learned men, not only to have founded a library, but also a school or academy, at Caesarea. Lardner, however, seems to doubt the fact; though he says, he is not prepared to contest it.

In the year 307, when the persecution raged against the Christianians, Pamphilus was apprehended, and carried before Urbanus, the Roman president at Caesarea, who, after trying his knowledge in various ways, required him to offer sacrifice. Pamphilus readily refused to obey him, defied his threatenings, and bid defiance to his malice. In the year 309, after he had endured, with the greatest constancy, a variety of torments inflicted upon him, he was put to death by the orders of Firmilianus, who had succeeded Urbanus in the presidency of the city. Eusebius, in speaking of Pamphilus, says, that "he was the great glory of the church of Caesarea, and, on account of his eminent virtue, the most renowned martyr of the age; a man, who, throughout his whole life, excelled in every virtue; in contempt and renunciation of this world, in liberality to the indigent, in disregard of all earthly honours and preferments, to which he might have aspired, and in an ablemious philosophical course of life. But he was especially eminent, and remarkable above all men of our time, for an unfeigned zeal for the holy scriptures, and for unwearied application in whatever he undertook, whether it were kind offices to his friends, or to others who fought his aid." Dupin. Lardner, Gen. Biol.

PAMPHYLIA, in Ancient Geography, a considerable province of Asia Minor, and which included Piddia, that occupied the northern part. Pamphylia was bounded on the south by the Mediterranean, and extended along the coast from Mount Ida, which separated it on the west in Cilicia; as far as the chain of mountains which separated it on the east from Cilicia; to the north it had Phrygia. The principal towns of Pamphylia, commencing westward, were Olbia, at the mouth of the Cataractes; Perga (Kara- bil) towards the east, at a small distance from thence, on the Cælius; Appalous on the south-east, the Eurymedon; Sede (Cordelloro) directly south, on the sea-coast; Cibyra (Ibuzas) situated to the north-east; Lybre on the north-east; and Cobyra on the Melos. Towards Phrygia were Tormecus (Eilenaz), a principal town of the people called Solymi, and of the small country called Ca-balia; Cremona; Crema (Kirbierz) to the north-east; Sandalium, a fortress north-west of Crema; Baris, south-east of Crema, in which the Romans established a colony; Lytineo (Ag-Jafon), east of Cormolous; Trogitis (Egridi), south of the lake, and south-east of Crema; Orando (Haviran), north of the lake; Selucia (Eufhar), at some distance east of the lake; and Penelisus, south-east of Selga; and Catena, upon the Eurymedon, towards the north-east. The island is found within the limits assigned by M. d'Anville to Pamphylia. See ISARIA.

PAMPHILHOS, in Geography, a town of Portugal, in Estramadura; 34 miles N.N.E. of Thomar.

PAMPINFORME CORPUS, or PLEXUS PAMPINIFORMIS, in Anatomy, the veins of the testis, which communicate and divide very frequently. See Generation.

PAMPLIEGA, in Geography, a town of Spain, in Old Castile; 12 miles S.W. of Burgos.

PAMPLONA, or PAMPELANA, a city of Spain, and capital of the province of Navarre, partly situated on a little eminence, and partly in a fertile plain, on the banks of the Arga, near the Pyrenees. It is surrounded on all sides by lofty mountains, at the distance of two or three leagues. This city is said to have been built by Pompey, after the defeat of Sertorius, whence it derived the name of Pompeipolis. It is a fortified town, and defended by two castles, one in the town and the other contiguous, though without the walls. This last place, which is the citadel, was built by Philip II.; it is strong from its situation on a rock; it has five bastions covered with stone, and good fosses; a deep moat, of considerable extent, renders the approaches to it difficult towards the sides on which it could be attacked. This citadel has a handsome tower, several magazines, a square ornamented with trees, and an armory in the centre of the fortresses; which is round, and opens by five grand and open streets, which lead to the five bastions. Here is a hand-mill of ingenious conformation, that would be useful in case of a siege; it is a large machine, composed of several wheels, which turn five grinding-stones, with as many hoppers; 120 loads, or 360 quintals of wheat, may be ground with it daily: it is turned with the hand, or
PAN

may be worked by horses. This town boasts of having been the first in Spain which received the light of the gospel; its bishopric, one of the most ancient in Spain, was re-established after the expulsion of the Moors; it is suffragan to Burgos. The chapter of the cathedral comprehends twelve dignitaries, as many canons, and forty-four prebends and chaplains. There is another chapter in the same cathedral. This town is the residence of the viceroy of Navarre. Its population consists of about 2800 families, composed of nearly 14,000 persons, occupying 1652 houses. In this capital of Navarre the states hold their gatherings. The college for the instruction of youth is an university, founded in 1608.

Pampeluna contains a cathedral, three parishes, nine convents of monks, and two of nuns.

The city itself is confined and ill-built, but its streets are kept remarkably clean. There are some squares, two of which have tolerably handsome houses, particularly that which is appropriated to bull-fighting. The town is deficient of agreeable society, which fome have ascribed to the severity of the police. The commerce consists mostly of imports, and its manufactures are few and inconsiderable. Those of parchment and of leather, and another of coarse cloth, are of little importance; here also they make common carthenvare, and blank wax, which they import; 75 miles N.N.W. of Saragossa, and 172 N. N. E. of Madrid. N. lat. 42° 50'. W. long. 1° 46'.

Pampulna, or Pampeluna, a town of South America, in the new kingdom of Granada; having in its vicinity gold mines; 170 miles N. N. E. of Santa Fe de Bogota. S. lat. 6° 30'. W. long. 71° 36'.

Pampus, a channel between the Zuyder Zee and Amsterdam.

Pampus, in Ichthyology. See Stromateus Paru, and Chetodon Glauce.

Pamuchlen, a name by which fome call the species of cod-fish, commonly named by authors afellus sriatus. See Gadus Callarias.

Pamunky, in Geography, the ancient name of York river, in Virginia; but now restricted to the southern branch formed by the confluence of the N. and S. Anna. This and the northern branch, Mattaponi, unite and form York river, jult below the town of De la War.

Pan, in Mythology, the son of Mercury and Penelope, and the deity who presided over huntsmen, shepherds, and those whose occupations led them to frequent the fields. The fable says, that Mercury transformed himself into a he-goat to please Penelope; and to this circumstance is attributed the origin of his horns and cloven feet, as well as the whole tribe of fauns and fayurs. He is called Pan, tala, it is said, because Penelope, in the absence of Ulysses, granted favours to all her lovers, and Pan himself was the fruit of this intercourse. However, Epimenides says, that he was the son of Jupiter and Calilla; others say, that he was the son of the Air and a Nereid, or of the Heaven and Earth. He is commonly represented with a shepherd's crook, and a kind of flute, with many pipes. He was particularly revered among the Arcadians, to whom he illuded oracles, and who celebrated, in honour of him, the Lupercalia. Evander carried the worship and feasts of Pan to Rome.

The Egyptians give a different account of this deity. According to them, he was one of the generals of Osiris, who engaged with Typhon; and whole army being situated in a valley, all the avenues of which were guarded by the enemy, he ordered the soldiery in the night to march with loud exclamations, which being returned in echoes, terrified the enemy, and put them to flight; whence they say comes the expression of panic terror. But Bochart pretends that there is no other reason for making Pan the author of those terrours, except that the Hebrew word Pan or Phan, denotes a man under conformation. Diodorus Siculus says, that Pan was so much honoured by the Egyptians, that his statues were to be seen in all the temples, and that to his honour they had built in Thebas the city of Chemmis, that is, the city of Pan. This author, who takes no notice of Mendes in Lower Egypt, where that god was in high veneration, adds, that he had accompanied Osiris in his expedition to the Indies, together with Anubis and Macedo. We do not learn from Herodotus why the Egyptians represented the god Pan under the figure of a goat; but ancient mythologists assure us, that they were induced to do this, because Pan, having found the gods in Egypt, wister they had fled from the giants, advised them, as the means of preventing their discovery, to cloathe themselves with the figures of different animals; and as a pattern to them, he himself assumed that of a goat. Upon the whole, all the Greek fables relating to Pan are said to amount to these particulars: that he was one of the greatest gods of Egypt; that he was honoured especially at Mendes; that his worship was brought into Greece by the Egyptian colonies; that he became more remarkably famous in Arcadia; that Evander made him known in Italy, where he came and settled with his colony some years before the Trojan war; and that at last the worship of this god was received at Rome with the festivals which were celebrated to his honour. Polyaenus attributes to Pan the invention of the order of battle of the phalanx, and of the distribution of an army into the right and left wings, or horns, whence, it is said, he derived his horns. The name Pan, which signifies all, has led some to make him the symbol of nature.

Diodorus makes Pan one of the attendants upon Osiris in his Indian expedition. The fame author, however, tells us, that he was the leader of a troop of fauns and fayurs, or wild and rustie men, much addicted to dancing, and feats of activity, who were presented to Osiris in Ethiopia; and with whom that prince was so much pleased, that he retained them in his service.

Pan was the inventor of the instrument called the syrinx, or sylula; which invention has given birth to a fable in Ovid's Metamorphoses.

A nymph of late appear'd, as Dian haste,
Whole beauteous form all other nymphs surpass'd;
The pride and joy of fair Arcadia's plains,
Belov'd by deities, ador'd by fauns,
Syrinx her name; by Sylvans oft purf'd,
As oft would th'o the wanton gods delude.

Descending from Lycaeus, Pan admires
The matchless nymph, and burns with new defires.
A crown of pine upon her head he wore,
And vainly trode her pity to implore:
For ere he could begin, she took her flight,
And, wing'd by fear, the foone was out of sight,
Nor flay'd to hear the courtship of the god,
But bent her course to Ladon's gentle flood;
There by the river flot'd, and tir'd before,
Relief from water-nymphs her pray'r's implore.
Now while the am'rous god, with speedy pace
Juit thought to i'ra'n her in a fond embrace,
He fills his arms with reeds, new rising on the place.
And while he fighs, his ill-usuces to find,
The tender canes were shaken by the wind;
And breath'd a mournful air, unheard before;
Which greatly Pan furpris'd, yet pleas'd him more.

Admiring
Admiring this new music, Thou, he said,  
Who can't be the partner of my bed,  
At least shalt be the comfort of my mind,  
And often, often, to my lips be join'd!  
The tuneful reeds he form'd, and wax'd with care,  
Which will retain the name of his ungrateful fair.

—Dryden.

Pan was regarded by the Egyptians, after his apotheosis,  
as the god who presided over the whole universe, as H'i,  
some, implies. He represented nature and fertility, and was  
god of the woods and fields, wholly taken up with the  
pleasures of a country life: dancing constantly with the  
fauns and satyrs, and running after the nymphs, to whom he  
was such a terror, that it is supplicated by some the word  
panic is derived from Panici terrae, with which those who  
were said to have seen him were seized. A pulousius, however,  
gives an agreeable description of him. "By chance the  
god, Pan, happened to be seated on a little eminence near a  
river, and, always constant in his love to the nymph Syrinx,  
transformed into a reed, he taught her to produce all kinds  
of agreeable sounds, while his goats were skimming round  
him, and feeding on the banks."

Lucian describes him as the companion, minister, and  
counsellor of Bacchus, a servant of all work: having  
occasionally employed in the capacity of shepherd, musician,  
dancer, huntsman, and soldier. "In short, he served not only  
as maestro di cappella, to direct the Bacchaneal, but was so  
expert in playing upon flutes, and was such an excellent  
piper on the flutta, that Bacchus was never happy without  
him. We have the authority of the grave Virgil, and of the  
fentimental and pious Plato, for his attributes. Pau-  
inas Corinth, cap. 22.

Pan, in Agriculture, a term applied to the bed or flooring  
upon which the cultivated soil lies or is placed. Mr. Mar-  
shall, in speaking of the Norfolk soils, remarks, that "imme-  
diately under the cultivated soil, a hard crust, provincially 'the  
pan,' occurs universally. And under this sublustrum of various  
qualities an unfastidious ocean of sand may be considered  
as the prevailing sublustrum. In some places a hungry  
gravel, but more frequently an absorbent brick-cart is the  
immediate subsoil."

And that "marl sometimes refers to near the surface, but  
feldspar so high as the pan. This seems to be universally  
considered as a distinct something, poisonous in its nature,  
and partaking neither of the soil nor the subsoil. It is  
not his intention to ridicule this received opinion; it may  
be well founded; but to him the pan appears to be a  
production, not of nature, but of art; or, to speak more  
accurately, a consequence of the Norfolk cultivation carried  
on time immemorial with the Norfolk plough, whole  
broad fléat share, being held invariably in a horizontal po-  
sition, and (unless in following) invariably at the same  
depth, the surface of the subsoil becomes formed by the action  
of the share, the prelude and fléat of the heft of the plough,  
and the trampling of the horse, into a firm even floor, upon  
which the soil is turned and returned in the same manner, it  
would be, if spread on a floor of fléat, or other material.  
But, be this as it may, and whether the pan is a natural  
or a fictitious production; it is a fact well established, that  
breaking it up for ploughing below the acculturated depth  
is very injurious to succeeding crops." And further, that  
"two reasons may be offered in explanation of this effect;  
the pan, year after year, and perhaps century after century,  
has been a receptacle of the seeds of weeds, which, by being  
trodden, or otherwise pellucid into it, have remained there,  
locked up from the sun and air, and thereby deprived of the  
power of vegetation. But no sooner are these seeds re-  
leafed from their confinement, by being brought to the  
surface with the plough, than they vegetate in myriads to the  
anoyance of the crop. The other reason is this,—the firm  
elcfe contexture of the pan renders it in a degree water-  
tight, it is at least a check to the rain-water which sinks  
through the soil, prolonging its stay in the sphere of vegeta-  
tion. But the pan being broken, the filter is no more; and  
the rain, which is not immediately retained by the soil,  
escapes irretrievably into an infaatable bed of sand, or some  
other absorbent subsoil."

It must, therefore, in many cases of tillage, be highly  
injurious to break or destroy this crusty layer, which pre-  
serves the manures, and contributes much to the production  
of good crops of different kinds.

—PANA, in Geography. See PUNA.

—PANACA, a burning mountain on the W. coast of  
New Mexico.

—PANA, in Medicine, from Pan, all, and auros, I  
cure, signifies an universal remedy, or one that is capable  
of curing all distempers.

Among the old practitioners, with whom the discovery  
of new drugs was often a pursuit of greater interest, than  
the investigation of pathology, several medicines were  
effectually cured of this appellation. But it is sufficient  
to take a very superficial view of the various organs subject  
to disease, of the various kinds of disease that affect the  
organ, and of the various ages and constitutions of  
different individuals, as well as of the different agency  
of the causes of disease, e.g. high living and lavation, hot  
and hard labour, cold and heat, the various species of con-  
tagion, marish effluvia, and other morbid exhalations, and  
the various poisons, animal, vegetable, and mineral, which  
are deleterious to the animal frame,—it is sufficient to glance  
at these ever-varying circumstances which necessarily modify  
the nature of diseases, in order to be satisfied of the  
abfurdity of the attempt to cure them all by one remedy.  
The pretenders to 
panaceas are, therefore, only found at  
prent among empirical impostors.

—PANACEA, Panace, or Panax, all-heal, is also applied to  
several plants, by reason of the extraordinary virtues ascribed  
to them.

There are three of the panaceas peculiarly famed among  
the ancients: the Herculean, Asklepius, and Chironian: these  
were so called from their inventors Hercules, Asklepius, and  
Chiron.

The first is the panax Herculea vera euculata folio, in  
English, true all-heal of Hercules. From the root and item  
of this is drawn, by incision, the gum opopanax.

The Asklepius, according to some botanists, is a kind of  
ferula, which Cax. Bawuis calls Libanomis ferula folio &  
feminine.

The Chironian, according to some, is a kind of helian-  
themum: according to Bradley, it is Doria's woundwort.

—PANACEA, in Mythology, one of the divinities of medicine,  
the pretended daughter of Asklepius, to whom were rendered  
divine honours, as well as to his other children, Hygeia,  
Thelefphorus, and Jaso.

—PANACMUS, in Biography, a musician, quoted by  
Aristides Quintnianus, whose definition of music agrees  
entirely with that of the Chinese. "Music (he said) was  
not only the order and arrangement of sounds proper to  
regulate the voice, but was likewise the regulator of all the  

—PANADA, Panata, or Panattela, a diet consisting of  
bread boiled in water to the consistence of a pulp; given to  
lick perfons whose digestion is weak, or to whom strong  
food would be improper.

The
The word is formed from the name of the principal ingredient *panis* or *bread.*

It is sometimes made thin, to serve as drink; and sometimes, likewise, is sweetened, &c. to render it more palatable.

**PANADOU** or **Manadou**, in Geography, a bay on the coast of Cape Breton island, near the S. part of the gulf of St. Lawrence.

**PANAIE** or **Panaie**, in Ancient Geography, a people of Thrace, in the environs of Amphipolis. They formed a part of the Helleni, according to Steph. Byz. and Thucydides.

**PANÆIUS**, in Biography, a celebrated philosopher among the Stoics, who flourished in the second century before Christ, was a native of Rhodes, and defended from ancestors who had distinguished themselves in the military transactions of the republic. His inclination leading him to the study of philosophy, he became a disciple of Antipater of Taras, but did not at this time approve the doctrines of the Stoics. He was a great admirer of Plato, whom he called divine, most wise, and most holy; and he freely borrowed opinions and sentiments from philosophers of every sect. From Rhodes he went to Athens, where he maintained the reputation of the school of Zeno, and had many disciples. His name having reached Rome, he went thither; his lectures were crowded by the young nobility; and he enjoyed an intimate acquaintance with several eminent Romans, particularly Scipio and Lucius. According to some writers he accompanied Scipio in some of his expeditions, and is said to have rendered him essential services; he at the same time employed his interdict with this great man in conferring various benefits on his fellow citizens at Rhodes. Panæius appears to have spent the latter part of his life partly at Athens, and he died at the last named city, but it is not at all certain in what year. None of his works have come down to us; but his moral doctrines were, doubtless, very excellent, since they are greatly extolled by Cicero, in his treatise *De Officiis.* Cicero. *Enthic. Phil.*

**PANAGE** or **Pannage**, in our Ancient Geography. See *Pannage.*

**PANAGIA**, in Geography, a small island in the Grecian Archipelago, scarcely a league in circumference; 16 miles N.W. of Santorin. N. lat. 30° 30'. E. long. 25° 5'.—

**Albo**, a town of European Turkey, in Romansia; 14 miles N. of Gallipoli.

**P.NAGRA**, in Ancient Geography, a town of Africa, in Libya Interior, upon the northern bank of the Niger. Poletomy.

**PANAGUR**, in Geography, a town of Hindostan, in Gurry Mundella; 10 miles N. of Gurrah.

**PANAILA**, a town of Naples, in Calabria ultra; 4 miles N. of Nicolota.

**PANAMA**, or **Tierra Firme Proper**, a province of South America, in the vicereignty of New Granada, bounded on the N. by the Spaniish main, on the E. by the province of Darien, on the S. by the Pacific ocean, and on the W. by Guayaquil. The towns and villages of this province are mostly situated in small plains along the shore, the other parts of the country being covered with enormous and craggy mountains, which are fertile, and of course uninhabited. In this province there are three cities, twelve villages, and a great number of rancheiras or Ceminent-province, is a city and sea-port, built on the isthmus of Darien, at the bottom of a large bay of the Pacific ocean. The first discovery of Panama is ascribed to Tello de Guzman, who landed here in the year 1515, when he found only fishermen’s huts, and from its peculiar approbation to this buffets, it was called “Panama,” denoting a place abounding with fish. In 1518, a colony was established here under Pedrarias Davila, governor of Terra Firme, and in 1521 this place was constituted a city. In 1570 it was taken and burned by the English adventurer, John Morgan; and afterwards rebuilt in its present situation, which is much more convenient, about 1/3 league from the former. Being at first generally conformed to wood, it was almost wholly destroyed by fire in 1737, and again rebuilt chiefly of stone. Panama was the seat of a royal audience, abandoned in 1752; and by the fire in 1756, and a decline of commerce, it was reduced to a miserable situation. Nevertheless it is still a strong city, the seat of a bishop, and contains several churches and convents. The harbour of Panama is formed in its road under the shelter of several islands, where ships lie safe, at the distance of about 25 or 3 leagues from the city. After its fall by the loss of the galleons, it was almost completely ruined by a dreadful conflagration in 1784. Its only remaining trade is with the villages in its jurisdiction, and with the province of Veragua, the goods being received by Portobello, mostly from Cartagena: the vessels from Peru commonly return empty. The neighbouring mountains produce excellent wood, especially the most esteemed mahogany (caoba), and cedar, with many precious balsams. The spirit of trade ridiculously maintains itself, as the chief inhabitants of both xexes felt baubles and trifles by means of their slaves. The royal chef is but poor, that it cannot even pay the garrison, which is now desolated from Cartagena. The trade with Guayaquil is maintained by a caye and short voyage; the passage of the line being rather accompanied with calms, while in the Atlantic it is esteemed dangerous. This circumstance, as Pinkerton fugges, may have led to the name of the Pacific ocean, given by the Spanish conquerors of Mexico and Peru, before Magalhaes had felt its tempests. N. lat. 8° 48'. W. long. 80° 15'.

**PANAMA Shell**, in Ichthyology, a species of dolium.

**PANAMAO**, in Geography, one of the Philippine islands, about 15 miles in circumference, of a triangular form. N. lat. 11° 27'. E. long. 124° 15'.

**PANAMARIBA**, a river of Guiana, which runs into the Atlantic, N. lat. 6°.

**PANAMGOODY**, a town of Hindostan; 25 miles S. of Tinevelly.

**PANAMOS**, a mountain of Peru, in the diocese of Truxillo; being part of the Andes.

**PANANGOODY**, a town of Hindostan; 18 miles S.E. of Madura.

**PANOON**, one of the Philippine islands, about 45 miles in circumference, mountainous, but watered with many streams; thinly inhabited. N. lat. 10° 7'. E. long. 123° 2'.

**PANAOUCTICK**, a river of Canada, which runs into the Saguenary, N. lat. 48° 24'. W. long. 70° 53'.

**PANARAGA**, in Geography, a town of the island of Java, and capital of a kingdom, situated on the southern side of the island; 60 miles E. of Mataram.

**PANAROUCHI**, a town of Hindostan, in the Carnatic; 16 miles from Cuddalore.

**PANARD**, Charles Francois, in Biography, an ingenious French poet, was born about the year 1690, at Courtville, near Chartres. He became distinguished as a writer.
writer for the stage, and produced a number of dramatic pieces of the light and humorous kind, which were in general well received, and some of them are still represented in the French theatre. His fate was never prosperous, but he directed against vice and folly in general, without making the application to individuals. His works are stamped with facility, nature, sentiment, wit, and good sense; but they are often negligent, prolix, and incorrect. He was uneducated, and drew all from his own sources. He died at an advanced age, in 1765. His works were printed at Paris, in 4 vols. 12mo. in 1763, under the title of "Theatre et Œuvres diverses de M. Panard."

PANARIA, in Geography, a town of Prullia, in Oberland; 5 miles S. of Liblat.—Also, one of the Lipari islands, between Lipari and Stromboli. N. lat. 35° 40'. E. long. 15° 21'.

PANARIS, or PARANTHUS, formed probably of παρά, upon, q. d. an aboeed at the root of the nails, derived from παρά, junta, and υγιεῖς, a word used by some authors to express a whitlow, or paronychia.

PANAROCO, in Geography, a river of Italy, which rises in the S. part of the duchy of Modena, and runs into the Po near Bondeno, in the Ferrarëse. It gives name to a department in Italy, composed of the duchy of Modena, with Miranda, containing about 211,448 inhabitants, who elect 15 deputies. Its capital is Modena.

PANARUCAN, or PANAROCAN, a town of the island of Java, on the N. coast, and capital of a kingdom of the same name, near the eastern part of the island. The principal commerce consists of slaves and long pepper. May of its inhabitants are Portugeuse. S. lat. 7° 30'.

PANASA, or PANASSA, in Ancient Geography, a town of India, on this side of the Ganges, and on its bank. This is the Panabob, or Parna, which feee. Tolemy.

PANASNESTI, in Geography, a town of Turkish Armenia; 28 miles N.W. of Cars.

PANAT, a town of France, in the departament of Averion; 17 miles S. of Rhodes.

PANATELLAH, a town of Hindoostan, in the cir-

car of Ruttunpour; 40 miles N.W. of Ruttunpour.

PANATHENÆA, in Antiquity, a feast cele-

brated at Athens in honour of Minerva, whom the Greeks called Athena.

Harpocration and Suidas refer its institution to Erich-thonius IV. king of Athens, who lived before Theseus. Theodoret, alone, says the feast was establisht by Orpheus.

Be this as it will, till Theseus, this was a particular feast of the city of Athens, and was called simply Athenaæa; but that prince uniting all the people of Attica into one republic, they afterwards all assembled at the feast; whence the name panathènæa, i.e. the feast of all Attica.

In effect all Attica was present; and each people sent a bullock for the sacrifices, and for the entertainment of the vast multitude of people assembled. At first it lasted only one day, but to add to its solemnity, it was continued afterwards for several days.

There were two kinds of Panathenæa; the great, celebrated every five years; and the little, every year, or every three years; if we may credit the author of the argument of Demophanes's oration against Mithas.

The ceremonies were the same in the great and the little Panathenæa; excepting for a peplos or banner, on which the actions of the goddesses were represented in embroidery performed by maidens, with the names or those who had distinguished themselves in the service of the republic; which was only borne at the greater. See PEPLUS.

PANATHENÆAN GAMES. See GAMES.

PANABUR, or PONIABS, in Geography, a river of Hindoostan, which rises near Ouscuta, in Myfore, and runs into the bay of Bengal, near Cuddalore.

Male flowers only are found on a separate plant, in more globos umbels, with larger leaves to the involucrum, a turbinate, coloured, entire perianth to each flower, and longer filaments, which, as well as the petals, are inferted into the perianth.

E II. Ch. Umbel of many rays. Berry compressed, with two seeds. Petals five, equal, recurved. Calyx five-toothed. Male flowers on a separate plant; their calyx entire.

Obf. This is the only known genus of the true digynous umbelliferous tribe, whose fruit is pulpy. That very natural order is fo liable to occasional variations in the organs of impregnation, or, in other words, so many of its genera or species are, more or less, constantly, polygamous, that it is definite they shold all be kept together in the Panentandra Digna, to which they properly belong; notwithstanding that difference of structure, which is laid to exist between the calyx of the male and that of the perfect flowers. Bernard de Jussieu remarked that there are sometimes three styles and three seeds; and his nephew refers Panax to his order of Arolia, as does Linnaeus to his own, nearly equivalent, order of Hederaeae. A. de Jussieu moreover suspected that Cypionia, of which he knew nothing but from description was not generally distinct from Panax, but we find no authority for believing the fruit of the former to be pulpy, though described in Linnaeus language as dicoccus, or two-lobed. The smooth, very juicy, and usually beautifully coloured berries of Panax, are peculiar and charactetistic.

flowers, on slender partial flanks, with but small traces of an involucrum. Calyx with five reflexed teeth. Petals ovate, reflected. Stamens longer than the petals. German ovate-oblong. Styles two; in some flowers half the length of the petals; first slightly divided, then incurved, with capitate figmas; in others longer than the petals, erect, parallel, straight, with acute, slightly spreading figmas. One flower in our specimen has a style of each description. The former are probably abortive, as far as we can judge from other umbelliferous plants. Thunberg says this species flowers in May and June. The corolla appears to be white. Nothing could have determined this plant to be that of Linneas, except the authority of an original specimen; for the difference between these writers, as to the genus and order, implies that they had counted the styles.

4. P. arboresum. Serrated Tree Gin-feng. Fortl. Prodr. 75. Linn. Suppl. 441. Leaves fingered; leaflets flaked, strongly ferrated. Stem arboresous. Umbels compound. Gathered by Forster in New Zealand. The stem is arboresous. Leaves alternate; at the foot footflanks four inches or more in length, four or few, spreading, unequal, elliptical or obovate, acute, smooth, coriaceous leaflets, each from two to four inches long, and supported by a partial flank an inch in length. Umbels large, compound and proliferous, of numerous, spreading, smooth rays. Calyx wavy, very slightly toothed. We find scarcely any traces of general or partial involucrum, nor have we seen the fruit.

5. P. undulatum. Wavy Tree Gin-feng. Aml. Guian. 949. t. 350. Leaves fingered; leaflets flaked, undulated; downy and thinly beneath. Stem arboresous. Umbels panicked. Gathered by Aublet in Cayenne, Hiania, and the spicaceous forests of Guiana, bearing half-rije fruit in the month of May. The French call it 'Arbre de Mai, or de St. Jean'; the Indians Morototoni, which last word is retained as the specific name in Aublet's letter-prems, though not in his plate. The trunk rises to the height of 100 feet, though only two feet thick, with a whitish bark, and a white light spongy wood. The branches are all at the summit, spreading in a round head, leafy at their extremities. Leaves alternate, flaked, of about eight flaked leaflets, much resembling the flanks, except that they are strongly undulated, not ferrated, and their under side is clothed with soft downy tawny down. The largest are eight inches long. Umbels alternate, collected into large panicules at the ends of the branches, with an ovate rigid bracteas at the base of each partial flank. Styles two. Fruit sometimes of three lobes. Aublet saw it but half ripe. Every part of the plant is aromatic.

6. P. attenuatum. Taper-pointed Tree Gin-feng. Swartz Ind. Occ. 562. Leaves fringed; leaflets flaked, ovate, coriaceous, with taper points. Stem arboresous. Umbels panicked. Native of mountainous woods in the islands of Guadeloupe and St. Christopher. A tree 40 feet high, with round, smooth, unarmured branches. Leaves alternate, on flanks a foot long, whose base is dilated into an ovate, pointed, sheathing intraloculaceous stipula, such as may be observed in other arborescent species of this genus, as well as of Aralia; the leaflets are few, rarely only three, on parallel flanks from one to two inches long, broad-ovate, smooth, wavy and coriaceous, about three inches long, with a taper point more than half that length; their under side pale, with one central rib, and numerous straight transverse lines, connected by reticulated veins. Umbels very numerous, on long, racemose, imperfectly whorled flanks, which flanks are themselves collected, about five together, into one large but imperfect
imperfect umbel, at the top of each branch. Partial involucrum of several minute, awl-shaped, deciduous leaves, like the bracteas. Calyces with five small teeth. Petals ovate, acute. Stamina five. Styles two, rarely three, combined. Stigmas spreading, obtuse. We have not seen the ripe fruit.

Swartz thought it a berry; but we rather suspect that he, like ourselves, had only seen dried specimens, and that it is by mistake he terms this plant a shrub.

7. P. fruticosum. Shrubby Compound-leaved Gin-feng. Linn. Sp. Pl. 1513. (Scutellaria tertia; Rumph. Amboin. v. 4. 78. t. 33.)—Leaves triply pinnate; leaflets filated, lanceolate, fringed with slender teeth. Stem shrubby. Umbels paniculate, native of the island of Ternate, from whence, according to Rumphius, it was brought to Amboyna. This is a shrub, about six feet high, used in its native climate for hedges. The leaves somewhat resemble parsley, whence the Dutch call it Tree Parsley. They are repeatedly compound, their leaflets lanceolate, acute, fringed with slender, almost pinous, teeth. Umbels irregularly collected into panicles. Styles two, rather spreading. Berries purple, resembling those of Juniper. The whole plant has a strong aromatic parsley-like flavour.

8. P. aculeatum. Prickly Shrubby Gin-feng. Ait. Hort. Kew. ed. 1. v. 3. 448. L'Herit. Stirp. Nov. v. 2. t. 99, unpublished. (Zanthoxylum trifoliatum; Linn. Sp. Pl. 1455.)—Leaves ternate; leaflets filated, crenate. Footstalks and branches prickly. Stem shrubby.—Native of China. Dr. Fothergill is said to have cultivated this shrub in 1773, and it is infixed in the English or French gardens about 1788, when L'Heritier had a figure taken; but we have never seen it with a living specimen. The flower is shrubby. Branches round, smooth, with a solitary hooked prickle under the insertion of each footstalk. Leavesalternate; each common stalk an inch and half long, with a small curved prickle at the top; leaflets three, broadly obovate or elliptical, an inch long, on short, partial stalks, smooth, crenate or somewhat ferrated. Umbels on simple stalks, longer than the footstalks, usually several together at the extremity of each branch, simple, of numerous rays. Involucrum of many minute downy leaves. Calyx with five short broad teeth. Stamina twice the length of the petals, with large white anthers. Styles two, short, at length recurved, with downy stigmas.

10. P. horridum. Palmate Prickly-leaved Gin-feng.—Leaves simple, alternate, palmate, ferrated, with prickly ribs. Stem shrubby, very prickly.—Gathered by Mr. Archibald Menzies, at Nootka Sound, on the west coast of North America. The branches are round, leafy, hirsute, befit with innumerable yellow prickles, most crowded about the insertion of each leaf. Leaves on long, furrowed, prickly, somewhat downy footstalks, heart-shaped, a span wide, deeply lobed, sharply cut and ferrated, of a fine green; smooth and veiny above; paler beneath, their veins hairy and befit with numerous, yellow, prominent prickles. Flowers numerous, in a terminal hirsute cluster or spikes, shorter than the leaves, whose lower branches are much elongated, imperfectly umbellate, bearing many crowded yellowish flowers, chiefly male, their flowers being large and conspicuous, their styles small or deficient. The upper part of the cluster consists of crowded, imperfectly umbellate, female flowers, each with two rather spreading styles, and blunt simple stigmas, but few or no stigmas, unless the latter have fallen off early, which seems to have been the case with the petals. Fruit nearly obicular, pulpy, crowned with the permanent styles. Seeds angular.

We have seen sketches from New South Wales of what appears to be another species of Panax, different from all the foregoing, with compound, elder-like leaves, and beautiful blueish berries, of which no doubt we may expect an account in the sequel of Mr. Brown's Prodromus.

Panax, in Gardening, contains plants of the herbaceous and shrubby perennial kind, of which the species cultivated are; the gin-feng (P. quinquefolia); the three-leaved panax (P. trifolia); and the prickly panax (P. aculeata).

Method of Culture.—The first and second sorts are increased by sowing the seeds procured from abroad upon a moderate hot-bed, or in pots plunged into it, in the early spring season; and when the plants have acquired a few inches in growth, removing them into beds or borders where the mould is good, and the situations sheltered.

The third sort is increased by layers or cuttings, laid down or planted out in the summer months in pots, and plunged into the hard-bed of the frame. When they have struck root, they may be removed into separate pots, and be constantly kept in the frame.

The two first sorts afford variety in the borders, and the last among flower collections.

Panay, in Geography, one of the Philippine islands, of a triangular form, about 180 miles in circumference, populous and fertile, and abounding in rivers. The chief article of exportation is rice. The Indians tributary to the Spaniards amount to about 17,000. N. lat. 11° 15'. E. long. 125° 15'.

Panayas, a town of Portugal, in Alentejo; six miles N.W. of Ourique.

Pancala Aurea, a name of a famous antidote composed of many ingredients, described by Myrcipus.

Pancalier, or Pancaler, in Geography, a town of France, in the department of the Po, on the Po; 12 miles S. of Turin.

Pancaria. the name of a sort of cake much used at Alexandria, and usually covered with paper for the sake of its keeping the longer.

Pancarpus, in Antiquity, a sort of spectacle or show, which the Roman emperors frequently exhibited to the people.

The word is formed from the Greek παν, all, and καρπος, fruit. Whence the name was also given by the Athenians to a sacrifice, in which all kinds of fruits were offered.

The pancarpus of the Romans was a kind of chace, or hunt: for the performance hereof, a number of beasts, as hares, deer, bullocks, &c. were shut up in the circus, or amphitheatre; into which trees were frequently transplanted, so as to form a kind of forest, wherein the beasts were let loose; whence the pancarpus was also called Sylvia.

The beasts were thus abandoned to the people, i.e. to all who were disposed to share in the pleasure of the chase, who pursued, shot, killed, and cut in pieces, all they could lay hold of. Hichogabalus, the Gordians, and Probus, gave this diversion very frequently, and it continued till the time of the emperor Julianus, in the sixth century.

Cafabon, Cujas, Pitthe, &c. make the pancarpus and Sylvia the same thing; Salmatius will have them different. The Sylvia, according to him, was such a diversion as that above
above described: but the pancarpus a combat, wherein robust people, hired for that purpose, fought with wild beasts; which opinion he confirms from Callian, Julius, Claudian, Firmicus, Mantius, and Caius-dorus.

PANCAWIR, in Geography, a town of Hindoostan, in the country of Malwa; 60 miles N. of Ougcin. N. lat. 24° 14'. E. long. 76° 6'.

PANCH, in Mill-making, a plank of oak upwards, and fir below, about eleven inches wide, laid over the hoops to the convexity of the mall on the foreside, to make a fair surface for the yard to slide up or down, and prevent its chafing or rubbing against the hoops: hence often called rubbing-panch.

PANCH, a thick texture made of plaited rope-yarn, wove very clofe. It is flattened round the yards or rigging, to prevent their surfaces being rubbed by the friction of some other contiguous object.

PANCHAEA, in Ancient Geography, an island of the ocean, upon the coast of Arabia. According to Diodorus Siculus, it was inhabited by natives of the country, Indians, Cretans, and Scythsians. In this island was a town called "Panara," whole inhabitants, according to Diodorus, were singularly happy. They had a temple of Jupiter Triphysian, of which this author describes all forts of marvellous circumstances. The other three towns were Hircæa, Dabi, and Oceanis. But the exuage of such an island is doubtful.

PANCHAGNI, an expiatory self-inflicted penance resorted to by Hindoo aetics. The word means five fires; and the mode of the penance is for the devotee to look constantly on the fun, with four other fires close to him. Such devotees are called Tapasvi, and are described in Hindoo books very circumstantially, but not, we may conclude, very faithfully, as "standing, with uplifted arm, without aid or support, day and night, feeding on air, immovable, on the right toe, on the afflicted earth," &c. &c. See Tapas.

PANCHAMA-MUKI, a name of the Hindoo deity Siva, meaning five-faced, he being so represented and described in pictures and books. When five-headed he has usually ten hands.

PANCHAW, in Geography, a town of Bengal; 43 miles N.E. of Doega. N. lat. 24° 30'. E. long. 85° 38'.

PANCHBEYA, a town of Bengal; 27 miles E.S.E. of Purnea.

PANCHCOWRYE, a town of Hindoostan, in Oude; 20 miles S.S.E. of Bahrait.

PANCHDOWNA, a town of Bengal; 20 miles N.E. of Dacca.

PANCHGARRY, a town of Bengal; 15 miles N.E. of Calcutta.

PANCHGUTHY, a town of Bengal; 10 miles S. of Oliapour.

PANCHMOOL, a town of Bengal; 10 miles E. of Roganapour.

PANCHPARA, a town of Bengal; 15 miles N.E. of Baffimpour.

PANCHPEER, a town of Bengal; eight miles S. of Oliapour.

PANCHREST, Panchrestos, ἀλός, useful, in Medicine, a panacea, or remedy for all distempers. See Panacea.

PANCHRESTARI, among the Romans, are those who prepared the pancreas, or universal remedy.

PANCHUS, the name given by some of the ancient writers on natural history to a gem which they say has all colours: probably the opal.

PANCYMAGOGUE, Panchymagogum, formed from ἄλος, all, ἄλος, or, and ἄλος, useful, in Medicine, a panacea, or remedy for all distempers. See Panacea.
four, rather smaller than the calyx, hooded, toothed, plaited and crimped, their claws inserted into the receptacle, at the base of each segment of the calyx. *Stam.* Filaments feven, awl-shaped, ascending, hairy half way up, inserted into the receptacle between the two longer segments of the calyx, and twice their length; anthers oblong, incumbent. *Petal.* not observed by Wildenow, who found in place of it a glan-
dular depressed body. *Lett.* who discovered the plant, noted a solitary pistil. *Peric. and seeds unknown.*

El. Ch. Calyx bell-shaped, in four deep segments. Petals four, hooded, plaited and crimped; with calyx. Stamens ascending, longer than the calyx. 

1. *P. biyga.* Native of Guinea. A tree, with round branches; the young ones clothed with silky down. Leaves alternate, abruptly pinnate, of two pair of flaked, ciliate, elliptical, entire, smooth, veiny leaves, each terminating in an elongated blunt point. *Flowers* of the younger ones downy, of the full-grown ones transversely wrinkled. Clusters utriform, short, simple, many-flowered, on the last year's branches. *Flowers* downy, on downy stalks. *Bulbs* ovate, oblong, downy, shorter than the flower-stalks.—We have some suspicion that this may possibly be the same genus with *Aitch.* whose characters are given in Tr. of the Linn. Soc. v. 4. 221, to which the name of *Pancrocia* muft, in that cafe, give place, as being of a later date, and by no means preferable in any respect. See *Arzella.*

**PANCRAS,** in Geography, a large parish in the Holborn division of the hundred of Oldfulton and county of Middle-
sax, England, is situated on the north side of London, and comprises about 2700 acres of land, including the sete of buildings. It is bounded by the parishes of Islington, Horn-
fey, and Finchley on the north; by Hampstead and Maryle-Bone on the west; by St. Giles in the Fields, St. George the Martyr, St. George-Bloombury, and St. Andrew's, Holborn, on the south; and St. James, Clerkenwell, on the eft. The increase of houses in this parish within the last forty years has excited the attention of all persons, who can recollect its condition previous to that period. The pro-
portion is calculated as upwards of twenty to one. The first augmentation of much consequence happened in the neigh-
bourhood of Tottenham-court-road, about the year 1795, when all the streets near Percy chapel were built. Somers-
town was begun in 1786, Camden-town in 1791, Fitzroy-
square in 1793, Brunswick-square in 1797, and Tavistock-
square about 1800. Kentish-town has been enlarged more than two-thirds within the last twenty-five years, and a con-
derable number of streets have been built between Bruns-
wick and Russell-squares, and the New Road. Many houses have likewise been added at Bridge-brige, and hence this parish is now far the most populous of any in the vicinity of London. According to the late parliamentary returns (1811), it contains 6743 houses, and 46,333 inhabitants.

Pancras is said to have been a parish before the Conquest; and is mentioned in Domesday book. It derived its name from the saint to whom the church is dedicated. That edifice is of ancient date, and is certainly the smallest parochial church in London, or its vicinity. It confits only of a nave and chancel. In this church and in the surrounding cemetery, are buried most of the Roman Catholics who died in the metropolis, among whom are several eminent French refugees. Here also reft the ashes of the illustrious Paoli, of Mary Wollnoncroft Godwin, of the chevalier d'Eon, and many other persons distinguished in their career of life by their actions or their writings. Besides the parish-church there are, as may be supposed, several chapels appropriated to public worship within this parish. Of thefe the principal are, Kentish-town chapel; Percy chapel, near Tottenham-
court-road; Fitzroy chapel; Woburn chapel; Bethel chapel, at Somers-town; St. James's chapel; Whitefield's chapel, belonging to the Methodists of Mr. Whitfield's per-
fusion; and St. Giles's chapel, attached to the parish of St. Giles's in the Fields. Several burying grounds annexed to other parishes are likewise locally situated in Pancras, as the cemeteries of St. Andrew, Holborn, St. George the Martyr, and St. George-Bloombury.

Many public institutions for charitable and other purposes are placed within this parish. At the head of Lamb's Conduit street stands the Foundling hospital, which was first esta-
blished in 1739, for the maintenance and education of found-
lings, and of other poor children who are admitted in their infancy. The hospital for inoculation, and the natural small-pox hospital, are situated in a site close to Bridge-
bridge turnpike. Both these excellent charities were founded in 1746, but the present buildings were only erected, the former in 1765, and the latter in 1793. In Gray's-Inn-lane is the Welsh charity school, built in 1771, and at Camden-
town is the Veterinary college, established in 1791. (See Ve-
isary.) In this college is a theatre for lectures and for dissections, and a room for a museum. The present pro-
feffor is Mr. Colman, who reads lectures on the anatomy, physiology, and pathology of the horse, from November till June. The pupils may twenty guineas on admission, which includes every expense, and they have besides the great privilege of attending the principal anatomical lectures in the metropolis. Near the college has lately been erected a large workhouse; and in different parts of the parish are several alm-houses and charity schools, which our limits pre-
clude us from enumerating.

At a place called the Brill, on which part of Somers-
town is built, was an entrenchment, suppos'd by Dr. Stuke-
ley to have been the camp of Caesar. Caen-wood, or Ken-
wood, at the northern extremity of the parish, is noted for having been the country seat of the celebrated earl of Mans-
field, who purchased it in 1755 from the earl of Bute. The pleasure grounds, including the wood, whence the manor derive its name, comprehend about forty acres, and display, both in their natural and artificial features, much beauty and picturesque effect. Adjoining are the refervors belonging to the Hampstead water-works.

A noted place of public entertainment, called Bagnigge-
well, is situated in this parish, in the valley between Pen-
ness and the Foundling hospital. It was first opened in 1767 as a tea-garden, soon after the discovery of the two mineral springs here, one of which is chalybeate and the other cathartic. Another mineral spring near the church was formerly in great repute, but is now abandoned. The water of this spring was similar in its properties and effects to that of St. Chad's-well near Bridge-brige, which is still held in considerable estimation for its ductile and aperient qualities. Lyfons's Environ's of London, vol. iii. edit. 1795. Supple-
ment by the same author, edit. 1811.

**PANCRASIIUM,** in the *Materia Medica,* a name used by some authors for the squill, of the root of which the oxy-
mel of squills is made.

**PANCRATIAN VERSE,** the name of a sort of Greek ve-
re, consisting of two trochees and a supernumerary syl-
bale: *Στριφόνι Καλόγερος.* It is so called from its suppos'd inventor Pancrates, who is said to have lived before the time of Melcager, another poet who flourished under the first successors of Alexander.

**PANCRATIATES,** in *Antiquity,* a combatant in the exer-
ercise called pancratium.

**PANCRATIATES** was also applied to one, who had gained the
the victory in all the kinds of exercise used in the pancratium.

PANCRATIUM, Πανκρατιον, compounded of παν, all, and στροφη, a turn, among the Antients, a kind of intermixed exercise, consisting of the lutce, (pale), or wrestling, and the boxing, pugilate, or caflus.

The pancratium was the third gymnastic exercise, and was not introduced till long after the others.

The people, who were engaged in these exercises, were called Pancraste; which name was also given to such as did not confine themselves to one exercise, but succeeded in several different ones.

As this exercise partook both of the caësus and the pale, as we learn from both Arifotle and Quinætian, the athlete borrowed many things from each of these sciences to render himself eminent in the pancratium. It was necessary for him to learn how to trip, and strike, and box, and grapple with his antagonist; to stand with firmness, fall with advantage, and rise with vigour and celerity, or maintain the combat upon the ground; to attack and to defend, to annoy and ·refit his enemy in every attitude; and to employ in one or other of those purposes every limb, and nerve, and finew, all the faculties and all the strength of his whole body, which is implied in the word pancratium; and this term gives the best account of an exercise, in which the combatants were allowed (under certain reñriictions) to make what shift proper of all the arms which nature had given them, both offensive and defensive, and of only those; for neither (as in the caësus) were their hands and fingers bound up or armed, nor their legs and feet prohibited from joining in the battle, nor were they constrained from striking, as in the pale. With no further arms than those, however, they were able so to mangle and injure one another, that it was thought proper to subject them to some reñriictions; that is, to confine, in which they engaged for victory and honour, should be disgraced by murder or malice, and the combatants be provoked to encounter one another in a manner more becoming bears than men. An athlete was therefore forbidden to kill his adversary designingly, to dig or pluck out his eyes, to tear him with his teeth, or strike him under the ribs with the ends of his fingers, but notwithstanding these reñriictions, if the combatants were left for the combatants to exercise their skill and strength, their courage and resolution; because it was a common practice for the pancratist to choke the throat and skin of his antagonist by twisting and entangling himself about his legs and arms; and to endeavour by fatigue, and pain, and suffocation, to worry him into a surrender of the victory. The pancratium was forbidden by the Spartan legislature, whilst he allowed and encouraged many contests so lefs rude and bloody; for the law of these two exercises requiring that one of the two combatants should yield either in words, or by stretching out his hand or finger, or by giving some other testimony of his doing, Lycurgus forbade his Spartans to engage in either of them, because, as he said, he would not have them accustom themselves to yield the victory not even in sport. The combatants in these exercises were naked; and as it was necessary to pair them, this, we may suppose, was done by lot. Paulaner speaks of a pancratist named Soiôrus, who had an easy method of obtaining the victory in these contests: his custom was to feize fall hold of his adversary's fingers, which he broke, and never quitted his hold till they renounced the contest. This method gained him twice Ithimian and Nemean, two Pythian, and three Olympic crowns, together with a statue at Olympia, and the surname of Acro-Cherites. Well's Pindar, vol. iii.
3. P. rotatum. Large-crowned Pancratium. Ker in Curt. Mag. t. 527. Ait. n. 3. (P. diciforme; Redout. Lilac. t. 155.)—Sheath with few flowers. Leaves linear. Staminates between the jagged segments of the horizontal nectary, Native of Carolina, in ground that is occasionally overflowed, from whence it was brought by the younger Michaux to Paris, and sent to Mr. Lodidge before the year 1803. It flowers in the flower, during most part of the summer, and increases greatly by offsets from the root. Leaves many-ribbed, linear, from half an inch to an inch wide. Flowers two, three, or more, with a segment of the sheath under each, white, nearly a span in diameter, from the great length of the linear channelled petals. The great flanels, and wide expansion, of the cup of the nectary, with its variously-jagged segments, between which the wide-spreading flaments, about twice its length, are attached, form the striking character of the present species, which Michaux in his Flora mitloek for the Mexicanum.

4. P. calathium. White Brazilian Pancratium. Ker in Curt. Mag. t. 1501. (P. calathiforme; Redout. Lilac. t. 333.)—Sheath with few flowers. Leaves linear. Staminates between the jagged segments of the cup-shaped nectary, and scattered, extending them in length. Tube nearly cylindrical. Native of the Brazils, from whence it was received by the late lady Amelia Hume, who favoured us with a specimen in May 1794. The leaves are linear, obtuse, an inch wide and two feet long. Flowers two or three from a sheath of as many or more divisions, white, very fragrant, somewhat drooping. Nectary large and cup-shaped, its segments nearly upright, variously and sharply jagged and toothed. Staminates about the length of the segments, and inclosed between them, bent inwards, each bearing a yellow anther longer than itself. Redoute's figure represents the nectary as large as a flower of the common White Lily, with longer and less jagged segments than are exhibited in the Bot. Magazine; but Mr. Ker considers it as merely taken from a stronger plant.

5. P. Amances. Golden Pancratium. Curt. Mag. t. 1224. Ait. n. 4. (Narcissus Amanaces; Ruiz and Pavon. Peruv. v. 3. 553; t. 283; f. a.)—Sheath with few flowers. Leaves lanceolate. Staminates between the abrupt toothed segments of the cup-shaped nectary, and about the same length. Tube with five furrows. Native of Lima and Peru. Imoported from the Brazilis, in §808, by Mefirs. Middlemill and Wood at Shepherd's bush, in whole flower it flowered in July 1809. This species is distinguished from all the preceding, by the golden yellow of its flowers, which are described as exceedingly fragrant, and used by the Peruvian women to ornament their hair. The shape and fize of the flowers most agree with the last-described, particularly the inflexed pointe of the very short flaments; but the segments of the nectary fem more abrupt, and more regularly toothed. The tube of the flower moreover has five strong furrows, and as many rounded angles. The leaves are more lanceolate, and broader, tapering to a point.

6. P. humile. Small Pancratium. Cavan. l. v. 3. 4. t. 207 f. 2. Willd. n. 3.—Sheath two-flowered. Leaves thread-shapled. Nectary cup-shaped, very short, in fix obtuse cloven segments. Staminates spreading, as long as the petals.—Gathered by Cavanilles in Andalucia, flowering in October, before the leaves come out. These are two only, fearfully six inches long, very slender. Stalk not quite so tall, slender, thread-shaped, bearing two yellow flowers from one stalk, on unequal capillary flanks. Petals elliptic-oblong, obtuse, each rather above half an inch in length. Nectary short, and rather flothy, cup-shaped, in fix cloven segments, more resembing that of a Narcissus, but Cavanilles expressly says it bears the flaments. The tube is short. Stamiocaps nectary, almost equal to the petals. This appears to us a very doubtful Pancratium, and if the lobes are not more firmly attached, it is short the nectary, but not the flaments, it ought to be removed to Nartsceus; see that article.

7. P. caribaum. Caribbean Pancratium. Linn. Sp. Pl. ed. 1. 291. ed. 2. 418. Willd. n. 4. (P. n. 11; Brown. Jum. 194. Narcissus tutes abius latifolius polyanthos major odo-rous, flaminus sex e tubi ampli margini exaltatius; Sloane Jam. v. 1. 244. Mart. Cent. t. 27.)—Sheath many-flowered. Leaves lanceolate.—Native of Jamaica, in lowland woods, very common, as well as in other fugar islands, according to Sloane and Browne. The bulb is said to be as large as a man's fist. Leaves two feet long, and about three inches broad, channelled or concave. Flowers-fall flat, two-edged, four feet high, solid. Flowers fix, leven, or more, large, white, fragrant; their tube, mistaken by Sloane for a partial foot-tall, fix inches long; petals five inches long; nectary with fix ribs, bearing the very long flaments. This is all we can gather from Sloane. Browne says the root is pretty acrid, and has been sometimes used in medicines; and in some of the fugar islands, to raise a forced bloom in their fading cheeks.—P. caribaum is a much-difticted species. Linnanus adopted it from the above authors, adding a reference to Comenin, which certainly belongs to what is now called amancon, see n. 12. He had however an original specimen in his herbarium, sent by Gronovius, with the synonymy of Sloane and Martyn; but this specimen con- ficts merely of a few separate flowers, which appear to belong to amancon, but can scarcely be ascertained. In this difficulty we leave the present species as we find it, the above synonym of Sloane and Martyn not being with certainty referrible to any of the following, whatever may become of the species, which neither accords with them, nor could possibly have fuggled the specific definition.

8. P. maritimum. Sea Pancratium. Linn. Sp. Pl. 418. Willd. n. 5. Ait. n. 5. Cavan. l. v. 1. 41 t. 56. Redout. Lilac. t. 1. S. Sali. Tr. of Linn. Soc. v. 2. 70. t. 9. (P. caro- linanum; Linn. Sp. Pl. 418. P. maritimum, et floribus rubris; Ger. em. 172. 173 f. 3. 4.)—Sheath many-flowered. Leaves linear, obtuse, g and us. These are equal and segments of the large cup-shaped nectary, and about the same length, incurved.—Native of the sandy sea-coasts of the north of Europe, frequent in Greece and the neighboring islands. Gerarde cultivated it in his garden, and it is still occasionally to be seen in collections, flowering in May and June, in the open ground, though much less frequent than the illyricum, which Miller mitloek for this. Our maritimum is, if any of the genus, the true var. fittus of Dioscorides. It is known by its narrow glau- cous leaves, and the large bell-shaped nectary, with twelve short, equal, entire segments, between every two pair of which it has an incurved flament, not exceeding them in length. Redoute's plate is excellent. The flowers are fragrant, usually white, but occasionally tinged with a faint red, whence the species was termed verecundum in Ait. Hort. Kew. ed. 1, where it occurs twice.

Neetary with six teeth bearing the flammes; the intermediate space way, obscurely toothed.—Native of the West Indies, said to have been cultivated by Miller in 1758. It flowers in the flower throughout the summer. Linnaeus having misquoted the synonym of Trew's Eriet under his illyricum, has, as Mr. Salisbury remarks, caused the present species to be sometimes called by that name, though the two are as unlike as possible. The present bears a great number of powerfully-clefted, large, white flowers, whose tubes are seven inches long, and their common stalk three or four feet high. Petals long, narrow, recurved and pendulous. Cup of the neetary wide and shallow, its six principal teeth bearing the very long flammes, while the intermediate space is merely way, with scarcely the appearance of teeth.

10. P. fragrans. Fragrant Pancratium. Salis. Tr. of Linn. Soc. v. 2. 72. t. 11. Wild. n. 6. Alt. n. 7. (P. foliis amplis ovoatis acutis petiolatis, spathe multiforma, floribus minoribus candidis fragrantibus.]—Sheath many-flowered. Leaves elliptical. Neetary teeth with six teeth bearing the flammes; the intermediate space way and close. Native of Barbadoes, flowering in our flowers in the summer. Mr. Salisbury first well distinguished this species, and suspected that the synonmys above quoted under P. caribium might belong to it, which we can scarcely believe. Willdenow seems to have rightly referred to Trew's Eriet. The scent of the flowers is very sweet. The scent of intermediate teeth to the neetary, in the place of which there is a notch, and the broad elliptical flohige, well mark this Pancratium. The tube of the flower is not half the length of the leaf.

11. P. speciosum. Great West Indian Pancratium. Salis. Tr. of Linn. Soc. v. 2. 73. t. 12. Wild. n. 8. Alt. n. 8. Redout. Liliac. t. 155. (P. caribium; Curt. Mag. t. 826.)—Sheath many-flowered. Leaves elliptical. Neetary teeth with six teeth bearing the flammes; the intermediate ones simple, acute.—Native of the West Indies, flowering in a flower most part of the summer. The leaves are numerous and broad, with contracted stalks. Flowers numerous, large, white, very fragrant, distinguished by the intermediate teeth of their neetary from the leaf. Martyn's t. 27, on which the Linnaean caribium is supposed to depend, is noted in Hort. Kew, as belonging to this species, which may be the cafe, though the neetary is there incorrectly drawn. The present is the finest of the whole genus, and most generally cultivated, by those who have the means to make it bloom in perfection, which sometimes takes place twice in one summer.

12. P. ambonence. Broad-leaved Cayenne Pancratium. Salis. Tr. of Linn. Soc. v. 2. 71. t. 10. Wild. n. 9. Alt. n. 9. Andr. Repof. t. 556. (P. declinatum: Jacq. Hort. Ind. v. 3. 10. t. 11. Narcissus americanus: flore multiplice also hexagono odorato; Commel. Hort. v. 2. 173. t. 87.)—Sheath many-flowered. Leaves elliptic-lanceolate. Neetary with six teeth bearing the flammes; the intermediate ones acute, deeply cloven.—Native of Guiana. Mr. Salisbury cultivated it before 1759, and Jacquin long before that period. This has narrower leaves, and much smaller flowers, than the flore multiplice, and the petals are more than the teeth to the neetary, which part seems to us well chosen by Mr. Salisbury for the specific differences, notwithstanding the doubts of other authors. The lying down of the stalk, when the feed-velis are forming, is, as he remarks, by no means peculiar to this kind of Pancratium, and therefore he could not retain Jacquin's specific name. Yet it may be doubted whether he had acquired to be equally indiscriminate.

13. P. illyricum. Starry Pancratium. Linn. Sp. Pl. 418. Wild. n. 10. Alt. n. 10. Curt. Mag. t. 718. Redout. Liliac. t. 153. (P. bellare; Salis. Tr. of Linn. Soc. v. 2. 74. t. 14. P. spathe multiforma, petalis planis, foliis linguatis; Mill. t. 197. Narcissus tertiis Matthioli; Ger. em. 173. N. contilotan-poliatus; Matth. Valer. v. 2. 580, excellent.)—Sheath many-flowered. Leaves lanceolate, obtuse, glaucous. Stammes between the deep, acute, cloven, widely-spreading segments of the neetary, and twice their length.—Native of the south of Europe. Lord Zouch is recorded as having cultivated this species in 1695. It is now not uncommon in our open borders, requiring no particular care, and flowering in May or June. Miller and others have mistaken this for the Linnaean maritimum, from which it is totally different. The leaves spread in two ranks, and are very glaucous, rigid, a foot long, conic, one inch and a half wide. Flower-stalk a little inclining, not fo long as the leaves, bearing numerous white flowers, of an agreeable scent, and well characterized by their starry appearance, caused by their widely-spreading petals and neetary, whose segments are cloven half way down, and much more deeply separated from each other, with the flammes between them.

14. P. ambonence. Ambaina Pancratium. Linn. Sp. Pl. 419. Wild. n. 11. Alt. n. 11. (P. ambonence; Salis. Parad. t. 84. Narcissus ambonensis, folio latissimo rotundato, floribus niveis inodoratis; Commel. Hort. v. 1. 77. t. 39. Rudb. Elv. v. 2. 238. f. 17. Cypa sylvestris; Rumph. Ambain. v. 6. 162. t. 70. f. 1.)—Sheath many-flowered. Leaves elliptic-heart-shaped, many-ribbed. Neetary in six deep segments, with two dilait teeth, bearing the flammes between their teeth.—Native of Amboyna and Java. We received it from the late Mr. Christopher Smith. Miller cultivated this species in 1759, but it has been lost till within a few years. It flowers in the flower early in spring. The remarkably broad heart-shaped leaves, of a pale green, with many floren ribs, abundantly distinguish this Pancratium from all the rest. The flowers are extremely numerous, white, without smell, their shape and proportion most like illyricum, the petals being about the length of the tube, but the neetary is essentially different, being divided above half way down into six broad wedge-shaped segments, each having two diversacated teeth, and between these teeth the flammes are inserted, extending far beyond them, and about half the length of the petals.

Pancratium, in Gardening, contains plants of the bulbous-rooted, flowery, perennial kind, of which the species cultivated are; the sea pancratium (P. maritimum); the Illyrian pancratium (P. illyricum); the Ceylonese pancratium (P. zeylanicum); the Mexican pancratium (P. mexicanum); the Caribbean pancratium (P. caribium); the Carolina pancratium (P. carolinanum); the broad-leaved pancratium (P. ambonensis); the narcissus-leaved pancratium, and the P. speciosum.

Of the seventh fort there are several varieties; as the American, which grows naturally in the islands of the West Indies, where it is called white lily; and the latifolium and obtatum also grow naturally in the same place.

Method of Culture. All these plants are capable of being increased by planting-off sets from the roots in the latter end of summer, when their flowers and leaves decay. The roots may be divided every second or third year.

In the two first sorts, the off-sets may be planted out in nursery-beds for a year or two, to become sufficiently strong, when they may be removed into warm sheltered dry borders; the first being sheltered from frost in severe winters, and the latter in very severe weather, by being covered with tanners' bark, straw, or peat-haulm. The second fort may also be increased by seeds sown in pots, and plunged in a hot-bed. The other sorts must be planted out in small pots filled with
PAN

with light earth, separately plunging them in the bark-bed of the loofe. They should be kept constantly in the tanbed, and have the management of other tender bulbs. In this way they generally succeed well.

The two first sorts afford variety in the dry warm borders of the pleasure-ground, and the other kinds produce variety as well as fragrance in the loofe collections.

PANCREAS, in Anatomy, a glandular body, situated in the abdomen, and connected to the beginning of the small intestine, in the cavity of which its excretory duct terminates. The structure of this gland to nearly resembles that of the salivary glands, that we refer on this part of the subject to our account of them in the article DEGLUTION, and to the general remarks in the article GLAND.

The shape of the pancreas is elongated: the right extremity, which is the largest part, is sometimes called the head of the pancreas (caput pancreatis): the left, which is smaller, its tail (cauda). The length is from eight to ten inches, and corresponds nearly to that of the stomach: the breadth is two or three inches, and the thickness about one inch. It is much the largest gland in the body of this particular kind of structure. It is said to weigh from two to six ounces; the specific gravity to that of water as 2089 to 1000.

This gland is deeply hidden in the upper and back part of the abdominal cavity—in the epigastric region, where it lies nearly transversely. The right or larger end lies in the concavity of the second curvature of the duodenum, and adheres closely to this intestine for a considerable breadth by a short and dense cellular tunic. The substructure of the organ, advancing over the anterior and posterior surfaces of the gut, seems to incline it. The portion, which lies along the intestine, is much broader than the rest of the gland, and was called by Winlow the pancreas minus, although it is not distinct from the rest. From the duodenum the pancreas stretches across the vertebral column into the left hypochondrium, directed a little upwards as well as to the right. Its left end, which is the smallest part, touches the interior end of the spleen, or is connected to it by the intervention of a portion of the stomach.

The anterior and posterior surface of the pancreas are nearly flat: but the whole is rather curved in accommodation to the projection of the vertebral column. The anterior surface, inclined forwards and slightly convex, is covered by the upper layer of the transverse mesocolon, through which it can be easily discerned behind the stomach and little omentum. The latter parts lie in front of it, and are in contact with the gland, when the stomach is empty: but when that bag is filled, it rises from the gland, which is then behind its jejunal arch. The posterior surface corresponds to the transverse part of the duodenum, from which the superior mesenteric vessels and nerves separate it. The superior edge, thicker than the inferior, and inclined backwards, is connected by copious cellular substance to the aorta and vena cava, the superior mesenteric vessels, and the left kidney and renal capsule. It polishes a groove, in which the splenic artery is lodged. The inferior edge is thin and inclined forwards, and placed between the upper layer of the transverse mesocolon and the duodenum.

The external surface is granulated, and the confidence of the organ, in its recent state, very firm. It becomes softer soon after death, and is very much softened, when putrefaction commences. The colour is a greyish-white, inclining to red.

The excretory duct (sometimes called ductus Wirungi, from Wirung, who discovered it in 1642) runs from one end of the gland to the other, nearly in its centre. It is remarkable for its whiteness, and is of denser and thicker than those of the salivary glands. Very fine tubes arise from the glandular acini, and unite together into veins: they end in a single tube, which gradually increases in size, as it proceeds from the left to the right end of the gland, does not follow quite a straight course, and is rather nearer to the anterior than to the posterior surface of the organ. When it arrives near the duodenum it has attained the size of a small writing quill, and it receives a branch rather larger than the others from the part called pancreas minus. It turns a little downwards to join the ductus communis choledochus at an acute angle, and the common tube immediately penetrates the coats of the duodenum, at the lower and posterior part of the second curvature of the intestine. (See LIVER.) The opening is smaller than the diameter of the duct before its end; and Soemmerring states that the entrance of the bile into it is prevented by a valve, "valvula fimbr cata util folis": Sometimes a small canal opens separately at a short distance from the common duct; or the great duct itself may terminate separately from the ductus communis choledochus; or there may be three pancreatic ducts opening into the duodenum.

The texture of the duct is tolerably firm: its internal surface is perfectly smooth.

It has no proper external covering: one surface has the anterior layer of the mesocolon lying on it, pretty closely, but the rest of the gland is connected by a loose cellular tunic to the surrounding parts.

The arteries of the pancreas are numerous and small, and produced from the gastro-duodenal, the splenic and the superior mesenteric: the veins join the superior mesenteric, the splenic and the gastro-duodenal, all of which end in the vena portarum. It has absorbes, in which nothing peculiar has been observed. The nerves, which are very small, and distributed on the arteries only, come from the celiac ganglion.

The points in which this and the salivary gland agree are; 1, the organization, including the excretory duct of the the excreting numerous small blood-vessels; 2, the being placed in a situation where they subject to motion from the surrounding organs. These, in the pancreas, are the trunks of the aorta, superior mesenteric and splenic arteries, the stomach, and duodenum.

In the mammalia and birds, the pancreatic and biliary ducts are sometimes united, sometimes separate; and sometimes there are two pancreatic ducts, one opening into the ductus choledochus, and the other separately.

The pancreas secretes a fluid, called the pancreatic juice or liquor, which is poured by its excretory duct into the duodenum. The difficulty of procuring this in a pure state has prevented any very accurate investigation of its chemical properties: but it appears, from whatever inquiries have been made, very closely to resemble the saliva. (See DEGLUTION.) The duct is always found empty after death.

In the controversy about the nature of the pancreatic fluid in the seventeenth century, numerous dogs were slaughtered without any very interesting results being obtained. De Graaf placed tubes in the pancreatic ducts of living dogs: phalanges were connected to the opposite end of them. In this way he collected two drachms, half an ounce, and even an ounce, in eight hours. Schuyt procured two and three drachms in two hours. (See De Graaf deucci pancreatii natura et usu; and Schuyt de veteri medicina.) Brunner attempted to cut out the gland, or to tie the duct in dogs. (Experimenta nova circa pancreas.) These tortures were inflicted in the attack and defense of a doctrine promulgated by Sylvius de le Boc, and very generally adopted, that
that the pancreatic liquor was acid, and the bile alkaline, and
that their mixture occasioned a fermentation in the stomach,
by which chylification was effected. These notions were
employed in explaining the fever of the cold stage of fever
attributed to the pancreatic juice, and alkaline remedies
were ordered to correct it.

We know that the salivary glands secrete their fluid very
largely during mastication (see Deglutition): this analogy
leads us to infer that the pancreas must furnish a large
quantity of fluid, which is mixed with the chyme from the
stomach. As we are ignorant of the quantity and exact
nature of this secretion, we cannot be expected to explain
what share it has in the changes which our food undergoes
in the alimentary canal. Haller's Elementa Physiologiae,
lib. 22. Siebold, Historia Syllematis Salviae, 4to. Jene
1797.

PANCREAS Aselli, in Comparative Anatomy, the large single
mecenteric gland of some animals, which holds the place of
the numerous smaller ones. See Mammalia.

It has its name from the author who first took notice of
it, Asellus. M. Perrault observes, that the fin called
plafic, has four hundred and forty pancreas; though it
has but five ducts opening into the intestine, three of which
correspond to eighty pancreas; and two of them to one
hundred a piece. See Fish.

PANCREATIC, in Anatomy, an epithet given to
various parts situated about the pancreas; as the duct of
the gland, its arteries, veins and nerves. See Pancreas.

Pancreatic Juice, an infeld, limpid juice or humour
separated from the blood, and prepared in the pancreas.
This juice is not acid as most authors have suppos'd;
nor alkaline, as some authors have thought; but a little
saline, and much resembling the salva in its origin, veifels,
and properties.

It is carried by the pancreatic duct into the duodenum,
where it serves to dilute the chyle, to render it more fluid,
and fit to enter the mouths of the lachets; and perhaps to
temper and dilute the bile, to change its virulence, bitterness,
colour, &c. and make it mix with the chyle, in order to re-
duce the several tastes, odours, and properties of the several
foods into one homogeneous one.

Janfion ab Almeleveen will have the pancreatic juice to
have been known to Hippocrates and Galen. De Graaf, a
Dutch phyfician, has found means of collecting a quantity
of it for experiments; and has published a treatife exrefis,
"De Succo Pancreatico."

Brunner relates, that the pancreatic duct, in several dogs,
having been tied and cut, they still continued to eat and
drink, and perform all the other functions of life as usual.
One of them feemed only to have the better action for it.

PANCSOVA, in Geography, a town and fortrefs of
Hungary, on the N. side of the Danube, in the hannat of
Femofar; 8 miles N. of Belgrade. N. lat. 45° 15'. E.
long. 12° 16'.

PANCTOU, a town of Thibet; 70 miles N.N.E. of
Laffa.

PANDA, a town on the N. coast of the island of Cum-
baya. S. lat. 8° 27'. E. Long. 118° 48'.
PANDA, in Mythology, a goddes who was invoked and
honoured as the proteftrefs of travellers and navigators.
The godfess of peace was also called Panda, because she
opened the gates of cities which were shut in time of war.
According to Varro, Panda is a surname of Ceres, derived
à pane danda, because she gave bread to mankind. According
to Arnobius, this godfess was so called because she
directed to the way to the capital to T. Tattus.

PANDAIA, or PANDAIA, in Geography, a town on
the N. coast of the island of Cyprus, in a bay to which it
gives name; 28 miles W. of Neofia.

PANDALEON, in Medicine, a remedy appropriated to
diseases of the breast and lungs, invented by the Arabians
and later phvsicians; consisting of grateful ingredients an-
swering the name end with the lefitus, but different from it
in form, in which it agrees with trochee; it differs however
in this, that troches are made in a certain figure, whereas
the pandalex, after the fugar is duly boiled, and the in-
gredients sufficiently mixed, is poured into a box, and be-
comes indurated, and a sufficient quantity is to be taken out
either in a fpoon, or on the point of a knife.

The pandalex, therefore, is a solid medicatme like a cake,
receiving its form from the box into which it is poured; and
it consists of powders, pectoral confervs, and lozenges of
fugar.

PANDANAE, in Botany, a natural order of plants.
recently eftablifhed by Mr. R. Brown, Prodr. Nov. Holl.
v. 1. 340, and fo denominated from Pandanus; which fee.
The characters are thus given.

Flowers either dicocious or polygamous; deftitute of a
perianth.

Male, Spadix entirely covered with filaments, each bearing
a fingle antler of two cells.

Female, Spadix entirely covered with germs: mostly com-
bined in parcels, each germs of one cell, with a feffile
clofely attached frjma. Drupas fibrous, mostly combined
in parcels, each drupa with one seed; or elfe berries of feveral
cells, with many seeds in each cell.

Albumen leathy. Embryo central, ered. Plumula incon-
spicuous.

Trunk arboreous, but often bending down footts to take
root, and sometimes weak and decumbent. Leaves imbric-
ted in three ranks, elongated, linear-lanceolate; claping
the item, their edges molt frequently fpinous. Floral leaves
smaller, often coloured.

This is a tropical family of plants, placed by its author
near the Areides, chiefly on account of the fimilarity of
their infloence, the want of a perianth, the texture of the
albumen, and the situation of the embryo; in all which
characters it differs widely from the Palmes, fee that
article, resembing the latter only in having an arboreetm
trunk.

A second genus, first obferved by fir Joseph Banks, and
 lately molt beautifully delineated by Mr. Ferdinand Bauer,
during his flay at Norfolk ifland, differs from Pandanus
in having a foft pulpuy fruit, with several minute flrated
eys in each cell, furnifhed at one fide with a longitudinal
appendage.

PANDANG, in Geography, a town on the W. coast of
the island of Celebes. S. lat. 3° 33'. E. long. 120°.
PANDANG Cebues, a town on the W. coast of the island
of Sumatra. S. lat. 4° 36'. E. long. 102° 57'.
PANDANUS, in Botany, a name adopted by Linnæus
from Rumphius, who fabricated it from the Malay Pandang,
which signifies to behold, and which is fuppofed to allude
either to the beauty of the tree in queftion, or to its con-
spicuous appearance at a distance. Whatever the meaning
may be, the structure of the word is uncoath, and we can-
not but regard that Forfker's Abrodaéylus was not retained
or if the genus must have a barbarous appellation, fancioned
by antiquity. Kaido of Rheede would furely have been pre-
ferrable to the above. By the manuscript of the Supplem-
entum Plantarum, it appears that the younger Linnæus, and not
his father, is responsible for the name we presume to diap-

Vol. XXVI.

Female. Calyx none. Corolla none. Drupas aggregate. 1. P. odoratissimus. Linn. Suppl. 424. (Male. P. verus; Rumph. Amboin. v. 4. 139 t. 74; female, P. spurius; ibid. 142. t. 75.) Kaida; Rheed. Hort. Malab. v. 2. t. 6 (?).—Trunk throwing out runners. Drupas obvolute at the summit.—Native of the East Indies; cultivated there, as well as in many of the South Sea islands, and, according to Forkall, in Arabia, for the sake of its male flowers only, whose fragrance is said to be very delightful, and powerfully diffusive. The young plant is without any leaves, and its long narrow pointed leaves, whose margins are serrated with spines, and whose under side is whitish and mealy, much resemble a Bromelia, to which genus Linnaeus, in his Fl. Zealandica, referred it. The floral-leaves are white, as well as the male flowers, which latter compose long, branched, dense spikes, in which nothing is discernible but innumerable filaments and anthers. The fruits, on a separate tree, resemble a Pine-apple, but is hard, dry, not eatable, nor of any use whatever. The cultivation of the female plant therefore is neglected. In an adult flate the trunk is eight or nine feet high, much branched, sending down numerous long shoots from its lower part, which take root in the earth.

We are by no means competent to unravel all the varieties, or rather species, of this plant, described by Rumphius and Rheedee, but which succeeding botanical travellers have left unexplained. Mr. R. Brown only has given definitions of the following two species, without any synonyms, and therefore we presume they are not supposed to be included among the above.

3. P. spiculis. Br. n. 2. Trunk without runners. Drupas depressed and trifoliate at the summit; very obtuse at the base.—Gathered likewise by Mr. Brown, in the same part of the world.

We have a specimen of a small, apparently distinct species, gathered by Commodon in the Isle of Bourbon, and which he says grows also in Madagascar, and on the coast of Coromandel. In this the summit of each drupa is conical and acute, and we cannot judge how far the fruit is advanced towards maturity. The whole compound female spike is scarcely more than two inches long.

Pandanus, in Gardening, contains a plant of the herbaceous, perennial, exotic kind for the house, of which, the species is sweet-scented pandanus, or screw pine (P. odoratissimus).

Method of Culture.—This plant may be increased by sowing the seeds, brought from the places where it grows naturally, in pots of light earth, and plunging them in the bark-bed of the flower, where they must be constantly retained, having the management usually practiced for other tender exotic plants.

They have a fine ornamental effect among other flower plants, in their large spreading foliage.

PANDECTS, PANDECTE, in Jurisprudence, the Digest, or collection made by Justinian's order, of five hundred and thirty-four decisions, or judgments of the ancient lawyers. On so many questions occurring in the civil law; to which that emperor gave the force and authority of law by an edict prefixed to them. The jurisprudence of the Pandæctes is circumsketched within a period of one hundred years, from the perpetual edict to the death of Severus Alexander.

The word is Greek, πανδεκτής, compounded of πᾶς, all, and ἄριστος, caput, I take; q. d. a compilation, or a book containing all things. Though others, as Bartoli, will have it formed from παν, and ἄριστος; as if these books contained the whole doctrine of the law.

The Pandæcts consist of fifty books, and make the first part of the body of the Civil Law; which see.

They were originally denoted by two π, π; but the copyists taking these π for β, the custom arose of quoting them by β. When the monuments of ancient Rome were neglected or destroyed by the envy or ignorance of the Greeks, the Pandæcts themselves escaped with difficulty and danger from the common shipwreck, and criticism has pronounced that all the editions and manuscripts of the web are derived from one original. It was transcribed at Constantinople in the beginning of the seventh century, and was successively transported by the accidents of war and commerce, to Amalphi, Pyia, and Florence, and is now deposited as a sacred relic in the ancient palace of the republic. The original at Constantinople was revered by Politian as the authentic standard of Justinian himself; but this paradox is refuted by the abbreviations of the Florentine MS. It is composed of two quarto volumes, with large margins, on a thin parchment, and the Latin characters betray the hand of a Greek scribe. The discovery of the Pandæcts at Amalphi (A.D. 1137) is first noticed in 1501 by Ludovicus Bologinus, on the faith of a Pisan chronicle, without a name or a date. The whole story, though unknown to the 12th century, embellished by ignorant ages, and suspected by rigid criticism, is not, however, destitute of much internal probability. The Liber Pandætarum of Pisa, was undoubtedly confounded in the 14th century by the great Bartolus. Pisa was taken by the Florentines in the year 1406; and in 1411 the Pandæcts were transported to the capital. Gibbon's Hist. vol. viii. p. 44. 8vo.

Papias extends the denominition of Pandæcts to the Old and New Testament.

There are also pandæta medicae, pandæcti medici: these are a kind of dictionary of things relating to medicine, compiled by Mat. Sylvacarius, of Mantua, who lived about the year 1297. Leuncclusus has published pandæcts of Turkey; and Bishop Beveridge pandæcts of the canons, "Pan- 

dæcta Canoni."" PANDEMON, πάνωνος, in Antiquity, the same with the festival Chalcia and Athenea.

It was so called from the great concourse of people that used to meet at this solemnity.

PANDEMOS, in Mythology, a name given to Venus; which see.

PANDERLA, in Geography, a town of Hindoostan, in Madura; 30 miles N. N. E. of Colipetta.

PANDIA,
PANDIA, PANIDE, in Antiquity, an Athenian festival in honour of Jupiter. For the origin of this solemnity, see Potter, Archæol. Grec. lib. ii. cap. 20. tom. i. p. 423.

PANDICULATION, PANDICULATIO, in a general sense, is a violent and tenfive motion of the folds, which usually accompanies the act of yawning; and is otherwise called Griffthing.

PANDIPOUR, in Geography, a town of Hindooftan, in Oude; 22 miles S. of Fyzabad.

PANDOLY, a town of Hindooftan, in Baglana; 25 miles N.W. of Junam.

PANDONER, a town of Hindooftan, in Dowlabad; 20 miles E. of Poorundar.

PANDOO, a town of Hindooftan, in Vifnour; 20 miles N. of Sattarah.

PANDOOKAN, a small island in the Sooloo Archipelago. N. lat. 6° 15'. E. long. 120° 34'.

PANDORA, in Mythology, the name of the first woman, according to Hefiod; fo called from was, all, and ἰδώρ, gift: because the gods united to confer upon her every quality and endowment that could conduce, as the fable says, to the misery of mankind. Pandora, it is farther said, kept these gifts in a vessel, the cover of which she opened, and they were dispersed over the face of the earth.

According to the fable, Jupiter, incensed at the conduét of Prometheus (see his article), ordered Vulcan to form a woman endowed with all perfections, whence her name of Pandora originated. The gods loaded her with presents, and sent her to Prometheus with a box full of all kinds of misery. This prince, unsuspecting the trick, would have nothing to do with her; but Epimetheus, to whom fhe offered herself, was so captivated with her charms, that he took her to wife, and had by her Pyyrha, the wife of Deucalion. His curiosity, too, led him to look into the fatal box, which he no sooner had opened, than there issued out of it that deluge of miseries which have since overrun this earth. He shut it up again in haste, but all was gone but hope, which had not time to escape, and this, of consequence, is the only blessing that remains with wretched mortals.

PANDOSIA, in Ancient Geography, a town of Italy, in Bratium, upon the W. coast, near the sea, and the boundaries of Lucania. It was founded by the Grecians, who made it the capital of their territory. It was situated on a small mountain, at the foot of which ran a stream called "Acheron."—Also, a town of Lipis, in the interior of the country.

PANDROSON, PANIDROSON, in Antiquity, an Athenian festival in honour of Pandrofia, the third daughter of king Cecrops, who, not disobeying Minerva, was rewarded by the Greeks for her piety with a temple, built after her death, near that of the gods; as Paufanius relates the ftyory.

PANDSA TALA, in Geography, a group of several fmall lakes in Thibet. N. lat. 30° 42'. E. long. 79° 26'.

PANDU, in Mythology, the name of a perfonage of some importance in the heroic history of the Hindoos. He was the father of the five brothers or Pandavas, whose conflells with the fons of Karu form the fubject of that splendid poem, the MAHABARAT, under which article the names and parentage of the Pandus, or Pandavas, and fome other particulars of them, will be found. To these five heroes, it is ufual in India to attribute the conftuction of any great work whose origin is loft in its antiquity. Such as the excavations on Elephanta, at Elora, &c.

PANDURA, or PANDORON, a musical instrument, used among the ancients, much resembling the lute.

The word, according to fome, is formed from the Greek ἱδώρ, and ἰδώρ, i.e. all gifts, all sorts of gifts. Ifidore de-

rives the name from its inventor Pandorus; others from Pan, to whom they attribute this invention, as well as that of the flute.

It has the fame number of strings with the lute; but they are of brafs, and of confequence give a more agreeable

sound than thofe of the lute. Its frets are of copper, like
thofe of the cithara; its back is flat, like that of the guitar,

and the rims of its table, as well as its ribs, are cut in semi-
circles.

Du-Cange observes, that Varro, Ifidore, and others of the

ancients, mention it as having only three strings; whence it

is sometimes alfo spoken of under the denomination

τριχόχορον, trichordum.

The instrument called the Pandura or Pandore, of the lute

kind, was very much in favour in our own country during the

17th century; but now, not only its fcale, but even its

form is forgotten. Julius Pollax relates that the Affyrians

made ufe of an instrument with three strings, called the

Pandore, or Pandarum, invented by the Arabians, and by

them called the trichord. Pythagoras attributes this inven-
tion to the Troglodies, and pretends that this instrument was

made of the water lute.

PANDURIFORME, FOLIUM, in Botany, a leaf so

named from its resemb lance to the form of an ancient lyre,
or τριχόχορον, being rounded and dilated at each end with a con-

traction in the middle. The form of the modern violin

seems to have been borrowed from that instrument, though

it does not clearly appear for what reafon. The leaf so de-
nominated is scarcely to be found but in the species of Rumes,
called from this resemblance, which is very correct and

striking, Fiddle Dock. See Leaf.

PANDYSIA, PANIDYSIA, in Antiquity, public rejoicings

when the feaon, through its coldness and intemperance,

forced the sailors to fay at home.

PANE, in Geography, a town on the N. coast of Sumatra. N. lat. 2° 40'. E. long. 99° 35'.

PANERAS, a town of Syria, called also Cadarea-Philippus (see CASSARAE); 24 miles E. of Srir.

PANEGRYIC, PANEGYRYS, or Panegyritis, an oration

in praise of some extraordinary thing, perfon, or virtue.

The name is Greek, πανευτεριος, formed of πενε, all, and αγιος, I affemble; because anciently held in public and fo-
ung assemblies of the Greeks, either at their games, their

feasts, or their religious meetings.

The panegyric is ranked among the demonstrative kind of

orations. See Oration.

To make their panegyrics the more solemn, they used to
genial with the praises of the deity in whose honour the games,

&c. were celebrated; then they defended to the praise of the people or country where they were celebrated:

then to the princes or magiftrates who prefided at them; and

at length to the champions, especially the conquerors, who

had gained the prizes in them.

F. De Colonia lays down two methods, or feries, observed

in panegyrics. The artificial, where, without any regard to

the order of time, every thing is reduced to certain heads.

Thus Tully refers the whole praise of Pompey to his kif in

war, his virtue, authority, and felicity.

The other natural; in which the order and time of his

story are observed. This feries he divides into three periods:

the space before the perfons birth; that wherein he lived; and,

if he be dead, that which fol owed his death. This natural

feries requires much lefs art, genius, &c. than the other.

The topics or fources of panegyric are, chiefly, the fa-

mily and country of the hero, auguries at his birth, his vi-

tues,
PAN

PANGY, also the name of a church-book in use among the Greeks: so called, as consisting of panegyrics, or discourses in praise of Jesus Christ, and the saints; it is found in MS. in most churches, but is not the same in all, each church having its particular saints; and the compilers of this kind of books usually fitted their collections to the taste of their own devotion. They are divided according to the order of months, and frequently consist of twelve volumes, answering to the twelve months of the year.

PANGYRIS, among the Greeks, a fair, or festival day, on which the people used to meet together. It exactly corresponded to the Nundine of the Romans.

PANEL, or PANELLA, in Latin, is derived, by Spelman, from the genitive of panel, a panel, or a counter-panel of an indenture, &c.

PANEL, or Pannel, is more commonly used for a schedule, or roll, containing the names of such jurors as the sheriff returns to pass upon any trial.

PANELLUS, in Latin, is, in Antiquity, a public festival, celebrated by an assembly of people from all parts of Greece.

PANEMUS, in Chronology, the Bocorion name of the Athenian month Metagenion, which was the second of their year, and answered to the latter part of our July and beginning of August.

PANEMUS, among the Corinthians, answered to the Attic month Boedromium, or, according to Petavius, to our November. In the ancient Macedonian calendar, it was the ninth month of the year; but after the conquest of Arabia, they gave this name to the sixth month.

PANEMUS, in Ancient Geography, a town of Egypt, and capital of a nome, called by Ptolomy "Neut." "Neut." is, in Geography, a town of the island of Ceilion: 24 miles N.N.E. of Columbo.

PANEROS, the name of a beautiful flone dedicated to Venus; it was called also by some pantoflas, and was probably one of the beautiful azata.

PANES, in the Ancient Theology. See Fauns.

PANEUTE, in Geography, a town of the island of Ceilon: 18 miles S. of Columbo.

PANGA, a town on the E. coast of Celebes. S. lat. 1° 54'. E. long. 121° 16'.

PANGA, a town of France, in the department of the Meuse, and chief of a canton, in the district of Metz. The place contains 232, and the canton 12,647 inhabitants, on a territory of 247,117 square kilometres, in 48 communes.

PANGAUS, in Ancient Geography, a mountain of Thrace, on the confines of Macedonia, the foot of which was watered by the Neftus.

PANGASIAN, in Geography, a town on the W. coast of the island of Lucon, and capital of a province or kingdom. N. lat. 15° 40'.

PANGASIAN, a small island in the Sooloo Archipelago. N. lat. 6° 8'. E. long. 120° 58'.

PANGASIAN, a small island in the East Indian sea, about 45 miles long, and 9 broad, situated between the islands of Celebes and Bontain. S. lat. 5° 5'. E. long. 122° 50'.

PANGIMODGOO, a small island in the South Pacific ocean, at the entrance of the harbour of Tongataboo.

PANGKER, a town of the duchy of Holstein; 3 miles N.N.W. of Lutkenborg.

PANGLO, or PINGLAR, one of the smaller Philippine islands; 60 miles N. of Mindanao.

PANGO, a town of Africa, capital of a province in the kingdom of Congo, on the Barbeila; 40 miles N. of Congo Bata.

PANGOLIN, in Buffon, in Zoology, the short-tailed manis, or Manis pentadactyla of Linneus; which see.

PANGONIA, in Natural History, the name of a genus of crytials.

The word is derived from the Greek παγονίαν, numerus, and παγονίαν, an angle, or bending, and expresses a crytial composed of many angles.

The bodies of this genus are single-pointed, or imperfect crytials, composed of dodecangular, or twelve-angled columns, terminated by twelve-angled pyramids, and the whole body, therefore, made up of twenty-four planes. Of this genus there are only three known species.

PANGOOTARAN, in Geography, an island in the Sooloo Archipelago, about 10 miles long and 4 broad. N. lat. 6° 15'. E. long. 120° 28'.

PANGUICI, a small island in the East Indian sea, near the coast of Queda. N. lat. 5° 50'. E. long. 100° 5'.

PANGY, a town on the E. coast of the island of Celebes, in Guunong Tally bay. S. lat. 1° 6'. E. long. 120° 15'.

PANJIAB, a province of Hindostan, watered by the five branches of the Indus, frequently called Labor, which see; though Panjab, being applied to a natural division of country, is applicable also to part of Moultan, which see.

The five rivers from which Panjab derives its name, are Behut or Jhykam (the Hydaspes of Alexander), the Chunnah or Junaub (Alexander's Aetynus), the Ravee (Alexander's Hydronet), the Beyah (Alexander's Phaphos), and the Setlege, Sutuluz, or Sutluj. The sources of all these rivers are fitted in the great chain of snowy mountains, that extend from Sirmoor to the north of Cashmere, and which are in fact the true Imus, which see. The eastern boundary of the Panjab is properly this ridge of mountains; but in a more limited sense, and particularly according to the ideas of the present times, the Panjab means the country situated without, or to the west of the hilly tract; and which is of considerable width, being possibly from 50 to 60 miles from the edge of the plains to the summits of the highest mountains. From the Setlege to the Jhykam, and to the hills that bound the Panjab, on the N. and E., it appears to be chiefly a tract of flat and very fertile land; and, indeed, the courses of the four eastern rivers very plainly indicate a regularity of surface and fertility of soil. But between the Jhykam or Behut and the Indus, there is a large proportion of hilly country, which may be supposed to influence the course of the Jhykam, and give it a different form from the others; the river conforming to the border of the hilly tract. The Panjab country being the frontier province towards Tartary, and the northern parts of Persia, from whence have sprung the conquerors of Hindostan in every age, Alexander excepted, their route to the interior parts of the country must have led through it. Nadir Shah's route was the ordinary one, by Attock and Lahore. For the other routes of Timur and Alexander, we refer to Rennell's
memoir. From thence we learn that the lower part of the
Panjab towards Moultan is flat and marshy, and inundated,
ilike Bengal, by the periodical rains, which fall between
the months of May and October. The revenues of this pro-
vince, under Aurungzebe, amounted annually to 206½
lacks of rupees.

PANJANY, an island in the East Indian sea, near
the coast of Siam, about 14 miles long, and 6 bread. N. lat.
S. 9° 42'. E. long. 98° 14'. — Alfo, a small island in the East
Indian sea, near the eait coast of the island of Borneo. N.
lat. 5° 15'. E. long. 117° 59'. — Alfo, an island near the
west coast of Siam, about 40 miles in circumference. N. lat.
8°. E. long. 98° 42'. — Alfo, a small island in the Pacific
ocean, near the coast north of New Guinea. S. lat. 3° 18'.
E. long. 155° 25'.

PANJAPILLY, a town of Hindooftan, in Calicut; oppo-
site to which is a passage through the Gouts, about 16 miles wide,
and 14 or 15 miles long, occupied by forest trees, and defended
by the fort of Ammanbay on the E., and Paicaucherry on
the W., and opening finally into the low country on the
Malabar coast, 42 miles S.S.E. from Calicut. N. lat. 10° 41'
45'. W. long. 75° 55'. The river of Panjany takes its course
from the Combeettore country, through the above-mentioned
opening; and is said to be navigable in the rainy season, for
small boats, to the foot of the Gouts. This circumstauce,
together with the inundated state of the country at that sea-
son, may serve to shew, that the country W. of the Gouts
has no great declivity, in a course of nearly 60 miles. This
river, as well as that of Darapuram, has its source from an
elevated plain, about 60 miles in extent, stretching itself across
the easterly mouth of the gap or valley already mentioned.
This plain rises suddenly from the level of the surrounding
country, like a vall terace; and the torrent bounds it on the
west.

PANJAPILL, a town of Hindooftan, in Myfore; 13
miles W.S.W. of Caveriapatnam.

PANJASSAS, a town of Ouvistan, on the Akanfas.
N. lat. 36° 25'. W. long. 94° 21'.

PANIC, or PANIC. Fear, a term used for a needled or
ill-grounded fright.

Polyphemus fetches the origin of the phraie from Pan, one
of the captains of Bacchus, who, with a few men, put a
numerous enemy to rout, by a noise which his soldiers raised
in a rocky valley, favoured with a great number of echoes.
This stratagem making their number appear much greater
than it really was, the enemy quitted a very commodious
encampment, and fled. Hence all ill-grounded fears have
been called paniies, or panic fears; and it was this that gave
occasion to the nymf Echo's being beloved by the
god Pan.

Others derive the origin of the expression hence; that, in
the wars of the Titans againft the gods, Pan was the first
who struck terror into the hearts of the giants. Theon
on Aratus says, he did it by the means of a sea-shell, which
served him for a trumpet, of which he was the inventor. See
Pan.

PANIC, in Botany. See PANICUM.

PANICASTRELLA, a fort of Italianized name,
formed by Micheli from Panicum, for what is now the Car-
cinus of Linnaeus and other botanists, which Micheli per-
cieved to be akin to that genus. There is certainly a relem-
blance in character, as well as in habit, to some of the num-
rious species which have been arranged under it. See PAN-
ICUM, and PENNISIUM.

PANICLE, in Gardening, is the part which shows
the particular mode of flowering in some plants, and which is of
two farts or descriptions, the one loose or diffuse, the other
clofe or bound up. See PANICULA.

PANICOLO, in Geography, a town of Naples, in La-
vora; 22 miles N.W. of Naples.

PANICULA, in Botany, is used by Pliny for the flowery
tuft which crowns the summit of the reed, as well as for the
male catkins of the fir tribe, whose denfe fcaly structure he
clearly mentions. Linnæus uses the word technically,
according to the frft meaning, for a particular kind of in-
florfeeence, called in English a panicule. In this the flowers
are defpofed in a fort of look or divided bunch or clufier, with-
out any order, as in the Common Reed, Arundo Phragmites,
and the Oat. If the flalks are diftinft, as in the latter
example, it constitutes a diffuse or lax panicule; if otherwise,
a clofe or denfe one. Panicula fuperba, implies a panicule
whose branches spread every way; fucuda is used when
they are all turned to one sife, ufually in a drooping manner.
The panicules of graffes are, for the moft part, femi-cortitlata,
or half-whelored, their principal branches being defpofed in a
clofe ring, half round the main flalk. Very denfe panicules
are found in fome of this family, as Agrostis folumfera, the
Fiorin graff, now fo much talked of; Panicum italicum, the
Millet; and efpecially the Phleum paniculatum, (see Engl.
Bot.t. 1877.) whose inflorefcence cannot be diftinguifhed
from a spike, till it is bent to one fide, by which means it feparates
into lobes. Some plants have a forked panicule, fo termed
becaufe a solitary flower is placed between each of its rami-
cations, as in various fpecies of Silene, Spergula, &c. A
remarkably divericated, or rigidly spreading, panicule is seen
in the Wall Lettuce, Preunftes muralis. The fugar-cane,
when it blooms, which moft Wett Indians will tell us never
happens, but which the writer of this has feen with admira-
tion, bears one of the largest and moft elegant panicules in
nature. The dilhfonnation between a panicule and a spike is in
calls very great, but particularly important in the natural
famly of graffes, where it feparates most of the genera into
two grand feotions. — A very compact panicule is, in some
inflances, termed a Thyrbus; see that article.

PANICUM, an old Latin name for the moft celebrated
fpecies of the genus, P. italicum, and which Faber and Am-
brofinus, after Pliny, declare to allude to its panicule of seed.
Certainly the inflorefcence of that graff, or corn, though
now termed a spike, answers pecufarily well to the claflical
idea of a panicule. (See PANICULA.) Other etymologists
deduce the word Panicum from panis, bread; for which,
however, it seems to have served less than many other farts
Ind. Occ. 139—178. Jull. 29. Lamarck Illttr. t. 43.
Michaux Boreal-Amer. v. i. 46. Géartn. t. 1. (Digi-
taria; Jul. 29.)—Clasf and order, Triandria Digynia.
Nat. Ord. Gramina.

Gen. Ch. reformed. Cal. Glume of two flowers, and
two, nearly ovate, ribbed valves; the outermost minute and
somewhat inferior; one flower perfect, the other either
neuter or male. Cor. of the perfect floret a glume of two
nearly ovate cartilaginous valves; the outermost convex,
embracing with its margins the inner one, which is smaller
and flatter; that of the neuter or male, often very small, a
glume of two valves; the outermost, in the bofom of the
smaller valve of the calyx, flattish and ribbed; the inner-
moot membranous, flat, with influfed margins. Necfary, in
the perfect as well as male florets, minute, gibbous, of two
leaves; in the neuter wanting. Stam. in the perfect and male
florets
fiorets only; filaments three, capillary; anthers oblong. 
P.f. in the perfect fiorets only, germin roundish; styles 
two, capillary; stigmas feathery. Peric. none, except the 
corolla closely combined with the seed. Seed solitary, 
clothed with the corolla, roundish, flattened at one side.

Eff. Ch. Calyx of two very unequal valves, contain-
ing two flowers, the outer one male or neuter. Corolla 
of two unequal valves, generally carniform, and involuting 
the seed.

Obf. Schreber remarks, that botanists, having overlooked 
the inner glume of the imperfect floret, considered its 
outer glume to belong to the calyx; hence the latter was thought 
to consist of three valves, of which the third was the 
leaf. We plead guilty to this charge, but have never been 
satisfied with the opinion we adopted. The inner valve of 
the imperfect floret, discovered by Dr. Stokes and Mr. 
Sowerby in *P. Crusc-galli*, is figured in Engl. Bot. t. 876; 
and though we agreed to refer it, as a fourth valve, to 
the calyx, this was, in reality, because we could displace no 
otherwise of the troublesome intruder. Mr. Brown has 
adopted the ideas of Mieg, Adanson, Forkell, and Schreber, 
on this subject, and we have profited by their corrections 
of the Linnean characters. It is necessary to observe, 
however, that the neutral floret very generally consists of but 
one valve, so that the above error might easily be committed.
—Our learned friend, in his *Prodr. Nov. Holl. v. 1. 131—
155*, has established three new genera as distinct from 
*Panica*, which we are to adopt. These are, 1st, *Cha-
maraphis*, distinguished only by having three styles instead of 
two, and confining but one species; 2d, *Orthopogon*, 
which has nearly equal calyx-valves, as well as smooth awns, 
and confines of *P. compositum* and *birtelm*., with a few new 
species; 3d, *Pennisetum of Richoid*, comprising *P. viride*, 
*verticillatum*, *glaucum*, *helvolum*, *italicum*, with a new species 
called by Mr. Brown *compreffum*, all which have a partial 
involucrum, composed of separate bristles, including one or 
three flowers. The genus of *Panica* is indeed overburdened 
with these, but above all things we hesitate to adopt 
*Pennisetum*, as its character is taken rather from a part of 
the inflorescence than of the flowers, and as it embraces the 
original *Panica* of the ancients, from whence, and its allies, 
all botanists have taken their ideas, in general, of the genus 
in question. We perceive, moreover, in *P. Crusc corvi*, *Crusc 
galli*, &c. something of an approach to a similar brily 
involucrum.

*Panica* consists of thirty-four species only, in Linn. 
Syst. Veg. ed. 14. Wildenow has eighty, having profited 
much by the labours of Retzius and Swartz, the former 
of whom has described many new species from the East, 
and the latter a considerable number from the West Indies. 
species, all among those of Wildenow. Five of them are 
natives of England. One new species only is defined in the 

The whole are distributed by Linnæus, and consequentely 
by Wildenow, into two fecciones, *flowers spiket*, and *flowers 
panicled*. The author last named has forty species in each 
feccion. Mr. Brown, however, who has defined thirty-
two new species of *Panica*, even as he limits the genus, 
from New Holland alone; besides five other new ones re-
ferred to his genera of which we have spoken above; he has 
divided *Panica*, upon new principles, into seven fecciones.

Of these, for want of knowing his new species, we can form 
no conclusive judgment; and we shall therefore content our-
theselves with the old arrangement, selecting a few examples, 
that may indicate certain subdivisions of the fecciones, or

**Seet. 1. Flowers spiket.**

Here are first nine species present themselves, which belong 
to Mr. Brown’s *Pennisetum*, and of which two are British.

(Gramen geniculatum; Ger. em. 15. f. 1.—Spike whorled; 
spikelets in fours. Involutum of two bristles, rough, with 
revered teeth to each flower. —Native of the warmer parts 
of Europe, in cultivated ground, especially where the situation 
is rather moist, but rare in England, chiefly occurring in 
Battersea fields and that neighbourhood. We have found 
it on the west side of Norwich, in gravelly fallow fields, 
flowering in July or August. The root is annual, fibrous.

Leerf. 13. t. 2. f. 2. (G. panici etfica epica simplici; 
Ger. em. 17.)—Spike cylindrical; spikelets crowded. 
Involutum of several bristles, rough, with erect teeth, and 
embracing two flowers. —Native of the warmer parts 
of Europe, rather less rare in England than the former, and 
usually found in more dry sandy ground. It is annual, 
flowering at the same time with the *verticillatum*, and, as 
far as we know, equally unprofitable to the agriculturist.
Small birds however are fond of the seeds of both species.

The spikelets in the prefent are irregularly crowded, not 
whorled. Flowers generally in pairs, with about fix bristles, 
which are rough with teeth that point forwards or upwards, 
a clear and decisive character. The same difference is ob-
servable in the direction of the minute brily teeth which 
form the roughness of the upper part of the *stem* in each 
species. These marks were, nevertheless, unknown to Lin-
neus, nor were his ideas clear concerning the two graffes in 
question.

(Pennisetum glaucum; Brown Prodr. Nov. Holl. v. 1. 195.) 
—Spike cylindrical; spikelets crowded. Involutum of 
many bristles, rough, with erect teeth, and unufually embracing 
two flowers. Cafe of the seed tranfverfely wrinkled. 
—Native of the south of Europe, as well as of America, the 
East Indies, and New Holland, being one of the most 
general of graffes, though not found wild in England. Its 
habit is like the two former, but the *flora* are taller and more 
erect; the herbage rather glaucous; the numerous bristles 
of the involucrum with a tawny or golden tinge, not purple; 
and the outer glume of the perfect *floret* curiously marked, 
in its upper part, with transverse wavy wrinkles. The upper 
part of the *stem* is strongly furrowed, but not rough to the 
touch.

Pl. 83. Wild. n. 8. Bauh. Theatr. 519. (Panica; 
t. 75. f. 2.)—Spike compound, drooping; interrupted at 
the
the bafe; spikelets clustered. involucre of many, very long, rough bristles. Common ralk woolly. —Native of both Indies. Cultivated in Italy and other parts of Europe. This is believed to be the true P. anum of the ancients, and its dropping panicule is described by Pinn, who speaks of it as not so much used as the Millet. P. miliaceum, in making bread, but weighing more than another grain, as well as increasing more in bulk when cooked. It is annual, with the habit of the foregoing, but much larger, the root producing several stems, four or five feet high, with broad harry leaves, and a follicle, very heavy, dense spike, or rather con- densed panicule, bent downwards, bcfet with innumerable very long bristles, and producing abundance of small oval smooth seeds, not higher than thine of P. glaucum.

P. germanicum, Wildl. n. 7, seems to us but a flawed variety, or perhaps the true wild flate, of the italicum.

After this tribe follows a train of species, with rather dif- tantly branched compound spikes, which Mr. Brown con- ders as properly belonging to P. anum. We cannot but concur with him in the union of three supposed species, under the following.

P. Cras galli. Loofe Panick-grafs. Linn. Sp. Pl. 83. Curt. Lond. facc. 4. t. 8. Engl. Bot. t. 876. Knapp. t. 11. Leef. t. 2. f. 3. (P. Cras cori; Linn. Sp. Pl. 84. P. Flammum; Retz. Obs. facc. 5. f. 17.)—Spike twice compound; its branches angular, rough and brilly, alternate or in pairs. Calyx angular, bifid, awned. —Native of Europe, North America, the East Indies, and New Holland, in cultivated or waste land, that is either moist or inundated. With us it is rare, flowering in July. This is a coarse annual grass, two feet or more in height. Leaves broad, harry, with long tufted Iheaths, and either no pila, or only a few hairs in the place of one. The common spike is four or five inches long, with a five-angled, rough and furrowed, common ralk, and from six to ten alternate branches, distant below, crowded into the top of the spike above. The branches are also slightly compound. Flowers crowded, all turned to one side, bifid or prickly, accompanied by scattered tufts of rather distant, fine, smooth, pel- lucid bristles, about as long as the flowers. The outer valve of the greater flower is bifid, and awned or pointed, like the valves of the calyx, of the nature of which it participates throughout the genus; the rest are smooth, that which in- vites the feed even and polished.

P. brizoides. Briza-like Panick-grafs. Linn. Mant. 184. Willd. n. 17. Att. n. 10. (Gramen panicum; multiplica spica maderapatanum; Pluk. Phyt. t. 191. f. 1.)—Spike compound; its branches alternate, eréct, oblong. Flowers crowded, turned to one side, without awns. Stem simple, smooth. —Native of the East Indies. A smooth pale grass, whose stem is simple, or rarely branched; the leaves long, loosely spreading, smooth and naked. Spike terminal, straight, composed of several alternate, oblong, obtuse branches, of crowded whitish-green flowers, all turned to one side. The outer glumes are ovate, tumid, with hairy ribs, the inner one which invetes the feed very smooth and shining.

P. cruciiforme. Caterpillar Panick-grafs. Sm. Fl. Græc. Sibth. v. 1. 44. t. 59.—Spike compound; its branches alternate, erect, close-pressed, linear, harry. Flowers crowded, turned to one side, without awns. Stem branched from the bottom. —Discovered by Dr. Sibthor in felds about the temple of Juno, in the island of Samos. Differs from the last in having a flender harry stem, branched from the bottom, with numerous bent joints; leaves short and spreading; branches of the spike more flender, linear, and harry; glumes less tumid, and the outermost valve of the calyx much more minute.

This tribe, including several more species, is followed by such as constitute the genus Orthopho, of Mr. Brown, (see that article) who indicates six species, P. Burmanni, Wildl. n. 20; birtellum and compositum, Linn. with three new ones named by him Orthopho annus, flaciius and imbricattus, the four last being found in New Holland. One example is sufficient.

P. birtellum. Rough-haired Panick-grafs, called in the West Indies Scotch-grafs. Linn. Sp. Pl. 84. Willd. n. 8. Att. n. 1. Hort. Gram. Afric. v. 3. t. 52.—Spike compound; its branches alternate, close-pressed. Flowers smooth, in pairs, turned to one side. Calyx with long, smooth, channelled awns. Leaves ovate, pointed. —Native of the West Indies, as well as of the south of Europe. Root biennial. Stem branched, deciduous, taking root at the joints, two or three feet long. Leaves spreading, ovate pointed, varying in breadth, ribbed, rough, beprickled with soft hairs; their sheaths extremely harry, particularly at the top and bottom. Spike terminal, conspicuous for the prominent purplish awns of the calyx, which are linear, obtuse, quite smooth, flattened or channelled above, three quarters of an inch long. The corolla has similar, but much shorter, awns. The common flark is winged and harry.

A tribe with fingered spikes, the Digitaria of Haller and Jussieu, succeeds. The differences in the number of the calyx-valves in different species, or their variability in the same, have caused a diversity of sentiments among botanists. The genus Cynodon. Brown Prodr. Nov. Holl. v. 1. 187, is formed out of this tribe. Their habit is especially their long, linear, clustered, but divaricated, spikes, give them an aspect very distinct from all the species we have hitherto mentioned.

P. sauinatum. Cocks-foot Panick-grafs. Linn. Sp. Pl. 84. Willd. n. 28. Att. n. 12. Curt. Lond. facc. 4. t. 7. Engl. Bot. t. 849. Knapp. t. 12. Schreb. Gram. v. 1. 119. t. 16. Hort. Gram. Afric. v. 2. t. 14. t. 17. Mart. Ruft. t. 78. (Iscbemon vulgare; Ger. em. 27.)—Spikes fingered; knotty on the inside at the base. Flowers in pairs, awnles. Sheaths of the leaves dotted. —Native of various parts of Europe, as well as of America; rare in England. It is annual, flowering in July, and prefers a rich soil. The stem is numerous, bent and decumbent at their base, spreading widely upwards, twelve or eighteen inches long, smooth, rigid, leafy. Leaves linear-lanceolate, broad, nearly smooth, generally shorter than their sheaths, which are iriculated, and besprickled with small cartaginous dots or tubercles, frequently producing fine hairs. Spikes about four or five, spreading, two inches or more in length, nearly umbellate, or at least approximately, linear, the common flake of each zigzag, winged, tufted at the bottom. Flowers dull violet, in alternate pairs leaning one way, on equal short partial flalks. Outer value of the calyx very minute, and often abortive. This is a hard coarse grass, of no agricultural use.

the streets of many towns, and flowers at various feasons.
The throng perennial roots, with smooth fibres, are formed of hard polished runners, shooting horizontally to a great extent in the dais, and clothed with the permanent sheathing baxes of the rigid, pungent, glaucous, hairy leaves. Flowering stems a span high, more or less, leafy. Spikes from three to five, shorter than in the last; their common flaks zigzag and angular, but not winged. Flowers solitary, alternate, close-prepled, at one side only. Calyx of two nearly equal lanceolate valves, almost as long as the corolla, which is compressed, polished and bearded. Mr. Brown notices the rudiment of a second flower, in the form of a naked bristle, at the base of the inner valve of the corolla. This was perceived by Mr. Lambert, Tr. of Linn. Soc. vol. 2. 309, to be no other than the *Agroctis linearis* of Koenig, Retzius, and Willdenow, Sp. Pl. v. 1. 375, the *Durvus* of the Hindoos, which the late Sir William Jones, in the 4th volume of his **Notes** Proceedings, has celebrated for the extraordinary beauty of its flowers, and its sweetness and nutritious quality as pulture for cattle. We cannot but remark what extraordinary celebrity is attached, every now and then, to one or gases or other, and how their fame pills away “like the morning cloud,” while the best graziers scarcely know perhaps, better than their fat cattle, any thing of the nature of the common never-failing herbage, to which they are both so much indebted. It is but justice however to the memory of the great Sir William Jones, to mention, that the very Panicum in question appears to be, as Dr. Sibthorp judged, the real *Agroctis* of Diococides, which that ancient botanist describes as having “jointed creeping scotus, throwing out sweet roots from their joints; and pointed, hard, broad leaves, like a small kind of reed, which are the food of cattle.” This description is very characteristic; and the gases is called by the modern Greeks, on whose coats it abounds, either *agroctis* or *agroctis*.

Section 2. Flowers paniced.

*P. repens*. Paniced Creeping Panick-gras. Linn. Sp. Pl. 87. Willd. n. 45. Ait. n. 18. Sm. Pl. Grac. Sibth. v. 1. 45. t. 61. Cavan. Ic. v. 2. 6. t. 110.—Panice with stiff upright branches. Leaves divaricated. Root creeping.—Native of the banks of rivers in the Levant; gathered by Dr. Sibthorp near Patania in Crete, flowering in June; by Mr. Schlanbum about 30 miles south of Naples; and by Brouflonet and Desfontaines at Algiers. It is found in Hort. Kew. to be cultivated in the East Indies. The root is perennial, creeping to a very great extent, and by no means annual. It throws out copious fibres from its joints, and many ascending flowers, twelve or eighteen inches high, simple, smooth, clothed with numerous, spreading, rather stiff leaves, whose margins and long sheaths are fringed with hair, but their under side is very smooth to the touch. Panice terminal, rather cleft, of numerous, upright, zigzag, rough-edged, repeatedly subdivided, slender branches; bearing a number of solitary, upright, smooth flowers. The glumes are ovate, timid, ribbed. Anthers yellow. Stigma purple, beautifully feathered, cylindrical. We are not informed whether the grain or the herbage be the object of culture in this plant.

*P. melacanthum*. Millet Panick-gras, or true Millet feed. Linn. Sp. Pl. 86. Willd. n. 49. Ait. n. 19. Holt Gram. Aulfr. v. 2. 16. t. 20. (Milium; Matth. Valgr. v. 1. 367. M. femine luteo vel albo; Bauh. Theatr. 502.)—Panice loose and flaccid. Sheaths of the leaves hairy. Glumes pointed, ribbed.—Native of the East Indies. Cultivated from time immemorial in the south of Europe for the sake of its seeds, which are among the more delicate, though not the most nutritious, kinds of grain. Small birds are very fond of these seeds, and the crop therefore requires strict vigilance while ripening. It is low in the spring. The root is annual. Stem four or five feet high. Leaves pale, broadish; their sheaths ribbed, dotted, clothed with long, spreading or deflexed, hairs. Panice terminal, lax and spreading, of innumerable, slender, compound, angular, rough-edged branches. Flowers larger than in the last, tufted, smooth, ribbed, awnless, a little drooping. Covering of the seed exquisitely polished.

*P. latifolium*. Broad-leaved American Panick-gras. Linn. Sp. Pl. 86. Willd. n. 62. Ait. n. 21. (Milium indicum late brevique folio; Moris. sect. 8. t. 5. f. 4.)—Lateral branches of the panice simply racemose. Leaves ovato-lanceolate, finely fringed at the base. Outer glumes obtuse, strongly furrowed, hairy.—Native of North America, from whence Kalm sent it to Linneus. This is perennial and hardy in our climate, flowering late in autumn. The very broad leaves, almost heart-shaped at their base, where they are finely and densely fringed, mark this species; their sheaths are tight and smooth. Panice wavy, loosely spreading, its branches angular, but scarcely rough; the lateral ones, for the most part, simply racemose, with distant flowers, on slender stalks of various lengths. The glumes are turgid, ovate, obtuse; the outer ones strongly ribbed and furrowed, clothed with short hairs; the inner highly polished, and perfectly even.

*P. oryzoides*. Rice-like Panick-gras. Swartz Ind. Occ. 162. Willd. n. 65. (Milium indicum arundineo caule; Sloane Jam. v. 1. 104.)—Panice nearly simple, erect. Leaves ovato-lanceolate; their sheaths finely fringed at the summit. Glumes acute, all smooth and even; the outer ones obliquely ribbed.—Native of mountainous shady places, in the south of Jamaica, according to Dr. Swartz, whose obfusc reference to Sloane leads us to suppose this is the plant the latter intended under the above name, which he says is “planted every where in Jamaica, yielding very great increase. It is thought to nourish little, and to be altringent as rice.” Linneus, who had a specimen from Browne’s herbarium, confounded it, at theugglegion of Solander, with *latifolium*, from which the present species widely differs, in having flowers three times as large, with perfectly smooth, even, pointed glumes.

*P. clandestinum*. Sheath-flowed Panick-gras. Linn. Sp. Pl. 86, excluding the synonym. Willd. n. 66.—Panicles simple, concealed in the hairy sheaths of the heart-shaped leaves.—Native of Pennsylvania, from whence Kalm communicated it to Linneus. The latter greatly errs in quoting a synonym of Sloane, which evidently belongs to his own *Cenchrus granularia*. We can indeed find no figure of the present species, nor have we seen it but in the Linnean herbarium. The stem is very much branched, round, purplish, smooth and polished. Leaves about three inches long and one broad, alternate, spreading, heart-shaped and minutely crenate at the base, flat, tapering gradually into a sharp point; smooth on both sides, finely inflated, paler beneath; sheaths nearly as long as the leaves, rather inflated, ribbed, befirkilled with cartilaginous umbilicated tubercles, as in *P. fangeinale*, many of which bear horizontally prominent bristles. Within the sheaths of several of the uppermost leaves are completely concealed solitary, simple panicles, or rather clusters, of but few flowers, whose outer glumes are ribbed, ovate, obutate and awnless, scarcely hairy or downy. The glumes do indeed greatly resemble those of *P. latifolium*, to which Linneus confiders this plant nearly allied.
PAN

allied. The sheaths of the leaves however, as well as the inflorescence are very unlike that species.

P. arboreifem. Tree Panick-grafs. Linn. Sp. Pl. 87. Wild. n. 67. Ait. v. 22.—Stem arboreifem, very much branched, smooth. Leaves heart-shaped-oblong, crenate, somewhat fringed, with smooth sheaths. Panicles capillary, level-topped, many-flowered. Glumes elliptical; the outer ones ribbed.—Native of the East Indies. Said to have been sent to Kew garden in 1776, by M. Thouin; flowering in the fove in March and April. We know neither figure nor description of this, except that Linnaeus says it vies in height with the most lofty trees, though the stem is fearfully thicker than a goose-quill. That part, in his specimens, is very much branched and divaricated, round, smooth, highly polished, slender, but hard and rigid, with many knotty joints, and hard fleshy buds, from whence the copious lateral flowers are produced. The leaves are lanceolate, point ed, three or four inches long, fearly one broad; ovate at the base, but much contracted, almost into a short footstalk, before they join the sheaths, as well as very hairy there at the back, though otherwise naked, or merely roughish to the touch. The sheaths are tight, hard, smooth and polished, crowned with a tuft of bristles. In the younger or flowering branches, the leaves are larger, with leaf elongation of the contracted part at their base. Panicles terminal, on long stalks, with repeatedly divided, long, capillary, smooth leaf, level-topped branches, bearing numerous, small, upright, solitary flowers, whose glumes are elliptical and naked; the outer ones ribbed; that which enucleates the seed highly polished. We are not certain of our two Linnaean specimens belonging to the same species, as only one of them has flowers, and the leaves differ as above mentioned, as well as in being more harsh, with larger stipulaceous bristles, in the barren specimen. The younger branches moreover are fribrate, and not so finely polished. Both however are marked, and considered as the same, by Linnaeus.

P. dracarifum. Straddling Panick-grafs. Linn. Sp. Pl. 86. Wild. a. 80. Ait. n. 25. Jacq. Hort. Schoenbr. v. 1. 10. t. 25.—Stem arboreifem, very much branched, divaricated, smooth. Leaves linear-lanceolate, entire, with smooth sheaths. Panicles rigid, compound, divaricated. Glumes obovate, tumid; the outer ones ribbed.—Native of Jamaica; flowering in our fove in summer. The stem agrees in habit with the last, and is perennial; climbing apparently to a great height if it meets with support; the branches copious, spreading, leafy, round, smooth and polished. Leaves about three inches long, and half an inch wide, lanceolate, acute, frayed, smooth, except at the edges, dark green; their sheaths much shorter than the leaves, ribbed, naked, a little swelling; each crowned with a short, membranous, fringed stipula. Panicles terminal, erect, twice compound, with alternate, divaricated, rigid, angular, zigzag branches, roughish at the edges. Flowers five times as big as the leaf and much fewer, being the size of a grain of wheat, bent to one side, obovate, polished; their outer glumes ribbed. Sometimes the glumes all assume a black or dark purple colour.

We have received from M. Delile, a celebrated French botanist and traveller, many specimens of this genus which appear to be nondecript. Of these some are the produce of North America, others of Egypt, and several of them very curious. They may probably have been published at Paris, since the specimens reached us, and therefore we shall not venture on their particular determination here. Michaux has also many species unknown to us. All these, added to the New Holland ones of Mr. Brown above-men-

PAN

tioned, will perhaps extend the species of Panicum to about 130 in all.

Panicum, in Agriculture, a genus of grasses of which there are several species, but none of which can be cultivated, except for bird-feed.

Paniefoile, in Geography, a lake of Africa, in Hoval, which communicates with the Senegal. N. lat. 16° 40'.

Panigarola. Jomene, in Biography, an Italian prelate, and one of the most celebrated preachers in the sixteenth century, was born at Milan, of a noble family, in 1548. At a very early age he discovered great genius and abilities, and befriends an uncommon facility in acquiring knowledge, he possessed surprising powers of memory, which enabled him to retain whatever he learned. Being sent to the university at Pavia he distinguished himself in a few months by the rapidity of his progress in learning; though it was, at the same time, a matter of great regret, that he rendered himself notorious for his irregularities and turbulent spirit. No disturbance ever occurred in the university, but Panigarola would be found deeply concerned in it; and fearfully a night passed, in which, at the head of pupils from Milan, he was not engaged in quarrels and battles with the fludents from Placentia, Pavia, or some other place. At length he excelled became so great, that the senate of Milan ordered his father to withdraw him from Pavia. He was now sent to Bologna, where, for some time, he rendered himself equally notorious for his ill conduct, and for the licentious example which he gave to his contemporaries. Suddenly an entire change took place in his mind, and he expressed a strong inclination for embracing the monastic life. He accordingly took the habit of St. Francis at Florence in 1567, when he was only nineteen years of age. His whole delight now confined in the most regular and punctual observance of the duties of the cloiffer, and in affiduous study. In the year 1570, the person appointed to preach the Lent sermons was suddenly taken ill, and Panigarola was appointed his substitute. The display of his eloquence on this occasion obtained for him the highest reputation. From this moment, wherever he appeared in the pulpit admiring crowds of all ranks attended. Pope Pius V. heard him, and was astonished; but thinking that so young a man stood in need of a more perfect acquaintance with the sacred scriptures, and the fathers, than it was possible he could have acquired so soon, recommended it to him to devote some time to close study. He accordingly went to France for this purpose, and attended the professors at the university of Paris. Upon his return to Italy his celebrity was so great, that there was no church sufficiently large to accommodate the crowds who were attracted by his preaching, and when he was upon a journey, he could scarcely pass through any city or town, without being, in a manner, compelled to preach. In 1586 he was consecrated at Rome titular bishop of Chryopolis, and appointed coadjutor to the bishop of Ferrara; but in less than three months he received an order to quit Ferrara, and the duchy, a disgrace which he attributed to the intrigues of a minister jealous of his renown, who perfused the duke that he betrayed the secrets of the 34th to cardinal Ferdinand de Medici. Under these circumstances he was received with great kindness by pope Sixtus V. who appointed him to preach at St. Peter's in the year 1587. In 1589 he was sent by the fame pontiff into France to encourage the party of the league against Henry IV. He was present at the siege of Paris, and employed all his eloquence in animating the citizens to submit cheerfully to the priva-
tions and miseries which they suffered during the memorable blockade of that place. He died in 1594, at the early age of forty-six. As an author, his most celebrated productions consist of several volumes of sermons, in Latin and Italian; besides these he published many other theological pieces, theses, orations, and poems; also "Paraphrasi sopra Demetrio Falero, &c." consisting of a learned commentary upon the treatise of Demetrius Phalerus on eloquence. Moreni.

**PANIGENA**, in *Ancient Geography*, a town on this side of the Ganges, and on a gulf of this river, between Palagua and Conagara. Ptolemy.

**PANIONIA**, in *Antiquity*, a festival in honour of Neptune, celebrated by a concourse of people from all the cities of Ionia.

One thing is remarkable in this festival, that, if the bull offered in sacrifice happened to be small, it was accounted an omen of divine favour; because that found was thought to be acceptable to Neptune.

**PANIS**, in *Geography*, an island in the Atlantic, at the mouth of the river Bandi, near the coasts of Africa. N. lat. 5.

**PANIS**, a tribe of Indians, 120 miles from the mouth of the river Platta, or Shallow river, a western branch of the Mfouri. This tribe numbers 700 warriors, in four neighbouring villages. They hunt but little, and have few firearms. They are often at war with the Spaniards in the vicinity of St. Fé, near which is the place of their abode.

**PANIS & cerevisiae officia**, in *Law*. See *ASSISA.*

**PANIS & cerevisiae emendatio*. See *EMENDATIO.*

**PANIS Daemon**, in *Natural History*, a name given by authors to a sort of coarse stone, common in Sweden, and some other places, and usually found in roundish, but somewhat flattened masses, resembling a loaf in form.

**PANION, in Ancient Geography**, a promontory of Europe, on the coast of the Thracian Bolphorus.

**PANIIUS, or PANEUS**, a mountain of Syria, which formed part of mount Libanus, and at the foot of which was situated the town of Paneus.

**PANK, in Botany**, a name, as we presume, of American origin, published by Feuillee, and adopted by Molina, though the latter has transferred it from the original plant of Feuillee, which is a Gunnera, to a totally distinct genus, termed by that author *Liuapanke*. Willdenow has retained this name, and thus it has found a place in a popular work, which we greatly lament, the word being, according to every found principle, inadmissible.—Molina. Chil. (the German edition according to Wild.) 119. Wild. Sp. Pl. v. 2. 486.—Clas and order, *Enneandria Monogynia*. Nat. Ord. near *Bacconia*? Eff. Ch. Calyx four-cleft. Corolla bell-shaped, four-cleft. Capsule of two valves, with one seed.

1. *P. tinctoria.*—"Leaves thick, five-lobed."—Native of moist situations on the mountains of Chili.—Root perennial. Leaves five-lobed, serrated, five-ribbed, papilary, downy, pulpy, permanent. Footstalks round, prickly, half a foot long, Calyx terminal. Flowers very numerous, on partial flanks. *Wild after Molina.*

Juffieu says, Gen. 452, that the stem is five feet high, with three or four leaves at the top.

2. *P. fuchsiolata*. Wild. n. 2. (Liuapanke ampliflimo Sonchi folio; Feuill. Peruv. v. 2. 742. t. 31.)—Leaves wider, clasping the stem.—Found by Feuillee on the mountains of Chili. The root is said to be perennial, tapering. Stem herbaceous, three feet high, simple, round, leafy. Leaves a foot long, lyrate, obtuse, slightly wavy, and finely toothed or crenate; their lobes rounded, clove, lying over each other, finely downy, reticulated with veins; their base oblong, clasping the stem; purplish brown and convex; the under side paler. Calyx terminal, erect, binate, many-flowered. Flowers crimson, the lowermost a little remote, and of six petals or rather segments, the rest of but four; each segment is oval, about half an inch long, with a violet spot in the middle. Stamens, according to Feuillee, only equal in number to the petals, or rather segments of the flower. There is a disagreement between his account and the clafs, as well as character, indicated by Molina. This species is used in dyeing black. It also serves to stop the bleeding of the piles, when immediate, as well as to relieve the pain of that complaint; the qualities of the herb being, as it seems, astringent.

For the Panke of Feuillee, a very different genus, see *Gunnera*, fp. 2.

**PANKINA**, in *Geography*, a town of Russia, in the government of Kovhan; 63 miles N.W. of Biilk.

**PANKIRA**, a town of Hindooftan, in Baglana; 12 miles N. of Sailer Mouler.

**PANKLIER**, a town of Curdiiftan, in the government of Van, on the lake Van; 25 miles E. of Aklat.

**PANKOVA**, a town of Russia, in the government of Irkutof, on the Ilum; 56 miles W. of Orlenga.

**PANLANG**, a town of the Birman empire, on the Rangoon branch of the Irrawaddy, from which the Rangoon is frequently called the Panlang-mioup. This was once a place of considerable magnitude, and is now of some importance; 16 miles N.W. of Rangoon.

**PANNAGE, PANAGE, or Panwage**, are used in our law-books, &c. for the most of woods; as of beech, acorns, &c.

As also for the running and feeding of swine, or other cattle, in forests.

And for the money taken by the agitators for the same.

**PANNAGIUM LIBERUM, or Free Panage**, was a liberty of free running of swine in certain forests or woods, granted by privilege to certain private persons, and several religious houses.

Linwood defines pannagium, by "paflus pecorum in nemoribus, & in silvis, utpote de glandibus, & alis fructibus arborum sylvestrium, quorum fructus alter non solent colliigiri." It is also mentioned, 20 Car II. "Quifque villanus habens decem porcos dat unum porcum de pannagio," by which it appears that one hog in ten was given for the pannage.

**PANAH**, in *Geography*, a town of Hindooftan, in the country of Allahabad; 30 miles E.S.E. of Chatter-pour. N. lat. 24° 48'. E. long. 80° 28'.

**PANNEL, in Law.** See *Panel.*

**PANNEL**, in the Scotch Laws, denotes the prisoner at the bar or person who takes his trial before the court of judiciary for some crime.

**PANNEL, or Panel, in Joinery, &c.** a tympan, or square piece of wainfot, sometimes carved, framed, or grooved in a large piece, between two mounters or upright pieces, and two traverses or cross pieces.

Hence also panels or panes of glass, are compartments or pieces of glass of various forms; square, hexagonal, &c.

**PANNEL, in Masonry**, denotes one of the faces of a hewn stone.

**PANNEL, in Rural Economy**, a low fluffed saddle.

**Pannels of a Saddle**, the two cushions or holsters, filled with cow, deer, or horse hair, and placed under the saddle on each side, so as to touch the horse's body, and prevent the bows from galling or hurting the back.
PANNELLA, Old, in Geography, a town of Hindooften, in Vifapour; 12 miles E. of Merritch. 
PANNELA, New, a town of Hindooften, in Vifapour; 22 miles W. of Merritch. N. lat. 7° 3'. E. long. 74° 58'. 
PANNERBARY, a town of Bengal; 8 miles N.E. of Garogot. 
PANNI, a town of Naples, in Capitanata; 9 miles S. of Treja. 
PANNICULUS ADPOSES, in Anatomy, the ftratum of fat placed under the skin. See Cellular Substances, and Mammals, Cellular. 
PANNICULUS CORNOSUS, in Comparative Anatomy, a thin subcutaneous ftratum of mucular fibres in animals, to which there is no corresponding structure in the human fubjeft. See Mammals. 
PANNIER, in Architecture. See Corbel. 
PANNIPUT, in Geography, a town of Hindooften, in the country of Delhi; 70 miles N.W. of Delhi. N. lat. 29° 25'. E. long. 77° 16'. 
PANNONA, in Ancient Geography, a town situated in the interior of the ille of Crete, between Gortyna and Gnous. Its ftratum. 
PANNONIA, a large province of Europe, which was known to the Romans in the time of Augustus. It was bounded on the N. by the Danube, on the W. by Noricum, on the E. by the Danube as far as its junction with the Savus, near Medea, and on the S. it extended as far as IIlyricum. The principal rivers of Pannonia were the Danube, the Dravus, and the Savus, which discharged themselves into the Danube, the Dravus E. of Murfa, and the Savus a little to the S. of Sirmium. It was during the war of Augustus with the Japydes and the Dalmatians that the Roman army penetrated into the country of the Pannonians. It became a Roman province under Tiberius. In the time of Antonine, Pannonia was divided into superior and inferior, the feparation being made by the river Arrabo (Raab); one of these divisions was called Pannonia prima, and the other Pannonia secunda. The more ancient inhabitants of Pannonia were the Scroffans and Taurici, who were in their origin Gauls. Ptolemy assigns to this country a great number of places; but none of them appear to be very confiderable. This country was occupied by a very barbarous people, when Philip, king of Macedon, conquered it; but they soon afterwards revolted, and Alexander reconquered them. The Gauls, under the conduct of Brennus and Belgus, forcibly transferred it to Ptolemy, brother of the king of Macedon. Caesar gained a settlement in part of it, and paused to it across the mounten, hence called "Alpes Jullie." Tiberius, as we have said, added Pannonia to the Roman empire, and it continued tributary to the Romans till the fall of their empire. It afterwards became subject to the Goths, and then to the Huns, from whom Hungary is said to have derived its name. 
PANNONICA BOLUS, in the Materia Medica, a name by which Kentom, and some others, have called the earth most ufually known by the name of bolus Tocasenitas. 
PANNONIUS, Janus, in Biography, a modern Latin poet, born in 1454, was a native of Hungary. He travelled into Italy for instruction in polite literature, in which he excelled, and for the spread of which he felt so much ardour, that he used every effort to promote the study of it in his own country. He was raised to the fee of Funckirchen, in Lower Hungary, where he died in 1472. He was distinguished for his proficiency in the Greek and Latin languages, in the latter of which he composed a variety of poems, which were printed separately, and also in the "Delitii Poetarum Hungarorum." An edition of them was published at Utrecht so lately as 1784, in two volumes 8vo. 
PANNUNAH, in Geography, a town of Hindooften, in the circar of Karih; 20 miles S.E. of Maltoy. 
PANNUS, derived from Æmurus, a web, a Latin word signifying cloth, web, &c. 
Pannus, in Medicine, a disease of the eye, popularly called the web. 

The pannus is an excrescence arising on the adnata or conjunctiva, lefs hard and membranous than the unguis; and representing a web, or plexus of little veins swelled with blood.

Its cause is, an obftruction of the blood in the minute veffels of that tonic.

Its cure is much the fame with that of the opthalmia.

A chief difference is, that, in the unguis, the membranous excrescence only covers part of the eye, after the manner of a nail; whereas in the pannus it covers the whole.

PANNYA, in Geography, a town of Bengal; 45 miles W. of Nagore. 
PANNYALLUM-CRUTCH, a town of Hindooften, in Tinelly; 15 miles S.E. of Collipetta. 
PANOCHIA, a name by which some chirurgical authors call baboes in the groin. 
PANOMI, in Geography, a town of European Turkey, in Macedonia; 16 miles S. of Saloniki.

PANOMPHÆUS, in Mythology, a designation given to Jupiter, because he was looked upon as the original author of all arts of divination, having the books of fate, and out of them revealing either more or lefs, as he pleased, to inferior demons.

PANOPOLIS, in Ancient Geography, a town of Egypt, in the Thebaid, and the capital of the Panopolite nome. 

PANOPSYIA, in Antiquity. See PANPSIA.

PANORAMA is a picture exhibiting a foccection of objects, such as may be by the rays of light intercepted by the surface of a hollow sphere or cylinder, from all points of external objects to the eye in the centre of the sphere, or at a fixed point in the axis of the cylinder. 
Panoramic Projection is the method of forming a panorama from the geometrical consideration of the properties of vision.

In the following principles of the panorama, the surface on which objects are supposed to be represented is that of a cylinder; though a sphere may be considered till more perfect, as its surface is every where equal distants from the eye, but a cylindric surface is more convenient for the purpose of delineation; and if the objects are not very distant from the interfeftion of a plane paffing through the eye perpendicular to the axis, the distortion will not be perceptible. We premife the following definitions.

1. The cylindric surface on which objects are to be represented, is called also the panoramic surface; and the picture formed is called a panoramic view, or panoramic picture.

2. The point of sight is the place where the organ of vision is placed, in order to receive the impression of the images of the objects on the panoramic picture.

3. An original object is any object in nature, or an object which may be supposed to exist in a given position and distance at a point, line, or solid.

4. An original plane is the plane on which original objects are supposed to be placed.

5. The point where an indefinite original line cuts the picture, is called the interfeftion of that original line.

6. The line on the picture where an original plane meets
or intersects it, is called the intersection of that original plane.

7. A line drawn through the point of sight parallel to an original line, is called the parallel of that original line.

8. A plane passing through the point of sight parallel to any original plane, is called the parallel of that original plane.

9. A surface of rays is that which proceeds from an original line, or from any line of the original object, by rays from all points of that line terminating in the eye. If the line in the original object be straight, the surface of rays is called a plane of rays, optic plane, or visual plane.

10. When the rays proceed from one or more surfaces of an original plane, the whole is called a pyramid of rays, or optic pyramid; and if the base is circular, it is called a cone of rays, visual cone, or optic cone.

In every kind of projection from a given point, the projection of a straight line upon any surface is the intersection of a plane of rays with the surface from all points of the straight line to the given point. Therefore the panoramic projection of a straight line is the intersection of the cylindrical surface and a plane. If a right cylinder is cut by a plane perpendicular to its axis, the section is a circle; if cut parallel to the axis, the section is a rectangle; and if cut obliquely to the axis, the section is an ellipse. If the surface of the cylinder be extended upon a plane with the sections of the cylindrical surface and a plane cut in each of the positions here stated, the section made by the plane perpendicular to the axis will be a straight line; and the section made by cutting it parallel to the axis will also be a straight line; but the section made by cutting it obliquely will be a curve of similar properties as that known to mathematicians by the name of the sinus curve, or figure of the lines; therefore the projection of every straight line in a plane passing through the eye perpendicular to the axis of the cylinder, will also be a straight line on the extended surface; and every straight line in a plane passing through the axis will also be a straight line on the extended surface, perpendicular to that formed by the plane passing through the eye perpendicular to the axis.

The panoramic projection of any straight line not in a plane passing through the eye perpendicular to the axis, nor in a plane passing through the axis, is in the curve of an ellipse; for in this case the optic rays which cut the cylinder will neither be in a plane parallel to the axis, nor in a plane perpendicular to it.

The panoramic representation of any straight line in a plane perpendicular to the axis, but not passing through the eye, is in the curve of an ellipse, and the optic plane will be at right angles to another plane passing through the axis at right angles to the original line.

In the panoramic representation of any series of parallel lines, the optic planes have a common intersection in a straight line passing through the eye, and the common intersection will be parallel to each of the original straight lines; therefore the indefinite representations will pass through the extremities of the common intersection.

In the panoramic representation of any series of parallel lines in a plane perpendicular to the axis, but not passing through the eye, the common intersection of the optic planes is parallel to the plane on which the original lines are situated.

In the indefinite representations of any number of straight lines parallel to the axis, the visual planes will have a common intersection in the axis, and will divide the circumference of the cylinder into portions which have the same ratio to each other as the inclination of the visual planes.

If an original straight line parallel to the axis be divided into portions, the representations of the portions will have the same ratio to each other as the originals.

If in any original plane there be a series of straight lines parallel to each other, and also another series of straight lines parallel to each other, and at any given angle with the former series, the common interferences of the visual planes will make the same angle with each other, which any line of the one series makes with any one of the other series, and the common interferences will be in a plane parallel to the original plane; and, therefore, if the original plane be perpendicular to the axis, the common interferences of the visual planes will also be in a plane perpendicular to the axis. Hence the common interferences of visual planes from any two systems of straight lines, parallel to any two straight lines at a given angle with each other in a plane perpendicular to the axis, are also in a plane perpendicular to the axis, and make the same angle with each other which the two lines in the original plane make with each other.

11. The two points where the parallel of an original line inclined to the axis of the cylinder meet the panoramic surface, are called the vanishing points of that original line.

12. The interference of an original plane is called the vanishing line of that plane.

13. A straight line drawn from any point in the axis of the cylinder at right angles to the same to meet the panoramic surface, is called the direction of the picture.

14. The centre of a plane parallel to the axis, is the point where a straight line from the eye perpendicular to the plane meets it.

15. The panoramic centre of a plane parallel to the axis, is the point where a straight line drawn from the eye perpendicular to the plane cuts the picture.

16. The station point, is the point where the axis intersects the original plane.

17. The centre of an original line, is the point where a straight line, drawn from the station point perpendicular to the original line, cuts the original line.

18. The panoramic centre of an original line, is the point where a straight line, drawn from the station point perpendicular to the original line, cuts the picture.

19. The distance of an original plane parallel to the axis from the picture, is the straight line drawn from the panoramic centre to the centre of the original plane.

20. The distance of an original line from the picture, is the straight line drawn from the panoramic centre to the centre of the original line.

21. The distance of an original plane, is the straight line drawn from the eye to the centre of the original plane.

22. The distance of an original line, is the straight line drawn from the station point to the centre of the line. An original line parallel to the axis of the panorama has no vanishing points.

An original plane parallel to the axis of the panorama has two vanishing lines.

The vanishing line of a plane perpendicular to the axis of the panorama, is a circle on the panoramic picture; but if the panoramic surface be extended upon a plane, it becomes a straight line.

The vanishing lines of all planes inclined to the axis are ellipses, and when extended upon a plane become circular curves, which are also termed panoramic curves, as being the only curve which the cylindrical picture produces when developed.

Problem I.

To describe the panoramic curve to given dimensions. Let A B
To describe the representation of a line in a plane perpendicular to the axis of the cylinder, giving the line on the original plane.

In $N'$, draw $G d$ perpendicular to $G H$; make $G d$ equal to the defcend or defection of the curve, and describe the quadrantal finical curve $d x$, and $d w$ will be the representation of a line perpendicular to the plane, in which the originals of $G v H$, $G x H$, $G y H$, and $G z H$, are situated.

**PROB. III.**

Given the indefinite representation $G x H$, $N'$, of a strafight line, to determine the finite portion, whose feet is A B, N 1.

Draw P A and P B, N 1, cutting the interfection at a and b; make $w a$, $N'$, equal to the extension of $K a$, N 1; and $w b$, $N'$, equal to the extension of $K b$, N 1; draw $a a'$ and $b b'$, $N'$, perpendicular to $G H$, cutting the curve $G v H$ at $a'$ and $b'$, and $a z b'$ will be the finite portion required; $a z y b', a z x b'$, and $a z x b''$, will be the same portions of the indefinite representations $G x H$, $G y H$, and $G v H$.

The following examples shew the application of the principles in the reprefentation of solid objects.

**Example 1.**—Let C D E F, fig. 2, N 1, be the plan of a house, in connection with the picture at C. Through the flation point P draw $G H$ parallel to $D C$, cutting the interfection of the panoramic picture in the points $G$ and $H$; also through P draw $K I$ parallel to $E D$, or $F C$, cutting the picture in $I$ and $K$; then $G$ and $H$ are the vanishing points of all lines parallel to $E F$ or $D C$, and I and $K$ the vanishing points of all lines parallel to $C F$ or $E D$; draw FP and DP cutting the picture at $f$ and $d$. Let $W V$ be the ridge of the building, bifecting $E W$ at $V$, and $E C$ at $V$; produce $W V$ to $Y$, cutting $I$ at $U$; make $U Y$ equal to the height of the house, $N'$; and make the angle $U Y Z$ equal to half the vertical angle of the roof, and let $Y Z$ cut $I K$ at $Z$; draw $X Q$ parallel to $Y Z$, cutting $K I$ or $K I$ produced at $Q$; draw $Z X$ parallel to $V W$; produce $E D$ to $x$, and $F C$ to meet $x Z$ at $T$; join $Q x$ and $Q T$, which are the interfections of the optic planes, formed by the inclined side of the roof, and the vertical planes standing upon $D E$ and $C F$; draw $I N$ parallel to $P O$ and $O N$ parallel to $I P$. To find the interfection of the optic planes, draw $P M$ perpendicular to $x Q$, cutting $x Q$ at $u$, and the panoramic interfection at $M$; from P, with the distance $P u$, describe the arc $u J$, cutting $P I$ at $J$; join $O J$; produce $N I$ and $O J$ to meet each other in S. In like manner, draw $P T$ perpendicular to $T Q$, cutting $T Q$ at $w$, and the panoramic interfection at $t$; from $P$ as a centre, with the radius $P v$, describe the arc $v w$, cutting $I P$ at $w$; join $O w$; produce $N I$ and $O w$ to meet each other in $R$; then $N O S$ is the interfection of the optic plane whose interfection is $Q x$, and $N O R$ is the interfection of the optic plane whose interfection is $Q T$.

Upon any convenient line I H, fig. 2, N 6, extend the panoramic interfection; according to the correpsonding places of $N'$, are shewn by similar letters; that is, I t, G d', d' C', C' f', f' K, and $K H$, N 6, would cover $K t, r G$, $G d'$, $d' C'$, $C' f'$, $f' K$, and $K H$, N 1. In N 6, draw $W K$, $G a$, d' d', C' c', f' f, k p perpendicular to I H.

In $N'$, produce $K P$ to $a$; make $P a$ equal to the radius of the cylinder; through a draw $i e$ parallel to $O P$; on $P a$ make $P J$ equal to $P J$, N 1, and $P y$, $N'$, equal to $P q$, $N'$; draw $j g$ and $q b$, $N'$, perpendicular to $P a$;
PANORAMA.

make $q$ $h$ and $j$ $f$ each equal to the height of the walls, $N^3_1$ and $4$; join $O g$ and $O h$; produce $O g$ to $i$, and $O h$ to $i$, meeting $o i$; produce $O j$ and $O q$ to meet $G a$ at $a$ and $k$.

In $N^3_6$, make $t R$ equal to $N R$, $N^4_1$; $G o$ equal to $G o$, $N^5_1$; $G l$ equal to $G l$; $K k$ equal to $G k$; $K i$ equal to $G i$; describe the panoramic curves $I K$, $I K$; $G H$, $G H$; then the curves $I k$ and $G k$ will cut each other at $c$, and the curves $I / K$, $G i / H$, will cut each other at $C$, so that the points $C$, $c$, will be in the same perpendicular; $C c$ will thus represent the angular line of the building; let the perpendicular $d d$ cut the curve $G i / H$ at $D$, and the curve $G k / H$ at $d$; and the intercepted portion $D d$ is the angular line at one end; in like manner, let the perpendicular $f f$ cut the curve $I l / k$ at $F$, and the curve $I o / k$ at $f$; and the intercepted portion $f f$ is the representation of the angular line at the other end; therefore $c C D d$ represents the front, and $c C F f$ the end, exclusive of the triangular part adjoining the roof, which will be formed in the following manner; make $x r$ and $x u$ equal to $G K$ each; describe the same panoramic curve $R C x$; and if the other semi-panoramic curve $x w w$ is described, and if $k K$ be produced to $w$, $w$ will be the vanishing point for the gable top; and if $k K$ be made equal to $K w$, $w$ will be the vanishing point of the other inclined plane of the roof; and thus the representation of lines and planes will have vanishing points and vanishing lines, as in the methods of describing the perspective representation of objects upon a plane surface; and if the points $d$, $D$, $c$, $C$, $F$, are found, and the lines $e d$, $C D$, and $e f$, $C F$, are made straight instead of being curved and produced, they will find their own vanishing points in the line $I H$; but more remote from each other than the points $G$ and $K$. What is here observed, is exemplified in $N^7_1$, as will appear sufficiently clear by a little reflection.

The example here shewn is very distorted, on account of the smallness of the panoramic cylinder, and the size of the object, which was obliged to be very large, in order to give a clear elucidation of the principles.

Example 2. fig. 3, shews the panoramic representation of a row of houses, upon the surface of a cylinder of greater radius than that of fig. 2, $N^1_2$, where the pictorial objects appear much more agreeable to the eye than that of fig. 2; the lines which form the roofs are in this example represented straight, though in reality they are curves, as a great deal of trouble is saved, and as the error occasioned by their introduction is so trifling as not worth regarding.

It now remains to shew the truth of the operations used in the construction of fig. 2; let it now be proved, that $x Q$ and $T Q$ are the interfections of the optic planes, formed by the inclined lines of the gables. From the definition given, an optic plane is that passing along an original line, and through the eye; therefore, if a straight line be drawn through the eye parallel to the original line, the line thus passing through the eye, and the original line, will be in the same plane, that is, both in the optic plane; and if two planes be drawn along two parallel lines, their interfections with a third plane will be parallel; now the parallels $F T$ and $K I$ are the interfections of two parallel planes; and $F T$ that of the vertical plane in which the inclined original line is situated, and $K I$ that in which the eye is situated, or in which the line parallel to the inclined line is situated; the point $T$ is the interfection of the inclined line of the roof, and the point $Q$ the interfection of the line drawn through the eye parallel to the inclined line of the roof; therefore the optic plane will pass through the points $T$ and $Q$, and consequently $T Q$ is the interfection of the optic plane, and the original plane. In the same manner it may be shewn that $x Q$ is the interfection of the optic plane, formed by the other inclined line of the farther gable in the same plane with the former line.

Next let it be shewn that the angles $N O S$ and $N O R$, $N^4_1$, are the inclinations of the optic planes, whose interfections are $x Q$ and $T Q$. The inclination of any two planes is measured by a third plane, perpendicular to their common interfection; now $T Q$ is the interfection of the optic plane, and $P v$ is perpendicular to $T Q$; and because $P v$ is equal to $P v$, and $P v$ perpendicular to $P w$, and equal to the height of the eye; conceive the plane of the triangle $P v O$ to be raised perpendicular to the original plane, so that the base $P v w$ may coincide with $P v w$; then $O$ will represent the eye in its true place, and the point $w$ will be upon $v$; and since the interfection $T Q$ would be perpendicular to the plane of the triangle, every line drawn in the plane of the triangle from $v$, would be perpendicular to the interfection $T Q$, and consequently, the line drawn in this plane from $v$ to $O$, would also be perpendicular to the interfection; therefore the angle $P v O$ is the inclination of the plane, and, consequentlty, the alternate angle $N O R$. In the same manner it may be shewn, that $N O S$ is the inclination of the plane whose interfection is $x Q$.

Now to shew that $N R$ is the deflexion of the curve made by the optic plane, it only requires to be considered that the transverse axis of the ellipsis made by the optic plane, is in the plane which measures the inclination of the optic plane to the original plane; for this purpose, $P O N R$ may be considered as a semi-section of the cylinder along the axis, and $N R$ a section upon the surface; therefore $O R$ will represent half the greater axis, and $N R$ the deflexion of the curve, or its descent below the vanishing line of the horizon. Fig. 2. $N^3_5$, is also to be considered as a section of the cylinder, of which $O P$ represents the axis, $G o$ and $O K$ the sides; and because the appearance of all points in the same plane perpendicular to the axis, at equal distances from the station point, will be at the same height on the surface from the original plane, or from the plane passing through the eye parallel to the original plane, their heights will be found by setting their distances upon $P a$, then erecting lines perpendicular to $P a$, from each point of the section; then setting the heights of the points upon these lines, and drawing lines from $O$ through the top of each perpendicular till they cut $G o$; then the distance from $G$ to each point of section, gives the distance of each point from the plane passing through the eye upon the panoramic surface.

Now let the cylinder be conceived to be enveloped by $N^5_6$, so that $I H$ may fall upon the circumference of a circle in a plane perpendicular to the axis, then every line will fall in its true position, and the representative object will produce the same pyramid of rays as the original object, the eye being supposed to be fixed at its true distance above the line $I H$; and, consequentlty, nothing more will be required to excite the existence of the object, than to give the representative surfaces their proper colours, light, and shades, according to the distance of the original.

Hitherto straight lines have been represented by portions of the sinical curve when extended, or by portions of an ellipsis, when the figure on which the objects are represented is brought in contact with the surface of the cylinder, as they ought properly to be; but if the radius of the cylinder is of sufficient extension, and the objects to be represented of proper magnitude, any attempt to represent straight lines by curves from the hands of an artist would be absurd, except when the object to be represented is very near to the panoro-
PANORAMA.

ratic surface, in which ease a curvature in the line may be feasible, also at a moderate distance: the curve can only be observed in a series of objects in a straight line; it will therefore be sufficient to represent the straight lines of each individual object by straight lines also, but to preserve the curve, or rather the polygonal figure inscribed in the circle curve in the series, as the inflations or angles will hardly be visible.

A straight line will therefore be represented by finding the representation of its extremities, and joining the representative points; but if it is of great extent, it may be found by finding a number of points, and joining every two adjoining points in succession by a straight line, and the whole will assume the form of a curve, which will be the representative of the straight line.

Plate II. shews a series of figures, such as may be supposed to constitute the whole of the practice of representing panoramic objects. S is the flat point; the objects are referred to in alphabetical order from A, B, C, &c. to H; each extreme point of the linear parts of the object has the same letter attached, with a numerical index, which indicates, in tracing round the circumference in progressive order, the points where the optic lines cut the panoramic surface are numbered with the same figure from the same object, each number having an index corresponding to that of the point of the object to be represented. The numbers are placed in successive order, agreeing with the order of the alphabet.

N° 1. The intersection of the panorama and the original plan, with the figures of the objects to be represented.

N° 2, 3, 4. Vertical sections of the panorama passing along its axis, in order to ascertain the heights of the several places of each object; E the point of sight or place of the eye, S the flat point, P Q a section of the cylinder, showing the heights of the objects.

The objects to be represented are, A, a point, the optic ray from which cutting the intersection at 1; B a straight line, the optic rays from which cutting the intersection at 2° 2'; C a line standing upon C, the optic ray from which cutting the intersection at 3°; D an inclined line, whose feet are represented by D', D''; E an angle, the optic rays from which cutting the intersection at 5°, 5°; F a triangle, the optic rays from which cutting the intersection at G', G''; H a rectangle, the optic rays from which cutting the intersection at J', J''; and, lastly, G a circle, the optic rays from which cutting the intersection at K, K'.

The distances of the objects are placed upon the panoramic sections N° 2, 3, 4, from S, upon the lines S, P, or upon P produced; then drawing lines from the points to E, give the heights upon P Q.

The perpendicular standing upon C, N° 1, is thus found: In N° 3, draw C C from C, perpendicular to S P, equal to the height of the perpendicular upon C, N° 1, and draw the straight lines C E, C E, N° 3. cutting P Q at 3°; then 3° is the panoramic length of C C. The upper extremity of the inclined line D will be found by ascertaining the panoramic height of the perpendicular, from the elevated end to the original plane.

N° 5 shows the panoramic representation of the several objects; V L is the vanishing line of the horizon; the intersections of the optic rays are extended upon V L from N° 1, the references upon the intersection N° 2, and upon V L N° 5, being the same. The heights of the several points are taken from the sections N° 3, 2, and 4, from Q downwards towards P, and placed from the corresponding points in V L, N° 5: also downwards upon the perpendiculars, gives the several points of the objects; thus a is the representation of the point A; N° 1; b, b, of B, B, &c. In the circle, the points for half the curve are found, the other half being repeated in the same order from the middle line, each line serving for two points, so that the three lines give eight points; the extreme lines are tangents which are equivalent to two points.

The points around the circumference of the intersection N° 2, are extended upon V W and X Y, according to the principle of Renaldinus, by letting three-fourths of the radius, without the circle, upon the opposite side of the tangents V W and X Y; and transferring the divisions of V W and X Y upon V L, N° 5, gives the points corresponding to the intersection.

The panoramic surface being enveloped by N° 5, the representations of the objects will be placed in their true positions, and will form the same picture at the point of sight, if correctly, painted as the objects themselves.

A practical method of forming all straight lines on the panoramic surface in its place, without development, is to ascertain the position of the objects, also the heights of the centres of the line to be represented; then fixing the eye in its position, and holding a straight edge parallel to the line to be drawn in a plane with the point of sight and the point representing the centre of the line, mark several points in the plane, on the panoramic surface; these points being joined, will give the representation of the line required.

In preparing for panoramic projections, whatever objects are intended to be represented, a proper point of view should be chosen from this situation; a sketch of all the surrounding objects should be made according to the development of the panorama; for though the painting itself may be performed upon the cylindrical surface, it is more eligible to sketch upon a plane. The next thing to be done is to take a survey of the objects, observing their positions to each other; then with a plane table fixed on the point of view quite level, take the faccecive angles of the surrounding objects by means of a movable limb which may carry two pieces, one at each extremity, perpendicular to the surface of the plane table; one piece being fixed in the supposed axis of the panorama, containing a light hole for the point of view, so that the movable part will consist of three bars, the bottom one serving as a straight edge for drawing the angles of position; the heights of the objects may be marked upon the other limb parallel to that fixed in the axis; and let it be observed, that the point of view in the axis, the edge of the limb which gives the heights of the objects, and the edge of the bottom bar by which the angles are drawn, must be in a plane passing along the axis: mark the vertical lines on the sketch, and the lines on the plane table, which show their position, with corresponding characters, otherwise it would be difficult to distinguish what the numerous lines apply to. The moveable edge of the index, which describes the circumference of the cylinder, should be of ivory, as the various heights may be marked with pencil, and rubbed out at pleasure, as these heights may be transferred to a piece of paper marking them with the same characters as that of the sketch, and with the addition of top of chimney, shaft, ridge of roof, top of wall, as the heights may be the terminations of such parts of the said objects, or instead of writing any mark, in drawing by representing a flight form of the parts of the object.

Instead of the ivory edge of the bar, which describes the panoramic surface, a flat, or very narrow aperture, formed by a double bar, may be used.

The tendency of every line, horizontal or inclined, may be found by a fifth bar, movable round a centre, which centre must be also moveable upon the edge of the limb which gives
gives the panoramic heights of the objects; the plane in which this fourth bar moves must be a tangent to the panoramic surface, at the line which is intersected by the plane passing along the axis, along the straight edge of the bottom bar, and along the edge where the heights of the objects are marked; then if the edge of this fourth moveable bar be brought in a plane with the eye and the original line, the angle which it forms with the edge of the vertical limb is the inclination of the line on the picture.

PANORMA, or PANORAMA, in Geography, a harbour on the N. coast of the island of Mycon. N. lat. 37° 29'. E. long. 25° 23'.

PANORMO, a town of Aflatic Turkey, in Natalia, on the S. coast of the sea of Marmora; 16 miles S.E. of Artaki.—Alfo, a town of European Turkey, in Albania, situated on a gulf of the Adriatic, opposite to the island of Corfu; 45 miles S.E. of Valona. N. lat. 40°. E. long. 20° 1'.

PANORMUS, in Ancient Geography, (Palermo,) a town of Sicily, situated towards the N.W., founded, as it has been said, by the Phoenicians. It held a distinguished rank among the towns of Sicily. In the year of Rome 499 it was taken by the Romans, and in 503 they gained a battle there under the orders of the proconsul Metellus. It afterwards became a Roman colony.—Alfo, a small gulf of Achaia, towards the N.W., into which the three rivers Charades, Leleus, and Bolineus discharged themselves—Alfo, a port of Greece, and the aitl on the E. coast of Attica, near the promontory of Sanium. Ptolemy.—Alfo, a town on the N. coast of the isle of Crete, between Cithium and Hecaleum. Ptol.—Alfo, a port of the isle of Cephalonia.—Alfo, a port of Epirus, near that of Oncheus. Ptol.—Alfo, a town of the Thracian Cherfonesus, between Eleea and Cardia. Pliny.—Alfo, a town of Macedonia, in Chalcedia. Ptol.—Alfo, a port of Africa, in Marmorica, upon the coast of the name of Lybia. Ptol.—Alfo, a port of the town of Oricum, on the Ionian sea. Strabo.—Alfo, a small port of Asia Minor, in Ionia, N.E. of the promontory of Poldium, S.E. of the promontory of Trogilium, and S. of Miletus. South of this port was the famous temple of Apollo Branchidae, and to this place strangers repaired to consult the oracle. The ancients pretended that the temple which discharged itself into the sea at this port, sprang from mount Mycale, and paifed under the sea till it re-appeared in the vicinity of this temple.

PANORPA, in Entomology, a genus of insects of the order Neuroptera: the generic character is, mouth lengthened into a cylindrical horned proboscis; feelers four, nearly equal; femmata three; antennae filiform, longer than the thorax; tail of the male armed with a chelate appendage; but in the female it is unarmed. There are nine species.

* Commonis. This, as its name imports, is the most familiar of all the species. It is frequently seen in our meadows during the early part of the summer. It is a long-bodied fly of a moderate size, with four transparent wings, elegantly variegated with deep brown spots; the tail of the male insect, which is generally carried in an upright position, is furnished with a forceps, somewhat in the shape of a lobster's claw.

Germanica. Wings equal, hyaline, tipt with brown. It inhabits Germany, and resembles the commonis.

Scorpius. Wings equal, black spotted with white; body dirty. It is found in different parts of North America.

Fasciata. The wings of this likewise are equal, yellow with black dots and bands. It is found in North America.

Hyemalis. Wings tubulate, slightly incurved, ciliate; the female is apterous. It is a small insect, and is found in Saxony.

Tippulata. Wings immaculate; abdomen falcate; the legs are very long. It inhabits Italy; the body is yellow, the wings equal.

Capensis. The wings are equal and immaculate; body ferruginous. It inhabits the Cape.

Japonica. Wings equal, hyaline, with two black wings. It is found in Japan.

Cos. Wings erect, lower ones nearly linear and very long. This is a native of Greece and the islands of the Archipelago, and is an insect of a very peculiar appearance. It is distinguished by having the lower wings fo extremely narrow or slender as to resemble a pair of linear procefts with an oval dilatation at the tip, while the upper wings are very large, oval, transparent, and beautifully variegated with yellowish-brown bars and spots.

PANOSPA. See Cicada Tiberiana.

PANOV, in Geography, a river of Russia, which runs into the Niznei Tunguski. N. lat. 64° 40'. E. long. 102° 54'.

PANREEDY, a town of Bengal; 30 miles S.S.E. of Currockdeagh.

PANSACCHI, Don, in Biography, an Italian ferious opera of a tenor voice, who having refided nine years in Spain, was allowed to qualify himself with the title of Don. He was in the service of the elector of Bavaria in 1772, when we often heard him. His voice was not bright, or very mellifluous; but his knowledge of music, intelligence in the drama, taste, and expression, were of a superior kind. He had acquired, by his long residence in Spain, the true national style of singing sepulchus, tenorilas, and other music of that country.

PANSAGUTCHY, in Geography, a town of Bengal; 8 miles N. of Rajmall.

PANSAI, or Pulo-Pansang, a small island in the gulf of Siam. N. lat. 9° 15'. E. long. 103° 30'.

PANSAR, a town of Hindooftan, in Guzerat; 16 miles N. of Amedabad.

PANSHAH, a town of Meckley; 55 miles S.S.E. of Munnpour.

PANSHALLA, a town of Guriel; 30 miles E. of Pati.

PANS-IENING, a town on the W. coast of the island of Formosa. N. lat. 25° 56'. E. long. 110° 52'.

PANSRUCKY, a town of Hindooftan, in Bahar; 27 miles S. of Bahar. N. lat. 24° 40'. E. long. 85° 44'.

PANTENUS, in Biography, a learned Christian philosopher of the Stoic sect in the second century, flourished, according to Cave, about the year 182. His descent, his country, and the time of his birth, are all uncertain. He is thought to have been one of the masters of Clement of Alexandria; and is mentioned with high respect by Alexander, bishop of Jerusalem, in a fragment of a letter to Origen, prefixed by Eusebius, in which he expressly says that Pantenus was the person who introduced him to the acquaintance of that master. He was held in very high estimation, and is referred to by Origen with great respect, and Photius speaks of him as a hearer of some of those who had seen the apohles, and even of the apohles themselves. He presided over the catherineal school at Alexandria with great reputation and figure. He was extremely zealous in the cause of Christianity, and undertook a mission into Ethiopia, to instruct the inhabitants in the principles of that
that religion. After his return to Alexandria Pantanus resumed the presidency of the catechetical school, in which he continued to explain the scriptures publicly under the reign of the emperors Severus and Caracalla. According to Jerome, there were, in his time, "Commentaries" of Pantanus upon the Scriptures, but there is nothing now remaining of his writings, excepting a short passage in the "Eclogae," ascribed to Clement of Alexandria, containing the following rule respecting the language used in the prophecies of the Old Testament; "that the prophets often express themselves in indefinite terms, and that the present tense is frequently used by them both for the pretetite and future." Pantanus is supposed to have died about the year 213. Dupin. Lardner.

PANTAIA, in Geography. See PANDAIA.

PANTALARIA, a small island in the Mediterranean, between the island of Sicily and Cape Bon, on the coast of Tunis; about 25 miles in circumference, and containing about 4000 inhabitants. Its chief productions are olives, figs, raisins, capers, and cotton; the cattle are numerous; but bread corn is imported from Sicily. The language is a mixture of Italian and African. N. lat. 36° 55'. E. long. 12° 15'.

PANTALEO, St., a town of the island of Sardinia, the site of which was anciently that of the episcopal city of Delft, or of Cagliari.

PANTALEONE, a small island in the Mediterranean, near the W. coast of Sicily, formerly united to the continent by a neck of land, which was destroyed by the inhabitants in order to secure themselves against the enemy. The ancient Motya stood in this island. N. lat. 37° 50'. E. long. 12° 28'.

PANTALEONE, in Music, a stringed instrument in Germany at the latter end of the seventeenth century. The inventor's name was Hebenricht; but from the success of his instrument, he assumed that of Pantalone. It was more than nine feet long, and had, when in order, 186 strings. The tone was produced by two *brogettes*, or flicks, like the dulcimer; it must have been extremely difficult to the performer, but seems to have been capable of great effects.

Mr. Binder, organist of the Duomo Kirk, at Dresden, was the last person who played upon it. It was this instrument, and the performance upon it at Paris in 1705, which gave birth to a very ingenious little work, under the title of "Dialogue pour la Muique des Anciens," by the abbe Chateauenuf. When we law the ruins of this instrument at Dresden, soon after the seven years' war, the strings were almost all broken, and the court was so impoverished as not to like to be at the charge of new mounting it. It used to be one of the musical curiosities of that city, during the time that the elector of Saxony was king of Poland.

PANTALOON, or Pantalon, the name of an ancient garment frequent among our forefathers, consisting of breeches and frockings all of a piece. A dress somewhat similar has been lately revived and much used.

The denomination comes from the Venetians, who first introduced this habit, and who are called Pantaloni, from St. Pantalon, who was formerly their patron.

PANTALON, on the Theatre, is a buffoon or maskèd person who performs high and grotesque dances, and swears violent and extravagant oaths and airs.

The word is also used for the habit and dress these buffoons usually wear; which is made precisely to the form of their body, and all of a piece from head to foot.

And hence those who wear a habit of this kind, for convenience under their other clothes, are called pantaloons of Venice. VOL. XXVI.

PANTANO, in Geography, a town of Sicily, in the valley of Noto; 10 miles S. of Modica.—Alfo, a town of Italy, in the department of the Panaro; 15 miles S.W. of Modena.—Alfo, a town of Naples, in Calabria Ultra; 9 miles E. of Bova.—Alfo, a river of Naples, which runs into the sea; 10 miles E. of Bova.

PANTAR, an island in the East Indian sea, of a square form, about 48 miles in circumference, separated from the E. coast of the island of Lamblen by the strait of Alvo; and from the W. coast of Ombay by a narrow channel, called the "Strait of Pantar." S. lat. 8° 10'. E. long. 124° 29'.

PANTARBE, in Natural History, a name given by authors to an imaginary flute, the virtues of which were similar to those of the magnet; but exerted upon gold as those of the loadstone upon iron. The ancients, as well as later writers, seem to have had an opinion, that there was such a flute as this, and the amphi tone of Pliny is described as possessing this remarkable quality; but neither they nor we ever found rest on from any experiment to believe that there was any such flute.

PANTHEA, It. see, among the Ancients, were single statues, composed of the figures, or symbols, of several different divinities combined.

Father Joubert, who calls them Panthea, and who has observed them on several medals, says their heads are most commonly adorned with the symbols or attributes belonging to several gods.

An influence of this kind we have in a medal of Antoninus Pius, which at the same time represents Serapis, by the bull he bears; the Sun, by the crown of rays; Jupiter Ammon, by the ram's horns; Pluto by the large beard; and Asclepius, by the serpent twisted in his hand.

M. Baudelot, in a dissertation on the Lares, will have the Panthea to have had their rife from the supererogation of thae, who, taking several gods for the protectors of their houses, united them all in the same statue, by adorning it with the several symbols proper to each of the deities.

PANTHEISTS, is a denomination by which the followers of Spinoza are distinguished, and derived from the nature of their doctrine, which confounds God with the universe; representing them as one and the same being, and admitting only one substance whence all things proceed, and into which they all return. See SPINOZISM.

PANTHEON, It. see, thus named from Pan, all, and theos, God, in Architecture, a temple, or church, of a circular form; dedicated to all the gods, or to all the sants.

The Pantheon of ancient Rome is of all these edifices the most celebrated, and that from which all the rest take their names. It was built by Agrippa, son-in-law of Augustus, in his third consulship, twenty-five years before Christ; though several antiquarians and artists have supposed that the Pantheon existed as long ago as the commonwealth, and that Agrippa only embellished it and added the portico. To this purpose they allege the authority of Dion Cassius, who speaking of Agrippa, says, he also finished or perfected the Pantheon.

It was dedicated by him to Jupiter Ultor, Jupiter the Revenger, according to Pliny's account; according to Dion Cassius, to Mars, Venus, and Julius Cæsar; but according to the most probable opinion, to all the gods; and had the name Pantheon, on account of the great number of statues of the gods ranged in seven niches all round it; and because it was built of a circular form, to represent heaven, the residence of the gods; or because it was dedicated to all the gods, (quasi pan- theon.) It has but one door. It
It was one hundred and forty-four, or, as Fabricius says, one hundred and forty feet diameter within, and just as much in height, and of the Corinthian order. The roof was curiously vaulted, void spaces being left here and there for greater strength. The rafters, forty feet long, were plated with brass. There were no windows in the whole edifice; but sufficient light was let in through a round hole in the top of the roof. Before each niche were two columns of antique yellow marble fluted, and of one entire block. The whole wall of the temple, as high as the grand cornice inclusive, was cased with divers sorts of precious marble in compartments: and the frieze was entirely of porphyry. The outside of the front was anciently covered with plates of brass gilt, and the top with plates of silver, in lieu of which lead was afterwards substituted. The gates were of brass, and of extraordinary size and workmanship.

The eruption of Vesuvius, in the reign of Tiberius, and a great fire in the reign of Titus, damaged the Pantheon very considerably: but it was successively repaired by Domitian, Adrian, and Septimius Severus: and it subsisted in all its grandeur till the incursion of Alaric, in the time of Honorius: on this occasion it was stripped of several of its statues and ornaments of gold and silver. About thirty-nine years after this, Genocide, king of the Vandals, took away part of its marbles and statues; at length pope Boniface IV., obtaining this Pantheon of the emperor Phocas, converted it into a church, without any alteration in the building; and dedicated it to the Virgin, and all the martyrs. And it still subsists at Rome under the title of Notre-Dame de la Rotonde. However, in 655, Constanzi II. stripped it of its inside and outside brazen coverings, which he transported to Syracuse.

There was also at Rome another Pantheon, dedicated to Minerva, as the goddess of medicine. It was in the form of a decagon, and the distance from one angle to another measured 221 feet. Between the angles there were nine chapels of a round figure, designed for so many deities: and over the gate there was a statue of Minerva. The Pantheon of Athens was in many respects little inferior to that of Rome, built by Agrippa. The Greek Christians converted it into a church, dedicated to the Virgin, under the name of Panagia. The Turks changed it into a mosque.

The Pantheon of Nismes, was a temple in that city, in which were twelve niches, for statues, supposed to have been defined for the twelve great gods.

In the Escurial is a magnificent chapel, called Pantheon, thirty-five feet in diameter, and thirty-eight high, from the pavement, which is of marble and Jasper inlaid. The whole inside of the chapel is of black marble, except the lustrum, and some ornaments of Jasper, and red marble.

In this chapel are deposited the bodies of the kings and queens: there are only places made for twenty-six; eight of which are already filled.

The square of the Pantheon, or "Piazza della Rotonda" is adorned with a fountain and an obelisk, and terminated by the portico of Agrippa. This noble colonnade consists of a double range of Corinthian pillars of red granite. Between the middle columns, a passageway opens to the brazen portals, which, as they unfold, expose to view a circular hall of immense extent, crowned with a lofty dome, and lighted solely from above. It is paved and lined with marble. Its cornice of white marble is supported by sixteen columns, and as many pilasters of Giotto antic: in the circumference there are eight niches, and between these niches are eight altars, adorned each with two pillars of less size, but the same materials. The niches were anciently occupied by statues of the great deities; the intermediate altars served as pedefials for the inferior powers. The proportions of this temple are admirable for the effect intended to be produced, its height being equal to its diameter, and it is, in form, a hemisphere. The Pantheon is the most noble and perfect specimen of Roman art and magnificence which time has spared, or the ancients could have wished to transmit to posterity. It has served in fact as a leison and a model to succeeding generations, and to it Constantine is indebted for Santa Sophia, and to it Rome, or rather the universe, owes the unrivalled dome of the Vatican. Upon the whole this is the most ancient edifice that now remains in a state of full and almost perfect preservation. It has nevertheless undergone many alterations from pillage and repairs, chiefly restricted to its decorations. It was first altered by Domitian, and afterwards repaired by Severus. The pillars, pilasters, and marble lining remain nearly as they were placed by the latter. It was plundered of part of its bronze ornaments, by Genocide, the Vandal monarch of Africa, and afterwards more completely stripped of all its metal decorations by Constantine, the grandson of Heracleus, in the 7th century. It was converted into a church by pope Boniface IV., about the year 699, and since that period has attracted the attention and enjoyed the patronage of various pontiffs. Although the Pantheon probably owes its preservation to its having been converted into a church; yet, leaving to it its principal character as a temple, it seems better adapted to the purposes of a mausoleum; and it has actually been in some degree appropriated to this use; for it contains at present the tombs or rather the bucrals of several distinguished characters, among which are the celebrated antiquary Winckelmann, Melsaiafo, Mengs, Poufain, Hanibal Carrucci, and Raffaello himself. Two musicians also, Corelli and Sacchini, have been admitted to the honours of the Pantheon.

The dedication of this church on the 11th of November, in the year 820, gave occasion to the institution of the festival of All Saints.

Pantheon, in England, a modern building erected in Oxford-street, London, begun in 1768, and finished in 1771, for concerts and other musical performances. It was built by Mr. James Wyatt, and regarded, both by natives and foreigners, as the most elegant structure in Europe, if not on the globe. This splendid and elegant edifice was opened as a place of public entertainment, on Monday, January 27, 1772. During the first winter there were assemblies only, without dancing or music, three times a-week. On other days, each person paid five shillings for seeing the building only. But the great room, though spacious, was so crowded on all these occasions, that in July, a general meeting of the proprietors was advertised, in order to take into consideration the enlarging of the building.

After the opera-house in the Haymarket was burnt down in 1790, this master-piece of architecture was transformed into a theatre for the performance of operas; when, though many of its internal beauties were hidden and annihilated, it still was a perfect model of a complete theatre in its new form. But unhappily, before it had been used as a lyric theatre two seasons, it was burnt down by some fatal accident or design, which has never yet been divulged to the satisfaction of the public.

During its pre-existent state, it was here that the Agnari and Pacchierotti exercised their talents; it was here that the king, queen, and royal family, with all the first nobility in the kingdom, assembled, at the commemoration of Handel in 1784; and it was here that one of the first bands in Europe graced the orchestra, alternately headed by Giordani, La Motte, Cramer, or Giornovichi, who, with Fischer, Crofidi,
Croftil, Cervetto, &c. produced effects in symphonies, concertos, sonatas, and vocal accompaniments, which had never before been heard in this country. No persons of taste in architecture, or music, who remembers the Pantheon, its exhibitions, its numerous, splendid, and elegant assemblies, can hear it mentioned without a sigh!

**PANTHER** in Zoology. See Felis Pardus, Leopardus, and Uncia.

**PANTHER** Greek, in Geography, a river of Kentucky, which runs into the Green river, N. lat. 37° 29'. W. long. 84° 48'.

**PANTERA LAPIS**, in Natural History, the name of a species of stone found in Egypt, and the East Indies, and described to be of a yellowish colour, variegated with dusky spots of the colour of tuscun on the skin of the panther. The writers of the middle ages have attributed many absurd properties to it; it seems to have been a species of agate.

**PANTHERINE TABLES**, Pantherina Menes, among the Romans, tables made of citron wood, which were held in such high esteem, as to equal the value not only of silver and gold, but likewise of pearls. They had this name from their being impoted after the manner of panthers.

**PANTICAPAEA**, in Ancient Geography, a town of the Tauric Chersonesus, according to Ptolemy and Strabo. This town became the capital of the kingdom of Cimmerian Bosphorus. Under the successors of Spartacus, according to Diodorus Siculus, Panticapaia was the place where the waters of the Palus Mocestis discharged themselves into the Euxine sea.

**PANTICAPES**, a river of European Scythia. According to Pliny it separated between the Nomades and the Georgians. Herodotus says that it took its rise from a lake situated towards the north, that it pursed a S.W. course and passed by Itea, which was the first country which those who have traversed the Borythines, near the sea. He adds that Panticapaia ran into the Borythines, a little above the mouth of this large river. Strabo, however, does not mention a river of this name; he might indeed have omitted it, and it might be the river now known under the name of Samara.

**PANTICOSA**, in Geography, a town of Spain, in Aragon; 13 miles N.N.E. of Jaca.

**PANTICUM**, or PANTICHUM, in Ancient Geography, a town of Asia, in Bithynia, between Chalcedon and Libyra, according to the Itinerary of Antonine.

**PANTIKA**, in Geography, a town of Asiatic Turkey, in Nataara, on the N.E. coast of the sea of Marmora; 13 miles S.E. of Conantimplum.

**PANTIN**, a town of France, in the department of the Seine, and chief place of a canton, in the district of St. Denis. The place contains 1172, and the canton 109,932 inhabitants, on a territory of 57,500 square miles, in 12 parishes.

**PANTIPOLIS**, in Ancient Geography, a town of India, on this side the Ganges, between Berders and Adyram. Ptolemy.

**PANTOMATRIUM**, a promontory on the N. coast of the isle of Crete, between the promontory Dion and the town Rithymne. Ptolemy.

**PANTOMIME**, among the Ancients, a person who could imitate all kinds of actions and characters by signs and gestures, without speaking.

The pantomimes made a part in the theatrical entertainments of the ancients; their chief employment was to express, in gestures and action, whatever the chorus sung, changing their countenance and behaviour as the subject of the song varied.

They were very ancient in Greece, being derived from the heroic times, according to some; but however this may be, they were certainly known in Plato's time. In Rome it was so late as the time of Augustus before they made their appearance. Under his reign and that of Tiberius, the pantomime, carried on by much gesticulation, was the favourite entertainment of the public. The people were moved, and wept at it, as much as at tragedies; and the paflion for it was so strong, that laws were obliged to be made for refining the senators from studying the pantomimic art.

As to the dress, it was various, being always fuel, as near as possible, to that of the person they were to imitate. The crocota was much used among the Roman pantomimes, in which, and other female dresses, they perforated women. See Mime, Ballet, and Bathylus.

**PANTON**, in Geography, a township of America, in Addison county, Vermont, on the E. side of lake Champlain, about 87 miles N. of Bennington.

**PANTO-SHOE**, in the management of farm and other horses, an old art of invention contrived for the purpose of receiving the narrow and hoof-bound heels of them, in particular cases. The fplunges of it are much thicker on the inside than on the outside, so that the part which rests upon the horn or hoof, runs sloping to the end, that the thickness of the inside of the shoe may bear up the heel, and throw or push it to the outside. Shoes of this kind were recommended by Guillet as proper for horses which had fallen quarters.

**PANUCO**, in Geography, a river of North America, which runs into the gulf of Mexico; 21 miles E.S.E. of Panuco. N. lat. 22° 40'. W. long. 98° 36'.

**PANUCO**, or St. Stephen, a township of Mexico, and capital of the province of Guadalajara. On the river of the same name, navigable for barks up to the town. It is the residence of a bishop, and contains about 500 families; 190 miles N.N.E. of Mexico. N. lat. 23° 30'. W. long. 99° 6'. See Guadalajara.

**PANUCO**, a town of South America, in the province of Tucuman; 15 miles W. of St. Fernando.

**PANVINILAO**, a town on the S. coast of the island of Luzon. N. lat. 14° 21'. E. long. 121° 30'.

**PANVINIO, Onorio**, in Biography, a very learned historian and antiquary, was born at Verona in the year 1520. From a very early period of his life he manifested an inatiable thirst for study, and to indulge it he entered into the order of the Augustines. He was sent to Rome to complete his studies, and in 1553 he was appointed to instruct novices in the sciences. After a few months' residence in Rome, he was sent to Florence to teach scholastic theology, but that science not being adapted to his taste, he quitted his charge, and obtained permission to live at large out of the cloister. He passed some time at Venice, where he printed one of his works, but his ordinary abode was at Rome, being patronized by Cardinal Marcello Cervini, whose pontificate, under the name of Marcellus II., was of too short duration to contribute to his advancement. From thence he pulled into the court of Cardinal Alexander Farnefe, with whom he travelled into Sicily in 1568, where he died. "Very few inaances," says his biographer, "are to be met with of such extensive erudition, and indefatigable industry, left by one whole career was restricted to such narrow limits. Besides his published works, which form a numerous catalogue, he left a still greater number in MS. either completed
er begun." One of the first objects of his labours was Roman history and antiquities. The "Fasti Confusa," though first brought to light by Sigerus, were published and illustrated with notes by him at Venice in 1557. He published treatises also, "De Antiquis Romanorum Nominiussen;" "De Principibus Romanis;" "De Republica;" "De Triumphiis et Ludis Cireenibus;" and "Topographia Roma." These valuable works are founded in a great measure upon ancient inscriptions, of which he had collected and copied nearly three thousand. He was a profound invetigator of sacred or Christian antiquities. Of his published works in this class are treatises "De Ritu Syphlorapian mortuos apud veteres Christianos;" "De Antiquo Ritu baptizandi Cathecumenos;" "De Primatu et Tituli;" "Chronicon Ecclesiasticum;" "De Episcopatus Tithis, et Dianconis Cardinalium;" "Annotations et Supplementa ad Planinam de Vita Pontificum;" "De Sententia praebis Urbis Romae Bafulicis;" "De Bibliotheca Vaticana." He had undertaken a general ecclesiastical history, for which he collected matter sufficient to fill six large manuscript volumes, which are preserved in the Vatican. He wrote a Chronicle of his own order, and a history of his native city, Verona, including an account of its antiquities, printed many years after his death.

PANWELL, in Geography, a town of Hindustan, in Vifapour; 60 miles W.N.W. of Poona.

PANYASUS, in Ancient Geography, a river of Macedonia, the mouth of which is placed by Ptolemy between Dyrhachium and the mouth of the river Aplus.

PAZA, or PENGIA, in Geography, a town of Africa, in Congo, in the province of Bamba.

PANZANO, a town of Eruria; 14 miles S. of Florence.

PANZEN, a town of Bohemia, in the circle of Leitmeritz; 15 miles N.N.E. of Leitmeritz. N. lat. 50 44' E. long. 14' 25'.

PANZERA, in Botany, named by Willdenow in honour of Dr. G. W. F. Panzer, a physician at Nuremberg, author of some well known tracts on Botany and Entomology. This genus was originally called Eperus by Aukl., and is considered by Schreber as not distinct from Dimorphus, though Willdenow says it is perfectly different in its foliage and other characters, as well as in other particulars. — Willd. Sp. Pl. v. 2. 542. (Eperus; Aukl. Guian. v. 1. 366. Jaff. 349. Linn. 335.)—Clad and order, Decadendra Monogynia. Nat. Ord. Lomentaceae. Linn. Leguminosae. Jaff.

Gen. Ch. Col. Perianth inferior, of one leaf, divided into four, broad, oblong, obtuse, concave segments. Cor. Petal one, broad, spreading, roundish, convolute at the sides of its base, inserted at the mouth of the calyx. Stam. Filaments ten, very long, variably inflatoxed, inserted into the calyx, thicker at the base, villous, nine of them united at the bottom, one single; anthers oblong, obtuse, two-celled, nodding, five of them barren. Ptil. German superior, stalked, nearly ovate; three very long, convolute; stigma obtuse. Peric. Legume coriaceous, compressed, rather downy, rough, long, hooked, with an acute, incurved point, of one cell and two valves, curled elastically. Seeds three or four, large, compressed, coriaceous, sometimes caraminate on one side. Eff. Fl. Calyx of one leaf, four-cleft. Petal one, lateral, convolute at the base. Filaments thickened at the base, bearded, five of them abortive. Legume. 1. P. falata. Willd. (Eperus falcatu; Aukl. Guian. t. 142.)—Native of woods, and banks of rivers, in Guiana. It flowered and bore fruit towards winter. — The trunk of this large tree is sixty feet in height, much branched at the upper part. Branches widely scattered. Leaves alternate, pinnate; leaflets in three pairs, opposite, nearly sessile, ovate-oblong, acute, smooth, entire, springing from the furrow of the leaf-blade. Stipulas two, small, deciduous. Flowers numerous, red. See Dimorphus Falcatu.

As there is so much diversity of opinion about this plant, we have thought it best to exhibit Willdenow's view of it, though it had been already mentioned under Dimorphus.

PANZY. See VIOLA.

PAO, in Geography, a river of South America, which rises near Valencia, in the province of Caracas, and after a course of about 100 miles, joins the Barigucemeto, in N. lat. 9° 20' and the united streams form the Portuguesa.— Also, a town of Coro; 50 miles S.E. of Ou-chuen.

PAO-DE-NAO, a town on the coast of Africa, near the river Camoroes, belonging to the Portuguese.

PAO-KING, a city of China, of the first rank; in Hou-ouang; N. lat. 27° 4'. E. long. 111'.

PAOLI, PASCAL DE, in Biography, a very distinguished character in modern times, born at Koffino, in the island of Corfica, in 1726, was the son of Hiacente Paoli, who had been always attached to the popular cause, and who, when all his attempts against the Genoese had proved unavailing, had retired with his family to Naples. Paical was educated among the Jesuits, and at their college he made a rapid progress in his studies, and displayed an understanding equally solid and capacious. He appears to have been formed by nature with powers capable of attacking to himself the hearts and affections of his countrymen; for his deportment was grave and prudent, and his judgment was mature by reflection rather than by age, whilst his patriotism was unquestioned, and his eloquence superior to that of any of his rivals. He was accordingly unanimously chosen generalissimo, in a full assembly of the people, when he had attained but to the 29th year of his age. He was not long in deciding how he should act; he complied with his country's call, and devoted himself to its service. Having taken leave of his father, now advanced in years, he embarked for the island, and was formally invested with the chief command. The situation of the island, in respect to its internal government, being exceedingly unpromising, this chief new-modelled the laws, and established the appearance, if not the reality, of subordination; he instituted schools, and laid the foundation of a maritime power. In 1761 the government of Genoa, perceiving the change lately effected among the natives, sent a deputation to a general council, convoked at Venice, for the express purpose of proposing terms of accommodation; but it was unanimously resolved never to make peace with the oppressor, unless upon the express condition of Corfica being guaranteed in the full enjoyment of its independence. A memorial to the same effect was also addressed, at the same time, to all the sovereigns of Europe. But appeals to the principles of freedom were not likely to obtain favour in royal cabinets, and nothing was gained by the memorial of the Corfiotes; indeed the court of France entered into a treaty with the Genoese, for supplying them with force to overrun the towns yet remaining in their hands. The presence of the French soldiers effectually prevented any progress towards freeing the island, and the only military action of any note that took place during the four years in which this treaty subsisted, was the conquest, by the Corfiotes, of the isle of Capraia.

At length, in 1768, the Genoese desiring of rendering the Rubbonians subservient to their will, transferred the sovereignty of Corfica to France, on condition of receiving in lieu of it 40,000,000 of livres. This was a thunderstroke to the wretched Corfiotes, but the noble leader remained firm.
firm to his cause; he roused and prepared the spirit of his followers for a fresh contention, and animated them to persevere, with additional zeal, in defence of their rights and liberties as an independent people, promising never to abandon them, but either to triumph or fall at the head of his countrymen. This heroic resolution was circulated with rapidity, and, when coupled with the justice of the cause in which he had embarked, obtained for him the esteem and regard of every lover of freedom and humanity throughout Europe.

He was at first tempted with the offer of being confirmed in his supreme authority, provided he would consent to hold it under the French government, but he rejected the proposal with indignation; he was a lover of liberty, and not attached to the mere exercise of power; and he nobly declared, in answer to the disingenuous application, as he thought it, that "the rocks which surrounded him should melt away, were he would betray a cause which he held in common with the meanest Coriscan." A rigorous war commenced, in which, for some time, the French were beaten, and in one instance their general was obliged to capitulate, with all his infantry, artillery, and ammunition. An immense force was now sent from France which overwhelmed the Coriscan patriots; they were defeated with great slaughter, and Paoli, left with only about 500 men, was surrounded by the French, who were anxious to possess their perfidious; he, however, cut his way through the enemy, and escaped to England with his friends, where they were received with all the sympathy and respect due from freemen to patriots who had so nobly supported the cause of liberty. Dumourier, who afterwards made a figure in the revolution of his own country, and was at length severely disgraced, served at this period against the Coriscans, with the rank of adjutant-general; and in his own memoirs, published a few years since, he pays very high compliments both to the people of the island and their chief: "it is astonishing," he says, "that this handful of islanders, destitute of artillery, fortifications, magazines, and money, should have kept France at bay during two campaigns, although she had no other enemy to cope with. But liberty doubles the valour and strength of men." The case of the oppressed Coriscans had excited much interest in this country, and it was but a few days before his final retreat, that he received a liberal subscription from a number of private individuals, of which number were Aldermen Beckford and Trecottie, and Samuel Vaughan, esq., who were also trustees for the sums raised, for the express purpose of enabling him to carry on the war against France. On his arrival Paoli was introduced at court, and the duke of Grafton, then prime minister, obtained for him a pension of £200 a year, which he liberally shared with his companions in exile.

From this time the ex-general lived a retired life, devoting himself chiefly to the cultivation of literature. During his retirement, which lasted more than twenty years, he was introduced to Dr. Johnson by Mr. Boswell, who had visited the general while he was in Corica; and who speaks of the interview with pleasure, saying, "the general spoke Italian, and Dr. Johnson English, and understood one another very well, with a little aid of interpretation from me, in which I compared myself to an ithyphalos, that joins two great continents."

At length the revolution that promised to raise France to the rank of a free state, extended its influence to Corica, and the national convention passed a decree by which that island was numbered among the departments of France, and entitled to all the privileges of the new constitution. The return of Paoli to the dignified station of its chief, was the first with of his liberated countrymen, and Paoli could not refuse their entreaties, which were enforced by the solicitations of the French assembly. He resigned his pension from the English court, took a grateful leave of the country in which he had been so hospitably entertained, and in the month of April 1790, presented himself at the bar of the national assembly at Paris, together with the Coriscan deputies. Soon after this he embarked for Corica, where he was received with an extraordinary degree of attachment and respect. He was elected mayor of Balta, commander-in-chief of the national guard, and president of the department; and, in short, he at once acquired more authority in the island, than before its subjugation by the French. He was, however, not quite contented; he was ambitious of seeing Corica wholly independent, which, upon the execution of Lewis XVI., was the prevailing wish of the Coriscans. The convention was soon apprized of their views, and summoned Paoli to their bar to justify himself against the charges exhibited against him; to gain time, he pleaded his age and infirmities as excuses why he could not comply with their demand. To a second order, more peremptory than the first, he replied in a different manner, and with more frankness. After this he repaired to Corte, the ancient capital, in the centre of the island, where, surrounded by his friends and adherents, he laughed at the proclamation which had been issued, declaring him a traitor, and setting a price upon his head. Sensible, however, that it would be impossible for a small island permanently to withstand the power of France, without foreign support, he resolved upon an expedition, which, though it was a renunciation of independence, promised to secure all the advantages of real liberty. This was an union of Corica with the crown of Great Britain; the particulars of this business will be found in the article CORSICA. Paoli, as will be seen in that article, returned to England, having unfortunately lost all his property, by the failure of a mercantile house at Leghorn, and passed the remainder of his life in great privacy. He died in London, February 5, 1807, in the eighty-second year of his age. Few foreigners, however distinguished, have been so much cared for in England as general Paoli. By living in habits of familiarity with men of letters, his name and exploits acquired high celebrity; and Boswell, Goldsmith, Johnson, and many others, equally eminent in the literary world, although differing in almost every thing else, cordially united in his praise. On the continent his reputation was greatly respected; it was usual to compare Paoli to Timoleon and Epaminondas. He was unquestionably a great man; but it is the opinion of those who have enjoyed the opportunity of studying his character, that he was a politician rather than a soldier; that he shone more in council than in arms; and that the leading feature of his public conduct was a certain degree of Italian policy, which taught him to refine and speculate on every event. Boswell's Account of Corica. Athenaeum, vol. i. Monthly Mag. vol. xxiii.

PAOLO, AGOSTINO, a learned ecclesiastical composer of music, scholar of Bernardo Nanini, and fuscitor in the pontifical chapel to Soriano. Antimo Liberati speaks of him as one of the most scientious and ingenious composers of his time, in every species of music then cultivated; and tells us, that while he was magistro di capella of St. Peter's church at Rome, he astonished the musical world with his productions for four, six, and eight choirs or chorusses; some of which might be sung in four or five parts only, without diminishing or eneravating the harmony. Padre Martini, who bears testimony to the truth of this eulogium, has inserted an Agnus Dei, in eight parts, of this composer, which is truly a curious production: three different canons being
being carried on at the same time, in so clear and natural a manner, both as to melody and harmony, that this learned father, who had been long exercised in such arduous enterprises, speaks of it as one of the greatest efforts of genius and learning in this most difficult kind of composition.

PAOLO, in Commerce, a small silver coin at Florence, Rome, and other places in Italy. As a money of account at Florence, the feudo d'oro is worth 7½ lire, 1½ palli, or 90 crazie. The ducato, or feudo corrente, called also the piastra, is an imaginary coin, valued at 7 lire, 106 palii, or 84 crazie; the lira = 1½ palii; the palli or grana = 8 crazie = 40 quattrini = 160 denari di lira; a tettone = 2 lire = 3 palii.

The coins in silver are pieces of 10 palii, or 6½ lire, called francoboni and leopoldoni; half dito, called francelfchi, of 5 palii; tallari, of 6 lire, or 9 palii; tessoni of 2 lire, or 3 palii; single, half, and quarter of 20, 10, and 5 folli; double, single, half, and quarter palii; double, single, and half crazie.

The piece called francoboni weighs 23 denari 10 grani, Florence weight, or 426 English grains; and the silver is 10 denari 22 grani, or 10 oz. 185 dwt. fine; and therefore contains 38 1/2 English grains of fine silver, or 419 grains of standard silver, and is worth 4 6d. sterling. According to this valuation, the feudo d'oro, of 7½ lire, = 52 6d. sterling; the ducato, or feudo corrente, of 7 lire, = 42 8d. sterling; the pezzo, of 5½ lire, = 37 10d. sterling; the lira is worth about 8d.; or 1 lira = 29½, 12 folli, 7 denari, or 4 ducati, 4 folli, 7 denari di ducato; or 5 pezze, 2 folli, 8 denari di pezzo, all in silver. For the paoli of Rome, see ROSE.

PAOLO, St., in Geography, a river of Sicily, which runs into the sea, on the E. coast, N. lat. 37 16'. E. long. 15 13'.—Also, a small island, near the coast of Naples, in the gulf of Tarento. N. lat. 40 42'. E. long. 17 6'.—Also, a town of Naples, in the Capitanata; 3 miles S.E. of Dragonera.

PAOLOS, in Geography, a town of Asiatic Turkey, in the province of Sivas; 25 miles W. of Sivas.

PAON, in Ornithology. See TRINGA Palustris, and PAVO Grisatus.

PAO-NGAN, in Geography, a city of China, of the second rank, in Pe-teche-li, on the river San-cam; 62 miles N.W. of Pekin. N. lat. 41 20'. E. long. 114 41'.

PAO-NING, a city of China, of the first rank, in the province of So-tchuen, comprehending within its jurisdiction ten cities.

PAOON, one of the smaller New Hebrides; which see.

PAOS, a town of Portugal, in the province of Beira; 16 miles N.W. of Vifieu.

PAO-TCHING, a town of Corea; 30 miles S. of Koang-techeou.

PAO-TCHUEN, a town of Corea; 28 miles S.S.W. of Koang-techeou.—Also, a town of Corea; 23 miles E. of King-ki-tao.

PAO-TING, a city, in the province of Pe-teche-li, in which the viceroy resides, and the most considerable in the province, next to Pekin. It has 20 others under its jurisdiction; the country round it is pleasant, and inferior in fertility to no part of China. In going from Pe-kin to the province of Chih-fu, it is necessary to pass through this city. N. lat. 38 45'. E. long. 115 14'.

PAOUALA, a town of Naples, in Principato Ultra; 4 miles N.E. of Benevento.

PAOWAH, a town of Hindooottan, in Bahar; 5 miles S. of Bahar.

PAP, in Rural Economy, a provincial term applied to the teats of cows, or other animals that give milk. The paps differ after the young is produced, and as the bodies of them contain the terminations of the tubuli laeiferi, where they are tortuous, and act as valves; they are dilatable, as they are squeezed becoming straight, and thus the milk has a free passage, whether the pressure be caused by the mouth of the young animal in suckling, or the hand in the act of milking. See Teat.

PAPA. See Pope.

PAPA, in Ornithology. See VULTUR.

PAPA, in Geography, a town of Hungary; 25 miles S. of Raab.

PAPA STOUR, one of the Zetland or Shetland islands of Scotland, is situated about a mile westward from the Mainland. This island extends about two miles in length, and one in breadth. Its soil is a rich land, producing excellent pasturage grasses, and even good crops of oats, with beans and potatoes. Along the coast are numerous small coves, or harbours, which afford a safe retreat to the boats employed in the Zetland islands. Here is a remarkable cave, by which the sea flows for a considerable distance into the interior of the island, under the rocks. The beach, being admirably adapted for drying fish, is occupied by a number of houles appropriated to that purpose. History of the Zetland Islands, by Dr. A.Edmonston. Sinclair's Statistical Account, vol. xx.

PAPA, or PAPAY-Stronfiay, one of the Orkney islands, off the coast of Scotland, is situated on the north-east quarter of the isle of Stronfiay. Though little more than three miles in circumference, its surface is remarkably level, and equally beautiful as fertile. Here are the ruins of two ancient chapels, one dedicated to St. Bride, and the other to St. Nicholas. On an eminence called Earl's know, are several graves, and some vestiges of buildings which formerly belonged to one of the ancient earls of Orkney. History of the Orkney Islands, by Rev. Dr. Barry, 3d edit. 1808, by the Rev. James Headrick.

PAPA, or PAPAY-Weeflay, one of the Orkney islands of Scotland, lies about one mile to the north of Weeflay. It is nearly four miles long, and one broad; and fearfully yields in fertility of soil to any district in Scotland. At its south-western extremity is a beautiful lake of fresh water, the centre of which is adorned with an islet, where are the ruins of the once noble chapel of St. Tredwell, to whom superflition, till lately, attributed many wonderful and miraculous works. History of the Orkney Islands, by Dr. Barry, 3d edit. 1808.

PAPACY. See See Popedom.

PAPAGAY, or PAPAGAY, in Ornithology. See Psittacus.

PAPAGAYO, in Geography, a river of Mexico, which runs into the Pacific ocean, 35 miles N. of Acapulco, N. lat. 17 40'. W. long. 101 46'.

PAPAGAYO Bay, or Parrot Bay, a bay on the North Pacific ocean, and on the W. side of the isthmus of Nicaragua, at a small distance from the western part of the lake of Nicaragua. N. lat. 11 10'. W. long. 87 36'.

PAPAKUNK, a town of New York, on the Papackton-N. lat. 42 51'. W. long. 74 38'.

PAPAL CROWN is a deep cap, or mitre of cloth of gold, encompassed with three coronets, or circles of gold, adorned with flowers; and the whole enriched with precious stones; having a globe at top, finished with a crofs. See Crown.

PAPALIVELA, in Geography, a town of South America, in the province of Quito; 50 miles N.W. of Arichidona.
PAPALOAPAIN, a river of Mexico, called Alvarado, or Alvarado; which fee.

PAPALQUIAN, a town of Mexico, in New Biscay; 130 miles N.W. of Durango.

PAPAMOW, a town of Hindostan; 8 miles N. of Allahabad.

PAPAN, in Ornithology, the name given by the inhabitants of the Philippine islands, to a species of duck common in their lakes and marishes. This is very large and beautiful, and is called by father Camelli anas regia; or the royal duck; it is not so common, however, as the little kind which they call solaygar.

PAPANAUD, in Geography, a town of Hindostan, in the Carnatic; 25 miles S.S.E. of Tanjore.

PAPAS, a lake of South America; 40 miles S. of Popayan.

PAPAS Alassi, or Papadonina, or Prince's Islands, a cluster of small islands in the N.E. part of the island of Maroma, at the entrance of the Straits of Constanitnople; 8 miles S. of Constanitnople. The islands known under the name of Prince's islands, are nine in number, four large, and five small. The frill is called "Prota"; the second, "Antigama;" the third, "Chalkia;" and the fourth, "Prinkipos;" to the fourth of the latter lies the little island, called "Rabbit" island; to the west are two small islands, one of which is known by the name of "Oxya," and the other by that of "Plata;" the two others are nameless rocks. The principal of these islands is Prinkipos; which fee.

PAPASILI, a town of European Turkey, in Romania; 32 miles N. of Adrianople.

PAPAVEER, in Botany, the Poppy, so called, according to the most learned etymologists, because it was commonly mixed with the pop, papa, given to children, in order to procure sleep. This plant and its name have ever been associated with the idea of sleep in most languages, in poetry and philosophy, in history and fable. Its juice is still the bell opiate known, and in the most general use.—Linn. Gen. 263; Schreb. 359; Willk. Sp. Pl. v. 2. 1144; Mart. Mill. Dict. v. 3; Sm. Fl. Brit. 565; Prodr. Fl. Græc. Sibth. v. 1. 358; Ait. Hort. Kew. ed. 2. v. 3. 288; Juss. 236; Tourn. t. 119, 123; Lamarck Illustr. t. 451; Gerth. t. 60;—Clas and order, Polyanthra Monogynia. Nat. Ord. Rhaeesae. Linn. Papaveraceae. Juss.

Gen. Ch. Cal. Perianth inferior, ovate, emarginate, of two nearly oval, concave, obtuse, immediately deciduous leaves. Cor. Petals four, roundish, flat, spreading, large, contracted at the base, alternately smaller. Stam. Filaments numerous, capillary, inserted into the receptacle, much shorter than the corolla; anthers oblong, compressed, erect, obtuse. Petal. German superior, fleshy, large, roundish; style none; stigmatic depressed, peltate, flat, radiated. Peric. Capsule oval, or somewhat oblong, crowned with the large, flat, permanent stigma, of one cell, though imperfectly divided into many, burrting at the top by numerous orices under the stigma. Seeds numerous, minute. Receptacles longitudinal folds, attached to the inside of the capsule, equal in number to the rays of the stigma.

Obf. The seed-veil differs in shape in different species, from globose to oblong, and the rays of the stigma differ greatly in number: according to the shape of the capsule appropriated to each species, is more or less oblong and narrow. The species are commodiously divided into two sections, distinguished by the roughness or smoothness of the capsule.

PAP

Sect. 1. Capsules brylly.

1. P. hybridum. Mongrel Poppy. Linn. Sp. Pl. 725. Engl Bot. t. 43. (Argemone capitula torulo; Ger. em. 373.)—Capsule nearly globular, furrowed, brily. Stem leafy, many-flowered.—Native of fields, on a light soil, in the more temperate or southern parts of Europe; rare in England, though we have several times gathered it sparingly about Norwich. The root is annual. Stem branched, about a foot high, leafy, covered with close-pressed bristles. Leaves dark green, alternate, doubly pinnatifid, in many narrow segments, brily like the stem. Flowers terminal, solitary, erect, smaller than usual in the genus. Calyx rough with tawny hairs. Petals deep red, with more or less of a violet spot at the base. Stamen violet. Pollen bright blue. Capsule the size of a filberd, deeply channelled, obovate, belet with adhering prickles. The whole herb partakes of the facted and disagreeable flavour common to its genus, but is feerily milky.

2. P. Argemone. Long rough-headed Poppy. Linn. Sp. Pl. 725. Curt. Lond. falc. 5. t. 38. Engl Bot. t. 643. Fl. Dan. t. 987. (Argemone capitula longior; Ger. em. 375.)—Capsules club-shaped, brily. Stem leafy, many-flowered.—Native of sandy fields, in various parts of Europe, flowering in June or July. Much like the last, but the segments of the leaves are generally broader, and the whole herb, as well as the flowers, is lighter. The bristles of the stem are not so closely applied. Stamen very broad at their summit, each anther being supported by a little partial flake. Stigma with only four or five rays, the capsule being slender, obscurely five-faded, by no means channelled like the former, nor is it so brily, except in the upper part. The flowers have been found double in England, but such a circumstance is rare. Both these species occur but sparingly, in a feathered manner, and never in the abundance of the common P. rhoeas hereafter described, let the soil and situation be ever fo favourable.

3. P. Alpinaun. Alpine Poppy. Linn. Sp. Pl. 725. Jacy. Aurfr. t. 83. Seguer. Veron. 416 t. 4 t. 4.—Capsule brylly. Stalk radical, single-flowered, brily, leafless. Leaves doubly pinnate.—Native of the mountains of Switzerland, Austria, the rocks of mount Baldus, Dauphiny, and the Pyrenees. Miller appears to have cultivated this species in 1759, but it is now rarely to be seen with us. Though tolerably hardy, it thrives best in a frame, flowering in May or June. Root perennial, torted. Leaves numerous, all radical, flat, thinly or significantly pinnatifid, the segments linear or obovate, deciduous, entire, rather glaucous, smooth or slightly hairy. Flower-flakes few, ascending, simple, five or six inches high, brily, with close hairs, leafless, each bearing one flower, shunt an inch and half broad, usually pale yellow, sometimes, according to Villars, reddish or whitish; Jacobin says it is constantly pure white in Austria. The anthers are always yellow. Capsule ovate, brily, with four, five, or six angles in the upper part, and as many rays to the stigma.

4. P. nudicaule. Naked-flaked Poppy. Linn. Sp. Pl. 725. Fl. Dan. t. 49. (P. nudicaule, flore flavo odorato; Dill. Elth. 322 t. 224.)—Stalk radical, single-flowered, brily, leafless. Leaves simple, pinnatifid.—Native of Norway and Siberia. More frequently seen in our gardens than the last, being a hardy biennial, flowering in June and July. The leaves differ from the last in being simply pinnatifid, and their segments much broader. The flake is a foot high. Flower of a most delicate sulphur colour, but with a disagreeable smell, at least in our opinion, Dillenius nevertheless compares it to the scent of a Jonquil.
and says it is chiefly perceptible in a morning and evening. Linnaeus considered the two species last described as too nearly related to each other, but they seem distinct, notwithstanding the agreement in their habit, the hairy calyx, and ovate bristly petal-capsule. The perfect is said to have occasionally a white flower.

Sec. 2. Capsules smooth.

Varieties with more or less double flowers, white, red or parti-coloured, are common in gardens, but if suffered to fertilize their seeds without a careful renewal of soil, their beauties and distinctions are transient in their offspring. The heads or capsules of this species are recommended as an opiate by Dioscorides, and its use is still retained; especially a red syrup is made of the flowers, which serves as a mild soporific for children.

6. P. dubium. Long smooth-headed Poppy. Linn. Sp. Pl. 726. Curt. Lond. fasc. 5. t. 37. Engl. Bot. t. 644. Fl. Dan. v. 902.—Capsules smooth, oblong. Stem many-flowered, hairy; the hairs on the flower-flasks close-preffed. Leaves doubly pinnatifid.—Native of fields in various parts of Europe, chiefly on a sandy soil, and not very abundantly, flowering in June and July. This approaches the last very nearly in habit, but the flowers are of a paler hue, the capsule slender, furrowed, with a stigma of only six or eight rays, and the bristles on the flower-flasks are closely preffed to the flask, not spreading as in P. Rhexas. Crantz thought this species a variety of P. Argemone, but there seems little reason for such an opinion. P. dubium, Jacq. Auftr. t. 25, if correctly drawn, is very puzzling. The bristles on the flower-flasks are represented deflexed, which is quite the reverse of our Linnaean specimen, as well as of the English ones; the petals are white, with a violet spot.

7. P. somniferum. White, or Garden Poppy. Linn. Sp. Pl. 726. Woodv. Med. Bot. 185. Engl. Bot. t. 2145. Builliard. t. 57. (P. fylletitre; Ger. em. 370.)—Calyx and capsules smooth. Leaves embracing the stem, glaucous, cut. Stem smooth in the lower part; rough with spreading hairs above.—Native of fields and waste ground in the south of Europe; rare in England. The Rev. Mr. White observed it to be truly wild on the sandy banks of the ten ditches in Marshfield. In gardens it is well known, as a hardy annual, sporting in the forms and colours of its rich beautiful double petals, but easily returning, if neglected, to its single falcate, and pale purple or white hue, having a violet flamin on each petal. The largest heads, for medical use, are obtained from the single-flowered kind, cultivated in warm countries on a fertile soil. Thse being wounded as they grow, yield a milky juice, which by drying becomes opium. The herb is erect, four feet or more in height, branched, very glaucous, with broad, obtuse, simple, lobed and crenate, wavy leaves, clasping the stem, which in its upper part only is naturally clothed with coarse spreading hairs. The buds droop, but the flowers are erect, with a faint unpleasant scent, a smooth calyx, large petals, and a nearly globose capsule, crowned with a stigma of many rays. The seeds are either dark brown or white, of a pleasant sweet flavour.

8. P. filiflorum. Hairy Red Poppy. Sm. Prod. Fl. Graec. Sibh. v. 1. 360. Fl. Graec. t. 492, unpublished.—Capsules smooth. Stem many-flowered, clothed with spreading hairs. Leaves clasping the stem, cut, hairy all over. Gathered, by Dr. J. Sibthorp, about the Bithynian Olympus. The root of this new and handsome species appears to be perennial. Herb about the size of the last, but of a bright green, not glaucous, and clothed with bristly hoary hairs, which spread horizontally on the stem, where they are very abundant, as well as on the flower-flasks, where they are sparingly scattered. The leaves are simple, broad, heart-shaped, and clasping the stem bluntly lobed and cut, hairy, with strong ribs and veins; the radical ones narrower, oblong, and stalked. Flowers about the size of the last, and indeed larger than the wild P. somniferum of Greece, drooping in the bud, then erect. Calyx bristly. Petals of a pale tawny scarlet, or full orange, with white claws. Anthers yellow. German obvate, smooth, glaucous, with fix ribs, and the same number of broad rays in the stigma.

9. P. virgatum. Wand-like Poppy. (P. orientale, teutneri incium, ad caulem floridum; Tourn. Cor. 17.)—Capsules smooth. Stem straight, paniced, many-flowered, rough with spreading bristles. Leaves pinnate, cut, bristly.—Native of Armenia. We described it formerly from Tournefort’s herbarium at Paris. The stem is straight and Riff, paniced, bearing a great number of flowers, and clothed with spreading rigid bristles. Radical leaves numerous, pinnate, cut, hipped, especially their ribs, all the points callos, and tipped with a bristle, as in those of P. orientale, which they in all respects much resemble. Flower-flasks fcattered, each bearing one, two, or three flowers. Calyx bristly. Petals red. German roundish, smooth. This species differs from the following one, having a straight, paniced, many-flowered stem, the bristles covering which are horizontal, not clofe-preffed.

10. P. orientale. Great Oriental Poppy. Linn. Sp. Pl. 727. Curt. Mag. t. 57. (P. orientale hirtiflumum, flore magni; Tourn. Cor. 17. Voy. v. 2. 118. t. 118. Comm. Rar. t. 34.)—Capsules smooth. Stem single-flowered, leafy, rough, with close-preffed bristles. Leaves pinnate, ferrated, bristly.—Native of the Levant. Tournefort found it near Erzerum, in Armenia, flowering in June. He introduced it into the gardens of Holland and France, and it has been, for about a century, a hardy perennial in our parterres, flowering early in summer, and very conspicuous for the great size, and peculiarly brilliant scarlet colour of its flowers, which are too dazzling to be looked on in the sunshine. They are nearly a span wide, with dark florets, and sometimes a black spot on each petal. German globosum, quite smooth and even, without ribs. Rays of the stigma fifteen, peculiarly dilated. The root creeps moderately, by which the plant is increased, for it scarcely ever ripens seed with us. Stems about two feet high, simple, leafy, round, densly clothed with erect, rigid, pungent, close-preffed bristles. Leaves molt numerous from the root, a foot long, dark green, harsh and bristly, pinnate, with ferrated decurrent segments. The juice of the plant is hot and acrid, yet Tournefort says the Turks and Armenians eat the unripe heads by way of luxury. They extract no opium from this species;
species; but perhaps the similarity of its flavour and effects, to that great foother of their cares, may cause it to be thus employed.

11. *P. fugax*. Small Fugacious Poppy. Lamark Dict. v. 5. 115.—Capsules smooth, orbicular. Stem panicked, many-flowered. Flowers short, petal involute, petals minut. Leaves pinnatifid, serrated, hispid. Brought by Michaux from Peru. It flowered in May 1789, in the royal garden at Paris. Poiret described it from Lamark's herbarium, and we know this species merely from his description, having seen neither specimen nor figure. He says it is distinguished by the stem, forming at the summit an ample panicle of many very small flowers, which last but a few hours. Each flower is slender, flat, serrated, smooth, about eighteen inches high, simple, except at the top. Leaves scattered, unifoliate, and in some of them, not unlike those of *P. orientalis*, but less deeply pinnatifid, no pinnate, furnished with a few long flat serrated teeth, the segments or teeth, more or less distant, each terminated by a long bristle. Petals pale red, very small in comparison with the rest of the genus, and extremely fugacious. Capsule small, globose, smooth, crowned with a conical, obtuse stigma, of four or five rays.

12. *P. cambricum*. Yellow Welsh Poppy. Linn. Sp. Pl. 727. Engl. Bot. t. 66. (P. cambricum perenne, flore fulguro, argenteo, fuscum, stem Diit. Elth. 300. t. 222. Argemone lutea cambrica; Moris. f. 3. t. 14. f. 12.)—Capsules smooth, oblong, beaked. Stem nearly smooth, bearing several flowers. Leaves pinnate, cut.—This species, one of the most elegant of our native plants, seems peculiar to rocky shady situations in Wales and Westmoreland; for the reference to Baushin's Prodromus, on which Linnæus grounds his assertion of its being found on the Pyrenees, appears to belong either to the *alpinum* or *nudicaule*. It is perennial, flowering in June; and may be cultivated in the moist shady parts of a garden, where, though each root does not, in general, last many years, the seeds fattening themselves in the undisturbed soil, will from time to time produce new plants. The stem is twelve or eighteen inches high, leafy, somewhat branched, clothed with a few rather upright hairs. Leaves tender and delicate, of a pale but pleasant green, pinnate, their common leaflets winged; their leaflets ovate, acute, cut or lobed, almost entirely smooth, glaucous underneath, each above an inch long. Flowers terminating the few branches, solitary, on long leaflets, about the size of *P. dubium*, but of a beautiful lemon colour, with stems like those of *M. cocc'inea*, or *M. micombricum*. The flowers, most people consider, are the Bergamot Pel. The stigma has about five rays, and is elevated on a sort of beak, resembling a style, above the ovate, smooth, five-ribbed capsule. The calyx is hairy. The herb when wounded discharges a yellow fluid, not unlike the juice of the common Cæliandine, to which indeed this plant is so nearly allied in botanical affinity, that such a coincidence is not surprising. The fame may be said of the American Sanguinaria.

*Papaver*, in *Gardening*, contains plants of the hardy, herbaceous, fibrous-rooted, annual, and perennial kinds, of which the species cultivated are, the white poppy (*P. fomifera*); the corn, or red poppy (*P. rhoeas*); the Welsh poppy (*P. cambricum*); and the Oriental poppy (*P. orientalis*). There are several varieties of the first sort, differing in the colour and multiplicity of their petals, which are preferred in gardens for ornament: the single-flowered sort is chiefly cultivated for use.

The chief of the common black variety of poppy has flarks about three feet high, smooth, and dividing into several branches; the leaves are large, smooth, deeply cut or jagged on their edges, and embracing; the petals purple, with dark bottoms; succeeded by oval, smooth capsules filled with black seeds, which are sold under the name of *macaw-feed*.

And of this there are many sub-varieties; as with large double flowers, variegated of several colours; with red and white, purple and white, and some finely spotted like carnations.

There are few plants whose flowers are so handsome; but as they have an offensive scent, and are of a short duration, they are not in general much regarded.

In the second sort there is a variety with an oval, black, shining spot, at the base of each petal, from which many beautiful garden sub-varieties are produced, which have double flowers, white, red bordered with white, and variegated.

The fourth has a few varieties, differing in the colour of the flowers; and it is said that the flower is sometimes double, but with us it is always single.

Method of Culture.—All the different sorts may be increased by seeds, and the two last sorts also by halves and planting out the roots.

The seeds should be sown in the autumn, or very early in the spring, but the former is the better season, either in the places where the plants are to grow, or in beds, to be afterwards planted out. The first is probably the best method, as these plants do not bear removing well.

When they are cultivated for ornament, seed of the finest double sorts should be carefully preserved and made late of, and be sown in patches.

In the practice of Mr. Ball, in cultivating the first sort for the purpose of preparing opium from it, "the seed was sown at the end of February, and again the second week in March, in beds three feet and a half wide, well prepared with good rotten dung, and often turned or ploughed, in order to mix it well, and have it fine, either in small drills, three in each bed, or broadcast; in both cases, thinning out the plants to the distance of a foot from each other, when about two inches high, keeping them free from weeds." They produced from four to ten heads each, and showed large flowers of different colours. "With an instrument something like a rake, but with three teeth, the drills may be made at once." He found that the plants did not bear transplanting; as out of 4000 which he transplanted, not one plant came to perfection.

The roots of the two last sorts may be divided in the autumn or spring, but the first period is the better, leaving some root fibres to each portion, planting them out where they are to remain, as soon afterwards as possible.

In all the sorts the plants only require afterwards to be kept free from weeds, and those raised from seed properly thinned out.

They all afford ornament and variety in the clumps, borders, and other parts of pleasure grounds and gardens; and the first sort may sometimes be grown to advantage for the purpose of having the juice which it affords made into opium.

*Papaveraceæ*, in *Botany*, a natural order of plants, the 62d in Jussieu's system, the 2d of its 13th class. This order owes its name to *Papaver*, the Poppy, the principal, and best known, of the genera that compose it. For the characters of this 13th class, see *Gerania*.

The *Papaveraceæ* are thus defined. Calyx mostly of two leaves, soon falling off. Petals generally four. Stamina either definite or indefinite. Germen one; style often wanting; stigma divided. Fruit either capsular or filiform, for the most part of a single cell, and generally with many seeds, which are affixed to lateral receptacles, each seed half covered with a membranous integument. Stem herbaceous, scarcely ever
ever shrubby. Leaves alternate. Juice in some instances coloured. See Papaver.

Papaver. See Carica.

Papaw. See Carica.

Papaw-tree of North America. See Annona.

Papaws, in Geography, a name given in the West Indies to the Negroes of Whidah, or Fida, in Africa. These are unquestionably the most docile and best-dooped slaves that are imported from any part of Africa. Without the fierce and savage manners of the Koromantyn Negroes, they are also happily exempt from the timid and despising temper of the Eboes. The cheerful acquiescence with which these people apply to the labours of the field, and their constitutional aptitude for such employment, are, without doubt, from the great attention paid to agriculture in their native country. Bofman speaks with rapture of the improved state of the soil, the number of villages, and the industry, riches, and obliging manners of the natives. He observes, however, that they are much greater thieves than those of the Gold Coast, and very unlike them in another respect, namely, in the dread of pain and the apprehension of death. They are, he says, so very apprehensive of death, that they are unwilling to hear it mentioned, for fear that alone should haunt their end; and no man dares to speak of death in the presence of the king or any great man, under the penalty of suffering it himself, as a punishment for his presumption. He adds, that they are addicted to gaming beyond any people of Africa. These propenities, it is said, are observable in the character of the Papaws in a state of slavery in the West Indies. That punishment which excites the Koromantyn to rebel, and drives the Eboe negroes to suicide, is received by the Papaws as the chastisement of legal authority, to which it is their duty to submit patiently. The cafe seems to be, that the generality of these people are in a state of absolute slavery in Africa, and having been habituated to a life of labour, they submit to a change of situation with little reluctance. Many of the Whidah negroes are found to be circumcised. Whether it be a religious ceremony common to all the tribes that go under the appellation of Papaws, has not been ascertained. It is practised universally by the “Nagoes;” a people that speak the Whidah language; but some Negroes on this part of the coast difavow the practice.

Papaya, in Botany, an Indian name, retained by Tournefort, Plumier, and Joffieu, for the Carica of Linneus, or Papaw-tree. See Carica.

Papazli, in Geography, a town of European Turkey, in Romania; 12 miles E.S.E. of Filippopoli.

Papenberg, an island of Japan, resembling a mountain, surrounded by the sea. The Dutch ships have been accustomed to anchor here for wind, when they wish to return to Batavia. Its Japanese name is "Takaboko," or "Takajama."

Papenberg Islands, five small islands in the East Indian sea. S. lat. 6° 54'. E. long. 131° 58'.

PAPER, a thin flexible leaf, usually white, artificially prepared of some vegetable substance, chiefly to write upon with ink.

The word is formed from the Greek μεταφερείς, pappus, the name of an Egyptian plant, called also βελός, biblos, on which the ancients used to write.

Various are the materials on which mankind, in different ages and countries, have contrived to write their sentiments; as on stones, bricks, the leaves of herbs and trees, and their rinds or barks; also on tables of wood, wax, and ivory; to which may be added plates of lead, linen rolls, &c. At length the Egyptian papyrus was invented; then parchment, then cotton paper; and, lastly, the common, or linen paper.

In some places and ages they have even written on the skins of fishes; in others on the intestines of serpents; and in others on the backs of tortoises. (Mabill. de Re Diplom. lib. i. cap. 8. Fabric. Biblioth. Nat. cap. 21, &c.) There are few forts of plants but have at some time been used for paper and books: and hence the several terms, biblos, codex, liber, folium, tabula, tillura, phylura, scheda, &c, which express the several parts on which they were written: and though in Europe all these disappeared upon their introduction of the papyrus and parchment, yet in some other countries the use of divers of them obtains to this day. In Ceylon, for instance, they write on the leaves of the talipot. And the Brahmin MSS. in the Tulinga language, sent to Oxford from Fort St. George, are written on leaves of the ampana, or palm Malabarica: Hermannus gives an account of a monfrorous palm-tree called codda pana, or palma montana Malabarica, which, about the thirty-fifth year of its age, rife to be fifty or eveny feet high, with plicated leaves nearly round, twenty feet broad; with which they.commonly cover their houses, and on which they also write, part of one leaf sufficing to make a moderate book. They write between the folds, making the characters through the outer cuticle. Knox. Hist. Ceyl. lib. iii. Le Clerc. Bibl. Univ. tom. xxiii. p. 242. Phil. Trans. N° 246. p. 472; seq. Vide Hort. Ind. Malab. p. 3. Phil. Trans. N° 145. p. 108.

In the Maldivian islands, the natives are said to write on the leaves of a tree called macaracuon, which are a fathom and a half long, and about a foot broad. And in divers parts of the East Indies, the leaves of the mula arbor, or plantain-tree, dried in the sun, served for the same use, till of late that the French have taught them the use of European paper. Ray, in fine, enumerates divers kinds of Indian and American trees which bear leaves proper to be used as paper; particularly one called xagua, which has something in it extraordinary; its leaves are fo large, and of fo clofe a texture, that they cover a man from top to toe, and shelter him from the rain, and other inclemencies of the weather, like a cloak; and from the innermost substance of those leaves, a paper is taken; being a white and fine membrane like the skin of an egg, as large as a skin of our vellum or parchment, and nothing inferior for beauty and goodnes to the best of our papers. Vide Savar. D. de Comm. tom. ii. p. 967. Vide Ray Hist. Plantar. tom. ii. lib. 32. Nouv. Rep. Let. tom. xii. p. 561.

Paper is chiefly made among us of linen, or hempen rags, beaten
beaten to a pulp in water, and moulded into square sheets, of the thickness required. But it may also be made of nettles, hay, turnips, parsnips, colewort-leaves, abelium, or any thing that is fibrous; nay, it may be made of white woolen rags: though this would not serve for writing, because of the hairiness. The Chinese paper is so fine, that many of the Europeans have thought it was made of silk; not considering, says Du Halde, that silk cannot be beat into such a pate, as is necessary to make paper: but it is to be observed, that the same author afterwards speaks of a paper, the same - component, made of the bills of silk worms; and the like, we are assured by others is done at Cathay. Hought. Colleet. N. 360. tom. ii. p. 418. seq. De- script. of China, p. 365. seq. Vide Buffleq. Legat. Turc. Epit. iv. p. 329.

Paper, with regard to the manner of making it, and the materials employed therein, is reducible to divers kinds: as the Egyptian, European, and Chinese paper: we also find mention of cotton paper, bark-paper, and abelium or incom- bustible paper.

Paper, Egyptian, is that which was principally used among the ancients: it was made of a rush called papyrus, or bilibus, growing Chiefly in Egypt, about the banks of the Nile: though it was also found in India; and Guiliandinus assures us, he saw in Chaldæa, at the confluence of the Tigris and Euphrates, large fens, in which, with his own hands he plucked a papyrus differing in nothing from that of the Nile. Strabo likewise speaks of a fort of papyrus growing in Italy; but we do not find this was ever used for making paper.

The description given by Pliny of the papyrus, or paperreed, is somewhat obscure. Its root, according to him, is of the thickness of a man’s arm, and ten cubits long; from this arise a great number of triangular stalks six or seven cubits high, each thick enough to be easily spanned; its leaves are long like those of the bull-rush; its flowers flaminous, ranged in clusters at the extremities of the stalks; its roots woody and knotty like those of rushes, and its taste and smell near akin to those of the cyperus, under which genus Linnæus has classed the papyrus. (See Cyperus.) Vide Plin. Hift. Nat. lib. xiii. cap. 11. Vide Theophr. Hift. Plant. lib. iv. cap. 9. and Delecamp, who gives us a figure of it, Hist. lib. xviii. p. 1883. See also Bauhin. lib. xviii. cap. 186, who, with Gefner, makes it a species of Cyperus. Grew Muf. Reg. Societ. p. 2. feft. 2. p. 225, seq. Maffei Itor. Diplom. Bibl. Ital. tom. ii. p. 246.

Befides paper, they made fials, ropes, and other naval rigging; as also mats, blankets, clothes, and even slips, of the stalk of the papyrus. Moles, we are told, when a child, was exposed on the banks of the Nile, in aborderuloptery, i.e. in a basket of papyrus. The Egyptian priests wore shoes of papyrus.

Guiliandinus, a Proflam physician before mentioned, has a celebrated work expressly on the ancient papyrus, by way of commentary on three chapters of Pliny, in which is amypl, and with great learning, explained all that relates to this subject; yet Scaliger has written a severe critique on it, in which some inaccuracies of Guiliandinus are pointed out; but this has not hindered Kirchmayer from adopting almost Guiliandinus’s whole book in his dissertation on the papyrus. Add, that the most ingenious and learned count Scipio Maffei has lately vindicated Guiliandinus against the exceptions of Scaliger, as well as of Volatus and Hardouin. (Vide Ifor. Diplomat. lib. ii. Bibl. Ital. tom. ii. p. 248. Melch. Guiliandini Papyrus, h. e. Commentarius in tria C. Plinii Majoris de Papyrus capita, fc. lib. xiii. cap. 11, 12, 13, first published at Venice in 1572, and afterwards at Amberg, in 1613; by Salmeuth. It seems, Guiliandinus intended a commentary on the whole of Pliny’s Natural History; but this small part, not exceeding a moderate page, taking him up full six months, it is no wonder he was discouraged from proceeding with the rest. In these three chapters he has restored about twenty passagges in the text of Pliny, not merely from his own conjecture, or the help of MSS. but from the nature of the things described, and the testimony of authors of the first rank: besides that, he had been upon the spot, where formerly the papyrus was manufactured, and had carefully examined all the ancient Greek and Latin authors who speak of it.

Jof. Jufl. Scaligeri Animadversiones in Melchioris Guiliandini Commentarium in tria C. Plinii capita, lib. xiii. Historie Mundi five Naturalis, quibus agit de l’Papyrus, firb published in the Lectiones Bibliothecarum Memoriales, of Rudolphus Capellus, at Hamburg, in 1682, where he follows Guiliandinus step by step, finds as many faults in him as his father had done in Cardan, and uses him altogether as coarsely; every where pointing out his literary millakes, and labouring to shew, that instead of restoring Pliny, he has often mifaken and corrupted him. M. Seb. Kirchmaierii Uffenhainemis Franci Diftantio Philologiae de Papyrus veterum, Wittebergæ 1666, 4to.

He had done better service, if, besides Guiliandinus, he had consulted others, and particularly Scaliger. But as he choe to follow one rather than many, and that too as the blind follow their guides, his fate has been much the same.

The origin of the art of making paper of the papyrus is very obscure; no doubt it was first discovered in Egypt. It is fixed more particularly to the city Memphis, Orig. lib. vi. cap. 10. in which he seems to be countenanced by Lucan, where he says,

"Nondum flamineas Memphiis contexere biblos"

Novarat—— Pharral. lib. iii. v. 222.

The era of this invention is warmly disputed: Varro, the most learned of the Romans, fixed it to the time of Alexander the Great, after the building of the city of Alexandria by that conqueror; but several objections, of no small weight, are brought against this decision. Pliny recites a passage out of a very ancient annalift, one Caius Hemina, wherein mention is made of paper books found in Numa’s tomb, five hundred and thirty-five years after his death, which had been buried with him: now Numa was prior to Alexander by above three hundred years. Guiliandinus, in effect, maintains, with great erudition, that the name and use of the papyrus were known to the Greeks long before Alexander conquered Egypt; and that the words βαβαλις and βαβιλων occur in their received figuration in authors prior to, or at least older than, Alexander; particularly Anacreon, Alexus, Plato the comician, Aristomenes, Cartinus, Antiphanes, Plato the philosopher, Eschylus, and Arifloit. And whereas some speak of a kind of unknown pseudo-biblos, in use before the discovery of the true fort, he argues, on the contrary, that the biblos mentioned by those authors, prior to the conquest of Alexander, appears from Herodotus, Theophratus, and others, to be the very same plant with the biblos, or papyrus, of which paper was afterwards made: even Homer and Hefiod, the most ancient Greek poets, and who by Herodotus’s testimony lived about four hundred years before himself, appear to have been no strangers to the papyrus, since they both make express mention of it. Vide Plin. lib. xiii. cap. 13. Guiliand. Papyrus. Membr. 2. Reim. Idea Syll. Antiq. Liter. p. 285, seq. Vide Kirchm. Diff. de Papyr. art. 11, feft. 2.
PAPER.

To this it may be answered, that supposing the plant papyrus known in Greece long before Alexander's conquest of Egypt; it no more follows, that they had then the use of paper; than it follows, that men had wine immediately on the discovery of the vine.

In reality, Guilielmus produces testimonies, from Anacreon and Alceus, in which the papyrus is employed for binding, and not for paper; add, that he ill translates Euthyphron, edusmi, since it was here is the torch itself. Nor does the poet say it was made of papyrus, but tied up with it. Vide Scalig. lib. cit. Reimm. ubi supra, p. 320, seq.

Some have even doubted whether the art of manufacturing the papyrus was so ancient as Alexander's time; chiefly on this ground, that, for two hundred years after Alexander, men wrote on skins, and on the banks of trees: but this is nowise conclusive. The scarcity of the new manufacture may account for it: for some ages afterwards, even as low as Tiberius, we read of such a scarcity of paper, that its use, even in contracts, was dispensed with by a decree of the senate, and the opinion of the judges. The same consideration may bring farther: paper might have been known in Egypt, Judaea, Syria, and Asia on this side Taurus, long before the birth of Alexander, though not in common use; but it might be later before the Europeans received it; and probably it was by means of Alexander's conquest that it first became publicly known there.

When the manufacture of the Egyptian paper ceased, it is another question; for, at present, the paper technia Egyptian may be reckoned among those arts that are lost. Eulathius, the learned commentator on Homer, te lift, that even in his time, vide in 1700, it was put; Mabillon, indeed, maintains, that it continued till the eleventh century after Christ; and cites one Frigidus, a monkish poet of the tenth century, as speaking of it as being of the age before his, that is, in the ninth; and that it continued longer, the fame Mabillon endeavours to evince, from several papal bulls wrote on it, as low as the eleventh century. Vide Euf- tath. ad Homer. Odyl. 2. Voff. de Art. Gram. lib. i. c. 37. Vide Mabill. De Re Diplomat. lib. i. cap. viii. 6. feq. Reimm. Idea Synt. Antig. Liter. p. 321.

Maffei, on the other hand, maintains, with more probability, that the papyrus was generally diffuse before the fifth century; for that we find no authentic records, written on it, dated since that time; whereas bulls of popes, cited by Mabillon, appearing rather to be written on cotton paper. But this, we may observe, relates only to the general and legal use of the papyrus. For that it should have continued to be made by particular persons several hundred years after it first began to give way, is not to be wondered at. Vide Maffei Itor. Diplomat. loc. cit. Bibl. Ital. tom. ii. p. 251.

In reality, a more commodious sort of paper, made of cotton, having been invented some ages before in the East, and coming to be introduced into Europe, seems to have brought the papyrus into disuse. To which the continual wars with the Saracens, by which the traffic to Alexandria was rendered precarious, might possibly not a little contribute.

Yet several books, written on leaves of the papyrus, have even continued to our days; Mabillon says, he had one of them; and adds, that there was another in the Petavian library, being a volume in small folio, containing several sermons of St. Augustine; he also mentions a third, containing that father's epistles, formerly belonging to the church of Narbonne, and afterwards in the custody of madame de Phirmacou; besides the homilies of Avitus, bishop of Vienne, and divers diplomas or charters, all written on the papyrus, which appear not to be less than eleven hundred years old. But the decisions of this learned father concerning MSS., notwithstanding all his diplomatic skill so highly boasted of, are not always infallible; with his taking the MS. of St. Mark's Gospel, at Venice, to be written on the Egyptian papyrus; and that of Josephus, at Milan, not to be so. Maffei shows, on the contrary, that the former is cotton paper; and that the latter appears, at first sight, to be Egyptian; but not the Venetian MS. is very old; but it has been so much used, that its leaves are, as it were, transformed into the original pape from whence they are made. Vide Mabill. Suppl. ad Libr. de Re Diplomat. Journ. des Scav. tomo. xxxii. p. ii. p. 992. Maffei, lib. cit. Bibl. tom. ii. p. 252. And Montfaucon. Paleogr. Græc. p. 14.

PAPER, Manner of making the Egyptian. They began with lopping off the two extremities of the papyrus, viz. the head and root, as of no use in this manufacture; the remaining item they slit lengthwise into two equal parts, and from each of these they stripped the thin fcaly coats, or pellicles, of which it was composed, with the point of a pen-knife. The innermost of these pellicles were looked on as the best, and these nearest the rod or bark the worst; they were kept apart accordingly, and constituted different sorts of paper.

These pellicles are called, in Pliny, by twelve different names; viz. philura, ramentum, scheda, cutis, plagula, corium, tenia, subtagnum, flatumen, pagina, tabula and papyrus.

The generality of critics, in lieu of a pen-knife, employ a needle to separate the pellicles; in which they are warranted by the common text of Pliny, "Preparatur ex eo charte, diviso acu in praelutus, fec quam latifsimas philiuras." But Guilielmus makes a correction here; he had found, by experiment, that the pellicles of papyrus cannot be separated by a needle; but that a very sharp knife is required; for which reason, instead of diviso acu, he reads diviso scapo. In which he is followed by Maffei, though Hardouin, Vosius, Pitifus, and others, retain the ancient reading. Vide Guiliand. Papyr. Membr. tomo. ii. p. 37; Maffei Itor. Diplom. ap. Bibl. Ital. tom. ii. p. 249, seq. Voff. De Art. Grammat. lib. i. cap. 37; Pitie. L. Ant. tom. i. p. 413, voc. Charta. Hardouin. ad Plin. lib. xiii. cap. 12.

As the pellicles were taken off, they extended them on a table; then two or more of them were laid over each other at random, so as that their fibres made right angles; in this state they were glued together by the muddy waters of the Nile. These, being afterwards pressed to get out the water, then dried and laid flat and smoothed by beating them with a mallet, constituted paper: which they sometimes polished farther by rubbing it with an hemisphere of glafs or the like.

In other countries where the waters of the Nile were not to be had, the pellicles were fastened together with a paste made of the finest wheat-flour, mixed with hot water, and a sprinkling of vinegar.

The ingenious and learned count de Caylus, in his account of the papyrus, informs us, that the intermediate part of the flalk was cut and separated into different lamination, which were cut apart, and dried in the sun for the manufacture. These laminæ were joined together horizontally or transversely, in sheets or leaves, upon a smooth board; then moistened with water, which diffolved a kind of viscid gum in the pores of the plant, serving to cement and render the whole uniform. The sheet, being thus formed, was put into a press, and afterwards dried for use. Such,
he says, was the process of making paper in Egypt; but as the sheets were coarse, brown, unequal, and imperfect, the Romans invented methods to bring the fabric to perfection. They contrived a glue or gum, by means of which they could occasionally enlarge the size and volume. They bleached it to a surprising degree of whiteness; they beat it with hammers, so as to render it more thin and less porous; they smoothed and polished it with ivory; and by a fort of calender gave it a thinning gloss, like that of the Chinese paper. According to the different degrees of delicacy, whiteness, and size, it acquired different appellations either from the names of particular manufactures, from the great personages who used it, or from the particular uses to which it was applied; such as the Fanniana, the Livian, the Claudian, the Imperial, the Hieratic and the Amphitheatric.

There were paper manufactures in divers cities of Egypt; but the greatest and most celebrated was that at Alexandria, where, according to Varro's account, paper was first made. It is certain at least it was from there that Greece and Italy was furnished, on account of the convenient situation of that port; and it is more than probable it was this that gave the Romans occasion to conclude the art had been invented there. It was not till late, when Egypt was reduced into a Roman province, that they had much intercourse, or even knowledge of the inland cities of Egypt, where paper was also made. The trade and consumption of this commodity were in reality incredible. Vopiscus relates, that the tyrant Firmus, who rebelled in Egypt, publicly declared he would maintain an army only with paper and glue, "papero & glutine." This, Cufaunon understands, as spoken of the produce and revenue of paper; though Salmasius takes it to be meant of the papyrus itself, which could supply most of the necessaries of life. Vide Montfaucon. Palaeogr. Græc. lib.1. cap. 2. p. 14.

We find divers species of Egyptian paper mentioned in ancient writers: some denominated from the places where they were manufactured; as 1. The Amphitheatric, supposed to have been made in some building belonging to an amphitheatre at Alexandria, though Gallandius, with others, extrahes it from Arthe's bill writing from it Arcadia, a city in the middle of the Delta, which was the place of its manufacture. What countenances this correction is, that we find mention of this paper before there was so much as an amphitheatre at Rome, much less at Alexandria. 2. Satistica, made in the city Sais. 3. Teniotica, or, according to others, Tatitica, whose place authors are not agreed on. There were also other forts denominated from the makers; as 1. The Fanniana, from the grammarian Rhein. Fannius Palazon, who kept a paper work. This kind was small, but finer than the Amphitheatrical paper; being first wrought at Alexandria, and afterwards finished at Rome. 2. Claudia, first made by order of the emperor Claudius. This was reputed the best of all, in that, besides the two pellicles, in common with the rell, it had a third. Others were denominated from the uses they were intended for; as, 1. Hieratica, the first or oldest fort, which was appropriated to religious uses; this was afterwards denominated Augilia and Liviana, in compliment to the emperor of that name, and his wife; who, according to Some, improved and made it whiter than before. 2. Emporitica, or Emporion, a small and coarse fort, serving for hopkeepers ues, to tie up goods, &c. The qualities for which the ancient papers were prized, were their thinnes, clofenes, whitenes, and smoothnes; though their breadth also considerably enhanced their value. That fort called charta Claudia was thirteen inches wide; the Hieratica, eleven; the Fanniana, ten; and the Amphitheatrica, nine; as to the Satistica, it exceeded not the diameter of the mallet it was beaten with.

Paper, Bark, if it may be so called, was only the liber, or inner whitish rind enclosed between the outer bark and the wood of divers trees, as the maple, plane, beech, and elm, but especially the tilia, pyrus, or linden-trees, which was that mostly used for this purpose. On this, stripped off, flattened, and dried, the ancients wrote books; several of which are said to be still extant. Vide Plin. Hist. Nat. lib. xii. cap. 11. Hardou. Not. ad eund. Suid. Lex. in voc. Cypriae. Ibid. Orig. lib. vi. cap. 13. Alexander. Alexand. lib. ii. cap. 50. Salmuth. ad Pancirol. lib. ii. tit. 3. p. 252, feq.

Mabillon and Montaucon speak frequently of manuscripts and diplomas on bark, and are very express in distinguishing between the papyrus used by the Egyptians, and the liber or bark in use in other countries. The two are alleged to differ in this, that the bark paper was thicker and more brittle than the papyrus, as well as more apt to cleave or suffer, by which the writing was sometimes lost; as is the case in a bark manuscript in the abbey of St. Germain's, where the bottom of the paper remains, but the outer surface, on which the letters had been drawn, is in many places peeled off. Vide Montfaucon. Palaeogr. Gr. lib. i. cap. 2. p. 15. Mabillon. de Re Diplom. lib. i. cap. 8. Reimann. Idea Syll. Antiq. Liter. p. 311.

But Maffei, it must not be forgot, combats the whole system of bark manuscripts and charters as a popular error; and maintains, that the ancients never wrote diplomas on bark; that the distinction between the papers made of papyrus and of cortex, is without foundation; that the only use of the tilia, or linden, was for making thin boards or tablets for diptycha or pocket-books, wherein they wrote on both sides, as is done among us; an advantage which they could not have in the Egyptian paper, by reason of its thinness.

A late French writer on the rules of criticism wanders still farther out of the way, when he speaks of a fort of paper, in Egypt, made of the pith of the cyprus: he describes the manner of preparation, which was by reducing this pith to a pulp, and then spreading it out in leaves. Vide Hou. St. Marie Reflex. sur les Regl. de la Crit. tom. ii. diff. 77. This we suspect for a chimera hatched only in the critic's brain.

Not but there occur divers anomalous forts of paper, which antiquaries are not a little puzzled what species to refer them to; such is that of two bulls in the archives of the church of Gironne, influed by the anti-popes Romanus and Formosus, between the years 891 and 895. They are two ells long and one broad; and consist of two leaves or pellicles glued together transversely, and are fold legible in most places. The conjectures of the French literati, in regard to these, are numerous; the abbot Hiraut de Belmont has a discourse express on the occasion. Some will have them made of the leaves of the alga, or sea-wrack; others of the leaves of a ruth, called la loga, growing in the marines of Rouillon; others of papyrus; others of cotton; and others of bark. So little certainty does there really appear to be in these things, on which the critics nevertheles often lay a great stress. Vide Mem. de Trev. Sept. 1711. p. 1559, eq.
from βαμβάκι, a word which anciently signified flax, though in after-times βαμβάκι and μαργαρίτα came to denote cotton), is a sort of paper which has been in use upwards of seven hundred years ago, as is shewn by Montfaucon from several authorities; what is more, cotton paper appears to have been very common at the beginning of that time, and consequently must have been invented long before, probably about the close of the ninth, or the beginning of the tenth century.

In the French king's library are MSS. on this paper, which, by the character, and other circumstances, appear to be of the tenth century. Be this as it will, from the twelfth century, cotton MSS. were more frequent than parchment ones. Vide Montfaucon. Palaeogr. Græc. lib. i. cap. 2. p. 17. feq. item. lib. iv. cap. 6. p. 209. Maffei, lib. lxi. Biblioth. tom. ii. p. 55.

Paper, Incombustible, is made of the lapis asbestos, or linum vivum, which will bear burning without being injured.

Dr. Bruckman, professor at Brunwick, has published a natural history of the asbestine, or incombustible paper; and what is most remarkable, has printed four copies of his book on this paper: they are deposited in the library of Wolfenbuttel. Vide Bibl. Germ. tom. x. p. 190.

The manner of making this extraordinary paper is described by Mr. Lloyd, from an essay made by himself. He pounded a quantity of the asbestos in a stone mortar, till it became a downy substance; then sifted it in a fine sieve, and by this means purged it indifferently well from its terreine parts; because the earth or ilones he could not pick out of it before, or at the pounding, being reduced to a powder, came through the fieve, the linen remaining. This done, he brought it to the paper-mill; and putting it in water, in a vessel just big enough to make a sheet of such a quantity, he dried it pretty much, and dried the workmen to proceed with it in the usual method, with their writing-paper mould; only to flir it about always before they put their mould in; considering it as a far more ponderous substance than what they used; and that consequently, if not immediately taken up after it was agitated, it would subside.

The paper made of it proved but coarse, and was very apt to tear; but this being the first trial, there is reason to believe it might be much improved; nor did the workmen doubt, but in case it were pounded in one of their mortars, for twenty hours space, it would make good writing-paper. Vide Phil. Trans. N° 166. p. 824. See Asbestos.

Paper, Linnen or European, is chiefly made of linen rags beaten to a pulp with great hammers, and the foil carried off by a continual supply of fresh water. conveyed among the pulp in little troughs, till it be rendered perfectly white.

Besides the chief use of this paper, which is for writing and printing, there is a great consumption of it in packing up goods; and on other occasions.

The manufacture of paper has got footing in most countries, though Holland and Genoa are the places where it has succeeded best. In the general it depends much on the quality of the linen worn in the country where it is made; where that is coarse and brown, &c. the rags, and consequently the paper made of them, must be so too. Hence the whiteness of the Dutch and Flemish papers, beyond the Italian and French, and much more the German papers. The English manufacture was a long while in no great reputation; but it is every day improving; insomuch that we now import little of the ordinary sorts, which were formerly all brought from abroad. Yet paper-mills are of some standing among us. We find one erected at Dartford as early as the year 1588, which we believe was the first, and which is celebrated by a noted poet of that age, Tho. Churchyard, in a work in verse, intitled "A Description and Difcourse of Paper, and the Benefits it brings; with the setting forth of a Paper-mill, built near Dartford, by a High-German, called Mr. Spilman, Jeweller to the Queen, Lond. 1588. 4to."

In reality, the deficiency of the English paper manufacture did not seem owing to much to the quality of our rags, as to the want of skill and attention in the makers; but the manufacture of paper has been very considerably encouraged in our country, and has already arrived to a great degree of perfection.

Anderlon, in his Hiift. of Com. vol. ii. p. 197. says, that till about the year 1600, there was fearcely any other kind of paper made in England, but the cotton-paper; but the war with France occasioning high duties on foreign paper, the French Protestant refugees settled in England chiefly, and also our own paper-makers now began to make white writing and printing paper, which, in length of time, has been brought to so great perfection, both for beauty and flubstance, that in our own time we import only certain kinds of Genoa and Dutch paper, which bears but a very small proportion to all the paper used in the British dominions. This has produced, it is said, a faving to Britain of 100,000l. which was paid annually to France for paper only.

Another writer says, that the English manufactures now provide above seven-eighths of the whole quantity of paper consumed in Great Britain.

Linen paper appears to have been first introduced among us towards the beginning of the fourteenth century. The learned Conrington denies, that there are many manuscripts of this paper above four hundred years old; with whom agrees the count Maffei, who finds no marks of its use before the year 1300. Vide Conrington. Epist. ap. Act. Erud. Libr. an. 1720. p. 94. Maffei Itor. Diplom. lib. ii. Bibl. Ital. tom. ii. p. 253.

Some indeed go much farther back; and take the lilio linte, mentioned by Livy, and other Roman writers, to have been written on linen paper; but Guiliandus, and after him Allatus, and others, have sufficiently refuted this notion; and shewn, that the lilio linte were written on actual pieces of linen cloth, or canvass, prepared for this purpose, such as painters still use; and not on paper made of linen rags. Vide Livi. Dec. i. lib. iv. Phil. Hist. Nat. lib. xiii. cap. 11. Prisc. L. Ant. tom. ii. p. 85. Guillard. Papyr. Memb. 25. Salmuth. ad Pancirol. lib. ii. tit. 13. p. 253.

Others run into the contrary extreme, and make paper the invention of a very late date. The Jesuit Inchofer dates its
PAPER.

itness origin about three hundred years ago; with whom agrees Milus, in his "Hortus Philosphicus," who maintains, that the art of making paper was not invented till about the year 1470. Of the same opinion seems Ray, who tells us the art of making this paper was not known in Guernsey till the year 1470, and when two persons, named Anthony and Michael, first brought it to Bailiff, out of Gallicia in Spain. In effect, if the invention be owing to the refugee Greeks at Bailiff, who fled thither after the falling of Constantino-ple, it must at least be posterior to the year 1452, when that city was taken. Some add a farther argument for the novelty of paper, drawn from the novelty of hemp cloth, which Rabelais, who died in 1535, mentions as first found out about a hundred years before him; and which was so scarce in the time of Charles VII. of France, who died in 1461, that one queen, this was the only woman in France that had a couple of shifts of it. Vide Mabill. de Re Diplom. lib. i. cap. 8. Reimm. Idea Sylv. Antiq. Liter. p. 313, seq. Balbin. Miscell. Hlst. Bohem. cap. 22. Aest. Erud. Lipf. 1682. p. 243. Ray Hist. Plant. lib. xxii. Phil. Trans. N.s. 288. p. 1515. Naud.iaen. p. 82. Nouv. Rep. Let. tom. xxvi. p. 571.

But these suggestions are refuted by Mabillon, from the testimonies of writers prior to the time here spoken of, and from many manuscripts of about four hundred years old, which are written on linen-paper. The Jefuit Balbinus produces divers inftances of paper manuscripts, written before the year 1440. An ingenious writer of our own country affures us, he had a piece of paper which he agreed well with the charter dated in 1358, in the thirty-second year of Edward III. He adds, that in the archives of the library belonging to the dean and chapter of Canterbury, is an inventory of the goods of Henry, prior of Chrift-church, who died in 1340, written on paper; and that in the Cotton Library there are several writings on paper, in the times of Edward III. and the fifteenth of Edward III., which coincides with the year 1335. And Dr. Prideaux affures us he has been a regifteration of some acts of John Cranden, prior of Ely, made on paper, which bears date in the fourteenth year of king Edward II. that is, anno Domini. 1320. Mabill. loco cit. Balbin. lib. cit. Phil. Trans. N.s. 288. p. 1515. Prid. Connect. p. 1. 1. 7. p. 571.

Add, that the invention of paper may appear more modern than it is, because records were not used to be written on it, but it was a considerable time confined to letters, and other fugacious compositions; which is so true, that, to this day, few instruments of any confquence are written on it, though it have been so long in use. It is even alleged, that Peter, the venerable abbot of Cluny, who died in 1117, has a paffeage in his book against the Jews, which plainly indicates paper books to have been known; on the authority of which Valesius, in his notes on the panegyric of Berengarius Augustus, referreps not to make paper upwards of 500 years old.

Father Hardouin affures us, he had seen records or diplomas of it prior to the 13th century. But this will hardly be credited. Count Maffei affures us, that in all his researches he could never meet with one more ancient than the year 1357. It is highly probable the learned Jefuit mistook a cotton manuscript for a linen one; a mistake easily made, as the chief difference between the two confines in the greater thinness of the linen paper. But it is known we have linen papers of very different degrees of thicknesses; and the like may be said of those of cotton. Vide Maffei Hor. Diplom. lib. ii. Bibl. Ital. tom. ii. p. 255, seq.

The invention, according to Prideaux, seems to have been brought from the East; because most of the old manuscripts, in Arabic, and other Oriental languages, are written on this sort of paper; some of which are certainly much older than any of the dates above-mentioned. This author thinks it most probable, that the Saracens of Spain first brought it out of the East into that country; from whence it was propagated through the rest of Europe.

Paper-Making. Nature presents us, as we have already observed, with a variety of substances from which paper may be made, as linen or hempen rags, the italks of nettles, flraw, hay, and the down of thistles. It may be also made of cotton, or white woolen rags, though such paper would not serve for writing, because of its hairiness. Of all these substances, linen or hempen rags alone are employed by the manufacturers, except a small quantity of cotton rags, which are sometimes mixed with the linen for inferior purpofes.

The chief process of making paper consists in separating the fibres of the rags, by grinding, into exceedingly fine and short filaments; which being mixed with water, till they make a fine pulp, may be taken up in a very thin and even layer upon a mould of wire cloth. Now by the draining away of the water through the wire, the filaments are left, interwoven or felted to completely among each other, that they will not separate without breaking, and when dry will make a sheet of paper; the strength and quality of which depend very much upon the materials it is made from, and the equality of length and fize to which the filaments are reduced by the grinding, which equality alone can cause the to float equally in the water of the pulp, and thus distribute themselves fairly and equally over the wire mould when taken up by it. For writing paper, a fine white colour is necessary, and this is obtained either by using the white rags by themselves, or by a chemical process of bleaching.

The in calculable advantages which the moderns have derived from the art of printing, would have been only imperfectly known, but for the invention of linen rags paper. A more plentiful and economical substance could not be conceived than the tattered remnants of our cloths, linen worn out, and otherwise incapable of being applied to the least use, and of which the quantity every day increases; nor could a more ready operation be imagined, than a few hours trituration in a mill. It has been observed by a French writer, that the dispatch of the process of paper making is so great, that five workmen in a mill may furnish sufficient paper for the continual labour of 3000 transcribers.

The art of printing would have been comparatively of little importance, without having the means of procuring a proper material to receive the impressions. Whilst the Egyptian papyrus was the only kind of paper, it would have been impossible to have procured it in sufficient quantities to have made large editions of books. The cotton paper, though in a progressive stage of improvement, was but a rude and perishable article, unfit for any of the nice purposes to which paper is now applied.

The invention of the art of paper making depended upon finding a material which could be procured in sufficient quantities, and which would be easy of preparation. Such is the paper now in use, of which we shall endeavour to describe the manufacture.

The operation of paper making admits of three divisions, viz. the preparation of the rags, the forming of the sheets, and the finishing of the paper. The succession of the several processes is as follows: 1. The rags are washed, or detufed, if they are dirty; then forfed into many qualities proper for different purposes. 2. The rags are bleached, to render them white; but this operation is sometimes deferred to the next stage of the process. 3. The washing engine of the paper mill
mill is employed to grind the rags, in water, till they are reduced to a coarse or imperfect pulp, called half fluff, or first fluff, in which state the bleaching is sometimes performed; or at other times it is bleached in the washing engine during the grinding. 4. The half fluff is again ground in the beating engine, and water added in sufficient quantity to make a fine pulp, which being conveyed to the vat, the preparation of the rags is completed, and the pulp or fluff is ready for making the fleets. 5. This is done by a workman who takes up a quantity of pulp upon a mould of fine wire cloth, through which the water drains away, and the pulp congeals on the sheet of paper. 6. Another workman takes the sheet of paper off. from the wire mould, and receives it upon a felt; he then covers it over with a second felt, evenly spread out, and continues this operation, which is called couching, till he has made a pile of sheets called a paff, containing six quires. 7. The paff of paper, with the felts, is placed in the vat-presses, and the whole is subjected to a strong pressure, to press out the superfluous water, and give the paper a solidity and firmness it would not otherwise have. 8. The pile of paper is removed from the vat-presses, the felts taken out from between the sheets, and they are pressed again by themselves, for a certain time, in a ceref press. 9. The sheets are taken from the press, and hung up, five or six together, on lines in the drying loft, till dry. The paper is now made, and only requires to be finished; but it should be observed, that the greater number of the processes of finishing are only performed upon fine writing paper, common printing paper being ready for packing up when dried. 10. The paper, in five or six sheets together, is dipped into a tub of fine lime, and afterwards pressed to force out the superfluity of water; it is then dried again in the drying loft, but in printing papers this process is rendered unnecessary, by fizing the fluff whilst in the engine, and adding certain ingredients. 11. An examination of each individual sheet of the paper is made, all knots and burrs are removed, and the bad sheets taken out. 12. A very large pile of paper is made, and pressed with a mull immense force, to render the sheets flat and smooth. 13. The pile is taken down, sheet by sheet, and another made, without turning the sheets over: by this means news surfaces of the sheets are brought in contact with each other, and the pile being again subjected to the presses, the surface of the paper is improved. This operation is called parting, and is repeated two or three times for the heft papers. The paper is now counted into quires, folded and packed up into reams for market. The strength and tenacity of paper depend upon the staple or fibre of the materials from which it is made. Rags of new cloth, and cordage, compose a tougher and stronger paper than old rags, which make a soft and pliable paper. The fluff of these materials presents a great variety, according to the quality of the hemp, or flax of which it is fabricated. Rags of fine new cloth, whether raw or bleached, stand in the first rank, after which old rags, cordage, &c. may be classed. The fortung of the rags is of so small importance in the art of making paper; for unless the rags, which are ground at the same time in the engine, are all of the same quality, both as to subflance and condition, the finest and best parts will be ground away in the mill, and carried off by the water before the coarser are sufficiently reduced to make a fine pulp. For this reason, in the fortung of the rags which are intended to make fine paper, the hems and seams shoulel be kept apart, and the coarsenes of the cloth, should be considered. That cloth which is made of tow, should be separated from that which is made from the longer fibres; cloth of hemp from cloth of flax; and lastly, the degree of wearing in the cloth should be attended to. For if rags, almost new, are mixed with those which are much worn, the one will not be completely reduced to a pulp, whilst the other will be so attenuated as to be carried off by the water, and pass through the hair-strainers of the engine; hence there must be a considerable waste in the operation, a real loss to the manufacturer, and even to the beauty of the paper; for the particles first carried off by the current of the water, are perhaps those which give it a smooth velvet surface, which is a great recommendation. When the fortung is imperfectly performed, the pulp or fluff is found to have cloudy parts floating in it, owing to some fibres being left reduced than others. This produces those cloudy papers wherein are seen by intervals parts more or less clear, and more or less weak, occasioned by flakes assembled on the wire of the mould, which are not sufficiently tempered and diluted to incorporate with more fluid parts. But as it is necessary, in many cases, to mix the different qualities of rags together, to produce various kinds of paper, this should be done by reducing the different forts of rags separately in the mill, as also the hems and threads of the fitching, because the sewing thread, being never so much worn as that of the cloth, and not to £asy to be reduced, forms filament in the paper. When the rags, unequally disposed for trituration, have been ground apart, the different pulp is may be mixed together without inconvenience, and will be found homogeneous or alike, having been ground during the time that was necessary for the state of the rags. Without this precaution the finest particles will be always lost, and of course the beautiful quality of the paper will be altered by the coarser. Therefore this care in fortung the rags produces a great beauty of the paper, without hurting its goodnes. It will, besides, be attended with the advantage of mixing a pulp, which will form the strength of the paper, with another which will give it softness and fluire; and thus two qualities may be united which otherwise existed separately.

There are people in London who, by dealing very extensively in rags, have it in their power to observe these precautions in fortung, and to fell separately all the different qualities to the paper makers. The fame may be said of those great manufacturers who have the perfections of their work at heart. As to small country mills, it is scarcely possible for them to make so great a choice. They are often obliged to lay up for fine many rags which are properly middling, and their middling may with better reason be referred for making the coarser fort of paper.

The people who go about the streets to buy up rags and old garments, sell them to the great dealers, who for the London market employ women to sort them into five sorts, which are denominated Nos. 1, 2, 3, 4, and 5, according to their respective qualities. No. 1 being superfine, and wholly linen, is used for the finest writing papers. The other forts have different degrees of fineness, down to No. 5, which is completely canvass, but is proper for making inferior printing papers, when it has been bleached to a good colour. There is also rag bagging, which is the materials of the strong canvas lacks the rags are fewed up in for carriage; and coloured rags, which confit of cotton, and are of all colours promiscuously mixed; but the blue are generally forted out, for the purpuse of making blue paper. The rag bagging and cotton rags are only fit for common papers. The rags are first put into a machine, called a duffer, made in the form of a cylinder, four feet in diameter and five feet in length. It is all through covered with a wire net, and put in motion on pivots at its ends by a connection with some part
part of the machinery. The whole is inclosed in a tight close box to keep in the dust. A convenient quantity of rags, before the forcing, is inclosed in the cylinder of the duffer, and the rapidity of its motion separates the dust from them, and it passes through the wires into the box. It is of considerable advantage to use the duffer before softing, as it makes that operation less onerous to the people.

The softing is performed by women and children, who are seated on benches, in a large room full of old linen, before a shelf or box, which is divided into fixe cases, to receive as many different sorts of rags. Each woman has a piece of pasteboard, hung from her girdle, and extended on her knees, upon which, with a long sharp knife, she unrolls sheets and flitches, and separates off all filth.

Whatever can be used, after being well examined, is distributed into one of the fixe cases, according to the degree of fineness, and the women throw the reft at their feet. The fixe cases are for the fixe different sorts of rags: the superfine; the fine; and flitches of the fine; the middling; the flanks, and flitches of the middling; and the coarse; without including the very coarse parts, which are totally rejected, at least for the making of white paper, but may serve for white brown paper; but even for this purpose they should be mixed up with a large part of coarse linen. Old paper may also serve for the same use, but the quality is considerable; it is therefore reserved for pasteboard, in the manufacture of which, the stuff being worked lefs time in the engine, and with lefs force, though with the same water, it will lefs much lefs than if worked sufficiently to make paper. Besides, paper that has been once fixed still gives the pulp a vicidity, which ought to be guarded against, as it prevents the fibres floating so completely detached in the water as is necessary to make them distribute themselves sufficiently equal and regular upon the wire moulded, to make a true and even sheet of paper.

Paper intended for bills of exchange, or other commercial and legal instruments, ought to be tough, in order that it may not be easily torn, when made as thin as it is necessary to be, for the ease of conveyance by post. For this, paper materials of the best quality must be entirely, or in large proportion, employed; and the price which the consumers are disposed to pay for the article is sufficient to allow the best materials, and still indemnify the manufacturer for his care and industry.

Common papers also require to be more or lefs tough, according to their thickness, and the use to which they are applied; but a clear white colour is sought in paper of every description, whether for writing or printing. The manufacturers of paper were formerly obliged to attend to the colour of the rags in the softing, as well as to their qualities; but of this care they are now in a great measure relieved, by the introduction of bleaching, which enables them to produce the finest paper, in point of colour, from any kind of rags. They have only therefore to find such materials as will make paper of a strong texture, and a fine even surface, knowing they can produce colour at pleasure. To bleach the rags by the oxymuriatic acid gas, they are first washed in hot water, by a freezing mill, such as is used for freezing cloth; this removes the dirt, and they are put into a receiver or chamber, made of wood, in a cubical form, and the joints are tight. It is provided with several bone retorts, which being filled with a mixture of manganite, with two-thirds its quantity of sea-salt, and a quantity of sulphuric acid equal to the salt, will, when moderately heated by small fuel-burnt furnaces, throw into the receiver a gas which quickly discharges any colour the rags may contain. This process, which is very similar to that used for bleaching cotton thread, was invented by Mr. Campbell, who had a patent for it in 1792. In his specification, he directs that the rags should, before they are put into the receiver to be bleached, contain about their own weight of fair water; the super-abundant water being pressed out. The rags should first be opened by a machine, called by the cotton manufacturers a devil, or some machine, of that nature, and they are to be distributed in the receivers, in layers spread on frames, so that they will not come in contact with each other, or they may be placed in the body of the receiver, and have stirrers or agitators, provided to expose every part of them to the action of the bleaching gas.

After the process, which must be concluded as soon as ever the rags are sufficiently bleached, left the gas should act upon and injure their quality, they are to be washed in water, and will be ready for the mill. Some manufacturers think that this mode of bleaching the rags makes them rotten, and injures the quality of the paper, which it certainly does if carried too far, though there is no doubt of the advantages of the process if well conducted.

The bleaching process has given rise to great complaints from the printers, as many printing papers are now made from cotton rags. The oxygenated muriatic acid being applied for the purpose of bleaching these rags, which discharges delicacy of colour, produces a paper of a good appearance, but of inferior staple. Nothing can be more perplexing to a printer, nor more detrimental to his labour, than this kind of bleached paper; for although it may be thick, and seem strong in the ream, no sooner does the water penetrate through it, than it loses its adhesive quality, and becomes so loose and soft as scarcely to bear handling, and in working under the presses sinks down into the cavities of the letters, leaving a part of its substance behind, after every impression, until it is clogs the type, that the work is rendered scarcely legible. Nor is it less exceptionable in point of durability, as it must mould away in a little time, with the common use that popular books generally undergo. Notwithstanding this it must be allowed, that if by bleaching the paper makers can produce a bad article from such materials as were otherwise of no use, they are also able to improve their manufacture when they use the same materials as formerly. It is found most advantageous to bleach the rags in the state of half stuff, that is, when they have been once worked by the mill, and the fibres being by that means separated, the gas has greater access to the interior parts, and they are bleached quicker, so as to have less danger of injury to particular parts, by too long an action of the gas.

Another method of bleaching is by muriatic lime put into the washing engine, which for printing papers is the best mode of any. We shall describe it in the process of washing.

The engines now used in the paper mills are constructed on such a powerful principle, that they are capable of reducing the strongest and toughest rags to pulp in a moderate time; whereas the old machines were not able to work the rags without fermenting them, as a previous process.

The following extracts from a French work, on the art of making paper, will shew the manner in which it was conducted 60 years ago.

"The rags, being sorted, are put into a large stone vat, fifteen feet long, ten broad, and three deep; water is poured upon them to the top during ten days, and eight or ten times every day without stirring them. They are afterwards left to rest the same number of days, and sometimes more or less, without pouring water upon them. Then being turned over, the centre is brought to the surface, to facilitate the fermentation; and after being turned again, they are still left fifteen or twenty days in fermentation.

Vol. XXVI.
tation, so that the rotting may last five or six weeks; the term is not fixed, but when the heat becomes so great, that the hand, thrust in, cannot endure it above some seconds, it is judged that it is time to stop it.

In mills, which have but few rags to work upon, they are left to rot longer, because the heaps being smaller, heat less, and with more difficulty, so that nothing can be justly determined of the time proper for the rotting part. It depends also on the quality of the rags; the finest linen does not rot so soon as the coarser; and linen that has been worn with more difficulty than new, because the internal humidity, which diffuses the fibres to fermentation, is more considerable in new or coarse, than in fine or worn linen. Such as are more or less strong, more or less worn, refit the action of rotting in different degrees, some being spoiled, when others have not gone through the first fermentation: so that the rags, which have been fortified with great care, ought to be left to rot together, to avoid the risk of altering the whole parcel, by the mixture of a portion of rags quite different from the rest. When champignons grow on the heaps of rags, it is reckoned to be a sign of their being well rotted.

Besides this, there is another method for disposing of the rags in the place for rotting and fermenting them. Having been wetted with water, a heap is made of them in a corner of the vaulted room, which is defined for that purpose. If they are watered from time to time, and when sufficiently heated, are transported into another angle of the same room, so that what was at the top of the first heap, is now laid under the second, and care is taken to throw water upon them from time to time. When this heap takes heat again, it is transported to the third corner, where, having fermented again, it is carried into the fourth angle; observing always to lay those rags under the heap that were at the top of the foregoing, and to water them often, for a reddish water will come from them, which it is very necessary to clear the rags of. When the heap in the first corner is brought away, another is formed in the same corner, which pallets in its turn to the several corners of the room.

Some, to accelerate the operation of rotting and fermenting, throw lime upon the rags. Perhaps a very small quantity of lime may be used: but if too much is laid on, the corroded rags will be too soon reduced into a pulp, and will pass through the strainer with the water, which ought to carry off only their fibre, and will occasion a considerable waffle. The use of lime, for the purpose of rotting rags, is absolutely prohibited in France.

Fermentation, or rotting, makes the paper even, curled as it were, soft, and gives it weight; if stopped too soon, the paper becomes crude, hard, light, fluff, requires more time to be worked, and the fcula, or pulp, does not so easily form a coagulation on the wire of the mould. It is sometimes observed, in regard to good rags that have not rotted, that the fcula is, as it were, enveloped in a viscid sub stance, which prevents its uniform precipitation; and this proves that rotting helps to clear off the unctuous matter in rags. If, on the contrary, the rags were left to ferment too long, a considerable waffle would be occasioned, and more matter required for the same quantity of paper, because the parts attenuated by fermentation, would be too readily carried off by the washing. And lastly, if they were left to heat too long, they would be reduced to duff, and burn into smoke and ashes.

The action of rotting was, at that period, thought necessary for abridging the labour of making paper, and facilitating the operation of the mill; but several advantages are procured by dispensing with it, now we are able to destroy the texture of the cloth and reduce it to pulp, without previously corrupting its substance by rotting it. The paper is much flouter, is less liable to break, and is also whiter, for the fermentation gave a yellowish hue to the surface of the rags, which the mill could not take out without difficulties, and never could entirely, if the rags were too rotten.

We now come to describe the structure of paper mills. In England they now work with cylinders, or engines, an invention which was brought from Holland many years ago, and found to be so great an improvement, that it has been universally adopted. The old mills, which are still in use in some parts of the continent, actuate a number of dampers, or pettles, which pound the rags in wooden mortars till they are reduced to a pulp. These mortars are cut out in a block of heart of oak, well seasoned, the cavity being of an oval figure, about eighteen inches broad, thirty inches long, and eighteen or twenty in depth; the bottom concave, and lined with an iron plate an inch thick, eight inches broad, and thirty long, shaped inwardly as a mould for a salmon, with the head and tail rounded. In the middle of the mortar is a cavity beneath the plate, and four or five grooves are cut, forming channels which lead to a hole cut from the bottom of the cavity quite through the block: it is covered by a piece of hair fiefed over the hollow. A plate is grooved to resemble teeth, on which the teeth of the hammerers, or hammers, can slide, to cut the rags in pieces. The use of the hair fief is to prevent any thing from going out except the foul water. Two hammers or pettles work side by side in each mortar, and are lifted alternately by the mill: they are sometimes made in the same manner as the dampers of an oil mill, to lift perpendicularly. In other mills they are large hammers moving on a centre like a fulling mill, and lifted by cogwheels, to the mill shaft in the same manner. The mortars are kept conflantly supplied with fair water, by little troughs, leading from a cistern, which is kept full by small buckets affixed to the floats of the water-wheel; these, when they have raised the water to the top, pour it out into the cistern, in the fame manner as the Peruvian wheel.

This rude and imperfect machine operated very slowly, and suffered a great part of the rags to escape being reduced, whilst other parts were beaten too much. It is not now to be met with in England, the Dutch engines having taken their place, to the great improvement of the paper trade; these are turned by water mills, and they require a very great power to actuate them, though their performance is far greater, with the same power, than the mortars.

The construction of the mills is varied in different situations; but to explain the best kind, we have in Plate 1. Paper Mill, given a drawing of one made with iron wheels, fig. 1. being an elevation, and fig. 2. a plan: the same letters of reference are used in both. The water-wheel which gives the motion cannot be seen, as it is situated beneath the floor, but its dimensions are marked by four dotted lines AAAAA: in the plan it is enclosed between the three walls of the house PPR, and a fourth wall Q, which is built up across the house, to support the floors N and O, on which the engines stand: the wall R has arches in it to admit the water of the stream to the wheel, a proper gate being fixed to regulate its quantity: the axis of the water wheel, which is of cast iron, comes through the wall Q, and has a large cog-wheel B upon it, which is the full size of the water wheel, and by the paper makers is termed the maifter-wheel: the extreme end of the shaft is furnished in a bearing, which lays on a beam G G, supported on a wall of masonary. The pinion C, called the wheeler,
The paper is turned by the mallet-wheel B, and on its axis is fixed the large spur-wheel D, called the fly-wheel, giving motion to the two pinions E, F, of the engines K and L: the shaft of the wheel D and pinion C are supported at one end in a frame H H I, and the other, in a bearing fixed in the wall Q. The engines K and L are placed on the floors N and O upon different levels, as shown by fig. 1, the bottom of L being higher than the top of K, so that the contents of L may be let down through a plug-hole in the bottom. The upper engine L is called the washer, where the rags are first worked coarsely, with a stream of water running through them to wash and open their fibres; after which washing they are called half-fluff, and are then let down into the beating engine K, to be ground, and reduced to a finiflied pulp, proper for moulding into sheets of paper.

By the arrangement of the wheels of the mill, the cylinders, k and l, of the two engines are contrived to make about from 120 to 150 revolutions per minute, when the water-wheel moves with its proper velocity: though the beating engine revolves much quicker than the washer, its pinion, F, having only 24 teeth, while the washer, F, has 28. The great wheel, B, has 196 teeth, and the pinion, C, 38 teeth; therefore it makes about 57 turns, for one of the water-wheel. The wheel D has likewise 196 teeth, and turns the washer, F, of 28 teeth about 36 times, for once of the water-wheel; and the beater, E, about 42 times. M is a cog-wheel, put in motion by the teeth of the great wheel B: on the extremity of its pinpule is a crank a, which, by a connecting rod d, gives a reciprocating motion to a lever c, for the purpose of working two pumps, e, f, which raise water into a cilfiner h, drawing it from the water of the mill-dam by a suction-pipe g. These pumps raise up a continual stream of air water, which is necessary to be kept running through the rags in the washing-engine, to carry away the dirt separated from them by the operation.

The engines are shewn at K and L, in the plan: each consists of a wooden vat or ciffern, divided by a partition in the middle; and in one of these divisions, their cylinders, k and l, are seen. These are provided with teeth or cutters, which act against similar teeth fixed in blocks, situated beneath the cylinders, to cut the rags between them, when they revolve. The structure of an engine is more minutely explained by figs. 1, 2, 3, 4, &c. of Plate II.; fig. 1 being a section through the length of the engine, and fig. 2, a horizontal plan. The large vat or ciffern, A A, is of an oblong figure on the outside, the angles being cut off; but the inside, which is lined with lead, has straight sides and circular ends. It is divided by a partition B B, also covered with lead. The cylinder, C, is fixed fast upon the spindle D, which extends across the engine, and is put in motion, as before described, by the pinion E, placed on the extremity of it. The cylinder is made of wood, and furnished with a number of teeth or cutters, fixed fast on its circumference, parallel to the axis, and projecting about an inch, as is shewn on a larger scale at fig. 5. Immediately beneath the cylinder, a block of wood, H H, is placed, and provided with similar cutters to those of the cylinder, which, when they revolve, pass very near the teeth of the block, but do not touch; the distance between them being capable of regulation, by elevating or depressing the bearings on which the necks, D, D, of the spindle are supported. These bearings are made on two levers, F, F, which have tenons at their ends, fitted into upright mortises, made in short beams, G, G, bolted to the fides of the engine. (See also fig. 3.) The levers, F, F, are moveable at one end of each, the other ends being fitted to slide and fall on bolts, in the beams G, as centres. The front one of these levers, or that nearest to the cylinder C, is capable of being elevated or depressed, by turning the handle of the screw b, which, as shown in fig. 3, acts in a nut a, fixed to the tenon of F, and comes up through the top of the beam G, upon which the head of the screw takes its bearing. Two braces are let into the middle of the levers, F, F, and form the bearings for the spindle of the engine to turn upon. The screw, b, is used to raise or lower the cylinder, and cause it to cut finer or coarser, by enlarging or diminishing the space between the cutters in the block and those of the cylinder.

Near K, figs. 1 and 2, is a circular breathing made of boards, and covered with fleet-lead: it is curved to fit the cylinder very truly, and serves but very little space between the teeth and breathing. An inclined plane, K, runs regularly from the bottom of the engine-vat to the top of this breathing; and at the bottom of it the block, H, is fixed. The engine is supplied with water by a pipe, Q, bringing it from the pump; this pipe delivers it into a small ciffern, M, adjoining, and communicating with the engine. The pipe has a cock, P, to stop the entrance of the water, when required, or to regulate the quantity of its discharge. The small ciffern has a grating fixed across it, covered with a hair-flainer, to catch any extraneous matter, which may come in with the water; or a flannel bag is sometimes tied over the orifice of the cock P, through which all the water must be filtered. When the engine is filled with water, and a quantity of rags put in, they are, by the revolution of the cylinder, drawn between its cutters and the teeth of the block H. This cuts them in pieces; then, by the rapid motion of the cylinder, the rags and water are thrown over the top of the breathing, upon the inclined plane: in a short time, this raises more rags and water into that part of the engine that is raised, and the tendency to a level in the equilibrium puts the whole contents of the vat in motion, down the inclined plane K, and round the partition B B, by which they come to the cylinder again in about the space of 20 minutes; so that the rags are repeatedly cut and chopped in every direction, till they are reduced to a pulp.

This circulation is of advantage, in turning the rags over in the engine, and causes them to present themselves to the cutters in a different direction every time; for as the cylinder cuts or clips in straight lines, in the same manner as a pair of shears, it is requisite to cut the rags across in different directions, to reduce them to a pulp. The manner of the cutting is this: the teeth of the block are placed rather inclined to the axis of the cylinder, as shewn by fig. 4, but the teeth of the cylinder are parallel to its axis; therefore, the cutting edges, when they meet, are at a small angle, and come in contact first at one end, and then successively the contacts proceed along to the other end, so that any rags interpersed between them are cut in the same manner as they would be between the blades of a pair of shears. Sometimes the plates or cutters, L, in the block, are bent to an angle in the middle, instead of being straight, and inclined to the cylinder: in this case, they are called elbow plates, and of course the two ends are both inclined to the axis of the cylinder in opposite directions. In either case, the edges of the plate of the block cannot be straight lines, but must be curved, to adapt themselves to the curve which a line traced on the cylinder will of course have. The plates or cutters of the block are united, by screwing them together, and fitting them into a cavity cut out in the wooden block H; their edges are bevelled away on one side only, as shewn at k in the section, fig. 4. The block is fixed in its place by being made dovetailed, and truly fitted into the
bottom of the cistern, so that the water will not leak by it. The end of it comes through the wood-work of the cistern, and projects a small distance on the outside of it, being kept up to its place by a wedge, so that by withdrawing this wedge, the block becomes loose, and can be removed, to sharpen the cutters, as occasion requires. This is done on a grindstone, the plates being first separated from each other.

The cutters of the cylinder are fixed into grooves, cut in the wood of the cylinder, at equal distances from each other round its circumference, in a direction parallel to its axis: the number of these grooves is twenty; and for the washer, each groove has two cutters or bars put into it; then a fllet of wood is driven in between them, to hold them firm; and the fillets are kept fall by spikes driven into the folio wood of the cylinder. The beater is made in the same manner, except that each groove contains three bars, and two fillets, as shewn in fig. 5.

In the operation of the cylinder, it is necessary that it should beinclined in a cafe, or its great velocity would throw all the water and rags out of the engine. This cafe is a wooden box L L, inclosed on all sides except the bottom: one side of it rests upon the edge of the vat, and the other upon the edge of the partition B B. The lines, e e, represent the edges of wooden frames, which are covered with hair or wire-cloth; and immediately behind these, the box is made with a bottom, and a ledge towards the cylinder, which makes a complete trough. The dark spaces, e e, in fig. 1, shew the situation of two openings, or inlets, through the side of the cafe, which lead to flat lead-pipes, h, h, fig. 2, which are placed by the side of the vat; the beam, F, being cut away for them. There are waste pipes, to convey away the foul water from the engine; for the cylinder, as it turns, throws a great quantity of water and rags up against the heves: the water goes through them, and runs down into the trough at e e, and from thence into the ends of the leaden pipes, h, h, fig. 2, by which it is conveyed away; d, d, fig. 1, are grooves for two boards, which, when put down in their places, cover the hair-sieves, and flop the water from going through them, if it is required to retain the water in the engine. This is always the cafe in the beating-engines, and therefore they are seldom provided with these waste-pipes, or at most on one side only; the other side of the cover being curved, to conform to the cylinder. Except this, the only difference between the washing-engine and the beater is that the teeth of the latter are finer, having 60 instead of 40 bars on its circumference; and it revolves quicker than the washer, so that it will cut and divide those particles which pass through the teeth of the washer.

In small mills, where the supply of water is limited, they frequently have but one engine, and use it both for washing and beating, by setting the screw so as to let the cylinder down and make its teeth cut finer; but the system of all considerable works is to have two engines, or four, if the supply of water is sufficiently great. We have seen a very capital paper mill containing five engines, where three of them are beaters and two workers; because the beating takes so much more time, that when the numbers are equal, the washers will often do too much for them, and they will have to stand still. A mill to drive four engines is generally made double, that is, it has two water-wheels, and all the machinery shewn in the plan; and if either of these give motion to three engines, they are arranged rather differently: thus the two beaters are placed on the same level with each other, and this removes them to a greater distance afloat than shewn in fig. 1, Plate 1; so that the ends of the two engines, when placed on the same floor or platform, will just touch each other. The washer is then placed on the opposite side of the wheel D, viz. where the word plan, fig. 2, is written, its pinion being upon the summit of the wheel, which raises it to the proper level: the vat of the washer has a valve or cock in each end, to let out its contents into either of the beaters at pleasure.

The mills with four-wheels, such as is given in our drawing, are not very common, though they work much better than the ordinary arrangement of the wheels for a paper mill: in this the shaft of the water-wheel has a large face, or crown-wheel, fixed upon it, which admits a wooden trunche fixed upon a vertical shaft, proceeding upwards through the floor of the mill, and there it carries two large horizontal crown or face-wheels, giving motion to the pinions of the engines, which are situated on opposite sides of the upright shafts. It is necessary to have two horizontal wheels, because of the different levels at which the engines must be placed. These mills are generally made in wood, in a very rude and eacrough manner, with crown-wheels and large cogs, so that the friction is very great. Their only recommendation to the paper-maker is their cheapness of erection; but this is only on account of their inferior workmanship, for to make a mill in iron with a vertical shaft and bevelled wheels, as they should be to work properly, would be far more expensive than the constrictus shewn in fig. 1, which is therefore adopted by those manufacturers who choose to have their mills made in a complete and durable manner.

The quantity of water which a paper mill pan command to turn its engines, generally limits the extent of its trade; and hence the manufacturers should attend to every improvement of the machinery which can increase their effect. Where the supply of water is constant, they work the engines day and night, though the making the paper, as it requires many workmen, is of course carried on in the day-time only. This system necessarily requires a large vat to be provided, with a barrel called the stock-chest, and a general receptacle for the pulp, where it is kept till wanted to be made into paper; at the same time this mixes the pulp of different day's work together, and produces an uniformity in the quality and colour of the paper, which is a great recommendation for printing large editions of books.

A very large and capital paper mill, at Maidstone in Kent, which is the principal seat of the paper trade in England, is worked by steam-engines, and is found to answer very well. The machinery and building of a paper mill should be well made, and firmly put together, otherwise its great velocity, and power, produces a tremor, which in time shakes every thing to pieces. The noise and vibration of a washing-engine is most tremendous; for when it revolves 120 times per minute, and has 40 teeth, each of which paless by 12 or 14 teeth in the block at every revolution, it will make near 60,000 cuts per minute, and each of them sufficiently loud to produce the most horrible growling sound which can be conceived. The beater revolving quicker, having 60 teeth, and 20 or 24 cutters in the block, will make 180,000 cuts per minute, which is still more rapid, as it produces a coarser musical note or humming, which may be heard at a great distance from the mill. This great number of cuts will account for an engine being able, in the course of four or five hours' working, to reduce a quantity of rags to those exceedingly minute filaments, of which paper is composed.

The operation of grinding the rags in the engines requires some management to produce the best effect: the operation of the washing-engine is to open the rags, and to separate their fibres from each other, rather than to cut them.
PAPER.

Then, and at the same time, by the stream of water which runs through, to carry off all dirt. At first putting into the washing-engine, they should be worked gently, not to cut, but only to rub the rags violently, that the water may have the best effect in carrying off the impurities: this is done by raising up the cylinder, so that its teeth do not touch the teeth of the block, for if the washer cut and divided the rags too much in the first instance, the water would carry away a considerable portion of the finest parts. The cock is at this time opened to admit a great stream of water. When this has continued 20 or 30 minutes, the bearing of the cylinder is let down low, that its weight reds upon the teeth of the cutter, and it now begins to cut the rags in pieces, the fupply of water is diminished, and the operation is at first white, but it will continue causing the cylinder to leap up a considerable height. After working about three or four hours, the engine will get to work very steadily, because the rags, though not reduced to a pulp, are cut very small, and make less resistance to its motion: at this period the washing is usually concluded, and the contents of the engine, called half fluff, discharged into a large basin, which allows the water to draw away. For some kind of paper it is thought advisable to let the half fluff remain four or five days to mellow, or indeed ferment; and if fermentation is at all proper, this must certainly be the best stage for it, when all the mists of rags is brought to an equal state of division of the fibres. The bleaching is, as before-mentioned, sometimes performed upon the half fluff, instead of bleaching the rags previously; but more commonly it is done in the washing-engine, and this is the most convenient method of all, as it requires no apparatus, and takes very little time, puts the manufacturer to no other expense than the bleaching cost (muriate of lime) by which it is performed, and the effect, if well managed, is equal to that of fermenting by the oxymuratic acid gas, commonly described. After the rags have been washed for four hours, as above-mentioned, if it is required to bleach the fluff in the engine, they flop the water from running in at the cock, and throw into the engine a quantity of bleaching salt, or muriate of lime. For fine rags, one or two pounds, more or less, are used, according to the quantity of rags the engine contains, which is usually one hundred weight: the two flinders, d, d, fig. 1. Plate II., are put down in the cover of the cylinder, to prevent the water getting away. In this state the engine is worked about an hour for the bleaching to take place, and during this time the rags lose their colour; but this does not colour the water, though it is rendered rather white and milky by the slat. The very best rags, when first put into the engine, are of a very yellow and dirty colour; but they become, by the bleaching, a very perfect snow white: the cylinder is gradually raised a very little during the bleaching, which being concluded, the watercock is opened again, the boards, e, e, are removed, and the washing continued about an hour to wash the slat away, which must be done very gently, or it will continue to act upon, and injure the quality of the materials.

The half fluff is next put into the beating-engine, and worked till it becomes a fine pulp, which will generally take four or five hours, water being let into it at proper times, to dilute the pulp to its proper consistence, but no water is let out of the beating-engine as in the washer. The quantity of water requires great judgment, as it has an influence on the quality of the paper; and the kind of water the manufacturer is obliged to employ must be considered. The fittest water is that which is soft, but not so soft as to make the paper which is made therefrom too strong; it must be only suitable to the kind of paper intended to be made thereon. The water that diffuses soap slat, is also the fittest for taking the grease out of rags. Paper-makers say that the water which is moift beaten, and that which comes from afar, makes a better curdled paper, flotter, and of stronger consistence, as to matter: if this is the case, it is probably because this water has had more time for depositing the flume, and other heterogeneous parts, and that, being more exposed to the air by motion, it is thereby in a better condition for dissolving grease and soap. Water, subject to be mudded by rain, and that which runs through marly grounds, ought to be avoided. In like manner, a paper mill ought not to be placed below other manufactories or machinery, which, by using the same water, might communicate to it a bad quality. The water of ponds, and rain water, are very good for dissolving soap, and may therefore be used for paper, if in a pure state. Water, impregnated with lime, by having run off from chalky foils, is generally very pure and clear to the eye, and is, therefore, much used for paper-making, but it is apt to deposit a slight incrustation upon the brine wires of the moulds, which they remove by occasionally washing them with vinegar.

For printing papers, the fixing is done in the beating-engine, towards the end of its operation, as we shall describe: the size is necessary to prevent the ink from sinking into the paper like blotting-paper; but printing-ink not being so fluid as writing-ink, the paper can be sufficiently fixed in substance, without subjecting the sheets to a separate operation after they are made. The size for the engine is composed of alum pounded very fine, and mixed up with a quantity of oil: about a pint and a half of this mixture, thrown into the engine at intervals, during the last half hour of the beating, is sufficient. In order to give that bloom, or blue cast to the paper which some kinds have, a quantity of powdered blue is frequently put into the engine at the same time. The pulp is now run off into the fluff-chest where the different kinds are mixed, and it is taken out as it is wanted with tongs, in the vats where the divets, &c. work to form the sheets.

The moulding of the paper should be carried on in a lofty room, well ventilated, and with a smooth and even ceiling, that the steam arising from the several vats of pulp may not be condened upon it, and fall in drops, for a single drop falling upon a sheet of paper, whilst it is moulding, will beat a hole through it, or at least spoil it. The people in this apartment work at the vats, with moulds, deckles, fets, vat prefs, and vat prefs. The vat used to contain the pulp is a tub, generally about five feet in diameter, and two and a half in depth. It is provided, on the upper part, with planks enclosed inwards, and even railed in with wood, to prevent any of the fluff from running over in the operation: a plank, pierced with holes at one of the extremities, is placed across the vat, and resting on the planks which surround the vat, forms a support to rest the mould upon, when a sheet of paper has been made, and it remains here a short time to drain off the superfluous water. The fluff in the vat is kept at a proper temperature, by means of a grate introduced at a hole in the side, and surrounded on the inside of the vat with a cafe of copper. For fuel to this grate charcoal or wood is used, and frequently, to prevent smoke, the wall of the building comes in contact with one part of the vat, so that the fire has no communication with the room where they make the paper. The paper is made into sheets upon the mould and deckle. The mould is a square frame, or shallow box, made of well-seasoned mahogany, and covered at the top with wire-cloth; its dimensions are an inch or an inch and a half larger than the sheet of paper intended to be made upon it. The wire-cloth of the mould is varied in proportion to the finsels of the paper and the nature of the fluff.
PAPER.

It consists of a number of parallel wires fretted across the frame, very near together, and tied fast through holes in the sides; also a few other longer wires, extending across in a direction at right angles to the former, and a considerable distance under, the small wires being bound down to them by fine wire at the intersections. This may be readily understood, from the examination of a sheet of some kind of paper on which the marks of the wires remain, because the paper is thinner in those places where the wire touched it.

By a modern improvement, these marks, called water-marks, are avoided, and the paper has a smooth even surface. For this, the wire is woven in a loom, exactly like cloth, and fretted over the frame of the mould. The wire-cloth is in this case made larger than the intended sheet of paper, and turned down over the sides of the frame, being sewed fast to it by fine wire, so that the cloth is strained tight over the frame. The wove paper, as it is called, when made on these moulds, is a very superior article to the old paper, particularly for books, but a prejudice still prevails in favour of the old paper with lines, which obliges manufacturers still to make it, though by no means so fine or good as the wove.

The deckle is a square frame of mahogany, bound with brafs at the angles; it is made very thin, and its outside corresponds with the sides of the mould, while the inside is of the sheet. This frame is necessary to retain the fluff of which the paper is made on the cloth, and it must be exactly flat, that it may fit upon the wire-cloth of the mould, otherwise the edges of the paper will be ragged and badly finished. The deckle, when placed upon the wire of the mould, forms a shallow sieve or mould, in which quantity of the pulp is taken up, and by the draining through of the water, the pulp is left in a sheet upon the wire. There is no fakening for the deckle, as it is moveable, and only held upon the mould, by the workman grasping the mould and deckle together in both hands at the opposite sides. This admits of the deckle being removed, that the sheet of paper may be taken up from the wire, by applying the mould upon a piece of felt. The felts are pieces of woolen cloth, spread over every sheet of paper, and upon which the sheets are laid, to detach them from the wire of the mould; they also prevent them from adhering together, and impeding part of the water with which the paper is charged, transmitting the whole of it when placed under the action of the vats.

The moulding of the paper is performed by three workmen, the doper, the coucher, and the lifter. The first of these having filled the vat with pulp, must be attentive to mix it up well; for this purpose, he employs two implements, one of which is a simple pole, and the other a pole armed with a piece of board, rounded and full of holes. This operation is repeated as often as the fluff falls to the bottom. In the principal mills they use for this purpose what is called a hog, which is a machine within the vat, that, by means of a small wheel on the outside, is made to turn constantly round, and keep the fluff in perpetual motion.

When the fluff and water are perfectly mixed, it is easy to perceive whether the previous operations have been complete. If the fluff floats close, and in regular flakes, it is a proof that it has been well ground, and the parts of the rags, which have escaped the cylinder of the engine, also appear. The doper stands in a niche, or hollow part of that kind of ledge or table which goes round the circumference of the vat; he holds a mould in both hands, by the two extremities, with the deckle applied exactly over the mould, as if only one piece; then inclining it a little towards him, he dips it into the vat, and brings it up again into a horizontal position. The superfluous part of the pulp flows over on all sides, and the quantity thought sufficient is shaken gently, from the right to the left, and up and down horizontally, until it is equally extended over the whole surface of the mould. These two motions are also accompanied by a slight shake, that serves to fix and flop the sheet. As the water drains through the wire, the fibrous parts of the fluff arrange themselves regularly on the wire-cloth of the mould, not only in proportion as the water escapes, but also as the workman favours this effect, by gently shaking the mould. This done, the mould is immediately laid on the edge of the vat, the deckle taken off, and the mould made to slide along the board which is laid across the vat, to the part where the sheet is to be laid or taken off. The board, which is but two inches in breadth where the sheet is laid, is nothing more than a deal board, which runs along the length of the vat, and is pierced with several holes at the extremity, for letting the mould drain into the vat.

The doper taking the deckle off the first mould, places it immediately on a second, which is given him for dipping in its turn; and the second workman, called the coucher, taking the mould off the board that runs across the vat with the left hand, раfes it gently, and lays it in an inclined position against one or two small pins, which are driven into the board on the edge of the vat. In this condition the mould remains two or three seconds of time for draining into the vat, whilst the coucher extends a felt, on which he applies the mould to take off the sheet, which being done he returns the mould to the doper.

They proceed in this manner, laying alternately a sheet and a felt, till they have made sixquires of paper, which is called a poll, and this they do with such swiftness, that in many forts of paper two men make upwards of twenty pollis in a day.

When the last sheet of the poll is covered with the last felt, all the workmen about the vat unite together, and submit the hsep to the action of the vat prefs. They begin at first to press it with a middling lever, and afterwards with a lever about fifteen feet in length.

The doper should be attentive, in distributing the matter on the mould, to reinforce the corner the coucher is to take hold of, in raising and extending the sheets; for without this precaution he would break a great many, and he if he takes up too much matter with his mould, if he does not equally extend it, or if he strikes his mould against the drainer. In all these cases the matter is accumulated in certain parts of the mould, producing something like ridges in the paper, or if he lets the matter reit on the mould, and does not distribute it immediately, there will be parts of unequal thickeners. When the vat is too hot, the stretching out of the sheet will be ill performed, because the water evaporates too soon from the mould. Add to this, that in letting the matter run towards one of the edges, by not giving his arm a regular motion, he may form a feather-edged paper, which may likewise happen if he does not extend his fluff sufficiently; or if the vat be too hot, or the fuccula of the pulp is too crude, and does not run well, if his arms are too stiff, and if he gives a bad shake, or if the mould be ill made.

In order to avoid drops of water, which, if they fall upon the paper, will make disagreeable spots, the mould should be raised readily; and as often as the coucher returns his mould to the drainer, he ought to be careful to shake his hands behind him; for without this precaution, his fingers, which are wet, would drop upon the sheet already laid, whilst he is covering it with the felt. If he is also too quick
in laying, the air detained and compressed under the sheet occasions a bulging, and makes some parts more clear than others.

In consequence of the construction of the mould, it is easy to perceive that the sheets of paper will take, and preserve, the impression of all the wires which compose it, and of the empty spaces between them. This is seen in examining a sheet of paper before the light, a greater opacity being found on both sides of each brazen wire, than towards the middle of the space. This thicknefs is occasioned by the pulp, which, in motion through the mould could not distribute, being stopped by the small wires, and flung more by the large copper wires. This defect is completely remedied by the improvement of weaving the wire of the mould like cloth. The traces of the old wires are most evidently perceived on the side of the sheet which was attached to the mould, and on the other side they form an assemblage of rounded risings. In the paper which is most highly finished, the regularity of these impressions is still visible; therefore it is evident, that all the operations to which it is submitted, have chiefly in view to soften these impressions without destroying them; it is necessary, therefore, to attend to the combination of labour which operates on these impressions. The cousher, in turning the mould on the felt, flattens a little the rounded eminences, which are in relief on one of the surfaces, and occasions, at the same time, the hollow places made by the wire-cloth to be party filled up; meanwhile the effort which is made in detaching the paper, produces an indefinite number of small hairs on every protruberant part of the sheet. Under the action of the prefs, fill with the felts, and then without them, the perfecting of the grain of paper still goes on. The velvety of the protuberances made by the wires of the mould are altogether flattened, and in consequence the hollows opposite them disappear also, but the traces formed by the interlaces of the wire, in consequence of their thicknefs, appear on both sides, and are rounded by the prefs.

The grain of the paper is often disfigured by the felts when they are too much used, or when the wool does not cover the thread. In this case, when the paper is submitted to the prefs, it takes the additional traces of the warp and the woof, and composes a surface extremely irregular.

The two sides of the felt are differently raised, and on which the hair is longest, is applied to the sheets which are laid down, and any alteration of this disposition would produce a change in the texture of the paper. The stuff of which the felts are made should be sufficiently strong; in order that it may be stretched exactly on the sheets, without falling into folds, and at the same time sufficiently pliant to yield in any direction, without injury to the wet paper. As the felts have to resist the reiterated efforts of the prefs, it appears necessary that the warp be made stronger, of combed wool, and well twilled. On the other hand, as they have to imbibe a certain quantity of water, and to retain it, it is necessary that the woof be of carded wool, and drawn out into a slack thread.

The paper remains in the vat prefs during the time that the next part of paper is preparing, and when it is removed to make room for that, the biffnels of the third worker, called the lifter, begins it is to take the sheets off the felt, (for they are caused to adhere to them by the action of the prefs,) and then making the sheets up into a second pile; but if the cousher works too fast, and the lifter finds himself hard pressed, he cannot stretch out his sheets exactly upon one another, so as to make a neat and compact pile, which is very necessary to make paper of a regular and equal thickness, when put under a second or wet prefs, which is done as soon as several of the piles are completed, and can be collected together.

This second pressure being made with all the sheets in contact with each other, expresses a great quantity of water from the paper, and gives the sheet a very considerable strength; it also tends to take out those creasques on the surface of the sheets, which were occasioned by the impression of the felt, though it is necessary to have felts in the first pressure, because the paper is then to soft and pulpy, that it would be pressed into a solid mass if the sheets touched each other.

The paper remains in the second prefs as long as it can, until another pile is made ready by the lifter. When the paper has undergone these operations, it is not only softened in the surface, but better felted, and rendered more plant in the interior parts of the stuff. In short, a great part of the water which it had imbued in the operation of the vat is diffipated. By the felting of paper is understood the approximation of the fibres of the stuff, and their interlacing, so as to adhere close together. The paper is felted in proportion as the water escapes, and this effect is produced by the management and reiterated action of the prefs; without this action the paper would be porous, and composed only of filaments without adhesion. When the sheets are very thin, and it is found, after the second pressure, that they are formed by a fcelula, which is still so saturated with a great deal of water, that they have little confidence, it is probable that the second prefs will join them to one another, and it is difficult to separate them; indeed they cannot well be taken off finely without tearing a great number. This is a product of the biffnels of the prefs has been badly conducted. To avoid all this inconvenience, it is necessary to bring down the prefs at firft gently, and by degrees with greater force, and to raise it as suddenly as possible. By this means the water, which is impelled to the sides of the heaps which has not yet escaped, returns to the centre, the sheets are equally dried, and the operation is executed without difficulty. The separation, sheet by sheet, is not necessary for drying, so that seven or eight may be taken together, which is called forming the pages; sometimes also a few number may do, when the paper is of a large size, but never less than three sheets are hung up together.

It is of more importance than we are aware of, that the sheets should thus remain, as it were, paled several of them together; if they were single, they could not sustain the moisure of the size, yet this moisure is sufficient to facilitate their separation; but to prevent their separating when they are hung up to dry, they should be placed so that the pages may receive the wind in the surface, and not in the sides and edges. When the paper is removed from the second prefs, it is taken to the drying lofts, which are very extensive apartments, usually the upper parts of all the buildings of the mill; the sides are formed by louver boards, which are a kind of lattice or boarding which can be opened or shut, to admit more or less air, at pleasure.

The sheets are taken upon a piece of wood like a T, and hung upon hair lines, stretched across large horizontal wooden frames, called fribriles, and these, as they are filled, are lifted up between upright polls to the top of the room, and retained by pegs put in the polls; then another frame being filled, is put up in its turn, and so on till the loft is filled from top to bottom.

The principal care in drying the paper, consists in gradually admitting the external air, and in preventing the cords from imbibing moisure; for this reason the lattices or louver boards should be constructed with great exactness, and the cords may be prevented from imbibing the water by covering them with wax. In using such cords, the moisure does not continue in the line of contact between the paper and the cord, which prevents the sheet from stretching in that particular place by its weight, and from
the folds which the moisture in the subsequent operations
might occasion. The cords are of considerable thickness,
by which means they diminish the point of contact, and give
a better and more equal circulation to the air. By these
precautions, the Dutch paper is dried equally, and is ex-
tr emely supple before the fizing. The time necessary for
drying the paper depends so much upon the rate of the at-
mosphere, and the thickness of the sheets, that it cannot be
flated with any degree of accuracy; but being dried, is
taken down, and fleeked, drefled, and shaken, to make the
dult fall out, and to separate the pages from one another.

It is then laid in heaps in the warehouse, and from thence
brought out in order to be fized. The fize for paper is
made of the freads and parings got from tanners, curriers,
and parchment makers. All the purifed parts, and the
lime, are carefully feparated from them, and they are in-
clofed in a kind of baffle, and let down by a rope and pul-
ley into the cauldron. This is a late invention, and ferves
two valuable purpofes: it makes it easy to draw out the
pie fes of leather when the fize is extracted from them by
boiling, and efay to return them into the boiler, if the opera-
tion is not complete. When the glutinous fubftance is
fufficiently extracted, it is allowed to fettle for some time,
and it is twice filtered before it is put into the vefsel in which
they dip the paper. Immediately before the operation, a
certain quantity of album is added to the fize. The work-
man takes a handful of the fheets, fmoothed and rendered
as supple as poffible, in his left hand, dips them into the
vesel, and holds them feparate with his right hand, that
they may equally imbibe the fize. After holding them
above the vefsel for a space of time, he feizes on the other
fide with his right hand, and again dips them into the vefsel.
When he has finifhed ten or a dozen of these handfuls, they
are fubmitted to the action of the prefs. The perforfous
fize is carried back to the vefvel by means of a fmall pipe.
The vefvel in which the paper is fized is made of copper,
and fuppiied with a grate, to give the fize, when neceffary,
a due temperature, and a piece of thin board or felt is
placed between every handful of sheets, as they are laid on
the table of the prefs. The Dutch are very careful in
fizing their paper, to have every sheet in the fame handful
of equal dryness, because it is found that the dry sheets
imbibe the fize more flowly than thofe which retain some
degree of moisture. They begin by fecting the pages in the drying house,
and after having made them supple, and having defroyed
the adherence between the fheets, they feparate them into
handfuls, in proportion to the dryness, each of them con-
taining that number which they can conveniently dip at one
time. Befides this precaution, they take care to apply two
sheets of brown paper, of an equal fize, to every handful:
this brown paper, being firm, folid, and already fized, is of
ufc to fupport the fheets.

It is the practice at some paper mills, to carry the paper
immediately it is fixed to the drying house, and hang it up
before it cools, fheet by fheet, on the cords; but particular
attention muft be paid to the lattices of the drying house, or
it is apt to dry too falt, whereby a great part of the fize
goes off in evaporation, or if too flow it falls to the ground.
The paper, being sufficiently dried for the laft time, is
carried to the building where it is examined, finifhed, and
prefled: this is called the faul. Women are here em-
ployed to remove all damaged and imperfect sheets: it is
then put into the dry prefs. shown at figs. 6, 7, and 8, of
Plate II., and fqueezed with a molt immenfe force, to render
the paper flat, and give it a good furface. The lever of
this prefs is fifteen or eighteen feet long, and ten or twenty
people are employed at the laft to work it, though they
sometimes use Samfon, that is, a windfafs like a crane, with
which they furface the lever of the ferew; but this ex-
cessive labour is altogether avoided, and a much greater
preffure given, by using Mr. Bramah's ingenious hydraulic
prefs, instead of the ferew prefses, which confume a great
portion of the power in friction. For a description of this,
see Press. Hydrofatic. The dry prefs is generally large
enough to hold two packs of ordinary paper, at once placed
one at the other's fide. When the compreffion is judged
fufficient, the heaps of paper are carried back to the table,
and prefled, that is, the whole turned, fheet by fheet, in fuch
a manner, that the furface of every fheet is exposed to a
new one, and in this fìtuation they are again brought under
the prefs. It is in extending these two operations some-
times to four or five times, that often as the furface of the
paper requires, that the perfection of the paper is confti-

tued. If the fuff is fine, or the paper flander, the parting is left
frequently repeated. In this operation it is neceffary to alter
the fitution of the heaps with regard to one another every
time they are put under the prefs; and also, as the heaps are
higher towards the middle, to place small pieces of felt at
the extremities, in order to bring every part of them under
an equal preffure. A fingle man, with four or five prefses,
may part all the paper produced by two vats, provided the
previous preffing is well performed. The work of the
parting generally lafts about two days, on a given quantity
of paper. The paper is now frofted into different lots, accord-
ing to its quality and faults, after which it is made up into
quires. The perfon who does this muft poftes fuch skill,
and be capable of attention, because he acts as a check on
thofe who separate the paper into different lots. He takes
the heaps with the right hand, folds them, examines them,
lays them over his left arm till he has the number requisite
for a quire, then brings the fides parallel to one another, and
places them in heaps of fome quires. And expert workman,
if proper care has been taken in afforting the lots, will finifh
in this manner 6000 quires in a day. The paper is after-
wards collected into reams of 20 quires each, and for the
laft time put under the prefs, where it is continued for 10 or
12 hours, or as long as the demand of the paper mill permits.

The operation of moulding the sheets of paper has, for
some years past, been performed by a machine which pro-
duces it an endles and continued fheet, instead of moulding
them feprately one by one; and this it does with fuch ac-
curacy and dispatch, that many paper-makers have procured
machines, notwithstanding their great expense of erection,
and the premium which they are obliged to pay the patentees
for working them. The firft idea of this curious machine
was brought from France, but it has been wholly perfected
here; and we think it one of the most important inventions,
as applied to the manufacture of paper, which has been
produced since the fourteenth century, when the method of
making paper from linen rags was firft discovered. In ge-
neral, the progress of invention is slow and gradual; and with
regard to the fabrication of paper, there have been very few
striking improvements in relation to machinery for nearly a
century, except the prefs. The procéfes for improving
the general texture and appearance of the paper, by the
more skilful use and application of fizing and hot-preffing,
have certainly made important advances, even in the course
of the last twenty years; while, for a much longer period,
the modification in the machinery used for the conversion
of rags into pulp, and of pulp into paper, have been very
fhip, and, for the moft part, very unimportant.

Mr. E. H. S. Scaly, FourniHenry and Scaly, Fourni Henry and Gamble,
are the proprietors of this invention, for which they have
obtained
obtained several patents during its progressive stages of improvement; but an Act of Parliament was passed in 1807, to extend the usual term of all these patents to fifteen years from that period, and they then enrolled a specification in the records of Chancery, detailing the machine, in its most improved state, and from this we have taken the following description; though it is scarcely possible to describe such a very complicated machine without figures. The pulp having been prepared, in the usual manner, to due consistence, by the admixture of water, kept in motion in the vat by means of what are denominated hologs, is let out through several circular apertures in front of the vat, which can be narrowed or widened at pleasure, by means of a sliding plate. These apertures admit the pulp into a trough, which has a low side, or lip, and over the edge of this it flows, in a continued cascade, or even sheet: this trough of the vat is placed at one end of the machine, so that the stream of pulp falls upon a wire-cloth, or web, of many yards in length, the ends of which being united together, it is extended horizontally, in the manner of a jack towel, over two rollers, one of them placed close under the lip, or mouth of the vat, so that the stream of pulp descends as little as possible. The wire is kept supported by several other parallel rollers, that it may not hang down or bag, but be kept as level as possible, and by a very ingenious contrivance is kept extended in breadth to a proper length; it therefore represents a table of several yards in length, which, by the revolution of the rollers, is kept in continual motion from the vat towards the end of the machine. The pulp is kept within bounds upon this table, according to the width intended to be given to the paper, by two pieces or rulers of wood, exactly parallel with each other, and also with the line of motion of the wire. Between the wire itself and these rulers are placed two endless straps of leather, as wide as the rulers, and revolving with the same velocity as the wire, but over different rollers. Similar rulers, and endless straps are also placed in contact with the lower surface of the wire, so that the wire is confined between them on each side, and the liquid pulp thus prevented from running off on the sides, and they act as deckles to the mould. As they move together, they occasion no friction to destroy the wire. Near that part of the wire upon which the pulp falls from the lip in the vat, there is placed a flap of oiled silk, or other material, to prevent the pulp from running back towards the vat over the roller of the wire.

As the wire revolves upon its rollers, and carries the pulp along upon its surface from the vat to the other extremity, it is conducted between two rollers, fitted up in the manner of a rolling mill, which cause a pressure upon the pulp and paper to force out the water, and are therefore called the wet-presses. In order to guard the pulp, which before passing between the rollers is in a soft flate, from being disfloded, or otherwise injured by the upper roller coming immediately in contact with it; a revolving endless web of felt is applied. This is made of the same width as the endless wire, but not so long, and it is extended, like that upon rollers situated above the wires; it is likewise brought between the rollers of the wet-presses, so that its under surface falls upon the surface of the pulp, or paper, and defends it from the action of the upper cylinder: the wire and the felt are thus brought into contact with the paper between them, and the required pressure is given by means of screws, which increase or diminish the distance of the large compressing rollers, and these being covered with flannel cloth, or felting, are prevented from injuring the wire webbing, as well as producing a better effect upon the paper than naked cylinders would do.

To prevent the water thus pressed out of the pulp from running back upon the paper, the wire is not only made to defend before it passes the wet-press, but there is also placed a small roller rolling upon the wire, as near the press as possible, and some part of the water is previously got rid of, by both the wire and felt, with the pulp between them, passing through a small pair of rollers, to the axis of the upper one of which rollers are hung weights, in order to give a slight pressure. The water that drains from the pulp is collected into a trough, and returned to the vat by means of a scoop-wheel instead of a pump, which might form the paper fluff into lumps or rolls, by the mutual friction or rubbing of any parts of the apparatus against each other, and the reason for returning the water into the vat is to prevent the loss of a considerable portion of the paper, fluff, blue, size, &c. which would otherwise be fulminated by its running to waste.

It is evident then, that if motion is given in the proper direction to the wet-press cylinders, having both the web and wire thus compressed between them, they will be drawn along by them, and caused to revolve upon those respective rollers; and that, as long as these webs continue so to revolve, and the pulp continues supplied and running upon the surface of the under web, so long will the machine continue making a sheet of paper, of continually increasing length. But as the paper, even after having passed between the rollers of the wet-press, is not of that consistency and strength as would allow of its being removed from the machine and cut in sheets, the new-made paper is cauffed to detach itself from the wire, at the moment it comes to the extreme roller, over which the wire revolves, and is immediately received upon a second web of felt, which is, like the former, stretched by two principal rollers and other subordinate ones. By the revolution of this web, which must have the same velocity as the former, the paper is brought between two rollers of brass or other hard metal, which are turned perfectly smooth, and placed some distance from the wet-press cylinders, but exactly parallel to them, and after passing through them, the paper is received and wound upon a reel, or roller, which is from time to time removed, and others applied in their room as they are filled with paper.

This is the general action of the machine, but there are a number of very ingenious movements, which we have not mentioned. The flapping movement of the mould, which is so necessary to make the pulp coagulate into paper, is, in this machine, given to the wire thus: the frame of the roller on which the wire is extended at the end near the vat, is so placed on the top of upright legs, which are movable on centres, as to admit the roller and wire with the deckle straps to move sideways a small quantity, and to return, in the manner of vibration, by the action of a crank. The number of these vibrations, or shakes, necessary in a given time, and the pace passed through by the wire in each, will vary according to the quality and preparation of the pulp. The number, however, may, by observation, be limited to one or two hundred per minute, and the space between a quarter of an inch, and an inch. To enable the paper-maker readily to give a proper velocity to the crank according to his judgment, the frame is turned by a small independent water-wheel, the velocity of which, and consequent number of vibrations, are regulated at pleasure, by the quantity of water admitted upon the wheel. The flapping plate in the vat, which admits the pulp to flow out as first mentioned, is regulated by a screw, by which the circular aperture may be opened or shut in any intermediate degree, so that the quantity of pulp required to run from the vat
PAPER.

Vat to the wire, may by this be regulated, and so adjusted to the velocity of the wire, as to produce a sheet of paper of any required thickness. The whole machine is turned by a water-wheel, which is preferable to any other power, as by it is obtained the most regular and uniform motion, and such as is best adapted for this purpose, though other first movers might be used.

As the paper is drawn off the endless wire by the motion of the revolving web of felt, it is necessary to have the riggers, or band-wheels, which communicate the motion from the rollers of the dry-press to those of the wet-press, made upon an adaptable principle, or capable of having their diameters increased or diminished, as occasion requires, whilst the machine is at work. By this adjustment, an exact correspondence is obtained between the velocity of the revolving wire and that of the revolving felting, for should one exceed the other in the smallest possible degree, the paper would either be torn aflutter, or carried round upon the under side of the web, and be spoiled. It is effected by a very ingenious application of an expanding rigger; which, the machine will make paper of any required width, by diminishing the distance between the deckles upon the wire; and for this purpose, the rollers over which the deckle fraps are conducted, are adjustable upon their spindles. The long sheet of paper, thus obtained, is unrolled from the reel upon a cutting table, having grooves, with deckle edges, placed at a proper distance; and thus the sheets, of the usual sizes, are cut off, by means of steel cutting wheels running into the grooves of the table, and prefled down by a loaded carriage. The reel of paper is placed parallel to these grooves, which are so much larger than the utmost width of the sheet, as is sufficient to let the carriage be retained upon either side while a sheet is taken off the table, and a sheet paper drawn on; in doing which, care is taken to keep the edges of the sheet at right angles to the grooves, for which purpose, direction lines are drawn upon the table. We have been informed by those who have seen these machines at work, that this method of cutting has been abandoned; and they are now worked with reels made adjustable to the required width of the sheet, and when a sufficient quantity is wound on it, is cut off by a knife, which, by cutting through the folds, divides the paper into separate sheets, which are ready for the operation of the second press. These machines are constructed with a cloth, so wide, that the continual sheet is cut up into two, and sometimes three in width, by which means it produces an immense number of sheets in a short time; but the greatest advantage is in making very large sheets, which it will do to almost any extent in length, and as much as two yards in width.

This machine is only adapted for making wove paper; but a patent has lately been taken out for carrying this invention farther, and making the paper with lines in it; but this is done with separate moulds, similar to those at present used, though worked by machinery, which in some measure resembles the other, the moulds being attached to an endless chain in lieu of the endless wire.

Chinese paper is of various kinds; some is made of the rinds or backs of trees, especially the mulberry tree and elm, but chiefly of the bamboo, and cotton tree. In fact, almost each province has its several papers. The preparation of paper made of the backs of trees, may be influenced in that of the bamboo, which is a tree of the cane or reed kind. The second skin of the bark, which is soft and white, is ordinarily made use of for paper: this is bent in fair water to a pulp, which they take up in large moulds, so that some sheets are above twelve feet in length: they are completed by dipping them sheet by sheet in alum water, which serves instead of the size among us, and not only hides the paper from imbibing the ink, but makes it look as if varnished over. This paper is white, soft, and close, without the least roughness, though it cracks more easily than European paper, is very subject to be eaten by the worm, and its thinness makes it liable to be soon worn out.

The celebrated Dr. Franklin has, in the American Philosophical Transactions, given the following account of the method used by the Chinese for making these large sheets of paper; supposing of four and half ells long, and half an elli wide. They have two large vats, each five ells long, and two ells wide, made of brick and lined with plaster, that holds water; in these the fluff is mixed ready to work. Between these vats is built a kiln, or stove, with two inclining fides, each side something larger than the sheet of paper; they are covered with fine flueco, that takes a polish, and are so contrived, as to be well heated by a small fire cirulating in the walls. The mould is made with thin, but deep fides, that it may be both light and fiff. When the mould is suspended at each end with cords, that pass over pulleys fixed to the ceiling, their ends connected with a counterpoise, nearly equal to the weight of the mould.

Two workmen, one at each end of the mould, lift it out of the water by the help of the counterpoise, turn it up, and apply it, with the fluff for the sheet, to the smooth surface of the stove, against which they press it, to force out a great part of the water through the wires. The heat of the wall soon evaporates the rest, and a boy takes off the dried sheet by rolling it up. The side next the stove receives the even polish of the fluts, and is thereby better fitted to receive the impression of fine colours. If a degree of sizing is required, a decotion of rice is mixed with the fluff in the vat. Thus, the great sheet is obtained smooth and fized, and a number of the European operations, of uniting the edges of several small sheets together, are saved. If the flue has two polished fides, and there are two vats, the fame operation is, at the same time, performed by two other men at the other end, and one fire serves both.

We conclude with full hinting the importance, in the present state of our political relations, and the extreme difficulty of obtaining rags, of directing the attention of manufacturers to other fubstances, from which paper may be fabricated. Silk, it is well known, has been used in the East as long ago as the seventh century, but the article is too expensive for general adoption. Cotton, when treated in a manner similar to that practiced with linen rags, affords an excellent paper, which at present forms a very extensive branch of the Levant trade.

The Japanese paper is, according to Kempfer, made of the bark of the morus papysifera salvea, or true paper tree. (See Japan Paper.) Other fubstances are the thistle of thistles, the bark of the fallow (sulcica capretata), hemp, flaws of hemp, flaws of fax, hop bines, flails of cabbage, of mallow, of common broom, of the fun-flower (benthium annuius), of mugwort, of elematis, &c. the down of the ear's-tail, the catkins of the white poplar, the huffs of maize, flraw, &c. Trials of some of these, and especially of flraw, have been made in England as far back as the year 1799; but much remains to be done; and as the occasion is important, especially as it relates to commerce, and to the propagation of arts and sciences, we should be happy to find, that some public-spirited individual, of enterprize and talent, would turn his attention to an extensive feries of experiments, for the purpose of ascertaining the merits of these or other fubstitutes for linen rags, in the fabrication of paper for writing and printing.
The excise duties on paper are subject, like other impositions of the same kind, to successive variation, both in their amount and rate; and so are likewise the bounties and drawbacks. And as, in the course of a few years, the enumerations of them would not only be useless, but erroneous, we shall content ourselves with observing, in general, that the principal act by which duties of excise are now collected, is the 43 Geo. III. c. 69; that by the 43 Geo. III. c. 81; more duties were added to those imposed by the former act, and by other subsequent statutes other duties increase the whole amount; and the particulars may be found in the schedules annexed to the several acts. We shall here subjoin some more permanent regulations.

Paper, which hath paid the duty may be exported, and also books; and drawbacks are to be allowed subject to the regulations preferred in several acts. (26 Geo. II. c. 78. 34 Geo. III. c. 20. 43 Geo. III. c. 69. ched. G.) The officer attending the packing of paper for exportation, shall take off the stamps from each ream or bundle, and any person obtruding him in this service shall incur a forfeiture of 50 l. (26 Geo. III. c. 77.) By 49 Geo. III. c. 98. certain duties of customs are also payable upon papers; but old rags, old ropes, or junk, or old filling nets, may be imported duty free. (11 Geo. I. c. 7.) By 32 Geo. III. c. 54. Officers of the customs shall cause any printed, painted or stained paper that is imported to be marked; and counterfeiting or forging the mark or number, subject to a forfeiture of 100 l.; and counterfeiting or forging any stamp or seal for making the impression, incurs a forfeiture of 500 l.; and any person who shall sell paper with such counterfeit stamps, knowing the same, shall forfeit 50 l. By 34 Geo. III. c. 20. the importation of books for sale, first printed in this kingdom, and reprinted in any other, incurs forfeiture of the same, and also of duty, and double the value of such book; provided this shall not extend to any book that has not been printed or reprinted in this kingdom, within twenty years before the same shall be imported, &c.

Every maker of paper or palleteboard, and every paper-stainer, shall take out a licence from the office of excise, annually, for which he shall pay 2 l., on pain of forfeiting 200 l. (24 Geo. III. c. 41. 43 Geo. III. c. 69. ched. A.) All brown paper, made of old ropes, or cordage only, without separating or extracting the pitch or tar from them, and without any mixture of other materials, shall be deemed paper of the second class or denomination, and be chargeable with the duty accordingly; and all other paper whatever (glazed paper for clothiers and hot-preachers excepted) shall be deemed to be of the first class or denomination. (42 Geo. III. c. 94.) No paper shall be painted or stained for lankings, except for which the duty on paper of the first class hath been charged, duly stamped, &c. (41 Geo. III. c. 8.) Nor is the maker to diminish any paper before it be charged, under the penalty of 50 l. and also fine paper. Palleteboard is to be made of paper charged, and unfiled for any other purpose, on pain of 100 l., together with forfeiture of the same, and utensils. &c. employed in making it. (42 Geo. III. c. 94.) By the same act, the maker of palleteboard shall produce to the officers all such paper as he intends to use for palleteboard, duly wrapped and stamped, after 24 hours' previous notice, on pain of 100 l.; nor shall any maker of palleteboard be a paper-maker, nor manufacture within a quarter of a mile of a paper manufactory, on pain of 100 l. Places of making or keeping paper, palleteboard, mill-board, scale-board, or glazed paper, all utensils and materials employed, shall be entered, on pain of forfeiture, and also of 50 l. (34 Geo. III. c. 20.) All paper shall be made up into quires, each quire consisting of 24 sheets, and such quires shall be made up into reams of 20 quires each; and all palleteboard, &c. shall be made up in parcels, each parcel containing at least a dozen of sheets, of one and the same denomination, and of equal dimensions, and not less than 24, nor more than 72 such sheets in every parcel; tied up, &c. in wrappers, and marked with the clasps of paper to which it belongs, the number of the reams made by the maker during the current quarter, &c. &c. on penalty of 200 l. and forfeiture. (42 Geo. III. c. 94.) Every maker may make his paper into quires without folding, provided that such quires, when made up into reams, be separated by a slip of coloured paper placed between each quire, and visible on the outside of the ream, and that the outline quires of each ream consist of a dozen and a half of sheets, at the option of the maker. Every maker, whose mill or workhouse is situated in any city or market-town, who shall have any paper, palleteboard, &c. to be weighed, and charged with the duty, shall give 24 hours (whether 24 hours) previous notice, in writing, to the officer of excise, who shall attend, and such maker, or his servant, shall produce to the officer all such paper, palleteboard, &c. duly tied up, that the duty may be charged previous to removal; and stamps shall be provided by the commissioners of excise; and if any person shall counterfeit such stamps, and fell with such counterfeit stamps, knowingly, he shall forfeit 500 l. (34 Geo. III. c. 20.), but this penalty is repealed, and the person committing the offence is adjudged guilty of felony, and subjected to transportation, as a felon, for seven years. 47 Geo. III. feft. 2. c. 30.

Paper-makers are enjoined to give notice to the proper officers of their names, places of abode, &c. and to make regular entries, on oath, every six weeks, of all paper, &c. made by them, on penalty of 50 l. and the duty shall be paid in six weeks after entry, on pain of double duty. 34 Geo. III. c. 20.

Paper-makers are forbid to remove or to conceal their paper, &c. till the officer has taken account thereof, on penalty of 50 l. and forfeiture of the paper, &c. (24 Geo. III. c. 18. 34 Geo. III. c. 20. 42 Geo. III. c. 94.) Nor shall paper, &c. be removed in less than 24 hours, under the same penalty; nevertheless it may be removed from one mill to another, upon giving 48 hours' notice, in writing, to the officer. Paper that has been stamped and charged, is to be kept separate from other paper, and also paper of one clas from that of another, on pain of 50 l.

Persons molesting officers in the execution of this act (34 Geo. III. c. 20.) incur a penalty of 100 l. and the penalties and forfeitures shall be appropriated, one moiety to the king, and the other moiety to the informer.

There is a drawback of the duties on paper exported; and also for books printed at Oxford or Cambridge, in the Latin, Greek, Oriental or Northern languages, and also for bibles, testaments, psalm-books, or books of common prayer, printed either in those universities, or by the king's printer, under certain conditions. 43 Geo. III. c. 69. ched. C.

Palleteboard, made of paper that hath paid the duty, shall not be charged with further duty. (34 Geo. III. c. 20. 42 Geo. III. c. 94.) Allowance shall be made on paper damaged, for which the duty hath been paid; upon seven days' notice; and allowance shall be made to clothiers and hot-preellers; on certain conditions. 42 Geo. III. c. 94. 43 Geo. III. c. 69.

Stained paper (besides the duty paid for the paper before staining) is subject, by the former acts, to a duty of 13d. a yard square. 43 Geo. III. c. 69.

Papers are of various kinds. With regard to colours,
PAPER.

they may be divided into white, brown, blue, &c. With regard to quality, into fine, second, bastard, superfine, &c. With regard to use, into writing, printing, pressling, cap, cartridge, copy, chancery, past, &c. With regard to dimensions, into demy, medium, fool's cap, pot, royal, super-royal, imperial, elephant, atlas, &c. With regard to country, into German, Lombard, Rochelle, Genoa, Holland, &c.

French paper is divided into large, middle, and small. To the small belong those called petit Romaine, petit Raifin, or Bâton royal, petit nom de Jesus, and petit à la main, all thus denominated from the marks impressed on them in making. Also the cartier, for the backs of playing cards; pot for the figure side; couronne, which has commonly the arms of the comptroller-general of the finances; tellier, with the arms of the late chancellor Tellier, and a double 'Y'; and champy, or à chaque la fermente, so called from its mark, the ferment which being extremely fine and thin, is used by fan-makers. To the middling sort belong the grand raifin simple, carré simple, cavalier, and lambert, the three last of which are for printing; l'eau, or de compate simple, carré double, l'eau double, grand raifin double, and couronne double, which three last are denominated double on account of their strength and thickness. Add to these the pantalon, or paper with the Dutch arms; and grand cornet, so denominated from the impression on it.

To the larger belong the grand Jesus, petit et grand fleur-de-lis, chapellet, colombier, grand angle, dauphin, soleil, and pétrole, which are thus called from the figures they bear, being all proper for printing either at the letter-pres or rolling-pres; also for merchants books, and for drawing on. The grand monde is the largest of all. Vide Savar. D. de Comm. tom. ii. p. 956, seq.

We have also printed paper, for hanging rooms. (See Paper hangings.) Stamped paper, to write obligations, deeds, and contracts upon. (See Stamp.) Ruled paper, for books of accounts, &c. To which may be added cut paper, and gilt paper, for letters, &c. See Gilding of Paper.

Paper, Blue, is a sort used by tradesmen to wrap up goods; as sugar-loaves, pieces of linen, &c.

Paper, Blotting, is paper not sized, and in which therefore ink readily sinks or spreads. It is used in books of account, &c. in lieu of sand, to prevent blotting and disfiguring the opposite pages. The same kind is likewise used by apothecaries in filtrating juices, and other matters, for which the manne Hippocratis is not so proper.

Paper, Teint, or demi-teint, for designing on, is either brown, blue, or bistred.

Paper, Bistred, is white paper washed over with a sponge dipped in water. Its use is to ease the labour of the crayon, in places which are to be shadowed the fame depth with the tint of this paper. For light places, they are made thereon with white chalk. Vide Cornell. Elem. de la Peint. Prat. cap. 15. p. 35. seq.

Paper, Marbled, is a sort of paper variously stained, or painted as it were with divers colours; made by applying a sheet on the surface of a liquor wherein colours diluted with oil or ox's gall are suspended. The manner of making it is thus: a trough is provided of the shape and dimensions of a sheet of the paper to be marbled, and about four fingers deep: this is made of lead or wood well joined, and pitched or primed to contain the liquor. For the liquor, a quarter of a pound of gum tragacanth is macerated four or five days in fair water; this they flir from time to time, and add to it daily fresh water, till it be of a consistence somewhat thinner than oil; then they strain it into the trough. The colours to be applied thereon, for blue, are indigo ground up with white lead, or Prussian blue and verdigris may be used; for green, indigo and orpiment, the one ground and the other tempered, mixed and boiled together with common water; or verdigris, a mixture of Dutch pink and Prussian blue, or verditer, in different proportions: for yellow, orpiment bruised and tempered; or Dutch pink and yellow ochre: for red, the finest lake, ground with raisings of Briail wood, which has been prepared by boiling half a day; or carmine, rose pink, vermillion, and red-lead; the two latter of which should be mixed with rose pink or lake, to bring them to a foster call: for orange, orange lake; or a mixture of vermillion, or red lead, with Dutch pink: for purple, rose pink and Prussian blue. Into all these colours, properly ground with spirit of wine, they put a little ox or fish gall, which is two or three days old; and if the colours dilute not of themselves sufficiently, they add more gall: on the contrary, if they spread too much, the gall is over-dosed, and must be corrected by adding more of the colour without gall.

For the operation of marbling, when the gum is well settled in the trough, they extend a sheet of paper, and plunge it very shallow into the liquor. Suddenly lifting it out again, in order to flir up, and raise the subfusing gum towards the surface, and for the more universal impregnating of the liquor.

This done, and all the colours ranged in gallipots on the table, where also the trough is placed, they begin by dipping a brush of hog's hair into any colour, commonly the blue, and sprinkling it on the surface of the liquor: if the colour has been rightly prepared, it will dilate itself duly therein. This done, the red is applied in the like manner, but with another pencil; after this the yellow: lastly the green. For white, it is made by only sprinkling fair water, mixed with ox's gall, over the liquor.

When all the colours are thus floating on the liquor, to give them that agreeable cambletting, which we admire in marble paper, they use a pointed stick; which being applied by drawing it from one side of the trough to the other, with adresses, flirs up the liquor and fluctuating colours; then with a comb, made of wood, about five inches long, with bristles, about two inches in length, and a quarter of an inch distant from each other, taken by the head with both hands, they comb the surface of the liquor in the trough, from one extreme to another, permitting only the teeth to enter: this being performed with a gentle and uniform motion, makes those clouds and undulations on which the beauty of the paper depends.

If it be farther desired to have the colours lie in any other fantastical pollice, repre{senting serpents, or the like, it is effected with the pointed stick above-mentioned, by drawing it over what has been already combed; but this must be done with a dexterous hand, and with a shallow dip into the liquor, circling, as if you would draw the flourid, or figured letter.

Lastly, the colours being in this pollice, the operator displays and applies on them a sheet of white moulded paper; to do which, artill like, requires a skilful only to be obtained by practice; because the surfaces of the liquor and the paper are to meet equally in all parts; which done, before the colours have time to seak through, which, unless the paper be very thick, will be in the space of two or three pulses, he lifts up the paper nimblly, and with an even hand; and then, after spreading it a while on a board, hangs it on a line to dry; which, when sufficiently done, they first rub it with a little soap, and then polish it with a marble stone,
PAPER.

It must be observed, that the sprinkling of the colours is to be renewed, and all the other ceremonies performed with the stick and comb, at every application of fresh paper, by reason that every paper takes off all the colour from the liquor. Vide Kirch. de Luce & Umbra, lib. x. par. 2. cap. 4. Merr. Observ. on Neri de Art. Vitru. cap. 42. p. 312. Thought. Collect. tom. ii. p. 419. feq.

Some attempts have been made to enrich the marbling, by mixing gold and silver with the colours; which furnished well in many attempts in the French king's library, though the expense has hindered the practice from obtaining. Savar. ubi supra.

Mr. Boyle tells us, that paper, besides its common ufe, may be made into frames for pictures, fine embossed work, and other parts of furniture. For this purpose, a convenient quantity of the belt white fort may be steeped for two or three days in water, till it becomes very fift; then reducing it by the mortars and hot water into a thin pulp, it is laid on a sieve to draw off its supernuous moiture; then putting it into warm water, wherein a considerable quantity of fresh glue, or common fize, has been difolved, it may afterwards be put into moulds to acquire the defigned figure; and when taken out may be strengthened, as occasion requires, with platter, or moistened chalk, and when dry painted or overlaid.

This hint is fince improved into a regular manufacture, under the name of paper macher.

Another ufe of paper is to flop up cracks or fiftures in wooden veffels to hold water; for, in this cafe, it will forcibly dilate, and fill the place in which it is to lodge.

Paper, Chinefe, is of various forts; some is made of the rinds or barks of trees, especially those abounding in sap, as the mulberry-tree and elm, but chiefly of the bamboo and cotton-tree; but, in reality, almost each province has its peculiar paper; that of Se-tchuen is made of hemp; that of Ko-kiang, of foft bamboo; that used in the northern provinces, of the bark of the mulberry-tree; that of the province of Che-kiang, of wheat or rice-fraw; that of the province of Kiang-nang, of the fkin found in the filk-worms balls; in fine, in the province of Hu-quang, the tre-chu, or Ko-chu, furnishes the principal material for paper.

As to papers made of the barks of trees; the manner of their preparation may be exemplified in the imitate of that of the bamboo, a tree of the cane or reed kind, being hollow, and divided into joints; but much larger, smoother, harder, and stronger, than any other fort of reed.

For this paper, they ordinarily only ufe the second coat or fkin of the bark, which is foft and white; this they beat in fair water to a pulp, which they take up in very large moulds or frames, fo that they have fleets ten or twelve feet long, and fometimes more. They are completed by dippmg them fleet by fleet in alum-water, which ferves instead of the fize ufed among us; and not only hinders the paper from too freely imbibing the ink, but gives it that luflre which at first light makes it look filvered, or at leaft varnifhed over.

The paper thus made is white, foft, and clofe, without the leaf roughnefs to flop the motion of the pen, or occa- tion the rifting of any of its fibres; though being made of the bark of a tree, it cracks more easily than the European paper: add that it is more apt to take moifture, that the dull flicks it to; and that the worms foort get into it; to prevent which laft inconveniency, they are obliged often to beat their books and expofe them to the fun. Add, that its thinnefs making it liable to be foon worn out, the Chinefe are under a frequent neceffity of renewing their books, by fresh imprifions taken from their blocks. Vide Le Compt. Nouv. Mem. fur Chin. lett. 7. Kuhl. Bibl. Nov. Libr. an. 1697, p. 67, feq. Lett. Edif. & Cur. tom. xix. p. 479.

But the paper of the bamboo, it is to be oberved, is neither the belt, nor the moft ufed, in China. In the former of these repects, it yields the priority to the paper made of the cotton-fhrub, which is the whiteft and finest, and at the fame time leaft subject to the inconveniences above-mentioned; because it keeps as well, and is as durable, as the European paper.

Dr. Grew thinks we may have plants in England, which contain in them a down that in all probability would make as fine a paper as that made by the Chinefe, from their cotton-fhrub. By which it appears he misjudged that the Chinefe paper was made not from the rind of the cotton-fhrub, but from the down or cotton itself. Vide Grew Muf. Reg. Soc. par. ii. feft. i. cap. 5. p. 215.

But the paper in most common ufe in China, is that made of the tree called chu ku, or ku chu, which Du Halde compares, firft, to a mulberry-tree, then to a fig-tree, then to a cyancmore-tree, and laftly, to increafe the embarrainment, to a strawbery-tree. By all which, we know no more of it than if he had laid nothing about it.

The method of preparing it for paper, is by firft scraping off lightly the thin outside of the tree, which is greenish; then they take off the inner rind in long thin fips, which they blanch in water, and in the fun; and afterwards prepare them in the fame manner as the bamboo. It must not be forgot, that in the other trees it is only the inward bark that ferves for making paper; but the bamboo, as well as the cotton-fhrubs, have this peculiarity, that not only their bark, but their whole fulblance, may be employed, by means of the following preparations.

Out of a wood of the largest bamboos, they select fhoots of a year's growth, which are about the thicknefs of the calf of a man's leg: thefe they trip of their firft green rind, and fplit them into ftraight pieces of fix or seven feet long; the pieces thus fleft, they fleep in a pond of muddy water, till they rot and grow foft by the maceration. In a fortnight they take them out, wash them in clean water, spread them in a large dry ditch, and cover them with lime for a few days; then they take them out again, and having washed them a second time, they flip them into fmall filaments, which they expofe in the fun to dry and whiten; they throw them into large coppers, where they are thoroughly boiled, and laftly, reduce them by the froke of large hammers to a thin palle or pulp.

After this, they take fome fhoots of a plant called ko-ting; they foak them four or five days in water, till there come out an unctuous fity fort of juice; this they mix with the pulp of which the paper is to be made, somewhat in the fame manner as painters temper their colours; care being taken not to put in too much, nor too little of it; on which the goodnefs of the paper much depends.

When they have mixed the juice of ko-ting with the fleft bamboo, and beaten the whole till it refembles a thick clammy water, they pour it into a large deep refevoir, confiding of four walls, raised breath high, and having the fides and bottom fo cemented, that the liquor cannot run out, nor foak in.

This being done, and the workmen placed at the fides of the refevoir, they dip in their moulds, and take up the surface of the liquor, which almoft instantly becomes paper; the mucilaginous and gleye juice of the ko-ting binding the parts, and rendering the paper compact, foft, and gloify, qualities
qualities which the European paper never has when first made.

To harden the sheets, and make them bear ink, they dip
them into alum water: this operation is called sanding,
from the Chinesè word san, which signifies alum. The
manner is this: six ounces of thin glue, cut very small, are put
in divers sortings of water, which they afterwards boil
up, flitting it all the time to prevent lumps: when the whole
is reduced to a liquid substance, they throw it into three
quarters of a pound of calcined alum, which they melt
and incorporate with it.

This mixture is next poured into a wide basin, across
which is laid a small round stick; then they flit the edge
of each sheet in another cleft from end to end, and in this
manner dip the sheet, gently drawing it out as soon as it is
wetted, by flitting it over the round stick. When the whole
sheet has been passed nimbly through this liquor, which
makes it whiter, and more compact, the long stick that holds
the sheet by the edge is flitted into a hole in the wall, and
the sheet hung up to dry.

As to the mould, with which they take up the sheet, its
frame is so contrived, that it may be raised or lowered at
pleasure; and its bottom is not made with wire as ours, but
with little slender strips of bamboo, drawn several times
through holes made in a steel plate, whereby they are ren-
dered as fine as wire: they are then boiled in oil till tho-
roughly soaked, that the mould may enter lightly into the
water, and not sink deeper than is requisite to take up mat-
ter enough for a sheet.

To make sheets of any extraordinary size, care is taken
to have a referror and mould large in proportion. This
mould is supplied by strings which pass over the pulley;
and the moment these pull up the frame, the workmen,
placed aside the referror, affix to take the sheet off; work-
ing together in a regular manner. See Paper japana.

For drying the sheets when taken off, they have a hollow
wall, whole sides are well whitened; at one end of it is an
aperture, through which, by means of a pipe, they convey
the heat of a neighbouring furnance; and at the opposite end
is a small vent to let out the smoke. By help of this fort of
floe, they dry the paper almost as fast as it is made.

Silvering of paper, as it is called, is another secret among
the Chinesè men, practiced at a very small charge, and without
using any silver. In order to this, they take two scruples
of glue, made of neat's-leather, one scruple of alum, and
half a pint of clear water: these they simmer over a flow
fire, till the water is consumed, that is, till no more steam
arises; then on a smooth table they spread some sheets of
paper, and on this, with a pencil, they apply two or three
layers of the glue: then they take a powder made of t alc
boiled, and mixed with one-third the quantity of alum; the
two are ground together, sifted, and the powder boiled again
in water; then dried in the sun, and lastly pounded again.
This powder they flit through a fine sieve, spreading it uni-
formly on the sheets prepared as above: after which they hang
them in the shade to dry; and this effected, they lay them
again on the table, and rub them gently with clean
cotton to take off the superfluous talc. This serves a second
time for the same purpose. With this powder, diluted in
water, mixed with glue and alum, they draw any figures at
fancy on the paper. Vide Du Halde, Descrip. Chin. tom. i.
p. 763.

The era of the invention of paper, among the Chinesè,
was, according to Martini, about 160 years before Christ.

Paper, Japan. Paper is made in Japan of the bark of
the morus papryfera sativa, or true paper-tree, after the fol-
lowing manner: every year, when the leaves are fallen off,
Bark is divided, and would come at last to be so thin and minute, that it would run out at the holes of the sieve and be loft, and at the same time also, what hard knots or flocks, and other heterogeneous useless particles remain, must be carefully picked out, and put up with a coarser sort of bark for worse paper. The bark being thus prepared, is put into a narrow tub, with the fat flimsy infusion of rice, and the infusion of the oreni root, which likewise is very flimsy and mucilaginous. These three things being put together must be stirred with a thin clean reed till they are thoroughly mixed and wrought into a uniform liquid substance, of a good consistence; this succeeds best in a narrow tub, but afterwards the mixture is put into a larger one, which is not unlike those made ufe of in our paper-mills; out of this tub the leaves are taken off one by one, on proper patterns made of bulrushes, instead of brafs wire, called mats. Nothing remains now but a pipe management in drying them; in order to this they are laid up in heaps, upon a table covered with a double mat, and a small piece of reed is put between every leaf, which flanging out a little way, letters, is time, to lift them up conveniently, and take them off finely. Every heap is covered with a small plank or board, and the same shape and size with the paper, on which the laid weights, firft, indeed, small ones, left the leaves, being then wet and tender, fhould be prefled together into one lump, but, by degrees, more and heavier, to prefs and squeeze out all the water. The next day the weights are taken off, the leaves are lifted up one by one, by the help of the small fliek above mentioned, and with the palm of the hand, clapped to long round planks made for this purpofe, which they will easily fliek to, because of the little humidity still remaining. After this manner they are expofed to the fun, and when quite dry, taken off, laid up in heaps, pared round, and fo kept for ufe or fale.

It has been observed, that the infusion of rice, with a gentle friction, is neceffary for this operation, because of its white colour, and a certain clammy fatness, which at once gives the paper a good consistence, and pleafing whitenefs. The fimple infusion of rice-flour will not do it, because it wants that clammines, which, however, is a very neceffary quality. The infusion spoken of is made in an unglazed earthen pot, wherein the rice grains are foaked in water, and the pot afterwards shaken, gently at firft, but stronger by degrees; at last, fresh cold water is poured upon it, and the whole percolated through a piece of linen. The remainder must go under the fame operation again, fresh water being put to it, and this is repeated fo long as there is any clammines remaining in the rice. The Japane& rice is by much the best for this purpofe, as being the whitefs and fattetl fort growing in Aia.

The infusion of the oreni root is made after the following manner: the root pounded, or cut small, is put into fresh water, which in one night’s time turns mucilaginous, and becomes fit for ufe, after it has been strained through a piece of linen. The different feafons of the year require a different quantity of water to be mixed with the root. They lay the whole art depends entirely upon this. In the summer, when the heat of the air diffolves the jelly, and makes it more fluid, a greater quantity is required, and lefts in proportion in the winter, and in cold weather; too much of this fluid mixed with the other ingredients will make the paper thinner in proportion; too little, on the contrary, will make it too thick, therefore a middle quantity is required to make a good paper, and of an equal thicknes; however, upon taking out a few leaves, they can easily see whether they have put too much or too little of it. Instead of the oreni root, which sometimes, at the beginning of the summer, grows very scarce, the paper-makers make use of a creeping shrub, called Jane kafura, the leaves of which yield a mucilage in great plenty, though not altogether fo good for this purpofe, as the mucilage of the above mentioned oreni root. They also ufe the juncus fatisfus, which is cultivated in Japan with great care and induftry. It grows tall, thin, and ftong; the Japane& make fairs of it, and very fine matts to cover their floors.

It hath been obferved above, that when the leaves are frefh taken off from the patterns, they are laid up in heaps, on a table covered with two matts. These two matts must be of a different fabric, one, which lies lowernift, is coarser, but the other, which lies upperift, is thinner, made of thin, flender bulrushes, which must not be twifled too clofe one to another, but fo as to let the water run through with ease, and very thin, not to leave any impression upon the paper.

A coarser sort of paper, proper to wrap up goods, and for several other ufe, is made of the bark of the kafura shrub, after the method above defcribed. The Japane& paper is very tight and ftong, and will bear being twifled into ropes.

A thick ftong sort of paper is fold at Siriga (one of the greateft towns in Japan, and the capital of the province of that name), which is very neatly painted and folded up, fo much in a piece as is wanted for a fuit; it looks fo like filken or woollen fluff, that it might be mistaken easily for them. A thin neat sort of paper, which hath a yellowift color, is made in Chuna and Tonquin, of cotton and bamboo: at Siam, the Siamites make their paper of the bark of the ploak-kioi tree, of which they have two forts, one black and the other white, both very coarse, rude and fimple, as they themselves are. They fold it up into books, much after the fame manner fans are folded, and write on both fides, not, indeed, with a pencil, in imitation of thofe more polite nations who live farther eafì, but with a rude flkus made of clay.

Thus far we have given a decription of the way of making paper in the Eafì, which the late learned Becmannus was fo dehifious to know, and fo earnestly intreated travellers to enquire into, being, however, mistaken, in supposing that it was made of cotton, whereas it evidently appears by this account, that all the nations beyond the Ganges make it of the bark of trees and thrubs. The other Aftnic nations on this fide the Ganges, the black inhabitants of the moft southern parts excpeted, make their paper of old rags of cotton fluff, and their method differs nothing from ours in Europe, except that it is more fimple, and the instraments they make ufe of are groffer. See Son.

Paper, flock, is a kind of paper-hanging, lately invented, which is embossed by means of choft cloth. The paper designed for receiving the flock is generally firft prepared with a varnish ground, of a proper colour; and it is not uncommon to print fome molafe, or other small running figure, in colours, on the ground, before the flock is laid on: this may be done with any pigment of the colour defired, tempered in varnish, and laid on by a print cut for the purpofe.

The manner of laying on the flock is either by means of a print, or by a fencil. But as the fencil can execute nothing but
but detached parts, and consequently is unfit for all designs
where running work, scrolls, or other more complicated
ornaments are introduced; it is extremely confined, with re-
spect to the nature of the designs for which it can be
employed; and the print is therefore most generally preferred.
The method of laying on the flock by means of a print
is this: a wooden print being cut (see Paper-hangings) in such
manner, that the part of the design, which is intended for
the flock, may project beyond the rest of the surface, the
varnish is put on a block covered with leather, or oil-cloth,
and the print is then used to lay the varnish on all the parts
where the flock is to be fixed. The sheet, thus prepared by
the varnished impression, is now to be removed to another
block or tablet; and to be flocked over with flock; which is
afterwards to be gently comfressed by a board, or some
other flat body, to make the varnish take the better hold of
it. Then the flock is to be hung on a frame till the varnish
be perfectly dry; at which time the superfluous part of the
flock is to be brushed off by a soft camel's-hair brush, and
the proper flock will be found to adhere in a very strong man-
ner. When the stencil is used, the same method is to be
performed; the varnish for holding the flock being laid on by
that instead of a print; and the flock afterwards flocked upon
it, as in the other cafe.

The usual method of preparing the flock is, by cutting
woollen rags, or pieces of cloth, with the hand, by means
of a large bill or chopping-knife. But it is much more easily
and better done by a machine; which may be worked by a
horse-mill, at the same time such mill is employed for cutting
diamonds, or any other similar purpose. In such cafe, the
construction of that part of the machine, which is made for
the cutting the flock, is this.

A box is made for containing the rags or cloth to be cut;
which is open at the top; and of such size, as may befit the
quantity of rags that the force employed can cut. A
blade is also to be made, the length of which is to be equal
to the breadth of the box; and it should be strong; and
must be charged with as great a weight as the force employed
can be made to raise with a quick motion. The box being
filled with the rags or cloth to be cut, is placed under the
knife, and made to move by hitches, after the stroke of the
blade is given, just so far as where it is proper the blade
should again cut the cloth or rags; while, at the same time,
the blade is lifted up, and let fall on the cloth, which it cuts
through, till by successive strokes, and the progressive mo-
tion of the box under it, the whole quantity of cloth or
rags in the box has been cut. The box must then be turned,
so that one of the sides may become the front; and the op-
eration must be repeated; by which means the cloth or rags,
having been cut both ways, will be reduced to the flake in
which the matter is called flock; and fit to be employed for
the purpose of paper-hangings. The work necessary for
conveying from the principal mover in the mill, the motion
for thrusting forward the box, and raising the blade, may be
easily supplied by any ingenious wheelwright, and need not
therefore be particularly described here.

There is a kind of counterfeit flock-paper, which, when
well managed, has very much the same effect to the eye as
the real: though done with less expence. The manner of
making this is, by laying a ground of varnish on the
paper; and having afterwards printed the design of the flock
in varnish, in the same manner as for true; instead of the
flock, some pigment, or dry colour, of the same hue with
the flock required by the design, but somewhat of a darker
shade, being well powdered, is flocked upon the printed
varnish, and produces greatly the same appearance. Handmaid
to the Arts, vol ii. p. 458, &c.

Paper-hangings are of several kinds; some of which are
made in the representation of limew-work, for covering ceil-
ings, or the sides of halls, stairs, cafes, passages, &c. and
others in imitation of velvet, damask, brocades, chintzes, or
such silks and stuffs as are employed for hanging rooms.

The principal difference in the manufacture lies in the
grounds; some of which are laid in varnish, and others in
the common vehicles for water colours.

The kind of paper employed for this use is a sort of car-
toon, manufactured for the purpose, which must be furred
before it be painted. Geo. lat. 2 c. 36.

The colours proper to be used for painting paper-hangings
are all those that can be used in water and varnish. But for
common designs done with water only, the following are
most proper.

For red, lake, vermilion, rose-pink, and red-ochre; for
blue, Prussian blue, verditer, and indigo; for yellow, the
yellow-berry waft, Dutch pink, and yellow ochre; for green,
verdigris, or for red, lead, with Dutch pink; for purple, a waft
made of woodgk, or a mixture of the lake, or rose-pink,
with deep coloured Prussian blue, or with indigo: for black,
ivory black, and in some nicer cafes lamp-black: for white,
whiting; and for the heightnings, white-lead.

Where great brightness is required, the lake should be used
for the crimson red, and Prussian blue for the blue;
but for many purposes, rose-pink used alone for the crimson
red, and indigo mixt with whiting for the blue, will answer
the purpose with greatly less expence. The lake, rose-pink,
Prussian blue, and Dutch pink, intended for this use, should
be procured in a moist state.

The colours used in varnish may be the same as those used
in water; but for this purpose, those just mentioned should
be obtained dry.

As for the vehicles of the colours; when water is used, it
must be mixed with size and gum Arabic or Senegal.

When varnish is used, it must be formed of oil of turpentine,
and the refinements which will dissolve in that menstruum.

With respect to the grounds for paper hanging, those that
are laid in water are made by mixing whiting with the size
above mentioned, and laying it on the paper, with a proper
brash, in the most even manner. Nothing more is necessary,
when the ground is to be left white; and the paper being
hung on a proper frame, till it be dry, is fit to be painted.

When coloured grounds are wanted, the same method
must be pursued; and the ground of whiting first laid; except
that, in paler colours, a second coating may sometimes be
spared, by mixing some strong colour with the whiting. But
where a greater force of colour is wanted, the pigment or
colouring substance must be tempered with the proper vehicle,
and then spread over the white coat. The varnish grounds
are made much in the same manner, by mixing the proper
colour with the varnish, and spreading it on the paper.

There are three methods by which paper-hangings are
painted: the first by printing on the colours; the second by
using the stencil; and the third by laying them on with a pen-
cil, as in other kinds of painting.

When the colours are laid on by printing, the impression
is made by wooden prints; which are cut in such manner,
that the figure to be expressed is made to project from the
surface, by cutting away all the other part. This, being
charged with the colours tempered with their proper vehicle,
by letting the print gently down on a block, on which the
colour is previously spread, conveys it from thence to the
ground of the paper, on which it is made to fall more forcible-
ly by means of its weight, and the effort of the arm of the
person.
PAPER.

perfon who ufe the print. The manner of doing this, when more particularly explained, is thus.

The paper being properly prepared by a ground of whiting, colour, or varnish, is laid on a proper block, on which a piece of leather is frafted. The colour, mixed with its proper vehicle, is spread on another piece of leather, or oil cloth, laid on a flat block, somewhat larger than the print; which is done by a boy or man who attends for that purpose; and having the colour by him, in a pot, spreads it with a brush on the block between every froke and impression the printer makes. The print is previously cut in such manner, correfpondently to the defign of the painting, that there shall be a projection on the surface answering to every part, where that colour intended to be conveyed by this print is necessary. The printer then takes the print either in his right hand, or, when too heavy to be fo managed, in both, and drops it gently on the block, just charged with colour; from whence he again immediately rises it in the mofl perpendicular direction, and lets it fall in the strongest, though mott even manner, he can, on the paper; increafing the force by all the additional velocity he can give the print. When this is done, the sheet printed is immediately taken off the block, and hung up to dry; and another being put in its place, the same operation is repeated, till the whole quantity of paper is printed. It is easy to conclude, that there must be as many separate prints, as there are colours to be printed; and they are to be used successively in the fame manner as the firft. But where there are more than one, great care must be taken, after the firft, to let the print fall exactly in the fame part of the paper, as that which went before: otherwise the figure of the defign would be brought into irregularity and confusion. In common paper of low price, it is ufual, therefore, to print only the outlines, and lay on the reft of the colours by f pencilling; which both faves the expence of cutting more prints; and can be practiced by common workmen, not requiring the great care and dexterity necessary to the using of prints.

The manner of f pencilling the colours is this. The figure, which all the parts of any particular colour make in the design to be painted, is to be cut out, in a piece of thin leather, or oil cloth. These pieces of leather, or oil cloth, are called f pencils; and being laid flat on the sheets of paper to be printed, spread on a table or floor, are to be rubbed over with the colour, properly tempered, by means of a large brufh. The colour baffling over the whole is confequently spread on those parts of the paper where the cloth or leather is cut away, and gives the fame effect as if laid on by a print. This is nevertheless only practicable, without great care, in parts where there are only detached mafles, or spots of colours: for where there are small continued lines, or parts that run one into another, it is difficult to preserve the connection or continuity of the parts of the cloth, or to keep the smaller corners cleaf down to the paper; and therefore, in fuch cafes, prints are preferable. S pencilling is indeed a cheaper method of fidding coarse work than printing; but without fuch extraordinary attention and trouble, as render it equally difficult with printing, it is far less beautiful and exact in the effect. For the outline of the spots of colour want that fharpenes and regularity that are given by prints; besides the frequent extrufions, or deviations from the just figure, which happen by the original mifplacing of the f pencils, or the shifting the place of them during the operation.

Pencilling is only ufed in the cafe of nicer work, fuch as the better imitations of the India paper. It is performed in the fame manner as other paintings in water, or varnish.

Vol. XXVI.

It is sometimes ufed only to fill the outlines already formed by printing; where the price of the colour, or the exactness of the manner in which it is required to be laid on, render the f pencilling or printing it left proper: at other times it is ufed for forming or delineating some parts of the defign, where a spirit of freedom and variety, not to be had in printed outlines, are defired to be had in the work.

The manner of proceeding with these several methods is, in common work, to fencil firft all parts of the colour in the defign, and to give an outline to the whole at last, by printing with brown or black: but where there is any running part of the defigns, fuch as scrolls, or the flemas or ftalks of creeping plants, or flowers, which are to be printed in any other colour than brown or black, a print mufi be ufed for them; though, if they require only brown or black, they may be done by the fame print which makes the outlines.

In the finer paper, where feveral colours are laid on with the prints, the principal colour is begun with; and the reft taken succesfively; the print for the outline being laid on last. In cafes where the pencil is to be ufed, the outlines in cerfeth to be made before the colours are laid on by the pencil, if fuch outline is to be made at all; because that is the guide to the perfon who lays on the colour; and confines them to a correcteness.

In paper printed with defigns in chiaro-fcuro, fuch as the imitation of Itouco work, and bas relieves, the order of printing must be, to lay on the ground colour firft; afterwards the shades; and laftly the lights: and the fame rule of fuccéffion must be obferved where the colours are pencilled. Handmaid to the Arts, vol. ii. p. 445; &c.

Paper-hangings may be flanged with that kind of tale called singlais, which being reduced to a grofs flaky powder, has a great refeemblance to thin filver fcales or powder. It is laid on by frewing over the varnish, which forms the ground, before it begins to dry. When it is laid on in a figure, for the representation of embroidery, the figure must be printed in varnish, and the tale burned upon it, and treated like flock. Small may also be ufed in the fame manner as flock or flangles. But hangings of this kind are now little ufed.

PAPER, ruled for the reception of musical characters. Roufieu was the firft, we believe, who made this a lexicographical article. Five parallel lines form what musicians call the flaff; upon which lines in the flaces are difpofed all the notes of the time-table and their places in the general fcale, regulated by clefs at the beginning of each flaff.

All our music for keyed instruments, till the latter end of the feventeenth century, was written on flaves of fix lines, of which the lowest in the treble clef, and highest in the bafe, was the middle C of the general fcale. See STAFF.

Almost all the music paper in Italy is ten-flaved, for the convenience of fcorings fongs with four instrumental parts: as the violinino primo, violinino fecondo, alter viola, voice part, and bafe. These being linked together by braces, are easily found, not only by the fingers, but by the instrumental performers, by whom they may be accompanied from the score.

The English have paper ruled at all forms and number of flaves. In general, for violins, of 12 flaves, and for the piano forte, and vocal parts, long quarto, as it is more on a level with the eyes, and conceals the vifage of the performers lefts from the audience.

PAPER, among Bankers, and other negociants, is also ufed for bills of exchange, bank and promiffory notes, &c.

Substituting paper for money, and giving the paper an
arbitrary value, was the way of paying debts introduced in France by Mr. Law. A royal bank was established, to which people were to carry their money, and receive the value of it in bills, which were to pass current in trade as if of current coin. (Vide Chevign. Scienc. des Perf. de la Cour. tom. ii. p. 292.) It was made confiscation of goods, and the gallies, for any man to keep above forty livres by him of any but paper money. When the regent was told what a rage was spirited up against him about the arrets of making paper current, and how openly the people threatened him, he answered coolly, the French were like watch-dogs, they would bark, but not bite: "Les Français refomblent aux chiens a garde. ils aboyent, mais ne mordent pas." Mill. Misc. Lett. tom. iv. p. 16.

Paper-Books, in Law, are the issues in law, &c. upon special pleadings, made up by the clerk of the papers who is an officer for that purpose.

Upon an issue in law, it is termed the "Demurrer-book." The clerks of the papers of the court of king's bench, in all copies of pleas and paper-books made up by them, shall subscribe to such paper-books the names of the counsel who have signed such pleas, as well on behalf of the plaintiff as defendant: and in all paper-books delivered to the judges of the court, the names of the counsel who signed these pleas are to be subscribed to the books, by the clerks or attorneys who deliver the same. R. Pach. Car. 2. 2 Litt. Abr. 260.

Paper-Frames, in Gardening, are such as are formed with oiled paper, upon a light frame-work of thin frips of wood. These frames are useful for several purposes in the early spring and summer season; such as in defending hot-beds, and sometimes in particular natural ground beds of curious tender plants, feeds, cuttings, &c.

When formed as above, they are made, either in a ridge manner, with two sloping sides, longways, or arch-fashioned, in dimensions from five to ten feet in length, and three to four in width, and two to three feet in perpendicular height; the wood-work is covered with large sheets of thin white paper, pasted on securely, and, when dry, brushed over regularly with linseed oil, to refit and shoo off the falling wet of rains and dews, and to render them more pellicul, so as to admit the rays of light, and the heat of the sun, in a proper degree. When thus prepared, and perfectly dry, they are ready for placing over the beds for the purposes required; in which the paper continues durable generally only one season; but the frame-work will last several years, by being fresh papered.

These kinds of temporary frames are also useful in some of the hand-gla.s. crops of melons, and occasionally in those of cucumbers, but more generally in the former; which after having advanced in growth, to fill and extend beyond the compass of the hand-gla.s.; they should be removed, and the paper-frames placed over the bed, covering it wholly in width and length, the runners of the plants being trained out regularly along the surface; continuing them constantly over the plants, which are thereby protected from external injuries, and inclement weather, either cold or excessive rains, winds, &c. likewise from the too powerful heat of the sun. See Cucumis Melo.

They may also be used for late hot-bed cucumbers, when in want of garden-frames or hand glases for the purpose, being placed over the bed, at once finally to remain: and with proper care in giving occasional air, water, and covering over the frames with mats in cold nights, and very hard rains, &c. cucumbers may be raised in a tolerable manner.

They may likewise be employed occasionally, in default of others, in the raising most of the less hardy or tenderer annuals, both in sowing them into hot-beds, and warm borders of natural earth.

Paper-frames may likewise be used advantageously in pricking out many sorts of small tender seedling plants in the hot summer months, to defend them from casual unfavourable night air, heavy rains, &c. and afford a fine growing shade from the hot rays of the mid-day sun. The fame kind of frames may still further be beneficial in raising many sorts of tender exotics, from small cuttings and slips in summer, both of the woody, herbaceous, and succulent kinds, either planted in hot-beds, or in the natural earth, as the different kinds may require: which being covered close with them, they exclude the outward air, admit the light and influence of the sun in a proper degree, and at the same time afford a peculiar kindly shade.

These frames are chiefly made in the forms mentioned above, in an open manner, having the ribs or spars twelve inches asunder, first forming a bottom frame, rather frowner than the other parts, with a ridge-piece supported at a proper height, extending longways in the middle; then narrow sides, ranged from the bottom to the ridge-rail at top, a foot distant, both for the advantage of paiving the paper regularly, and to admit a proper degree of light between them through the paper: but when of great length, it is proper to have one or two panels on one side, eighteen inches or two feet in width, to open outward with hinges, convenient for admitting air, and performing other occasional purposes: the whole being thus formed in the wood-work, it is then proper to extend lines of packthread crofs-ways of the ribs, going round each, level or even with the upper surface of the frame, continuing two or three rows a foot asunder, from the lower part upward, drawing other lines, crossing and interfettting these at the fame distance, regularly between the ribs of the frame-work; which arrangement of the lines is of especial service for the more effectual support of the paper when pasted on the frame, and strengthening it against the power of winds and heavy rains. The paper for this use should be of the larger strong printing or demy kind; which, previously to pasting on the frame, should be moderately damped with water, that it may not sink in hollows after being fixed; and as soon as thus prepared, it should be pasted on, fheet on fheet, in a regular manner, one large sheet and a half, or two at a time, generally ranging from the bottom to top, contriving to have whole ones along the ridge-rails above, extending lengthways and aerois, placed conveniently to join regularly with the other sheets below; and, if, at the interfejon of the pack-threads, a small square or round bit of the fame paper be pasted on the inside to the main sheets over that part of the packthread, it will give it additional strength against rain and wind. And, when the paper is thus pasted on, and perfectly dry, it must be oiled over with linseed oil, either raw or boiled; the latter is, however, rather apt to harden the paper, and more liable to crack or break: it may be applied by means of a printer's soft clean brush, dipping lightly, and brushing the outside of the paper all over, equally in every part; then placing the frame in some dry covered shed, to remain till the whole is thoroughly dry; when it may be used.

But though these sorts of frames may be cheap, and answer many little purposes of the gardener, they are not by any means so useful as those made with glases in the usual manner.

Paper-Mills, (in the court of king's bench) is where the writings belonging to that court are repotted.

Paper-Money, Currency, or Credit, as they are indifferently called, in Political Economy, is a subject of great importance, and
and no small difficulty. The different and opposite opinions which have been entertained respecting its nature, operation, and advantages and disadvantages, arise, partly from a want of regular and clear reference, in discussing this subject, to the undisputed and fundamental principles of political econo-
my, and partly from not attending to that particular branch of this science to which this subject more especially and closely belongs.

If we examine what the most celebrated and judicious au-
thors have written respecting paper money, we shall find that scarcely any of them have adverted with sufficient precision, and in a sufficiently decided and distinct manner, to the points of difference which exist between paper money issued by government, and which it is rendered obligatory upon the people to receive, and that species of paper money which confinks in the hands of bankers, payable to the bearer on de-
mand, and which pays current for the sums specified in them.

Of the former kind were the billagants and mandats issued by
the government of France during the first years of the Re-
volution; the paper money issued in America, before, and
during the war with this country; that which was issued by
the Dutch during their long arduous struggle for inde-
pendence; and, generally speaking, the paper money which
most of the governments on the continent of Europe have
found themselves compelled to issue during the French Re-
volutionary wars. It will be sufficiently evident, from the
lightest consideration of these two species of paper money,
that they differ completely and essentially in their nature,
and that we shall be led far astray from the truth in our dis-
cussions on paper currency, if we infer, from what has taken
place respecting the one species, what will probably, or must
necessarily take place respecting the other species.

In order that in this article we may not be led into any
confusion of these two species, it may be proper, before we
proceed, to consider the nature, effects, and advantages and
disadvantages of bank paper, properly and strictly so called,
brieñy to discuss the subject of government paper. In

general the paper issued by the governments on the continent of
Europe, contains no promise to pay either on demand, or at
the termination of a limited and specific period; it is, in real-
ity, nothing more than paper flammed with the amount of
the sum for which it is to pass current, and with such marks or
signatures, as may serve to distinguish what is genuine from
what is forged. Here, then, we at once perceive an essential
difference between government paper and bank paper; the
former is in fact, strictly speaking, paper money; or, in other
words, paper issued as money instead of the precious metals;
the latter, as we shall see more clearly and fully afterwards,
is not, strictly speaking, paper money, though thus denomina-
ted in general and popular language, but a written obliga-
tion to pay a certain sum of money on demand. Another
striking and essential difference between these two species of
currency arises from the distinction just pointed out; it is
plain, that if the written obligation to pay on demand is
given by persons who are of undisputed and established cre-
dit, few will be disposed to refuse such written obligation,
and therefore this species of paper currency will be received
without compulsion, and where the credit of the issuer or
issuers is undoubted, equally as metallic money. But the
reverse must be the case with regard to government paper
money, which contains no obligation to pay metallic money,
and therefore will never be preferred to the latter, or taken,
unfed in cases where there is no alternative. With respect to
bank paper, it is bought after; the taking of it is a matter of
choice; with regard to government paper, it is compulsory
on the people; the government which issues it, tenders it in
payment of the debts which it may have contracted, and it
is taken, only because, if it is refused, no other payment will be
made. It may, however, be remarked, that another cause
operates, in some degree, towards the acceptance and cir-
culation of compulsory government paper; for though this
paper contains no obligation or promise to pay in metallic
currency, yet as all governments necessarily receive large
sums from their subjects in taxes, the unwillingness of the
people to receive this compulsory money, is in some measure
removed, by the conviction that part of it will be taken
back by government in payment of taxes. It will be no
difficult matter to perceive what, in almost every case, must
be the consequence of an issue of compulsory government
paper; as long as any government combines itself to a metal-
cic currency, there is some check to the extravagance and
carelessnes of its expenditure; for if it be extravagant or
careless, it will experience great difficulty in replacing the
money it has thus expended; but, on the other hand, if it
substitute compulsory paper money in the room of its metal
currency, there can be no check to its carelessness or extra-
 vagance, except what arises from the necessary consequence
of an excessive issue of paper money.

This consequence it may be proper to consider somewhat
at large, since, though all authors are agreed, that an over-
issue, and consequent depreciation of compulsory govern-
ment paper may take place, and, in fait, has almost uniform-
ly occurred, yet great difference of opinion exists, whether,
in the case of bank paper, an over-issue and consequent de-
preciation can possibly occur. In order to keep quite sepa-
rate and distinct the question of the depreciation of govern-
ment paper currency, as it arises from a diminution of con-
fidence in the stability of the government which issues it, it
will be proper to consider this point; on the supposition, that
the confidence of the people in the stability of their govern-
ment remains the same, during the whole course of the in-
creasing issues of its paper currency; and to confine ourse-
elves solely to the investigation of the consequence produced
by an increased issue, and of the mode in which this con-
sequence is produced.

Money, of whatever it is composed, whether of metal or
paper, like every other commodity, depends, for its value,
and the price it is estimated at, on the proportion between it and
the commodities for which it is exchanged; if this proportion is altered or deranged,
the value of the money will be altered; if, while the quan-
tity of money remains the same, the quantity of the com-
modities is diminished, the money must necessarily bear a larger
proportion to them than it previously did; and consequent-
ly, its power to purchase them will be diminished; strictly
speaking, however, this cannot, with propriety and precision
of language, be designated a depreciation of the currency,
as the variation in its value or power of purchase, arises entireiy from a change in the quantity of commodities, and not, in the smallest degree, from any alteration in the quantity of the currency. But if, while the quantity of commodities continues stationary, the amount of the circu-
lating medium is increased, the consequence already pointed
out will equally ensue; that is, the power of the currency
to purchase commodities will be diminished; and the cur-
rency, therefore, so far as it is considered in relation to com-
modities, will be depreciated. But in all countries where a
compulsory government paper is issued, the metals, even
when coined, cannot be regarded solely as commodities, and
are affected, equally with all other commodities, by the in-
creased issue of the paper currency. As, therefore, there is
no check to the issue of government paper, and extravagant
or careless expenditure calls for increased issue, a deprecia-
tion of such paper necessarily ensues; and each stage in the
depreciation occasions a further issue, which in its turn in-
creases
creases the depreciation; for when the government perceives that one thousand pounds in paper money, for instance, will no longer command the same quantity of the commodities which it needs, that it would formerly do, but that one thousand and fifty pounds are requisite for this purpose, it is compelled to increase its issue of paper money in this proportion, and this increased issue, again raising the price of commodities, requires a still larger issue, the next time that the government has occasion to make a purchase.

Hitherto we have considered the question of the depreciation of compulsory government paper as arising solely from the circumstance of an increase in the quantity issued; but other causes are operating, at the same time, and towards the production of the same effect; for no compulsory government paper can possess the confidence of the people, and value or confidence are absolutely necessary to the character and uses of money, if that character is to be preferred inviolate, and those uses are to be obtained and preferred in their full and complete effect. On the first issue of compulsory government paper, it is received with reluctance; metallic money is preferred to it, and when it can be procured, a premium is willingly given for it, or, in other words, the compulsory government paper is at a discount. But, if this is the case at the first issue of it, and when the amount is comparatively small, we may easily conceive what will be the consequence, if a larger and constantly increasing quantity is forced on the people: this increasing quantity must act, not only in the manner which we have already described, towards its own depreciation, by the same process in which all commodities are depreciated by increase, but it will also operate towards its own depreciation in another manner. The very first issue of a compulsory government paper is a sufficient proof of an impoverished and embarrassed government; and every future issue, especially if the amount of the issue be increased, is a proof that the poverty and embarrassment of the government are increasing: but it is utterly impossible, that while the poverty and embarrassment of a government are increasing, the confidence which the people repose in it can remain stationary: it must diminish, and a diminution of public confidence in a government displays itself in no respect so unequivocally and materially as in the estimate which is formed of the value of the paper currency. Here, then, we perceive the real and full state of the case, whenever a government increases the issue of its compulsory paper: a larger quantity of a currency, on its first circulation received with reluctance, and only because no other mode of payment could be obtained, is issued; the increased issue, of itself, would necessarily diminish the value of the currency, but this consequence is increased by the suspicion which such a measure on the part of government creates, that the finances of government are on the decline; hence, from the operation of both these causes, viz. an increased issue, and diminished confidence, a depreciation of the compulsory government paper must necessarily ensue.

There is still another subject incidentally connected with paper currency, on which it may be proper to lay a few words, before we proceed to the immediate topic of this article. By many, bills of exchange, or exchequer bills, payable only at a certain time, and bearing interest, are considered as paper currency; and it is contended that an increase in the issue of them has exactly the same effect as an increase in the issue of government or bank paper. This notion, though certainly plausible, and maintained by writers of considerable acuteness and knowledge on the subject of political economy, a little reflection will serve to convince us is erroneous and unfounded. We have only to reflect on the nature and operations of currency, to be convinced that bills of exchange and exchequer bills do not form a part of it; and, indeed, that notes bearing interest, are by that very circumstance excluded from the character and operations of currency; and that the increased issue of these, so far from tending to depreciate the value of money, must rather operate to raise it. Under the article Money we endeavored to shew that the mere increase or diminution of the circulating medium did not necessarily tend to lower or raise the rate of interest; but that the rate of interest must depend on the quantity of money offered to be lent, and on the number of the borrowers, and the terms which they were willing and able to give: so that if the increased quantity of money thrown into the market was entirely employed in the purchase of commodities, and not offered to be lent, the rate of interest would not be affected, in the smallest degree, by this increased quantity; while, on the other hand, if the quantity of money in circulation continued the same, but part of it was withdrawn from the purchase of commodities, and offered to be lent, the rate of interest would fall. The fame train of reasoning which serves to establish these facts, will conduct us to a proper consideration of the nature and operation of bills of exchange and exchequer bills. They are brought into the market, not for the purpose of employing them in the purchase of commodities, but for the purpose of sale; and they are generally bought by those who wish to put out their money to interest: hence they may operate on the rate of interest, but they cannot operate on the price of commodities, unless it be, as has been already stated, to lower the price of commodities, or, in other words, to raise the value of money. That they may have this effect will appear from the following considerations: let us suppose that the money and commodities in any market bear a certain proportion to one another, and that this proportion is disturbed, by the introduction, either of a greater quantity of some of the commodities formerly in the market, or by the introduction of some new commodity; it is plain that in either case, if the quantity of money continue the same, that its value or power of purchase will be increased, since it will now exchange, not merely for the commodities formerly in the market, but also, in addition, for the increased quantity of the old commodities, or for the new commodities. If, instead of a new commodity properly so called, we suppose that a person comes into the market, willing to borrow money, and offering such a rate of interest, as secures to him part of that money which used to be expended in the purchase of commodities; in this case also, the value of the money, or its power to purchase must be increased, since it will now command, not only the commodities it formerly did, but also the interest offered for the sum wished to be borrowed. But in this question, it is a matter of mere indifference in what manner the interest to be paid is promised or secured; whether in the usual way, or by bills of exchange, or by exchequer bills. The general fact and consequence are precisely the same in all cases; if bills of exchange or exchequer bills are brought into the market, they are brought, not to purchase commodities with, but for sale; and if they are sold, for part of that money which used to be expended in the purchase of commodities, it is evident that the price of these commodities must be lowered, not raised, by the introduction of these bills of exchange, or exchequer bills; and consequently, that as their nature and operation is that of commodities, not of circulating medium, their issue cannot lower the value of money, but must, in some degree, tend to raise it.

Having thus cleared the way for the uninterrupted consideration of the more immediate and proper subject of this article, we shall arrange the remarks which we mean to offer under
PAPER CURRENCY.

under the following heads: 1. The real nature of bank notes. 2. The effects of this species of currency. 3. Its advantages and disadvantages, as compared with a metallic currency. 4. The nature and proceeds of the checks to the over-issue of bank paper, when it is payable on demand: and, 5. The state of bank paper, when not payable on demand, so far as regards its over-issue, and its supposed depreciation, arising from this or other causes.

1. Bank notes have very generally, but very erroneously and improperly, been denominated the representatives or symbols of coin. This is one, among many other instances of vagueness and confusion of ideas, arising from the injudicious and careless use of metaphorical language, which has so much retarded the advance of the science of political economy. What precise or clear idea can we attach to the terms representative of coin? or how can bank notes be so denominated? It has been justly remarked, "that the most accurate representatives of coin, are well fabricated counterfeiters, yet every man, when he knows them, refutes them in peace." Indeed it is not easy to perceive how this language came to be adopted, or where was the necessity or temptation to have recourse to metaphorical language, to express a fact sufficiently obvious, clear, and undisputed. A bank note does not represent coin; nor is it circulated and received on that account; but it is an obligation on the part of the person or persons who issue it to pay, on demand, a certain quantity of gold or silver. "A common cheque upon a banker, which nobody ever dreamed of calling a representative of money, is just as much a representative of it as bank notes; nay, in fact, the order which the manufacturer, on the Saturday night, puts into the hands of one of his workmen, to get from his clerk the wages of the week, is a representative exactly of the same description. The only real difference in practice is, that the one obligation generally passes but through one or a few hands, till it comes upon the obligee: the other passes through many hands, each accepting it as a satisfactory security for the valuable commodity which it is an order to receive."

Having thus, it is presumed, refuted, perhaps at the expense of more words than it deserved, the notion, that bank paper is a representative of coin, the next topic of enquiry under this head, is, what, in fact, does the person who issues the note oblige himself by such issue, and by the terms of the note, to pay on demand. This enquiry may, at first sight, appear as little necessary as the previous investigation, since the obligation on the note is clear and distinct: there is no vagueness or ambiguity about it, and, indeed, if there were, the value of the note would be in a great measure, if not entirely, destroyed. It is only of late years, that any question or doubt has been started respecting the nature of the obligation expressed on a bank note; and the strange and almost unintelligible opinion which has been broached on the subject, forming part, as it does, of the doctrine of abstract currency, scarcely deserves notice here, especially as this doctrine has been already canvassed under the article Money. A few words, however, may be spent to state this opinion; and it is believed an impartial statement of it, if it can be made intelligible, will render almost unnecessary any formal and direct refutation of it.

The leading principle of those who hold this opinion is, that the pound sterling is an imaginary or abstract portion of the currency, and not anything tangible or substantial: hence they infer, that as the bank note promises to pay one, five, or any given number of pounds sterling, the obligation laid on the issuer, is not to pay any precise and real sum, nor can the note be said to be depreciated, if it does not pass current: for the value of the metal expressed on it. In support of this opinion no argument is advanced; no reference to general, undisputed principles is made; it is left to struggle, arbitrary and absurd as it is, to relying solely on the hardy and reiterated assertions of its defenders: they forget that though there is no coin called a pound sterling, the value of a pound is known and acknowledged both by the laws and by common consent; that their doctrine is totally inapplicable to notes such as those common in Scotland, which promise the payment of a guinea, an existing and known coin; and that while the notes of the bank of England were payable on demand, their opinion was neither acted upon by the bank, nor entertained by themselves.

2. With regard to the effects of paper money, they may be considered under two heads: the effect it produces on the price of commodities, and the effect it produces on the metallic currency along with which it circulates. Mr. Hume entertained the notion that paper money raises prices, whereas Dr. Adam Smith, referring to what he considers as a general fact in the theory of circulation, that every addition of paper to the currency displaces an equivalent quantity of gold, holds a different opinion. This notion of Smith, however, must be received with some limitation: if by an addition of paper to the currency in any country, the price of any commodity is raised in that country so high, as will pay for its importation, it will be imported, and part of the metallic currency will probably be employed to pay for the commodity thus imported. But whenever the addition made to the currency by paper money is employed in the production of commodities, and the increase in the quantity of these commodities is in the same proportion as the increase to the currency, by the addition of paper money, there will be no reason for exporting gold, and the whole currency, confining of the precious metals, and of paper, will be no more than is necessary to circulate the increased quantity of commodities in the market. In considering this branch of the subject in a more extended sense, it will be necessary to look to the effect produced on the value of the precious metals, in the general market of the world, by the addition of paper to the currency of any particular country, in cases where that addition, not producing a corresponding increase in the quantity of commodities, enhances their price, and thus leads to the exportation of gold from the country where the paper currency is issued. In these cases, "the fame exportation of gold, which remedies the temporary rise that takes place in the particular country where paper has been issued, has a tendency to increase the supply of precious metal in the general market of the world, and thus to occasion a general rise of prices in which that particular country must participate. The whole quantity of bullion, of which Great Britain has spared the use by adopting a different medium of domestic exchange, is added to the general stock of the mercantile commonwealth, as much as if an equal quantity had been brought additionally from America; and the saving of that annual loss which would have been occasioned by the wane of British coin, is equivalent to an increase in the annual produce of the mines."

The above remarks display considerable command of the subject, and are worthy of that author, who by his analysis of, and observations on, "Thornton on the Paper Credit of Great Britain," contributed so materially to bring the Edinburgh Review into notice; we are, therefore, the more surprised that in the remark immediately following the passage which we have just quoted, he should have so completely misunderstood the subject and contradicted himself: we allude to the following observations. "But, on the other hand, it must be remembered that the use of paper money tends, in some degree, to lower the price of commodities. In proportion
tion as the instruments of commerce, or the machinery of manufactures are of a less expensive construction, the articles which they contribute to produce may be afforded at a lower rate. To employ paper money instead of gold, is to substitute a very cheap instrument of commerce in the room of a very expensive one." Now the inference to be drawn from the circumstances here alluded to, appears to us directly the reverse; when any saving of labour or expense takes place in the production or manufacture of any commodity, that commodity, costing less, can be sold at a lower rate, with an equal profit to the seller: in like manner, when paper, a very cheap instrument of commerce, is employed in the stead of gold or silver, very expensive ones, more paper money can be afforded in exchange for the same quantity of any commodity than could have been afforded of metallic money: but in this case certainly the price of the commodity is not lowered, but raised, since for more money is now given than was formerly given.

On the whole, with respect to the effect of a paper currency on the price of commodities, and on the precious metals with which it circulates, it may be remarked, that it must vary according to the circumstances under which the paper currency is emitted, and the quantity which is thrown into the market: and these variations in its effects will more properly be considered under the next head, viz. the advantages and disadvantages of a paper currency, as compared with metallic currency.

The first advantage resulting from the use of a paper currency, which occurs to the observation of a person reflecting ever so superficially on the subject, is, that by the substitution of paper in the room of gold and silver money, a very expensive instrument of commerce is replaced by one much less costly. So far the substitution of paper money must be advantageous to the community; the currency of a country is a part of its capital, which may be considered as unproductive; it is, indeed, necessary to carry on the operations of its commerce, but it does not, strictly speaking, increa that commerce; it is, therefore, of the utmost importance, that this instrument, thus unproductive, should be procured and kept in action, with the least possible expense. But where gold and silver alone are employed as the currency of a country, they must either be obtained directly from the mines at great labour or expense, or purchased by commodities on which the same quantity of labour and expense has been laid out. Again, if in a country, the currency of which consisted entirely or principally of gold and silver, a paper currency is introduced, it is evident that a part of its former metallic currency will be fet at liberty, and may be expended in the purchase of foreign commodities. Paper currency, as we have already shown, is in fact only an obligation to pay on demand a fictitious sum of gold and silver; it therefore might be inferred that the substitution of paper for gold and silver would not set at liberty any portion of the latter, since it would be necessary to retain the whole, in order to answer the demand of those who brought the paper currency for payment. But the fact is, that a comparatively small proportion of gold and silver is required to answer the demands occasioned by a very extensive paper circulation; those who issue bank notes find certain, with sufficient and perfectly secure provision, the exact amount of gold and silver, which it is necessary or prudent to keep by them, and the rest is employed in the purposes of commerce.

Whatever evils may have resulted from an injudicious and superabundant issue of paper money, there can be little doubt that this species of currency has been of great service in increasing the produce and extending the commerce of the country. Let us suppose an instance of common occur-

rence, and of no intricacy or complication in its details: a gentleman possesses a large estate, that is in a great measure in an uncultivated and unproductive state: he does not possess the capital adequate to the full improvement of it; and yet there can be no doubt, that if sufficient capital were laid out upon it, in a judicious and skilful manner, not only the owner, but the community, would be greatly benefited. In a country destitute of paper currency, he would experience great, perhaps insurmountable difficulties, in borrowing the requisite capital; whereas, in a country possessed of a paper currency, the means of improvement would be easily obtained, and a great increase of produce, and consequently of wealth, would be added to the public stock. Whoever has watched the progressive improvement of Great Britain, not only in the extended and superior cultivation of her foil, but in the increase of her manufactures and commerce, must be convinced that the rapid and great advances she has made in wealth within these few years, have been in a great measure owing to her paper currency.

The following passage from Smith's Wealth of Nations will set the advantages of a paper currency, perhaps, in a still clearer light. "It is not by augmenting the capital of the country, but by rendering a greater part of that capital active and productive that would otherwise be fo, that the most judicious operations of banking can increase the industry of the country. That part of his capital which a dealer is obliged to keep by him unemployed, and in ready money for answering occasional demands, is so much dead flock, which, so long as it remains in this situation, produces nothing, either to him or to his country. The judicious operations of banking enable him to convert this dead flock into active and productive flock; into materials to work upon, into tools to work with, and into provisions and subsistence to work for; into flock which produces something, both to himself and his country. The gold and silver money which circulates in any country, and by means of which the produce of its land and labour is annually circulated and distributed to the proper consumers, is, in the same manner as the ready money of the dealer, all dead flock. It is a very valuable part of the capital of the country, which produces nothing to the country. The judicious operations of banking, by substituting paper in the room of a great part of this gold and silver, enable the country to convert a great part of this dead flock into active and productive flock; into flock which produces something to the country. The gold and silver money which circulates in any country may very properly be compared to a highway, which, while it circulates and carries to market all the corn and grain of the country, produces itself not a tingle pile of either. The judicious operations of banking, by providing, if it may be allowed so violent a metaphor, a fort of waggon-way through the air, enable the country to convert, as it were, a great part of its highways into pastures and corn-fields, and thereby to increase very considerably the annual produce of its land and labour. The commerce and industry of the country, however, it may be acknowledged, though they may be somewhat augmented, cannot be altogether so fecure, when they are thus, as if were, supplanted upon the Dedalian wings of paper money, as when they travel about upon the solid ground of gold and silver. Over and above the accidents to which they are exposed from the unskillfulness of the conductors of paper money, they are liable to several others, from which no prudence or skil of those conductors can guard them."

The disadvantages and evils of paper money, indeed, arise from the same causes which produce its advantages and benefits: we must never forget, that the foundation of paper money
PAPER CURRENCY.

money is credit; that it is, in fact, an obligation to pay on demand a certain sum of metallic currency. Credit does not create capital, it only sets that portion of capital in operation, which would otherwise be inactive: the person who gives credit, in reality gives part of his capital, which he has not the disposition or the means to employ; and the person who receives credit or capital, by employing his industry and skill along with his borrowed capital, is enabled to repay it, and the stipulated interest. So long as the credit of the lender is good, and the repayment of the borrower punctual or unmixed, so long a paper currency thus established, if not pushed too far, must be beneficial to the lender, the borrower, and the nation at large. But let us suppose that from any cause, confidence in the paper money of a country was destroyed or shaken, and we shall immediately perceive the disadvantages and evils of this species of currency, as compared with a metallic currency. Where the commercial transactions of a country are entirely carried on in a metallic currency, opinion has no room for operation: no confidence is reposed; commodities are sold, not for what may or may not be worth the value which they represent or promise, but for what poffeffions absolute and intrinsic value. No circumstance will point out and exemplify the difference between a paper and a metallic currency more clearly and strikingly, as the invasion, or dread of invasion, in the countries in which they respectively exist. If a country, the currency of which consisted principally or entirely of paper, were actually invaded, or threatened with invasion; or even, if its internal state were convuluted or disturbed, or its finances considerably disarranged, its paper currency would be immediately affected: its value would fall, in proportion as the confidence reposed in it was diminished: people would prefer metallic currency for this strong and obvious reason, that whoever had poffeffion of the country, whatever change took place in its government, or into whatever circumstances of political or financial embarrassment and confusion it was thrown, the value of the metallic currency would remain unchanged, whereas the value of the paper currency would be subject to constant variation, and might probably be totally destroyed.

It is sometimes objected to a paper currency, that by exchanging commodities for it, we, in fact, get nothing valuable, whereas when we sell our commodities for gold or silver, we obtain something of real and intrinsic value: but this observation amounts to nothing, provided the credit of the paper currency be good; it is, indeed, founded on the erroneous idea, that when we sell our commodities, we look for any thing else in the money which we receive, but the certainty that it will be taken from us at an undiminished value. When a person sells a quarter of wheat for five pounds, it must be a matter of perfect indifference to him, whether he receives five pounds in silver, or five pounds in paper, provided he is convinced that in the purchase of what he may want, the latter will go as far as the former: in selling his wheat he is never disturbed by the idea, that five pounds in silver have intrinsic value, i.e. value as metal, while the five pounds in paper possess no intrinsic value; the power each poffeffion over commodities is all he regards, and if that power be equal, their value, for all the purposes he needs them for, is equal in his estimation.

It has also been objected to paper currency, that its use is solely confined to transactions of domestic traffic; and consequently that a country, which has no other species of currency, must go to a foreign market to purchase commodities at a great disadvantage; the fact is undeniable, that generally speaking, a paper currency is without value in a foreign country, but the inference by no means follows, that on this account foreign commodities must be purchased by a country which possesses only a paper currency, at a great disadvantage. On the first establishment of a paper currency, the very reverse must be the case; or to speak more correctly, the establishment of a paper currency setting loose a portion of the metallic currency, this may be employed in purchasing a larger quantity of foreign commodities, than the country could afford to purchase, while this metallic currency was necessary for the circulation of its internal commerce. But, even after a paper currency is established, foreign commodities may be purchased at an equally cheap rate, as they were while the currency was metallic; for in the first place, foreign commodities are seldom purchased by the coin of the country purchasing, but either by bullion, or the interchange of commodities; and secondly, while a bank note for a guinea will exchange for a guinea, it will always command, indirectly, the same quantity of foreign commodities, as could be purchased, if the currency were entirely metallic.

But the objection to paper currency, urged most frequently, and with the most confidence in its appropriateness and solidity, arises from the extreme facility with which it may be increased; the strong temptations to increase it, and the evils to the community, to which an improper increase will give rise. The consideration of this objection naturally leads us to the fourth head of our dissertation, viz. the nature and proceeds of the checks to the over-issue of bank paper, when it is payable on demand.

It may be proper first to consider what is meant by an over-issue of paper money: the term is too often used without any clear and definite idea being attached to it. When the quantity of circulating medium, whether metallic, or of paper, is increased in a country, the increase either operates to the production of a great quantity of commodities, that is, is usefully employed, or it merely operates to raise the prices of the commodities already in existence: before, therefore, the addition of any sum to the circulating medium can be said to be an over-issue or not, the effects produced by it must be traced and ascertained: if a correspondent addition to the quantity of commodities has taken place, there cannot be said to be an over-issue of currency; but if no such correspondent addition has taken place, as the sum added to the currency cannot be inactive or unapplied, a rise of price must take place, and then an over-issue may justly be said to have occurred. Those who sell as well as buy, probably will not be much or long injured by this rise, since any addition to the currency is not long in adjudging itself to the various commodities in the market, and consequently, if some commodities are bought dearer, other commodities are also sold dearer: but those persons, whose whole property consists in money, are injured, when there is an over-issue of the currency; i.e. when an addition to the currency does not produce a correspondent addition to the commodities in the market. While the currency is entirely metallic, they are in a great measure guarded from a sudden or violent rise of prices, or depreciation of money, their sole property; since before any great addition can be made to the circulating medium, additional labour must have been bestowed on the mines. But where paper currency is established, the case at first sight seems different; the value of their property, i.e. money, is at the mercy of all who can issue bank notes; if, however, we investigate what actually takes place, where there is a paper currency payable on demand, we shall find that the property of the moneyed man is guarded as effectually, though not so directly, as if the currency were metallic. Let us suppose a large addition to be made to the paper currency of any particular district in this country;
country; this addition operates either to the rise of prices solely, or to the increase in the quantity of commodities; in the latter case, the monied man has no cause to complain; there is indeed more money in his neighbourhood, but as there are also more goods, the value of his money is not affected. On the other supposition, that the increase to the paper currency raises the price of commodities, let us see what will occur: those commodities, the price of which is raised, will be purchased in another district, where they have not undergone a similar rise; but before they can be purchased, the local notes must be exchanged for such as are current in the district where the purchase is to be made; or, in other words, some part of the over-issued notes will return to the bank which issued them. This will be a sufficient proof and warning to the bank, that they have issued more notes than the commercial transactions of the district required, and as on notes almost immediately returned, the expense in manufacturing them, and their proportion of the establishment must far exceed the profit made on them while they were in circulation, the bank will be careful in future not to over-issue their notes.

A process similar in all its steps, and in its result, will take place, if the bank of England, while subject to be called upon for cash payments, should over-issue their notes: the over-issued notes will either spread themselves over the country, for the purchase of such commodities as have become cheaper in the country than in London, by the addition to the circulating medium, or they will be returned to the bank of England for gold, wherewith to go to a foreign market.

Thus it would appear that the property of the monied man is rather more precarious, and better protected from depreciation, in a country, the currency of which consists of paper payable on demand, than in a country, the currency of which is entirely metallic; since, in the former country, the real and well understood interest of those who issue the paper money must lead them most carefully to avoid any over-issue; whereas in a country, the currency of which is entirely metallic, though no addition to it, sufficient to raise the prices, can long remain in it, yet it may both remain longer, than an over-issue of paper money, and be repeated more frequently.

We now come to the last head, viz., the state of bank paper, when not payable on demand, so far as regards its over-issue, and its supposed depreciation arising from this or other causes.

The suspension of cash payments in the bank of England, in the beginning of the year 1797, forms a most memorable era in the history of the science of political economy; and the undiminished confidence which after this measure was, and is repaid in the bank of England notes, has shaken to the foundation many favourite theories in this most intricate and delicate science. By some it is alleged, that the confidence in bank of England paper remained the same, even after the suspension of cash payments, because there was a general and well-founded belief, that the bank was able to pay all its notes in specie; but something more than mere ability would seem necessary to inspire or continue confidence. Of what moment is it to the holder of a bank of England note, to be told that the bank can pay it in specie, if he knows that they will not, and that he cannot compel them? By others it was argued, that the confidence was still continued, because it was expected, that in a short time cash payments would be resumed; this consideration might have operated on some persons, at the time of imposing the restriction, but now it can have no weight, as the expectation that cash payments will soon be resumed, must be utterly banished from the mind of every man; and yet no diminution of confidence has taken place. The continued confidence, without diminution, in the bank of England paper, after they were relieved from the obligation to pay in cash, seems to have arisen from the following circumstances: all the principal merchants, and government itself, declared their willingness to receive bank paper as before; the mass of the nation were content with this, for, as has been remarked under the article Money, though intrinsic value is indifferently necessary, at first to give circulation, yet, in process of time, that circumstance is never adverted to, except by those who purchase it to watch the variations in the value of the metals of which the money is formed. The nation at large knew, that the bank would no longer pay in cash, but they also knew, that bank of England paper, though thus deprived of its intrinsic value, would be received the same as before by all those to whom their principal or most common payments were to be made: as, therefore, the bank of England paper still retained the character and uses of money, the alteration in its intrinsic value was not adverted to.

With respect to the danger of over-issue, when cash payments are suspended, it is argued, that it is merely chimerical; since no one will pay interest to the bank for money, from which he does not expect to derive more profit than the interest he pays; and consequently, as all issues are made for commercial purposes, they will not be carried to a greater extent than the state of commerce requires. But it may be very true, that there are no issues, but what the state of commerce requires, and what will produce, or are expected to produce a profit to the borrower; and yet there may be an over-issue of bank paper, or, in other words, an issue, that will raise the price of commodities; since, in many instances, the profit expected by the borrower, may arise from this increase of prices. Let us suppose a merchant wishes to buy largely cotton, corn, or any other commodity, and for this purpose gets his bills discounted at the bank of England; his speculations succeed, and he makes a large profit; in this case, the price of the cotton or corn is necessarily increased by the greater sum brought into the market for the purchase of it, by means of the discount afforded by the bank of England: there is a real commercial transaction; and yet, as there is no increase in the quantity of commodities, but a mere transfer, the bank notes issued for this purpose ought to be considered an over-issue, that is prejudicial to the property of the monied man, though advantageous to the bank and the merchant.

It is evident that paper money, when not payable in cash on demand, must be more liable to depreciation from any doubt respecting the security of the country, than if it could be converted into cash at pleasure; but how far it is liable to depreciation from other causes, is a question on which there is much difference of opinion. If, as we have endeavoured to shew, there may be an over-issue, i.e. such an issue as will raise the price of commodities, the price of gold and silver bullion must rise as well as all other commodities; but when the bullion price of the metals rises above the mint price, the coin will soon be regarded only as a commodity, and will in spite of all laws and penalties be bought and sold as such. When a difference in the estimated value of paper currency and metallic currency takes place, from whatever cause it may arise, one of two effects follows: either the paper currency and the metallic currency will be equally current, each at its respective value; or the metallic currency, being regarded solely as a commodity, will disappear. Where depreciation has occurred from want of confidence, it has generally happened, that the paper and metallic
metallic currency have circulated together, each at its own value; but where depreciation has taken place, from an increase in the quantity of paper, from a diminution in the quantity of the precious metals, or from an increased demand for them, it has generally happened, that the metallic currency, being regarded solely as commodity, has disappeared. These two different effects may easily be accounted for; a rise in the price of bullion, occasioned by an over-issue of paper, by a diminished supply of bullion, or by an increased demand for it, is only known to, and acted upon by, comparatively a few people; the great mass of the nation, as has been already observed, in receiving or paying money, do not advert in the slightest degree to the character or value of the money as bullion, but only to its character and value as a means of interchanging commodities; the variations in its bullion value, therefore, are unheeded both in their payments and receipts; they are, however, constantly and carefully watched by all whose business consists in dealing in bullion, and as soon as the bullion value of coin exceeds its mint value, it disappears from circulation by their means. The case is widely different, when there is any alarm respecting the credit of the paper currency; in this all are immediately and deeply concerned; all are eager to exchange it for the precious metals, and under these circumstances, as the precious metals, in their character of coin, can thus be exchanged for as much paper as they could command as bullion, there is no temptation to withdraw them from circulation. It is not just, therefore, to infer, that the paper currency of a country is not depreciated, because two prices do not exist, if the other effect of depreciation, viz. the disappearance of the precious metals, has taken place; each circumstance marks depreciation, but of a different kind, and arising from different causes. On the other hand, it is not fair to infer, that where the credit of the paper currency, or in other words, a difference of value between the paper currency and the coin it promises to pay, may arise, like a difference of value between any other two commodities, from the quantity of the one being increased, or the demand for it being diminished, or from the quantity of the other being diminished, or the demand for it being increased.

**PAP**

Paper offices, in the palace of Whitehall, is an ancient office, where all the public writings, matters of state and council, proclamations, letters, intelligence, negotiations of the king's ministers abroad, and generally all the papers and dispatches that pass through the offices of the secretaries of state, are lodged, and disposed in the way of library. It was chiefly from this noble repository that bishop Burnet had materials for his History of the Reformation.

**PAP**

Paper portraits and pictures. One Elizabeth Pyberg, who lived at the Hague in 1690, cut in paper not only verses, as Loo and House of Dyke, but even faces to an extreme likeness. Mr. Ellys affirms us, the did king William and queen Mary, better than any homer he had ever seen, and refrained 1000 guilders for the pieces; which were too curious, that he could not believe the queen's drably not to be point till he had most accurately examined it. Vide Phil. Trans. No. 286, p. 1418.

**PAP**

Paper, stamped. See Stamp.

Papers, a term used for writings, especially those relating to a man's estate, property, dealings, or the like. In which sense, papers include books of accounts, invoices, and orders; also deeds, bonds, charters, and the like.

Papers are also sometimes used for manuscript books.

Papers are more particularly used of late days for gazettes, journals, and other public news-writings.

We have daily papers, weekly papers, morning papers, evening papers, occasional papers, political papers, literary papers, papers of entertainment, &c.

**PAPETTO, in Commerce**, a small silver coin of Rome, valued at two pence. The papetto of 1775, weighs 3 dwt. 8½ gr., contains in pure silver 72.8 gr., and is valued at 10½ d. florins.

**PAPHIS, in Ichthyology**, a name by which some have called the gar-fish. See Esox Belone.

**PAPHLAGONIA, in Ancient Geography**, a province of Asia Minor, situated on the Euxine sea, between Bithynia to the W., and the gulf Amyclen towards the E., to the N. was Galatia. When other divisions were introduced, the province of the Halfepeut, &c. the name of Paphlagonia disappeared. On the northern coast it had a considerable promontory, that of Caramblos (Kararamo.) The river Parthenus served for a considerable time as a boundary between Paphlagonia and Galatia. Towards the E. the mouth of the Halys served as a limit to Paphlagonia on that side. In the interior of the country were the Heneti or Veneti, regarded as the progenitors of those who afterwards passed over into Italy; they occupied the parts towards the N. In the centre of Paphlagonia was a country called Dоманто, which included a considerable town under the name of Germanopolis (Kaitamont.) This country was bordered on the S. by a chain of mountains called Olygalius (Mount Erkhas.) In the country called Blaucan, S. of these mountains, was Doece (Tofuch), and towards the E. Pompeiopolis.

**PAPHOS, (Bafa or Bafa)**, a town on the island of Cyprus towards the W., at the bottom of a small creek, terminated by the promontory Zephyrion. In this town was a very ancient temple of Venus, whence her appellation "Paphian." Of its origin there have been many conjectures. Tacitus pretends, that it was built by Aeneas, and that the goddess, having conceived in the midst of the waves, was landed in this place. He adds, that every one offered any victims according to his pleasure, but the most select were males. It was prohibited to spill any blood on her altar. Paunianas relates, that the Arcadians, in returning from the war of Troy, were cast by a tempest on the isle of Cyprus. Agapenor, their chief, founded a colony at Paphos, and there erected a temple in honour of Venus.

In this temple was an oracle, which was consulted by Titus, in his way to compliment Galba upon his elevation to the empire. When Cato was sent to the isle of Cyprus, he was affured by Ptolemy, that if he retired without opposition, he should want neither money nor honour, and that the Roman people would confer upon him the profitable and honourable post of chief priest of Venus. The first town that bore the name of Paphos was in the interior of the country; the second was on the sea-coast.

**PAPIA, in Botany**, a name given by Micheli, to what he supposed a new genus, in honour of Joseph del Papa, physician to several of the Tucan princes of the Medici family, whom he celebrated for his various learning, eloquence, virtue, and affability, as well as his zeal in promoting the studies of Medicine and Botany. Whatever the merits of this gentleman might be, the plant consecrated to immortalize them, after having been named Orvalia by Linnaeus, is now confidered as the very fame plant with his Lamiurn Orvala; see that article.

**PAPIAN-Popesian Laws, in Roman Antiquity**, was enacted by the consuls M. Papius Mutilus, and Q. Popaeus Secundus. This law obliged all men to marry at a certain age, established great exemptions and privileges in favour of those that had children, and laid heavy fines on all who, after a certain age, continued single. It was also called the B od.

Julian
PAP

Julian law, because it had been published by the order of Augustus, who was of the Julian family. The severity of this law was mitigated by Tiberius.

PAPIAS, in Biography, bishop of Hierapolis, a city of Phrygia, who flourished in the early part of the second century. He is supposed to have died a martyr; and the author of the "Alexandrian Chronicle" affirms, that he suffered at Pergamos, during the severe persecution in the reign of Marcus Aurelius. As these facts are not noticed by Eusebius or Jerome, Lardner does not think them entitled to much credit. Irenæus speaks of him as a hearer of John, and a companion of Polycarp; the John here mentioned is supposed by some to be the apostle of that name, but Eusebius observes, that "Papias does not say that he heard or saw any of the apostles, but only that he received the things concerning the faith from those who were well acquainted with them, that he received the apostles' sayings from those who conversed with them, and that he was a hearer of Aristion, and John the Presbyter." Eusebius and Jerome esteemed him as a good man, but extremely credulous, and of very shallow abilities, who delighted much in hearing and telling stories, and relating miracles, which he learned from tradition. But Dr. Lardner says, "I esteem the testimony very valuable, which he has given to the gospels of St. Matthew and St. John. If Papias had been a wiser man, he had left us a confirmation of many more books of the New Testament." Papias was the first person who propagated the famous notion concerning a Millenium, or personal reign of Jesus Christ upon earth for a thousand years after the resurrection, when he believed the elect should be gathered together at Jerusalem, and enjoy all the felicity imaginable during that period. He was author of five books, entitled "An Explanation of the Oracles of the Lord," of which only a few fragments are preserved in the works of Irenæus and Eusebius. Lardner, vol. ii. edit. p. 1788.

PAPIER MACHE' is made of cuttings of white or brown paper, boiled in water, and beaten in a mortar, till they are reduced into a kind of paste, and then boiled with a solution of gum arabic or of lye, to give tenacity to the paste, which is afterwards forced into different toys, and formed into various figures. When dry, it is done over with a mixture of size and lamp-black, and afterwards varnished. See GILDING, JAPANNING, and VARNISH.

PAPIGOHAVEN, in Geography, a bay on the E. coast of Scotland, and county of Caithness; one mile N. of Wick.

PAPILIO, the Butterfly, in Entomology, a genus of insects of the order Lepidoptera. The generic character is, antenna thickening towards the extremity, commonly terminating in a knob or clavated tip; wings, when fitting, crested and meeting upwards. They fly in the day-time. The prodigious number of species of this numerous and beautiful tribe has made it necessary to divide the whole into sections, intituled from the habit or general appearance, and, in some degree, from the distribution of the colour of the wings. This division of the genus is," says the late excellent naturalist, Dr. Shaw, to whose labours we have frequently been indebted, "conducted by Linnaeus in a peculiarly elegant and instructive manner; being an attempt to combine, in some degree, natural and civil history, by attaching the memory of some illustrious ancient name to an insect of a particular call."

The first Linnean division consists of Equites, which are distinguished by the shape of their upper wings; these are longer, if measured from their posterior angle to their anterior extremity, than from the same point to the base. Some of this division have filiform or sharpened antenne, in which they resemble moths, but may commonly be distinguished by their habit or general shape. The Equites are denominated Troes or Trojans, distinguished by having red or blood-colorded spots or patches on each side their breasts; or Achivi, Greeks, without red marks on the breast, or gayer colours, in general, than the former, and frequently having an eye-shaped spot at the inner corner of the lower wings.

The second division consists of Heliconii, which are distinguished by wings that are narrow and entire, frequently naked or semi-transparent; the upper ones are oblong, the lower ones very short.

The third division consists of the Danai, so called from the sons and daughters of Danaus. They are divided into Danai candidi, which have whitish wings; and Danai festivi, in which the ground-colour is never white, and the wings are variegated.

The fourth division consists of the Nymphales, distinguished by the edges of the wings being coalesced or indented. It is subdivided into the Nymphales gemmata, in which the wings are marked with eye-shaped spots; and Nymphales phalerata, in which the wings are without those spots.

The fifth division contains the Plebeii. These are commonly smaller than the preceding kinds of butterflies, and are subdivided into Rurales and Urbicola; the wings of the former are marked with oblique spots; those of the latter have for the most part transparent spots.

The above distribution, says Dr. Shaw, is not entirely accurate; the task of arrangement, though apparently very trifling, is really extremely difficult. The blood-coloured spots, mentioned by Linnaeus as characteristics of the Trojans, are not always found; and the anterior angle of the wings in the Achivi is not always marked with an eye-shaped spot. The safest method, therefore, is to consider each of the Equites as are of a dark or mourning colour, as belonging to the Troes, and those of gayer or livelier ones to the Achivi. The under wings in some of the Heiconii are slightly indented, and might perhaps as well have been referred to the Nymphales phalerata; the under wings of the Danai festivi are also often indented; and the family of the Plebeii is also very inaccurate, many of these insects having characters which would more properly entitle them to a place in some of the other divisions.

The larvae of butterflies are universally and emphatically known by the name of caterpillars, and are extremely various in their forms and colours; some being smooth, others beset with either simple or ramified spines, and some, especially those belonging to the division Equites, are observed to protrude from their front, when disturbed, a pair of short feelers, somewhat analogous to those of a snail. (See ENTOMOLOGY.) In our account of the species, we shall give, in general, little more than the name, specific character, and native place where it is known.

Species.

Equites. Trojans.

PARK. Wings tailed, that is, furnished with a pair of lengthened procces, black; the lower ones with a large blue spot and purple eye, and seven lunules beneath. It is found in China and other parts of Asia.

BIAx. Wings tailed, black, both surfaces nearly of the same colour; the lower ones with five fuscous lunules. It inhabits China, and has five red crescents on the lower wings.

HELENUS.
PAPILIO.

Helenus. Wings tailed, black; the lower ones with a white spot and double purple lunule. Found in Asia.

Theseus. Wings tailed, brown, both surfaces of the same colour; the lower pair with nine red lunules, dotted with white. It is found in the island of Sumatra.

Polytes. Wings tailed, black, both surfaces of the same colour; the upper ones with a band composed of five white spots and red lunules. It is an inhabitant of Aia.

Mithus. Wings tailed, black; the upper ones with a white band; lower ones with a band of five red spots and lunules. It is found in the island Tranquebar. It is thought to be a variety of the last.

Hector. Wings tailed, black, both surfaces of the same colour; the upper pair with an uninterrupted white band; lower ones with numerous crimson spots. The thorax is red on each side. It is a native of the East Indies, and feeds on the Arrilolochia or Birdworth.

Ascansius. Wings tailed, black, with a common white band, both surfaces alike; the lower ones clouded red. It inhabits Brafil.

Antenor. This is a very large species, measuring six inches and a half in extent of wings. Its colour is black, with numerous cream-coloured spots and patches; and the under wings, which are tail, are edged with a row of red crescent-shaped spots. It is a native of India.

Troilus. Wings tailed, black; the upper ones with pale marginal spots; lower ones with pale spots above, and fulvous ones beneath. Found in North America.

Illioneus. Wings tailed, black; the lower ones with a blackish border, fulvous at the angle of the tail, with red spots beneath. It inhabits Georgia.

Glaucus. Wings tailed, brown; the lower ones blue-black, fulvous at the angle of the tail, with yellow lunules beneath. It inhabits America.

Palmirus. Wings tailed, black, with green-gold specks, and a common blue-green band. It is found at Tranquebar.

Crinis. Wings tailed, black, with green-gold specks, and a common blue-green band; the lower ones beneath with green, blue, and cinereous lunules. It is found in Africa.

Deiphoeus. Wings tailed, black, the base beneath spotted with red; the lower ones with seven red and almost angular spots. It is found in divers parts of Asia.

Peleus. Wings tailed, black; the upper ones with a white band; the lower pair with white marginal lunules, and two red dots. It is found in India.

Asterias. Wings tailed, black, with two mucular bands; angle of the tail fulvous, with a deep black dot. Found in America.

Pheboronta. Wings tailed, black, spotted with blue; lower ones with an interrupted white band beneath. Found in the island of Cayenne.

Phileon. Wings tailed, black; the lower ones with a greenish gloss, and seven eye-like spots beneath. It inhabits America.

Cybus. Wings tailed, black, the margin spotted with white; lower ones with a white mucular band, and marked beneath with seven red lunules. A specimen is preserved in the British Museum.

Pammon. Wings tailed, black, both surfaces of the same colour; the margin is spotted with white; lower ones with seven white spots.

Asius. Wings tailed, black, with a common white band; lower ones spotted with red beneath, at the base, and tip. Found in South America.

Acamus. Wings indented, tailed, brown, both surfaces of the same colour; upper ones with a yellow band; lower ones with red, blue, and yellow lunules. Found in Jamaica.

Laodochus. Wings indented, tailed, black; the upper pair with an abbreviated yellow band; lower ones with fuscous, blue, and white lunules beneath. It inhabits Brafil.

Achates. Wings tailed, black, rufous at the base, both surfaces nearly of the same colour; the lower ones with white spot divided into eight parts. It is found in China. There is a variety of this species named Papilio Alcmen, with brown wings, black at the base; the upper ones with a rufous spot; lower ones with white spots.

Lynden. Wings tailed, black; upper pair with a white streak; lower ones with a white spot in the middle, and red lunules. It is found in India.

Polydorus. Wings tailed, both surfaces alike; lower ones with a fusc-cleft spot at the future, and seven red lunules. It inhabits India.

Coon. Wings tailed, both surfaces alike; upper ones brown; lower ones black, spotted with white at the base, and a double yellow spot at the angle of the tail. It inhabits China.

Antiphus. Wings tailed, black, both surfaces of the same colour; the lower ones with seven red lunules. It resembles the Polydorus, and is found in India.

Darkanus. Wings tailed, the upper pair with a green round spot; lower ones with a red palmate spot. It is found in Brafil.

Tros. Wings indented, tailed, black, both surfaces alike; upper ones with an abbreviated white band; lower ones with a mucular red one. It is found in Brafil.

Antimachus. Wings indented, elongated, black; upper ones with subradiate fulvous spots; lower ones with a rufous disc speckled with black. It is found in Africa.

Priamius. Wings indented, silky; upper pair above green, with a black disc and edge; lower ones with from four to six black spots. This, says Dr. Shaw, should take the lead, not only from the corresponding dignity of the name, but from the exquisite appearance of the animal itself, which Linnaeus considered as the most beautiful of the whole papilionaceous tribe. It measures more than six inches from wing's end to wing's end; the upper wings are velvety-black, with a broad band of the most beautiful green-gold, and of a fatui lucre, drawn from the shoulder to the tip, and another on the lower part of the wing, following the shape of that part, and of a somewhat undulating appearance as it approaches the tip; the lower wings are of the same green colour, edged with velvety-black, and marked by four spots of that colour, while at the upper part of each, or at the part where the upper wings lap over, is a square orange-coloured spot; the thorax is black, with splinkings of vivid green in the middle; and the abdomen is of a bright yellow or gold colour. On the under side of the animal the distribution of colours is somewhat different, the green being disposed in central patches on the upper wings, and the lower being marked by more numerous black as well as orange spots. It is a very rare insect, and is native of the island of Amboyna.

Amphirius. Wings indented, black, both surfaces alike; upper ones with yellow spots; lower ones with a yellow disk.

Remus. Wings indented, black, both surfaces nearly alike; lower ones with yellow marginal spots on each side. It inhabits Amboyna.

Laomedon. Wings indented; upper pair brown, lower
ones black, with a double rufous spot at the angle of the tail. It inhabits China.

**Memnon.** Wings indented; all of them marked beneath with rufous at the base. It inhabits China.

**Astrapian.** Wings indented, black, both surfaces of the same colour; the upper ones with a faint white band, including a smaller one, lower ones spotted with black. It is found in India.

**Protenor.** Wings indented, black; the lower ones beneath with an irregular red spot at the angle of the tail. It is found in India.

**Agenor.** Wings indented, black, sanguineous at the base; lower ones white on the edge, with black spots. It is found in China.

**Achilles.** Wings indented, black, both surfaces alike; lower ones with seven ovate scarlet spots.

**Sarpedon.** This is a highly elegant species; the wings are of a lengthened shape, and the lower pair are stretched downwards into a pointed process; the whole animal is black, with a broad, interrupted, sea-green stripe, or band, passing through all the wings; on the lower part is also a border of crescent-shaped green spots.

**Polydamas.** Wings indented, black, bronzed with a spotted yellow band; the lower ones with flexuous red lunules beneath. This is found on the Antitoliachia anguicida.

**Androgus.** Wings indented, black, bronzed; the lower pair beneath with red, blue, and yellow lunules. It inhabits Surinam.

**Peranthus.** Wings indented, tailed; above green at the base, beneath pale at the tips, lower ones with leon fulvous lunules. It is found in China.

**Anthemidion.** Wings indented, brown, both surfaces alike; upper wings with radiate white, lower ones with a five-elled red spot, and red lunules. It inhabits Ambonya.

**Zacynthus.** Wings indented, black; the upper ones with a green-white spot, lower ones with a palatal red one. It inhabits Brazil.

**Dimas.** Wings indented, black, both surfaces alike; the upper wings with a white spot divided by the veins; lower ones with a palatal red spot. This also is a native of Brazil.

**Ideus.** Wings indented, black; upper pair with an abbreviated yellow band; lower ones with a palatal red spot and dots. Found at Madras.

**Vergus.** Wings indented, black; upper pair with a round green spot in the middle; lower ones with a palatal sanguineous spot. Inhabits Surinam.

**Aeneas.** Wings indented, black; upper pair with a green spot above; lower ones with a red palatal spot. It is found in India.

**Ilius.** Wings indented, black; upper pair with a white spot, lower ones beneath with red dots at the base and angle of the tail. This is an American insect.

**Iphidamus.** Wings indented, black, both surfaces uniform; upper pair with an abbreviated white band; lower ones with a broad red one.

**Bates.** Wings indented, greenish; lower pair rather pale at the inner margin, beneath brown, with red lunules. It inhabits Surinam.

**Pompeius.** Wings indented, black, both surfaces uniform; lower pair with red spots. It inhabits Surinam.

**Polymeron.** Wings indented, black, both surfaces nearly of the same colour; lower pair blueish towards the tip, and spotted with black and white. Found in divers parts of Asia.

**Pantomus.** Wings indented, black, both surfaces uniform; upper pair spotted with white, lower ones with white spots, including some black ones. It is found in India. There is a variety in which the upper wings are clouded; lower ones with yellow spots.

**Pandarus.** Wings slightly indented, both surfaces nearly alike, blackish, spotted with white; lower pair yellow, with green black eyes; the pupil blue. It inhabits India.

**Action.** Wings indented, black, both surfaces alike; common dist of the second pair of a brilliant gold-colour. It inhabits Surinam.

**Hercules.** Wings indented, black, both surfaces alike; dist of the lower ones yellow, dotted with black. It inhabits India.

**Eurypylus.** Wings indented, black, both surfaces alike, with an interrupted green band and spots; lower pair beneath spotted with red. It inhabits India.

**Cressida.** Wings indented; upper pair hyaline, with two black spots; lower ones black, with a white spot. It is found in New Holland.

**Harmonia.** Wings scalloped, white; both surfaces alike; upper pair with a black spot; under ones with a brown margin, and five white dots. It inhabits New Holland.

**Equites.** **Greeks.**

**Ripheus.** Wings with six tail-like processes, black with green bands; lower ones with a large red patch, including two black dots. It inhabits Coromandel.

**Leto.** Wings tailed, both surfaces alike, black with a shining green band, and numerous narrow stripes. This is an American insect.

**Lavinia.** Wings tailed, black, barred with green, beneath silvery with fulvous stripes. It inhabits America.

**Brutus.** Wings tailed, white, with a black border; lower pair with a brown band beneath. It inhabits Africa.

**Dolicacaon.** Wings tailed, white, with a common black border; lower ones with marginal white dots on each side. It inhabits America.

**Ulysses.** Wings tailed, black, with a blue radiating dill; lower pair with even ocellate spots beneath. This species is found in Asia.

**Diomedes.** Wings tailed, black; the dill unequally radiate with blue; the lower ones with blue lunules. It inhabits India.

**Protesilaus.** Wings tailed, both surfaces nearly alike, white with brown bands, and a single red one beneath; angle of the tail red. It is found in America.

**Antilochus.** Wings tailed, both surfaces alike, yellow, with black bands and margin; the tail is white, and as long as the wings. It is an inhabitant of North America.

**Podalirius.** Wings tailed, both surfaces nearly alike, yellowish, with double brown bands and margin; lower ones with five blue ocellate spots, and a reddish line beneath. This is found in our own country, and other parts of Europe. Mr. Donovan has given a figure of it.

**Antipates.** Wings tailed, white; the margin brown, barred with white; the lower ones beneath yellowish at the base, and barred with black. It inhabits America.

**Alcibiades.** Wings tailed, white; upper ones with black bands on the margin; lower ones beneath ferruginous...
at the tip, dotted with black. It inhabits Tranquexbar. It
lefs than the P. podalirius.

Pomphius. Wings tailed, white; the border barred
with white; lower ones beneath with furrigious spots,
marked with black. This is an Indian infect.

Sion. Wings tailed, black, with green entire band,
stripes, and dots; lower ones with a red line underneath.
It is found in India, and is half the size of the Podalirius.

Acapetor. Wings tailed, black, with green macular
bands; lower ones with a fangninese line beneath. Found
in Africa.

Tiyastes. Wings tailed, black, with a yellow band and
spots; lower ones with a red line beneath. It inhabits
Brazil.

Chiron. Wings tailed, black, barred with brown;
underneath white, on the fore parts with furrigious streaks.
It inhabits India.

Criton. Wings tailed, above brown, beneath glaucous,
with a white band on both sides. It is a small brown infect,
and inhabits Surinam.

Orsiloches. Wings tailed; upper ones with two white
bands; lower ones with one; beneath white at the base,
with a fulvous band. This also is an inhabitant of Surinam.

Curius. Wings tailed, both surfaces alike, black;
upper pair with two hyaline bands; lower ones with a
single white one. It inhabits Siam. A specimen is pre-
served in Sir Joseph Banks' museum.

Octavius. Wings tailed, hyaline, with a red margin
and stipe. It inhabits Surinam.

Lecanes. Wings tailed, black, with two white bands;
the angle of the tail has two red dots. Found also in
Surinam.

Melibeles. Wings tailed, brown; upper pair with a
red stipe; lower ones with two; beneath shining blue. It
inhabits Surinam.

Homerus. Wings tailed, black, with a yellow band;
lower ones yellowish underneath, with seven eyes. It
inhabits America.

Turnus. Wings tailed, both surfaces alike, yellow,
with black margin, and five abbreviated bands; angle of
the tail fulvous. Found in America.

* Machaon. This is an insect of great beauty, and
may be considered as the only British species of Papilio,
excepting the* Podalirius, belonging to the tribe of Equites.
It is commonly known among the English collectors by
the title of the Swallow-tailed butterfly, and is of a beautiful
yellow, with black spots or paches along the upper edge
of the superior wings; all the wings are bordered with a
deep edging of black, decorated by a double row of cres-
cent-shaped spots, of which the upper row is blue, and the
lower yellow. The under wings are tailed, and are marked
at the inner angle or tip with a round red spot, bordered
with blue and black. The larva, or caterpillar of this
species, feeds principally on fennel, and other umbelliferous
plants, and is sometimes found on rue. It is of a green
color, encircled with numerous black bands, spotted with
red, and is furnished on the top of the head with a pair of
short tentacula of a red colour, which it occasionally pro-
trudes from that part. In the month of July it changes
into a yellowish-grey angular chrysalis, affixed to some part
of the plant, or other neighbouring substance, and from
this chrysalis, in the month of August, proceeds the com-
plete infect. It frequently happens that two broods of this
butterfly are produced in the same summer; one in May,
having been in the chrysalis flate all the winter; the other
in August, from the chrysalides of July.

Thersites. Wings tailed, yellow, with a black border;
lower ones with yellow lunules. It is found in America.

A specimen is found in Dr. Hunter's museum.

Chalcus. Wings tailed, black, with two yellow ma-
cular bands; lower ones beneath with a yellow ilet and
fulvous lunules. Found in America.

Menestheus. Wings tailed, black, with white spots in
streaks; lower ones with rufous and blue fulvous lunules.
It inhabits India.

Xuthus. Wings tailed, black, with white spots in
streaks; lower pair underneath with subfuscate blue and
fulvous. It inhabits India.

Theander. Wings obliquely tailed, brown, with a yellow
band and macular streaks; lower ones beneath chefnut-
brown, on the disk with black liner. It inhabits Sierra
Leone.

Thoas. Wings tailed, black-brown, with ochre yellow
bands; lower pair yellow beneath, with a black band and
blue lunules. This is found in South America. Dr.
Shaw has given a figure of it.

Cresphontes. Wings tailed, black, with a green band;
lower ones with a blue band beneath. Found in India.

Polycaon. Wings indented, tailed, black, with a yellow
band; lower ones with fulvous blue and yellow lunules
beneath. It is found in Surinam.

Ajax. Wings tailed, both surfaces alike, brown with
yellow bands, lower ones beneath with red streaks, and ful-
vous at the angle of the tail. Found in North America.

Agamejaon. Wings tailed, black spotted with green;
lower ones with three rufous lunules beneath. It inhabits
Asia.

Orestes. Wings slightly tailed, above black, beneath
yellowish, all of them with a snowy disk and two black bands.
It inhabits Africa.

Pylades. Wings indented, snowly, with a black border
dotted with white; angle of the tail with a rufous eye.
This also is an African infect.

Demoselus. Wings indented, black, with yellow spots
and bands, the under ones with a blue and rufous eye. It
is found in different parts of the East Indies.

Euphus. Wings indented, brown spotted with yellow;
lower ones with a rufous spot at the angle of the tail. It
is found in China.

Leonidas. Wings indented, both surfaces nearly alike,
black spotted with green, lower ones with a green disk. It
inhabits various parts of the continent of Africa.

Tyndareus. Wings indented, black spotted with
green; lower ones varied beneath with green, brown, and
red, the base dotted with black.

Antheus. Wings indented, black barred, and spotted
with green; lower ones variegated beneath, with three red
lunules. It is found in Amboyana.

Nireus. Wings indented, black, with a green gilt band,
beneath blackish. It is found in India.

Laedemon. Wings indented, black, with whitish mar-
ginal lunules; lower ones chefnut brown, with seven black
lunules beneath. Inhabits Malabar.

Zenobia. Wings indented, black, with a common white
band, and marginal spots; lower ones beneath yellow at the
disk, and rufous with black. It inhabits Sierra Leone.

Cynorta. Wings indented, black, with a snowy band;
lower ones beneath yellow at the base; dotted and rufous
with black.

Amphimacus. The wings of this infect are indented,
black, with a shining blue band; beneath white on the fore part, cinereous behind. It inhabits India.

**Amphitroid.** Wings indented, black, with an unequal yellow band; lower ones beneath with a stripe of yellow dots and blue lunules. Inhabits America.

**Hippocoon.** Wings indented, black, spotted with white, the common disk white. It inhabits Sierra Leona.

**Dissimilis.** Wings indented, with dilated veins, black, with white arrow-shaped spots; lower ones with marginal yellow spots beneath. Found in Asia.

**Assimilis.** Wings slightly scalloped, both surfaces alike, black, with blue-white dots; lower ones with scarlet dots.

**Hypispyle.** Wings indented, yellow, varied with black and radiate at the tip; lower ones with seven red dots. Found in the southern parts of Europe on the Arilocholochia clematitii.

**Trapezus.** Wings entire, fulvous; all of them with four blind eyes. Found in Ruffia.

**Fortunatus.** Wings entire, brown; lower ones marbled with white; black beneath. It inhabits Lapland.

**Clytus.** Wings very entire, brown; upper pair with a yellow band, lower ones with five eyes. It inhabits Africa.

**Hyperbius.** Wings very entire, brown, with a fulvous patch; upper ones with a bipupillate eye, lower ones blind beneath. It is found in divers parts of Africa.

**Cassius.** Wings very entire, brown; upper pair with a double eye; lower ones with three eyes.

**Florimel.** Wings very entire, brown; under surface of the upper ones with two eyes, of the lower ones with seven.

**Philocles.** Wings very entire; brown; upper pair with a tripupillate eye, lower ones with transverse waved lines. It inhabits India.

**Renatus.** Wings very entire, both sides alike, black, with a common white band; upper pair with a tripupillate eye. It is found in Surinam.

**Cresus.** Wings very entire, blue, with numerous black streaks; upper ones with a tripupillate spot above. It is found in Surinam.

* Hyperanthus. Wings entire, brown; under side of the upper pair with three eyes, the lower ones with five. It is an European insect and found in this country.

**Clerimon.** Wings slightly scalloped; upper pair with a black eye above, all of them with four minute eyes beneath.

**Zachleus.** Wings entire, brown, with two eyes above; under side of the upper pair with four, of the lower ones with five eyes. All the eyes have a white pupil.

**Ethus.** Wings very entire, brown; upper pair with a bipupillate eye, lower ones with three eyes above, beneath black, with a white dot in the middle. It is found among the highest mountains of Lapland.

**Oeopus.** Wings very entire, above black, immaculate; beneath brown, with about three eyes on the upper, and five on the lower ones. It inhabits Ruffia.

**Zangis.** Wings very entire, brown; all of them beneath with a single eye, that on the upper ones bipupillate. It is found in Carolina.

**Phigion.** Wings entire, above brown, immaculate; lower ones beneath with yellow streaks, and three oblong eyes. It is preferred in the British Museum.

**Areolates.** Wings very entire, above brown, immaculate; beneath with a common telfaceous streak, margin, and circles, on the upper pair four eyes, on the lower ones fix, the middle ones elongated. It is found in Georgia, and has been figured to be a variety of the P. canthus.

**Symbius.** Wings very entire, above brown, immaculate; under surface of the upper ones with five eyes, of the lower ones with fix, the middle ones blind.

**Perlusi.** Wings very entire, brown; under side of the upper ones with ocular spots; of the lower ones with feven. It inhabits New Holland.

**Martius.** Wings very entire, black; under side of the upper pair with four, of the lower ones with seven ocular spots.

**Terminus.** Wings entire, brown, with a rufous patch; upper pair with a single eye above, lower ones with four. Found in New Holland. A specimen is preferred in the museum of Sir Joseph Banks.

**Sirius.** Wings very entire, dull rufous; upper pair with two eyes above, lower ones with four. This is also a New Holland insect, and is likewise in Sir Joseph Banks' museum.

**Corvus.** Wings very entire, dull, cinereous; lower ones with four approximate eyes.

**Davus.** Wings very entire, fulvous; upper pair with an eye, and white bands beneath, lower ones with fix eyes. It is found in Germany.

* Paphilus. Wings very entire, yellow; under side of the upper ones with a single eye, of the lower ones cinereous, with both and four ocellar eyes. This and the next species are found in England and other parts of Europe.

* Arcanius. Wings very entire, ferruginous; under surface of the upper ones with a single eye, of the lower ones with five, separated by a band.

**Leander.** Wings very entire, brownish; lower pair beneath cinereous, with fulvous tip and fix eyes. Common in the southern parts of Europe.

**Sabelius.** Wings entire, brown; upper pair with four blind eyes above, and fix pupillate ones beneath.

* Hero. Wings very entire, fulvous; under surface of the upper pair with a single eye, of the lower one with five. This is an English insect, and is described and figured by Mr. Donovan.

**Arctius.** Wings entire, brown; upper pair with bipupillate eye on both sides; lower ones nearly blind. Found in New Holland. A specimen is in the museum of Sir Joseph Banks.

**Phryneus.** Wings entire, above white, beneath brown, with white veins and five eyes. Found in Ruffia.

**Hyphius.** Wings entire, both sides alike, white with brown bands; upper pair with a black eye, lower ones brown. Inhabits the East Indies.

**Baldus.** Wings very entire, brown; upper pair with an eye on each surface, the pupil double; lower ones with four eyes above, and fix beneath. It is a small insect and a native of India. A specimen is in the museum of Dr. Hunter.

**Magus.** Wings very entire, dull, fulvous; upper pair with an eye on each side, the pupil double; lower ones with two eyes above and three beneath.

**Dromus.** Wings very entire, black; upper pair with the disk rufous, in which is a double eye. It inhabits the West Indies.

**Eunomus.** Wings very entire, half brown; upper ones with a black tripupillate eye on both surfaces. It inhabits the West Indies.

**Ephynus.** Wings very entire, blue, with purple bands; upper pair with an eye on each side, which is tripupillate beneath. It inhabits Surinam.

**Tullius.**
**PAPILIO.**

_Tullius._ Wings very entire, dull, cinereous; upper pair brown at the tip, with a tripped pupillate eye on each side. It inhabits Germany.

_Aceria._ Wings scalloped, above brown; upper pair with two eyes and two white spots; lower ones marbled beneath. It inhabits Russia.

_Fidia._ Wings indented, above brown; upper pair with two eyes and two white dots; lower ones with an angular black streak beneath. It inhabits Africa.

_Terula._ Wings scalloped, black; under side of the upper pair with two eyes, of the lower with cinereous bands. Inhabits Italy.

_Cordula._ Wings indented, brown; upper pair with two eyes, and two white dots on both sides, lower ones with two black dots. It inhabits Italy, and is the size of the former ones.

_Fauna._ Wings indented, above brown; upper pair with two eyes, and two white dots; lower ones grey beneath. It inhabits Germany.

_Feronia._ Wings indented, marbled with blue, brown, and white on the upper surface, all of them with fix eyes. It inhabits the East Indies.

_Mera._ Wings indented, brown; upper pair with an eye, including a keeler one on both sides; lower ones with three eyes above, and fix beneath. Found in this country, as the afterilke does not.

_Roxulana._ Wings indented, brown; above blind; lower ones waved beneath, with seven eyes, the inner one with a double pupil. It inhabits several parts of Asia.

_Proserpina._ Wings indented, fulvous; upper pair black at the tip, with yellow dots; lower ones marked beneath with four eyes, the middle ones blind. A specimen is in the museum of Sir Joseph Banks.

_Lycas._ Wings indented, upper pair brown and spotted with yellow and white; lower ones ferruginous, with fix blind eyes; beneath variegated.

_Alope._ Wings indented, brown; upper pair with a yellow band on each side, and two eyes; lower ones with a single eye above, and fix beneath. It inhabits India.

_Clidaria._ Wings indented, brown; lower ones with a blue band, in which are five black eyes; a brown band beneath, with five eyes.

_Lacies._ Wings indented, brown, with a blue band beneath; upper pair with five eyes, lower ones with fix. Inhabits Guiana.

_Herse._ Wings indented, rusty-brown; upper pair dotted with white; lower ones with lemon blind eyes.

_Defania._ Wings indented, brown; upper pair with five eyes on each side; lower ones with fix, and a white scalloped band. It is found in Germany.

_Pegala._ Wings indented, brown; upper pair with a rusty band and single eye; lower ones with an eye above, and fix beneath. This is an American insect, and is found in Dr. Hunter's museum.

_Brises._ Wings indented, brown, with a green glos and white band; the upper ones have two eyes; the lower ones none. Found in Germany. The eyes, in this species, are sometimes wanting on the upper surface.

_Manto._ Wings slightly indented, brown; with four ocellar dots on the upper and three on the lower wings; the under face of the latter cinereous with brown waves. It is found in Austria.

_Autonoe._ Wings indented, brown, subfuscate with yellow and two pupillate eyes; upper ones brown at the base beneath. It is found in Russia.

_Semele._ Wings indented, brown, with a cinereous fulvous marginal band, in which are two eyes; upper pair

with a fulvous disc at the base beneath. It is found in divers parts of Europe.

_Arctius._ Wings indented, above brown, with a macular rufous band; upper pair with a single eye on each surface. It is found in Germany.

_Hermione._ Wings indented, brown, with a pale band; upper pair with two eyes above, and one beneath. It is found in France and Germany.

_Circe._ Wings indented, brown, with a white band on both surfaces; upper pair with a single eye. This is an European insect.

* Phebus._ Wings indented, brown, both sides alike upper pair with two violet eyes.

_Peregra._ Wings indented, brown; upper pair with an oblique eye, a yellowish streak beneath; lower ones with ocellar black dots. Inhabits Surinam.

_Delila._ Wings scalloped, black; upper pair with a small eye; under side of the upper one with two eyes, of the lower one with fix, the fourth larger. It inhabits Guinea, and is middle-sized.

_Ligea._ Wings indented, brown, with a rufous band; upper pair with four eyes, the lower with three on each surface, all spotted with white beneath. Found in Europe.

_Batheus._ Wings scalloped, brown, with the disk ferruginous; upper pair with a bipupillate eye on both sides, lower ones beneath brown, with a white band. It is found in Barbary.

_Medusa._ Wings slightly scalloped, brown, both surfaces alike, all of them with a yellow macular band, and about four eyes. This is found in Austria.

_Euphrone._ Wings entire, black with a red band; upper pair with two eyes above and three beneath, lower ones with three above and five beneath. It inhabits Germany.

_Blandina._ Wings indented, brown, with a rufous ocellate band; lower ones brown beneath, with a cinereous band. Found in Germany.

_Grelea._ Wings lightly indented, black; upper pair with four connected spots on each side. It inhabits the highest mountains of Lapland.

_Aphra._ Wings entire, brown with fix eyes; lower ones covered with cinereous down. It inhabits Russia.

_Erina._ Wings indented, brown, with a macular fulvous band and ocellar black dots. It is found in Germany.

_Arachne._ Wings entire, black, upper pair with a rufous band on each side, containing two eyes; lower ones with an indented cinereous band beneath. It inhabits Austria, and is the size of the last.

_Pyrrhia._ Wings entire, brown, with a red band, which is dotted with black on the upper pair, and macular on the lower ones. It inhabits Austria.

_Casuaria._ Wings entire, brown, with a rufous band, containing three ocellate black spots; the lower ones with only dots beneath.

_Arete._ Wings entire, brown with a rufous band; lower ones with a stripe of white dots on each side. It inhabits the moun- taneous parts of Austria.

_Salome._ Upper wings brown, with a rufous band containing a single eye; lower wings with three eyes, beneath an indented white streak, and five eyes. This species is found at Gibraltar.

* Galathaea._ Wings indented, varies with brown and yellowish-white; under surface of the upper one with a single eye; of the lower ones with five.

_Argo._ Wings indented, white streaked with black; upper
upper pair with a single eye, the lower ones with five. It
found in Russia.

* Lipessa. Wings slightly indented, cinereous, with brown waves; the upper pair has a white band, lower ones with four ocular white dots. It inhabits India.

* Plutella. Wings indented, brown, with a yellowish disk; upper pair with a black eye, and double pupil on each side; lower ones with flowy ocular spots beneath. It is found in many parts of Germany.

* Izda. Wings slightly indented, brown, with a yellow disk; the upper pair with a black bipupillate eye on each side, the lower ones variegated with grey beneath.

* Mellifera. Wings indented, brown, with a white disk; lower surface whithish, with two eyes on the upper pair, and seven on the lower ones.

* Cadma. Wings indented, fulvous; lower ones beneath white on the disk, with two eyes, the pupil double, blue. Inhabits America.

* Janleia. Wings indented, brown; upper pair beneath yellow, with a single eye on each side; lower ones with three dots beneath. In the male, the upper pair of wings has a yellow patch, including a single eye on each side.

* Clymen. Wings indented, brown, with a ferruginous patch; lower ones with about three eyes above, and four beneath. Inhabits Russia.

* Parale. Wings indented, brown, beneath cinereous, with two eyes on the upper pair, and seven on the lower. It inhabits India.

* Eudora. Wings indented, brown; upper pair with a ferruginous disk on each side, containing a single eye in the male, and two in the female. It inhabits Germany.

* Taritha. Wings indented, black; upper pair with a single eye; all of them paler beneath, with a threat of ocular dots. It inhabits the East Indies.

* Tisiphone. Wings indented, brown; upper pair with two eyes on each side, lower ones with fix. The pupils all are violet. It is found in Germany.

* Hallia. Wings indented, above brown, immaculate, beneath with yellow bands; upper pair with five eyes, the lower with seven. It inhabits India.

* Rumina. Wings indented, variegated; upper pair with fix red dots above, lower ones with four. It inhabits the southern parts of Europe.

* Plecia. Wings indented, both sides alike, fulvous, with numerous brown dots. It inhabits Cayene.

* Allica. Wings indented, both surfaces nearly alike, obtuse, fulvous, with numerous black spots, each including a white one. It inhabits Siam.

* Melicerta. Wings indented, both sides alike, black dotted with white; upper pair with a common white interrupted band. This is an African insect.

* Acthis. Wings indented, with black bands, above black, beneath fulvous. This is found in many parts of Europe and Asia.

* Ascene. Wings scalloped; upper pair black, with a yellow band and bafe, lower ones yellow, with brown bands beneath. Found in India.

* Spilitta. Wings indented, black, with a common white band; lower ones yellow beneath, with black dots at the bafe, a white band in the middle, and dots at the tip.

* Silissa. Wings indented, above brown, beneath ferruginous, spotted with black, and a maocular white band on both surfaces. It inhabits Europe.

* Camilla. Wings indented, dark brown, with a white band, and dots on each side; lower ones silvery blue at the bafe.

* Lucilla. Wings indented, above brown, beneath chefnut-brown, with macular white band both sides. It inhabits Austria.

* Caeorni. Wings indented, black; upper pair with a white streak and spots; lower ones with a white band above, beneath white, with four brown bands and marginal spots. It inhabits India.

* Hcrsilia. Wings indented, white, with a fulvous border, lower ones fulvous, beneath two white bands, and a dot in the middle. It inhabits America.

* Sophia. Wings indented, variegated with yellow, fulvous and black, the margin brown, dotted with black; white lunules on the lower ones. It inhabits India.

* Dorothea. Wings scalloped down; lower ones with a fulvous band dotted with black, and a black dot beneath. It inhabits India.

* Auge. Wings indented, brown; upper pair with three green bands; lower ones with a fulvous band dotted with black, a black dot at the base beneath. It inhabits India.

* Ethesia. Wings indented, black, with a yellow disk; beneath variegated with brown and yellow, the bafe dotted with black. It inhabits Africa.

* Narva. Wings indented, black, with a line of white dots behind; upper pair with yellow spots, lower ones with a yellow disk. This is found in Africa.

* Maruana. Wings indented, fulvous; upper pair black at the tips, with a white band; lower ones with four ocular yellow spots.

* Cocalia. Wings indented, brown; upper pair spotted with black and yellow; all of them grey beneath, with a line of white dots. It inhabits India.

* Lucina. Wings indented, brown, with teflaceous spots; lower ones with two rows of whitish spots beneath. It inhabits Europe.

* Cinxia. Wings indented, fulvous, with black spots; lower ones with three whitish bands, dotted with black beneath. It inhabits Europe.

* Parthe. Wings indented, varied with black and fulvous; lower ones beneath yellowish, waved with black, the bafe with four black spots, and two fulvous bands, the hinder one composed of spots. This is an European insect.

* Didyma. Wings indented, fulvous, spotted with black; lower one beneath yellow, dotted with black, with two continued fulvous bands. It inhabits Russia.

* Fascella. Wings indented, varied with fulvous and brown; lower ones beneath white, dotted with black, with two fulvous bands, the lower composed of lunules.

* Athalia. Wings scalloped with fulvous, dotted with black; lower ones beneath white, dotted with black, with two fulvous bands. It inhabits Russia.

* Hylla. Wings indented, fulvous, speckled with black; lower ones brown at the bafe, beneath whitish. This is found in the East.

* Dictyna. Wings indented, black, with fulvous spots; lower ones beneath fulvous, with white spots at the bafe, and band in the middle, the tip with yellow lunules.

* Cynthia. Wings indented, black, with fulvous and yellow bands; lower ones beneath fulvous, with yellow bands. It inhabits Austria. In the male there are a few white spots.

* Maturna. Wings indented, varied with fulvous and black; lower ones beneath with yellow bands, and waved black stripes, the bafe impunctured. It inhabits Europe.

* Amoena. Wings indented, fulvous, spotted with black; lower ones beneath white, with two fulvous bands, the lower speckled with black. This is found in Rilla.

* Hecate. Wings indented, fulvous, spotted with black;
all of them with two flares of black dots at the tip. This is found in Auloria.

* Artemis. Wings indented, fulvous, variegated with black; lower ones with a flare of black dots on each side.

Amaryllis. Wings indented, fulvous with black spots, and a punctured flare; lower ones variegated beneath, a black dot at the base, and a flare at the tip.

* Dia. Wings fulvous, spotted with black; lower ones beneath purple, the base with yellow and silvery spots, and an oblong ring band in the middle.

Dryope. Wings indented, brown, with rufous spots, the tip fulvous; beneath with rufous spots, surrounded with a white ring. It inhabits Sierra Leone.

* Levana. Wings decussated, variegated, beneath reticulate, upper ones with a few white spots.

Phora. Wings indented, brown, beneath reticulate with white; the upper pair with a white interrupted band on each side. This is an European species.

Pandora. Wings indented, fulvous, spotted with black; lower ones beneath scarlet, immaculate.

Pales. Wings slightly indented; fulvous, with black bases and spots; lower ones beneath nut-brown, and variegated with yellow and silvery. This is found in Auloria.

Danae. Wings indented, fulvous, spotted with black; lower ones beneath yellow, with rufous veins, the tip silvery, fuscous. Inhabits Auloria, and is found on the Rubus idaei.

Heliconii.

Horta. Wings entire, red, upper one hyaline at the tip, lower ones beneath whitish dotted with black. This is an inhabitant of Africa.

Quirina. Wings entire, hyaline, disc of the upper pair fulvous, speckled with black. This is found at Madras.

Calliope. Wings entire, yellow; upper pair with three black flares; lower ones with three black bands. It inhabits India.

Melite. Wings entire, yellow; upper pair black, with two yellow lines, and a band. Inhabits India.

Mopsa. Wings entire, both surfaces alike, yellow and black, the margin dotted with white. It inhabits India.

Myrrha. Wings entire, fulvous, spotted with black; upper pair black at the tip, with yellow spots; lower ones black, with a fulvous band behind. It inhabits India.

Lycaete. Wings entire, fulvous, tint with black; upper pair spotted with yellow.

Lyssimnia. Wings entire, fulvous, with a yellow band, the tip black, with a white spot on the upper pair.

Clara. Wings scalloped, black, spotted with yellow, and a common tattaceous base. It is found in Surinam.

Egena. Wings entire, upper pair fulvous, with a yellow band, the tip spotted with yellow, and a row of white dots on each side. This is an American species.

Eva. Wings entire, both surfaces alike, black; upper pair with fulvous flecks at the base, and spots at the tip, disk of the lower ones fulvous, with a black band. It inhabits Surinam.

Lybia. Wings entire, upper pair black, with two fulvous bands; lower ones fulvous, with a marginal black band. It inhabits India.

Vesta. Wings entire, yellowish, the margin dotted with black. It inhabits China.

Hypartia. Wings entire, fulvous, dotted with black, the margin black, immaculate. It inhabits Africa.

Viole. Wings entire, fulvous, dotted with black; margin of the lower ones black, with seven white dots. It inhabits India.

Terebinc. Wings entire, fulvous; lower pair dotted with black. It inhabits Asia.

Serena. Wings entire, fulvous; base of the lower pair dotted with black. Found in India.

Polymina. Wings entire; upper pair with black spots, and tip and yellow band; lower ones with three black bands, the middle one ferrate. This is found in America.

Hippodamea. Wings entire, upper pair black, with three hyaline bands; the lower ones are like hyaline hyaline.

Irene. Upper wings black, with yellow spots, and a fulvous line at the base; lower ones fulvous, edged with black. It inhabits America.

Saphio. Wings entire, without surfaces alike, black-blue; upper pair with a white band; lower ones edged with white. Inhabits Jamaica.

Urania. Wings entire, brown, with a white disc; lower ones with two eyes each. This is found in India.

Donis. Wings entire, black; upper pair spotted with yellow; lower ones radiate, with blue at the base above. It is found in Surinam.

Olympia. Wings entire, black; upper pair with an oblong fulvous spot at the base, and white ones at the tip, lower ones fulvous at the base.

Crisia. Wings entire, black; upper pair acuminate with a yellow band; lower pair with a yellow disc. It inhabits America.

Hecale. Wings entire, black; upper pair with a white band; lower pair with white marginal dots beneath. Found in Surinam.

Ricini. Wings entire, brown; upper pair with two yellow bands on each side; lower ones rufous at the base. It inhabits America.

Sara. Wings scalloped, black, with a blue base; upper pair with two yellow bands; lower ones with red beneath. It inhabits Guiana.

Aranea. Wings black; upper pair with a yellow sleeper at the base, and two bands; lower ones with a red band beneath.

Brassolis. Wings entire, brown; upper pair spotted with yellow; lower ones beneath with red rays. It inhabits Surinam.

Thales. Wings nearly entire, and alike on both surfaces, black, with red rays at the base; the upper pair is spotted with yellow. It inhabits Surinam.

Myrtia. Wings entire, black; upper pair with two yellow bands; lower ones with a rufous disc. It inhabits Surinam.

Nasia. Wings entire, black; upper pair with two yellow bands; lower ones with a yellow disc.

Cephalia. Wings entire, black; upper pair with an abbreviated white band; lower ones fulvous at the base, and radiate beneath. It inhabits Cayenne.

Psidia. Wings entire, brown; upper pair with three hyaline bands; lower ones with two. It is found in India.

Aspasia. Wings entire, black, with hyaline flecks and spots; lower ones yellow at the base. It inhabits Tranquebar.

Æole. Wings entire, black; upper pair with hyaline spots; lower ones with a hyaline disc.

Charitoniea. Wings entire, black, upper pair with three yellow bands; lower ones with two. It inhabits America.

Melipomene. Wings entire, black; upper pair with a red band; lower ones with red dots at the base beneath. It inhabits America.

C c

Phyllis.
Papilio.

Phyllis. Wings entire, black; upper pair with a red band; lower ones with a yellow one. It inhabits Brazil.

Cléo. Wings entire, brown; upper pair spotted with white; lower ones with a white band. It inhabits America.

Thalia. Wings entire, brown; upper pair spotted with yellow; lower ones irritable. It inhabits India.

Rosalia. Wings entire, both surfaces alike, fulvous; upper pair with a yellow spot; lower ones with two black streaks. Inhabits Surinam.

Euryta. Wings entire, both surfaces alike brown, with a white band; lower ones irritable, the base is dotted with black.

Umbera. Wings entire, brown, with a teftaceous bâfe; lower ones speckled with black.

Aedeia. Wings entire, spotted with white; upper pair greenish; lower ones with a yellow band. It inhabits India.

Thallo. Wings entire, black; upper pair with two yellow bands; lower pair with a fling one. It inhabits China.

Anticha. Wings entire, black; upper pair with two white bands. It is found in India.

Camena. Wings nearly entire, brown, dotted with black; lower ones with a red band. It inhabits Africa.

Macaria. Wings entire, brown; upper pair with a black bâfe, and broad rufous band in the middle; lower ones dotted with black at the base.

Zetes. Wings brown, dotted with black; lower pair with a fulvous band, dotted with black, the margin beneath with pale dots. It inhabits Guinea.

Persiphone. Wings entire, brown, dotted with black; upper pair with a white spot, margin of the lower ones black, immaculate.

Petra. Wings entire, black; upper pair with two spots; dîk of the lower ones fulvous, irritable with black, the base beneath is irritable with black. This species inhabits Africa.

Jodutta. Wings entire, black; upper pair with two white spots, dîk of the lower ones white, irritable with black, the base beneath dotted with black.

Parthenia. Wings entire, black; upper pair with a four-cleft fulvous and hyaline spot; lower ones with a fulvous band, beneath yellow with black dots and lines.

Lycia. Wings entire, both surfaces alike, brown, spotted with white; dîk of the lower ones white, with black dots. It inhabits Sierra Léona. There is a specimen in Mr Joseph Banks' Museum.

Pamphile. Wings entire, both surfaces alike, brown, spotted with yellow; dîk of the lower ones ferruginous, irritable with black. It inhabits Brazil.

Papilion. Wings entire, brown, varied with white, with black spots and margin. It inhabits Guinea.

Marcia. Wings entire; upper pair brown, immaculate; lower ones yellowish, dotted with black. This, and also the two next, are found in Africa, and specimens are preserved in Mr Joseph Banks' Museum.

Cecilia. Wings white, in the middle dotted with black; margin of the lower ones black, beneath it is dotted with white.

Bonasia. Wings entire, brown, with a common fulvous band; bale of the lower ones dotted with black.

Euterpe. Wings entire, black, with a fulvous band and white dots. It inhabits America.

Sussanna. Wings entire, black, dotted with white, a fulvous spot at the bale and band behind. It is found in Africa. A specimen is in Mr Joseph Banks' Museum.

Hyperet. Wings entire, white, with black veins; lower ones beneath yellow, the margin spotted with red. It inhabits India.

Pasithoe. Wings black, slightly radiate, with white, and a central white dot; lower ones beneath sulphur, with black margin and veins; the base is red. There is a variety, in which the wings are entire, black, spotted with white; lower ones beneath yellow on the disk, with a red band at the base.

Eurytrea. Wings black; upper pair with two red bands; lower ones with fix red streaks. Found in Surinam.

Elato. Wings entire, black; upper pair spotted with yellow and red at the base; lower ones irritable with red. This is found in India.

Belladona. Wings entire, black; upper pair with hyaline dots; lower ones with yellow spots.

Julia. Wings indented, fulvous; upper pair with two black streaks; lower ones black on the band margin.

Hippona. Wings indented, tail varied with yellow and black; lower ones with four white dots. It inhabits India.

Parnassii.

Apollo. Wings entire, white, spotted with black; lower ones with four eyes above and fix beneath. This is a native of many parts of Europe, but has not been observed in these islands. It is something larger than the common great cabbage butterfly. The caterpillar is black, with small red spots, and a pair of short retractor tentacula in front; it feeds on orpine and some other succulent plants, and changes into a brown chrysalis, covered with a kind of violet-coloured powder.

Phœbus. Wings entire, both surfaces alike, white, spotted with black; lower ones with three red spots, circled with black. It is found in the wilds of Siberia.

Mnemosyne. Wings entire, white, with black nerves; upper pair with two black marginal spots. It inhabits Europe.

* Crategni. Wings entire, white, with black veins. This is sometimes called the hawthorn butterfly, and is well known in this country. It is of the size of the common cabbage butterfly, and is seen in the months of June and July.

Andromacha. Wings entire, both surfaces alike, dotted with black; the upper pair is dusty and naked; the lower ones yellowish. It is found in New Holland.

Macane. Wings oblong, entire; the upper pair is hyaline, with black veins; the lower ones black, with a white band. It inhabits Africa.

Pieria. This species has semi-transparent wings, with the lower pair marked by two oblong black spots, with a yellow ring and centre. It is a native of South America.

Anacardi. Wings entire, hyaline, greenish; lower ones brown at the tip, with two eyes. It is found in America.

Nersea. Wings scalloped, brown; lower ones with a snowy band, the disk is fulvous, with two black eyes. It inhabits America.

Andromeda. Wings hyaline white; lower ones red at the tip, with a single eye in each. It is found in America.

Diaphanus. Wings entire, hyaline, white, the margins brown. It inhabits Jamaica.

Hyalinus. Wings entire, both surfaces alike, upper pair hyaline, with black bands and margin; lower ones teûtaceous.

Obscuratas. Wings testaceous hyaline; upper pair with a yellow band.

Idea. Semi-transparent wings, white, with black spots and veins. It inhabits India.
PAPILLO.

Cypharis. Wings entire, black, with two white bands, those of the upper pair oblique, of the lower ones punctate. It inhabits America.

Diana. Wings entire, black, dotted with white; upper pair above bluish; lower ones with a row of white dots. A native of India.

Dinysis. Wings entire, brown; upper pair with two white dots, all of them with numerous ones beneath. A specimen of this is in the British Museum.

Dioctetaius. Wings entire, black; upper pair with an interrupted white band; lower ones with white lines at the base, and a double row of dots at the tip. A native of the East Indies.

Claudius. Wings entire, black; upper pair with a blue gloss, and dotted with white; lower ones with white lines. It inhabits Tranquebar.

Niavius. Wings entire, black; upper pair with a white band; lower ones with a common white spot at the base. A native of Sierra Leone.

Damocles. Wings entire; upper pair black; lower ones brown with a white disk. It inhabits Afa and Africa.

Corus. Wings entire, black, all of them with a double row of white dots. A native of India, as is also

Tulliolus. Wings entire; upper pair black, with a maculately white band; lower ones brown, above immaculate, beneath dotted with white.

Sylvester. Wings entire, brown, with a maculate white band.

Cochlus. Wings entire, both surfaces alike, black, with a maculate white band; abdomen red, with black belt. In Dr. Hunter's Museum.

Liberalis. Wings entire, lead colour, under surface of the upper pair green, of the lower ones fulvous. It inhabits Ambyonia.

Radamanthus. Wings entire, black, with a blue gloss; upper pair with a marginal white spot; the lower ones with a white spot and four lines. It is a native of Afa.

Zoilus. Wings entire, black; upper pair with three white spots, lower ones with a white disk. It is a native of New Holland.

Cynthiaeus. Wings entire, black with teataceous veins, and a white band, which in the upper pair is interrupted. It inhabits Africa.

Aretusius. Wings entire, black with blue spots; lower ones with red dots beneath. It is found in Surinam.

 Clymenus. Wings entire, with a blue band; upper pair beneath, fangacious; lower ones beneath, white with black rings and dots. It is a native of Brazil.

Staminus. Wings entire, black dotted with white and a common white band, which is interrupted in the upper pair.

Jassus. Wings entire, brown with black streaks; upper pair with a marginal white spot, beneath paler with brown streaks. It inhabits Cayenne.

Antiochus. Wings entire, black with a common fulvous band above. It is a native of China.

Syphax. In this the wings are entire and black; the upper pair has a white band; the lower ones with a marginal red one.

Evathus. The wings are entire, black; upper pair with two yellow bands; the lower ones are marked with a yellow band and red spots, beneath red with a yellowish macular band. It is a native of India.

Licas. Wings entire, brown; upper pair with two white bands; lower ones with a single white band and red spots, beneath cinerous with white bands. It is a native of Surinam.

Phalaris. The wings of this species are entire and brown; the lower pair with two maculate white streaks.

Pleusius. The wings are entire, both surfaces alike; upper pair greenish with a fulvous band; lower ones immaculate. It inhabits Surinam.

Pheoton. In this the wings are entire, black, with white and rufous spots. It is a native of America.

Sophus. The wings are entire; upper pair black, the disk fulvous, spotted with black; the lower ones brown, with a black streak and dots.

Galantinus. Wings entire; above black, with fangacious bands; upper pair with two white dots at the tip.

Cesius. Wings entire, brownish; lower ones beneath with a red orb of nine spots. It inhabits India.

Cherses. Wings entire, dusky; lower ones red, with black bands above, and a flowy dot, in the middle beneath. It is a native of Africa.

Hesperus. The wings of this are scalled, brown with black waves, upper pair with white dots.

Mirus. The wings are scalled, brown, slightly fasciate with teataceous; lower ones beneath brown at the base, and variegated at the tip.

Tytius. Wings entire, brown spotted with white; upper pair with ocular black dots. It inhabits Surinam.

Eupalus. The wings are entire, brown; lower ones with a blue band, beneath green, with a black dot. It inhabits Africa.

Pintius. Wings entire, both surfaces alike, brown; upper pair with three yellow spots; lower ones white on the lower half. It is a native of India.

Archippus. Wings scalled, fulvous, with black veins, the margin black, dotted with white; upper pair with fulvous spots at the tip. It is a native of America.

Plexippus. Wings entire, fulvous, with dilated black veins, the margin black, with white dots; upper pair with a white band at the tip. It inhabits America.

Erippus. Wings entire, dull teataceous, the edge black dotted with white; disk of the lower ones immaculate, beneath with black veins, and white dots. A native of China.

Mesippus. The wings of this are scalled, and fulvous, the edge black, dotted with white, lower ones with a black curve. Found in America.

Chersipus. Wings entire, fulvous, the margin black, dotted with white; disk of the lower ones white, with black dots.

Alcippeus. Wings entire, fulvous, the margin black, dotted with white; disk of the lower ones white, with black dots. This and the two following are natives of America.

Eupus. The wings are entire, fulvous; the margin black, of the upper pair with a white band, of the lower ones with white dots.

Eresimus. The wings scalled, teataceous, the tip and margin black dotted with white; lower ones beneath with an obfeolute macular whitish band.

Dioceppus. Wings scalled, fulvous, with a common black border dotted with white; lower ones beneath with three black dots, and a streak of white ones behind. It inhabits India.

Gilippus. Wings entire, both surfaces alike, fulvous, spotted with white, the margin black, with white dots. It inhabits America.

Hegesippus. Wings entire, both surfaces alike, black, C c 2 } spotted
PAPILIO.

*Brassieae.* The wings of this insect are rounded, entire, white; tip of the upper pair brown. This is the common large white butterfly known in our gardens; it proceeds from a yellowish caterpillar freckled with blue and black spots, and which changes during autumn into a yellowish-grey chrysalis, affixed to a perpendicular direction to some wall, tree, or other object; some filaments being drawn across the thorax, in order the more conveniently to secure its position. The fly appears early in the spring, and is seen almost through the summer.

*A. Raphe.* Wings entire, white; upper pair tipped with brown; male with a brown spot on each, female with three brown spots on the upper, and one on the lower pair. This is common in our own country.

*A. Napi.* Wings entire, with dilated green veins beneath. It inhabits Europe and Asia.

*A. Sinapis.* Wings entire, white; upper pair tipped with brown. This and the three preceding are the insects which in the caterpillar or grub state commit such ravages in our gardens.

*Narica.* Wings snowy; upper pair with a brown spot before the tip. It inhabits Guiana.

*Raphani.* Wings entire, white, the tip black, spotted with white; the lower ones beneath with black veins, and covered with yellowish meal.

*Castalia.* Wings entire, white; above immaculate, beneath yellowish at the base. A native of India.

*Poppea.* Wings entire, white; the margin dotted with black; upper pair with a ferruginous spot at the base. It is found at Sierra Leone.

*Sylvia.* Wings entire, white; tip of the upper pair brown, with a brown spot beneath. Inhabits Sierra Leone. A specimen is in Sir Joseph Banks' museum.

*Paulina.* Wings entire, white, edged with black; lower surface of the upper pair with a yellow spot at the base, of the lower ones immaculate. It is found in India.

*Argante.* Wings entire, fulvous; beneath speckled with ferruginous. It inhabits Brazil.

*Monstia.* Wings entire, white, edged with brown. Found in America.

*Amaryllis.* Wings entire, both surfaces alike, dull white, upper pair with a black lunule. A native of India.

*Argia.* Wings entire, white; upper pair black at the tip. It inhabits Sierra Leone.

*Nephele.* Wings scalloped, white; upper pair with a black dot above, all of them with a brown one beneath. It inhabits China.

*Amathonte.* Wings rounded, white at the tip with black;
black; margin of the upper pair beneath nut-brown. Inhabit America.

Philota. Wings entire, grey; upper pair above white, tipt with brown. It is a native of America.

Lythea. Wings entire, white; upper pair brown at the base of the rib, and at the tip. Found in India.

Calypso. Wings entire, upper pair with a black dot and tip; lower ones beneath yellowish, the margin dotted with black. This is a native of Sierra Leone.

* Daphidice. Wings entire, white, with a brown margin, beneath marked with yellowish-white and green. It inhabits Europe and Africa, and is common here.

Cneora. Wings entire, white, the margin black, with a streak of dots. It inhabits India.

Nerissa. Wings entire, white, with a black margin; beneath with black veins. It is a native of China.

Demophile. Wings white, with two brown bands and margin; lower ones beneath flesh-colour. It is found in Cayenne.

* Cardumines. Wings entire, white; upper pair, with a brown exterior margin and black dot; lower ones with brown streaks. It inhabits America.

Hecabe. Wings entire, yellow, the outer margin black; beneath dotted with brown. A native of India.

Agave. Wings entirely yellow; tip of the upper pair above black; beneath chestnut-brown. It is found at Cayenne.

Teutonia. Wings entire, white; lower ones beneath with black veins and yellow spots. It is found in New Holland.

* Mythis. Wings entire, white; margin of the lower ones beneath black with a red band. This is a native of New Holland; and a specimen is in the museum of Sir Joseph Banks.

Argentiona. Wings entire, white, the border black spotted with yellow; the lower ones are yellow, the tip black with a Rufous macular band.

Nigrina. Wings entire, white tipt with black; beneath black with a fanginous flexuous streak on the lower ones. It inhabits New Holland. A specimen is in Sir Joseph Banks' museum.

Mania. Wings white; upper pair brown with a broad white band. This is found in the East Indies.

Sara. Wings entire, black with a common white band. It inhabits Sierra Leone. Sir Joseph Banks has a specimen.

Corone. Wings entire, white edged with black; beneath black radiate with fulvous at the base. Found at Surinam.

Melania. Wings entire, white tipt with black; lower ones dull glistous beneath. It inhabits New Holland. There is a specimen in Sir Joseph Banks' museum.

Scylla. Wings entire, yellow; upper pair white with a black border; all of them clouded beneath. It is found in the East Indies.

Filipanthia. Wings entire; upper pair with a black spot and tip; lower ones yellow; beneath nut-brown at the tip.

Judith. Wings entire, both surfaces alike; upper pair white with black veins and margin; lower ones fulvous edged with black. This is a native of Poulencador; a specimen is in Sir Joseph Banks' museum.

Amata. Wings fulvous, bordered with black. Beneath they are greenish. This and the three following are natives of the East Indies.

Cyprea.
CYPREA. Wings entire, fulvous, the margin is black, with fulvous spots; beneath greenish, with a fulvous dot and moniliform fringe.

DANAË. Wings white; upper pair saffron at the tip, with a black band and margin; beneath with an abbreviated moniliform fringe.

PYRENE. Wings rounded, yellow, with a fulvous spot in the middle, the tip black; lower ones beneath with seven ocellar white spots. It is found in America.

RAHEL. Wings entire, yellow; above edged with black; beneath immaculate. This and the following are natives of India.

MESSALINA. Wings entire, white tip with black; beneath yellow, with a marginal chefnut-brown spot. It inhabits India.

ÆNIPPE. Wings yellow; underneath they have yellow ocellar brown dots; on the upper pair fix; on the lower ones seven. It inhabits China.

EVIPPE. Wings entire, yellowish; upper pair tip with black; lower ones white beneath. It is found in Asia.

CHARISME. Wings entire, both surfaces alike, white with a black border; which on the upper wings has two yellow spots, and one on the lower. A native of Johanna Island.

THALAM. Wings entire, yellow; upper pair white above the margin; all of them with a ferruginous fringe beneath. It is found in Africa, and also in Europe.

* EDUSA. Wings entire, fulvous with a black dot and margin; beneath greenish; upper pair with a black dot; lower with a silver one. It inhabits Europe.

EUPHENO. Wings entire, yellow; tip of the upper pair black, fulvous in the middle; lower ones with three brown fringes beneath. Found in the southern parts of Europe.

BELIA. Wings entire, white; lower ones subfuscate with grey beneath. It is a native of Barbary.

PHRONIMA. Wings entire, white; base of the rib and tip black; lower ones beneath yellowish, with two darker bands. This and the next are natives of America.

PSAMATHE. Wings entire, white; tip of the upper pair black spotted with white; lower ones beneath greenish with two darker bands, the foremold incurved.

PALAEO. Wings entire, yellow, with a black tip and fulvous margin; lower ones with a silver dot beneath. It is found in Europe, as is the next.

* HYALE. Wings entire, yellow, the tip black, spotted with white; lower ones with a fulvous spot, a silver dot with a smaller contiguous one beneath. In the male, the margin of the wings is immaculate; in the female it is spotted.

AURORA. Wings entire, fulvous; upper pair with an ocellar dot beneath; lower ones with a double silver one. Thought to be a variety of the last.

NICIPPE. Wings entire, fulvous, tip with brown; upper pair with a black lunule on each side; the lower ones beneath speckled with red. This is found in Virginia.

LESIA. Wings entire, fulvous; upper pair with a brown dot, all of them beneath pale with a snowy one. It is found in Patagonia. Sir Joseph Banks has a specimen.

SENNÉ. Wings yellow, each of them beneath with a double ferruginous dot. This is a native of America.

MARCELLINA. Wings entire, yellow; each of them beneath has a double silvery dot. It inhabits Surinam.

EUNICE. Wings entire, yellow, the margin dotted with black; the lower ones beneath with a double silvery ferruginous dot. A native of Carolina.

CATILLA. Wings yellow; upper pair with a black dot and margin; all of them beneath with a chefnut spot, which on the lower ones contains a double silvery dot. It inhabits Tranquebar.

PROTERIA. Wings entire, angular, fulvous; upper pair with a black exterior margin. There is a specimen in Dr. Hunter's museum.

GNOMA. Wings white; upper pair with a black dot, all of them beneath with a silver dot. Found in India.

DRAE. Wings yellow; lower surface of the upper pair with a ferruginous dot, of the lower ones with a silvery one. It inhabits America.

PHILIPA. Wings entire, yellow; upper pair acuminate, varied with black, and with a black dot; lower ones with a red dot; all have a silvery one beneath.

* RHAMM. Wings entire, angular, yellow; each with a ferruginous dot in the middle. Inhabits Europe.

PHILEA. Wings entire, angular, yellow; upper pair with a pale spot, lower ones with a pale border. It is a native of India.

CYPRIA. Wings slightly tailed, yellow, the margin dotted with black.

MÆRULA. Wings entire, angular, yellow; upper pair with a black spot and ferruginous one beneath; lower ones with a ferruginous spot on both sides. Inhabits India.

POMONA. Wings subangular, white; upper pair with a black dot; beneath yellow with two silver dots on the lower ones. A native of New Holland, and is in Sir Joseph Banks' museum.

FLORELLA. Wings subangular, white; upper pair with a brown dot; lower ones beneath with three silver dots. Native of Africa, and is among Sir Joseph Banks' collection.

CLEOPATRA. Wings entire; upper pair with a fulvous dish above, and ferruginous dot beneath; lower ones with a ferruginous dot on each side. Found in Europe and Africa.

Nymphales.

JASIS. Wings two-tailed, brown, yellowish behind; beneath with a white band. Found in different parts of Africa.

THURIS. Wings tailed, brown, with a common white band, reaching half way on the upper pair. It is a native of India.

CAMILLO. Wings two-tailed, white, with fulvous bands, edged with black; lower ones with a black caudal spot. It is found in Africa, and is in Sir Joseph Banks' museum.

SEMIPRIS. Wings two-tailed, white, the margin black, dotted with white.

THIRAT. Wings indented, two-tailed, above black, spotted with blue; the margin is dotted with white. It inhabits Amboyna.

CASTOR. Wings indented, two-tailed, fulvous, edged with black; beneath with a white band and white spots, including a black one. This and the next are found in Guinea.

POLLUX. Wings indented, two-tailed, brown, with a yellow band; beneath with a white band and spots, including a black one.

ÆCLIS. Wings indented, two-tailed; above black; beneath cinereous, with black waves, and an ocellar fulvous spot. It inhabits Amboyna.

PAULUS. Wings indented, two-tailed, fulvous, tip with
with black; lower ones beneath variegated with a white spot at the base. A native of Jamaica.

**Ethiochus.** Wings two-tailed, blue-brown, with a white band on each side; the lower ones edged with green. It inhabits Sierra Leon.

**Fahus.** Wings indented, two-tailed, brown, with yellow bands; the base beneath with black waves; the tip with fulvous dots. It inhabits India, and is in the museum of Sir Joseph Banks.

**Horatius.** Wings indented, two-tailed, black; lower ones fangnute at the tip, with black ocellar dots.

**Eudoxus.** Wings tailed, with a common red band; beneath with slivery spots, including some black ones. It inhabits Africa.

**Celeus.** Wings slightly tailed, streaked with white and yellowish, and a white band in the middle; lower ones beneath with a streak of ocellar dots. It is a native of Siam, and is among Sir Joseph Banks’ collection.

**Militades.** Wings tailed, brown; lower ones with a white spot, all beneath with a white band and single eye.

**Varanides.** Wings tailed, above brown, with fulvous and black spots; the base is white. It is an Indian insect.

**Themistocles.** Wings tailed, chestnut-brown, with brown bands; lower ones with black dots.

**Periander.** Wings tailed, both surfaces alike, white, with yellow bands; the tip brown, streaked with white. It is a native of India, and is in the collection of Sir Joseph Banks.

**Lycurgus.** Wings tailed, black, with blue marginal lunules; beneath these are five white dots on the lower ones. It is a native of Africa.

**Decius.** Wings tailed, with a common white band; lower ones rufous at the tip, with two eyes and two white dots. It is found in Guinea.

**Sabinus.** Wings tailed, brown, with a fulvous band; beneath grey, with a white band and ocellar dots. It inhabits Amboyna.

**Doreus.** Wings tailed, with a green band above, and a white one beneath. It inhabits Africa, and is in the collection of Sir Joseph Banks.

**Paralides.** Wings tailed, black, with yellow marginal lunules; upper pair with a yellow band; lower ones with a macular rufous band. It is found in America, and is in the collection of Dr. Hunter.

**Orontes.** Wings tailed, black, with two greenish bands; the tail is white and distant. It is a native of India, as is also the next.

**Aegistus.** Wings tailed, undulate with brown and yellow, and about three caudal eyes.

**Solon.** Wings tailed, black, with yellowish bands, brown at the base.

**Empedocles.** Wings tailed, brown; upper pair with an abbreviated macular green band; lower ones beneath with two black spots, and a rufous lunule at the angle of the tail. It is a native of India, and in the collection of Sir Joseph Banks.

**Euryalus.** Wings tailed, black; lower ones blue before the margin, with black spots, including a white pupil. It inhabits Amboyna, as does the next.

**Nisus.** Wings tailed, black; upper pair with a fulvous band; lower pair with a submarginal white one.

**Phidippus.** Wings slightly tailed, brown; beneath with white biocellate bands, and two blind eyes at the tail. It inhabits India.

**Xiphares.** Wings indented, tailed, black; upper pair with white spots; lower ones with a yellow band. Found in Africa.

**Aurelius.** Wings slightly tailed, brown; the tip black, spotted with white; lower ones with two eyes beneath. It inhabits India.

**Bernardus.** Wings tailed, fulvous; upper pair black at the tip, with a yellow band; lower ones with a streak of ocellar dots. It is found in China.

**Gerdratus.** Wings tailed, brown; upper pair with an ocellar spot at the tip, beneath ferrugineous, with a white dot on the upper, and two on the lower ones.

**Chorinæus.** Wings tailed, brown; upper pair falcate, with a fulvous band. It inhabits Surinam.

**Laertes.** Wings tailed, brown, blue at the base; lower ones above with five white dots, beneath with four ocellar dots. Found in Surinam.

**Morvus.** Wings tailed, above brown, with a blue base; beneath greenish-grey. A native of India, as are the two following.

**Octavius.** Wings tailed, black, with an abbreviated green band; beneath grey, with a brown streak.

**Eribotes.** Wings slightly tailed, fulvous, with a blueish base; beneath grey.

**Itys.** Wings slightly tailed, fulvous, tift with yellow; beneath variegated at the base; the lower ones are blue at the base. This and the two following are inhabitants of Surinam.

**Cymodoce.** Wings slightly tailed, brown, the base shining blue; lower ones with a single eye on each fide.

**Basaltide.** Wings slightly tailed, fulvous, tift with black; under surface of the upper pair with two ocellar dots, of the under ones with three.

**Arinos.** Wings indented, tailed, fulvous, spotted with black; lower ones with two eyes beneath. It inhabits Amboyna.

**Panthera.** Wings indented, tailed, brown, beneath waved; lower ones with two eyes on the disk, and five blueish ones on the margin. It inhabits Tranquebar.

**Rohria.** Wings indented, tailed, brown; upper pair with a white band; lower ones with seven eyes beneath, most of them dotted with white. It inhabits India.

**Rebecca.** Wings indented, tailed, brown, immaculate; beneath paler, with two nut-brown streaks and white subocellar dots. Found in Guinea.

**Erota.** Wings slightly tailed, brown, with black waved, and a common white band in the middle; lower ones with two eyes on each fide. A native of Africa.

**Europa.** Wings slightly tailed, brown; lower ones beneath with a whitish ocellar band. Found in America.

**Acheronta.** Wings indented, tailed; upper pair red at the base; the tip is black, spotted with white. It inhabits Brazil.

**Troglodyta.** Wings indented, tailed, rufous, with a brown streak and hind margin. It inhabits America, and is in the collection of Dr. Hunter.

**Thyris.** Wings indented, tailed, fulvous, with black streaks; lower ones beneath glaucous, dotted with black. It inhabits South America.

**Portia.** Wings indented, tailed; beneath grey, speckled with black. It inhabits the South American islands.

**C. Aureum.** Wings indented, tailed, fulvous, spotted with black; lower ones marked with a gold C beneath. It is found in Asia.

**Isidore.** Wings falcate, tailed, fulvous; upper pair with two pale dots in the middle, and black at the tip. It is found in India.

**Bella.**
Bella. Wings slightly tailed, testaceous; upper pair black at the tip, with a yellow band and white spots; margin of the lower ones yellow, with black streaks. This and the six following species are all inhabitants of India.

Furcula. Wings tailed, brown, fulvous at the base; upper pair with a blue band.

Euroclydia. Wings indented, tailed, brown, with a common fulvous disk; lower ones variegated beneath.

Phorcys. Wings slightly tailed, indented, brown; beneath with darker streaks, and two cincere dots on the lower ones.

Cheiris. Wings indented, tailed, brown; beneath variegated, with a streak of yellowish dots.

Lethia. Wings indented, tailed, fulvous; upper pair black at the tip, with a yellow band and spots.

Aerina. Wings tailed, brown, with a common fulvous disk; upper pair with a black lunule. It inhabits St. Thomas's island.

Fatima. Wings slightly tailed, black, with a common yellow band; lower wings with the band abbreviated, and four rufous spots. It is found in India.

Achilles. Wings indented, black, with a broad blue band; beneath brown, with three or five eyes. Found in America.

Medon. Wings above black; upper pair with a yellow band, and white at the tip; lower ones with a blue disk. It is found in India.

Erithronius. Wings indented, black; lower ones with a blue band; beneath green, with a streak of white dots. It inhabits Africa, and is in the museum of Dr. Hunter.

Ceres. Wings indented, black; upper pair with a white band; disk of the lower ones blue, with a black dot. It inhabits Sierra Leone.

Ursula. Wings indented, black; hind ones with a blue border, and marginal black band; beneath they are marked with fulvous spots. It is a native of America.

Apo. Wings indented, black, with a common greenish disk beneath, dotted with black, with a rufous spot at the base of the lower ones. It inhabits Sierra Leone.

Philocrates. Wings indented, brown; lower ones with two eyes, the pupil black, and three white dots. It is found in India; as is the next.

Menetho. Wings indented, brown, the margin spotted with yellow; the lower ones have three eyes beneath.

Lucetius. Wings indented, black, with fulvous bands; beneath with black spots, surrounded with a blue line. Found in Guinea.

Epistropheus. Wings indented, grey-white; upper pair black at the tip; lower ones with a streak of yellow eyes beneath. It is a native of America.

Helene. Wings indented, brown, with two greenish bands; one on the lower wings entire. It inhabits America.

Ganymedes. Wings indented, above black spotted, and streaked with green; upper pair with a macarol snowy band. A native of India.

Demophon. Wings indented, above black, with a green band; beneath grey, streaked with white. Inhabits Cayenne.

Nestor. Wings indented, brown, with a bright blue common disk, and white spots; beneath with three or four eyes. This species inhabits America.

Perseus. Wings indented, pale blue, the tip black, with ferruginous spots; beneath they are waved with three or four eyes. Inhabits Surinam.

Aristides. Wings indented, brown, spotted with yellow; lower ones with two eyes beneath. Found in India.

Telema. Wings indented, brown, with a common blue radiate area, each with eyes beneath. A native of America, as are the two following.

Menelaus. Wings indented, above highly polished, blue; beneath clouded brown, with ferruginous eyes.

Teucer. Wings scalloped, livid brown; beneath clouded, and on the lower ones three eyes, the last very large.

Automedon. Wings angular, scalloped, brown; beneath livid, with an eye at the angle of the tail. Inhabits Surinam.

Hecuba. Wings indented; upper pair red, edged with black; lower ones black; all of them ochreolate beneath. It inhabits Cayenne.

Metellus. Wings indented, fulvous, the hind part black; under surface of the upper pair with three eyes, of the lower ones five. This is a native of Surinam.

Idomeneus. Wings indented, blue; upper pair with a broad brown upper margin, and abbreviated white band; lower ones with a large yellowish eye beneath. Inhabits America.

Ito. Peacock Butterfly, so called on account of its great beauty. It is rather a common species in this country. The wings are angular, indented, fulvous, spotted with black, and on each there is a large blue eye. "The ground colour of this insect," says Dr. Shaw, "is orange-brown, with black bars, separated by yellow intermediate spaces, on the upper edge of the superior wings; while at the tip of each is a most beautiful large eye-shaped spot, formed by a combination of black, brown, and blue, with the addition of whitish specks; on each of the lower wings is a still larger eye-shaped spot, confining of a black central patch, varied with blue, and surrounded by a zone of pale brown, which is itself deeply bordered with black. The caterpillar is black, with numerous white spots, and black ramified spines; it feeds principally on the nettle, changing to a chrysalis in July, and the fly appearing in August."

Polythea. Wings indented, angular, fulvous, tippet with black; beneath brown, with blue streaks and eyes, fix on the upper, and five on the lower ones. A native of Sumatra.

Almna. Wings angular, fulvous, spotted with black; lower ones with a larger eye, and a double pupil, all nut-brown beneath. It inhabits Asia.

Asteria. Wings indented, varied with yellow; lower ones with a larger eye and double pupil; beneath pale, with about three eyes. This inhabits India.

Oenone. Wings denticate, yellow, edged with black; lower ones blue at the base. This is an Asiatic insect.

Flirta. Wings subangular, brown, with fulvous spots, and two eyes; lower ones beneath ferruginous, with about three eyes. This and the next are found in India.

Lemonias. Wings indented, brown, dotted with yellow, all of them with a single eye.

Vellida. Wings indented, brown, with a fulvous band behind, and two eyes. It inhabits Amsteram island. A specimen is in Sir Joseph Banks' museum.

Orithia. Wings indented, brown; all with two eyes above, upper pair with a single eye beneath. This inhabits Jamaica.

Clelia. Wings indented, black; upper pair with an interrupted white band and spot at the tip; lower ones with a blue spot on the disk. It is a native of Guiana.

Penella. Wings indented, above brown; all with two eyes beneath. A native of Surinam.

Zelina.
ZELMA. Wings angular, yellow, subfuscate with brown; lower ones with six eyes on each side, and a white streak beneath. It inhabits New Holland, and is in Sir Joseph Banks' collection.

TEREA. Wings angular, indented, above brown, with a fulvous band and streak of white dots on the upper pair, and of ocellar ones on the lower. A native of Sierra Leone.

LAODICE. Wings angular, above black with a greenish band on each side, including a streak of ocellar dots. Found in Guinea.

LAMPEIA. Wings indented, brown; upper pair with a fulvous band; lower ones with five eyes above, and fix beneath. This and the next are natives of India.

GLYCERIE. Wings indented, brown; upper pair with a fulvous band, under surfaces of the upper pair with one, of the lower with two blind eyes.

* MEGARA. Wings indented, yellowish-brown with dark bands; upper pair with a single eye; lower ones with five eyes above, and fix beneath. This is found in our own country, and has been described and figured by Mr. Donovan.

AEGIRA. Wings indented, brown, spotted with yellow, upper pair with an eye on each side; lower ones with four eyes above, and dots beneath. This belongs to England, and is described in Lewin's butterflies.

XIPHA. Wings indented, brown, spotted with yellow; upper pair with an eye on each side; lower ones with three eyes above and four beneath. Found in the island of Madeira, and is in the collection of Sir Joseph Banks.

MINERYA. Wings indented, fulvous, the tip black, spotted with white; lower ones with five blind eyes above, and seven pupillate ones beneath. It is a native of America.

OCYPETE. Wings indented; above brown, immaculate; beneath glaucous, with three dark streaks; lower ones with five eyes. It inhabits Surinam.

OCHRHOE. Wings indented; above white tint with brown; beneath brown with two white bands; lower ones with five eyes. A native of Surinam.

PENELOPE. Wings slightly indented, brown, with a single eye; lower ones with two beneath. It is found in Surinam.

ARANEA. Wings slightly indented, brown; lower ones blueish with five eyes beneath. This is found in Surinam.

ATLITA. Wings indented, brown with a blue gloss; beneath fulvous, with waved glaucous streaks, and five blind eyes on the lower ones. It is middle-sized, and a native of the East Indies.

JATROPH. Wings angular, pale with waved brown streaks; upper pair with a single eye, lower ones with two. This is a native of America.

LAOMEDIA. Wings indented, grey; upper pair with fix eyes; lower ones with five, some of them are blind. It inhabits India, as does the next also.

LIBYA. Wings indented, brown; beneath lineate, with fix eyes on the lower ones, the pupill filvery.

HERDONIA. Wings indented, both fixe alike, grey; each with fix ferruginous eyes. An Austras insect.

TULLIA. Wings indented, brown, with ocicular spots, beneath a violet band, which on the lower ones has two eyes. It inhabits China.

MEROPE. Wings indented, fulvous, with a single eye, and black tip; lower ones beneath cinereous with three minute eyes. It inhabits New Holland, a specimen of it is in the museum of Sir Joseph Banks.

JOLE. Wings indented, fulvous, dotted with black; lower ones with five eyes beneath, the last with a double pupil. It inhabits Guinea.

HERONIE. Wings indented, brown, with an oblique white streak beneath; upper pair with two eyes; lower ones including others within them. It inhabits Surinam.

EGERA. Wings indented, above black, with a common white band; lower ones with two eyes beneath. This and the two following inhabit America. Dr. Hunter's museum contains a specimen.

SERINA. Wings slightly indented, above green; lower ones beneath with a white disk and two eyes.

POSTUERIA. Wings indented, green with brown spots and margin; lower ones beneath with white bands, and two eyes.

MYLIITA. Wings indented, black, with three macular white bands, lower ones with two eyes. A native of India.

ARTEMISA. Wings indented, black; upper pair with white spots, lower ones with white bands, and two silverly eyes beneath. It inhabits America.

DORINEME. Wings indented, brown; beneath blue with black bands, and three pair of eyes. This inhabits Surinam.

JANTHE. Wings indented, above brown, slightly barred with white, lower ones with five blind eyes. It inhabits Cayenne.

LAOTHOE. Wings angular, indented; lower ones above brown, with a white dot, and fix blue eyes. This is a native of Surinam.

GONERILLA. Wings indented, black, spotted with white, and a common rufous band; lower ones with four eyes. This is an inhabitant of New Zealand.

ITEA. Wings indented, black; upper pair with a yellow band and dot; disk of the lower ones rufous, with four eyes. It inhabits New Zealand, and is thought to be a variety of the last.

PORTLANDIA. Wings indented, brown; lower ones with five blind eyes above, and seven pupillate ones beneath. It is a native of America.

* CARDUI. Wings indented, fulvous, variegated with white and black; the lower ones have four eyes beneath. This is an English insect, and is described by Mr. Donovan.

HUNTERA. Wings subangular, fulvous, varied with white and black; lower ones beneath reticulate with white, and with two eyes.

ALLIONA. Wings indented, brown; upper pair with two eyes, the posterior one blind. Inhabits Portugal.

TULBAGHIA. Wings indented, both surfaces nearly alike, brownish, with a yellow band; lower ones with five eyes. It inhabits the Cape of Good Hope.

PIPELIS. Wings crenate, both surfaces alike, black; disk of the lower ones fulvous, with seven eyes. It inhabits India, as does the next.

CLAUDIA. Wings crenate, black, with a fagineous patch; lower ones fulvous with seven eyes.

BLOMFIELDIA. Wings indented, yellow, tint with black; lower ones beneath brown, waved with white, with four eyes, the middle ones blind. It inhabits Brazil. Specimens of this and the two next are in the museum of Sir Joseph Banks.

BANKIA. Wings angular, above brown; disk of the upper pair yellowish, with a black eye, in which is a double pupil. It inhabits New Holland.

D D

SOLANDRA.
PAPILIO.

**Solandra.** Wings angular, brown; upper pair with an eye, and also a contiguous one that is smaller; lower ones with two above, and four beneath. It inhabits Ortheitz.

**Polydecta.** Wings indented, brown; upper pair with an eye; lower ones with two above and seven beneath. It inhabits Tranquebar.

**Tolumia.** Wings indented, black; lower ones beneath with fuscous and blue streaks and five eyes, the posterior one very large. This and the next inhabit India.

**Mornia.** Wings indented, brown; lower ones with two eyes on each side, and three white dots. A specimen may be seen in Dr. Hunter’s museum.

**Juliana.** Wings indented, brown, spotted with white; lower ones with two eyes on each side. This is a native of Amboyna.

**Leda.** Wings angular, brown, upper pair with a double eye above; beneath reticulate with grey, and fix eyes on the lower ones. It inhabits Sierra Leona.

**Lenia.** Wings slightly indented, brown; lower ones black behind, with white and blue dots, and eyes beneath. There is a variety with brown hyaline wings, the lower ones with five occellate white spots. It is found at Cayenne.

**Dyndimene.** Wings indented, brown; lower ones above violet, with four white dots. It inhabits Surinam.

**Luna.** Wings indented, brown, with darker streaks; lower ones with two eyes, and they all have underneath four white dots.

**Iphita.** Wings angular, indented, brown, with darker bands; all with five eyes beneath. It inhabits China.

**Calisto.** Wings indented, black; lower ones with a red band, and five eyes above, seven beneath. This is an African insect.

* Iris. Wings indented, brown, with a blue glos, and whitish interrupted band on each side; all with a single eye, those on the upper pair above blind. This is figured by Donovan and Lewin.

**Ilia.** Wings indented, with a blue glos, and interrupted white band on each side; they have all a single eye. It inhabits Germany, and is probably a variety of the former.

**Beroe.** Wings entire, brown, with a blue glos; lower ones with a single eye; beneath chefnut-brown with a reddish margin. It inhabits Africa.

**Atia.** Wings indented, both surfaces nearly alike, black, with a streak of pale dots, and a macular pale marginal band. It inhabits Africa.

**Pupuli.** Wings indented, brown, with white bands and spots; beneath yellow, with white bands and blueish spots. This is an European insect.

**Chrysipe.** Wings indented, black, with a common rufous patch; lower ones beneath brown, spotted with black. This is a native of New Holland, and is preferred in Sir Joseph Banks’ collection.

**Cydippe.** Wings indented, black, with white spots, and a common rufous patch; the base beneath is tectaceous, varied with black and blue. A native of India.

**Marica.** Wings indented, tectaceous, the tip black, with a white band on the upper, and blue spots on the lower pair. It inhabits Africa.

**Althea.** Wings indented, brown, with an angular indented white band and streak. It inhabits Guiana.

**Amphiceda.** Wings indented, brown, the common disk cinereous, with brown waves; beneath grey at the tip with black lunules. It inhabits Guiana.

**Penthesilia.** Wings indented, black, with white spots, and a common rufous patch; lower ones beneath with yellow bands, and a white one spotted with black. It is a native of India.

**Berenice.** Wings indented, black, with a common red band; lower ones beneath spotted with black, white, ferruginous and yellow. This and the next inhabit Sierra Leona.

**Semire.** Wings indented, both surfaces nearly alike, with a green band, and fulvous spots, the base fulvous, dotted with black.

**Cyane.** Wings indented, black; upper pair with a white band; disk of the lower ones white, dotted with black. Found in India.

**Vitillia.** Wings indented, black; beneath spotted with white. This species inhabits Amboyna.

**Zenosia.** Wings indented, black, with a common white band, and marginal spots; base of the lower ones beneath yellow, streaked with black. It inhabits Sierra Leona.

* Antiope. Wings angular, indented, black-brown, with a whitish border, behind which is a row of blue spots.

**Cacta.** Wings angular, indented, upper pair black, the base purple, with a fulvous spot. It inhabits India.

**Pythia.** Wings angular, indented, brown with a white spot on the upper pair; beneath grey, with a streak of black dots on the lower ones. It inhabits Guinea.

**Zingha.** Wings angular, indented, brown, the tip black, with blue streaks, and a macular fulvous one. It inhabits Sierra Leona.

**Protogenia.** Wings indented, fulvous, the border black spotted with white. It inhabits Java.

**Amestris.** Wings angular, indented, black with rufous and blue lunules, beneath darker. It inhabits India, as does the next also.

**Lamina.** Wings angular, black with a common white band on each side, beneath spotted with rufous.

* Atalanta. Wings indented, black; upper pair with a red band and white spots, the lower ones bordered with red behind. This, as the admirable butterfly, has been described and figured by Donovan, Lewin, and Dr. Shaw; the latter says “it is of the most intense velvet-black colour, with a rich carmine-coloured bar across the upper wings, which are spotted towards the tips with white; while the lower wings are black, with a deep border of carmine colour, marked by a row of small black spots; the under surface of the wings also presents a most beautiful mixture of colours; the caterpillar is brown and spiny, feeds on nettles, and changes into a chrysalis in July, the fly appearing in August.”

**Archesia.** Wings indented, brown with a common fulvous band, which on the upper pair is half blue. It is a native of Java.

**Charonia.** Wings indented, black, with a blueish band. It inhabits India.

**Bibliis.** Wings indented, both surfaces alike, black; lower ones with a macular red band. It inhabits America.

**Hyperia.** Wings indented, black spotted with white; lower ones beneath with yellow spots, and a rufous band in the middle. Inhabits India. A specimen is in the British Museum.

**Prosope.** Wings indented, brown with a common fulvous band, which on the upper pair has two black dots. It inhabits New Holland, and is in the museum of Sir J. Banks.

**Echo.** Wings indented, brown, all beneath with a row of white dots. It inhabits Surinam.

**Octavia.** Wings indented, brown, the disk angular, fulvous,
PAPILIO.

fulvous, dotted with black, beneath with yellow spots at the base. This is a native of Sierra Leone.

LUBERTINA. Wings indented, obscure green, spotted with white, black, and rufous. Found in China.

JANASSIA. Wings scalloped, green, bronzed, with black dots on the upper pair; beneath yellowish, with black dots at the base.

* POLYCHLORIS. Wings indented, fulvous, spotted with black; upper pair with four black dots above. This is found in England, and divers parts of Europe.

V. ALBUM. Wings angular, fulvous, spotted with black; all with a white spot above; lower ones with a white humule beneath. Found in several parts of Europe.

* URTICA. Wings angular, fulvous, spotted with black; upper pair with three black dots, the inner one square. It inhabits this country, and has been described and figured by Donovan and Lewin. The larva is spinous, variegated with brown and green, head black; pupa toothed, brown, with gold dots. This insect and many others of the same genus, as the Atalanta, Polychloris, Io, &c. soon after their enlargement from the chrysalis flake, discharge a few drops of reddish-coloured fluid, which, in places where they have appeared in large numbers, has had the appearance of a flower of blood, and having of course been greatly magnified, the fact has been recorded by writers as a prodigy ominous of some extraordinary event.

CLYTEMNESTRA. Wings angular, black; beneath spotted with white; upper pair with a yellow band on each side. Inhabits Surinam.

DIREC. Wings angular, brown; upper pair with a yellowish band, beneath undulate with black. Found in various parts of India; as are the two following.

THIAGULUM. Wings angular, fulvous, the disk dotted with black; lower ones beneath cinereous with white waves, and a white angle in the middle. It is a native of Italy.

MERIONE. Wings indented, fulvous, edged with brown; lower ones beneath brown, with white and blue spots and streaks. It inhabits Surinam.

ALIADNE. Wings angular, fulvous, undulate black streaks; upper pair with a white marginal dot. Found in the island of Java.

BOLINA. Wings indented, black; upper pair with two, lower ones a single blue-white spot; beneath rufous, with a white band. Found in the East Indies.

THECOL. Wings indented, black, with a white-blue spot, all of them have a streak of white dots; beneath brown, with a white band. Found in India.

LASTINASSA. Wings indented, black, with a thinning blue spot; beneath brown, with white lunules. It inhabits Asia.

CLYTA. Wings indented, black; outer margin of the upper pair spotted with white; lower ones with a triple row of white and yellow spots. This and the next are natives of India.

COCTA. Wings scalloped, indented, brown; lower ones blueish at the tip. It inhabits India.

UNDULARIS. Wings indented, above brown; lower ones ferruginous at the tip, with a white dot beneath. It inhabits Coromandel.

MONIMA. Wings indented, brown; lower ones paler, blueish at the angle of the tail, with a black streak. It inhabits the East Indies.

HIARRA. Wings indented, black, with a common white band, which is abbreviated on the upper pair. It inhabits India.

AMATHA. Wings angular, indented; above brown, with white dots, a red band, and waved black line. It inhabits Cayenne.

MELICHOR. Wings slightly indented, dotted with white, above brown, beneath yellowish. It inhabits Africa.

MELANTHIA. Wings indented, above brown, dotted with white, beneath pale cinereous. It inhabits Guinea. A specimen is to be seen in sir J. Banks' museum.

LEUCOTHEE. Wings indented, above brown, with three white bands; beneath yellow, with three white bands marked with black. It is found in divers parts of Asia.

MEDEA. Wings indented, falcate, black, with three marginal yellow bands; angle at the tail red. A native of Surinam.

BLANDINA. Wings indented, above brown, beneath yellow, with two blue streaks, and dots marked with black on the lower ones. This and the next are found in Sierra Leone.

HOSTILIA. Wings indented, brown; the base fulvous dotted with black; upper pair spotted with yellow at the tip.

NAUPHIA. Wings slightly indented, both surfaces nearly alike, black; upper pair with four white spots above, lower ones with a white band. It inhabits South America.

HELIODORA. Wings indented, fulvous, with three black bands. It is found at Siam, and may be seen in the museum of sir Joseph Banks.

OPHONE. Wings indented, brown spotted with white; beneath with numerous black ocular spots. It inhabits Guinea.

LITHURIA. Wings indented, fulvous, with black bands; lower ones beneath with white bands, spotted with black. It inhabits India.

AMPHIONE. Wings indented, black, clouded with blue; upper pair with a white band on each side; lower ones beneath radiate with red. It inhabits South America.

OPIA. Wings indented, brown; upper pair reticulate, lower ones barred with yellow. This and the next are found at Sierra Leone.

CITTHA. Wings indented, brown, with ocular spots; lower ones beneath cinereous, with two brown spots and a streak.

PHEGEA. Wings indented, brown; upper pair with a ferruginous or white band; disk of the lower ones ferruginous or white; beneath paler, waved with black. It is found in India.

SALMIS. Wings indented, black, radiate with blue; beneath brown, with a white band. It inhabits Africa.

PELEA. Wings indented, black; upper pair with arrow-shaped white and black spots; beneath cinereous, with black lunules. It is a native of the East Indies.

NURINA. Wings indented, black, with a white band, which on the upper pair ends in a rufous spot. It inhabits New Holland, and may be seen at sir J. Banks.

VEKILIA. Wings indented, brown, with a common white curved band, blueish at the edges. This and the three following are natives of India.

ALCINEA. Wings indented, black, with an interrupted blue band, each with seven white marginal dots.
PAPILIO.

PHERUSA. Wings indented, fulvous, with three brown bands, those on the upper pair longitudinal, on the lower ones transverse.

AGATHA. Wings indented, above fulvous, beneath glaucous, lower ones with a black dot above, and three beneath.

LAURA. Wings angular, indented, brown, with a common band, which is fulvous on the upper half, and snowy on the lower; lower ones beneath silvery with a snowy band. It inhabits Jamaica.

LYDIA. Wings indented, yellow, black above the margin; beneath with a streak of black dots. It inhabits Surinam.

IPICILA. Wings indented, above brown, with a common white ferruginous spot at the angle of the tail. Found in South America.

LIBERIA. Wings indented, fulvous; upper pair with a black curve at the tip; lower ones with a black dot above, and three ocellar ones beneath. It inhabits India.

AMASIA. Wings indented, green; lower pair with marginal black dots above, and eyes beneath. Found at Surinam.

ETHIOPIA. Wings indented, blue; tip of the upper pair black, dotted with white. A native of Africa.

VERONICA. Wings indented, above greenish, beneath ferruginous, with a paler band. It is found in Guinea.

GNDIA. Wings indented, tesselate, upper pair brown at the tip, with a white band; lower ones with a fulvous streak and black lunules. It is found in India.

PERSEA. Wings indented, oblong, black, spotted with yellow, and with a common red disk. It inhabits India.

NEEREA. Wings indented, above brown, spotted with white beneath, with white spots surrounded with a red line. There is a variety of this species, wings slightly, tailed, black; upper pair with a red dot, disk of the lower ones edged with red. Natives of India.

PROCIS. Wings indented, fulvous, with black spots and a white band, beneath variegated. Inhabits China.

MAJA. Wings indented, brown; upper pair spotted with white, lower ones immaculate. It is found in Brazil.

ERYMANTHUS. Wings indented, fulvous; upper pair black at the tip, with a yellow band; lower ones with black lunules above, and a streak of ocellate dots beneath. Inhabits China.

CARENTA. Wings falcate, indented, brown, spotted with yellow; upper pair black at the tip, with four white spots. Found in Surinam.

MARIA. Wings indented, varied with brown and fulvous; upper pair with three rows of white lunules; lower ones with a white band. It is found in Siam, and a specimen is in Sir Joseph Banks' museum.

CELTIS. Wings angular, indented, brown, with fulvous spots, and a single white one; lower ones beneath grey. Found in Southern Europe.

F. ALBUM. Wings angular, indented, fulvous, spotted with brown; lower ones with a snowy line beneath. It is found in Russia.

HARPPIA. Wings falcate, indented, brown, with a common blueish band, dotted with black.

MELISE. Wings indented, brown; lower ones beneath marbled with grey. It is found in America.

LEA. Wings indented, brown; upper pair with a fulvous band, lower ones with a white one. Found in India.

MEKTENTIA. Wings indented, brown; upper pair with a fulvous band above, and blue central spots beneath. Inhabits Surinam.

NIPHE. Wings indented, yellow; tip of the upper pair black, with a white band; lower ones beneath silvery with five eyes. It inhabits China. There is a variety, of which the wings above are fulvous, spotted with black, without the yellow tip and white band.

THYELIA. Wings indented, fulvous, spotted with black; lower ones beneath, with a white band and two scarlet dots at the base. It is a native of India.

PAPHIA. This is a highly elegant insect, of a fine orange-brown colour above, with numerous black spots and bars; beneath greyish, with narrow silvery undulations on the lower wings, and black spots on the upper. It proceeds from a yellowish-brown spiny caterpillar, living principally on nettles. This insect is generally found in the neighbourhood of woods. There is a variety cinereus, spotted with black, peculiar to Russia.

CYTHEREA. Wings indented, green, spotted with black; lower ones beneath grey, with three silvery spots and two bands. An inhabitant of the East.

CESTHOSIA. Wings indented, fulvous, spotted with black; lower ones beneath brown, at the tip, with a glaucous gloeis, and ending in an interrupted silvery band. It inhabits Russia.

CYTHEREA. Wings crenate, brown; upper pair with a fulvous band; lower ones with a common silvery one; beneath with a lanceolate silvery band. It is found in India.

* AGALIA. Wings indented, fulvous, spotted with black; beneath it has twenty-one silvery spots. This is found in England and other parts of Europe.

APHRODITE. Wings indented, fulvous, spotted with black; lower ones beneath brown, with twenty-four silvery spots. A native of South America.

MYRINA. Wings indented, fulvous, spotted with black; beneath with thirty silvery spots. It inhabits North America, as do the two following.

CYBELE. Wings indented, fulvous, spotted with black; beneath thirty-four silvery spots.

IDALIA. Wings indented, fulvous, spotted with black; beneath with thirty-seven silvery spots.

DIANA. Wings indented, brown, with a common black disk; lower ones beneath with nine silvery spots.

* ADIPPE. Wings indented, fulvous, spotted with black; beneath there are twenty-eight silvery spots. This is an English insect.

* LATHONIA. Wings slightly indented, pale, fulvous, spotted with black; beneath with thirty-seven silvery spots. This and the next, like the last, are English insects.

* EUROSYNE. Wings indented, pale, fulvous, spotted with black; beneath with nine silvery spots.

SELENE. Wings indented, fulvous, with black; lower ones beneath, with twelve silvery spots; a distinct black dot at the base and streak behind. This is found at Kiel.

NIOBE. Wings indented, fulvous, spotted with black; beneath with pale spots, and three silvery ocellate ones. Found in various parts of Europe.

COLUMBINA. Wings indented, fulvous, spotted with black; lower ones beneath with two silvery streaks. It is found in America, as is the next.

BELLOCIA. Wings indented, fulvous, spotted with black; lower ones beneath silvery at the tip, with five ocellate spots.

PHALANTA. Wings indented, fulvous, spotted with black; lower ones beneath; glaucous at the tip, with three silvery ocellate spots. Found in the East Indies.

THASIS. Wings indented, fulvous, the margin streaked with black; beneath glaucous; lower ones with a silvery band and ocellate dots. Native of America.

GREPUS. Wings entire, brownish; beneath a streak of white dots. It is found in India.

POSTHUMOUS.
PAPILIO.

Posthumous. Wings falcate, entire, brown, with a blue disk; lower ones beneath grey immaculate.

Sopho.é. Wings entire, brown, with a ferruginous band; lower ones beneath chestnut-brown, with two eyes. It inhabits America.

Xanthus. Wings entire, brown, with a ferruginous band; lower ones beneath marbled with grey and two eyes. It inhabits Asia.

Cassio. Wings scalloped, brown, with a ferruginous band, banded at the tip; lower ones beneath cinereous, with two eyes. It inhabits America.

Berceinthus. Wings entire, above black, with a marginal yellow band; lower ones beneath with fix ocellar spots. Found at Surinam.

Arcadius. Wings entire; upper pair black, spotted with blue and white; lower ones brown; beneath chestnut-brown. It inhabits Africa.

Honorius. Wings entire, blue; upper pair black at the tip, with a brown rib; lower ones dotted, with black at the base and iridescent at the tip.

Oeation. Wings entire, brown, with a fulvous marginal fbleak; lower ones beneath, nearly naked, with seven eyes. Found at Surinam.

Polixenes. Wings entire, brown; lower ones beneath clouded with brown and grey. It inhabits North America, and is in the museum of sir Joseph Banks.

Cephalus. Wings entire, black, spotted with white; lower ones beneath grey, with a white band on each side. It is found on the Guinea coast of Africa.

Constantius. Wings entire, dull, cinereous, with a marginal streak of brown dots.

Martians. Wings entire, black; upper pair with a fulvous disk; lower ones with a streak of white dots. It is a native of Surinam.

Arctia. Wings entire, above ferruginous, immaculate, beneath brown, with two darker streaks. It is found in Siam; a specimen is preferred in sir Joseph Banks' museum.

Nero. Wings entire, fangeous, with a brownish margin; lower ones on edge beneath. This is a native of Asia. It is in the British Museum.

Polyxenes. Wings entire, above black, beneath chestnut-brown, immaculate. This is found in Surinam.

Aeopus. Wings entire, brown with a yellow band; upper pair beneath, with a single eye at the base. It inhabits India, as does the next.

Oebinus. Wings entire, above brown, with a blue band and ferruginous spot, beneath green, with a whitish band.

Lucinthus. Wings entire, barred with black, above blue, beneath fulvous. It inhabits Surinam.

Liope. Wings entire, fulvous, the border brown, with fulvous spots; lower ones yellowish, with fulvous waves. It is a native of Guiana.

Arminius. Wings, both surfaces alike; fulvous, with reddish lunules and dots.

Morpheus. Wings entire, fulvous, spotted with black; lower ones with a streak of black dots on each side.

Lysidice. Wings entire, blue, with a black border above, and bands beneath. Found at Surinam.

Euhemerus. Wings entire, brown, with a white band, which in the lower ones is terminated on each side by a fulvous spot. Native of Cayenne.

Dardus. Wings entire, brown; upper pair with a blue eye in the middle of each side; all beneath with two ocellar streaks. This and the next are found at Surinam.

Arcas. Wings entire, blue; upper pair spotted with white; lower ones with a black and white marginal spot. It inhabits Surinam.

Canthus. Wings entire, above brown, immaculate; lower ones with fix eyes beneath. Found in North America.

Eurhythus. Wings entire, brown; upper pair with two eyes on each side; lower ones with a single pupil, one above and four beneath; all of them with a double pupil. It is found in the island of Jamaica.

Hermes. Wings entire, brown; immaculate with fix eyes on the upper pair, three of which are blind. Found at Brazil.

Ithius. Wings entire, with a yellow disk; lower ones with a single eye above and one beneath. A native of New Holland. Preferred in sir Joseph Banks' museum.

Meneus. Wings entire, brown; upper pair with a single eye above; lower ones with seven beneath and a white band. It inhabits China.

Cranor. Wings entire, brown; lower ones with a single bipupillate eye above, and five beneath, the first and fourth bipupillate. It inhabits India.

Merus. Wings entire, brown, both surfaces alike; upper pair with four eyes, the anterior one with a double pupil; lower ones with five. It is an African insect.

Hesperia. Ruralis.

Cupido. Lower wings fix-toothed; tailed; beneath whitish, with silvery spots. It inhabits America.

Cinedus. Wings fix-toothed, tailed, white, with a black border; lower ones with silvery spots beneath. A native of Surinam.

Agrippa. Wings three-tailed, blue with a black border, beneath cinereous, with a white streak and two rufous spots at the angle of the tail. It is a native of America.

Helius. Wings three-tailed; upper pair black, lower ones blue; beneath cinereous, with two brown streaks and two eyes at the angle of the tail. This is an inhabitant of Africa.

Janias. Wings three-tailed, blue, with a black border; beneath green. It inhabits Surinam.

Pythagoras. Wings three-tailed, with a yellow border; beneath black, varied with white, and a white band in the middle. It inhabits India.

Amor. Wings three-tailed, brown, the disk beneath variegated, and a golden streak behind on the lower ones. It inhabits India.

Hesiodus. Wings three-tailed, black with a blue disk, beneath white, with a common greenish streak, and two silvery spots at the angle of the tail. It is found in India.

Timon. Wings three-tailed, greenish at the base; beneath white, with an abbreviated red band on the lower ones. It inhabits America; a specimen is in Dr. Hunter's museum.

Monous. Wings three-tailed, brown; beneath snowy, slightly barred with brown; the lower ones with two gilt eyes. This is a native of Africa, and preferred in sir Joseph Banks' collection.

Faunus. Wings three-tailed, brown; beneath white, with two fulvous streaks. It inhabits Africa.

Lisias. Wings three-tailed; upper pair brown, with a fulvous spot; lower ones beneath white, spotted with black. It inhabits Poulincard, and is in sir Joseph Banks' museum.

Hymen. Wings three-tailed, spotted with white beneath; upper pair white above. It inhabits Africa, and like the last is to be seen in sir Joseph Banks' museum.

Gabrielus. Wings nearly three-tailed, glossy blue; lower
PAPILIO.

lower ones beneath brown, with white bands before the tip. It is found in divers parts of America.

PINDARUS. Wings nearly three-tailed, blue, with a black border; beneath brown, with silver and fulvous spots. It inhabits India.

CHITON. Wings three-tailed, blue with a brown border; beneath yellowish-white, with black bands.

PELION. Wings nearly three-tailed, blue, with gold dots and a brown border. It inhabits America.

AUNS. Wings nearly three-tailed, blue, with a black border; beneath black, with white bands. It is an American insect.

PETUS. Wings nearly three-tailed, blue, with a black border; beneath brown; the base rufous dotted with white. It inhabits Surinam.

PREIA. Wings two-tailed, brown; the disk beneath brown, with a waved streak, which on the upper pair is fulvous, on the lower ones black. It inhabits Tranquebar.

ETOLUS. Wings two-tailed, upper pair black; lower ones blueish, beneath whitish, with a black dot at the base, and two at the tip. It inhabits India.

VULCANUS. Wings two-tailed, above brown, with fulvous spots; beneath variegated with fulvous yellow and silvery streaks. It is a native of India.

GANXIMEDES. Wings two-tailed, blueish, with a brown border; beneath greenish, at the base with gold dots. It inhabits America.

MARS. Wings two-tailed, brown; lower ones with a rufous spot and two white dots, and an oblique band beneath; a native of America.

CELEUS. Wings two-tailed, white; beneath with alternate brown and white bands, and a triple rufous eye at the angle of the tail. It inhabits Surinam, as do the next.

EMATEON. Wings two-tailed, glossy blue, beneath black speckled with blue.

DIDYMUS. Wings two-tailed, brown, the base beneath red with white ocellar dots.

EROSINE. Wings two-tailed, brown, upper pair with seven red dots, lower ones with three; upper pair with three silvery dots. It inhabits the Cape of Good Hope.

ISOocrates. Wings two-tailed, brown, two approximate, waved, darker streaks, and a double black spot at the angle of the tail. This, and the two following, are found in India.

ATYS. Wings two-tailed, brown, with a blue disk; beneath cinereous with brown veins, the base with a fulvous spot, and white dots.

SOPHOCLES. Wings two-tailed, black, with a common blue disk; beneath white, with vivid yellowish streaks, the lower ones with a fulvous dot at the tip.

EURIPIDES. Wings two-tailed, with a blue disk; beneath brown, with an abbreviated white streak on the upper pair, and two angular rufous streaks and marginal ocellar spots on the lower ones.

PHOLEUS. Wings two-tailed, blue; beneath black, with green and blue bands. A native of Surinam.

ANACREON. Wings two-tailed, brown, beneath waved with white, and a macular fulvous streak behind. This and the next species are natives of India.

THALES. Wings two-tailed, black, with blue lunules beneath, lower ones beneath with an abbreviated sub-marginal gold band.

ENDYMION. Wings two-tailed; beneath green, with rufous and gold specks, lower ones with a black streak and red band.

VENUS. Wings two-tailed; lower surface of the upper pair green, speckled with gold; of the lower ones gold, spotted with green and black. There is a variety of this species, of which the wings are three-tailed, blueish, tipt with black; beneath golden, speckled with black.

ECHION. Wings two-tailed, above brown, beneath palish, with a rufous band, and terminal red eye. Found in America.

TELEIUS. Wings two-tailed, shining blue; lower ones with a marginal angular black streak beneath. Found in America.

DIODUS. Wings two-tailed, black, the thinner margin blue; beneath cinereous, with white spots, and a double rufous spot at the angle of the tail. It is found in India, as is the next.

CECROPS. Wings two-tailed, black, with a red band beneath.

HEMION. Wings two-tailed, above brown, immaculate; lower ones beneath with three blueish bands at the angle of the tail. A native of Surinam.

SFINX. Wings two-tailed, blueish; beneath cinereous, with a double black spot at the angle of the tail. This and the next are natives of India.

MELIEUS. Wings two-tailed, blueish, with a brown border; beneath yellowish, with brown streaks on the upper pair, and black ones on the lower, angle of the tail black, with blue rings.

MECENAS. Wings two-tailed, black, with a blue disk beneath, with chestnut-brown clouds. It inhabits China.

TIRREUS. Wings two-tailed, brown; lower ones beneath with a waved white streak, and black marginal lunules, the middle ones rufous. This and the next are natives of India.

XENOPHON. Wings two-tailed, brown, with a yellow disk; beneath cinereous, with a white streak in the middle, joined to a brown one.

MARSYS. Wings two-tailed, above blue, beneath blueish with black dots. A native of America.

BATHIS. Wings two-tailed, blue, with a black eye; beneath brown, with white bands, angle of the tail rufous.

CYANUS. Wings two-tailed, shining blue; beneath with a white disk. Native of Surinam.

HYACINTHUS. Wings two-tailed, shining blue; under surface of the lower ones black in the middle, with a white band. It is found in India.

HALESUS. Wings two-tailed, blue, edged with black; lower ones each side spotted with gold at the tip. It is found in America.

ACHLES. Wings nearly two-tailed, brown fulvous spots, beneath yellowish, with gold spots. It inhabits India, as does the next.

PERICLES. Wings two-tailed, black; beneath brown, waved with white, angle of the tail with a double silvery spot.

FORMOSUS. Wings two-tailed, brown; beneath yellowish, with red and gold spots. It inhabits Surinam, as does the next.

METON. Wings two-tailed, white, with a brown border; upper pair with an ocellar gold spot.

THERO. Wings indented, nearly two-tailed, blackish, with fulvous spots, beneath with silvery spots. A native of Africa.

LIGER. Wings two-tailed, white, tipt with black, beneath brown, with white streaks, and lunules. An inhabitant of Surinam.

HARPA. Wings tailful, fulvous, spotted with black, beneath cinereous, with gold dots. A native of America.

VALENS. Wings tailed, brown; beneath yellowish, with
PAPILIO.

with spots including gold ones. A native of Surinam, and so is the next.

Perion. Wings tailed, fulvous, with a brown border and bands, beneath dotted with gold.

Augustus. Wings tailed, white, with a brown border; beneath varied with ferruginous and yellow, the lower ones with two cinereous streaks. It inhabits America.

Centaurus. Wings tailed, bluish, with a brown border, beneath cinereous, with ocular spots at the base. It inhabits New Holland, and is, with the next two, in the museum of Sir Joseph Banks.

Gerontes. Wings tailed, black, with a common transverse white spot; upper pair with an eye, lower ones with a double eye. Native of Africa.

Jubatus. Wings tailed, fulvous, with a brown border; beneath cinereous, with a white streak, lower ones with two black dots. It inhabits Siam.

Ceranus. Wings tailed, bluish; beneath chefleet-brown, at the base spotted with white. It inhabits India.

Pann. Wings tailed, brown; upper pair with a fulvous spot; lower ones with a black sub-marginal one; beneath cinereous, with two eyes at the angle of the tail. Found in Africa.

Phorbas. Wings tailed, brown, with a white disk; beneath white, with cinereous streaks, and two black dots at the angle of the tail. It inhabits India.

* Betule. Wings slightly tailed, brown; beneath yellowish, with two white streaks on the lower ones.

* Pruni. Wings slightly tailed, above brown, with a red spot at the tip of the lower ones; lower wings beneath, with a fulvous marginal band dotted with black. This and the last species are found in this country.

Spini. Wings tailed, brown; beneath cinereous, with fulvous marginal lunules, and a bluish spot near the tail. It is found in Germany; on the Prunus spinosa, hence its specific name.

Favonius. Wings slightly tailed, brown, with fulvous spots; beneath cinereous, with two white streaks; lower ones with a sub-marginal fulvous band, and bluish at the angle of the tail. It is found in America.

* Quercus. Wings slightly tailed, blueish; beneath cinereous, with a white streak, and double fulvous dot near the tail. A native of England, and other parts of Europe.

Linceus. Wings tailed, brown, immaculate; lower ones beneath with a lunulate white and rufous streak. Inhabits Russia, resembles the P. spinosa.

Cer asi. Wings tailed, brown, immaculate; beneath a white streak, and fulvous lunules near the tail. This is a Russian insect.

Symethus. Wings slightly tailed, brown, with a white spot on the disk, upper pair tipped with black. Found in America.

Botica. Wings tailed, blueish; beneath cinereous, with white streaks, angle of the tail with a double gilt spot. Found in Europe and India.

Apidanus. Wings tailed, blue; lower ones beneath brown, varied with blue, angle of the tail with a double gilt spot. Inhabits Surinam.

Ælianus. Wings tailed, white; beneath cinereous, with white streaks, angle of the tail with a black eye. Found in the East Indies, as are the two following.

Stephen. Wings tailed, brown, with a blueish disk; beneath cinereous, with a white band, and a double rufous eye at the angle of the tail.

Cricus. Wings tailed, blueish; beneath varied with white and brown, the lower ones with two dots at the angle of the tail.

Theophrastus. Wings tailed, brownish; beneath white, spotted with black; lower ones with five marginal gilt dots. It is found in Morocco.

Columella. Wings tailed, brownish; beneath cinereous, with a streak of black and white dots, and two fulvous spots on the lower ones. Found in the South American islands.

Cleo. Wings tailed, brown; beneath cinereous, with a red streak on the upper pair, and band on the lower ones, angle of the tail with a double rufous eye. A native of Brazil; a specimen is in the museum of Sir Joseph Banks.

Procides. Wings tailed, above brown; lower ones white, with two black dots. It is found in Africa.

Alcydes. Wings tailed, black, with a blue gloss, beneath ferruginous, with a yellow streak. It inhabits Sierra Leone.

Philippus. Wings tailed, brown; beneath white, with two fulvous streaks, and two white ocular black dots at the angle of the tail. It is a native of India.

Atymnis. Wings tailed, fulvous; upper pair tipped with black. Found at Siam.

Eryx. Wings tailed, black; beneath green, with a slightly indented and spotted margin on the lower ones. It inhabits China.

Æolus. Wings tailed, blue, with a black spot on the upper pair; all beneath with a white band streaked with black. This and the two following inhabit India.

Coriolanus. Wings indented, tailed, dull cinereous, with a common ferruginous streak.

Plinius. Wings tailed, varied with white and brown; lower ones beneath with a double gilt spot at the angle of the tail.

Acion. Wings tailed, blue; lower ones beneath black, with green-gold streaks at the tip. Found in Surinam.

Democritus. Wings tailed, shining blue; beneath black, spotted with white. Inhabits India.

Amyntas. Wings tailed, blue, with a black margin; beneath cinereous, with black dots, and two ferruginous ones on the lower pair at the angle of the tail. It inhabits Austria.

Timius. Wings tailed, varied with fulvous and brown; upper pair beneath with ocular black dots. It inhabits Surinam, as does the next.

Simæthys. Wings tailed, brown; beneath green with a silvery fringe.

Sedi. Wings tailed, blue, the margin spotted with white; beneath white, with square black spots and a rufous band. Inhabits Germany.

Phidias. Wings tailed, blueish, with a brown border; beneath cinereous, all with a black dot at the angle of the tail. This is an Indian insect.

Hercoglyptus. Wings tailed, blue; beneath green, with a streak of black and white dots on the lower ones. This and the next are inhabitants of India.

Strabo. Wings tailed, blue; beneath cinereous, with white waves; lower ones with two marginal dots, and two at the angle of the tail.

* Rumi. Wings slightly tailed; above brown; beneath green. This is found in our own country, and other parts of Europe.

Plato. Wings tailed, blue, with a brown border; beneath cinereous, with white waves; lower ones with a black bipupillate eye. This and the fix following are natives of India.
PAPILIO.

ROSIMON. Wings tailed, white, with a black border, and dots on the disk; beneath dotted with black, angle of the tail with three gold dots.

HIPPOCRATES. Wings tailed, brown, tipt with white; beneath white, dotted with black.

THEOCRITUS. Wings tailed, greenish, with a darker rib; beneath black, dotted with yellow.

LINUS. Wings tailed, white, tipt with brown; beneath with white and black bands, angle of the tail with three white dots.

PARRHASIIUS. Wings tailed, blue; beneath cinereous, with white streaks; lower ones with marginal gold dots.

AMYNTOR. Wings indented, tiiled, black, with a fulvous spot at the base, the tip with a yellow band.

NARCISSUS. Wings indented, brown, with a blueish disk; beneath with red spots and bands with silvery edges. Inhabits New Holland, as does the next.

APELLESE. Wings indented, fulvous, with a border; lower ones beneath with rufous bands and silvery edges.

HERACLITUS. Wings indented, black, with a fulvous spot on the upper pair; lower wings with a blue spot above, and yellowish streaks and blue dots beneath. It is a native of America.

PLAUTUS. Wings indented, brown, above immaculate, beneath with transverse black and white lines. It inhabits India.

THYSBE. Wings denticulate, fulvous, spotted with black; lower ones beneath striate, black spotted with gold. Inhabits Africa.

NAIS. Wings indented, the base silvery, with gold streaks. A native of the Cape of Good Hope.

MELEAGER. Wings indented, blue, with a black border, beneath grey, with black ocellar dots. It inhabits Germany.

EPULUS. Wings entire, brown, with fulvous spots; beneath variegated. Inhabits Surinam.

ARION. Wings above blue, edged with brown, and spotted with black, beneath grey, with numerous small eyes. This inhabits our own and other countries of Europe.

EREBUS. Wings entire, brown; all with a streak of ocellar dots beneath. It inhabits Germany.

ARCTOS. Wings entire, blue, edged with brown, beneath grey-brown, with numerous eyes. Inhabits Austria.

DAMON. Wings entire, blue, beneath grey-brown, with numerous dots and a white band on the lower ones.

CYLLARUS. Wings entire, blue edged with black; beneath grey-brown, with a streak of ocellar dots, the hind ones blue at the base. This is an European insect.

ARGIOLOUS. Wings entire, blue edged with black, beneath blueish-grey, spotted with black. This species is common to this and other European countries.

ACIS. Wings entire, blue, beneath grey-blue, with oblong, black simple dots. It inhabits Austria.

ALBES. Wings entire, brown, immaculate, beneath cinereous, with a streak of ocellar dots. Found in England.

CAJUS. Wings entire, brown, with a blueish disk, beneath varied, cinereous and white, with brown ocellar dots. It inhabits India.

OTIS. Wings entire, brown, with a blue base, beneath cinereous, with a dot in the middle, and streak on the upper pair, and numerous ocellar dots on the lower ones. Found in China.

*ARGUS. Wings entire, lower ones beneath with a ferruginous border, and silvery blue eyes. This and the three following are found in England, and other European countries.

*HYACINTHUS. Wings entire, blue, lower wings beneath with a marginal row of red eyes, and a circle of black ones on the disk.

*ARTAXERXES. Wings entire, brown, upper pair with a white dot in the middle; lower ones with rufous marginal lunules, beneath with rufous and white dots on the margin.

*TITUS. Wings entire, brown, immaculate; lower ones ocellate below, and a marginal fulvous streak behind.

OPILETE. Wings entire, blueish, with a blackish edge; lower ones beneath cinereous, with ocular black dots, and two fulvous lunules. It inhabits Russia, as does the next.

TRITON. Wings entire, blueish, beneath a ferruginous streak, and numerous black dots.

*CORYDON. Wings entire, blue edged with black; beneath cinereous with black ocellar dots, lower ones with a central white spot. This and the next are found in England.

*ADONIS. Wings entire, blue, with a black marginal streak, beneath cinereous, with numerous ocellar dots, and a white central one on the lower ones.

DORYLAS. Wings entire, blue, beneath cinereous, with a dot in the middle of the upper pair, and streak of ocellar dots behind. It is found in Austria.

HYLUS. Wings entire, with a black lunule in the middle, and marginal dots; beneath cinereous, with ocellar dots. It inhabits Austria.

BATTUS. Wings entire, blackish-blue beneath, whitish with numerous black dots; lower ones with a continued fulvous band. Found in Germany.

ARGIADAS. Wings entire, blue, with a brown edge, beneath grey-brown, with a lunule in the middle, and two streaks of ocellated dots. It inhabits Saxony.

AMPHION. Wings entire, blue edged with black; beneath cinereous, ocellate with black; lower ones with red lunules, marked before with a white lunule, behind with a black gold dot. It inhabits Germany.

ACREON. Wings entire, brown, beneath paler, with black ocellar dots; lower ones with a white and red band and streak of gold dots. It is found in Russia.

HERBUS. Wings entire, brown, variegated with blue; lower ones blue, with a white inner margin. It inhabits Surinam.

AVIUS. Wings entire, both surfaces alike, brown, with two blue streaks at the tip. It is a native of the West Indies.

ACANTHUS. Wings entire, brown, immaculate, beneath pale ferruginous, with blue bands and yellow border. It is found at Surinam, as is the next.

CENEUS. Wings entire, black, with blue waves; the margin dotted with white.

ERINUS. Wings entire, brown, beneath cinereous, with a double black dot on the hind angle of the lower ones. It inhabits New Holland; a specimen is in the museum of Sir Joseph Banks.

ICARUS. Wings entire, above with brown bands, beneath with alternate white and black bands. Found at Surinam.

PARCIMON. Wings entire, brown, beneath cinereous with white waves; lower ones with ocellar black dots at the base and eye of the tip. It inhabits Africa.

DAMORFERES. Wings entire, brown, beneath cinereous waves, lower ones with a double gilt eye. Inhabits New
New Holland. Specimens of this and the last are in Sir J. Banks' museum.

Ceraunus. Wings entire, brown, with a blue gloss; beneath cinereous, lower ones with ocellar black dots at the base, and an eye and dot at the tip. This species and the next inhabit the South American islands.

Catilina. Wings entire, brown, with a blue gloss; beneath with white bands and two blue eyes at the angle of the tail.

Mintheus. Wings entire, brown, lower ones beneath with ocellar red dots, and an eye at the angle of the tail. It inhabits America.

Hyalan. Wings entire, above brown, immaculate, beneath cinereous, dotted with black. It inhabits the East Indies.

Telephus. Wings entire, black; upper pair dotted with white; lower ones above rufous at the base, beneath blue, varied with black. It inhabits America.

Emylus. Wings entire, black dotted with white; upper pair with a yellow band; all beneath variegated. It inhabits Surinam.

Callipe. Wings entire, brown, with a common white disk, the border cinereous, subocellate. It inhabits America.

Pelops. Wings entire, white, with a common brown border, on which are a few fulvous spots, and a streak behind. It inhabits Cayenne.

Lamia. Wings entire, brown, with a common abbreviated white and fulvous band. It inhabits Cayenne, as does the next.

Cachrys. Wings entire, blue, with a double white spot on the upper pair, beneath cinereous, with black lines.

Lagus. Wings entire, blue, with a double white spot on the upper pair, beneath cinereous, with black lines. It inhabits Surinam.

Meecenas. Wings oblong, both surfaces alike, black, with a common red band and line on the upper pair. Found at Guadaloupe.

Mantis. Wings oblong, entire, variegated blue and brown, with a common white band. It inhabits Africa.

Midas. Wings subangular, brown, with a white tip, beneath white at the base, with a rufous streak. It inhabits India, as do the three following.

Birulus. Wings entire, brown; beneath white, with a fulvous band dotted with brown on the lower pair.

Aenetus. Wings entire, above brown, with a white spot, beneath white, immaculate.

Phaenius. Wings entire, fulvous, with a brown margin, beneath white, immaculate.

Bias. Wings entire, black, with a blue gloss, beneath brown, with a white hind margin. Inhabits Cayenne.

Phareus. Wings entire, both surfaces nearly alike, red, with a black border. This and the next species inhabit Surinam.

Tacitus. Wings entire, fulvous, outer margin of the upper pair black, spotted with yellow.

Cenetus. Wings entire, white, outer margin of the upper pair brown spotted with white. A native of India.

Procas. Wings entire, both surfaces alike, black, with yellow disk, on the upper pair a yellow spot. This and the following inhabit Surinam.

Alpheus. Wings entire, black; upper pair with two yellow spots, lower ones with a single one at the base.

* Hippothoe. Wings entire, orange edged with black and white; beneath cinereous, with numerous black ocellar dots. Found in England.

* Virgaurea. Wings subangular, fulvous, edged with black; beneath with black and white dots. Found in this and other European countries.

Chryseis. Wings gold, with a blue margin, lower ones slightly indented, beneath dull grey, with numerous ocellar dots. It inhabits Austria.

Sallustius. Wings entire, fulvous, varied with black; upper pair beneath dotted with black. Lower cinereous, with brown spots. This and the next inhabit India.

Florus. Wings entire, fulvous, edged with black, the base beneath dotted with black.

Huber Wings brown, dotted with black, beneath cinereous, with numerous ocellar dots. It inhabits Austria.

* Phlegas. Wings entire, fulvous, dotted with black, beneath blue. It inhabits England.

Arcas. Wings entire, fulvous, with black margin and dots, lower ones beneath grey, immaculate. Inhabits the Cape of Good Hope.

Ballus. Wings entire, fulvous, with a brown margin; lower surface of the upper pair dotted with black, of the lower ones green, edged with brown. It inhabits Spain.

Helle. Wings entire, fulvous, with a blue gloss; all beneath with numerous ocellar dots. It is found in Germany.

Xanthus. Wings entire, brown, with black dots, and a marginal fulvous band, beneath yellowish, with numerous dots. It is found in Russia.

Garbus. Wings brown, dotted with black, and edged with white, beneath greenish, with numerous dots. It inhabits Austria. Probably the other sex of the last.

Thersamon. Wings slightly tailed, fulvous, with numerous ocellar dots beneath; upper pair beneath fulvous, lower ones cinereous. It inhabits Russia.

Lucianus. Wings entire, dotted with black, above fulvous, beneath cinereous. Inhabits Guadaloupe.

Pentheus. Wings entire, fulvous, spotted with black; tip of the lower ones white, dotted with black. It inhabits Surinam, as well as the next.

Urbicus. Wings entire, glossy-blue, beneath pale chestnut-brown at the base, upper pair with a tripplicate eye.

Thyra. Wings indented, the disk fulvous, dotted with black, beneath purplish, with silvery spots. It is found in Guinea.

Zeuxo. Wings entire, the disk fulvous, dotted with black; upper pair with silvery dots. This and the two next are found in different parts of Africa.

Juba. Wings entire, black, with a fulvous disk, beneath with a white band, and abbreviated flecks.

Lara. Wings entire, subfuscous; upper pair with one eye above, and the lower ones with two.

Cephus. Wings entire, brown, beneath with blue bands and a finge eye on the upper pair, and two on the lower ones. It inhabits India.

Domitianus. Wings entire, brown, upper pair with a green spot; lower ones with a green band; beneath pale ferruginous, with silvery dots, and marginal streak. It inhabits Guadaloupe.

Livius. Wings entire, black, with a blue spot on the disk; lower ones beneath cinereous, with rufous bands that are silvery at the edge. This and the next inhabit India.

Romulus. Wings entire, brown, beneath green, with a rufous spot on the lower one.

Actorius. Wings entire, both surfaces alike, brown dotted with white. Inhabits Surinam.

Cassius. Wings entire, above white, with a brown border on the upper pair, and five white dots on the hind margin of the lower ones. This is a native of Surinam.

Eoe Isarchus.
PAPILIO.

ISARCHUS. Wings entire, blue, with a white band on the lower ones, beneath varied with white and black. This and the next are of America.

CARACTACUS. Wings entire, brown, with a white spot on the disk, beneath variegated, a brown band with a slightly oval edge on the lower ones.

OURANUS. Wings entire, both surfaces alike, black with a common white band, ending in a red spot behind. Found at Surinam.

HALAUDUS. Wings entire, blue, with a black border, beneath white, the margin dotted with black. It inhabits the East Indies.

TALUS. Wings entire, with brown and blue bands, and an abbreviated red band beneath. Found at Surinam.

NELEUS. Wings entire, both surfaces alike, black; upper pair with ten white dots; lower ones with a white disk. Found in India.

ATHENON. Wings entire, brownish, with a common white disk, and a brown half band behind. It inhabits America.

REGULUS. Wings entire, black, with two yellow bands, the posterior one on the upper wings interrupted. Found in America.

Hisron. Wings entire, black, with three yellowish bands, the hind one interrupted. Inhabits India.

TARQUINIUS. Wings entire, black; upper pair with an oblong yellow spot at the base, lower ones yellow, spotted with black at the angle of the tail. Found also in India.

GEMELLUS. Wings entire, yellowish, with a brown border, beneath white, with a red streak in the middle and marginal lunules. Inhabits Cayenne.

PTOLOMÆUS. Wings entire, ferruginous, with brown streaks; beneath blue, paler at the base. This, and the four that immediately follow, are natives of India.

ARCHIMEDES. Wings entire, black, with a blue disk, beneath brown, immaculate.

LUCUS. Wings entire, both surfaces nearly alike, fulvous, with black waves.

OVIALUS. Wings entire, dotted with gold; above fulvous, beneath yellowish.

SURTONIUS. Wings entire, yellow, with a brown border; under surface of the upper pair with silvery black dots; of the lower pair cinnereous.

ELECTRON. Wings entire, both surfaces alike, black, with a yellow band and fangnious dots at the tip. It inhabits Cayenne.

SAGARIS. Wings entire, black, with a common transverse fulvous spot. This and the next inhabit Surinam.

EUHYÈS. Wings entire, black, with a blue spot; beneath rufous in the middle, with white bands.

PHERECUS. Wings entire, both surfaces alike, black; upper pair with a linear red band. This and the next are natives of America.

LYSIPPUS. Wings angular, brown, all of them with a red streak, beneath with cinnereous dots.

ÆMULIUS. Wings entire, cinereous, spotted with brown and white; the lower ones pale above; beneath all dotted brown. inhabits India.

GEMINUS. Wings rounded, blue, with a black border, in which is a blue streak; lower ones beneath subfuscata, with brown. A native of America.

LUCANUS. Wings entire, black, with a yellow disk; lower ones beneath red, with square brown spots. Inhabits India.

PERDITUS. Wings entire, both surfaces alike, black, with a fulvous band. It inhabits Cayenne, as does the next.

PYRAMIS. Wings entire, brown, with a blue gloss, and a fulvous band; lower ones beneath grey.

PHIASSUS. Wings entire, both surfaces alike, black; upper pair with a double fulvous band. This, and the four following inhabit India.

THECYNIDES. Wings entire, black, with a fulvous spot on the disk, beneath cinereous, with rufous waves.

VIRGILUS. Wings entire, black, with a blue thinner margin, beneath grey, with three whitish lunules, including a black dot on the lower ones.

PETRUS. Wings entire, blue streaked with black, beneath brown, cinnereous, dotted with black.

NUMITOR. Wings entire, brown, with a yellow disk on the lower ones, beneath yellow, immaculate.

PHIASSUS. Wings entire, brown, spotted beneath; lower ones with two eyes above on the hind part, and one beneath. It inhabits Africa.

CTES. Wings entire, brown, beneath fulvous, with punctuated gold streaks. A native of Surinam.

HEGON. Wings entire, brown, with numerous macular fulvous bands. Inhabits Jamaica.

Hesperis. Urbiola.

EXCLAMATIONIS. Wings entire, divaricate, brown; upper pair with a yellow line and dots under it. Inhabits India.

*COMA. Wings entire, divaricate, fulvous, with a black line on the upper pair; beneath spotted with white. This is found in England.

PROPTERUS. Wings divaricate, black, spotted with yellow; lower ones beneath with alternate, rufous, and yellow bands. This and the next are natives of India.

TIBULLUS. Wings entire; upper pair black, spotted with yellow; lower ones yellow, with a black border.

LINEA. Wings entire, divaricate, fulvous, edged with black. It inhabits Austria.

*SILVANUS. Wings divaricate, dark orange, with square yellow spots above, and whitish ones beneath. This is an English butterfly, as well as the next.

*THAUMAS. Wings divaricate, orange, with a darker patch at the base, the upper pair, in the male, with a black line in the middle.

OTHO. Wings divaricate, brown, with fulvous spots at the base, and nearly square yellow ones each side on the disk.

ARIGAS. Wings divaricate, fulvous, with an oblique black band and bend margin. This is a native of India.

VITELLUS. Wings divaricate, fulvous; upper pair with a brown margin and spot in the middle; lower ones with a brown border. Inhabits the South American islands.

COLO. Wings divaricate, fulvous, with a brown striate margin and spot in the middle. It inhabits India.

*PANICUS. Wings divaricate, dark brown, with fulvous spots. Inhabits England, and has been described and figured by Mr. Donovan.

HELIUS. Wings divaricate, brown; upper pair dotted with white; lower ones striate beneath with white. Inhabits Cayenne.

ORIGENES. Wings divaricate, both surfaces alike, brown, with a streak of white dots; upper pair tettaceous at the base. It is a native of India.
PAPilio.

Nostrodamus. Wings divaricate, brown; upper pair with a macular whitish band above; lower ones cinereous beneath. Inhabits Barbary.

Pheus. Wings fimbriate, divaricate, brown, with an interrupted yellow band on the upper pair. This and the next are natives of Surinam.

Helius. Wings fimbriate, brown; lower ones fulvous at the inner margin.

Metis. Wings entire, brown, with scattered fulvous spots; lower ones beneath yellow, immaculate. Inhabits the Cape of Good Hope.

Disconoides. Wings entire, brown, spotted with yellow; lower ones beneath yellow and brown. It inhabits Tranquebar.

Plutarch. Wings entire, brown, speckled with gold; upper pair with a telescopious spot at the tip above, and telescopious outer margin. This and the next are natives of India.

Epictetus. Wings entire, black, with a yellow disk; upper pair with a brown spot, including a yellow lunule; lower ones beneath yellow, immaculate.

Silenus. Wings tailed, brown, beneath pale chestnut, with yellowish streak. It inhabits Africa.

Orion. Wings tailed, brown; upper pair with semitransparent spots; lower ones with white tints. This and the next are inhabitants of Surinam.

Eudoxus. Wings tailed, brown; upper pair with a white band on each side; lower ones on the under surface only.

Phoebus. Wings tailed, brown, with transparent spots; antennae hooked. A native of America.

Chemnus. Wings slightly tailed, brown, with hyaline spots and yellow hind margin. It inhabits America.

Tityrus. Wings slightly tailed, brown; upper pair with a yellow band on each side; lower ones with a silvery streak beneath. A native of America.

Murexus. Wings slightly tailed, brown, with hyaline spots. This and the next are natives of India.

Meatus. Wings slightly tailed, black; upper pair with hyaline spots; lower ones beneath brown, with a white band at the base.

Epictetus. Wings slightly tailed, brown, spotted with yellow; lower ones beneath with a silvery band. A native of Surinam.

Lycaidas. Wings slightly tailed, brown, with black teeth; upper pair with a yellow band on each side; lower ones beneath clouded with brown at the base, and afterwards white. It inhabits America.

Niclus. Wings slightly tailed, fulvous; upper pair brown at the tip, with a yellow hyaline spot. It is found at Cayenne, as is the next.

Mercurius. Wings slightly tailed, brown, yellow at the base, with hyaline dots on the upper pair; lower ones beneath black, with a cinereous band.

Thrysses. Wings slightly tailed, brown, with a yellow band on the upper pair, beneath all of them purple, speckled with yellow. It is found in America.

Alpheus. Wings slightly tailed, black, with a red band; beneath variegated. A native of the Cape of Good Hope.

Prentus. Wings slightly tailed, black, spotted with green, beneath ferruginous, spotted with yellow. This also is a native of the Cape.

Phocas. Wings slightly tailed, brown, with diaphanous spots; lower ones beneath with a black dot at the base. A native of America.

Momus. Wings slightly tailed, brown, with hyaline streaks at the base, and spots at the tip. It inhabits Cayenne.

Vespasius. Wings slightly tailed, rusty-brown; upper pair with whitish dots on the tip. Found in India.

Rhietus. Wings slightly tailed, fulvous; outer margin of the lower ones blue-black. This and the three next inhabit Surinam.

Clonias. Wings slightly tailed, black; upper pair with a snowy band; lower ones beneath bluish, tail fangious.

Aratus. Wings slightly tailed, black; upper pair with a snowy band; lower ones beneath greenish, with abbreviated yellow streaks.

Palæmon. Wings slightly tailed, bluish; upper pair with a rufous dot in the middle; lower ones rufous at the angle of the tail.

Julianus. Wings slightly tailed, brown; upper pair spotted with yellow; lower ones beneath varied with brown and glaucous. It inhabits Jamaica.

Brontes. Wings slightly tailed, both surfaces alike, brown; upper pair with a snowy band; lower ones with a snowy margin. It inhabits America.

Aratus. Wings tailed, both surfaces alike, black; upper pair with a transverse snowy spot; tail ferruginous.

Alexis. Wings tailed, brown; lower ones with a bluish band beneath. This and the next are natives of India.

Mithridates. Wings rounded, black, with a purple spot and band behind, including paler lunules.

Jupiter. Wings without tails, black with a green gloss, beneath green, with black veins and margin; head and tail fangious. It inhabits Africa.

Cassander. Wings without tails, both surfaces alike brown, immaculate.

Polybius. Wings without tails, black; upper pair with a fulvous spot; lower ones yellow at the angle of the tail. This and the three following are natives of India.

Thræx. Wings without tails, brown, with a few diaphanous spots; antennae hooked.

Ennius. Wings brown; upper pair with hyaline spots; lower ones above black, with a yellow disk, beneath brown, with a white disk.

Scipio. Wings without tails; upper pair with a hyaline white band on each side, above black, beneath green.

Marcus. Wings without tails, brown, with hyaline spots; lower ones beneath with two yellowish fillets; the thinner margin fulvous. It inhabits Cayenne.

Flesus. Wings without tails, brown; upper pair with diaphanous spots; dish of the lower ones white, dotted with black. A native of Africa.

Cicero. Wings rounded, brown; upper pair with white hyaline spots; lower ones with a white hyaline disk. It inhabits the East Indies.

Atticus. Wings rounded; upper pair brown, with black spots and hyaline dots; lower ones hyaline, with black spots. It is found in India.

Clericus. Wings rounded, brown, subfuscate, with black; upper pair with hyaline dots. This and the next four inhabit different parts of the continent of America.

Lucas. Wings without tails, brown; upper pair with yellow hyaline spots on both surfaces.

Juvenalis. Wings without tails, brown; upper pair spotted with black, and dotted with white.

Bathyllus. Wings without tails, brown; upper pair...
with diaphanous square white spots; lower ones beneath with clouded waves.

*ARBUS.* Wings without tails, brown; upper pair with white diaphanous spots; all of them beneath palish purple at the tip.

*NEPUS.* Wings rounded, black; upper pair dotted with white; lower ones white at the angle of the tail above and beneath, with a white disk. It inhabits India, as do the next five species.

*NERVA.* Wings entire; upper pair brown, spotted with white; lower ones above black immaculate.

*CELIAS.* Wings entire; upper pair brown, with diaphanous spots; lower ones black, with a snowy spot in the middle.

*TEPTILIANUS.* Wings entire, rounded, blueish, spotted with black; the upper pair with white dots.

*ORCUS.* Wings rounded, brown; upper pair spotted with yellow; lower ones beneath blueish.

*DOMUS.* Wings without tails, dull cinereous, dotted with brown; upper pair with hyaline spots.

*NOBeth.* Wings without tails, brown; upper pair with hyaline dots; lower ones beneath white; the margin brown, with six occellar dots. Inhabits America.

*SLVITUS.* Wings without tails, brown; the disk yellowish, spotted with brown; lower ones beneath cinereous, with brown waves. Inhabits the Cape of Good Hope.

*SALUS.* Wings indented, fulvous, with black bands; upper pair with hyaline spots; lower ones hyaline in the centre. Inhabits Surinam.

*JACCHUS.* Wings without tails, spotted with yellow; lower ones with fix snowy dots. Inhabits New Holland.

*GENUS.* Wings indented, both surfaces nearly alike, black; upper pair with three hyaline spots; lower ones with blue bands. This and the next are natives of India.

*ALVARIUS.* Wings indented, black; upper pair with yellow and white spots; disk of the lower ones yellow, with black dots.

*ANAPHUS.* Wings entire, both surfaces alike, brown; lower ones yellow at the tip. Inhabits Surinam.

*SEBALUS.* Wings without tails, varied with brown and black; lower ones beneath yellow at the angle of the tail. It is found in America.

*EVADNUS.* Wings without tails, brown, with a yellow disk; upper pair with subcellar silvery dots beneath. Inhabits the Cape of Good Hope.

*BIXE.* Wings rounded, brown, greenish at the base; lower ones beneath a yellow band. Inhabits America.

*POLYCLYTUS.* Wings slightly tailed, green-brown, with a white spot on the upper pair; beneath with fulvous silvery spots on the margin. Native of India.

*ARACANTUS.* Wings rounded, entire, brown; lower ones beneath grey, with occellar spots. It inhabits Austra.

*BUSIRIS.* Wings oblong, entire, black; upper pair with two yellow spots and dots; lower ones with a yellow disk. This is a native of India.

*PINSTRATAS.* Wings entire, brown; lower ones with a yellow disk above, and a snowy band, dotted with black beneath. It is a native of America.

*HERES.* Wings rounded, entire, black; upper pair with a white spot; lower ones with a white band. This and the next are natives of Surinam.

*EUROILUS.* Wings rounded, entire, black; upper pair spotted with white; lower ones fulvous, with black veins.

*PHILEMON.* Wings rounded, entire, black, immaculate. Native of America.

*THRASIBULUS.* Wings entire, black, with blue lunules; lower ones beneath at the angle of the tail cinereous, dotted with brown. This and the following are natives of India.

*CLEIUS.* Wings entire, both surfaces alike, black; upper pair with a yellow band.

*ZELIUS.* Wings entire, both surfaces alike, black; lower ones edged with white; head and tail fangueous.

*MENUS.* Wings entire, glossy green, black, edged with white; lower ones beneath with a white band; mouth and tail red. A native of America.

*PHILIDUS.* Wings entire, glossy black, edged with white; mouth and tail red. Inhabits Asia.

*AMATUS.* Wings entire, black, with a yellow hind-margin; head and tail red. A native of America, and so is the next.

*ASCLEPIAS.* Wings entire, black, with fulvous spots, the margin dotted with yellow.

*LVCAGUS.* Wings rounded, entire, blue-green, immaculate; tail red. Inhabits Surinam.

*CATUS.* Wings rounded, entire, black; upper pair dotted with white; lower ones with a streak of white dots. This and the next following species are natives of India.

*JOVIANUS.* Both surfaces of the wings alike, black; lower ones radiate with blue and white.

*SALVIANUS.* Wings entire, brown, spotted with green; lower ones beneath white, with a margural streak of brown dots.

*OILEAS.* Wings rounded, entire, variegated with black and white; lower ones beneath cinereous, with waved black streaks. It is found in America.

*MAMON.* Wings entire, white, with black margin and spots. Inhabits Cayenne.

*TALUS.* Wings entire, both surfaces alike, brown; upper pair with white dots and red base; lower ones with a white disk. Found in India.

*MIMAS.* Wings entire, brown, with a ferruginous margin; beneath with a streak of black dots. This and the next inhabit Surinam.

*GENUS.* Wings entire, both surfaces alike, yellow, with a black border; upper pair with yellow bands.

*PELOPIDAS.* Wings entire; upper pair dull cinereous, with a brown line in the middle; lower ones cinereous. This and the next species are natives of India.

*GALEXUS.* Wings entire, both surfaces alike, brown, spotted with yellow.

*AMELIE.* Wings indented, divaricate, brown, with cinereous waves; upper pair with hyaline dots; lower ones with white dots beneath. Inhabits this country.

*ALCII.* Wings divaricate, variegated with brown and cinereous; upper pair with hyaline dots; lower ones beneath cinereous, immaculate. Inhabits Russia.

*SID.* Wings entire, divaricate, black, with square white spots; lower ones beneath cinereous, with two yellow bands. Inhabits Russia.

*FRITILLUS.* Wings entire, divaricate, black, dotted with white. It inhabits Europe.

*CALBA.* Wings entire, divaricate, black, dotted with white; lower ones beneath grey, with two white bands. It inhabits Tranquebar.

*MELVUS.* Wings entire, above black, beneath greenish, with white lines and spots on both surfaces. Inhabits the East Indies.

*LAVATER.* Wings entire, brown; upper pair with white spots; lower ones with white dots; all with a snowy lunule in the middle. It inhabits Germany.

*MENTILUS.*
PAP

Menalca. Wings entire, both surfaces alike, white edged with black. It inhabits India.

Menippus. Wings entire, fuscous, brown, with a broad white band, in the middle of which is a brown dot. It inhabits Surinam.

Clito. Wings entire, both surfaces alike, black; upper pair dotted with white; lower ones with a white band. It inhabits Cayenne.

Vibius. Wings entire, black; upper pair with three white dots; lower ones tipped with white. Inhabits Surinam, as do the two next.

Curius. Wings entire, both surfaces alike, black; upper pair with four white dots; lower ones immaculate.

Phoeneus. Wings entire; upper pair brown; lower ones yellow.

Tages. Wings entire, denticulate, brown, with oblong white dots. A native of England and other parts of Europe.

Neso. Wings entire, sub-reversed, brown, upper pair with four white scattered dots above. This and the two remaining species are natives of India.

Shio. Wings entire, reversed, blackish, every where spotted with white.

Pygmeus. Wings entire, brown, immaculate.

Papilio-Mufca, a name given by some authors to a series of small insects, which seem to be of a middle nature between the fly and the butterfly classies. Its wings are in part covered with those scales in form of dust, which render the wings of the butterfly kinds opaque, and in part are transparent and glossy. Reaumur has called the wings altes vorées, glossy wings. Reaumur's Hist. of Insects.

Papilion-Bourdon, a name given by the French authors to a fort of butterflies, which while they feed keep upon the wing with a humming noise like that of the humble-bee. Reaumur. See Dipters and Papilio.

Papilion-a-gane, bald butterflies, a name given by the French naturalists to a fort of butterfly, of which there are several species. The sides of the wings of these butterflies are jagged, and one of the jag run out to far beyond the rest as to represent a fort of tail falling from the creature. Reaumur.

Papilionaceæ, in Botany, the 32d among the natural orders of Linnaeus, comprising a principal part of the Leguminose of Buffieu; see that article, and Papilionaceous Flowers; see also Diaphela. In addition to what is to be found under the last-named article, respecting the qualities and uses of these plants, it may be mentioned that Linnaeus, in his Prefaces, has observed that scarcely any of them are medicinal, except Glycyrrhiza, the Liquorice, for Gauges, though recommended against the plague, is scarcely to be trusted, which we can readily believe. He affirms moreover that they have scarcely any scent. If this be the case with the flowers, the Spurium junceum and Lathyrus odoratus are powerful exceptions, indicated by his editor; to which Mr. Salter has added Corenilla volatina, Lupinus lacteus, Vicia faba, and various species of Trifolium. The herbage of some Papilionaceæ acquire a very penetrating durable scent, of a peculiar kind, in drying; as the common and blue Mellilot, Trifolium officinale and carucaum; with most of the genus Trigonella. The seeds of this family are of a flatulent quality, and both bael suited for the food of hard-working people.

Some of this order are very remarkable for their occasionally subterraneous mode of fruiting. Lathyrus amphicarpus, as well as Vicia amphicarpa of Dorrans, see Wild. Sp Pl. v. 3. 1105, bear some flowers from their roots, considerably below the surface of the ground, which are pale and deformed, but having perfect anthers and stigma, produce good seed. The same individual plants have abundance of flowers and seeds upon their stems above, like those of their natural order. Others, after flowering, bury their flower-flasks and ripening germs in the ground, in a very curious manner. Such are Gloine subterranea, Arachis hypo- gena, and our English Trifolium subterraneum, which last fixes itself by fuplementary radicles from the tops of the buried flanks.

Papilionaceous Flowers, Flores papilionacei, are formed from a fancied resemblance in their form to a Papilio, or Butterfly, see the last article. This denomination appears, as Tournesort suggests, to have originated with the bug-ious and learned Valerius Cordus, who in his Historia Sannum, chap. 162, applies it to the flowers of the Bean. The word does not occur in the Lexicon of David Kyber, published in 1553, by the care of their common friend the great Conrad Gesner, eight years before the latter printed the works of Cordus.

Linnaeus has very particularly described such flowers in his Genera Plantarum 358, at the head of his class Dia- delphia, which is composed of them.

Calyx. Perianth inferior, of one leaf, bell-shaped, withering; its base gibsous, attached by its lower side to the flower-flask, obtuse and containing honey at the upper; its mouth with few acute, erect, oblique, unequal teeth, of which the lowermost is longest, and has no hollow; the upper pair short and furthest sunder, the bottom is internally moist with honey, including the receptacle.

Corolla, called papilionaceous, is unequal; each petal being distinguished by an appropriate name, as follows.

The standard is one petal, larger than the rest, which it lies over and covers, in a flatish horizontal position. Its claw is inserted into the upper margin of the receptacle; and what projects beyond the calyx approaches to a roundish, almonl entire, figure, having an elevated longitudinal line, especially towards the extremity, as if the petal were deprested at the sides. That part of the petal nearest the base, approaches to a semicylindrical shape, embracing the parts beneath. The border of the petal is deprested at each side, but a portion near the margin is reflected upwards where the divided tube, or claw, ends; where the halved limb, or border, begins to expand, are two posterior concave impressions, prominent beneath, which comprees the wings lying under them.

Wings two equal petals, one at each side of the flower, under the standard, incumbent at the margin, parallel, roundish-oblong, broadest outwards, straightest at their upper edge, more dilated into a roundish form at the lower. The base of each is divided, the lower portion thereof elongated into a claw, inserted at the side of the receptacle, and about the length of the calyx; the upper portion being shorter and inflected.

Keel, the lowest petal, is usually deeply divided, situated under the standard, within the wings, boat-shaped, concave, compressed at the sides, in the position of a boat upon the water, articulated at its base, whose lower part is extended into a claw, as long as the calyx, inserted into the receptacle, its lateral and upper segments being shorter, and twisted together with the corresponding parts of the wings. The sides of the keel agree with the wings in form, and nearly in situation, except in being interior to them, and somewhat lower. The outline of this petal, constituting the actual keel, extends half way in a straight line, then it gradually ascends, in a segment of a circle; but the margin, or upper edge, is slanting to the end, where it unites in a blunt angle with the other.

Stamens
Stamens for the most part united, in two sets; their filaments of different shapes: one inferior, embracing the pistil; the other superior, lying upon that part.

The inferior filament, bearing the germen, is in its lower half membranous, cylindrical, with a longitudinal slit above; the upper portion consists of nine awl-shaped divisions, having the same length and curvature as the keel of the corolla which incloses them, the intermediate or lower ones longer than the others in alternate pairs.

The superior filament is of a slender awl-shaped figure, lying over, and covering, the figure in the former, to which it answers in situation, being simple, and rather less permanent, so that, separating at its base from the former, it allows of the escape of the honey at each side.

Anthers in all, equal, terminal, ten in all; one upon the upper filament; nine on the respective divisions of the lower.

Pistil one, superior.

Germen oblong, somewhat cylindrical, slightly compressed, straight, the length of the cylinder, formed by the inferior filament, by which it is embraced.

Style awl-shaped, slender, ascending, the length and position of the segments of the lower filament, among which it is stationed, withering.

Stigma downy, at the upper part, immediately beneath the anthers.

Papillae an oblong, compressed, obtuse legume, of two valves, having a longitudinal future as well as below, both straight, except that the upper slopes downwards towards the base, and the lower upwards near the extremity; it bursts finally along the upper future.

Seeds several, roundish, smooth, fleshy, pendulous, marked with the slightly prominent embryo, near the interior of the scar. In germination the cotyledons retain the form of the two halves of the seed, (but do not always rise above ground.)

Receptacles of the seeds minute, very short, taper at the base, attached to the seeds by an obtuse oblong disk, all inflected along the upper future only, but in an alternate order, so that when the valves are separated they adhere alternately to each valve."

Such is the character of the diadelphous papilionaceous flowers, composing the third order of the 17th class in the Linnaean system; see Diadelphum. There are however many papilionaceous genera which have flowers with ten separate and distinct stamens, and which therefore range in the class Decandria; see that article. Of the plants for our purposes Linnaeus knew but few, chieftly his Sophora, Anatys, and Ceri; but recent discoveries, especially in New Holland, have greatly added to the list; see Daviesia, Dellwynia, Compholobium, Mirrella, Pultenaea.

Neither are the flaments of the diadelphous tribe uniformly constructed in the precise manner above described. Some few, like Smilax, have them in two equal sets, five anthers to each; in others five of the anthers are occasionally imperfect. The corolla itself is liable to exceptions. In Amorpha it consists of a standard only, the wings and keel being deficient; in some species of Erythrina the wings are scarcely discernible, however conspicuous the other petals. In Trifolium the corolla is often really monopetalous, the standard, wings, and keel, though retaining much of the form and aspect proper to papilionaceous flowers, being all firmly united below into a tube. So in many genera of the Diadelphum Decandria, the two sets of flaments are really united into one, by a tubular base; thus becoming properly monadelphous. Yet the rest of their structure is such, as to evince their inseparable affinity with the others, like which they all appearance perfectly diadelphous.

Linnaeus thought too much fire had been laid upon the figure of the legume, in characterizing the genera of this tribe, and he recommends the calyx as leading to very solid distinctions. He has also recourse to the stigma, which is certainly, in many cases, a very important part. He recommends, in his Gen. Pl. 360, according to the usual principles which justly guided him, that the foliage should not be referred to for generic characters; yet in his Systema Vegetabilium he very commodiously indicates certain distinctions in the habit of the class Diadelphum, by which the genera differ from each other; some having twining stems, as Phasophus, Dolichos, Chloria and Glicina; some abruptly pinnate leaves, as Orbis, Pflum, Labrythus, Vicia, Erumum, Apectus, and Absis; while in others the leaves are pinnate with an odd leaflet, as Biferrula, Averallatus, Phaca, Hedsfarum, Glycerbia, Indigofera, Gagea, Coluta, Amorpha, &c. and in a third tribe the leaves are ternate, as Trifolium, Lata, Medicago, Erythrina, Genista, Cyrtus, Oonisa, Trigonella, and most of the climbing genera. Yet some species of Hedyfarum have simple, others pinnate leaves, and several Genista have simple ones.

Papillae in Anatomy, small prominences on various organs of the body, particularly the skin and tongue. (See integuments and tongue.) The word papilla is also applied technically to the nipple of the breast.

Papillaris, in Botany, a name used by some authors for the common lamplium, or nipple-wort.

Papillarum, in Anatomy. See PAPILLAE.

Papillae Processe, a name which the ancients gave to the olfactory nerves, from the place of their origin, to the os cribrum. See Nervous System.

Papillon, Philibert, in Biography, an industrious man of letters, the son of an eminent advocate at Dijon, where he was born in 1666. He was brought up to the profession of the law, but he afterwards embraced the ecclesiastical state, and received priest's orders in 1694. Previously to this he had obtained a canonry of no great revenue, but sufficient for his wants, since his great ambition was to be provided of a good library, in order that he might devote himself to the cultivation of literature. His researches went chiefly to literary history, especially that of his own province, and the works of several other writers were enriched by his cells. He supplied P. Le Long with memoirs inferred in his "Bibliotheque des Histoires de France," and also with materials for his "Bibliotheque Sacree." To M. P. Desmolets he communicated a number of critical and biographical articles for the use of his "Memoires d'Histoire et de Literature!" and in Niceron's memoirs, the lives of Peter Abelard and James Amyot are by his hand. The principal work of the abbe Papillon was his "Bibliotheque des Auteurs de Bourgogne," which appeared after his death in two volumes folio. He died at Dijon in the year 1738. He was endeared to all his acquaintance by his modesty, frank, and amiable disposition. Moreiri.

Papillosum Folium, in Botany, is a leaf covered with soft succulent tubercles or granulations, of which the Ice Plant. Mesembryanthemum crystallinum, is a striking example; see LEAF. Papulosum is nearly equivalent, and is sometimes used by Linnaeus for the same thing, though he errs in ever making it synonymous with verrucosum. The latter character consists in hard cartilaginous warts, equally perceptible in the dried specimen and in the living one; the former, depending on succulence, changes its appearance greatly by drying, yet is clearly discernible to an experienced eye, even in that state, in the foliage of many species of

Mesem-
Mefembryanthemum, on which it then forms minute orbicular depressions.

PAPIMOUAGON, in Geography, a lake of Canada, 70 miles N. of N.E. of Quebec. N. lat. 50°. W. long. 69° 20'.

PAPIN, DENYS, in Biography, an ingenious physician, the son of Nicholas Papin, also a physician, was born at Blois. He took the degree of doctor, and travelled to England, where he was elected a fellow of the Royal Society, in December 1680. He passed the following year in London, and published an account of a machine which he had invented, and which will bear his name; this was "The New Digger, or Engine for the hoisting of Bones," 1681. It soon appeared in France, with the title of "La Maniere d'Amollir les Os, et de faire cuire toutes fortes de Viandes en peu de tems et a peu de frais." Paris 1682. The machine consists of a very strong metal boiler, with an air-tight cover screwed down with great force; hence the contained matter, being incapable of escaping either by evaporation or by bursting the machine, may be heated to a degree far beyond that of boiling water, so as to deflavour the bones of bones and cartilages. He afterwards improved this digester, and it has since been much employed in chemical and philosophical experiments. He affixed B-smle in various experiments, of which an account is given in the history of the Royal Society. Papin was a Calvinoist, and was therefore prevented from returning home by the revocation of the edict of Nantes. He afterwards resided at Marburg, where he taught the mathematics, and published a "Fasciculus Differtationum de quibusdam Machinis Physicis," 12mo. 1696, and in 1707, he published at Frankfort an account of a machine which he had invented for raising water by the action of fire, entitled "Ars nova ad aequam ignis adminiculo efficacissime elevandam."

His father, Nicholas Papin, was author of several works, which, however, are nearly forgotten. Two of them related to the powder of Sympathy, which he defended; and one to the discovery of Harvey, which he opposed. Eloy Dilet, Hill de la Med. Gen. Bio.

PAPINACHIOIS, in Geography, a river of Canada, which runs into the Saguenay; N. lat. 48° 24'. W. long. 70° 50'.—Also, Indians of Canada, so named from the river. N. lat. 50° to 51°. W. long. 69° to 71°.

PAPINIANUS, in Biography, a celebrated Roman lawyer, who attained to the rank of pretorian prefect under the emperor Severus, in the year 194. His profound knowledge of the law, and his incorruptible integrity, gave him great influence during this reign, the rigours of which he softened by his counsels as much as lay in his power. On his death-bed, Severus recommended his sons Caracalla and Geta to the care and protection of this faithful servant; and he accordingly used all his efforts to preserve that fraternal union between them, which soon appeared in danger of dissolution. Caracalla deprived the prefect of his post, but did not banish him from his person, and when he had perpetrated the execrable murder of his brother, he earnestly solicited him to compose a paper in justification of it, to which he replied, that it was easier to commit a murder than to defend, and that it was a second murder to vitiate the memory of the innocent. A man so honest was not likely to exit long, he was probably sacrificed to the emperor's resentment. In 212, Papinian composed a great number of works, and formed several illusive disciples. His authority as a lawyer rose beyond that of any of his predecessors; the emperor Valentinian I. made a decree, that in cases in which the opinions of judges should be divided, the preponderance should be given to that which should have the support of Papinianus.

PAPIO, PAPIONES, in Zoology, the name of those species of monkeys which we call baboons; which were:

These are all species of the Simia in the Linnaean system. See Simia.

PAPIRA, or Papyra, in Ancient Geography, a town of Afa, in Galatia, upon the route from Pallinium to Ancya, between Vindia and Ancya; according to the Itinerary of Antonine.

PAPIRE-MASSON, John, in Biography, an historian, was born, in 1544, at Saint-Germain-Leval, in France. He was brought up among the Jesuits, and for some time taught in their seminaries in Italy and France. He afterwards quitted the society, studied the law at Angers, and was afterwards appointed an advocate in the parliament of Paris; it was on this occasion that he changed his family name of Maffon into Papire-Masson. His works are "Annalium, l.b. iv," relating to the history of France; "Notiss Episcoporum Galliae:" "Vita Joannis Calvini;" "Elegia Virorum Illirium;" "De Episcopis Urbes Roman;" "Depicrrio Fluminum Galliae;" "Agobardi, Episcopi Lugdunensis, Opera." All his works are laid to display considerable learning and research, but they are not to well esteem with regard to accuracy. He distinguished himself by his learning and integrity, and obtained the post of substitute to the procureur-general. He died in 1614, much regretted by men of letters of whom the principal were his particular friends. His life was composed by De Thou, Moret.

PAPIRIA, in Botany, a name originally given by Thunberg, in the Lund Transact. ns, to the genus which he and all other botanists have subsequently called Gethylia; see that article.

PAPRIAN CODE, a collection of imperial constitutions, &c. made by a private lawyer, whose name was Papirius. See Code.

PAPRIUS CURSOR, the elder, in Biography, an eminent Roman commander, was master of the horde to Papirius Craufis, when dictator, in the year 339 B.C. He was consul for the first time in the year 333 B.C., and was nominated dictator in the year 332 B.C. Having appointed Quintus Fabius Rullianus to be his master of the horde, he marched against the enemy, strictly enjoining Fabius not to engage during his absence. A favourable opportunity, however, occurred, and his master of the horde disobeyed the injunction, and gave the Samnites a total defeat, for which breach of discipline he was condemned to death by the dictator, but the sentence was not executed. Papirius, during the remainder of the campaign, applied himself to the recovering of the affections of his followers, which had been alienated by his severity, and then he attacked the enemy, who were reduced to sue for peace. He was chosen consul a second time in the year 320 and again a third time in the following year, when he reduced Satricum, which had revolted, and put all the Samnite garrisons to the sword. For his exploits in this and the preceding campaign, triumphal honours were decreed him. In the consulate of Fabius Rullianus and Marcus Brutus, B.C. 310, the latter having fullained great losses in an engagement with the Samnites, it was determined again to raise Papirius to the dictatorship, as the commander most to be relied on in the public danger. A decree was accordingly passed, enjoining Fabius to nominate Papirius to that high office. He was again successful, and received a third triumph. This was probably his last public service, as his name occurs no more in history. He expatriated all his contemporaries in military talents. In person he was tall and majestic, of great bodily strength and vigour, and so swift of
of foot, that he obtained the surname from that circumstance. He kept his troops, as well as himself, in constant exercise, and maintained strict discipline. Univer. Hist. Livy.

Papirius Cursor, the younger, son of the preceding, was created consul B. C. 293, in conjunction with Spurius Car- villius. In his contests with the Samnites he was very successful, and gave a proof of superiority to that superlition which was so prevalent among the early Romans. Being informed, as he was about to advance to battle, that the keeper of the sacred chickens had falsly given a favourable report of the augury derived from their eating, and that in the fact the preface was inauspicious; he replied, that he should undertake the report as it was given, and that if the keeper had deceived him, the vengeance of the gods would fall on him alone. He therefore placed the man in the front of the battle, where he was killed by an unknown hand before the armies came to a close engagement. The battle terminated in favour of the Romans: the Samnites were not only totally defeated, but lost their camp. For this and some subsequent successes he obtained a triumph at the end of the campaign. Papirius, in his second con- culate with the same colleague, was equally successful against the same people, which put an end to a war that had lasted for seventy-two years. The confuls next sub- dued the Lucanians and Bruttians, and proceeding to Tarsentum, invested that city which had been the first to in- vite Pyrrhus into Italy. Papirius, by the offer of favourable terms, gained possession of the citadel, and the town soon surrendered, and became tributary. From this period nothing more occurs relating to this valiant commander. Univer. Hist.

Papirius, in Botany, see Papirius; also the misprinted name Broussonnetia.

Papist. Under this head, we shall present the reader,

I. With an account of the difference between Papists, reputed Papists, Papist Recusants, and Papist Recusants Convict, in the legal acceptance of those words. 11. With a short view of the tenets of the Roman Catholic religion, as distinguished, 1st, in so thefe which they confider as articles of their faith; 2dly, thofe which regulate their discipline; and, 3dly, the opinions of their private doctrines.

II. We shall now present the reader with a short view of the tenets of the Roman Catholic religion. They are distinguished into, 1st, those which Roman Catholics consider to be the articles of their faith; 2ndly, those which regulate their general discipline; and, 3dly, the opinions of their private doctrines.

All of them are thus stated and explained by the Rev. Joseph Berrington, a Roman Catholic priest, in his "State and Behaviour of the English Catholics, from the Reformation to the year 1780."

II. 1. "The following rule," says this intelligent writer, "is the grand criterion by which each article of our faith may be distinctly ascertained."

"This rule is:—All that, and only that, belong to Catho- lic belief, which is revealed in the word of God, and which is propounded by the Catholic church to all its members, to be believed with divine faith.

"Guided by this certain criterion, we profess to believe,

1. "That Christ has established a church upon earth; and that this church is that which holds communion with the see of Rome, being one, holy, Catholic, and apop- tolical.

2. "That we are obliged to hear this church; and therefore, that she is infallible, by the guidance of Almighty God, in her decisions regarding faith.

3. "That St. Peter, by divine commission, was appointed the head of this church, under Christ it's founder; and that the pope or bishop of Rome, as successor to St. Peter, has always been, and is at present; by divine right, head of this church.

4. "That the canons of the Old and New Testament, as propounded to us by this church, is the word of God; as also other traditions, belonging to faith and morals, which being originally delivered by Christ to his apostles, have been preserved, by constant succession, in the Catholic church.

5. "That honour and veneration are due to the angels of God, and his saints; that they offer up prayers to God for us; that it is good and profitable to have recourse to their intercession; and that the relics or earthly remains of God's particular servants are to be held in respect.

6. "That no sins ever were, or can be remitted, unless by the mercy of God, through Jesus Christ; and, therefore, the man's justification is the work of divine grace.

7. "That the good works which we do, receive their whole
whole value from the grace of God; and that by such works we not only comply with the precepts of the divine law, but that we thereby likewise merit eternal life.

8. "That by works done in the spirit of penance, we can make satisfaction to God for the temporal punishment, which often remains due, after our sins, by the divine goodness, have been forgiven us.

9. "That Christ has left to his church power of granting indulgencies; that is, a relaxation from such temporal chattelments only, as remain due after the divine pardon of sin; and that the use of such indulgencies is profitable to sinners.

10. "That there is a Purgatory, or middle state; and that the souls of imperfect Christians, therein detained, are helped by the prayers of the faithful.

11. "That there are seven sacraments, all instituted by Christ: baptism, confirmation, eucharist, penance, extreme unction, holy orders, marriage.

12. "That in the most holy sacrament of the eucharist, there is truly, really, and substantially, the body and blood, together with the soul and the divinity of our Lord Jesus Christ.

13. "That in this sacrament there is, by the omnipotence of God, a conversion or change of the whole substance of the bread into the body of Christ, and of the whole substance of the wine into his blood: which change we call transubstantiation.

14. "That, under either kind, Christ is received whole and entire.

15. "That in the mass or sacrifice of the altar is offered to God a true, proper, and propitiatory sacrifice for the living and the dead.

16. "That by the sacrament of penance, the sins we fall into, after baptism, are by the divine mercy forgiven us.

17. "These are the great points of Catholic belief, by which we are distinguished from other Christian societies; and these only are the real and essential tenets of our religion. We admit also of the other grand articles of revealed and natural religion, which the gospel and the light of reason have manifested to us. To thefe we submit, as men and as Christians; and to the former, as obedient children of the Catholic church.

II. 2. "There are points of discipline also, which regulate conduct, and to which we pay obedience; as fasting on particular days, communion in one kind, celibacy of churchmen, use of the Latin language in public service, and other similar practices. But as these vary, and may be either altered or suppressed by due authority, they belong not to what is properly styled the faith of Catholics.

III. 3. "Opinions also, whether regarding belief or practice, of particular schools, or of particular divines, constitute a distinct and separate object. Great latitude in the forming such opinions is allowed, and consequentlly it will be often abused. It has been in the power of some men to give an undue weight to such opinions, whereby Catholics themselves have been too often imposed upon.

"They have ignorantly confounded the inventions of fallible men with the unerring declarations of heaven. Of this circumstance our enemies have many times taken an unfair advantage, and the faith of Catholics has suffered from the false representation. Some opinions may deserve respect, but others should be despised and reproved.

"And it should be noticed, that most of the charges brought against us are founded on this false supposition, that the opinions of private men, or of whole societies, are as much a part of our real creed, as the articles I have mentioned. When all this extraneous matter, whether of dif-
and required to be taken in their stead. The statute made in the second session of the first year of king George I. c. 15, contains an oath of supremacy, in the same words as the oath of supremacy, required to be taken by the first of king William and queen Mary. By that oath persons are made to swear, “That no foreign prince, perfon, prelate, flate, or potentate, hath, or ought to have, any jurisdiction, power, supremacy, pre-eminence or authority, ecclesiastical or spiritual, within this realm. It was required to be taken by the persons therein named, or to be tended to any person, for any two justices of the peace, and persons refusing the oath so tended, were adjudged to be Papist recusants convict, and to forfeit and be proceeded against, as such. This was the constructive recusancy referred to above. It was not the offence itself of recusancy, which, as we have already observed, confounded merely in the party abjuring himself from church; it was the offence of not taking the oath of supremacy, and the other oaths preferred by the act of 1 Geo. I. the refusal of which was, by that statute, placed on the same footing as a legal conviction on the statutes of recusancy, and subjected the party refusing to the penalties of those statutes. This was the most severe of all the laws against Papists.

The punishment of recusancy was penal in the extreme; and the persons objecting to the oath in question, might be subjected to all the penalties of recusancy, merely by their refusing the oath when tendered to them. It added to the penal nature of these laws, that the oath in question might be tendered at the mere will of two justices of peace, without any previous information or complaint before a magistrate or any other person. Thus, by refusing to take the oath of supremacy, when tendered to them, they became liable to all the penalties of recusancy; and the same refusal, by 7 & 8 Will. III. c. 4, and 1 Geo. I. c. 13, restrained them from practicing the law, advocates, barristers, solicitors, attornies, notaries, or profilers, and from voting at elections.

With respect to receiving the sacrament of our Lord’s supper, by 13 Car. II. (commonly called the Corporation Act,) no person can be legally elected to any office relating to the government of any city or corporation, unless, within a twelvemonth before, he has received the sacrament of the Lord’s supper according to the rites of the church of England; and he is also enjoined to take the oaths of allegiance and supremacy, at the same time that he takes the oath of office, or in default of either of these requisites such election shall be void.

As to the declaration Against transubstantiation, by 25 Car. II. c. 2. (commonly called the Tell Act,) all officers, civil or military, are directed to take the oath, and make the declaration against transubstantiation in the court of King’s Bench or Chancery, the next term or at the next quarter sessions, or, by subsequent statutes, within six months after their admission; and also, within the same time, to receive the sacrament of the Lord’s supper, according to the usage of the church of England, in some public church immediately after divine service and sermon; and to deliver into court a certificate thereof, signed by the minister and churchwardens, and also to prove the same by two credible witnesses, upon forfeiture of 500l. and disability to hold the office.

With respect to the declaration against Popery; the act passed in the 30th year of Car. II. lat. 2. c. 1, contains the declaration, and prefers it to be made by members of either house of parliament, before they take their seats; by it they declare their disbelieve of the doctrine of transubstantiation; and their belief that the invocation of saints and the sacrifice of the mass are idolatrous.

III. 7.
III. 7. With respect to the laws affecting their landed property. How this was affected by the laws against recusancy has been already mentioned. By the 11 & 12 W. III. c. 4, it was enacted that a person educated in the Popish religion, or professing the same, who did not, in six months after the ages of sixteen, take the oaths of allegiance and supremacy, and subscribe the declaration of 30 Car. II., should, in respect of himself only, and not of his heirs, or posterity, be disabled to inherit or take lands by descent, devise, gift, or limitation, in possession, reversion, or remainder: and that during his life, till he took the oaths, and subscribed the declaration against popery, his next of kin, who was a Protestant, should enjoy the lands without accounting for the profits, and should be incapable of purchasing; and that all estates, terms, interests, or profits, out of lands, made, done, or suffered by use, or in truant for him, should be void. By 3 Jac. I. c. 5, 1 W. & M. c. 26, 12 Anne stat. 2. c. 14, 11 Geo. II. c. 17. Papists, or persons professing the Popish religion, were disabled from presenting to advowsons, and other ecclesiatical benefices, and to hospitals and other charitable establishments. By annual acts of the legislature, Papists, being of the age of eighteen years, and not having taken the oaths of allegiance and supremacy, were subjected to the bar of the double land tax.

By a statute made in the second session of the first year of Geo. I. c. 55, they were required to register their names and estates in the manner and under the penalties therein mentioned; and by 3 Geo. I. c. 18, continued by several subsequent statutes, an obligation of enrolling their deeds and wills was imposed on them. Such were the principal penal laws against Roman Catholics, "inmensus salus super alias ascercatarnum legum cumulus," (Liv. 3. 34.), at the time of the accession of the house of Brunswick.

IV. To the enlightened and humane temper of the times during the reign of his present majesty, his Roman Catholic subjects are wholly indebted for any repeal of this large and grievous code. Two acts have already passed for their relief.

IV. 1. The first of these acts was passed in the 18th year of his majesty's reign. It enacted, that so much of the 11 & 12 W. III. as related to the prosecution of Popish priests and Jesuits, and impairing Papists who keep schools, or to disable Papists from taking by devise or purchase, should be repealed as to all Papists continuing in the Popish religion, who, within six months after the passing of the act, or their coming of age, should take the oath preferred by the act.

This act was an essential benefit to Roman Catholics; but its best effect in their regard, was its operation on the public mind, by lessening the prejudices generally entertained against them, and bringing them and their fellow-subjects into habits of social intercourse and amity, which the penal code had too much interrupted. It can only be conceived by those who witnessed it, what a sudden and extensive effect, in this regard, was produced by this single act of parliament.

IV. 2. A more extensive relief from the penal laws was granted to the English Roman Catholics by an act of the 31st year of the reign of his present majesty. The extent and the conditions of this relief will be stated under the article Toleration.

V. 1. It has been already shown, how the law stands on the Corporation and Test Acts. The statute of the 18. William and Mary, (commonly called the Toleration Act), exempts all Difenters, except Papists, and such as deny the Trinity, (with regard to whom an alteration has lately taken place, see Trinity,) from all penal laws relating to religion, provided they take the oath of allegiance and supremacy, and subscribe the declaration against popery, and pay to some congregation registered in the bishop's court, or at the sessions. But there is nothing in this act which affects, either with the Test Act or the Corporation Act, so far as they impose the obligation of receiving the Lord's supper or adorning offices, or electing to serve in corporations. With respect, therefore, to the Test Act and the Corporation Act, there are the only acts which subject the Protestant dissenters to any penalties or disabilities. To these the Roman Catholics are subject, equally with the Protestant dissenters. There is, therefore, no penalty or disability that affects the Protestant dissenters, to which Roman Catholics are not subject equally; but there still remain several penal laws, the effect of which is most severely felt by Roman Catholics, but the effect of which is not, in any manner, felt by Protestant dissenters.

V. 2. The first of these is the 30th Car. II. stat. 2. c. 1, which provides that no person should fit or vote in the house of peers, or be a member of any house in the house of commons, till he has taken the oaths of allegiance and supremacy, and made and sworn the declaration against popery, and repair to some congregation registered in the bishop's court at the requisition of a candidate, are disabled from voting at elections.

V. 3. By the 7th and 8th of W. III. c. 27, those, who refuse to take the oath of supremacy, tendered tender, refused to them; Quakers, and even Jews, having the full enjoyment of the right of presentation.

V. 4. By several statutes, Roman Catholics are disabled from presenting to advowsons. This disability is peculiar to them; Quakers, and even Jews, having the full enjoyment of the right of presentation.

V. 5. Lastly, Roman Catholics alone feel the penal operation of 1 Geo. I. stat. 2. c. 13, which requires all persons, bearing offices, civil or military, or holding command or place of trust, or receiving pay or wages, by reason of any patent or grant from his majesty, to take the oath of supremacy under the penalty of 500l. and under other penalties.

Such are the penal laws under which the Roman Catholics of England labor. They have presented petitions to both houses of parliament for their repeal, and with them succeed; but we still more anxiously wish for that time, when the imperial parliament of the united empire will see the injustice and impolicy of every restriction on religious opinion, and at once abolish the whole religious penal code.

The Declaration and Toleration signed by the English Catholics in 1789.

We, whose names are hereunto subscribed, Catholics of England, do freely, voluntarily, and of our own accord, make the following solemn Declaration and Protestation:

Whereas sentiments unfavourable to us, as citizens and subjects, have been entertained by English Protestants, on account of principles which are ascertained to be maintained by us and other Catholics, and which principles are dangerous to society, and totally repugnant to political and civil liberty;—it is a duty that we, the English Catholics, owe to our country as well as to ourselves, to protest, in a formal and solemn manner, against doctrines that we condemn, and that constitute no part whatever of our principles, religion, or belief.

F f 2

We
We are the more anxious to free ourselves from such imputations, because divers Protestants, who profess themselves to be real friends to liberty of conscience, have, nevertheless, avowed themselves hostile to us, on account of certain opinions which we are supposed to hold. And we do not blame these Protestants for their hostility, if it proceeds (as we hope it does) not from an intolerant spirit in matters of religion, but from their being misinformed as to matters of fact.

If it were true, that we, the English Catholics, had adopted the maxims that are erroneously imputed to us, we acknowledge that we should merit the reproach of being dangerous enemies to the state; but, we detest those unchristian-like and execrable maxims; and we severally claim, in common with men of all other religions, as a matter of natural justice, that we, the English Catholics, ought not to suffer for or on account of any wicked or erroneous doctrines that may be held by any other Catholics, which doctrines we publicly disclaim, any more than British Protestants ought to be rendered responsible for any dangerous doctrines that may be held by any other Protestants, which doctrines they, the British Protestants, disavow.

First, We have been accused of holding, as a principle of our religion, that princes excommunicated by the pope and council, or by authority of the see of Rome, may be deposed or murdered by their subjects, or other persons.

But, so far is the above mentioned unchristian-like and abominable position from being a principle that we hold, that we reject, abhor, and detest it, and every part thereof, as execrable and impious: and we do solemnly declare, that neither the pope, either with or without a general council, nor any prelate, nor any priest, nor any assembly of prelates or priests, nor any ecclesiastical power whatever, can absolve the subjects of this realm, or any of them, from their allegiance to his majesty George the Third, who is, by authority of parliament, the lawful king of this realm, and of all the dominions thereunto belonging.

Second, We have also been accused of holding, as a principle of our religion, that implicit obedience is due from us to the orders and decrees of popes and general councils; and that therefore if the pope, or any general council, should, for the good of the church, command us to take up arms against government, or by any means to subvert the laws and liberties of this country, or to exterminate pernicious of a different persuasion from us, we (as is alleged by our accusers) hold ourselves bound to obey such orders or decrees, on pain of eternal fire:

Whereas, we positively deny that we owe any such obedience to the pope and general council, or to either of them; and we believe that no act that is in itself immoral or dishonest can ever be justly formed by or under colour that it is done either for the good of the church, or in obedience to any ecclesiastical power whatever. We acknowledge no infallibility in the pope; and we neither apprehend nor believe that our disobedience to any such orders or decrees (should any such be given or made) could subject us to any punishment whatever. And we hold and insist, that the Catholic church has no power that can, directly or indirectly, prejudice the rights of Protestants, inasmuch as it is strictly confined to the refusing to them a participation in her sacraments and other religious privileges of her communion, which no church (as we conceive) can be expected to give to those out of her pale, and which no person out of her pale will, we suppose, ever require.

And we do solemnly declare, that no church, nor any prelate, nor any priest, nor any assembly of prelates or priests, nor any ecclesiastical power whatever, hath, have, or ought to have, any jurisdiction or authority whatsoever within this realm, that can, directly or indirectly, affect or interfere with the independence, sovereignty, laws, constitution, or government thereof; or the rights, liberties, persons, or properties of the people of the said realm, or of any of them, save only and except by the authority of parliament; and that any such assumption of power would be an usurpation.

Third, We have likewise been accused of holding, as a principle of our religion, that the pope, by virtue of his spiritual power, can dispense with the obligations of any compact or oath taken or entered into by a Catholic; that therefore no oath of allegiance, or other oath, can bind us, and, consequently, that we can give no security for our allegiance to any government.

There can be no doubt but that this conclusion would be just, if the original proposition upon which it is founded were true; but, we positively deny that we do hold any such principle. And we do solemnly declare, that neither the pope, nor any prelate, nor any priest, nor any assembly of prelates or priests, nor any ecclesiastical power whatever, can absolve us, or any of us, from, or dispense with, the obligations of any compact or oath whatsoever.

Fourth, We have also been accused of holding, as a principle of our religion, that not only the pope, but even a Catholic priest, has power to pardon the sins of Catholics at his will and pleasure; and therefore, that no Catholic can possibly give any security for his allegiance to any government, inasmuch as the pope, or a priest, can pardon perjury, rebellion, and high treason.

We acknowledge also the justness of this conclusion, if the proposition upon which it is founded were not totally false. But, we do solemnly declare, that, on the contrary, we believe that no sin whatever can be forgiven at the will of any pope, or of any priest, or of any person whomsoever; but that a sincere sorrow for past sin, a firm resolution to avoid future guilt, and every possible atonement to God and the injured neighbour, are the previous and indispensible requisites to establish a well-founded expectation of forgivenes.

Fifth, And we have also been accused of holding, as a principle of our religion, that ‘no faith is to be kept with heretics;’ so that no government which is not Catholic can have any security from us for our allegiance and peaceable behaviour.

This doctrine, that ‘faith is not to be kept with heretics,’ we reject, reprobate, and abhor, as being contrary to religion, morality, and common honesty: — and we do hold and solemnly declare, that, of faith with any person whomsoever can ever be justified by reason of or under pretence that such person is a heretic or an infidel.

And we further solemnly declare, that we do make this Declaration and Protestation, and every part thereof, in the plain and ordinary sense of the words of the name, without any evasion, equivocation, or mental reservation whatsoever.

And we appeal to the justice and candour of our fellow citizens, whether we, the English Catholics, who thus solemnly disclaim, and from our hearts abhor, the above mentioned abominable and unchristian-like principles, ought to be put on a level with any other men who may hold and profess those principles?

The above Declaration and Protestation was signed by one thousand seven hundred and forty persons; including several peers, and two hundred and forty-one clergymen of the Catholic religion.

PAPIUUCHI, in Geography, a town of Mexico, in the province of Mayo; 150 miles N. of Santa Cruz.

PAPLACH,
PAPLAH, a town of Aisa, and capital of a small country, dependent upon Thibet; governed by a rajah; 93 miles N. of Fyzabad. N. lat. 28° 20'. E. long. 82° 53'.

PAPOUL, 5th., a town of France, in the department of the Aude, before the revolution the see of a bishop; four miles E. of Caillaudary. N. lat. 43° 20'. E. long. 7° 4'.

PAPOZZE', a town of Italy, in the department of the Lower Po; 22 miles N.E. of Ferrara.

PAPPAN, a town of Prussia, in the patinate of Culm; 10 miles S.E. of Culm.

PAPPENBURG, a sea-port town of Earl Friesland, on a canal which communicates with the Ems. Although it has been lately erected, it contains 19 yards for ship-building, 2 churches, 400 houses, and 3000 inhabitants. To this port belong 160 vessels, the largest of which carry 160 harts, with about 100 small craft; 20 miles S. of Emden. N. lat. 53°. E. long. 7° 28'.

PAPPENHEIM, a town of Bavaria, and capital of a county, in the bispohic of Aichfatt, on the Altmuhl. The established and universal religion is Lutheranism; 12 miles N.W. of Aichfatt.

PAPON, John Peter, in Biography, was born in the year 1738, at Puej, near Nice. He entered while he was young into the congregation of the Oratory, and became a distinguished member. He passed his life in tranquility, exempt from ambition and intrigue, and his spirits were fearceely affected by the loss of pension, which constituted his chief support, at the commencement of the revolution. During the reign of the infamous Robespierre, he took refuge in the department of the Puy-de-Dôme, whence he afterwards returned to Paris. He died in 1807, in the sixty-fifth year of his age. His principal works are as follows: "An Ode to Death," inserted in the collection of the Floral Games of Toulouse: "L'Art du Pepe et de l'Orateur;" "Voyage de Provence," 2 vols. 12mo.; "Histoire de Provence," 4 vols. 4to. He wrote some pieces relative to the French revolution, and a work entitled "Epoques memorables de la Pele," in two vols. 8vo. To the history of Provence many ancient documents were annexed; and for the purpose of discovering new authorities the author took a journey to Naples, and procured, among other pieces, the Quittance given by queen Joan to pope Clement VI. for the price of Avignon, which he fold him.

Gen. Ch. Cal. Glume of two long, linear, somewhat compressed, very thin, pointed, awnless valves, containing two florets; the outermost valve a little the shortell. One floret below the other, longer, softer, bearded at the base, perfect; the second raised upon a short ilalk, smaller, pressed close to the back of the former, bearded, neater; above there is the rudiment of a third, sometimes of a fourth. Cor. Glume of two valves, shorter than the calyx; the outermost ovate, swelling, angular, terminated by numerous, nine to thirteen, very long, straight, unequal, feathery or rough, spreading awns, its edges embracing the inner glume, which is lanceolate, acute, rather longer and narrower than the outer. Nectary minute, of two linear leaves. Stami. Filaments three, capillary; anthers oblong. Fil. German ovate, superior; style two, short; stigma villos. Peric. none, except the corolla, which encloses the seed, but is not united to it. Seed solitary, ovate, compressed, pil-lucid.

Eff. Ch. Calyx of two linear, nearly equal, valves, containing two florets, with the rudiments of more. Corolla of two valves, the outermost with numerous awns.

Obi. The outer glume of the lowermost floret is villous at the back and fides; the inner glume is hollowed out at the back, for the reception of the upper, or neater, floret. The awns have the appearance of the down of the seeds of syngeneceous flowers. Schreb.

1. \textit{P. alpescovoidium} Vahl. Symb. v. 3. 1606. 511. (Saccharum pappiferum; Lamamck Illnifs. v. 1. 155.)—Awns thirteen, minutely toothed.—Native of South America. Root perennial. Stem branched, three or four feet high, smooth. Leaves convoluted, acute, flrated, shorter than the stem. Puricule or spike erected, compound, eighteen inches long, resembling that of \textit{Agrostis paniaca}, Wildl. Sp. Pl. v. t. 365. Engl. Bot. t. 1704. Wildl. The calyx, according to Vahl, contains sometimes four florets, though only one is perfect.

2. \textit{P. migrans}. Brown n. 1.—Awns nine, feathery. Spike compound, somewhat cylindrical, with imbricated lobes. Glumes very finely downy. Leaves and sheaths naked, roughish. Gathered by Mr. Brown, in the tropical as well as southern parts of New Holland, and at Port Jackson.

5. \textit{P. gracile}. Br. n. 4.—Awns nine, feathery. Spike divided in the lower part; simple above. Glumes downy. Leaves involute, smooth, as well as the stems.

We have taken the specific characters of all the five species from Mr. Brown, having seen no specimen of any of them.

PAPPOSE PLANTS, in Gardening, are all those which have a downy kind of flowers, or a fort feathery crown of the same nature, which adheres to the seeds of many of them, as are exemplified in the lettuce, the dandelion, the low-thistle, groundsel, and some other forst. A great many of these kinds of plants also produce compound flowers, the seeds of which are furnished with a portion of this downy fulbance adhering to the top part of each, so as in some degree to resemble a shuttle-cock, being naturally framed for flying, in order to spread and disseminate the seed, and transport it to considerable distances by the wind, so that it may be fown and deposited in different lots and situations, instead of being confined to a single spot.

Among this class of plants are some of the most troublesome weeds, the seeds of which are, by the means which they thus possess, carried and scattered in the gardens and fields, to the great inconvenience and trouble of the gardener and farmer.

These are likewise frequently called winged seeds. See the following article, and Weeds.

PAPPUS, in Botany and Vegetable Physiology, Seed-down; the hairy or feathery, sometimes chaffy, radiant crown of the feed, in the natural order of Compound Flowers, or Syngeneceous clafs, &c. Such being the true chaffical acceptance of this Latin word, as well as the Greek \textit{pappos}, from whence it comes. The use of this part is to waft the seed to a distance, in dry and windy weather, when the \textit{pappus} is most light and expanded; by which means such
such plants are widely dispersed. Finally it either slips off,
by the drying and contraction of the summit of the seed,
as in Thistles; or the seed having fixed itself in the earth,
the down is broken off by the wind, or some other acci-
dental cause; in either case the seed is left behind, to ger-
minate without further disturbance. The down, having ful-
filled its primary definition, often serves a secondary pur-
pose in the economy of nature; being hoarded up by birds,
and the smaller quadrupeds, to compose or to line their nests,
or winter retreats. Its texture is not such as to render it
fit for being woven, by human art, for any use.
Gärtner properly refrains the term pappus to compound
flowers; though Linnaeus and others use it indiscrimin-
ately for such, and for the hairy appendages to the top,
filaments, or bafe, of other seeds, even when they are enclosed in a cap-
fule; witnesses Epilobium, Ajeglaia, and many others of the
Contortus, Salix, Eriophorum, &c. Gärtner uses the word
Coma, when such an appendage is situated at the top of the
seed; Pubes when it originates from the bafe or filaments, as in
Gypsium, the Cotton plant.
The proper Pappus of fyngeous compound flowers is
either falked, as in the Common Dandelion, or felfie, as in
the Thistle; in both which examples its rays are of a fea-
chey structure. In Hieracium the rays are, or ought to be,
fimple; but such a structure is very rare, what are so de-
ferred being for the most part rough or toothed, at leaf,
if not more or less branched or feathery. In Cicerium,
and several other genera, the pappus consists of dilated chally
feathery parts, either flat, or fringed, or furnished with their bafe,
which clearly shows the affinit of the part to a calyx. This
more strikingly appears in Stachis, in which the term is ad-
mitted, even by Gärtner, that genus having compound,
though not fyngeous, flowers. Here the pappus is
double, very variously and curiously constructed in the dif-
ferent fpecies. Bidens has a pappus of two, three, or four
rigid barbed bristles, evidently contrivd fo for the purpose
of attaching the feeds to the coats of animals, or to any
thing else that may come in the way, in order to aid in their
diffusion by that means, instead of their being wafted on
the wings of a light feathery feed-down. The variety of
structure in the part in question is indeed highly curious,
some plants having two forts of pappus to the different
florets of the fame flower; see Hedyhuis. A judicious,
but not indiscriminate, attention to its differences, affords
one of the bell clues to a knowledge of the fyngeous genera;
but in this as well as other cafes no difference must
be considered as absolute; the genus always being required
to give the character, not the character the genus.
Pappus in Biography, a very eminent Greek mathematician
of Alexandria, who flourished in the fourth century,
during the reign of Theodosius the Great, who preceded over
the empire from the year 379 to 395. Such of his works
as are still extant, prove that he was profoundly skilful in
the mathematical sciences: the greater part of his productions
are probably loft, among which are a "Commentary
upon Ptolemy's Almagest;" " A Description of the Rivers
of Lybia;" " An Universal Chronography;" a treatise
"On Military Engines;" " Commentaries upon Ariftarchus
of Samos, concerning the Magnitude and Diftance of the Sun
and Moon." Reference is made by Marinus, a disciple of
Prœclus, to his "Mathematical Collections," in eight books,
of which the last six, and part of the second remain. They
were among the manuscripts presented by Sir Henry Saville
to the Bodéican library at Oxford. To this work, Marcus
Melambius annexed some Iemmata, from the seventh book,
in Greek, with a version of his own, to his "Dialogue on
Proportions;" published at Copenhagen in the year 1663;
and Dr. Wallis printed the last twelve propositions in Greek,
from the Savilian MS. with a Latin version and notes at the
end of his edition of Ariftarchus' treatise "On the Magnitude
and Diftance of the Sun and Moon;" and also in the third
volume of his "Mathematical Works." In the year 1703,
Dr. David Gregory gave part of the preface to the feventh
book, in which the author treats of the geometrical analyses
of the ancients, &c. in Greek, accompanied with the Latin
version of Commandini, in the Prolegomena to his edition
of English; and in 1706 Dr. Edmund Halley printed the
whole preface, in Greek and Latin, in the Prolegomena to
his edition of the Conics of Apollonius. And, to mention
no other infallses of a like kind, we may observe, that
the whole of what remains of the "Mathematical Collections,
" was published at Bologna in 1660. For an analysis of these
collections, we refer to Hutton's dictionary, art. Pappus.

PAPRA, in Geography, a town on the W. coast of Siam.
N. lat. 8° 10'. E. long. 98° 30'.

PAPREMIS, or PAPREMIS, in Ancient Geography, a
town of Egypt, and the capital of the Papremite nome.
In this place the hippopotamus was regarded as a sacred animal:
and Mars was honoured with a fignular ceremony. Upon
the festival appropriated to this deity, the priests bore upon
a four-wheeled chariot the flature of the god, which was en-
closed in a small chapel of gilt wood; and while they en-
deavoured to force the chariot and flature into the temple of
that divinity, men armed with clubs flogged in the way to hinder
it; and as the priests who accompanied the procession
had likewise arms, there ensued an engagement, when
naturally many people muft have loft their lives. The Egypt-
ians, however, maintained that nobody died of the wounds
they received upon that occasion.

PAPS, in Geography, the two remarkable mountains of
the county of Kerry, Ireland, about eight miles E. by S.
from Killarney.—Alfo, two remarkable hills of Upper Ca-
nada, on the N. shore of lake Superior.

PAPUA. See New Guinea.

PAPUDA BAY, a bay on the coast of Chili, in the
South Pacific ocean, five leagues N. of the shoals of Quin-
taro and four from port Liga; the water is deep, the an-
chorage good, and the entrance fafe.

PAPULA, in Medicine, a diminutive of papa, the
nipple, signifies a fmall, hard, and acuminated elevation of the
surface of the skin, which has an inflamed bafe, but feldom
contains a fluid, or tends to suppurate. It is fynonymous
with the English term pimple.

This appellation has been applied by medical writers to a
confiderable variety of eruptions; but, in the more accurate
nomenclature of cutaneous difeases, adopted by the late
Dr. Willan, its signification is limited, as above, to a minute
fumour, which appears to originate in an inflammation of
the papula of the skin, by which these are enlarged, ele-
vated, and indurated, and made to affume more or less of a
red colour; they do not end in suppuration like pufules,
but commonly terminate in a fcory exfoliation of the cuticle.
The moft accurate nofologists, indeed, ftem to have agreed in
retrenching the meaning of the word to this fene. Thus
Sauvages defines papula, "Phyma parvulum, defquamari
See alio Linnæi, Gen. Morbor. clafs xi. ord. 4.) Among
the ancients, Celsius feems to have underftood the term in
the fame acceptation, although he applies it generally,
apparently to the lichen. De Medicinæ, lib. v. cap. 28.

The papula eruptions constitute the first order in Dr.
Willan's ingenious classification of difeases of the skin; and
of these he has described three distinct genera; namely, the
Strophiums, red-gum, or tooth rogue, of children; the Li-
chen,
PAPYRUS, from papyrus, Lamarck Illistr. t. 762, a name given by that author to the Paper Mulberry, in allusion to the use made of its bark, from which most of the East Indian and Chinese paper is prepared, as well as the cloth of Othello. This plant, originally found by Linnaeus under Morus, was separated from thence, as a distinct genus, by l'Héritier, who called it Broussonetia, in honour of his friend P. M. Augustus Broussonet, M. D. an excellent botanist and ichthyo-logist, who first introduced this valuable tree alive into the French gardens. He was also one of the most zealous diffusers of the Linnean school in that country, and an undisguised opponent of those, who, from envy or prejudice, depreciated the merits of the great naturalist of Sweden. Hence it seems that Lamarck was not inclined to adopt the name l'Héritier had proposed, if he was actually acquainted therewith, and he retailed that sort of neglect or opposition which he had, in many instances, received from his rival. Ventenat, however, and Willdenow, have restored Broussonetia, which has every claim to preference, and it is adopted in this country, where the merits and amiable character of Dr. Broussonet are well known to several, who have sincerely deplored the misfortunes which, like many good Frenchmen, he experienced under Robespierre, and his subsequent untimely death. One of our predecessors has passed over this name; see Broussonetia, as it is very erroneously printed. We beg here to leave its just claims, though out of its alphabetical place.

Female, on a separate plant, Cal. Perianth inferior, tubular, of one leaf, with four, rarely but three, segments, permanent. Cor. none. Petal German somewhat falked, ovate, compresed; fryle lateral, awl-shaped, elongated, permanent; stigma simple. Pet. none, except the elongated, pulp, coloured, forked, club-shaped receptacle, on which the seed is elevated as on a flak, and enclosed between its points. Seed solitary, ovate, partly covered by the forks of its pulp supporter, and accompanied by the capillary withered style. Common receptacle globose, very denly covered with flowers spreading every way, and interpersed brily permanent scales.

Eff. Ch. Male, Calyx in four deep segments, Corolla none.

B. papyrifera. Paper Mulberry. Andr. Repov. t. 488. (Morus papyrifera; Linn. Sp. Pl. 1399. M. fativa, folius urice morte, cortice papyrifera; Kempf. Am. Exot. 476, (477.)—Native of Japan; probably also of China, and the South Sea Islands. At least it is cultivated in all those countries. It appears from Miller to have been introduced into England before the year 1759, by the late duke of Northumberland. Dr. Broussonet saw the female tree in fruit at London, and possibly, as Poiret indicates, at Edinburgh, in 1752, and carried it with him to Paris, where the male only had previously been known, and consequently no fulpinion could have arisen of its not being, as Linnaeus supposed, a Morus, though dioecious. (See Morus) it there bore fruit, which it continually does at Kew, and in other gardens, being quite hardy, and blooming all summer long. This is a deciduous tree, of a moderate size, with the aspect of a mulberry, or rather of some arborecent Ulrice. Branches alternate, round, downy, leafy at the extremities. Leaves alternate, falked, ovate or somewhat heart-shaped, acute, serrated, deeply lobed and incised without any regularity, so that scarcely two can be found precisely alike; their upper fide of a dull hoary green, very rough with minute cartilaginous tubercles; the under paler and downy, with numerous veins. Stipula in pairs, ovate, pointed, downy. Flowers axillary, falked; the male in very dense, cyllindrical, blunt, drooping, greyish spikes, which have the aspect of catkins; female on a distinct tree, in equally dense, green, globular heads, about an inch in diameter. As the fruit advances, numerous scarlet, juicy, club-shaped, incurved bodies are protruded in every direction, in whose summits the feed is lodged. These have a sweet flavour, but are not of consequence sufficient to render the fruit an object of cultivation, though it is not defilute of beauty.

The chief importance of this tree, consists in the ufs of its bark. The clothing of the inhabitants of the South Sea Islands, in their primeval simplicity, was almost entirely prepared from it, several layers of the bark being laid over each other, and incorporated by beating, aided with some flight cement; and so elegantly coloured with the natural productions of the country, as to excite the admiration of our most intelligent voyagers. Kempf gives a particular account of the preparation of the Japanese paper from this bark. For this purpose the branches of the present year, after the leaves are fallen, in December, are chofen, and being cut into pieces about a yard long, are boiled, till the bark shrinks, and is equally separable from the wood, which is then thrown away. The bark being dried, is preserved till it is wanted. In order to make paper, it is soaked for three or four hours in water, after which the external skin, and the green internal coat, are scraped off. At the samte time the stronger and firmer pieces are selected, the produce of the youngest floots being of an inferior quality. If any very old portions present themselves, they are, on the other hand, rejected as too coare. All knotty parts, and every thing which might impair the beauty of the paper, is also removed. The chozen bark is boiled in a lixivium, till its downy fibres can be separated by a touch of the finger. The pulp so produced is then agitated in water, till it resembles tufts of tow. If not sufficiently boiled, the paper will be coarse, though strong; if too much, it will be white indeed, but deficient in strength and solidity. Upon the various degrees and modes of washing the pulp, much also depends, as to the quality and beauty of the paper. Macilage obtained from boiling rice, or from a root called Orang, Kempf. 474, one of the mallow tribe, is afterwards added to the pulp. The paper is finnished much after the European mode, except that falks of rushes are used instead of braids wires. See Paper.

PAPYRUS. See Cyperus.

PAQUASHE
PAR

PAQUASHE LAKE, in Geography, a lake of North America. N. lat. 50° 48’. W. long. 93° 30’.

PAQUILIGASTA, a town of South America. In the province of Tucuman; 40 miles S.S.W.of S. Miguel de Tucuman.

PAR, a term of nobility. See Peer.

PAR, CATHERINE, in Biography, sixth wife of Henry VIII. was daughter of Sir Thomas Par, and received, according to the custom of the age, a learned education. She was known to be friendly to the reformation, and on that account bishop Gardiner, and others, whose zeal and bigotry were ever displayed against the reformers, endeavoured to effect her ruin, but by her practice she preferred the king’s favour till her death. In the year 1544 she was so much in the confidence of her royal spouse, that he made her regent while he went with a great army into France. After this she had a narrow escape from imprisonment, of which Mr. Hume has given an interesting account. Immediately after the death of the monarch she married lord Seymour: the ceremony was, indeed, performed with so much haste, that the historian already quoted, says, “had she soon proved pregnant, it might have been doubtful to which husband the child belonged.” She was extremely ill-treated by this second husband, which so much affected her, that she died in child-bed in the year after her marriage. Hume, vol. iv.

Walpole’s Royal and Noble Authors.

PAR of Exchange. This subject, which is so very familiar in the mouths of commercial men, yet so little understood, has been already incidentally noticed under the article Exchange; but as what was said of it there refers more to its practical nature, than to the general principles on which it is founded, and by a knowledge of which alone it can be satisfactorily and fully ascertained, we shall enter more regularly and systematically into the discussion of it in this article. Most of the difficulties, and much of the obscurity, which encompass that part of the science of political economy, which relates to the commerce between nations, would be removed, if we were to consider this commerce as exactly the same in its nature, operations and effects, as the trade that is carried on between different parts of the same kingdom, or even between two individuals: by bringing the subject thus within a narrower compass, and placing it in a point of view more familiar and more within the reach of our observation and experience, we should be enabled to examine it more attentively, and so render ourselves acquainted with it more accurately, not only in its general principles, but in its minute and complicated details. These remarks will apply with peculiar force and propriety to the subject which we are about to discuss: in entering upon it, if we take our illustrations and examples, not from what passes in the commercial intercourse of two distinct nations, the denomination and value of whose currency differs, but from what occurs in the commercial transactions that are carried on between different parts of the same kingdom, we shall clear the way so completely, as to be enabled to proceed without impediment, confusion, or difficulty.

Let us take, as an example, the commercial intercourse between London and York: and suppose that in the former city, there are merchants who owe to their correspondents in London the sum of 2000L, and merchants who have demands on their correspondents in London to the same amount. The obvious and natural mode of settling these claims, would be for the merchants who have money to pay in London, to pay the amount to the merchants who have money to receive in London: by this mode the York merchants, so far as they alone were concerned, would have their business settled; but there would yet remain to be arranged the pecuniary business of the London merchants, who either were indebted to the York merchants, or had money to receive from them: the mode of adjusting their business would be equally obvious and natural. The York merchant who had received the 2000L. from his brother merchant in the same city, as a settlement of the debt to that amount due to him in London, would in return give him an order for that sum on the London merchant his debtor; which order, transmitted to London, would serve to discharge the debt that the York merchant owed in the capital. It is easy to perceive what trouble and expense are saved by this arrangement: were it not adopted, the York merchant who owed 2000L. in London, must have arranged this debt to London; and a similar expense must have been incurred by the other York merchant, or by his debtor in London, in transmitting the 2000L. from London to York. When the general plan of adjusting the debts in this mode was once arranged, there would be no difficulty in carrying it into execution, as the currency in York and London were exactly the same; but the cafe, in this respect, would be altered, if Dublin and London were concerned, instead of York and London. The currencies of England and Ireland differ in real value, though they are exactly the same in denomination. Let us now suppose that a merchant in London owes 2000L. in Dublin, and another merchant has 2000L. to receive in London. They would respectively have the freight and insurance of this sum, if in London they could adjut what they have respectively to receive or pay in Dublin: had the currencies of Ireland and England been exactly the same in real value, as they are in denominative value, there could not be the slightest difficulty in making this arrangement; but as there is a difference in the real value of the currencies of these two countries, this difference must be satisfactorily and exactly ascertained before any arrangement can take place. When this difference in the real value is determined, the par of exchange is said to be fixed; or in other words, the sums in the currencies of the two countries, which contain exactly the same quantity of the precious metals, are ascertained. In the case we are now supposing, viz. that between England and Ireland, the currency of the latter country is about eight per cent. worse than the currency of England; or in other words, the denominative value of the currency of the two countries being the same, there is about eight per cent. les of the precious metals in the coin of Ireland of the same denomination as of England: a debt of 2000L. in Ireland, therefore, could be discharged for eight per cent. less of real value, than the same nominal debt could be discharged for in England: on this account the English merchant, who owes this sum in Ireland, and who wishes to discharge his debt by paying a sum of money to the other English merchant, who has owing to him 2000L. in Ireland, will only pay to the latter 2000L. minus eight per cent.; and the latter, if he receives this sum, will receive the full amount of his debt. It may perhaps be thought that the latter will refuse to accede to this mode of settling his debt: but a little reflection will convince us that in this, as in the former case between York and London, both merchants are accommodated in an equal degree by this arrangement; for let us see how they must proceed, if they did not accede to it. The merchant who owes the 2000L. in Ireland would be obliged to transmit there as much bullion as would be equal in value to 2000L. Irish currency; and the merchant, who had money to that amount to receive from Ireland, could get from that country only as much bullion, as that sum of Irish currency would purchase: hence, as the expense of freight, insurance, &c. would be the same in each case, it would evidently be for their
their mutual advantage to settle their debts and payments in the manner which has been described.

The general rules, therefore, in fixing the par of exchange between any two countries, is by ascertaining the real value of the coin of thefe countries: if the fame quantity of gold or silver is contained in two coins of two countries, these coins are equal in value to each other; if there is more gold or silver contained in the coin of one country, than in the coin compared with it of the other country, the values are not equal, but proportional: and the proportions can always be accurately expressed by the smaller coins, of which the larger ones that are compared are compounded. Thus, let us suppose that the ruble of Russia, and the half-crown piece of Britain, contain exactly the fame quantity of silver of the fame fineness: then the par of exchange between Britain and Russia will be the ruble and the half crown piece; but if the intrinsic value of either or both of them may be changed, though their denominations remain the fame, the par is more commonly expressed by the smaller coins which form them, as in the cafe of the half-crown, by the pence which compose it; and the par of exchange between England and Russia, is said to be, when the ruble of the latter country is at thirty pence. Again, let us suppose that the crown piece of Great Britain and the dollar of Spain are compared, and that it is found that the former contains more silver of the same purity than the latter: the difference can easily be ascertained, and as the crown piece is divided into, or composed of, smaller coins, this difference, when ascertained, can with similar accuracy. The crown piece is equal to sixty pence: the dollar, we shall suppose, contains one-tenth less silver than the crown piece; if the par between Spain and England, therefore, is measured by a reference to these two coins, it will be expressed, by rating it at four shillings and sixpence British for the Spanish dollar. The advantage, and even necessity, of supposing the coins thus compared divided into their component parts, will be further illustrated when we come to consider the circumstances that affect the real or nominal par of exchange.

It may seem superfluous to inquire upon what principle equal quantities of the precious metals are supposed to be of equal value in different countries; yet this requires investigation. Let us suppose that a merchant of London, who owes 2000l. in Dublin, is not able to obtain a bill on that city, and has no other mode of discharging his debt but by transmitting the money. Let us further suppose, that for this purpose he cannot transmit English money to Ireland: how is he to proceed? The only mode he can adopt, is to purchase in London as much bullion as will serve for, or may be coined into, 2000l. in Dublin; he cannot discharge his debt by the mere bullion he transmits; could he do this in all cafes, the principle, that equal weights of bullion were always of equal value in all countries, would be without exception, and would be a fundamental principle, beyond which we could not proceed in illustrating the doctrine of the par of exchange. But if cafes may occur, in which the bullion and the mint value of the precious metals differ, then, in these cafes, we must look beyond this principle, for a principle more steady upon which to ground the doctrine of the par of exchange. Let us suppose that the merchant who owes 2000l. in Dublin, being perfectly well acquainted with the quantity of the precious metals contained in this sum of Irish currency, purchases that quantity in London, and transmits it to Dublin: in the mean time, a difference has taken place in this city, between the bullion and the mint value of the precious metals; the bullion value has fallen, so that the quantity of bullion transmitted will not fall for 2000l. Irish currency. In this case we perceive, that by fixing the par merely by a reference to the quantity of the precious metals in the coins of any two countries, we should fix it inaccurately; it may, indeed, be alleged, that the bullion and mint value of the metals can never differ much, nor for a long continuance; but as they may, and do differ, though to ever so trifling an amount, and for ever so short a time, we must correct the principle on which the par of exchange is fixed: thus corrected, it will stand thus; —the par of exchange must be estimated, not by a comparison between the quantities of bullion contained in the coins of any two countries, but by a comparison between the quantities of bullion which these coins will purchase; this is the accurate principle; but as in most cafes the bullion and mint value are equal; and as, where an inequality does exist, it is very trifling, and continues but for a very short period, the usual manner of computing the par of exchange is, in most inferences, sufficiently just and accurate.

It must, however, be observed, that the comparison of the coins of different countries has not been made with all that skill and attention which ought to have been employed upon it: indeed the par seems to have been fixed at a time when the art of affaying metals and determining their positive and relative purity was comparatively but little known.

But the loose and inaccurate mode in which the par of exchange has been fixed, as well as the unfoundedness of the principle, which would infer an equality of value in the coins of two countries from the circumstance of their containing the same quantity of the precious metals, will be further confirmed and illustrated by a reference to the coinage of France before the revolution. At that time a duty, or seignorage of eight per cent. was paid on all bullion brought to the mint for the purpose of being coined. Let us suppose that a Louis d'or, and an English guinea, contained each the same quantity of gold, of the same purity, and that that quantity was a quarter of an ounce, according to the principle that we are examining, the exchange between England and France would be paid to be at par, when a guinea in London purchased a bill on Paris for one Louis d'or,线条, in this case, a quarter of an ounce of gold in London purchased neither more nor less than a quarter of an ounce of gold in Paris. But a little reflection will serve to convince us, that when a guinea in London purchased a bill for a Louis in Paris, the exchange, instead of being at par, was in fact favourable to England eight per cent.; for, let us suppose that the merchant who had to pay the Louis in Paris could not obtain a bill in London, but was obliged to send bullion to Paris to discharge his debt; how much bullion must he send for that purpose? if a quarter of an ounce of gold would serve to discharge his debt; then, on the supposition that he procured a bill, and paid for it only a guinea, or a quarter of an ounce of gold, the exchange would be at par; but he would find, if he sent only a quarter of an ounce of gold to Paris, that it would not discharge his debt of a Louis. When his gold is brought to Paris, it must either be coined, or fold, before the debt can be discharged: if it is taken to the mint, eight per cent. will be kept to pay the expenses of coinage; consequently, when converted into money, it will not discharge his debt by eight per cent.; if the gold is fold, it will not produce a Louis, or a coin of a quarter of an ounce of the same metal, by eight per cent.; for no person will give the same weight of coined gold for uncoined gold, when the coinage cost eight per cent. The merchant in London, therefore, who has a Louis to pay in Paris, must pay for a bill to that amount the quantity of bullion contained in a Louis, and

Vol. XXVI.
eight per cent. more; or, in other words, he must pay a guinea, and eight per cent. more; and by purchasing a bill on Paris at this rate, he loses nothing, nor does the person who sells the bill gain anything by the transaction; for let us suppose that he can find no merchant to take his bill, but is obliged to get the money due to him in Paris, or in the best manner he is able; with the Louis due to him there, he purchases bullion; and as coined gold is eight per cent. more valuable in Paris than uncoined, he gets for his Louis, (all along supposed to weigh an ounce,) an ounce and one-eighth of uncoined gold, which, when brought to England and taken to the mint, will procure him a guinea, and one-eighth per cent. On the suppositions, therefore, which we have proceeded upon, that a guinea and a Louis contained the same quantity of gold, and that the duty on coinage in France was eight per cent., the par of exchange between England and France would not be a guinea for a Louis, but a guinea and one-eighth per cent. for a Louis; or, in other words, a bill for an ounce of coined gold in Paris, would be worth in London an ounce of gold, and one-eighth per cent. Hence it is evident, that the par of exchange ought not to be fixed by a reference merely to the quantity of the precious metals contained in the coins of two countries; and that the exchange between any two countries is actually at par, when no more is paid for a bill on one of these countries, than would be necessary to procure the bullion that could be sold for, or coined into the sum expressed in the bill, though the sum paid, and the bullion it could procure, were really greater than the sum expressed in the bill.

There is yet another case, which will require to be considered, before we proceed to state and examine those circumstances which affect the nominal and real par of exchange. The currency of almost all countries consists of two different kinds of metals, gold and silver, (for copper, though forming part of the currency, need not enter into our investigation.) The gold and silver currency of all countries is fixed by the proportionate value of these two metals: let us suppose the proportionate value of gold and silver to be as 1 to 15, i. e. that one ounce of gold is worth fifteen ounces of silver. There may be some little difference in this proportionate value in different countries; but the great bullion market of the world keeps it nearly the same, and generally pretty steady. What would be the effect on the par of exchange, on the supposition, that in one of two countries which trade with each other, the proportionate value changed; let us suppose, for instance, that in England the proportionate value continued as stated above, 1 to 15, while in France silver became so much more abundant, that the proportionate value was 1 to 16. Would the par of exchange be affected by this circumstance? and if it were affected, in what mode, and to what extent would it be affected? In the case supposed, the price of silver would fall in France while it continued steady in England; or, in other words, if we suppose no duty on coinage to exist in either of these countries, the bullion price of silver in France would fall below its mint price, and silver bullion would exchange for less gold bullion than it did before; but the proportionate value between coined gold and silver would remain the same. It might, at first sight, appear, that a merchant in London, who had a debt to discharge in Paris, would be benefited by this circumstance; as, it may be said, he might transmit gold bullion, which, in Paris, would command a larger quantity of silver than formerly; undoubtedly this would be the case, for every ounce of gold transmitted to Paris, he would get sixteen ounces of silver instead of fifteen, as formerly; and if his object were to bring this silver to England, and there exchange it for gold, he would profit by the alteration in the proportionate value of the two metals, since in England he would obtain an ounce of gold for fifteen ounces of silver, and thus have a profit of one ounce of silver in the transaction; but in the case here supposed, that he has a debt to discharge in Paris, he would not be benefited by the alteration in the proportionate value of the two metals, unless he took the sixteen ounces of silver to the mint, for if he sold the silver bullion, he would get as much less for it as its value had fallen in proportion to gold: if, however, he took sixteen ounces, instead of fifteen, to the mint, it is obvious that he would get more silver coin, and consequently that his ounce of gold, by this variation in the proportionate value of the two metals, would enable him to discharge his debt on easier terms, provided it could be discharged in silver. But if the amount of the debts were very great, payment of it in silver could not legally be enforced. This circumstance, joined to the consideration that the proportionate value of the gold and silver currency of any country must always be kept as nearly as possible the same as the proportionate value of gold and silver bullion in that country, will always prevent the par of exchange being much, or for any length of time, affected by a change in the relative value of gold and silver in any two countries. On the contrary supposition, that gold falls and silver rises, it is evident, that, for instance, one ounce of the former metal is worth only fourteen ounces of the latter, it is obvious that the comparatively greater expense of the freight of silver will prevent a merchant from taking advantage of this circumstance, and consequently will keep it from having any material influence on the exchange.

In treating on this subject, it is of the utmost importance to distinguish accurately and clearly between the nominal and the real par of exchange; they are often confounded both in theoretical and practical writings. The cause of this confusion will be at once explained by a consideration of the circumstances that affect the nominal par of exchange as separate and distinct from those circumstances which affect the real par of exchange. The most obvious circumstance that has influence on the nominal par of exchange, is the depreciation of the currency of a country, or a diminution of its real and intrinsic value; as the denomination of the currency continues the same, though its real and intrinsic value is diminished, the par of exchange will also continue the same. Thus, let us suppose, that when the par between Russia and England was fixed, the ruble of the former country, and the half-crown of the latter, each contained exactly the same quantity of silver, of the same purity, and that that quantity was half an ounce. When, therefore, a ruble, exchanged for half a crown, the exchange was at par; let us now suppose, that the ruble of Russia, though still retaining that denomination, no longer contains half an ounce of silver, but only a quarter of an ounce of that metal. In this case it will not exchange for half a crown, or thirty pence, but only for half that sum, or fifteen pence; but the par between the two countries being still considered as fixed at thirty pence the ruble, the rate of exchange will appear to be very much against Russia, when the ruble is quoted as only worth fifteen pence, whereas, in fact, when the ruble will purchase a bill on England for fifteen pence, it purchases its full value; all this is very clear and obvious; but the mode in which this difference in the power of the ruble over British currency takes place, requires some illustration; and this illustration will confirm the position we laid down, that in considering the par of exchange between the two countries, we ought to look beyond the quantity of the precious metals contained in the coins of these countries.
PAR OF EXCHANGE.

To the power of the metals over these coins, when sold for them. Instead of supposing that the ruble was all at once lowered so much, as to contain only a quarter of an ounce of silver, instead of half an ounce, let us suppose that the diminution in the quantity of silver contained in this coin was very trifling, and did not produce a correspondent rise in the nominal price of silver or bullion; or, in other words, that a ruble, though less by one, two, or three per cent. than half an ounce of silver, still would purchase half an ounce of silver bullion. In this case, would the nominal par of exchange between England and Russia be changed? We apprehend not; and for this reason, if a merchant in London, who wished to purchase a bill on Petersburg, refused to give at the rate of half a crown a ruble, on the ground that the ruble no longer contained the same quantity of silver as half a crown, that is, half an ounce, and not being able to obtain the bill on lower terms, determined to transmit bullion, he would soon be convinced, that to discharge his debt, he must pay as much as if he had bought the bill at the rate of half a crown the ruble for, on the supposition made, that the nominal price of silver in Peter- burg had not risen in proportion to the debasement of the ruble, but that this coin, though containing one, two, or three per cent. less silver, still purchased as much silver bullion, he would be obliged to transmit as many half ounces of silver as he had rubles to pay, and consequently it would have been more advantageous for him to have purchased the bill on Petersburg, at the rate of half a crown the ruble.

Thus, we perceive, that unless the power of the coin of any country over bullion is diminished, the mere circum-

stance of the diminution of the intrinsic value of that coin will not affect its exchangeable value, with the unaltered coin of another country, for so long as it can purchase the same quantity of bullion as formerly, it will exchange on equal terms with the foreign coin as formerly. It may, indeed, be objected, that the coined precious metals will always purchase, neither more nor less, than the same quantity of the uncoined metal, which they respectively contain; and consequently, if they contain less than formerly, they will purchase less than formerly; but this, though undoubtedly true in general, is not true universally. Where confidence and credit are great in any country, and where the coin has its intrinsic value slowly and gradually diminu-

ished, merely by the circumstance of its being worn, the nominal value of bullion will not always correspond with the actual depreciation in the value of the coin. Indeed, setting aside the consideration of confidence and credit, there is a great difference between coin worn by use, and coin reduced in the same degree, when it first comes from the mint: in the latter case, no perfon in possession of bullion will sell it for the same number of coined pieces of gold or silver, as he did before their debasement, because, by taking his bullion to the mint, he can get a greater number of coined pieces out of it; he will, therefore, no longer sell his silver at five shillings per ounce, if these five shillings contain only half an ounce of silver, because at the mint he can get his ounce of silver coined into ten shillings; this price, therefore, he will ask for his silver per ounce; and, as has been often remarked, if the price of bullion rises in nominal value, the nominal rate of exchange will rise in the same proportion; so that a foreign coin, containing an ounce of silver, will exchange for ten shillings, instead of five, and thus the exchange will appear to be unfavourable, when, in fact, it is not so, no more being given for the foreign coin than would be necessary to purchase the silver that would fell for it. But it is different, when the coin of a country has undergone a flow and gradual diminution by wear;

in this case, if the bullion merchant refuses to sell his bullion at the old price, what alternative has he: he refuses, for in-

stance, to take five worn shillings for an ounce of silver: but if he carries his ounce of silver to the mint, he gets from it, when coined, only five shillings, which, in the purchase of commodities, are of no more value than the five worn shillings that he refused for his ounce of bullion. In this case, the rate of exchange cannot be even nominally altered; since the coin, though worn, will still fell for as much bullion as formerly, and consequently a debt to be paid in that coin will require as much bullion to discharge it as formerly.

Hitherto we have confined our remarks and illustrations entirely to those cases, in which the metallic currency of a country is supposed to be debased or worn; we shall now examine what effect on the par of exchange will be produced by a paper currency. So long as this paper currency is not depreciated, the nominal par of exchange will be precisely the same as the real one: this position will easily be made out. Let us suppose, as formerly, that the ruble of Russia is the par of the half-crowns of England; and that in the foreign country a paper currency is issued, and that paper rubles circulate as well as metallic ones: so long as these paper rubles are equivalent to the metallic ones, so long will the real and nominal par of exchange be precisely the same. For, as we have already explained, the metallic ruble of Russia is deemed the par of the half crown of England, not (briefly speaking) because each coin contains the same quantity of silver of the same standard, but because the one coin will purchase as much silver, as if sold, or coined, will be equivalent to the other coin; while, therefore, the paper ruble will exchange for the silver ruble, it must have the same command over silver bullion as the silver ruble, and consequently must indirectly have the same command over the half-crown of Eng-

land. Let us now suppose that the paper currency of Russia is depreciated, from whatever cause: and that, in con-

sequence of this depreciation, a paper ruble will no longer exchange for a silver ruble, nor purchase the quantity of silver bullion contained in a silver ruble. In this case the nominal par of exchange will no longer coincide with the real par of exchange, but will rise above it in the same ratio precisely as the paper ruble has fallen in value below the metallic ruble: if it require a paper ruble, and one-tenth of a ruble, to pur-

chase the coin contained in a silver ruble, or if a silver ruble, by the depreciation of paper currency, becomes equivalent to one paper ruble, and one-tenth of a paper ruble, then the real par between England and Russia will be a half-crown of the former country for a paper ruble and one-tenth of a paper ruble of the latter country. This will be the real par of ex-

change; but as the par is still supposing to continue as it was, that is, a half-crown of England for a ruble of Russia, the exchange will appear to be conformable to Russia, when in fact it is at par.

From these remarks and illustrations, it is sufficiently evi-

dent, that the real par of exchange between two countries must be ascertained by the following processes: the object of the merchant who has a debt to discharge in a foreign coun-

try, is to pay no more, in his own country, for the means of discharging that debt, than it would cost him to effect it in the foreign country. If he were obliged to pay the debt in the foreign country, he must of course procure the coin of that country; and, therefore, for the purpose of discharg-

ing it in his own country, he must content to give as much as would be necessary to procure the sum which he owes. If, in the foreign country, the precious metals in bullion and in coin are exactly of the same value, he could discharge his debt there by transmitting the precise quantity of bullion contained in the sum he owed; but if, as was the case in

France
PAR OF EXCHANGE.

France before the revolution, the precious metals in bullion were not equivalent to the precious metals when coined, he would be obliged to transmit as much more bullion as was necessary to make them equivalent, and consequently, if in his own country he paid no more than the price of this bullion for a bill to discharge his foreign debt, he, in fact, bought his bill at par. The same general illustration might be pursued with respect to a bill bought with a depreciated paper currency; if no more were given for the bill, than would have been sufficient to have purchased the bullion necessary to discharge the debt; the bill, in this case, was bought at par, though nominally much more was given for it.

There is only one other case, in which the nominal and real rate of exchange can differ, and this case is thus explained by Smith in his Wealth of Nations: we shall give his explanation, and then offer some remarks on it, as at first sight the fact which it unfolds may seem to militate against the doctrine we have laid down on this subject.

"In some places, as at Amsterdam, Hamburg, Venice, &c. foreign bills of exchange are paid in what they call bank money; while in others, as at London, Lisbon, Antwerp, Leghorn, &c. they are paid in the common currency of the country. What is called bank money is always of more value than the same nominal sum of common currency. A thousand gilders, of the bank of Amsterdam, for example, are of more value, than a thousand gilders of the bank of Amsterdam currency. The difference between them is called the agio of the bank, which at Amsterdam is generally about five per cent. Supposing the current money of the two countries equally near to the standard of their respective mints, and that the one pays foreign bills in this common currency, while the other pays them in bank money, it is evident, that the computed exchange may be in favour of that which pays in bank money, though the real exchange should be in favour of that which pays in current money; for the same reason that the computed exchange may be in favour of that which pays in better money, or in money nearer to its own standard, though the real exchange should be in favour of that which pays in worse. The computed exchange before the law, regulation of the gold coin, was generally against London with Amsterdam, Hamburg, Venice, and I believe, with all other places which pay in what is called bank money. It will by no means follow, however, that the real exchange was against it. Since the regulation of the gold coin, it has been in favour of London, even with those places. The computed exchange has generally been in favour of London, with Lisbon, Antwerp, Leghorn, and if you except France, I believe with most other parts of Europe that pay in common currency, and it is not improbable that the real exchange was so too."

The cause of this difference between bank money and the common currency of Amsterdam, &c. is explained by Smith himself, in his digression concerning banks of deposit. In Amsterdam, &c. the coin in circulation consisted of the currency of different countries; and consequently differed very much in its intrinsic value, and was also liable to great variations of value. Hence, even if there had been no banks of deposit, these various coins must have paid in exchange for bullion, not according to their denominative, but according to their real value, and, as we have already explained, the rate of their exchange fixed by the command which the respective currencies of two countries, that trade with each other, possesse over bullion. This difference between the bullion and the mint value of the various coins circulated in Amsterdam, would be confirmed by the circumstance, that the bank of deposit, when a sum of money in these coins was paid into it, gave credit only for the actual quantity of bullion which they contained. A merchant in London, therefore, who gave five per cent. above the nominal par for a bill on Amsterdam, to be paid in bank money, gave no more than the real value of the bullion which he was to receive, and consequently, in fact, bought his bill at par.

Having thus considered, at sufficient length, the different circumstances which affect the nominal rate of exchange, we shall now advert to those circumstances which have a tendency to raise or lower the rate of exchange, actually, above or below par.

Let us suppose that the merchants in London have bought goods in Paris to the amount of 2000 Louis d’ors; while other merchants in London have sold goods in Paris to the same amount: the latter draw bills for that sum, and the former become purchasers of these bills. At what rate will these bills be purchased? Undoubtedly at the real par of exchange, whatever that may be, since the supply and demand are exactly equal. If, therefore, the par of exchange be a guinea for a Louis, the merchants who have drawn bills upon Paris to the amount of 2000 Louis, will receive for them 2000 guineas; and thus each party will be accommodated, and have the expense of freight and insurance in transmitting or receiving what they owe, or what is owing to them. Let us now suppose that the bills in London on Paris are ill at 2000 Louis, but that, owing to the London merchants having purchased fewer goods in Paris, there is a demand for bills on Paris only to the amount of 1500 Louis: in this case it is evident that the price of bills on Paris will fall, as the proportion between the demand and the supply is altered; the supply is the same, but the demand is become less; hence a bill on Paris for a certain number of Louis, will no longer command in the London market the same number of guineas; that is, it will no longer be sold at par; but at two, three, or five per cent. below par. In this case the exchange is said to be unfavourable to France, because French money in the London market, or what is the same thing, a bill for French money, will no longer bring its real and intrinsic value. On the other hand, let us suppose the amount of the bills in London on Paris to be still 2000 Louis, but the demand for these bills increased from 2000 to 2500 Louis; on this supposition it is equally plain that the exchange between London and Paris will rise above par, or, in other words, that for a bill for a certain number of Louis, more than the same number of guineas will be paid. In this case the exchange is said to be favourable to Paris, and unfavourable to London, because for French money, or a bill for French money in London, more than its equivalent in British money is paid.

There are several points to be investigated, connected with a real variation in the rate of exchange between two countries; in the first place, to what amount can the exchange become unfavourable to any country? In the second place, what effects does a favourable or unfavourable exchange produce on the commercial transactions of two countries; thirdly, by what process is the exchange, when it varies from the real par, brought back to that par; and, lastly, can the exchange between any given country, and all the other countries with which it trades, be, on an average, for any length of time, either above or below the real par.

In the first place, to what amount can the exchange become really unfavourable to any country? Let us suppose that a merchant in London wishes to purchase a bill on Paris for 500 Louis, but that owing to the small supply of such bills, or the great demand for them, he finds he must pay for it ten per cent. above par. He will, before he agrees to these terms, enquire whether he cannot discharge his debt in Paris at a cheaper rate; the most obvious and simple mode is by the purchase and transmission of bullion; and if he finds that
he can purchase bullion at the mint price, and can send it over to Paris at a cheaper rate than ten per cent., he will naturally prefer this mode of settling his debt, to giving such a high premium for a bill on Paris. In fact, therefore, the exchange can never become unfavourable to any country, to a greater amount per cent. than will pay for the transfusion of bullion: it may, indeed, he alleged that where the price of bullion has risen, the exchange may become unfavourable to the amount of that rise, added to the amount of the charges of transfusion; but from what has been already said respecting the nominal rate of exchange, it will be sufficiently apparent, that the rate per cent. above the computed par, which is paid for a bill, must not be considered as indicating or measuring a really unfavourable exchange, but that this must be considered as indicated and measured solely by the amount of the sum paid for the bill above the price of the bullion which it would purchase. It is not easy to fix the rate per cent. which the transfusion of bullion to any particular country would cost; it must vary from the different caufes. In the circumstances of Europe, since the French revolutionary wars, the difficulty and risk of transmitting bullion to any part of the continent, or subject or exposed to the French arms, must have been greatly increased; and consequently, from this cause, independently of the operation of other caufes affecting the nominal rate of exchange, the real rate of exchange between Great Britain and the continent may become unfavourable to a greater degree than it would other wise have been.

In the second place, what effects does a favourable or unfavourable exchange produce on the commercial transactions of two countries trading with each other? It is abundantly clear and evident, that if the exchange between England and France is unfavourable to the former country, the bullion will pay a higher price for all the commodities the imports from France. The British merchant indeed purchases them in France at the same rate as formerly: he gives, we will suppose, ten Louis for a pipe of wine; but let us consider what in fact he will pay for this wine, when the exchange is at par, and when it is unfavourable to England. In the former case, he will pay for a bill for ten Louis, exactly ten guineas (on the supposition that a guinea and a Louis form the real par), while, in the latter case, he must pay for a bill for ten Louis, ten guineas, and one, two, or three per cent. more, according as the exchange is more or less unfavourable to England; consequently, though he purchases the wine at the same rate in Paris, it costs him more in London, French money, or a bill for French money, being there worth more than its real and intrinsic value; or, in other words, the demand for these bills being greater, or the supply of them less, than formerly. — Let us now reverse the cafe, and suppose that the exchange is favourable to England; that in the London market there are more bills than formerly on Paris, while the demand for them is the same; under these circumstances, bills on Paris may be purchased under par; and consequently the price of wine bill continuing the same in that city, the English merchant, by purchasing bill under par, will in reality purchase it at a cheaper rate. The general conclusion is, that when the exchange between London and Paris is favourable to the former city, i. e. when a certain sum of English money is worth more than its par, in the purchase of bills on Paris, then, in this case, French goods may be brought into England at a cheaper rate; whereas, if bills on London on Paris are above par, or in other words, if the exchange is unfavourable to England, so that for a bill for a certain sum on Paris, more than its par in English money is given, then, in this case, French goods will be bought at a dearer rate.

We are now, in the third place, to examine by what proceeds the exchange, when it varies from the real par, is brought back to it: what we have unfolded and illustrated under the second head, will, in some degree, explain this process. Let us suppose that the exchange between London and Paris is unfavourable to the former place one, two, or three per cent., or that one, two, or three per cent. must be given in London, as a premium for a bill on Paris. It is abundantly evident that in this case, the supply of bills is not equal to the demand; this is indicated by the rise in the price of them above par; but it is well known, what takes place when the demand for any commodity, becoming greater than the supply of it, raises its price: capital and industry are withdrawn from other sources of employment, and directed to the commodity, of which there is an inadequate supply. The same will take place with respect to bills of exchange; as it has become a profitable concern to deal in them, more of them will be brought into the market, but it is evident that no man can draw a bill of exchange, unlefs he has property or credit in the country on which the bill is drawn. Bullion, therefore, or goods, will be sent into France from England, when bills on France bear a premium in England; and though they fell in the former country for no more than they would have done when the exchange was at par, yet as a bill for the sum at which they are sold bears a premium, that premium secures a profit to the exporter of the bullion or merchandise. By this exportation more bills on France are presented in the London market, and the price of them is reduced, till it reaches par. On the other hand, let us suppose that there are more bills on France in the London market than there is a demand for; or, in other words, that the exchange is favourable to London; in this case, by what proceeds will the exchange be brought to par? The quick-fighted interest of commercial men will soon effect this: in the first place, the English merchant, finding that his bills are at a discount, will send his exports to France; and in the second place, it has already been stated and explained, the low price of bills on France will act as a motive to the importation of more French commodities, which, of course, will create a demand for more bills, and thus bring the exchange back to par.

Hitherto we have considered the unfavourable exchange, or (to speak more correctly) the exchange, when either above or below par, as brought back to par, solely by the transactions of merchants, and by the actual transfusion of commodities; but perhaps it is more frequently brought back to par by other means. There are, in all commercial countries, merchants who deal principally in bullion and bills of exchange; a correpondence is kept up among these merchants; and they accommodate and benefit each other, according as the rate of exchange rifes or falls in their respective countries. Thus, let us suppose that two merchants, one in Paris and the other in London, have entered into a correspondence of this nature; and that in London, bills on Paris bear a large premium. In this case, the London merchant draws bills on his Paris correpondent, which are duly honoured; and the latter sends the premium on them with the former. If, on the contrary, bills on Paris on London bear a premium, the Paris merchant draws on his London correpondent, who in his turn duly honours them, and divides the profit. Thus it is evident, that an unfavourable exchange may be brought back to par, without the transfusion of bullion or goods, and solely, as we observed, by credit: but it is also evident, that if the exchange continues unfavourable to England, for example, for
for a considerable length of time, the kind of transaction we have been describing cannot go on, without the transmission of bullion or commodities.

There is another mode by which, when the exchange deviates from par, it is brought back to it. Let us suppose that bills in London on Paris bear a high premium, and that bills in America on Paris are at a considerable discount. In this case, bills, like all other commodities under similar circumstances, will leave the place where they are cheap, and seek the place where they are dear; or, in other words, the American merchant will bring his bill on Paris to the London market. He will be the more induced to do this, if, in addition to the circumstances that bills on Paris are cheap in America and dear in London, it should happen that bills in America on London are dear; and this was exactly the case during the earlier years of the second French revolutionary war. England imported more from France than she exported to it; America exported more to France than she imported from it, and imported more from England than she exported to it: the consequence was, that in London bills on Paris bore a premium, while bills on Paris in America were at a discount, and bills in America on London at a premium. Under these circumstances, let us suppose an American merchant who had imported goods from England; he wishes to purchase a bill in America on England, to pay for these goods; but he finds that for it he must pay a premium, while, at the same time, bills in America on Paris are at a discount: he therefore purchases a bill on Paris, instead of a bill on England; and this bill, which he purchases at a discount in America, he sells at a premium in London; thus discharging his English debt for less than its real value; whereas, if he had discharged it by purchasing in America a bill on England, he must have discharged it for more than its real value. Let us now consider the effect of this transolution on the rate of exchange in America and England. In the former country, the exchange with England was unfavourable, or, in other words, there was a greater demand for bills than could be supplied; consequently they were at a premium, or the exchange was below par: but the American merchant, by purchasing a bill on Paris, instead of a bill on England, lefens the demand, and thus brings the exchange nearer to par. By the same operation, he increases the demand for bills on Paris, which before were in too large a supply, and consequently at a discount; or, in other words, the exchange between America and Paris was above par, or favourable to the former. Thus we perceive that in America, by a very simple process, a process to which interest will always be a sufficient motive and guide, the rate of exchange with two distinct countries is brought back to par. Let us now follow the effect of the same transaction in England: the American merchant pays his English debts with a bill on Paris, and consequently, by increasing the supply of these bills, reduces the premium on them; or, in other words, reduces the exchange between England and France nearer to par.

The concluding inquiry is, whether the exchange between any given country, and all the other countries with which it trades, can, on an average, for any length of time, be above or below the real par? This question is one of most importance than difficulty; and we shall probably arrive at its true and satisfactory solution, by the following considerations.

In the first place, it has been abundantly shown, that the interest of the merchant prompts him to take advantage, either of a favourable or unfavourable rate of exchange, in such a manner as most certainly, and in no long space of time, to reduce it to par. If it were, therefore, even possible for any nation to have an unfavourable rate of exchange with all the other nations with which it trades, this would soon be rectified by the commercial transactions of its merchants.

But in the second place, such an event could not take place at all, even for the shortest space of time; for let us consider what it implies, and would produce. It implies that the nation, supposing to be so circumstanced, purchases more commodities than it sells. Let us even for a moment suppose this to be the case: the overplus of its purchases must be paid for; but by the hypothesis, only its bullion and coin can be employed for that purpose; and if they are exported, commodities must become cheap; if commodities become cheap, buyers will flock into it; or, in other words, its exports will increase, and consequently the rate of exchange will be restored to par, or perhaps raised above it.

In the whole of this discussion, and in most discussions on the par of exchange, it is supposed to be affected only when the trade between any two countries is not balanced or equal; that is to say, when one country imports more commodities from the other country than it exports to it. But there are several other circumstances which affect the par of exchange, though it was not necessary, in discussion, and explaining the general principles of this subject, to enter upon them: the most material and common of them may, however, be noticed.

In the first place, besides the merchants who require bills on any particular country, to pay for the commodities they may have purchased there, government has frequently occasion for these bills, for the purposes of public, civil and military expenditure, &c. The history of the present and of the last war affords many striking instances of this fact, and of the consequences produced on the rate of exchange, by the increased demand for foreign bills on the part of government.

In the second place, all persons who are leaving the country to settle abroad, or who have money to transmit abroad, though not for mercantile purposes, naturally prefer purchasing bills of exchange; and consequently, from this cause, the rate of exchange is affected.

Lastly, another source of demand for bills of exchange arises in England from the dividends on the stock held by foreigners, as these dividends are usually transmitted by means of bills of exchange.

When, therefore, the rate of exchange is unfavourable to a country, it by no means follows that that country is importing goods to a greater amount than it exports. If bills of exchange were bought after, and employed solely to pay for goods imported, this would be a legitimate inference; but as they are employed for other purposes, such a conclusion is erroneous.

We have thus endeavoured to illustrate the doctrine of commercial exchanges, on the general principles of political economy; and if, in some parts of this article, we may seem to have been too minute, and to have defected too familiar, our apology must be derived from the anxiety we felt not to leave obscure any part of the subject, and from our conviction that political economy, more than any other science, requires ample and familiar illustration.

Par, in Geography, a river of Bavaria, which runs into the Danube, four miles below Ingoldstadt.

Par Vagus, in Anatomy, the eighth pair of nerves. See Nervous System.

Para, in Commerce, a small Turkey coin, 40 of which are equal to a piaffe, and contains three aperes.
PARA, Grand Para, in Geography, the most northern of the colonies or governments of Brazil, in South America. This government comprehends that part of Guiana which belongs to the Portuguese, on the north side of the river Amazons, extending from the union of the river Madeira to the Atlantic, about 600 miles from east to west, and 250 from north to south. It produces abundance of cotton, sugar, vanilla, chocolate, coffee: a fleet laden with these articles has usually sailed every year for Lisbon. The climate is extremely hot; and the woods abound with valuable timber of great solidity and brilliant colours, and some trees that yield odoriferous balsams. (See Balsam.) The capital Para, situated at the mouth of the great river Tocantin, which receives that called dos Bocas, into which a natural canal from the Maranon is called Tapirapa) has been opened by the violent tides. This is a rich and handsome town, with a parish church and a college. Besides a citadel, it has a fortress, with a strong train of artillery, and a garrison of four companies. S. lat. 1° 45'. W. long. 50°.

Para, a large river of Brazil, formed by the union of the Tocantin and the Guanapan, which runs about 150 miles in a north-easterly direction, separating the island of Marajo from the continent, and discharging itself into the Atlantic, about 29 miles S. of the Line. — Afo, a river of Brazil, which rises about 150 miles W. of Villarina, and runs into the S. Francisco, S. lat. 16° 50'. — Afo, a town of Turkish Armenia; 90 miles N.N.E. of Cars.

Para Huan, a town of Chinefa Tartary, on the river Kerlon. N. lat. 48° 6'. E. long. 113° 14'.

Para, in Mythology, is the name of the Hindoo goddes Parvati, in the character of Prakriti; which see. It means life, or generation.

ParabitA, in Geography, a town of Naples, in the province of Otranto; 10 miles N.W. of Aleppo.

Parable, παράβολα, formed from παράβολλω, to oppose, or compare, a fable, or allegorical instruction, founded on something real, or apparent, in nature, or history; from which a moral is drawn, by comparing it with some other things, wherein the people are more immediately concerned. (See Allegory.) Or, it is that figure of sentences, which illustrates a thing by comparing it with some other, to which it bears a resemblance.

Such are those parables of the ten virgins, of Dives and Lazarus, of the prodigal son, &c. in the New Testament.

Aristotle defines parable, a similitude drawn from form to form. Cicero calls it a collateral, others a simile. F. de Colonna calls it a rational fable.

The Hebrews call it בַּשַּׁל, from a word which signifies either to predominate, or to assimilate; the Proverbs of Solomon are by them also called בַּשַּׁל parables, or proverb.

Glauций defines a parable a simile, by which a fictitious thing is related as real, and compared with some spiritual thing, or accommodated to signify it.

Some make parable differ from fable; Grotius and others use the two terms promiscuously. Kircher derives the use of parables from the Egyptians.

Parable, according to the eminently learned bishop Lowth, (Lectures on the Sacred Poetry of the Hebrews,) is that kind of allegory which consists of a continued narration of a fictitious event, applied by way of simile to the illustration of some important truth. The Greeks call thefe allegories αἰσχροί (or apolouges,) the Latins fabulae, or fables: and the writings of the Phrygian fage, or thofe composed in imitation of him, have acquired the greatesf celebrity.

Nor has our Saviour himself disdained to adopt the same method of instruction, of whose parables it is doubtful, whether they excel most in wisdom and utility, or in sweetness, elegance, and periphrasis. As the appelation of parable has been applied to his discourses of this kind, the term is now restricted from its former extensive signification to a more confined sense. This species of composition occurs very frequently in the prophetic poetry, and particularly in that of Ezekiel. If to us they should forcibly appear obscure, we must remember, that in those early times, when the prophetic writings were indited, it was universally the mode throughout all the eastern nations, to convey sacred truths under mysteries figures and representations. In order to form our judgment upon this subject, Dr. Lowth has briefly explained some of the primary qualities of the poetic parables; so that, by considering the general nature of them, we may decide more accurately on the merits of particular examples.

It is the first excellence of a parable to turn upon an image well known and applicable to the subject, the meaning of which is clear and definite; for this circumstance will give it periphrasis, which is essential to every species of allegory. If the parables of the sacred prophets are examined by this rule, they will not be found deficient. They are in general founded upon such imagery as is frequently used, and similarly applied by way of metaphor and comparison in the Hebrew poetry. Examples of this kind occur in the parable of the deceitful vineyard (Luke v. 17—27) and of the ulifets vine (Ezek. xix. and xix. 10—14.) for under this imagery the ungrateful people of God are more than once described. (See also Ezek. xix. 1—9. Ezek. xxxi. Ezek. xvi. and xxxiii.) Moreover, the image must not only be apt and familiar: but it must be also elegant and beautiful in itself; since it is the purpose of a poetic parable, not only to explain more perfectly some proposition, but frequently to give it some animation and splendour. As the imagery from natural objects is in this respect superior to all others, the parables of the sacred poets consist chiefly of this kind of imagery. It is also essential to the elegance of a parable, that the imagery should not only be apt and beautiful, but that all its parts and appendages should be periphrastic and pertinent. Of all these excellencies, there cannot be more perfect examples than the parables that have been just specified: to which we may add the well-known parable of Nathan (2 Sam. xii. 1—4.) although written in prose, as well as that of Jotham (Jud. ix. 7—15.) which appears to be the most ancient, and approaches somewhat nearer to the poetical form. It is also the criterion of a parable, that it be consistent throughout, and that the literal be never confounded with the figurative sense: and in this respect it materially differs from that species of allegory, called the continued metaphor. (See Isaiah, v. 1—7.) It should be considered that the continued metaphor and the parable have a very different view. The sole intention of the former is to embellish a subject, to represent it more magnificently, or at the most to illustrate it; that, by describing it in more elevated language, it may strike the mind more forcibly; but the intent of the latter is to withdraw the truth for a moment from our sight, in order to conceal whatever it may contain ungraceful or disgusting, and to enable it secretly to inculcate itself, and obtain an ascendancy as it were by stealth. There is, however, a species of parable, the intent of which is only to illustrate the subject; such is that remarkable one of Ezekiel (chap. xxxi.), of the cedar of Lebanon; than which, if we consider the imagery itself,
The parabola, in Geometry, is a curve line made by the common intersection of a conic surface and a plane which cuts it, and is parallel to another plane that touches the same conic surface.

A conic secton made by a plane ever fo little inclined to the parabola on the one side, is an ellipse; and a section made by a plane inclined ever so little on the other side, is an hyperbola: thus the parabola is the limit between these two curves, to which they both continually approach, while their transverse axes increase more and more; being, as it were, the passage from one of them to the other.

While all the planets move round the sun in orbits of a small, or a moderate degree of eccentricity, the comet describe ellipses so aloofingly eccentric, that they cannot be distinguished from parabolas during the short time these bodies continue visible.

If a heavy body be projected from the earth's surface, and if we abstrackt from the resistence of the air, and suppose gravity to act in parallel directions, the path described by the projectile will be a parabola.

Again, if we wish to collect parallel rays of light in a single point by reflecting them from a curve surface; we must employ for this purpose the concave curve generated by the revolution of a parabola about its axis, which will reflect all the parallel rays incident upon it to the focus of the generating parabola.

On all these accounts the parabola merits much attention. We have already treated of it along with the other conic sections; and it only remains that we add here those properties deserving notice which are peculiar to this curve.

Prop. I. Ordinates drawn to two diameters of a parabola from one another's vertices, will cut off equal abscissas. See Plate of Conies, (Parabola), fig. 1.

Let A E be an ordinate to the diameter whose vertex is B, and B D an ordinate to the diameter whose vertex is A: then the abscissas A D and B E will be equal. Draw the tangents A F and B F meeting in F; join A B; draw F K, cutting the curve in H, parallel to A D and B E; also draw H M and K N parallel to B D.

Then (Cor. 31. Conies)
\[ H^2 : BD^2 :: A M : A D; \]
but on account of the similar triangles K A N, B A D, K N', or \( H M^2 : BD^2 :: AN^2 : AD^2; \)
therefore \( (11. 5. E.) \)
\[ AM : AD :: AN^2 : AD^2; \]
consequently A D is a third proportional to A M and A N; or to F H and H K.

And in like manner it may be shown that B E is a third proportional to F H and F K;

therefore \( A D = BE. \)

Prop. II. The part of the diameter of a parabola intercepted between an ordinate (fig. 2.), and a tangent drawn from the same point in the curve, is bisected in the vertex of the diameter.

Let the ordinate M A, and the tangent M D, meet: the diameter, whose vertex is V; then \( AV =DV. \) Draw V L parallel to M D to meet the diameter passing through M: then V L will be an ordinate of that diameter (19. Conies); therefore \( (4) \)
\[ ML = DV = VA. \]

Prop. III. A diameter of a parabola drawn through the intersection of two tangents will bisect the chord that joins the two points of contact.

Let \( T P \) and \( T Q \) (fig. 3.) be two tangents of a parabola; then \( TK, \) a diameter drawn through their intersection, will bisect the line drawn between the points of contact. Let P M be an ordinate drawn to the diameter which passes through Q, and let P T meet the same diameter in L. Then \( (2) \)
\[ MQ = QL; \]
but \( T Q \) is parallel to \( PM \) (Conies, 19.); therefore also \( PT = TL, \) and \( P K = KQ. \)

Prop. IV. A tangent of a parabola makes equal angles with a diameter and a straight line drawn from the point of contact to the focus.

Let \( MP \) (fig. 4.) touch a parabola in \( M, \) it will make equal angles with a diameter \( MK, \) and the line \( MF \) drawn from the focus to the point of contact. Let \( KG \) be the directrix of the parabola, \( MK \) perpendicular to \( KG, \) \( MQ \) perpendicular to the axis, and let the tangent meet the axis in \( P. \) Then (Conies, Def. 24.) \( GV = VF; \) and \( (2) \)
\[ VP = VQ; \]
therefore \( PF = GQ = MK = (Conies, 43.) MF; \)
therefore \( (5. 1. E.) \) the angle \( FMP = \) the angle \( FPM = \) the angle \( PMK. \)

Prop. V. A straight line drawn from the intersection of two tangents of a parabola to the focus, will bisect the angle contained by two lines drawn from the focus to the points of contact of the tangents.

Let \( TP \) and \( TQ \) (fig. 5.) be two tangents of a parabola, having its focus at \( F; \) then, having drawn \( TF, PF, QF, \) the angle \( PFT \) will be equal to the angle \( T F Q. \) Draw \( PM \) and \( QN \) perpendicular to the directrix, and join \( TM, TN. \) In the two triangles \( TPM, TPF, \) \( TP \) is common; \( PM \) is equal to \( PF \) (Conies, 43.); and \( (4) \)
the angle \( T PM = \) the angle \( T P F; \) therefore \( (4. 1. E.) \)
\[ TM = TF; \]
and the angle \( TPM = \) the angle \( TFP. \) In like manner, the two triangles \( QTN, QTF, \) have \( QT \) common; \( QN = QF; \) and the angle \( TQN = \) angle \( T QF; \) therefore \( TN = TF; \) and the angle \( T QF = T N Q. \) And because \( TM = TF, \) and \( TN = TF; \) therefore \( PM = TN, \) and the angle \( TNM = T NM \) (5. 1. E.) Now it was shewn that \( TFQ = T N Q = \) complement of \( T NM; \) and \( TFP = T MP. \)
Therefore an Arithmetica in bifera ther.

Let the param.; indefinitely B N, B N', B N'', &c. will be the ordinates of the parabola that belong to the abscissae B D, B D', B D'', &c.; which is manifest, since, from the nature of the circle, we have, B N = A B × B D; B N'' = A B × B D', &c. Hence, if we complete the parallelogram B M, B M', B M'', &c. the several points M, M', M'', &c. will be in the curve of the parabola.

2. When the directrix A B (fig. 11.), and the focus are given, the curve may be described by finding points in the following manner. Through F draw G P perpendicular to the directrix, then G P will be the axis of the parabola; through any point P of the axis, draw M m parallel to A B, and from the centre F, with the distance G P, describe a circle to intersect M m in the points M and m; then will M and m be points of the curve. (Conics, 43.)

3. When the directrix and the focus are given (fig. 12.), the curve may be thus described by a continued motion. Let the ruler E D H be in the plane of the paper, and the edge E D applied, that the edge E D may be upon the directrix A B, and the edge D H, which is perpendicular to E D, on the same side of A B with the focus F; take a thread or string, exactly equal in length to the part of the edge D H, and fix one end of it in the focus F, and the other end to the extremity of the ruler H: then if a pencil is kept upon the edge D H, so as to stretch the thread tight, while the edge E D is made to slide along the directrix, the pencil will describe a parabola. (Conics, 43.)

But although the curve of a parabola cannot be constructed by very convenient or very simple means; yet it is expressed by an equation of a more simple form than any other curve. If we denote by y the ordinate which corresponds to the abscissa x in a parabola, having p for the parameter of its axis; then the equation of the parabola will be

\[ y^2 = 4px. \]

This equation is less complicated than even that of the circle, which curve is on a footing in this respect with the ellipse and hyperbola. If the curve be admitted into elementary geometry, while the known curves of the conic sections are classed as a higher branch of that science; the reason of this preference of the circle in the construction of geometrical problems is to be sought for in the more easy and simple description of the curve, not in the nature of its equations. But this is a point so well discussed by the admirable Sir Isaac Newton, in his "Arithmetica Universalis," when treating of the linear construction of equations, that we must refer our readers to that work.

**Quadrature of the Parabola.**—The quadrature of the parabola is a discovery that will always be interesting to geometers. It is still the most remarkable instance in the history of mathematical learning, of the exact equality of a curve-lineal to a rectilinear space. We are indebted for it to Archimedes, the most inventive geometer of antiquity. The original work in which this discovery is contained, has happily been preserved; and it is the most curious monument extant of the power of inventive genius to employ in the search of truth means the most unconnected with the subject in content.
templation, and the least likely to be successful. The treatise of Archimedes on the quadrature of the parabola consists of two parts: in the first part the author details the reasons, founded on mechanical considerations, and the nature of the lever, by which his discovery was originally made: in the second part, he demonstrates the same thing more naturally from principles purely geometrical. The whole treatise is well worth the attention of mathematicians: but in this place we must confine ourselves to demonstrate concisely the discovery of Archimedes. This we shall do in a manner strictly rigorous, and not differing essentially from the mode of investigation traced out by the illustrious inventor.

We call equidistant parallel lines those that cut any firsht line that crosses them into equal parts.

**Prop. I.** If a triangle $\triangle ABC$ (fig. 13) be inscribed in a segment of a parabola, by drawing a diameter $DC$ to bisect the base; and if a polygon $AMCNB$ be likewise inscribed in the same segment by drawing four equidistant diameters which will divide the base into four equal parts; the excess of the polygon above the triangle will be one-fourth part of the triangle.

At $A$ draw a tangent of the curve to meet the diameters $EM$ and $DC$ in $H$ and $K$. Because $AD$ is bisected in $E$, $AC$ will be bisected in $S$; therefore $HM = MS$ and $DC = CK$ (2). Therefore the triangle $AHS = \frac{1}{2}$ the triangle $AMS$ = the triangle $AMC$; but the triangle $AHM = \frac{1}{4}$ of the triangle $ACK$ (19.6: E.) = $\frac{1}{4}$ of the triangle $ACD$. For like reasons the triangle $CND = \frac{1}{4}$ of the triangle $CDB$. Therefore the sum of the two triangles $AMC$ and $CND$, which is the excess of the polygon $AMCND$ above the triangle $ACB$, is equal to one-fourth part of the triangle $ACB$.

**Prop. II.** If a triangle $\triangle ABC$ (fig. 14) be inscribed in a segment of a parabola by drawing a diameter $AB$ to bisect the base of the segment; the excess of the segment above the triangle will be less than the triangle.

Because $AB$ is ordinately applied to the diameter $DC$, therefore $AB$ is parallel to $F G$, a tangent of the curve at $C$; draw $AF$ and $BG$ parallel to $CD$; then these lines will be diameters, and the part of each above the vertex being without the curve, the parallelogram $AFGD$ will contain the segment of the parabola. Now the excess of the parallelogram above the triangle $ABC$, is exactly equal to the triangle; therefore the excess of the segment above the triangle is less than the triangle.

**Prop. III.** To investigate the area of a segment of a parabola.

Let $\triangle ABC$ be a segment of a parabola, and let the triangle $\triangle ABC$ (fig. 16) be inscribed in it by drawing the diameter $DC$ to bisect the base of the segment; the area of this triangle we shall denote by $a$.

Draw the diameters $EN$, $FO$, to bisect the parts $AD$, $BD$; by which means the base $AB$ will be divided into 4 or 2 equal parts, and a polygon $\triangle ANCQ$ will be inscribed in the segment, the excess of which above the triangle $ABC$ is equal to one-fourth part of the triangle (first prop.); consequently the area of the same polygon will be equal to

$$a + \frac{a}{4},$$

which space is less than the segment. Again, the excess of the segment $\triangle ANC$ above the triangle $\triangle ANC$ is less than the triangle $\triangle ANC$ (2d prop.); and the excess of the segment $\triangle CQB$ above the triangle $\triangle CQB$ is less than the triangle $\triangle CQB$; therefore the sum of these two exceeds, which is equal to the excess of the segment $\triangle ABC$ above the polygon $\triangle ANCQ$, will be less than the sum of the two triangles' $\triangle ANC$ and $\triangle CQB$; that is, it will be less than $\frac{a}{4}$ (first prop.)

Hence the space

$$a + \frac{a}{4} + \frac{a}{4} = \frac{a}{4},$$

will be greater than the segment $\triangle ABC$.

And if we inscribe another polygon $\triangle AMNOC$, in the segment, by drawing diameters to bisect the intervals between the diameters of the last polygon, so as to divide the base of the segment into 8, or 2 equal parts; then the excess of this polygon above the last polygon will be equal to the sum of the triangles $\triangle AMN$, $\triangle NOC$, $\triangle CQB$, $\triangle QBR$; but the sum of the triangles $\triangle AMN$ and $\triangle NOC$ is equal to one-fourth part of the triangle $\triangle ANC$; and the sum of the triangles $\triangle CPQ$ and $\triangle QRB$ is equal to one-fourth part of the triangle $\triangle CQB$; therefore the excess above-mentioned is equal to one-fourth part of the sum of the triangles $\triangle ANC$ and $\triangle CQB$; that is, it is equal to $\frac{1}{4}$ of $\frac{a}{4}$ or to $\frac{a}{4}$. Therefore the area of the polygon formed by dividing the base into 8, or 2, equal parts, will be equal to

$$a + \frac{a}{4} + \frac{a}{4} = \frac{a}{4},$$

which is less than the segment $\triangle ABC$. Again, the excess of the segment $\triangle ABC$ above the same polygon, is less than the sum of the triangles $\triangle AMN$, $\triangle NOC$, $\triangle CPQ$, $\triangle QRB$; that is, it is less than $\frac{a}{4}$; therefore the space

$$a + \frac{a}{4} + \frac{a}{4} + \frac{a}{4},$$

is greater than the segment $\triangle ABC$.

In like manner, if we continue to inscribe new polygons in the segment, by drawing diameters which shall bisect the intervals between the diameters of the preceding polygons, after $n$ bisections, which will divide the base of the segment into $2^n$ equal parts, we shall come to an inscribed polygon whose area is equal to

$$a + \frac{a}{4} + \frac{a}{4} + \frac{a}{4} + \ldots + \frac{a}{4} = \frac{a}{4^n},$$

which is therefore less than the segment $\triangle ABC$. But we can prove, as is done above, that the excess of the segment above the polygon is less than $\frac{a}{4^n}$; therefore the space

$$a + \frac{a}{4} + \frac{a}{4} + \frac{a}{4} + \ldots + \frac{a}{4} + \frac{a}{4} = \frac{a}{4^n},$$

will be greater than the segment.

Now, if from the area of the polygon, viz.

$$a + \frac{a}{4} + \frac{a}{4} + \frac{a}{4} + \ldots + \frac{a}{4} = \frac{a}{4^n},$$

we subtract its fourth part, the three-fourths which remain will be equal to $a - \frac{a}{4^n}$; therefore the area of the polygon will be equal to $\frac{a}{4^n} - \frac{a}{3^n}$, which is less than the segment; and the space proved above to be greater than the segment will be equal to $\frac{4a}{3^n} - \frac{a}{3^n}$. Between these two
two limits the area of the parabolic segment is contained, how great forever may be the number of bisections denoted by \( n \).

But \( \frac{4a}{3} \) is the only quantity which, for every value of \( n \), is contained between the foregoing limits, viz.: 

\[
\frac{4a}{3} = \frac{1}{4} \cdot \frac{a}{n^2} - 1
\]

\[
\frac{4a}{3} - \frac{1}{3} \cdot \frac{a}{n^2}
\]

For it is manifest that \( n \) may be taken so great, that the difference between the two limits shall be less than any assignable space. Therefore the area of the segment of the parabola is equal to \( \frac{4a}{3} \); that is, it is equal to four third parts of the triangle inscribed in it, by drawing a diameter to bisect the base; or, which is the same thing, it is equal to four third parts of the triangle that has the same base and altitude with the segment.

The area of a parallelogram circumscribed about a segment of a parabola (fig. 15.), being double of the triangle inscribed in the segment; the area of the segment will be two-third parts of the parallelogram.

The modern analysis furnishes a much shorter way of determining the area of a parabola than the process though elegant method of the ancient geometers. Let \( p \) denote the parameter of a diameter of a parabola; \( y \) an ordinate; \( x \) the corresponding abscissa; and \( m \) the angle of the which ordinate cuts the diameter; then the fluxion of the area of the semi-segment of the parabola will be \( m \cdot y \cdot x \); but \( y' = \rho \cdot x \), and \( y = \rho \cdot x^2 \); therefore the fluxion of the semi-segment is \( m \cdot \rho \cdot x^2 \cdot \frac{x}{2} \); and the fluent, or the area itself, is \( \frac{1}{2} \cdot m \cdot \rho \cdot x^2 \); and by substituting \( y \) for \( \rho \cdot x^2 \), the semi-segment of the parabola is \( \frac{1}{2} \cdot m \cdot y \cdot x \); and the whole segment is equal to \( \frac{1}{2} 	imes 2 \cdot m \cdot y \cdot x \), that is, to two-thirds of the circumference parallelogram.

Reduction of the Parabola.—About the year 1650, Van Heuraet, a Dutch mathematician, invented a method of reducing the rectification of any proposed curve to the quadrature of another curve derived from the former by a geometrical construction; and in this way he shewed that the rectification of the parabola could be accomplished by the quadrature of the hyperbola. This discovery is explained by the author in a letter to Francis Schoten, infested by that mathematician in the edition of Des Cartes' geometry, which he published in 1659. Inventions of this kind, although they might be very interesting at the time they were first made known to the public, are now only objects of curiosity to such as wish to inquire into the history of mathematical learning; we shall therefore proceed to investigate the length of an arc of a parabola, by the general method now in use.

Let \( 4 \rho \) denote the parameter of the axis of a parabola; \( y \) an ordinate to the axis; \( x \) the corresponding abscissa; \( x \) the length of the arc extremity of the vertex; then, as is proved in the method of fluxions, \( \dot{z} = \sqrt{x^2 + y^2} \); but the equation of the curve is \( y^2 = 4 \rho \cdot x \); therefore \( y = 2 \sqrt{\rho \cdot x} \); consequently \( y = \dot{z} \sqrt{x} \); and \( y^2 = \dot{z} \cdot \frac{\dot{z}}{x} \); and \( y \); therefore, by substitution, \( \dot{z} = \sqrt{1 + \frac{\rho}{x}} \frac{x \dot{z} + \ddot{z} \cdot \rho \dot{z}}{\sqrt{x^2 + \rho \cdot x}} \).

Suppose \( z = \sqrt{x^2 + \rho \cdot x} \); then by taking the fluxions

\[
\dot{z} = \frac{\dot{x} \cdot \sqrt{x^2 + \rho \cdot x}}{\sqrt{x^2 + \rho \cdot x}} \; \text{hence} \; \dot{z} = \frac{\dot{x}}{\sqrt{x^2 + \rho \cdot x}} \]

and by taking the fluents, and restoring the value of \( z \), we get

\[
s = \sqrt{x^2 + \rho \cdot x} + \frac{1}{2} \rho \cdot x \; \text{hyp. log.} \frac{x + \frac{1}{2} \rho \cdot x + \sqrt{x^2 + \rho \cdot x}}{\frac{1}{2} \rho}
\]

which is the expression of the length of an arc of a parabola estimated from the vertex, cut off by an ordinate corresponding to the absciss \( x \).

The area of a frustum, or zone, of a parabola, included by two parallel right lines, and the intercepted curves of the parabola, may be found by the following rule; viz. To one of the parallel ends add the quotient arising from the division of the square of the other by the sum of the said ends; multiply the sum by the altitude of the frustum, or distance of the ends; and \( \frac{4}{3} \) of the product will be the area. Or, divide the difference of the cubes of the diameters by the difference of their squares, and multiply the quotient by \( \frac{4}{3} \) of the altitude. Then

\[
\frac{D + d}{D + d} \times \frac{4}{3} a, \; \text{or} \; D \; \frac{D + d}{D + d} \times \frac{4}{3} a = \text{the area;} \; D, \; d \; \text{being the two ends and} \; a \; \text{the altitude.}
\]

For by a property of the parabola,

\[
\frac{D D - d d}{D D - d d} = \text{the altitudes of two complete segments, whose baises are the ends} \; D, \; d \; \text{of the frustum; and consequently their difference, or the frustum, is} \; \frac{4}{3} a \; \frac{D D + D D + d d}{D D + D D}
\]

\[
\frac{4}{3} a \times D D + \frac{d d}{D D + d d} = \frac{4}{3} a \times D D + \frac{D D}{D D + d d}
\]

Hence a parabolic frustum is equal to a parabola of the same altitude, and whose base is equal to the end of the frustum, increased by a third proportional to the sum of the ends and the other. Consequently in the one end \( D C \) (Plate XXIII. Miscellany, fig. 9.) produced of a parabolic frustum \( A B C D \), take \( C E = \) the other end \( A B \); raise \( E F \) perpendicular to \( E C \) and \( \equiv C D \); draw \( D F \), and perpendicular to it \( F G \) meeting \( E C \) produced in \( G \); then, if upon the base \( C G \) be described any parabola \( C H G \), touching the line \( A B \), it will be equal to the frustum \( A B C D \). For

\[
C G = C E + E G \equiv A B + E G = A B + E F \equiv \frac{D C}{D E} = \equiv A B + \frac{D C}{D C + A B}
\]

Hutton's Menurcation.

Parabola, Quadrature of. See Quadrature, and the article Parabola p. 599.

Parabola, Rectification of. See Rectification, and Parabola.

Parabola, Centre of gravity of. See Center of Gravity.

Parabola, Centre of oscillation of the. See Center of Oscillation.

Parabolas of the higher kinds are algebraic curves, defined by \( a^{n-1} x = y^m \). E.g. by \( a^2 x = y^3 \), \( a^3 x = y^4 \), \( a^4 x = y^5 \), \&c. See Curve.

H h 2

Some
Some call these paraboloids; more particularly, if \( a' x = y' \), they call it a cubical paraboloid. If \( a' x = y' \), \&c., they call it a bi-quadratical paraboloid, or a furfoidal paraboloid. And in respect of these, the paraboloids of the first kind, above explained, they call the Apollonian, or quadratic paraboloid. Those curves are likewise to be referred to paraboloids, in which \( a x^2 = y' \); as \( x, a x^2 = y' \), \&c., which some call semi-paraboloids. They are all comprehended under the common equation, \( a^2 x = y' \), which also extends to other curves, to \( y' \) to those in which \( a^2 x = y' \).

Since in paraboloids of the higher kinds, \( y' = a^2 x - 1 \), if any other semi-ordinate be called \( y' \), and the abscissa corresponding to it \( z' \), we shall have \( y' = a^2 x - z' \), consequently \( y' = a^2 x - z' \). It is a common property, therefore, of these paraboloids, that the powers of the ordinates are in the ratio of the abscissas. But in semi-paraboloids, \( y' = a^2 x - z' \), \&c., \( z' = a^2 x - z' \). The powers of the semi-ordinates are as the powers of the abscissas, one degree lower, \( x, y' \). In cubical semi-paraboloids the powers of the ordinates \( x' \) and \( y' \) are as the squares of the abscissas \( x^2 \) and \( z^2 \).

Parabola, Helicoid. See Helicoid.

Parabola, Ofellacity, in Geometry, is used particularly for that parabola which not only osculates or measures the curvature of any curve at a given point, but also measures the variation of the curvature at that point. See M’Laurin’s Appendix to his Algebra, p. 117, Cramer, Analyse des Lines Courbes, p. 559. See also Curve.

A curve, strictly speaking, may have an indefinite number of osculatory paraboloids at any of its points; but the application may be restricted to that particular parabola which meets the curve so closely, that no other parabola can be drawn between them; and this parabola will measure the variation of curvature of the curve at that point.

See Variation of Curvature.

Parabola, Resistance of. See Resistance.

Parabolani, Parabolans, among the Ancients, was a kind of gladiator, called also the confeder.

The name was given them from the Greek, a??&eis, to throw, precipitate; because they threw themselves on danger and death.

Parabolani, or Parabolans, is also used in Church History, for a set of people, especially in Alexandria, who devoted themselves to the services of churches and hospitals.

The parabolani were not allowed to withdraw themselves from their function, which was the attendance on the sick. They made a kind of fraternity; amounting sometimes to six hundred persons, dependent on the bishop.

The design of their institution was that the diseased, especially those infected with the plague, might not be without attendance.

Parabolic Asymptote, in Geometry, is used for a parabolic line approaching to a curve, so that they never meet; yet by producing both indefinitely, their distance from each other becomes less than any given line.

There may be as many different kinds of these asymptotes as there are paraboloids of different orders.

When a curve has a common parabola for its asymptote, the ratio of the subtangent to the abscissa approaches continually to the ratio of two to one, when the axis of the parabola coincides with the base; but this ratio of the subtangent to the abscissa approaches to that of one to two, when the axis is perpendicular to the base. And by observing the limit to which the ratio of the subtangent and abscissa approaches, parabolic asymptotes of various kinds may be discovered. See M’Laurin. Flux. art. 357. See also Asymptote.

Parabolic Conoid, or Paraboloid, a solid figure generated by the rotation of a parabola about its axis. The circles conceived to be the elements of this figure, are in an arithmetical proportion, decreasing towards the vertex.

A parabolic conoid is a cylinder of the same base and height as \( x = 2 \); and to a cone of the same base and height, as \( x = 1 \). See Conoid.

1. The curve surface of a paraboloid may be found by the following rules.

Rule 1.—To the square of the ordinate, or semi-diameter of the base, add four times that of the axis, and the square root of the sum will be the tangent to the curve at the base, and intercepted by the axis produced; call this tangent \( t \); then we shall have \( t = \sqrt{y'' + 4 x x} \), \( x \) being the axis, and \( y \) the ordinate. Then by the rule at the close of the article Paraboloid, find the area of the frustum of a parabola, whose parallel ends are \( t \) and \( y \), and its altitude = \( \alpha \), and this area multiplied by \( \frac{3 \times 145}{59} \) will be the curve surface of the paraboloid A B C required.

Plate XXXI. Bisellians, fig. 10.

Calling the ordinate \( y \), the abscissa \( x \), the curve \( z \), and the parameter \( p \); also \( a = \frac{3 \times 145}{59} \); the equation of the generating parabola will be \( p x = y \); hence \( p x = 2 y x \), and the fluxion of the surface \( t = 2 a y z = 2 a y \sqrt{y'^2 + x'^2} = \frac{4 a y^2}{\sqrt{4 p p + y y}} + y y; \) and, by taking the correct fluents, the surface \( t \) will be \( \frac{4 a x}{3 p} \times \left( \frac{4 p p + y y}{2} \right) - \frac{1}{2} a p p = \frac{3}{2} \) \( a y \times \left( \frac{y y + 4 x x}{2} \right) = \frac{3}{2} a y \times \left( \frac{y y + 4 x x}{2} \right) \frac{1}{y y} \) \( x x \) \( = \frac{3}{2} \) \( a y \times \left( \frac{t + y}{t + y} \right) = \frac{3}{2} \) \( a y \times \left( \frac{t + y}{t + y} \right) \); putting \( t = \sqrt{y y + 4 x x} = B E \), the tangent to the curve at the extremity of the ordinate, and intercepted by the axe produced. Q. E. D.

Corol. 1.—In C B produced take B G = the tangent B E; erect G H perpendicular to G B and equal to B D; join D H, and perpendicular to it H I, meeting B G produced in I; take B K = \( \frac{1}{2} B I \); and upon KC describe a circle meeting B L. perpendicular to B C in L. And the circle whose radius is B L, will be equal to the curve surface of the paraboloid B A C.

For, by the construction, B L \( = K B \times B C = B C \times \frac{1}{2} B I = \frac{3}{2} B D \times (B G + G I) = \frac{3}{2} B D \times (B E + G H) \), \( G D \) \( = \frac{3}{2} B D \times \left( B E + \frac{B D^3}{B E + B D} \right) \),

\( = \frac{3}{2} y \times \left( \frac{t + y}{t + y} \right) \).

Corol. 2.—The curve surface of the paraboloid is to the area of its circular base, as I K is to B D.

For the base is \( a \times B D^2 \), and the curve surface \( a \times \frac{3}{2} B I \times B D = a \times I K \times B D \).

Corol. 3.—If M be the focus of the generating parabola, and there be taken A N = M C = A D + A M, and the double
double ordinates $PNO, QMR$ be drawn; the surface generated by $BAC$, will be to the area $QOR$, as $a = 3.14159$, to 1, or as the circumference of a circle to its diameter.

For the surface,
$$s = \frac{4a}{3} \times \left(\frac{1}{3} \rho \varphi + y \rho\right) - \frac{1}{6} a \rho \varphi = \frac{4a}{3} \times \left(\frac{1}{3} \rho \varphi + \rho \varphi x \right) - \frac{1}{6} a \rho \varphi = \frac{4a}{3} a \times \left(\frac{1}{3} \rho + x \right)
$$

$s^2 = \frac{1}{3} \rho \varphi + \rho \varphi x - \frac{1}{6} a \rho \varphi = \frac{2}{3} a \times MC \sqrt{MC} \times \rho - \frac{1}{6} a \rho \varphi = \frac{2}{3} a \times AB \sqrt{AB} \times \rho - \frac{1}{6} a \rho \varphi = \frac{2}{3} a \times \rho \varphi.
$

Rule 2.—Divide the difference between the cube of the tangent and the cube of the ordinate, by four times the square of the axis; multiply the quotient by $\frac{1}{3}$ of the ordinate, and the product again by $3.14159$ for the surface. Thus,
$$\frac{1}{3} y^2 - \frac{1}{3} \rho \varphi = \text{the surface} \quad \text{where} \quad t = \sqrt{y^2 + 4 \rho \varphi}
$$

H. The curve surface of the frustum of a paraboloid, having its altitude and the diameters of its ends given, may be thus found.

Divide the difference of the squares of the semi-diameters of the ends, by their distance, or by the altitude of the frustum; or divide the difference of the squares of the whole diameters, by four times the altitude; and the quotient will be the parameter of the axis of the generating paraboloid.

Find the two sums arising from the addition of the square of the parameter and the square of each diameter; multiply each sum by its root, and divide the difference of the products by the parameter; multiply the quotient by $3.14159$, and the product will be the surface of the frustum.

That is,
$$\left(\frac{\rho \varphi + D \varphi}{D}\right)^2 - \left(\rho \varphi + d \varphi\right)^2 \times \frac{1}{6} c = \text{the surface} \quad a = \text{the altitude, and} \quad c = 1.571459$$. 

In the investigation of rule 1. of the last problem, it appears that $\frac{4a}{3} \times \left(\frac{1}{3} \rho \varphi + y \rho\right) - \frac{1}{6} a \rho \varphi \times \left(\rho \varphi + D \varphi\right) - \frac{1}{6} c \rho \varphi \times \left(\rho \varphi + D \varphi\right) = \frac{1}{6} c \rho \varphi$, is the segment whose base diameter is $D$; and $\frac{1}{6} \rho \varphi \times \left(\rho \varphi + d \varphi\right) - \frac{1}{6} c \rho \varphi$, is the surface of the segment whose base diameter is $d$; and, by taking the difference, $\frac{1}{6} c \rho \varphi \times \left(\rho \varphi + D \varphi\right) - \left(\rho \varphi + d \varphi\right) \times \frac{1}{6} c \rho \varphi = \text{the surface of the frustum, the diameters of whose ends are} D, d$.

And the parameter is $\frac{D \varphi - d \varphi}{D}$, appears thus:
$$\frac{D \varphi - d \varphi}{D} \times \frac{4a}{3} \times \left(\frac{1}{3} \rho \varphi + y \rho\right) - \frac{1}{6} a \rho \varphi = \text{the surface}$$. Since $\rho \varphi = y^2$, therefore $\rho \varphi - Y \rho \varphi = Y \rho \varphi - y \rho \varphi$, and $\rho \varphi + Y \rho \varphi = \text{the diameter} \times \frac{4a}{3}$. 

III. The solidity of any segment of a paraboloid, whose base is either perpendicular or oblique to the axis, may be found by the following rule. For both right and oblique segments, multiply the base by half the altitude, and the product will be the content. Let $b$ denote the base, $a$ the altitude, $\varphi$ any variable absciss, or part of the diameter drawn through the middle of the base, and $t$ the line of the angle formed by this diameter and its ordinate, to the radius $r$.

Then as $a : x : : b : \frac{1}{2} x a$ is the section corresponding to the absciss $x$. Therefore $\frac{1}{2} x a \times b i x$ is the fluxion of the fold; and, by taking the fluent, the fold itself will be $\frac{1}{2} a x ;$ which, when $x = a$, becomes $\frac{1}{8} a^2$ for the whole fold, whose base is $b$ and altitude $a$. Q. E. D.

Corol. 1.—A paraboloid is equal to half a prism of the same base and altitude. Also a prism, a semi-pheroid or semi-sphere, a paraboloid, and a pyramid, all of equal bases and altitudes, are to one another as the numbers $1, \frac{1}{2}, \frac{1}{3}, \frac{1}{4}$; and are, therefore, in a discontinuous geometric proportion, whose ratio is that of $3$ to $2$. Which will appear by comparing the above value with the paraboloid with that of the other solids.

When the base of the paraboloid is perpendicular to the axis, or when the paraboloid is right, the semi-pheroid, or semi-square, will also be right; and the prism and pyramid will be the right or common cylinder and cone, the common base being a circle. But if the paraboloid be oblique, by having its base oblique to the axis, the common base of all the solids will be an ellipse; the semi-spheroid will also be oblique, by having its base oblique to the axis; and the prism and pyramid may be either right or oblique.

Corol. 2.—If upon the diameter $NP = BC$ be the conjugate axis of the frustum of the section $AB$, be described a circle; (Plate XIXI. Mijlham, fig. 11.) the oblique paraboloid, or segment $AHB$, will be equal to the right paraboloid whose base is that circle, and its altitude $MH$. For, the diameter of the circle being the conjugate axis of the base of the paraboloid, the circle will be to that base, as the conjugate is to the transverse axis, that is, as $C$ to $A$; but $HK$ is to $HM$ in the same proportion of $C$ to $A$; consequently $HK \times$ elliptic base $A B$ will be $HM \times$ circular base $NP$ or $BC$.

It is also evident, that all segments, right or oblique, having the same vertex $H$, and the transverse axes of whose bases pass through the same point $M$, and terminate in $AC$, $OP$, parallel to and equidistant from $HM$, will be equal to one another.

Corol. 3.—If $B$, $b$ denote the two bases, or parallel ends, of the frustum of a paraboloid, either right or oblique, and $d$ the distance of the ends, or the altitude of the frustum; then $\frac{1}{2} d \times (B + b)$ will be the solidity of the frustum.

For, by this problem, $\frac{1}{4} A B$ is the segment whose base is $B$ and altitude $A$; and the base of the whole base is $b$ and altitude $a$; therefore the frustum, or the difference of the segments, is $\frac{1}{2} A B - \frac{1}{2} a b$. But, by the nature of the paraboloid, $B - b : d : a - a :: B : A = \frac{B d}{B - b}$, and $B - b : d : b :: a = B - b$ which values of $A$ and $a$ being substituted for them, we obtain $\frac{1}{2} A B - \frac{1}{2} a b = d B - b B - b = \frac{1}{2} d \times (B + b)$.

Corol. 4.—Let $AGBb$ be a right frustum, $HI$ the diameter to the double ordinate $AB$, and $HK$ perpendicular to $AB$, that is, $HK$ is the altitude of the oblique segment $A H B$. Then the value of the oblique segment $A H B$ is $\frac{1}{2} n \times AB \times BC \times HK$, putting $n = 785398$. But,
PAR

But, by the property of the figure, \( DB^2 - DC^2 \): 
\[ DB^2 - DI^2 = AC : HI = \frac{DB^2 - DI^2}{AC} \times AC; \]

hence \( HM = HI - IM = HI - \frac{1}{4} AC = \frac{DB + DC}{DB - DC} \times 4CA = \frac{BC \times CA}{8 DI}; \) and, by similar triangles, 
\[ AB : CB : HM : HK = \frac{HM \times CB}{AB} = \frac{AC \times CB}{8 DI}; \]

therefore the oblique segment \( AHB \), or \( \frac{1}{2} n \times AB \times CB \times HK \), will be 
\[ \frac{CB^3}{8 DB^2} \times DE \times n = \frac{CB^3}{b B^2 - AG^2} \times AC \times \frac{n}{2} \times n. \]

Or, by substituting the value of \( AC \), viz. 
\[ DB^2 - DC^2 \]

\[ DE = \frac{CB \times 2 DI}{DB} \times DE, \text{ instead of } \frac{DE}{b B^2 - AG^2} \]

of the greater ungula \( b AB \).

Corol. 5.—If \( DE \times b B^2 \times \frac{1}{2} n \), the value of the right segment \( b E B \), be taken the above value of the oblique segment \( AH B \), there will remain \( b B^2 - AC^2 \times DE \times \frac{1}{2} n \) for the value of the greater ungula \( b AB \).

Corol. 6.—And if from the said value of the oblique segment \( AH B \), be taken that of the right segment \( AE G \), 
\[ AG^4 \]

viz. \( b B^2 \times DE \times \frac{1}{2} n \) or \( \frac{AG^4}{b B^2 - AG^2} \times AC \times \frac{n}{2} \), there will remain \( \frac{CB^3}{b B^2 - AG^2} \times DE \times \frac{n}{2} \) or \( \frac{CB^3}{b B^2 - AG^2} \times AC \times \frac{n}{2} \) for that of the less ungula \( AG B \). Hutton's Menuration.

PARABOLIC CUSCUS, a solid figure, formed by multiplying all the \( DB^2 \)s (Plate XIII. Analytis, fig. 3.) into the \( DS^2 \)s: or, which amounts to the same, on the base \( APB \) erect a prism, whose altitude is \( AS \); this will be a parabolical cuscus, whose section will be equal to the parabolic pyramidoid; insomuch as the component rectangles in one are severally equal to all the component squares in the other.

PARABOLIC PYRAMIDOID, a solid figure, generated by supposing all the squares of the ordinate applicates in the parabola so placed, as that the axis shall pass through all their centres at right angles; in which case the aggregate of the planes will form the parabolic pyramidoid.

The solidity of this body is had by multiplying the base by half the altitude; the reason of which is obvious; for the component planes being a series of arithmetical proportions beginning from \( \alpha \), their sum will be equal to the extremes multiplied by half the number of terms, that is, in the present case, equal to the base multiplied by half the height.

PARABOLIC SPACE, the space or area contained between any entire ordinate, and the curve of the parabola.

The parabolic space is to the rectangle of the ordinate into the abscissa, as \( 2 \) to \( 3 \): to a triangle inscribed on the ordinate as a base whose altitude is the abscissa, the parabolic space is as \( 4 \) to \( 3 \).

The segment of a parabolic space, is that space included between two ordinates. See PARABOLA.

QUADRATURE of a parabolical segment. See QUADRATURE, and PARABOLA supera.

PARABOLIC SPECULUM or MIRROR. See MIRROR.

PARABOLIC SPINDLE. See PYRAMIDOID and SPINDLE.

PARABOLIC SPIRAL, in Conics. See HELICOID PARABOLIC.

PARABOLIFORM CURVES, a name sometimes given to the parabolas of a higher kind.

PARABOLOIDES, parabolas of the higher kinds. See PARABOLAS of the higher kinds.

PARABOLOID, Centre of gravity of a. See CENTER.

PARABOLOID, Quadratic. Cubical paraboloid, furfoidal paraboloid. See PARABOLAS of the higher kinds.

PARABOSCO, GIROLAMO, in Biography, organist of St. Mark's cathedral at Venice, and according to Credcenbei (Stor. del Vulg. Pof) a most admirable performer. "Whoever," says Ant. Fran. Doni, (Librarim Tratt. inn.) "is endowed with heaven with the power of receiving and communicating pleasure, should imitate Parabosco; who can not content with that musical excellence, with which he has given such delight, both in public and private, and acquired such fame, has afforded equal pleasure by his literary and poetical talents, in the publication of works, that are as much esteemed for their wit and learning, as originality." He then gives a list of his tragedies, comedies, miscellaneous poems, and letters; adding, that "he hoped his novels would soon appear in print, which, for their invention and style, he thought the most admirable productions of the kind that he had ever read." They were afterwards published under the title of "Gli Dipinti," &c. 1486; and we purchased them at an extravagant price, as curiosities, at the sale of the late Hon. Topham Beanclear's books; but find, on perusal, that Doni spoke of them as he did, perhaps, of his musical abilities, with the partiality of a friend. Several of the motets and madrigals of Parabosco are inserted in the collections that were published about the middle of the sixteenth century, some of which we took the trouble to score, but found in them no subject; but little design or contrivance. And if his literary character did not impose on his friends, and on the writers who speak of his musical productions, his fame as a composer must have been established on works superior to those, which are mere remembrance, or notes heaped on each other totally devoid of meaning with respect to melody.

PARABRAMA, in Mythology, is a name given to the first of the gods of India.

PARABYSTE was one of the five principal civil tribunals of Athens.

PARAC, in Geography, a town of the island of Borneo; 200 miles N. of Banjar-Maffim.

PARACA, a town of Peru, in the audience of Lima; 12 miles S. of Pisco.

PARACELS, or Pracels, a chain of small islands, with rocks and islets, in the Chinece sea, parallel to it, and about 60 miles E. of the coast of Cochinchina. This range is about 300 miles long, and 60 broad from N. lat. 11° 40' to 16° 10', and E. long. 110° to 111°. The navigation is dangerous, on account of several currents among them.

PARACELSIUS. See PâE PHILoPHoRS.

PARACELSIUS, in Biography, an extraordinary adventurer in chemistry and physic, in the early part of the sixteenth century, is said to have been born at Emsfulen, a little village near Zurich, in Switzerland, in 1493; and his father, called William de Hebenheim, is supposed to have been the natural son of a grand master of the Teutonic order,
order, and a practitioner in medicine in Carinthia, in the begin-
ning of the following century. With a view of dignify-
ing himself and his family, his son assumed the names of
Philippus, Aureolus, Theophrastus, Paracelsus, Bombastus de
Hohenheim. But Thomas Erasmus affirms, that there was
no family bearing any of these names in that part of Swit-
zerland, either noble or ignoble; and Haller was credibly
informed, that Paracelsus was a native of Gafis, in the canto
of Appuzel, and of an obscure family of the name of Ho-
chener, which was still existing there. His father gave him
early a turn for his own pursuits, and put him under the care
of John Trithemius, abbot of Spanheim, at that time emi-
ent for his knowledge of the sciences, and as chancer, or
its infancy was called. He afterwards followed another
master of the art, Sigismund Fugger, and from both these
he learned many secrets. If any credit is due to his own
statements, he received instructions from several other tutors,
whom he has named; although in one of his treatises, he
denies having had any instructors at all. He very soon
commenced a sort of rambling life; for he says, he had
examined the principles of the medical art with great at-
tention, and found them defective and erroneous in all points,
and therefore he resolved, after having visited the schools of
France, Italy, and Germany, to travel in pursuit of medical
truth, and not only to search for it among physicians, and
other learned persons, but among barber-surgeons, monks,
conjurors, old women, and quacks of every description.
He makes a pompous display of the names of all the coun-
tries which he thus visited, during a peregrination of several
years, and of the important acquisitions in science which he
thus collected, with the view of impressing on the world the
highest opinion of his superiority; for he seems to have pos-
sessed the talents of impertinent and successful quackery in an
eminent degree. Even the learned Erasmus appears to have
conflated him, especially after a fortunate cure of his friend
Probenius, the celebrated printer of Basle, in an attack of
gout, (although the latter died of apoplexy a few months
afterwards,) and Oporinus, an eminent citizen of that place,
left his family to follow him. In the course of his travels
he had doubtless collected much information concerning me-
tallic chemistry; which, however, he perverted to the vain
search of the philosopher's stone; and by the bold use of
some active medicines, especially mercury and opium, the
administration and properties of which were not understood
by medical men, he had certainly effected many cures, where
ordinary medicine had failed; and while these successful
cases were blazoned forth, with the usual exaggeration, the
unsuccessful ones, and the mistakes were long pa3sed over in
silence. To such a height, however, his reputation had been
raised in Switzerland, that the magistrates of Basle were
induced to engage him, at a large salary, to fill the
chair of medicine in their university. In the years 1527
and 1528, he gave lectures daily, sometimes in barbarous
Latin, but more frequently in German; and although he
first acquired several enthusiastic adherents, yet the bar-
barism, vanity, and extravagance of his lectures at length
disgraced the students, and he was soon left without an
audience. Indeed nothing could exceed the ridiculous pride
and bombaft, with which he assumed the supremacy, the
monarchy of medicine, and the contempt which he affected
among all the teachers and universities in the world. Seated
in his professorial chair, at his first lecture, he publicly
burnt the works of Galen and Avicenna, averring that his
cap contained more knowledge than all physicians, and
that the hair of his beard had more experience than all the uni-
versities. "Greeks, Romans, French, and Italians," he
exclaimed; "you Avicenna, you Galen, you Rhazes, you
Mofue; you doctors of Paris, you of Montpellier, you of
Swabia, you of Mfina, you of Cologne, you of Vienna;
and all you throughout the countries that are washed by the
Danube and the Rhine, and you who inhabit the islands of
the sea, Athenian, Greek, Arab, and Jew; you shall fol-
low and obey me. I am your king, the monarchy of phyfic
is mine," &c. That such an extravagant enthufiaft should
not long retain his professorial chair might be anticipated.
A quarrel with the magistrates of Basle, on account of a
decision against him in respect to a demand of fees, which
was deemed exorbitant, increased his displeasure, and he
suddenly quitted that place in 1531. From this time he re-
 fused chiefly in Allace, and in different parts of Germany,
leading a life of extreme intemperance, in the lowest com-
pany, being frequently in a state of continued intoxication
for many days and nights in succession. Nevertheless he
still maintained his reputation by extraordinary cures,
occasionaliy effected by his powerful remedies, though his failures
were equally conspicuous. But the most signal failure of
his boSted remedies occurred in his own person; for after
pretending to the power of extending human life to an inde-
finitive limit, by virtue of his elixir, he died in 1541, at an
inn at Salzburg, in the forty-eighth year of his age, in
consequence of an attack of fever, and was buried in the
hospital of St. Sebastian, to which he bequeathed the little
property that he possessed.
Notwithstanding the reputation, and the numerous eu-
logies beflowed on this singular man, it can scarcely be faid,
that either scientific chemistry or medicine is much indebted
to him for its advancement. The fundamental doctrines of
his chemistry, which resolved every thing into three elements,
falt, sulphur, and mercury, and which were for a long time
considered as correct, or, in fact, borrowed from his predecessor,
Basil Valentine. And as to his medical skill, it consisted princi-
pally in the bold administration of some powerful remedies,
which had been heretofore thought too dangerous to be used.
His most favourite medicine was opium, a drug with which,
it is obvious, he would be able in many instances to afford
great and speedy relief; but with which also few permanent
cures could be effected, and much mischief would necessarily
be produced, when it was misapplied. Antimony and mer-
cury were also medicines which he liberally prescribed, and
he used various preparations of them of the most active kind.
He was indeed one of the first to employ mercury for the
cure of the vehenal disaese, and of course he mist, in this
fevere and newly distingusihed malady, have been successful
in a degree, to which none of his contemporaries, who did
not resort to that remedy, could attain; and this success
was a source of considerable emolument. In fact, he was
perhaps the more favored with a stabilial benefit on man-
kind, by the introduction of mercury as a cure of this
malady; and in this point confits his principal merit in
regard to medicine. For his total ignorance of anatomy
and rational physiology, his inability from want of litera-
ture to investigate the doctrines of the ancients, which he
so boldly impugned, and his employment of a barbarous
jargon, as well as his infatuated notions of magic, alchemy,
gemancy, and all the other branches of mythical impo-
ture, are totally adverse to any claim on his part to the im-
provement of medical science; and indeed he appears to
have been entirely delirious in clear and methodical views
upon any subject. We shall not pretend therefore to enter
into any detail of the unintelligible jargon and absurd hypo-
theses which he employed, or to enumerate the immense
farrago of treatises, which made their appearance under his
name after his death, the notices of which occupy above
nine quarto pages in the Bibliotheca of Haller; for the
first
first we are unable to comprehend, and the latter would be
a waste of time. The most complete edition is that of Ge-
neva, in three volumes folio, 1658. He published little
while he lived. See Semert. de Connenfri et Diffenfis Gale-
nicorum, &c. cum Chymicis, cap. iv. De Paracelso.

Paracentesis, from paracenté, to make a perfora-
tion, in Surgery, signifying the operation of tap-
ing, or making an opening into the thorax, abdomen, or
bladder, for the purpose of discharging the fluid confined
in these parts in cases of empyema, hydrothorax, ascites,
and retention of urine. Effused blood may also require an
opening to be made into the chest. For an account of pa-
racentesis thoracis, in different cases, we refer to Em-
physma, Emphysea, Extravasation, Hydrothorax, and
Wounds of the Chest.

Paracentesis of the Abdomen, or Tapping — The belly is subject
to two kinds of dropy; one has received the name of
aflects; the other is termed encysted. In the first, the fluid
is effused in the general cavity of the peritoneum; in the
second, it is contained in a pouch, or cyst; whence the
name of the disorder is derived. The first case is the most
common, and affects indiscriminately both sexes; the
second is more rare, and prevails itself often in women
than men.

The treatment of these two species of dropy belongs to
the physician; but when they have made considerable pro-
gress, they demand the aid of surgery, an operation of
which may facilitate the action of the medicines exhibited,
procure a degree of relief, which would be in vain expected
from physic, and tend to prolong the life of the patient.
The operations alluded to, are the puncture, or paracen-
tesis, which consists in letting out the collected fluid, by
piercing the abdomen with an instrument expressly con-
structed for the purpose, called a trocar.

In cases of aflects, the abdomen cannot be prudently or
safely tapped, unless the quantity of water be considerable.
By this observation, however, we are far from meaning to
diffuse practitioners from deferring the operation as a last re-
source. On the contrary, we are decidedly advocates for
the performance of paracentesis at an earlier period than
it is usually done; and we would earnestly recommend
the faculty to give their patients a better chance of recov-
ery, by having them tapped before their constitutional
strength is too much reduced. The operation is no hin-
drance to the trial and continuance of such medicines as are
likely to prove beneficial. Hence, as soon as paracentesis
can be done, without risk of injuring the viscera, or
rather as soon as the abdomen is sufficiently distended with
fluid to render the introduction of the trocar safe, the op-
eration appears to be advisable.

There is much reason for believing that paracentesis
would in numerous instances be something more than a pa-
liative measure, if it were referred to at an earlier period
of the disease. Le Blanc, in his "Precis d'Operations,"
affirms us, that he was constantly in the habit of prac-
tising the operation immediately when he distinctly felt the fluctua-
tion of the fluid in the abdomen, and that the success of the
operation was very great. Even in the ordinary mode of prac-
tice, the operation of paracentesis sometimes effects a
radical cure, and the fluid never accumulates again. (See
Journal de Medecine, tom. lxvi.) It is highly probable,
that this would be the case more frequently, if the opera-
tion were properly practised. (Fothergill in Med. Obser-
vations and Enquiries, vol. iv.) There appear to be two
cases which tend to hinder the salutary effect of the ope-
ratio. The first is, that if the disease recur after it has
been once practised, all hope of radical cure is generally re-
nounced. The second cause is, that the operation is almost
always repeated too late, not until the belly is again prodi-
giously distended. But, in order to give the best chance of
a radical cure, the operation should be repeated frequently
and at short intervals. Default used to tap dropical pa-
ients once a week, and in many cases, after he had performed
the operation two or three times, the disease was dropped.

Even when the operation does not itself accomplish a
radical cure of ascites, it at least promotes and facilitates this
defirable event. There cannot exist a doubt, that it is
impossible for the means, which the physician prefers with
a view of cure, to produce their free and full effect
while the abdomen is distended with water, and the func-
tions of the viscera thereby more or less disturbed. Expe-
rience has proved, that medicines, which were found to be
ineffectual previously to the operation, have frequently had
the desirable effect after the water has been evacuated.

Serious and even fatal symptoms have sometimes followed
the operation of paracentesis, and, hence it has been con-
sidered by certain practitioners as a proceeding attended
with danger. But the foregoing unpleasant consequences are
not to be ascribed to the operation; but either to the phy-
sician, who has recommended it to be performed too late,
or an improper period, or else to the surgeon, who has
executed it without the requisite skill and caution. For,
how frequently it happens, that it is not undertaken until
the abdomen is swelled with a prodigious quantity of water, and
the patient is in an extreme state of disorder and debility,
partly from the long duration and high degree of the disease,
and partly from the effect of the large quantities of violent
medicines which have been exhibited. The operation is
here plainly unfeasible and too late. If the sudden dis-
charge of the fluid should now give rise to alarming con-
sequences, the occurrence would prove nothing more, than
that the operation, like every other means, is not proper at
every time, and under any circumstances. In such cases
the right opportunity of doing it is past. It ought to have
been referred to at an earlier period. It is a certain fact,
that the sooner dropical patients are tapped, the less dan-
gerous and the more beneficial is the operation. Immedi-
ately when there is a sufficient quantity of fluid in the abdomen
to produce a manifest fluctuation, paracentesis is practicable;
and no sooner do medicines begin to debilitate the patient,
or become ineffectual, than the operation is indicated as a
measure which should not be deferred. But even in those
very instances in which paracentesis has been improperly
delayed, modern surgery is furnished with a method of ob-
viating the perilous symptoms, which are liable to arise from
the sudden evacuation of the large quantity of fluid, as we
shall presently have occasion to explain.

The following are the ordinary symptoms of aflects. A
smooth uniform swelling extending over the whole abdomen,
but most prominent at that part which happens to be the
most dependent. A thinning or glossy appearance of the
integuments, which is particularly observable in the early
flage of the disorder, and becomes obvious when the com-
plaint has attained a high degree, and the abdomen is ex-
cessively tense and distended. An edematous swelling of the
feet and perineum, especially when the disease is making pro-
gress. Thirst, dry skin, colicky bowels, and hardened
ulcers; a scanty secretion of thick dark-colored urine;
difficulty of breathing, especially in the recumbent posture;
and, lastly, the fluctuation of the fluid in the abdomen.
The latter symptom can be distinctly felt by the surgeon,
when he places the palm of one of his hands upon one side
of
PARACENTESIS.

of the patient’s belly, and taps gently with two fingers upon the opposite side.

There is one cafe, which bears considerable resemblance to droppiness of the belly, and may easily lead a careless surgeon to commit a serious mistake. We here allude to a retention of urine, that has existed a considerable time, and has attained a very high degree. In this instance, the bladder is sometimes so enormously distended, that it produces an uniform swelling of the whole belly, attended with a fluctuation and protuberance at the most dependent part of the abdomen. As, in this case, the bladder has lost its power of contraction, it always remains distended and dilated; but while the preface of the abdominal muscles is reflected, the bladder, and the bladder alone is acted upon. This circumstance prevents the retention of urine by provoking the bladder, and is apt to lead the practitioner into the error of mistaking the cafe for droppiness.

The instrument with which the paracentesis of the abdomen is performed, is called a trocar, of which there are several kinds. The celebrated Richter thinks the common one the best. Most of the modern alterations, which have been made in the construction of trocars, have only tended, says he, to render the employment of these instruments more difficult. There is no reason for the ordinary objection, that the common trocar cannot be introduced without considerable force. If the part into which it is about to be passed be made tense, very little force will be necessary, especially if care be taken to rotate the instrument gently as well as pull it forward. Hence, all the inventions, which have originated from this supposed imperfection, are, according to Richter, entirely useless. He represents the trocar with a double edged point as needleless. The proposal of Mr. Cline, to make a puncture with a lancet, and then to introduce into the opening of a blunt-pointed trocar, is alleged to be superfluous. Nay, these innovations are flated to be worse than useless. A cutting instrument is liable to injure the blood-vessels, and bring on a weakening degree of hemorrhage; and it is said, that the wound, thus made, does not so readily heal as that made with a common trocar. That cutting edged instruments are attended with the inconvenience of being apt to wound enlarged veins, and produce a disagreeable degree of hemorrhage, is a truth, of which the writer of this article has recently met with a convincing example. A female, who had strong aversion to being tapped with a trocar, prevailed upon him to make the opening with a lancet. The puncture was made in the linea alba, about three inches below the navel. A stream of dark-colored venous blood continued to run from the wound the whole time the water was flowing out of the cannula, and did not cease until a compres was applied. The quantity of blood lost could not be less than a pint, or a pint and a half. In many cases, the loss of so much blood would prove fatal to a drophical patient, and is a thing which one must always feel anxious to avoid.

It was the general plan, a few years ago, to introduce the trocar at the middle of a straight line drawn from the navel to the anterior superior spine of the os ilium, or at the central point of the space between the navel, the spine, the crux of the ilium, and the lower laryngeal ribs, and the puncture was made on the left side, in order to run no risk of injuring the liver in the event of this viscus happening to be enlarged. In operating in the first of these situations, the intention of the surgeon was to make an opening into the abdomen at the linea semilunaris. Modern practitioners usually prefer making the puncture in the linea alba, for several weighty reasons. The first is that in the old method, you are not sure of introducing the trocar in the exact situation of the linea semilunaris, and consequently may unnecessarily wound the thick muscular parietes of the abdomen instead of merely a thin tendinous part. Another still more important objection is, that the epigastric artery has sometimes been wounded by very skillful men, even by professed anatomists, in the attempt to tap in the linea semilunaris. In drophical cafes, the rectus muscle is frequently much broader than in a healthy subject; and as it always yields to the dilatation of the fluid in a greater proportion than the lateral layers of muscles, the above-mentioned measure is very likely to cause the wound to be made near the course of the epigastric artery.

When the operation is to be performed in the linea alba, (and, except in cafes of encysted dropfy, we would always recommend this mode,) the trocar should be introduced about three inches below the navel. As soon as the instrument meets with no further resistance, it is not to be pushed more deeply, without any object, and with a possibility of injuring the viscera. The cannula alone is now to be conveyed a very little further into the opening, at the same instant that the fillet is withdrawn, in order to allow the fluid to run out.

Notwithstanding the fluctuation of the water may be plainly felt at the part where the puncture is about to be made, the surgeon must refrain from being too bold with the trocar, lest he wound some of the viscera. A bowel may lie very near the peritoneum, when a manifest fluctuation is perceptible at the part, the intervention of a very small quantity of fluid sufficing to cause such a sensation to the fingers of an examiner. Cautious, therefore, in this operation is a most prudent and necessary virtue.

Sometimes the surgeon feels a fluctuation over the whole abdomen, but in a weak and indistinct way. In this circumstance, when the patient is not at the same time affected with anæsthesia, which of course must tend to weaken the sensation of a fluctuation, the surgeon has reason for supposing, either that the disease may be encysted dropfy, or that the fluid contained in the abdomen may be thick, or else that the tumour of the belly may be occasioned by hydatids.

In performing paracentesis, the practitioner should always be careful to avoid wounding the cutaneous veins, which, in drophical persons, frequently attain a vast size, and become capable of emitting a large quantity of blood. In drophical patients, the navel swells in such a manner, that it puts on the appearance of a bladder of water. In this cafe, a propofal has been started to open the tumour of the navel with a lancet, taking care to make only a small aperture, so that the fluid may not be all discharged suddenly, but may be some days in dribbling away. It is said, that in performing paracentesis in this way, there is not only no bleeding, but no risk of any perilous symptoms, so gradually does the water make its escape. The alarming indisposition, which often immediately arises from the sudden discharge of the fluid in the ordinary operation, is a source of considerable uneasiness both to the patient and the surgeon; and the avoidance of this is undoubtedly a desideratum of importance. Another advantage of the plan, which we have just now been speaking of, is, that the little opening does not directly close up, to that the continuance of the oozing from it prevents for some time any re-accumulation of fluid in the abdomen. The practitioner may the more readily make up his mind to this operation, by considering, that if a puncture be not made into the swelling of the navel, a spontaneous opening is in time generally produced; that when
PARACENTESIS.

when this has happened, and the fluid been thus discharged, no bad consequences have ensued; and, lastly, that the method has been already practised with success. (See Sim's Obald. in the Memoirs of the Medical Society, vol. iii.)

The apprehension of an umbilical hernia being the consequence, which Garengeot and others entertained, is, as Mr. Samuel Sharp conjectured, quite unfounded, especially when the puncture is small, as it always ought to be, (Richer's Anfangfr. der Wundarzt, Band 5, § 143.) Sometimes the water descends into the empty sac of a scrotal hernia, and diffends it in a considerable degree. Here we may without hesitation adopt the plan of discharging the water from the cavity of the peritoneum, by puncturing the hernial sac. Frequently, in the female subject, the fluid of ascites presses upon the vagina in such a manner, as to produce a kind of prelapse of the latter part, which has the appearance of a pouch filled with water. In a case of this description, the fluid has been evacuated from the abdomen, by puncturing the tumour of the vagina with a trocar, and the wound has healed very favourably. Bishop on Medical Communications, vol. 1, ii.

The plan of tapping males from the rectum, and women from the vagina, has been suggested as one deserving of general imitation. In 1788, Macaron, a surgeon at Turin, addressed a letter upon this subject to the secretary of the French Academy of Surgery, mentioning three examples, in which the operation had been done in the foregoing way, and requiring such further information as could be given him. Allan, a member of the academy, was the only one who knew anything about the method. He recollected having, in 1767, presented to the society a memoir, in which he discussed the question, whether paracentesis from the bladder and rectum might not have advantages. (See Sabatier's Médecine Opératoire, tom. i. p. 173.) We join Richter in the opinion, that, as a general practice, this does not deserve recommendation, and that it should only be purged, when nature indicates it, by presenting a tumour either in the vagina or rectum.

In the operation of paracentesis, it is prudent to employ an assistant in compresing both sides of the abdomen; by which means, the contained fluid will be urged in larger quantity towards the place where the trocar is to be introduced; the integuments will be rendered tense, so that the instrument will penetrate with greater ease; the determination of the water towards the part about to be punctured, will increase the distance between the peritoneum and the viscera of the abdomen; and, of course, the likelihood of these being touched with the point of the trocar will be diminished. As such compression should be maintained till the end of the operation, the assistant ought to put himself in a position, in which he will be able to do what is required of him without the least remission.

It is customary with many operators to oil the trocar, just before using it; and this plan has come into vogue from a supposition, that the instrument will now pierce the flesh with greater facility. For our own part, we have always regarded this fashion as equally useless and harmless: its omission is far more proper than that of many other circumstances, which are too frequently neglected. The patient is mostly tapped as he sits in a chair, or upon the edge of his bed. The surgeon is to hold the trocar in his right hand, in such a manner that the handle of the instrument is exactly in the hollow of the palm, while the fore-finger is applied along the cannula to within an inch and a half of the point of the trocar. The end of the finger prevents the instrument from piercing too far, which it would otherwise be apt to do in a very sudden way.

If it be a common round trocar that is used, its entrance will be greatly facilitated by rotating it a little, at the moment it is pushed forward. The sudden celiation of all resistance apprises the operator of the point of the instrument having passed through the peritoneum. The trocar, or espert, is now to be immediately withdrawn, care being taken to keep back the cannula with the left thumb and fore-finger. Sometimes the fluid suddenly ceases to flow, which circumstance is generally owing to a part of the omentum, or intestines, having fallen against the inner opening of the cannula. In this case, the part causing the foppage must be pushed back by means of a probe, passed through the tube. Frequently the obstruction is produced by membraneous flakes, which the water sometimes contains; here the introduction of a probe will also remove the foppage.

When most of the fluid has been discharged, the viscera often come directly into contact with the inner end of the cannula, which, if moved about, will bruise and injure the parts. Hence, towards the end of the operation, the tube should always be held entirely motionless. Although it is always proper to draw off as much of the water as possible, yet the practitioner must be careful not to push and handle the lower part of the abdomen too forcibly, with a view of squeezing out the whole of the fluid, lest he press the bowels against the cannula, and excite inflammatory symptoms.

Sometimes swooning, extreme prostration of strength, and violent pain, occurring and after the operation. These evils are imputed to the sudden evacuation of the water, the consequent sudden relaxation of the distended parts, and the copious influx of blood into the containing and contained parts of the abdomen from the fist of the circulation. Experience has proved, that this alleged cause of the indisposition and even danger, which are apt to take place upon the discharge of the water, is founded in reality. A patient died during the operation; upon examination of the body, all the vessels of the brain were found quite empty, while those of the abdomen were filled with blood. (Richer's Anfangfr. Band 5, p. 147.) Several pans have been gaggled, with the view of preventing the dangerous consequences under consideration. Some writers advise us not to let out all the fluid at once; but, after discharging only a part of it, to stop up the cannula securely in its place, and let out a certain quantity of the water every day. There is too great reason to apprehend, however, that the cannula, being a hard extraneous body, if left long in the wound, with a portion of it in the abdomen, would rub against and irritate the bowels, so as to excite inflammation, and other dangerous effects, especially when the quantity of fluid in the cavity of the peritoneum has been reduced to a small quantity. Others have recommended a repetition of the operation from time to time, and discharging on each occasion only a part of the fluid. The objections which have been urged against this plan are, that the water, which is left after the first performance of paracentesis, would ooze through the puncture, so as to prevent it from healing; and that if the operation were to be repeated a certain number of times, the quantity of fluid would be so small, that the abdomen could not be again punctured, without risk of the intestines being wounded by the trocar.

The means, commonly referred to for the prevention of the bad symptoms apt to be produced by the operation, is making prefigure with a bandage, or towel, applied round the body, as soon as the fluid has been discharged. The method seems, indeed, to be a rational one, and well calculated to answer the end proposed; but, unfortunately, if
PARACENTESIS.

It be not adopted till after the fluid has been let out, it is not likely to be of much service. After the water has been discharged, the head symptoms have in general already come on. It was observed by Bertrand, that a patient became faint in the operation every time the assistant remitted the pressure of his hands on the abdomen; a fact which proves, in Richter's opinion, that, in proportion as the parts cease to be compressed by the evacuation of the water, the blood is determined into them.

The celebrated Dr. Alexander Monro was the inventor of a sort of belt, for making the necessary pressure on the abdomen, during the operation of paracentesis; and it is certainly well adapted to the purpose. It is furnished with straps and buckles, which are fastened behind the patient; while in front it is provided with an aperture at the place where the trocar is to pass. It is applied before the operation, and, in proportion as the water escapes, the straps are drawn more and more tightly; so that when the whole of the fluid has been let out, the abdominal viscera are just as much compressed as they were before the performance of the operation. This belt, being applied previously to the puncture, the water is more particularly urged towards that point which is left uncompressed, namely, the place where the opening in the bandage is situated, and where the surgeon means to introduce the trocar. Here the integuments become prominent and tense, so that the instrument penetrates more readily, and without risk of injuring any of the internal parts. When Monro's belt or girdle is not at hand, a very good way of keeping up the requisite pressure, during the operation, is by means of a sheet, which is to be put round the abdomen, and to be gradually tightened by the assistants, in proportion as the fluid escapes. Immediately after the water has been discharged, a piece of lint and the emplastrum saponis are to be applied to the wound; a flannel comprehs, sprinkled with camphorated spirit or brandy, is to be laid over the abdomen; and a tight flannel roller put round the body. The patient is to be got into bed as quickly as possible, and may take the following draught: R Ammoniae Muriat. gr. x., Mist. Camph. fivis Tinct. Opii lii xxx ft. laevit.

In operating at the middle of the fore part of the abdomen, that is, at the line alba, the surgeon cannot wound any artery of magnitude; though it is possible for him even here to have hemorrhage from a varicose enlarged vein, should he be bonid to wound such a vessel. The writer of this article, as already related, had a patient, who lost a very large quantity of blood, after being tapped in the linea alba with a lancet. But the most perilous kind of bleeding is that which proceeds from a wound of the epigastric artery, and which must ever be regarded as a serious objection to tapping at the side of the abdomen; because, in this method, no surgeon can be sure of not producing it. As the epigastric artery lies deeply, the blood may become extravasated in the abdomen, and the patient die of the consequences, without any continuance of external hemorrhage from the wound. When the wound bleeds profusely, the preceding artery having been injured, surgical authors advise us to introduce into the opening a cylinder of wax, of sufficient diameter to fill up completely the track of the trocar. Bellec, a French surgeon, first adopted this plan with success; but in withdrawing the wax, after it had answered its purpose, it broke, and the part of it left behind did not come away till some time afterwards. Hence this practitioner was led to give the preference to the employment of a piece of a narrow wax-candle, the wick of which would render the whole stronger, and more certain of being drawn out again entire. Sabatier very properly thinks a piece of a thick bougie might be still better. (Sabatier, Médée Opératoire, tom. i. p. 178.) Thus far we have been speaking of paracentesis, as performed in cases of ascites: it is next proper to say a few words on the subject of encysted dropsies, and describe the mode of operating for them.

Sometimes the fluid is not contained in the cavity of the peritoneum itself, but in a preretinal phalus, the difease being then termed encysted dropsy. Various parts of the abdomen may be the seat of this disorder. The left lobe of the liver has been found dilated into a sort of pouch, that was filled with an aqueous fluid. It is more common, however, for the omentum to be affected; but the ovariis and the cellular sublance of the peritoneum are the parts, in which the discharge takes place the most frequently of all.

Dropsy of the ovary makes its appearance first as a circumcised moveable swelling on one side of the abdomen, and, in the beginning, is not uncommonly supponed to be a solid tumour. In general, the swelling enlarges very slowly, and the patient suffers no particular inconveniences from it. At length, however, it undergoes a rapid increa of size, and diffounds equally every part of the belly, so that it may now be easily mistaken for an ordinary case of ascites. Dropsy of the ovary may be determined from the latter disease by paying attention to the following circumstances. Both in the early and more advanced stage, the feel of a fluctuation is never so plain as in ascites. Sometimes the fluid is contained in a large number of cysts, which have no communication with each other, and sometimes it is very thick and viscid; in which circumstances, frequently any fluctuation at all is usually distinguishable. In particular instances, even when the whole abdomen appears, on a cursory view, to be every where uniformly dilated, the prominences and inequalities caused by the separate cysts may be felt on more careful examination. The swelling of the abdomen hardly ever sinks downward to the mould depending part, as it does in ascites. The urine is generally secreted in the ordinary quantity, and is of a natural quality. Even when the tumour has attained considerable magnitude, the patient has fewer complaints than in common dropsy; the breathes more freely, moves about easily, looks better, and is less troubled with thirst. In numerous instances, the patient suffers no inconveniences whatever, excepting such as are directly produced by the size and weight of the swelling. The menzne of many patients are also quite regular, notwithstanding the dilatation is advanced. The navel never swells, as it occasionally does in ascites. But although these are the usual symptoms of encysted dropsy, the disease is subject to several varieties, which sometimes facilitate the diagnosis, sometimes render it more difficult. For example, in certain cases, the fluctuation is as plain as in ascites. In others, the urine is thick, and secreted only in small quantities, and the feet swell, as is common in this latter disease. The swelling may increase with great rapidity, or it may only enlarge from time to time, and at length remain a good while stationary. Sometimes, as the disorder advances, pains occur in the cyst, and the patient is afflicted with colic, constipation, fever with emaciation, &c.

The fluid found in a droopy ovarian is never of a bright yellow colour, and transparent, as the water of ascites commonly is; but is always more or less discoloured, fcatid, and blended with matter, blood, or a thick sediment. When, therefore, the exact nature of the case is not known before the operation is done, it is always ascertained then by the quality of the discharged fluid. Sometimes the fluid contained in the ovary is of a gelatinous kind. In other instances, this viscus is found filled with hydatids. In most
caries, the ovary is at the same time in a cirrhous state, and the inner surface of the cavity which it forms is ulcerated. Numerous patients live a considerable time with this disease. Twenty and even thirty years have been known to elapse, ere the disorder proved fatal.

Dropsy of the ovary is mostly observed to afflict women who have either had many children, or repeated abortions. It is generally incurable. Internal means avail little; the operation by which the fluid is let out is the only useful proceeding, and even this procures merely temporary relief, for, in general, the face soon becomes filled with fluid again. Sometimes, indeed, the operation proves hurtful, and hastens the patient's dissolution. In the first performance of it, a clear fluid is usually discharged; but when it is repeated, the water is turbid, and mixed with blood and matter. The more frequently the operation is done, the more quickly does the water continue to accumulate again. Paracentesis seems not only to promote the ulceration of the ovari, but also to lower the patient, and bring her to the grave sooner than she would otherwise have arrived at. Certain it is, at all events, that numerous patients, who have not been operated upon, have lived a long while with dis ease, while reiterated operations have in general been soon followed by a fatal termination.

Hence, when the swelling is not very large, and not productive of great inconvenience, we are advised by Richer to refrain from every means, and from the operation itself. He acknowledges, however, that there are cases where the operation may be judiciously and advantageously practised; namely, when the swelling is exceedingly large, and attended with much inconvenience. That it may be usefully done in certain instances, seems to be proved by examples, in which it was repeated forty-one times, (Medical Communications, vol. ii), sixty-five times (Mead), and even 155 times (Philos. Transact. vol. lix.)

When it is known beforehand, that the disea e is an en- cysted dropy, one should choose rather a large trocar, because the fluid is usually thick, heavy, and viscous, and will not readily flow out through a narrow cannula. The place for making the puncture is not so determinate as in cases of aficites. The trocar is to be introduced where the tumour is not prominent, where the fluctuation is most distinct, where there is no obvious induration, and where there is no risk of wounding the epigastric artery. Dropical enlarged ovaries are generally adherent to the peritoneum; but when they are not so, the performance of the operation may not be followed by any bad effects. Sometimes, both the ovaries are at the same time distended with fluid. In this case, after an ovary has been tapped, the operation may be practised on the other. When the water is contained in several different cysts, it is sometimes necessary to make no less than four or five punctures, in order to discharge a sufficient quantity of the fluid. In particular examples the fluid is so gelatious, that it will not pass through the cannula, and, in this circumstance, it has been usual to dilate the puncture by an incision, so as to let out the contents of the swelling; but the camps have commonly had a fatal termination. Richter decidedly recommends us not to imitate the practice, but to withdraw the cannula, and abandon all thoughts of evacuating the fluid.

Since the discharge of the water, by means of a trocar, as in aficites, only palliates the disease for a short time, the question has been flitted, whether any thing can be done with a view of effecting a radical cure? With this design, several plans have been suggested, the merit or demerit of which can only be determined by future and repeated experience. Le Dran has advised us to make an incision into the swelling, so as to let the fluid which is daily secreted into the face, have constantly a ready issue, and to keep the diseased cavity continually empty, in order that it may have an opportunity of contracting. (See Mem. de l'Acad. de Chirurgie, tom. vi.) The operation is done in two ways: viz., either a trocar is first introduced, and, after the water has been let out, and a director has been passed in through the cannula, the latter is taken away, and an incision four inches long made on the director; or else a trocar with a cannula having a suffice in it, is employed, through which suffiere the puncture is enlarged with a dilator.

After the operation, emollient injections are to be employed until the matter is of good quality, and then an attempt must be made to promote the closure of the aperture with injection of an astringent nature. Le Dran assures us, that such an operation has been actually practised with success. In cases where the cavity of the ovary is divided into several cysts, or where it is filled with a gelatious fluid, or hydatids, and where, consequently, the palliative method is inapplicable, this operation is the only practicable undertaking.

There are so many things to be taken into consideration, however, that the surgeon will hardly be inclined to adopt such practice in ordinary cases. The uncertainty whether the ovary is adherent to the peritoneum, is often an unpleasant circumstance. A dropical ovary is also commonly in a cirrhous state, a thing that must render the radical cure difficult, and even impossible. Before attempting it, we are advised by Le Dran always to let out the water with a trocar, and then examine whether any cirrhous induration can be felt, and, if it be perceptible, not to think of undertaking the radical cure. Le Dran also assures us, that cirrhous swellings, which may sometimes be felt at first, frequently follow during the continuance of the suppurition. This desirable event Richter thinks cannot be expected to happen often, and he apprehends that after the water has been discharged, the indurated part of the ovary will not always admit of being felt. The strongest argument against this operation, however, arises from the ill success which has hitherto attended it. In general, the suppurative fluid afterwards becomes more copious and degenerated, and the patient dies of a lingering fever, at an earlier period than she would probably have done, had the operation not been done at all. In one example, Le Dran converted the wound into a fistula, by which means the patient lived a long while in a very tolerable condition.

Other practitioners, fearful of the free entrance of the air into a large incision, have suggested the plan of letting out the water with a trocar, and then introducing through the cannula a flexible hollow bougie, which is to be kept in the opening, until either a complete cure, or a fistula is produced.

Richter represents this operation as attended with several advantages, and no hazard. It has always been observed, that patients who have submitted to the palliative operation, always find themselves very well, until the fluid has accumulated again in considerable quantity. This last radical operation has at least the advantage, that while it keeps the face empty, it also keeps the patient in the same tranquil state as is generally enjoyed for some days after the palliative method. When an incision has been made, it generally heals up again very soon, so that it becomes necessary to introduce a cannula. Thus, even supposing a large opening were useful, it is only of short duration. A few days after an incision has been made, the patient is in the same state as if a mere puncture had been practised, and a necessity arises for dilating the wound to its original size. We have noticed, that
PARACENTESIS.

that the incision has been known to change into a fistula, with which the patient survived a long while with tolerable health. By means of the puncture and flexible tube, an artificial fistula is immediately made. There is also only this difference between the incision and the puncture, that by the latter, the patient is at once placed in a state, in which experience proves that the mortally finds herself well, and capable of living a considerable time. On the contrary, the operation by incision always puts the patient's life at first into imminent danger.

There can be no doubt that paracentesis, and the employment of a flexible tube, will be more likely to prove successful the sooner they are tried. Experience shows, that the more frequently the water is drawn off by the palliative operation, the more blended with matter, the more bloody, and the more turbid it becomes, and the more rapidly it collects again. It appears also, that the repeated emptying and filling of the cyst again, always renders the patient's condition worse, and promote ulceration within the dropical cavity. A flexible tube should always be introduced directly after the first palliative operation, so as never to suffer the cyst to be filled again. The more the cyst is diluted before it is the first time punctured, the more likely is it to be in a morbid state, and the more improbable is the attempt at a radical cure to succeed : the water, therefore, should always be discharged as early as possible, and a flexible tube be immediately introduced. By observing this rule, we may reasonably expect to accomplish in many instances a radical cure, and, when this success does not attend the plan, we may redetermine that the fate of the patient will at all events be mitigated, and her life prolonged. During the first few days, the operation is occasionally followed by vomiting, fever, &c. which symptoms, however, are commonly unattended with danger, and soon go way to proper treatment. Richter's Anfangegrund, &c. band 5, kap. 6.

Some practitioners have recommended repeating the palliative operation from time to time, with a view of effecting a radical cure. Unfortunately, however, the cyst of a dropical ovary cannot, in general, be safely tapped until considerably distended, and hence the plan does not promise much success; but in those kinds of excysted dropy which lie more superficially, the method may answer better.

The excysted dropy of the peritoneum is commonly seated in the cellular substance, between this membrane and the peritoneum. Here the cyst, which contains the fluid, is formed of condensed cellular substance. The prognosis must evidently be more favourable than in dropy of the ovary. The surgeon detects the existence of the disease at an earlier period, and with greater facility, while the things to be considered, and the dangers to be feared in the treatment, are much fewer, and the hope of a radical cure far stronger than in a dropical affection of the ovary. The cyst may be formed at any point of the circumference of the abdomen. Sometimes several cysts present themselves at the same time, forming at first so many separate tumours, which, as they enlarge, at length make one general swelling, in which, however, some irregularities may always be distinguished. The appearances and gradual changes of this sort of excysitied dropy resemble those which accompany dropy of the ovary, with the exception of such symptoms as depend upon the different situations of the two diseases. When the cyst is situated at the lower and anterior part of the abdomen, the cyst may at first be easily mistaken for pregnancy; but a little attention to the different circumstances which characterize excysitied dropy and pregnancy, will soon dispel the error. In this kind of dropy, a fluctuation may in general be more plainly felt, than in dropy of the ovary. The face is sometimes filled with hydatids, and the disease is most frequent in women who have had many children.

As the swelling is soon obvious, and lies under the integuments and muscles, the palliative operation may be safely undertaken at a very early period, and be repeated when the cyst becomes at all prominent again. Here there is no possibility of an extravasation in the abdomen, nor of any of the viscera being wounded. A radical cure is frequently effected, as the case is not complicated with any floridous induration, and the attempt may be made early, before the cyst is of large size. The bell mode of performing this operation is as follows: a puncture is first to be made, and a flexible tube introduced, which is to be kept in until the cavity of the cyst is as much contracted as possible; the wound is then to be dilated, and the cavity allowed to suppurate and fill up by the granulating process. Sometimes a fistula will after all remain, but it is attended with still less inconvenience than such a consequence usually is in cases of dropical ovaries. See Richter's Anfangsgründe der Wundartzneykunst, band 5, kap. 6.

Paracentesis of the Bladder.—This operation becomes indispensable, when the symptoms of a retention of urine are urgent, and this fluid cannot be voided through the natural channel so soon as the circumstances of the case absolutely require. The operation is proper also, only where all other means of promoting the evacuation of the urine have failed, and where there is reason to hope that the natural pialage for this seetion will be in a moderate length of time re-established: for it is to be regarded merely as a palliative measure, and such a case is not very frequent. The operation itself is not the occasion of much danger, and the chief peril mostly arises from the puncture having been too long deferred.

Although, however, it appears to us, that the operation of puncturing the bladder ought not to be long postponed, after milder methods have decidedly failed, we believe that these methods will almost always prove successful under skilful hands, and that the operation may generally be avoided. In the opinion of Defaut, there are very few instances in which a surgeon, expert at introducing the catheter, cannot pass this instrument into the bladder, and consequently the cases in which paracentesis is absolutely necessary, must be exceedingly infrequent. This affection, says Bichat, might be confirmed by a multitude of cases. During the years of the time when Defaut was principal surgeon of the Hôtel-Dieu at Paris, where diseases of the urinary passages, and more especially obstructions of the urethra, are constantly numerous, this distinguished practitioner never had occasion to puncture the bladder, except in one example. This case happened soon after his appointment to the hospital, and he was unable to declare, subfsequently, that if he had then had as much experience, and had possed as much skill in introducing the catheter as he had afterwards acquired, he might, perhaps, have extricated this individual patient from the necessity of submitting to the operation. But as Bichat observes, since it is not every practitioner that is skilful enough to make the catheter surmount the various obstructions which may present themselves to its passage, without risk of producing a false passage, or doing other serious mischief; and since the urethra may sometimes be totally obstructed, so that no catheter nor bougie, though introduced as far as the fopbage, can serve to give exit to the urine; the operation, in these circumstances, becomes positively indispensable, for the purpose of relieving the urgent symptoms arising from the retention, and in order to prevent the bladder from bursting. Œuvres Chirurg. de Defaut, par Bichat, tom. iii. p. 316.
PARACENTESIS.

The circumstances in which puncturing the bladder becomes necessary and proper, will be hereafter noticed again. See Urine, Retention of.

There are three situations in which the surgeon may tap the bladder; viz. from the perineum; above the es pubis; and from the rectum. As the first mode of operating is nearly exploded, and has nothing to make it preferable to the two others, we shall omit a description of it in this work.

Paracentesis of the Bladder above the Pubes.—There are some practitioners who prefer making a perpendicular incision, about two inches in length, through the integuments and fat, covering the lower part of the linea alba. When this plan is followed, the wound ought not to be made, as some authors direct, with its lowest part full an inch above the os pubis. There is no great reason for keeping so far from this bone, and the lower the incision is made, the nearer it is to that part of the bladder which is the most desirable to puncture, and the further it is from the peritoneum. Hence, the lower angle of the incision should nearly meet the upper part of the symphys pubis. A cut of the same length is next to be made between the pyramidal muscles, and, this being done, the surgeon will be able to feel with his finger the prominent dilated bladder. A trocar, the curvature of which forms the segment of a circle seven inches in diameter, is now to be introduced into the exposed part of this viseus. When this instrument is held with its convexity upward, that is, towards the patient's nave, it can be more conveniently introduced obliquely downward, and backward, into the bladder, in the direction of the axis of this organ, than any straight trocar can possibly be. M. Sabatier observes, a curved instrument of this kind is also much less likely to penetrate the back part of the bladder and wound the rectum, besides having this advantage, that when the urine is discharged, and the bladder collapsed, the cannula will not be so apt, as that of a straight trocar, to slip out of the part into which it has been introduced. De la Médecine Opératoire, tom. ii. p. 128, 129.

However, there can be no doubt, that when the bladder is certainly dilated with urine, and the swelling distinct and prominent, it is perfectly safe to introduce the trocar at once into the bladder, without any preliminary division of the integuments, fat, &c.

When the operator perceives, by the want of resistence, that the point of the instrument is in the bladder, he is to take hold of the mouth of the cannula, and while he pushes the tube farther inward, he is to withdraw the filet. The cannula is to be allowed to remain in the wound after the urine is evacuated. Its mouth may be closed with any kind of flopper, which cannot infinue itself into the bladder, and it may be kept from slipping out by means of two pieces of tape, which are to be passed through the two little rings at the sides of the instrument.

There are surgeons who recommend an elastic gum catheter to be paffed into the bladder through the cannula, and then taking the latter away. The advantage of this practice is not at all obvious, and, as for ourselves, we are positively adverse to the practice. An elastic gum catheter does not fill the wound; consequently, the urine is discharged, not only through the tube, but also between the sides of the wound and the circumference of the instrument, so that the chance of the urine becoming diffused into the cellular membrane is not guarded against, as it is by allowing the cannula to remain in the wound, at least two or three days, until the inflammation has closed the intertices of the surrounding cellular subfintance, and removed the possibility of the urine becoming extravasated. It is now known, that, after the above period, the cannula may be safely taken out, and easily introduced as occasion may require.

Another objection to introducing an elastic gum catheter is the length of such an instrument, the end of which would produce irritation in the bladder. The use of long, straight cannulae is known to form a communication between the bladder and rectum, in consequence of ulceration, or sloughing, produced by the pressure of the points of these instruments on the back part of the bladder. Mr. Samuel Sharp mentions his having seen this accident. Critical Enquiry, &c. p. 127, edit. 4.

It is obvious, that the outlet made for the urine by the operation of paracentesis, is merely designed as a temporary one, and that as soon as the impediment to the passage of the urine through the urethra is removed, the wound ought to be allowed to heal.

Whenever the prostrate gland is known to be very much enlarged, one would certainly prefer this mode of operating to puncturing the bladder through the rectum. The wound is made in a situation where there is no risk of injuring any part of importance; but, in this method, little as the chance may be of an extravasation of urine taking place, it is undoubtedly a possible event, and the opening is not made in a depending place, so that the whole of the urine cannot very well be voided through it.

Paracentesis of the Bladder from the Rectum.—The patient is to be put in the posture which is usually chosen for the lateral operation for the stone. (See Lithotomy.) An affilant is to make pressure on the abdomen, just above the os pubis, in order to make the prominence of the bladder plainer to the surgeon's finger in the rectum. A curved trocar, with its point drawn within the cannula, is to be introduced with the right hand and conveyed upon the left fore-finger, as high as the surgeon can reach up the intestine, along the swelling formed by the dilated bladder. The instrument should be kept exactly in the central line of the front portion of the rectum, and, when conveyed sufficiently beyond the prostrate gland, the point of the trocar is to be pushed into the bladder, through the interior part of the intestine.

This operation is so easy and safe, that it must be allowed to merit a general preference. The coats of the rectum and bladder are here almost in immediate contact, and the instrument has to penetrate no thickness of substantia. The operation is not more painful than venefection, and the dilated bladder is so distinctly perceptible to the finger, that no mistake can will be made. The only chance of doing mischief arises from the situation of the vesicula feminales; but all risk may be avoided, by introducing the finger very high up the rectum, and making the puncture exactly in the central part of the swelling. The trocar must, of course, be of a length sufficient to admit of the operation being done according to these principles.

The only inconvenience following the operation, is the necessity of keeping the cannula introduced through the anus until the urine refumes its natural course. This circumstance is not only very troublesome when the patient is walking, or sitting down, but is particularly incommoding when he goes to stool. The difficulty of voiding hardened feces, however, while the instrument is introduced, may always be obviated by injecting a cryter. Whenever the patient has a motion, it is, of course, necessary for him to hold the cannula with his fingers, or else it would be protruded.

We have no facts on record, however, which justify the conclusion,
PAR

PAR

conclusion, that any ferious harm would result from with- 
drawing the cannula immediately after paracentesis of the 
bladder from the rectum. If the urethra were not pervious 
at the time, the frequent passage of the urine through the 
puncture would probably be sufficient to keep it from be-
coming closed, and the occasional passage of this fluid, 
through the lower part of the rectum, would be far less an-
noying, than the continual presence of the cannula. There
is one instance in which the cannula was inadvertently with-
drawn fourteen-eight hours after the operation, and could not 
be introduced again. The urine was discharged into the 
rectum, through the puncture, for five days afterwards, and, 
as soon as it began to pass out through the urethra, the 
wound healed, without leaving any fatal communication 
between the bladder and the intestine. (Bentley in Med. 
Communications, vol. i.) Richter, indeed, affirms us, that 
the cannula has even been taken out immediately after the 
operation without any ill consequences. (Anfangstr. &c. 
b. 6 p. 328.) Women seldom require the performance of 
paracentesis of the bladder. Retrospective uteri, however, 
is one cafe, which may render such proceeding absolutely 
necessary. The operation may be done in two ways, viz. 
from the vagina, and above the pubes. See Sabatier’s 
Médecine Opératoire, tom ii. Sharp’s Critical Enquiry, 
&c. Richter’s Anfangstr. &c. band 6. First Lines of 
The Practice of Surgery, by Samuel Cooper, edit. 3. 
&c. &c.

PARACENTRIC Motion, in Astronomy, a term used for 
so much as a revolving planet approaches nearer to, or 
recedes farther from, the sun, or centre of attraction.

Thus, if a planet in A, (Plate XVII. Astronomy, fig. 2.) 
moves to B, then S B — S A = b B, is the paracentric 
motion of that planet.

PARACENTRIC Solicitation of Gravity amounts to the same 
with the vis centripeta, and in astronomy, is expressed by 
the line A L. (Plate XVIII. fig. 3.) drawn from the point 
A parallel to the ray S B (minutely nearer S A) till it 
intercept the tangent B L.

PARACHO, in Geography, a town of Hindoostan, in 
the circuit of Gohud; 15 miles N. of Narwa.

PARACHUTEAS, a town of West Florida, near 
the Apalachicola. N. lat. 31° 24'. W. long. 85°.

PARACHURECOIL, a town of Hindoostan, in Ma-
rawar; 7 miles N.W. of Tripolite.

PARACHUTE, a machine in the form of an 
umbrella, sometimes annexed to a balloon, and sometimes 
used separately, and serving to buoy up a heavy body in its 
ascend, or to prevent its precipitate fall (as its name 
imports) in the atmosphere. (See AEROSTATION.) 
Umbrellas have been used for this purpose from remote 
times in various parts of the East Indies. In the "Historical 
Relation of the Kingdom of Siam," by M. de la Loubere, 
who visited that country in the years 1687 and 1688, we 
have an account of the manner in which umbrellas were 
employed in the diversions of the court of Siam. "There 
did one," says this writer, "some years since, who leaped 
from a loop, &c. so as to send himself only by two umbrellas, 
the hands of which were firmly fixed to his girdle: the wind 
carried him accidentally sometimes to the ground, some-
times to trees or hedges, and sometimes into the river. He 
so exceedingly diverted the king of Siam, that this prince 
had made him a great lord, he had lodged him in the pa-
lace, and had given him a great title, or, as they say, a 
great name." See UMBRELLA.

PARACLET, a name which the church has given to the 
Holy Spirit; from the Greek Ἐπαριστός, q.d. comforter, or 
advocate.

PARACME, Ἐπαριστος, a Greek word signifying decla-
rion, or a thing’s being put its height.

PARACOPE, or PARACOENUS, a word used by Hip-
pocrates to express a flight delirium in fevers.

PARACUSIS, from Ἐπαριστος, non recte audito, signifi-
nces, in the language of the nofologists, depraved hearing. 
The term is not applied to simple deafness, that is, to a mere 
diminution or abolition of the sense of hearing, but to 
those varieties of imperfect hearing, in which all sounds 
are heard incorrectly; as for instance, with hissing, ring-
ing, or other noises; and to over-acute as well as obtuse 

PARACYANANCHE. See CYANAN.

PARADANGA, in Geography, a town of Bengal; 25 
miles E.N.E. of Rungpore.

PARADE, the show, or expofure of any thing to view, 
in all its advantages and ornaments.

Bed of parade, is that in which a poorfion lies at 
feate.

PARADE, in War, a place where troops assemble, or draw 
together, in order to exercise or go on any service.

PARADE is more properly the appearance of the officers 
and foldiers at a post assigned them, to put themselves 
under arms, in the belt order they can; either to mount, 
or break up the guard, or to form a battalion, on some 
other occasion.

PARADE, in Fencing, is the action of parrying or turning 
on any push or stroke.

There are as many kinds of parades, as of strokes and 
attacks; as the parade inward, outward, above, below, 
figured, &c.

PARADE is used in France for a species of farce, which 
was merely designed to amuse, and to excite mirth.

PARADE DE ROURO, in Geography, a town of Portugal, in 
the province of Entre Duero e Minho; 16 miles N.N.E. 
of Braga.

PARADELLA, a town of Portugal, in the province 
of Beira; 12 miles S.E. of Lamego.

PARADES, a town of Spain, in the province of 
Seville; 5 miles S. of Carmona.

PARADIAZEUXIS, near a disjuncion, was in the 
ancient Greek music, according to Bucchius Senior, 
the interval only of a tone between the firings of the two 
tetrachords; such is the disjuncion, for instance, which oc-
curs between the tetrachord tymnemonen, and the tetrach-
ord dieuzegmonen. See thefe several words.

PARADIES, DOMENICO, in Biography, a Neapolitan, 
arrived in England in 1742, at the beginning of lord Middlefex’s 
oper regency. In 1747 he let "Petonte," or Phaeton, 
for the theatre in the Haymarket. The drama was written 
by Vanechi, afterwards manager of that theatre. In ex-
amining the airs of this opera, as set by Paradies, that were 
printed, the first seems very common and ill-phrased, nor is 
there much eftro, or grace, in any of his songs that we have 
seen. Indeed he seems to have had no great experience as 
an opera composer. And during his residence in England 
he acquired more reputation by the leflions he published for 
the harpsichord, and the scholars he made on that instru-
ment, for which he was an admirable master, than by his 
vocal compositions. His little scholar, Frederic, after-
wards Mrs. Wynne, gained him so much reputation as a 
harpsichord master, that he was appointed to instruct the 
young pianlces at Leicester-Houfe; and had soon the offer of 
more sclholars elsewhere than he could undertake.

His boof of 12 leflions has great merit: Oareing be-
tween
tween Scarlatti and Alberti, and adding many new passages of brilliant execution, strung together in a masterly manner; yet they seem detached, and to form no fyle, or unity of melody.

PARADIGM, Paradigma, formed from παράδειγμα, exemplar, of αὐτός, and δεῖπνον, q.d. juxta deipnò, an example, or instance, of something said or done. See Example.

Grammarians have appropriated the word paradigm to examples of declension and conjugations, which may serve as models for other words of the like kind.

PARADIGRAMMATICE, is used by some for the art of making all sorts of figures in plaster. The artists in this are called styphochi.

PARADIN, William, in Biography, an indelirious French author, who flourished in the 16th century, but of whose personal history little more is known than that he was living about the year 1582. His most important works were "The Chronicle of Savoy," divided into two parts: the first part treats of the counts, and the second of the dukes of that country; "Archd's History of the Septuagint:" "Hilary of his own Times;" and "Memoirs of the City of Lyons."

PARADIS, Madame Charlotte Teresa, a young person, equally distinguished by her talents and misfortunes, was the daughter of M. Paradis, secretary to his imperial majesty, in the Bohemian department, and god-daughter to the late empress queen.

At the age of two years and eight months, she was suddenly deprived of sight by a paralytic stroke, or palsy in the optic nerves.

At four years old, she began to listen with great attention to the music she heard in the church, which suggested to her parents the idea of having her taught to play on the piano forte, and, soon after, to sing. In three or four years' time she was able to accompany herself on the organ in the "Stabat mater" of Pergolesi, of which she sang the first sopranos, or upper part, in the church of St. Augustine, at Vienna, in the presence of the late empress queen; who was so touched with her performance and misfortune, that she settled a pension on her for life.

After leaving of several masters at Vienna, she purified her musical studies under the care of Kozeluch, who has composed many admirable lessons and concertos on purpose for her use, which she played with the utmost neatness and expression.

At the age of thirteen she was placed under the care of the celebrated empyre, Dr. Mefmer, who undertook to cure every species of disease by animal magnetism. He called her disorder a perfect gutta serena, and pretended, after she had been placed in his house as a boarder for several months, that she was perfectly cured; yet refusing to let her parents take her away, or even visit her, after some time, till, by the advice of the barons Stöckl and Wenzel, Dr. Ingenhousz, professor Barth the celebrated anatomist, and the express order of her late imperial majesty, she was taken out of his hands by force; when it was found that she could see no more than when she was first admitted as Mefmer's patient. However, he had the diabolical sagacity to affect that she could see very well, and only pretended blindness, to preserve the pension granted to her by the empress queen; and since the decease of this princess, the pension of Mad. Paris was withdrawn, indisputably, with all other pensions granted by her imperial majesty.

Mad. Paradis quitted Vienna, in order to travel, accompanied by her mother, who treated her with extreme tendernefs, and was a very amiable and interesting character. After visiting the principal courts and cities of Germany, where her talents and misfortunes procured her great attention and patronage, she arrived at Paris, and remained there five or six months, and received every possible mark of approbation and regard in that capital, both for her musical abilities, and innocent and engaging disposition.

When she arrived in England, she brought letters from persons of the first rank to her majesty, the prince of Wales, the imperial minister, count Kagenecck, lord Stormont, and other powerful patrons, as well as to the principal musical professors in London. Messrs. Cramer, Abel, Solomon, and other eminent German musicians, interceded themselves very much in her welfare; not only as their countrywoman, but as an admirable performer.

She went to Windsor, to present her letters to the queen, and had the honour of playing there to their majesties, who were extremely satisfied with her performance, and treated her with that condescension and kindness, which all who are so happy as to be admitted into the presence of our gracious sovereigns, in moments of domestic privacy, experience, even when left intitled to it by merit and misfortunes than Mad. Paradis. Her majesty was not only graciously pleased to promise to patronize and hear her frequently again in the course of the winter, but to afford her all the protection in her power; as did his royal highness the prince of Wales, to whom she since performed, at a grand concert at Carlton house, to the entire satisfaction and wonder of all who heard her.

Besides her musical talents, which were indisputable for neatness, precision, and expression, particularly in the great variety of admirable pieces she executed the hands of her master, Kozeluch, Mad. Paradis was extremely well educated, and was very ingenious and accomplished; as she was able, with printing types, to express her thoughts on paper, almost as quick as if she could write. She understood geography, by means of maps prepared for her use, in which she could find and point out any province, or remarkable city in the world; and was likewise able, by means of tables formed in the manner of draught-boards, to calculate, with ease and rapidity, any sums or numbers in the first five rules of arithmetic. She is likewise said to have distinguished many colours and coins by the touch; played at cards, when prepared for her by private marks unknown by the company; and in her musical studies, her memory and quickness were wonderful; as she learned in general the most difficult pieces for keyed instruments, however full and complicated the parts, by hearing them played only on a violin; and since her arrival in this kingdom, she was enabled, in this manner, to learn to perform some of Handel's most elaborate and difficult organ fugues and movements in his first book of sonatas, as well as his Coronation Anthem, and more popular compositions.

Since her arrival in England she received a cantata, written for her in the German language, by the celebrated French master of mathematics, M. Pfeiffer, of Colmar, who is himself blind. This cantata has been admirably set to music for her own voice and accompaniment on the piano forte, and she executed it in a truly pathetic and able manner. Her voice was not so powerful as her hand; but it is touching in itself, and her knowledge of music and circumstances rendered it doubly interesting.

Madame Paradis, having entreated Dr. Burney, who had letters from Germany in behalf of her ingenious daughter,
ter, and was very zealous in her service, to translate this cantata; we have procured the following copy of his version:

Cantata, written in German for Mad. Paradis, by her blind friend M. Pfeffel, of Colmar, and set to music by her music-maker, M. Leopold Kozeluch, of Vienna, November 11, 1784.

Imitated by Dr. Burney.

"The new-born infant sporting in the sun,
Is the true folement of my infant ftre.
When e'ry prize for which life’s race is run
Was hidden from me by malignant fate.
"Infant destruction quench’d each visual ray,
No mother’s tears, no objects were reveal’d!
Extinguish’d was the glorious lamp of day,
And e’ry work of God at once conceal’d!
"Where am I plunged? with trembling voice I cried,
Ah! why this premature, this sudden night?
What from my view a parent’s looks can hide,
Those looks more cheering than celestial light!
"How should I wander through the gloomy maze,
Or bear the black monotony of woe,
Did not maternal kindness gild my days,
And guide my devoun footsteps to and fro!
"There! great in goodness as in power,
Whole fav’rite tree of boundless sway,
Was benefits on all to fower,
And wipe the tear of wretchedness away.
"When ftilt my hand and voice effay’d,
Sweet Pergolefi’s pianos flrians,
Her pitying goodness displayed,
To cherish and reward my pains.
"But now, alas! this friend to woe,
This benefactor’s no more!
And though my eyes no light below
They’ll long with tears her losc deplore!
"Yet still where’er my footsteps bend,
My helples ftate has found a friend.
The weathes my feeble talents share,
The balmy facile friends employ,
Lifting the soul above despair,
Convert calamity to joy."

Paradise. See Plate Forme.

Paradise, in Geography, a township of America, in Pennsylvania, in the county of York, containing 1275 inhabitants.

Paradise, a term primarily used for the place in which Adam was seated, during his innocence; and from which he was expelled for defoying God: this is called, in a stricter manner, the Terrestrial Paradise.

The word is formed of συγκλητος, orchard, a place flor’d with apples, and all kinds of fruits. Moses calls it the Garden of Eden, q. d. garden of delight, from τῆς, έδάφος, solipton, plaisure.

The critics are in dispute about the precise place of Paradise. Some, as Hardouin, &c., will have it in Judea, in the place where now is the lake Geneareth; others, as Le Clerc, &c., in Syria, towards the springs of the Orontes, and Chryforhoe; but in neither of those places do we discover any track of the rivers with which the Paradise in Moses’s description was watered. Calmet, and some other ingenious critics, have placed the terrestrial Paradise in Armenia, near mount Ararat, where Noah’s ark was left; and imagine they there discover the sources of the four rivers which watered the garden of Eden, &c. Euripides; Hiddekel, now the Tigris; Gihon, now Araxes; and Pison, now Phazo. But Dr. J. Chardin affures us in his travels, that the Phazzo springs out of the mountains of Caucasus, northward of the kingdom of Imereti, and far enough from mount Ararat: besides, that in Armenia we have no signs of the countries of Havila and Ethiopia, which those rivers washed after their departure from Eden.

There are various other opinions, as to this point: Poffellus will have Paradise placed under the north pole; grounding his notion upon an ancient tradition of the Egyptians and Babylonians, that the celtic or sun’s way was at first at right angles to the equator; and so passed directly over the north pole. Others are again limiting it to any one place, and contend, that it included the whole face of the earth, which was then, as it were, one continued scene of pleasures, till altered upon Adam’s transgression.

However, both these opinions are equally incompatible with the account in the book of Genesis; others, as Origen, Philo, &c., interpret the scripture relation of Paradise allegorically.

But the most common and probable opinion is that of Hopkinton, Huet, Bochart, &c., who place Paradise between the confluence of the Euphrates and Tigris, and their separation. These rivers are two of those in which the garden of Eden was watered: Pison was a branch arissng out of one of them after their separation; and Gihon another branch arissing from the other, on the side of Armenia, or the isle: accordingly Ethiopia, one of the countries which those rivers washed, was incontestibly Arabia Deserta; for Moses calls his wife, who was of this country, an Ethiopian; and Havilah, the other country, must have been the Chulafan in Peria; where were anciently found gold, bdellium, the onyx, &c., mentioned in Moses’s description.

The great difficulty in this system is, that Moses speaks expressly of four rivers, each of which had its source in the garden of Eden; whereas this gives us only two rivers, which were separated into four branches. See Eden.

Paradise is also used in the New Testament, and by Christian writers, for the final habitation of the blessed, or Heaven: which see.

Paradise Lost, a poem, which, whether it be referred or not to the class of those poems that are denominated Epic (see that article), is justly deemed one of the highest efforts of poetical genius, and in one great characteristic of the epic poem, majesty and simplicity, fully equal to any which bear that name. With respect to the choice of his subject, it has been questioned whether Milton was altogether happy; and it has been fuggled, that, if it had been more human, and less theological, and more connected with the occurrences of life, so as to have afforded a greater display of the characters and passions of men, his poem would have been more acceptable and pleasing to the bulk of readers. However, his subject was suited to the daring fabilit of his genius. To this purpose Dr. Johnson affures us, (Life of Milton,) that "he seems to have been well acquainted with his own genius, and to know what it was that nature had bestowed on him more buntifully than upon others; the power of displaying the vail, illuminating the splendid, enforcing the awful, darkening the gloomy, and aggravating the dreadful. He therefore chose a subject, on which too much could not be said; on which he might tire his fancy, without the censure of extravagance."

In the conduct of the subject which he has selected, he has shown a very wonderful stretch of imagination and in-
vention, and he has admirably sustained the various characters he has assumed, and made the most of the scanty materials which he derived from the sacred scriptures. Some, indeed, have lamented that he has added to these a variety of incidents, which have served to perpetuate erroneous doctrines in theology, and a system of demonology of his own creation, without sufficient warrant from the sacred writings. However this be, "the general tenor of his work is interesting; he seize and fixes the imagination: engages, elevates, and affects us as we proceed; and this is always a sure test of merit in an epic composition. The artful change of objects: the scene laid now in earth, now in hell, and now in heaven, affords a sufficient diversity, while unity of plan is at the same time perfectly supported. We have full life and calm scenes, in the employments of Adam and Eve in Paradise; and we have busy scenes, and great actions, in the enterprise of Satan, and wars of the angels. The innocence, purity, and amiablenes of our first parents, opposed to the pride and ambition of Satan, and the happy contrast, that reigned throughout the whole poem" though the conclusion is, in Dr. Blair's opinion, too tragic for epic poetry. Although the nature of Milton's subject did not admit any great display of characters, those which he has introduced are supported with much propriety. Satan is the best drawn character in the poem, inasmuch that some have said, either seriously or jocularly, that he was the hero of his poem. (See Hero.) The different characters of Beelzebub, Moloch, and Belial, are well painted in their eloquent speeches. Among the good angels, always described with propriety, though with greater uniformity than the infernal spirits in their appearance, the dignity of Michael, the mild condescension of Raphael, and the tried fidelity of Abdiel, form characteristical distinctions. In the adventurous attempt to describe Almighty himself, and to recite dialogues between the Father and the Son, Milton, as we might naturally expect, has been most unsuccessful. With regard to human characters, the innocence of our first parents, and their love are finely and delicately painted. Eve is more perfectly characterized than Adam. He then allures, seduces, tempts, and deprives her of her innocence, which he had formerly imparted. Milton's distinguishing excellence is his sublimity, in which he far surpasses Virgil, and every other poet, and is thought by some to excel even Homer. The prospect of hell, and of the fallen host, the appearance and behaviour of Satan, the confutation of the infernal chiefs, and Satan's flight through chaos to the borders of this world, manifest the most lofty ideas that ever entered into the conception of any poet. Indeed, the fifth and second books are continued inances of the sublime. In the sixth book there is also much grandeur, particularly in the appearance of the Messiah; but in this book, the witticisms of the devils upon the effect of their artillery, form an intolerable blemin. It is observed that Milton's sublimity is different from that of Homer. That of the latter is generally accompanied with fire and impetuosity; while Milton's poises more of a calm and amazing grandeur. Homer warms and buries us along: Milton fixes us in a state of astonishment and elevation. Homer's sublimity is most conspicuous in the description of actions. Milton's in that of wonderful and superlative objects. Milton also abounds with his sublimity, much of the beautiful, the tender, and the pleasing, in many parts of his works. Milton's language and verification poetry high merit. His style is full of majesty, and wonderfully adapted to his subject. His blank verse is harmonious and diversified, and affords the most complete example of the elevation, which our language is capable of attaining by the force of numbers. "Upon the whole," as Dr. Blair observes in the conclusion of his criticism upon this poem, "Paradise Lost is a poem that abounds with beauties of every kind, and that justly enliveth its author to a degree of fame not inferior to any poet; though it must be also admitted to have many inequalities. It is the lot of almost every high and daring genius, not to be uniform and correct. Milton is too frequently theological and metaphysical; sometimes harsh in his language; often too technical in his words, and affectedly orientitious of his learning. Many of his faults must be at tributed to the tendency of the age in which he lived. He discovers a vigour, a grasp of genius equal to everything that is great; if at some times he falls much below himself, at other times he rises above every poet, of the ancient or modern world." Blair's Lectures, vol. iii.

Mr. Addison's criticiums on the Paradise Lost contained in the "Speculator," are in every body's hands. They comprehend the fable, the characters, the sentiments, and the language of this poem. See Action, Epic Poem, Fable, &c. &c. See also the biographical article of Milton. Paradise, Bird of, in Ornithology. See Paradisaea.

Paradise, Golden Bird of. See Oriolus Aureus.

Paradise Sound, in Geography, a bay on the S.W. part of Phcenicia, on the coast of Newfoundland. N. lat. 47° 30'. W. long. 54° 15'.

Paradisaea, The Bird of Paradise, in Ornithology, a genus of birds of the order Picz, of which the generic character is; bill covered with a belt of downy feathers at the base; feathers of the sides very long; two of the tail-feathers naked; legs and feet very large and strong. These birds chiefly inhabit New Guinea, from which they migrate in the dry season into the neighbouring islands. Their feathers are used in these countries as ornaments for the head-dresses; and the Japanese, Chinese, and Persians import them for the same purpose. Among the latter, the principal people attach these brilliant collections of plumage, not only to their own turbans, but to the houblings and harness of their horses. They are seldom found many degrees beyond the equator. Gmelin enumerates twelve species, Shaw fifteen, and Latham only eight. We shall give those of Gmelin.

Species.

Afoda; Greater Bird of Paradise. Chefsaut; neck beneath gold-green; feathers on the sides longer than the body; the two middle tail-feathers are long and feathery. There is a variety which is less, and the body above is yellow; the feathers on the sides are yellowish-white. The two long tail-feathers are naked, straight, and tapering to the tip; the tail, as it is improperly called, is nothing more than the long feathers of the back and flanks. These birds are found in the Molucca islands, and those surrounding New Guinea, particularly in Aroo, where they arrive with the wetterly or dry monosson, and whence they return to New Guinea, when the easterly or wet monsoon sets in. They are seen going and returning in flights of thirty or forty, conducted by a leader, which flies higher than the rest. During this flight they cry like starlings. By a sudden shifting of the wind, their long scapular feathers are sometimes dishevelled as to preclude flying, when they fall to the ground, or are lost in the water. In the former case they cannot fly again into the air, without gaining an enmense, and are secured by the natives, and killed on the spot, as they cannot be preferred alive by art. They are likewise caught with bird-lime, or shot with blunt arrows, or are sometimes intoxicated with the berries of Manfpermum coccus put into the water which they are accustomed to drink. Their real food is not known with certainty. According to some authors, they feed on the red berries of the Waringa-tree, the Ficus benjamina; ac-
Rein-others the are fixteen good chin Angularly fruit, name but propofition the very the (hort filky, tinually the quill-feathers fpiendid when having in inhabits the There and this two Crefted faid back, tuft folded. ocean, yellow, quill-feathers the wings a about two Crefted faid back, tuft folded.

Tristis; Grakle Bird of Paradise. This has a triangular naked space behind the eyes; the head and neck are brown. It inhabits the Philippine islands; is nine inches and a half long; feeds on fruit, infefts, mice, and every kind of grain; builds twice a-year in the forked branches of trees; it lays four eggs; when young it is eafily tamed, and becomes docile and imitative. The bill and legs are yellow; the body is brownish; the frst quill-feathers are white from the base to the middle; tail-feathers, except the middle ones, are ripe with white. This bird has a great afinity in all its habits to the grakle genus, yet, on account of the downy feathers at the base of the bill, it is placed among the birds of Paradise.

Magnifica; Magnificent Bird of Paradise. Chefnut-brown above, chin green, with golden lunules; crown with a tuft of yellow feathers. It inhabits New Guinea, and is about nine inches long. This is a singularly beautiful species, and a figure of it is given by Latham. The frst quill-feathers are brown, secondary deep yellow; middle tail-feathers very long, with a short fringe; legs and bill yellow, the latter black at the base and tip.

Cirrata; Crested Bird of Paradise. Head, neck, and wings black; tuft of hairs near the crown and frontlet yellow. It inhabits New Guinea, and is eighteen inches long.

Nigra; Gorget Bird of Paradise. Black; beneath light green; hind head, nape, crown, and band on the middle of the belly fine green, under the chin a spangled gold-coloured crescent. It inhabits the islands of the Indian ocean, and is twenty-eight inches long. There are twelve unequal tail-feathers, the outer ones five inches long, and the two in the middle about twenty-two inches.

Leucoptera; White-winged Bird of Paradise. Black; crown shining copper; quill-feathers white, edged with black on the outside; the tail is very long and wedged.

Suprema; Superb Bird of Paradise. This species is crested; the head, crown, and belly are green; the chin is violet, filky; wings black; tail with a shade of green. It is found in New Guinea, and is about ten inches long. The bill is black; the legs are brown; under the wings a tuft of loofe, black, filky feathers, as long as the wings when folded.

Furcata. This is black; under the wings is a downy tuft; feathers in the middle of the belly like a forked tail; tining-green.

Aurea; Gold-breasted Bird of Paradise. Crefted, black; crown, cheeks, and chin violet-black; throat, spot on the neck, and breast shining-green; at the region of the ears, on each side, are three long brilft feathers. It inhabits New Guinea, and is the size of a turtle dove.

Virides; Blue-green Bird of Paradise. Sea-green; back, belly, rump, and tail steel-blue. It inhabits New Guinea, and is sixteen inches long. The bill is thick and black; the plumage on the head is filky, and on the body it appears as if it were crisp at the tips.

Alba; White Bird of Paradise. This is entirely white, and is the rarest of all the species. It is found in the Papuan islands. A variety of it is black on the fore-part, and white on the hind-part.

"In the second edition of Pennant's Indian Zoology," says Dr. Shaw, "may be found a good general description from Valentyn, of this remarkable genus, by Dr. J. Reinhold Forster, preceded by a very learned dissertation on the fabulous phoenix of antiquity, a bird of the size of an eagle, decorated with gold and purple plumes, and more particularly described by Pliny, as having the splendor of gold round the neck, the reins of the body purple, the tail blue, varied with rofe-colour, the face adorned with waffles, and the head furnished with a crest. This imaginary bird, Dr. Forster supposes to have been no other than a symbolic Egyptian illustration of the annual revolution of the sun, and the conversion of the great year, which corresponds with the supposed life of the phoenix, and from which period the fame course of seafons and positions of the heavenly bodies is renewed." These notions, then, says Dr. Forster, are to be explained by the theology of Egypt. Though the birds of Paradise were never known to the ancients, and though what has been said by the Egyptian priests concerning the fabulous phoenix, has but little agreement with the bird of Paradise, yet it is remarkable that the names applied both by the Indian and European nations to these birds, appear to attribute something of a supposed celestial origin to them. In all probability, says Dr. Shaw, this notion has arisen merely from their transcendent beauty, and the singular disposition and delicacy of their plumage.

Paradisiaca, in Botany, a name given by some authors to the arbor vitae, or thy. Paradisus, among Ancient Church Writers, denoted a square court, before cathedrals, surrounded with piazzas, or porticos for walking under, supported by pillars. Matthew Paris calls it parvifus.

Paradoxa, formed from ἀπαραδοθ, opinion, in Philosophy, a proposition seemingly absurd, because contrary to the received opinions, but yet true in effect.

The Copernican system is a paradox to the common people; but the learned are all agreed as to its truth.

Geometricians have been accused of maintaining paradoxes; and it must be owned, that some use very mysterious terms in expressing themselves about asymptotes, the sums of infinite progressions, the areas comprehended between curves and their asymptotes, and the folids generated from these areas, the length of some spirals, &c. But all these paradoxes and mysteries amount to no more than this: that the line or number may be continually acquiring increments, and those increments may decrease in such a manner, that the whole line or number shall never amount to a given line or number.

The necessity of admitting this is obvious from the nature of the most common geometrical figures: thus, while the tangent of a circle increases, the area of the corresponding sector increases, but never amounts to a quadrant. Neither is it difficult to conceive, that if a figure be conceived towards a bafe, and have an asymptote parallel to the bafe (as it happens when we take a parallel to the asymptote of the logarithmic curve, or of the hyperbola, for a bafe), that the ordinate in this case always increases while the bafe is produced, but never amounts to the distance between the asymptote and the bafe. In like manner, a curvilinear area may increase while the bafe is produced, and approach con-
and occasionally to a certain finite space, but never amount to it; and a solid may increase in the same manner, and yet never amount to a given solid. See Logarithmic Curves.

A spiral may in like manner approach to a point continually, and yet in any number of revolutions never arrive at it, and there are progressions of fractions which may be continued at pleasure, and yet the sum of the terms shall be always less than a given number. See Macaulay's Fluxions, book i. ch. 10. seq. where various rules are demonstrated, and illustrated by examples, for determining the sympotmes and limits of figures and progressions without having recourse to those mysterious expressions which have of late years crept into the writings of mathematicians. For, as that excellent author observes elsewhere, though philosophy has, and probably always will have, mysteries to us, geometry ought to have none.

Paradoxes, Hydrostatical. See Fluid.

Paradoxi, or Paradoxologi, among the Ancients, were a kind of mimes or buffoons, who diverted the people with their drolling.

They were also called ordinarii, for this reason apparently, that, as they spoke without study or preparation, they were always ready.

They had another denomination, viz. nianiochlogi, q. d. tellers of children's tales; and beside were called aretologi, of a, τό, virtue, or talking much of their own rare talents and qualifications.

Pare, in Zoology, the name of a species of serpent, called also anguis Rculaupii. It is a perfectly innocent and harmless creature, and is so little dreaded by the inhabitants, that it is common about their houses, and even sometimes gets into their beds. Its mouth is full of very small teeth, and when much provoked, it is sometimes known to bite, though without any bad symptoms attending the wound; it is a very long kind, and is of a yellowish-green colour on the sides, and blackish on the back; it has two small eminences on the neck, and between them two small fins. It is very common in Spain, Italy, and most other of the warm countries.

Parænesis, παράνενσις, formed of παρά, and πνευμ, I praise, a Greek term, signifying adoration or exaltation.

Paragaudæ, among the Romans, a sort of wraiths, either wholly of gold, or of silk adorned with gold, which were interwoven in garments and not sewed to them. The garment was sometimes of one colour, in which it was woven one paragaudæ; others were of two colours, and had two paragaudæ; and some had three colours, and three paragaudæ. They were worn both by men and women.

Parage, Paragium, in Law, an equality of blood or dignity, but more especially in land, in the partition of an inheritance between coheirs.

Parage, Paragium, is more properly used, in ancient custom, for an equality of condition among nobles, or persons holding nobly.

Thus, when a heifer is divided among brothers; in this cafe, the younger hold their part of the elder by parage, i. e. without any homage or service.

This still obtains, in some measure, in Scotland, where the husbands of the younger sisters are not obliged to any faith or homage to the husband of the elder; nor their children to the second degree.

This parage being an equality of duty or service among brothers and sisters, some have called it frairage and parentage.

The Customary of Normandy defines: enre by parage to be, when a noble heifer being divided among daughters, the eldest does homage to the chief lord for all the rest, and the youngest hold their parts of the reft by parage, i. e. without any homage or fealty.

Parage cesates at the sixth degree inclusively. It likewise cesses when any of the stirners fell their part.

Paraglossa, from παρά, κείμ., and γλωσσα, the tongue, in Surgery, a prolapsus of the tongue; or a protrusion of it from the mouth.

Paragoge, παράγωγη, in Grammar, a figure whereby a word is lengthened out by adding a syllable at the end of it: as in dider for diēt.

Paragoge is also a word used by medical writers to express a reduction of luted bones.

Paragogic, formed of παρά, and γράφω, I write, compounded of παρά, and γράφω, in Grammar, denotes something added to a word without adding any thing to its sense.

In the Hebrew, the נ is frequently paragogic; as in פָּרָשָׁה, for פָּרָשָׁה, I will praise. The paragogic letters are the five following, viz. נ ד ר צ, to which some add the נ.

The use of paragogic letters is only to give a more full and agreeable sound to words, either for the sake of the verfe, or the smoothness of the period. As in the Hebrew letters are sometimes added "euphoniz gratia," fo likewise the four following letters, viz. נ ד ר צ, which, according to the grammatical rules, ought to be prefixd, are omitted.

Paragon, in Geography, one of the largest of the Calamianes iflands, in the East Indian sea.

Paragone, in Natural History, the name given by many to the bafalkes, a black marble, used as a touchstone.

Paragraph, Παράγωγον, a term in Jurisprudence, signifying a section or division of the text of a law: otherwise called an article.

Such a law is said to be divided into so many paragraphs.

The character of a paragraph in quotation, is "

Among the Greek poets, paragraphs, παράγωγον, were a species of critical notes, serving to mark the couplets, epistles, and other divisions of odes, and other poetical compositions. This paragraph, as described by the Ilochial of Arithophanes, was a short line, with a dot at the extremity of it.

Paragua, in Ornithology, the name of a Brazilian parrot, of the fize of our common green parrot; but its back is all black, and its breast and the forepart of its belly are of a beautiful red: its eyes are black, with a red circle round them: its beak brown, or a very dusky grey, and legs and feet grey. See Psittacus Paraguana.

Paraguare, in Geography, a town of Brazil, on the river of the Amazonas. S. lat. 3° 10'. W. long. 65° 35'.

Paraguay, or Palawan, the most westerly of the Philippine islands, about 180 miles in length, and 21 in breadth; 190 miles E.N.E. of Mindanao. N. lat. 8° 12' to 11° 31'. E. long. 117° 21' to 119° 40'.

Paraguay, a river of South America, which rises about W. long. 58° between the 5th and 6th degrees of S. lat. After pursuing an almost due S. course, it joins the Plata in S. lat. 28'. W. long. 60° 36'. The word Paraguay' means "the crown," or a king's flag.

Paraguan, a province of the vicerealty of La Plata or Buenos Ayers, called the "Government of Paraguay." This government lies S. of Santa Cruz de la Sierra and E. of Tusuman. Southward it joins to that of Buenos Ayres, and eastward it is terminated by the captainship of St. Vicente in Brazil, the capital of which is the city of St. Paulo. These countries were first discovered by Sebastian Gaboto or Cabot (see Cabot), who, coming to the river of Plata in the year 1526, failed up the Parana in small boats,
PARAGUAY.

barks, and thence entered that of Paraguay. In 1536 he
was succeeded by Juan de Ayolas, to whom Don Pedro de
Mendoza, the first governor of Buenos Ayres, had given a
commission, together with a body of troops, military forces,
and other necessaries; and, afterwards, by his orders, Juan
de Salinas founded the city of Nuestra Señora de la Af-
fusion, the capital of the province; but the discovery of
the whole, and consequently the conquest of the people
who inhabited it, being still imperfect, it was prosecuted
by Alvar Nunez, named Cabeza de Baca, or Cowhead,
who, while serving on the death of Don Pedro de Men-
doza, procured for him the government of Buenos Ayres.
The only settlements, in the whole extent of this govern-
ment, is the city of Allfomption, Villa Rica, and some other
towns, inhabited by converted Indians, who were once en-
tirely under the administration of the Jefuits. The province
is distinguished by its fertility, and though it produces none
of the precious metals, it is the most opulent in the new
viceroyalty, on account of its various vegetable productions,
and the prodigious herds of horses, mules, cattle and sheep,
which enliven its exte-tive plains. The northern parts,
however, of Paraguay have been little explored, as the set-
tlements of the Jefuits were chiefly in the southern districts,
and among the adjacent Abipons and Guaraniis. It was
in the year 1580 that the Jefuits were first admitted into
these fertile regions, where they afterwards, in the reign of
Philip III., founded the famous Missions, which in Eu-
rope have been known under the name of Paraguay, but in
America Uruguay, from the river of that name on which they
were situated. Actuated by motives of religion and of
interest, they were diligent and zealous in the service
affixed them of converting the Indians to the Catholic
faith; and by a gradual progress their labours were attended
with very considerable success. The Jefuit missions had
previously been approved of by the court of Spain, that for the
more effectual accomplishment of their purposes in conver-
ting and civilizing the Indians, they should be independent
of the governors of the province, and that they should an-
nually receive from the royal treasure 60,000 piastres for de-
fraying the expenses of cultivation; on condition that as
colonies were formed and the lands cultivated, the Indians
should pay yearly a piastre per head to the king, from the
age of eighteen to fifty. The Jefuits thus encouraged em-
barked in the execution of their enterprise with singular re-
olution and ardour, and notwithstanding the difficulties with
which they had to contend, succeeded in civilizing the bar-
barous Indians, introducing among them useful and polite
arts, and forming them into a state of mutual association
and amity, of profitable labour and domestic comfort.
Their missions extended over a country, which contained about
200 leagues N. and S. and about 150 E. and W.; and the
number of inhabitants was about 300,000. From the im-
measurable they derived all kinds of wood, and the exten-
sive pastures were covered with at least two millions of cattle.
The grass was divided into parishes, and each parish
was under the direction of two Jefuits, who officiated, the
one as refector, and the other as curate. The establishment
was supported at an expense, which, comprehending the
magnificent structure and ornaments of the churches, was
not very considerable; as the Indians supported themselves
by their own labour. The products of the ground and
cattle belonged to the Jefuits, who provided instruments of
various trades, for glags, knives, needles, chaplets of heads,
gunpowder, and mantics. Their annual revenues consisted
in cotton, tallow, leather, honey, and more especially
Matbe, or herb of Paraguay (which fea,) monopolized by
the society, and yielding, according to the statement of
Dr. Robertson in his "History of America," 500,000
pesos, at 4s. 6d each. The whole system of administration,
planned and conducted by the Jefuits, was so formed as to
keep the Indians in perfect subordination to the rector;
whilst they were provided with means of instruction in
various departments of science, such as music, painting,
sculpture, and architecture, and also of manufacture and
trade; and at the same time their attention was directed to
the regular performance of religious ceremonies and duties.
The society of Jefuits was thus employed in extending its
missions, and establishing its authority, when their designs
and labours were entirely terminated by the Spanish court,
which decreed their expulsion throughout its widely spread
dominions. The missions upon the Uruguay, of which we
have above given a concise account, were not the only ones
founded by the Jefuits in South America; northward and
southward they made progress in carrying out their plans of
government into effect, and multiplying their establishments.
When their effects in this province were catastrophic, it was
expected that large sums of hoarded money would have been
found; but these, in their whole amount, were very trifling.
Their magazines, indeed, were furnished with all sorts of
merchandise, consisting of the products of the country, and
of goods imported from Europe; the number of their slaves
was also very considerable, inasmuch, that at Cordova alone
they reckoned 3500. In detailing botanical notices, with
respect to the province of Paraguay, by the assistance of
Dobrizhoffer's communications, in the first volume of his
work, we shall curiously mention the tree, which bears the
quinquina or Jefuits' bark, the faraparilla, robart, jelly,
saffiiras, the guayacur, the zamour, called from its form the
drunkard, the mangay, yielding the elastic juice applied in
Europe to various purposes, the caa, from which is obtained
the resin called dragon's blood, the cupay, whose precious
oil is used in medicine, the nux vomica, the vanilla, the tree
which yields chocolate, the timbalib, which supplies floure of
a beautiful golden gum, that is run into moulds and formed
into croffets, necklaces, and ear-rings, straight and lofty
cedars, and the American pine called curry, harder than the
European, and marked with red veins, of the knots of which
exuding a red juice, and appearing varnished, the Guaraniis
make elegant images: several species of the algaroba or
carob tree, of which are made a bread by pounding it in a
mortar, and a wholesome drink by infusing it in cold water,
which is said to be a radical cure for consumptions, and to
possess a strong diuretic virtue: the paraguay already men-
tioned, numerous and beautiful species of palm, figs, peaches,
pomegranates, lemons, and large oranges. Among the
native fruits are the jujub, the chanar, the yacuri, the qua-
byra, of a species of which canes are made for divine ser-
vice, the paffion-flower plant, the fruit called queme, yield-
ing a delicious pulp, the mammon growing on the
trunk of a tree, and approaching to the melon, the tatay,
producing a fruit like the mulberry, the alaba, whose fruit
is delicious and refreshing, the goya, the pips of which are of
a splendid violet colour, and triangular shape, used by the
Indian women for making necklaces, the tarayau, re-
sembling the olive, the molle, yielding a copious and fra-
grant gum, the bocaba, banana, and anana, the manie, the
cotton-tree, which is a common plant, the hevil, yielding a
bark useful in tanning, the feibo, bearing flowers of a violet
colour, the izaqui, whose leaves dilute a copious supply of
water, the ant-tree, the chofen haunt of these insects, the
umbu, which might cover 50 men with its thick shade, the
willow, the ambay, used in striking fire, the urucu, a shrub
yielding a strong scarlet dye, indigo, cochineal, kahile, whose
beautiful yellow is used by dyers and painters, the
paraguay
caracueta of the Guaranis, or maguey of the Mexicans, resembling an aloe, reeds of a prodigious size, the sugar-cane, various species of rosemery, rue, mint, sage, borragine, &c.; maize, or Indian corn, of which is made the favourite drink of the Indians, called chicha, or aloja; potatoes of large size, white, red, and yellow, which latter are the best, the mani, resembling the almond in taste and form, of which there are several kinds, the oil of which is superior to that of the olive; European beans, peas, melons, cucumbers, lettuce, turnips, mustard, cresses, leeks, and onions, apargarus found wild in the fields, wheat in large quantities, and the vine. Paraguay in particular produces a generous and healthy wine, but the roots are destroyed by the prodigious number of ants. Of quadrupeds it has been said, that here are the glama orlama, the guanaco, the macmorro, or chillhueque of the Chilefe, the vicuna, and the paco or alpaco. (See Camelus.) As a late author, Azara, has omitted them in his work, and it has been accordingly affirmed, that they are totally unknown in Brazil, a town in Paraguay. The American tiger or jaguar is chiefly known in Paraguay, and the feloids to the north. Other animals are the wild cat, the elk, the ant-bear, a kind of deer, &c. A species of otrich is found in the wide plains of Paraguay. Dobrizhoffer counted nine kinds of small rodents, or humming-bird, in this province; and here are also about 20 kinds of serpentis, among which the rattlesnake is not uncommon. See LA PLATA.

PARAGUAY, or Paragoué, in Natural History, is a celebrated plant of the shrub kind, growing in some provinces in South America, especially in that of Paraguay, whence its name, though better known among us under the designation of South-sea tea. See Ilex Voüitoria. This plant, which does not rise above a foot and a half high, has very slender branches, and leaves somewhat like those of fenna; it may be looked on as a kind of occidental tea, which, like the oriental, is taken infused in hot water, to which it communicates a colour and smell nearly like those of the boil tea seen in Europe.

There are two kinds of paraguay, the one called simply paraguay; the other caamin, (which fee,) by the Spaniards, seracamini; which last is most esteemed, and sold for a third more than the other.

The first the Spaniards called the serca-cam-pob, i.e. herb with little flakes, because full of broken branches; this is chiefly used by the Indians and slaves: the latter is the drink of the negroes. But both are of so much use, and esteemed of such absolute necessity, that nobody in that part of America will live without them. The works of the mines of Potosi would stand still, but that the masters take care to supply the flaks that labour therein with paraguay, which is their constant remedy against those mineral items, with which they would otherwise be suffocated. Nor will a servant engage himself with any matter, but upon this among other conditions, that he have nothing but paraguay for drink.

The paraguay makes one of the most considerable articles of the South American commerce. At Peru, Chili, and Buenos Ayres, there are above two millions worth fold per annum; which used to pass almost altogether through the hands of the Jefuits.

The preparation of the plant, and the making it into drink, is much the same with that of tea, except that they infuse both the leaves and the wood, that they drink it immediately out of the vessel it is made in, without letting it have time to infuse, by reason of the black tincture it gives; and that, to prevent leaves and all from coming, they fix it through a silver or glass pipe, which goes round the company one after another. Frazier.

Befide all the virtues which the eastern people ascribe to their tea, as to be good in diseases of the head, hreaf, and chronic against phlegm, and to extirpate fire, the Americans attribute to them's like virtue, of purifying all kinds of waters, how foul and corrupt ever, by only infusing it therein, either hot or cold. Thus, having always some of it with them, if they meet with none but the worst waters in the vault dearts to be crossed in going from Buenos Ayres to Peru and Chili, they are not afraid to drink them, after steeping some of the plant a little while therein. It is also held foreign against the fever and putrid fevers.

PARAGUR, in Geography, a ruined town of Hindoftan, in the circar of Gohud; 25 miles S. of Narwa.

PARAH, in Commerce, a corn meafure in the East Indies. At Madras, the garee, corn-meafure, contains 80 parahs, or 400 marcals, and the marcal, 60 olocks. The marcal should meafeure 750 cubic inches, and weigh 27 lb. 2oz. 2dr. avoirdupois of fresh spring water; hence, 43 marcals = 15 English bushels, and the garee = 17¾ English quarters nearly. When grain is fold by weight, 925½ lbs. are reckoned for 1 garee, being 18 candies 12 ½ marcals.

At Bombay, the candy, corn-meafure, contains 8 parahs; the parah, 16 adowlies, 64 feers, or 128 tickers. This serves for wheat and all grain but rice, or bafey, which is sold by the bafey meafure, as follows; the morah contains 4 candies, or 25 parahs; the parah, 20 adowlies, 150 feeers, or 300 tickers.

PARAH, in Geography, a town of Bengal; 10 miles W. of Rognatpur. N. lat. 23° 4'. E. long. 86° 39'.

PARAIBA, or PARA-IBA, a town of Brazil, and capital of a province or captnacy of the fame name, which it derives from that of a river, on the S. bank of which it is situated, about 10 miles from the sea; the river being navigable above the town for ships loaded with 600 or 700 hogheads of sugar. The harbour is large, but rather dangerous on account of the sand-banks. The town has many flately houses, decorated with marble pilars, besides large warehouses and magazines for the accommodation of the merchants. The mouth of the river is defended by three forts. The Portuguese, who took possession of this town and territory in 1584, after having expelled the French, have increased its buildings, planted sugar-canes, erected sugar-mills. The whole territory is fertile in sugar-canes, and abound in Brazil wood, cattle, tobacco, cotton, &c.; 60 miles N. of Fernambuco. S. lat. 7° 15'. W. long. 34° 3'.

PARA-IBA de Sul, a river of Brazil, which runs into the Atlantic, S. lat. 7° 15'. There is another river in the south, of the fame appellation.

PARAKIN, a town of Servia; 32 miles N.N.W. of Niffa.

PARALAMPSIS, from pœra laµkéw, to shine a little, in Surgery, a white opacity of the cornea of the eye.

PARALAPUTTY, in Geography, a town of Hindoofan, in Myfore; 10 miles from Sankeridurgum.

PARALEA, in Botany, so called by Aublet from the Caribbean word parala, a genus of that author's, of which the characters, as far as concerns the female parts of fructification, and the nature of the fruit itself, are unknown. It belongs to the Polyandra, or rather Dodecandra, of Linnaeus, and is ranged by Juffieu among his Guaiacinae with indefinite flaments, between Cipinita of Aublet, and Hespera of Garden and Linnaeus, both which are now known to belong to the Symphoros of Jacquin and Linnaeus, as the Herrick first figured. We may therefore presume to reduce the parala to the same genus; even though no such collection of its flaments into parcels has been observed, as is found in various species of Symphoros already known; for that might easily
The true place of a star is that point of the heavens B, (fig. 4.) in which it would be seen by an eye placed in the centre of the earth as at T. The apparent place is that point of the heavens C, in which the star appears to an eye on the surface of the earth as at E. Now, as, in effect, we view a celestial body not from the centre, but from the surface of our earth, which is a semi-diameter distant from the centre; we see it by a visual ray, which passing through the centre of the star, and proceeding thence to the surface of the mundane sphere, marks out another point C, which is its apparent place.

The difference of places, is what we call absolutely the parallax, or the parallax of altitude; by Copernicus it is called the commutation; which, therefore, is an angle formed by two visual rays, drawn from the centre, the other from the circumference of the earth, and traveling the body of the star; and is measured by an arc of a great circle intercepted between the two points of the true and apparent place, C and B.

The nature and effects of the parallax may be otherwise familiarly illustrated by adverting to Plate XVIII. fig. 9. Let C be the centre of the earth, A the place of the spectator on its surface, S any object, Z H the sphere of the fixed stars, to which places of all the bodies in our system are referred; Z the zenith, H the horizon; draw C S M, A S n, and m is the place of S seen from the centre, and n from the surface. As the place S A C passes through the centre of the earth, it must be perpendicular to its surface, and consequently pass through the zenith Z; and the points m, n, lying in the same plane, the arc of parallax, m n, must lie in a circle parallel to the horizon; and hence the azimuth is not affected, if the earth be a sphere. Now the parallax, m n, is measured by the angle m S n, or A S C; and (by trigonometry) C S = C A \cdot \sin S A C or \sin S A Z its supplement: \sin S A C the parallax = \frac{C S}{C A \cdot \sin S A Z}.

But C A being confitent, on the supposition of the earth's being a sphere, the fine of the parallax varies as the sine of the apparent zenith distance directly, and the distance of the body from the centre of the earth inversely. Hence, a body in the zenith has no parallax, and at s in the horizon it is the greatest. If the object be at an indefinitely great distance, it has no parallax; and therefore the apparent places of the fixed stars are not altered by it. As n is the apparent place, and m is called the true place, the parallax deprecies an object in the vertical circle. For different altitudes of the same body, the parallax varies as the sine, s, of the apparent zenith distance; therefore, if \( p = \) the horizontal parallax, and radius be unity, we have: \( 1 : s : p = p \), the fine of the parallax. In order, therefore, to determine the parallax at all altitudes, we must first find it at some given altitude.

Vince's Elem. of Astronomy, 1810.

Parallax of Declination, is an arc of a circle of declination S I, (fig. 6.) whereby the parallax of altitude diminishes the declination of a star.

Parallax of Right Ascension and Deflection, is an arc of the equator D d, (fig. 6.) whereby the parallax of altitude increases the ascension, and diminishes the deflection.

Parallax of Longitude, is an arc of the ecliptic T t, (fig. 7.) whereby the parallax of altitude increases or diminishes the longitude.

Parallax of Latitude, is an arc of a circle of latitude S I, whereby the parallax of altitude increases or diminishes the latitude.

Parallax, Mensural, of the Sun, is an angle formed by two right lines, one drawn from the earth to the sun, and another...
PARALLAX.

another from the sun to the moon, at either of their quadratures.

Parallax of the annual orbit of the earth, is the difference between the heliocentric and geocentric place of a planet, or the angle at any planet, subtended by the distance between the sun and earth.

Parallax is also used for the angle made in the centre of the star by two right lines, drawn, the one from the centre, the other from the surface of the earth.

This is also called parallactic angle. Hence the parallax diminishes the altitude of a star, or increases its distance from the zenith; and has, therefore, a contrary effect to the refraction.

The parallax of altitude C B, (fig. 4,) is, strictly, the difference between the true distance from the zenith CA, and the apparent distance B A.

The parallax is greatest in the horizon; in the zenith, or meridian, a star has no parallax at all; the true and apparent places then coinciding.

The horizontal parallax is the same, whether the star be in the true, or the apparent horizon.

Few, if any, of the fixed stars have any sensible parallax, by reason of their immense distance, to which the semi-diameter of the earth is but a mere point. See Star.

Hence also, the nearer a star is to the earth, the greater is its parallax, at an equal elevation above the horizon; and Saturn is so high, that it is difficult to observe in him any parallax at all.

The parallax increases the right and oblique ascension, diminishes the declination; diminishes the northern declination and latitude in the eastern part, increases them in the western part; increases the southern in the eastern and western part; diminishes the latitude in the western part, increases it in the eastern. The parallax, therefore, has just opposite effects to the refraction.

Hence the parallax of the remote star S (fig. 5,) is less than the parallax of the nearer L, at the same distance from the earth, than before observed.

The lines of the parallactic angles M and S, of stars equally distant from the centre of the earth T, will be in like manner, as the distances of the stars seen from the vertex Z M, and Z S. Hence, the distances from the vertex decrease, i.e. as the altitudes decrease, and hence also, the parallax affects the altitude of the star, from the horizon to the zenith.

The doctrine of parallaxes is of the utmost importance, in astronomy, for determining the distances of planets, comets, and other phenomena of the heavens; for the calculation of eclipses, and for finding the longitude. Methods of finding the parallaxes of the celestial phenomena are various: some of the principal and safer follow.

To observe the Parallax of a celestial Phenomenon.—Observe when the phenomenon in the same vertical with a fixed star which is near it, and measure its apparent distance from the star; observe, again, when the phenomenon and fixed star are at equal altitudes from the horizon; and again measure their distance. The difference of those distances will be, the true distance of the phenomenon from the earth, which will be the parallax sought. The parallax of a phenomenon may be likewise found by observing its azimuth and altitude; and by marking the time between the observations, and its arrival at the meridian.

All required to find the parallax of the moon is, the parallax of right ascension; to find the effect of the magnitude of the semi-diameter of the earth, with regard to the phenomena of its motion, it is sufficient to know how far the meridian, to which the eye refers it, deviates from the true meridian. This is what M. Cassini found and practised with regard to Mars; and what M. Maraldi has since practised with regard to the moon. The whole mystery here consists in having the moon's true motion, which refers to the centre of the earth; and its apparent motion, which refers to the place of observation: the difference of these, which is greatest in the horizon, or horary circle of six o'clock, gives the horizontal parallax for that latitude; whence the general parallax, or that under the equator, is easily found: the parallax of any parallel being to that of the equator, as the semi-diameter of this parallel is to that of the equator. See the practice of this method exemplified in finding the parallax of Mars.

Parallax, to observe the Moon's.—Observe the moon's meridian altitude, with the greatest accuracy, and mark the moment of time: this time being equated (see Equation), compute the true latitude and altitude, and from these find her declination, and from her declination, and the elevation of the equator, find her true meridian altitude: if the observed altitude be not meridian, reduce it to the true altitude, for the time of observation: take the refraction from the observed altitude, and subtract the remainder from the true altitude; and the remainder is the moon's parallax.

By this means Tycho, in 1583, Oct. d. 15 hor. 5; 19', from the moon's meridian altitude observed, 13° 38', found her parallax to be 54 minutes.

To observe the Moon's Parallax in an Eclipse.—In an eclipse of the moon, observe when both horns are in the same vertical circle; in that moment take the altitudes of both horns; the difference of the two being halved, and added to the least, or subtracted from the greatest, gives nearly the visible altitude of the moon's centre: but the true altitude is nearly equal to the altitude of the centre of the shadow at that time. Now we know the altitude of the centre of the shadow, because we know the sun's place in the ecliptic, and its depression under the horizon, which is equal to the altitude of the opposite point of the ecliptic in which the centre of the shadow is; thus have we both the true and apparent altitude, the difference whereof is the parallax.

Parallax, in order to find the Moon's. Let a graduated emblem, as D A E (the larger the better), Plate XVIII. Afternoon, fig. 8, having a moveable index with sight-holes, be fixed in such a manner, that its plane surface may be parallel to the plane of the equator, and its edge A D in the meridian; so that when the moon is in the equinoctial, and on the meridian D E, the same may be seen through the sight-holes, when the edge of the moveable index cuts the beginning of the divisions at o. On the graduated limb D E; and when the moon is so seen, let the precise time be noted. Now, as the moon revolves about the earth from the meridian to the meridian again, in about 24 hours, 48 minutes, the same will go a fourth part round it in 6 hours, 12 minutes, as seen from C, or from the earth's centre or pole. But as seen from A, the observer's place on the earth's surface, the moon will seem to have gone a quarter round the earth when she comes to the sensible horizon at O; for the index, through the sights of which she is viewed, will be at 90° from D, where it was when she was seen at E. Now, let the exact moment when the moon is seen at O, in or near the sensible horizon, be carefully noted, (allowance being made for the horizontal refraction, which is about 34°) so that the moon's centre will appear 34 minutes above the horizon, when her centre is really in it; that it may be known in what time she has gone from E to O; which time subtracted from 6 hours 12 minutes, (the time of her going from E to L), leaves the time of her going from O to L, and affords an easy method for finding the angle O A L, or the moon's horizontal
PARALLAX.

horizontal parallax, which is equal to the angle A L C, by the following analogy: as the time of the moon's describing the arc E O is to 90°, so 6 hours 12 minutes to the degrees of the arc D E, which measures the angle E A L, from which subtract 90°, and there remains the angle O A L = A L C, under which the earth's semi-diameter C is seen from the moon.

Astronomers have proposed the following method, for more accurately determining the moon's parallax: let two observers be placed under the same meridian, one in the northern hemisphere, and the other in the southern, at such a distance from each other, that the arc of the celestial meridian included between their two zeniths, may be at least 80 or 90 degrees. Let each observer take the distance of the moon's centre from his zenith, by means of an exceeding good instrument, at the moment of her passing the meridian: add these two zenith distances of the moon together, and their excess above the distance between the two zeniths, will be the distance between the two apparent places of the moon. Then as the sun of the natural lines of the two zenith distances of the moon is to the radius, so is the distance between her two apparent places to her horizontal parallax. If the two places be not exactly under the same meridian, their difference of longitude must be accurately taken, that proper allowance may be made for the moon's declination, while she is passing from the meridian of the one to the meridian of the other. Ferguson's Astr. p. 307. quarto, 1773.

Otherwise: take the meridian altitudes of the moon, when it is at its greatest north and south latitudes, and correct them for refraction: then the difference of the altitudes, thus corrected, would be equal to the sum of the two latitudes of the moon, if there were no parallax; consequently the difference between the sum of the two latitudes and the difference of the altitudes, will be the difference between the parallaxes at the two altitudes. To find from them the parallax itself, let S, s, be the lines of the greatest and least apparent zenith distances; P, p, the lines of the corresponding parallaxes: then as, when the distance is given, the parallax varies as the sine of the zenith distance, as we have shewn at the beginning of the article Parallax,

\[ S - s = P - p \]

the parallax at the greatest altitude. This supposes that the moon is at the same distance in both cases; but as this will not necessarily happen, we must correct one of the observations, in order to reduce it to what it would have been, had the distance been the same, the parallax at the same altitude being inverely as the distance. If the observations be made in those places where the moon passes through the zenith of one of the observers, the difference between the sum of the two latitudes and the zenith distance at the other observation will be the parallax at that altitude.

Since, from the moon's theory, we have the ratio of her distances from the earth in the several degrees of her anomaly; those distances being found by the rule of three in semidiameters of the earth, the parallax is then determined to the several degrees of the true anomaly.

De la Hire makes the greatest horizontal parallax 1° 11' 23'', the smallest 54°.5''. The moon's distance, therefore, when in her perigee, is, according to his calculation, 55°.7', that is, almost 56 semidiameters; in her apogee 63°.09, that is, 63.2 semidiameters of the earth.

M. le Monnier determined the mean parallax of the moon to be 57°.12''. Others have made it 57°.18''. According to the Tables of Mayer, the greatest parallax

Vol. XXVI.
the horizontal parallax was $23^\circ.6$. Hence, if the ratio of the distance of the earth from Mars to its distance from the sun be found, we shall have the sun's horizontal parallax, the horizontal parallaxes being inversely as their distances from the earth.

To observe the Parallax of Mars.—1. Suppose Mars in the meridian and equator, in H, (fig. 11.) and that the observer, under the equator in A, observes him culminating with some fixed star. 2. If now the observer was in the centre of the earth, he would see Mars constantly in the same point of the heavens with the star; and therefore, together with it, in the plane of the horizon, or of the sixth hour; but since Mars has some sensible parallax, and the fixed star has none, Mars will be seen in the horizon, when in P, the plane of the central horizon; and the star, when in R, the plane of the true horizon: observe, therefore, the time between the transits of Mars and of the star through the plane of the sixth hour. 3. Convert this time into minutes of the equator; by this means we shall have the arc PM, to which the angle PAM, and consequently the angle AMD, is nearly equal; which is the horizontal parallax of Mars.

If the observer be not under the equator, but in a parallel IQ, that difference will be a less arc QM; wherefore, since the little arcs QM and PM are at their fixed ID and AD; and since $\triangle ADG$ is equal to the distance of the place from the equator, i.e. to the elevation of the pole; and therefore AD to ID, as the whole to the co-fine of the elevation of the pole; say, as the co-fine of the elevation of the pole ID is to the whole line AD; so is the parallax observed in I, to the parallax to be observed under the equator.

Since Mars and the fixed star cannot be commodiously observed in the horizon; let them be observed in the circle of the third hour: and since the parallax there observed, TO, is to the horizontal one PM, as 1S to 1D; say, as the line of the angle IDS, or $45^\circ$, (since the line D'O is in the middle between the meridian D'H and the true horizon D'M,) is to the whole line AID; so is the parallax TO to the horizontal parallax PM.

If Mars be likewise out of the plane of the equator, the parallax found will be an arc of a parallel; which must, therefore, be reduced, as above, to an arc of the equator.

Lastly, if Mars be not stationary, but rather direct, or retrograde, by observations for several days; find out what its motion is every hour, that his true place from the centre may be assigned for any given time.

By this method Cassini, to whom we owe this noble invention, observed the greatest horizontal parallax of Mars to be twenty-five seconds, or a little less; but, by the same method, Mr. Flamsteed found it near thirty seconds. By the same method, the same author, Cassini, observed also the parallax of Venus.

It must be here noted, that the observation is to be made with a telescope, in whose focus are situated four threads, cutting each other at right angles, A, B, C, D, (fig. 12,) and the telescope is to be turned about, till some star near Mars be seen to pass over some of the threads, that the threads AB and CD may be parallel to the equator, and therefore AC and BD may represent circles of declination: thus, by means of the perpendicular threads, the situations of the star, and of Mars, in the meridian, and circle of three o'clock, will be determined.

Another Method of finding the Parallax of a celestial Body. Let EQ be the equator (fig. 13,) P its pole, Z the zenith, or the true place of the body, and r the apparent place, as depressed by parallax in the vertical circle $Z k$, and draw the secondaries, $P K, P b$; then $a b$ is the parallax in right ascension, and $r s$ in declination. Now, 

$$\omega r = \omega s \odot (\omega d); \sin \omega r s, \text{ or } Z \odot P$$

$$\therefore \omega = \frac{\omega s \odot \cos \omega a}{(\omega a)}; \text{ or } Z \odot P$$

therefore, by substitution, $a b = \frac{\omega r \odot \sin Z \odot P}{\cos \omega a};$ but $\omega r = \text{ hor. par.} \times$

$$\text{sin. } Z \odot P \times \text{sin. } Z \odot P$$

Therefore, for the same star, where the hor. par. is given, the parallax in right ascension varies as the sine of the hour angle. Also, the hor. par. = $a b \times \cos \omega a$.

For the eastern hemisphere, the apparent place, $b$, lies on the equator to the east of $a$, the true place, and therefore the right ascension is increased by parallax; but in the western hemisphere, $b$ lies to the west of $a$, and therefore the right ascension is diminished. Hence, if the right ascension be taken before and after the meridian, the whole change of parallax in right ascension between the two observations, is the sum (i) of the two parts before and after the meridian, and the hor. par. $= \frac{s \odot \cos \omega a}{\text{sin. } Z \odot P \times s}$. On the meridian there is no parallax in right ascension, for $a b = \frac{\omega r \odot \sin Z \odot P}{\cos \omega a}$, and on the meridian, the angle $Z \odot P$, and consequently its sine, vanishes.

To apply this rule, observe the right ascension of the planet when it passes the meridian, compared with that of a fixed star, at which time there is no parallax in right ascension; about six hours after, take the difference of their right ascensions again, and observe how much the difference, $d$, between the apparent right ascensions of the planet and fixed star has changed in that time. Next, observe the right ascension of the planet for three or four days when it passes the meridian; in order to get its true motion in right ascension; then, if its motion in right ascension, in the above interval of time, between the taking of the right ascensions of the fixed star and planet on and off the meridian, be equal to $d$, the planet has no parallax in right ascension; but if it be not equal to $d$, the difference is the parallax in right ascension; and hence the horizontal parallax will be known. Or one observation may be made before the planet to the meridian, and one after, by which a greater difference will be observed.

Ex. On Aug. 15, 1719, Mars was very near a star of the fifth magnitude, in the eastern quadrant of Aquarius; and at 9h 18' in the evening, Mars followed the star in 10h 17^\circ; and on the 16th, at 4h 21' in the morning, it followed it in 10h 1'": therefore, in that interval, the apparent right ascension of Mars had increased 16^\circ in time. But, according to observations made in the meridian for several days after, it appeared that Mars approached the star only 14^\prime in that time, from its motion; therefore 2'" in time, or 30'" in motion, is the effect of parallax in the interval of the observations. Now the declination of Mars was 15°, the colatitude 41° 10', and the two hour angles 49° 15' and 56° 39'; therefore the hor. par. $= \frac{30^\prime \odot \times 15^\prime}{\text{sin. } 41^\circ 10' \times \text{sin. } 49^\circ 15' + \text{sin. } 56^\circ 39'} = 27^\prime 5^\prime$. But at that time, that the distance of the earth from Mars
Mars was its distance from the sun, as $37^2$ to $100$; and, therefore, the sun’s horizontal parallax comes out $101^2$.

Besides the effect of parallax in right ascension and declination, it is manifest that the latitude and longitude of the moon and planet must also be affected by it; and as the determination of this, in respect to the moon, is in many cases, particularly in solar eclipses, of great importance, we shall proceed to shew how to compute it, supposing that we have given the latitude of the place, the time, and consequently the sun’s right ascension, the moon’s true latitude and longitude, with her horizontal parallax.

Let $H$ $Z$ $R$ (fig. 14) be the meridian, $\gamma$ $E$ $Q$ the equator, $p$ its pole; $\gamma$ $C$ the ecliptic, $P$ its pole; $\gamma$ the first point of Arcturus, $H$ $Q$ $R$ the horizon, $Z$ the zenith, $Z$ $L$ a secondary to the horizon passing through the true place $r$, and apparent place $t$, of the moon; $P$ $t$, $P$ $r$, which produce to $t$, drawing the small circle $t$, parallel to $o$ $v$; then $r$ is the parallax in latitude, and $o$ $v$ the parallax in longitude.

Draw the great circles, $\gamma$ $P$, $P$ $Z$ $A$ $B$, $P$ $p$ $d$, and $Z$ $W$, perpendicular to $P$ $t$; then, as $\gamma$ $P$ $P$ = $90^0$, and $\gamma$ $P$ $d$ = $90^0$, $\gamma$ must be the pole of $P$ $p$ $d$, and therefore $d$, $\gamma$ $P$ $d$ = $90^0$; consequently $d$ is one of the folioll points, $z$, or $\gamma$ $p$. Also, draw $Z$ $x$ perpendicular to $P$ $r$, and join $Z$ $\gamma$, $p$ $q$, $x$.

Now, $E$, or the angle $\gamma$ $p$ $E$, or $Z$ $p$ $\gamma$, is the right ascension of the mid-heaven, which is known; $P$ $Z$ = $A$ $B$ (because $A$ $Z$ is the complement of both) the altitude of the highest point, $A$, of the ecliptic above the horizon, called the nonascensional degree, and $\gamma$ $A$, or the angle $\gamma$ $P$ $A$, is its longitude; also, $Z$ $p$ is the co-latitude of the place, and the angle $Z$ $p$ $W$ is the difference between the right ascension of the mid-heaven $\gamma$ $p$ $E$, and $\gamma$ $x$.

Now, in the right-angled triangle $W$ $Z$ $p$, $W$ $P$ $t$, we have \( Wp : \sin Wp = \sin WP :: \tan WP = \cot WP \cdot \cot Wp \cdot \tan WP \cdot \cot WP \); therefore,

\[
\log \tan WP = \log WP + \log \cot WP - \log \cot WP = 10;
\]

and as we know $\gamma$ $p$ $P$, or $\gamma$ $P$ $z$, the true longitude of the moon, we know $A$ $P$ $p$, or $Z$ $p$. Also, in the triangle $W$ $P$ $z$, we have $\tan WP = \cot WP$. Again, in the triangle $Z$ $P$ $x$, we know $Z$ $P$, $P$ $x$, and the angle $P$, from which the angle $Z$ $p$ $P$, or $t$ $r$, may be thus found. In the right-angled triangle $Z$ $P$ $x$, we know $Z$ $P$, and the angle $P$; hence, rad. $\times$ $\cos Z$ $p$ $x$ = $\cot Z$ $P$ $x$ $\tan P$ $x$; therefore,

\[
\log \tan P x = \log WP + \log \cot WP - 10;
\]

therefore we know $t$ $x$; hence, $\sin t$ $x$ = \( \tan P x \cdot \cot WP \). Also, in the right-angled triangle $Z$ $r$ $x$, we have rad. $\times$ $\cos Z$ $r$ $x$ = $\cot Z$ $r$ $x$ $\tan r$ $x$; therefore,

\[
\log \cot Z r = 10 + \log \cos Z r - \log \tan r x.
\]

With this true zenith distance $Z$ $r$, find the parallax, as if it were the apparent zenith distance, and it will give you the true parallax nearly; add this, therefore, to the true zenith distance, and you will get nearly the apparent zenith distance, to which compute again the parallax, and thus you will get the true parallax, $r$, extremely nearly; then, in the right-angled triangle $r$ $s$, which may be considered as plane, we have rad. $\cos r$ = $r$ $s$ $\tan r$; therefore,

\[
\log rs = \log rt + \log \cos r - 10 = \log \text{par. latitude.}
\]

Also, rad. $\sin r$ = $r$ $s$ $\cot r$; therefore,

\[
\log ts = \log rt + \log \sin r - 10
\]

and hence, $\tan t$ $s$ = $t$ $s$ $\cot t$ $s$; therefore,

\[
\log ev = 10 + \log ts - \log \cos t v = \log \text{par. long.}
\]

Ex. On January 1, 1771, at $9^h$, apparent time, in lat. $53^o$ $N$, the moon’s true longitude was $3^o$ $18^\circ$ $27^\prime$ $35^\prime$; and latitude $5^o$ $30^\prime$ $S$, and its horizontal parallax $61^o$ $9^\prime$; to find its parallax in latitude and longitude.

The sun’s right ascension was $28^o$ $22^\prime$ $24^\prime$ by the Tables, and its distance from the meridian $135^\prime$; also, the right ascension $E$, of the mid-heaven, was $57^o$ $22^\prime$ $24^\prime$; hence, the whole operation for the solution of the triangles will stand thus:

\[
\begin{align*}
\text{Tr. ZW} & & (ZpW = 32^o37'58") & + & (10 + \cot 19.925386) \\
\text{Tr. ZW} & & (ZpW = 37^o0') & + & \cot 10.1228856 \\

The value of \( t \) is \( r \circ - r \circ \), according as the moon has N. or S. latitude.

The order of the signs being from east to west, from A towards C is eastward, and from A towards \( \phi \) is westward: now the parallax depressing the body from \( r \) to \( r \circ \), increases the longitude from \( r \circ \) to \( r \circ \); but if the point \( e \) had been on the other side of \( A \), it would have lain the contrary way; hence, when the body is to the east of the nonesimal degree, the parallax increases the longitude; and when it is to the west, it diminishes the longitude. Hence, ubi supra.

PARALLAX. To find the Sun's.—The great distance of the sun renders its parallax too small to fall under even the most immediate observation; indeed, many attempts have been made, both by the ancients and moderns, and many methods invented for that purpose. The first was that of Hipparchus, followed by Prolemy, who made the sun's horizontal parallax \( 2' \), 50", and Tycho, who made it \( 3' \), 4", &c.; this was founded on the observation of lunar eclipses: the second was that of Aritharchus, whereby the angle subtended by the semidiameter of the moon's orbit, seen from the sun, was fought from the lunar phases; but these both proving deficient, astronomers are now forced to have recourse to the parallaxes of the planets nearer us, as Mars and Venus; for from their parallaxes known, that of the sun, which is inaccessible by any direct observation, is easily deduced. For, from the theory of the motions of the earth and planets, we know, at any time, the proportion of the distances of the sun and planets from us; and the horizontal parallaxes are in a reciprocal proportion to those distances; knowing, therefore, the parallax of a planet, that of the sun may be found from it.

Thus Mars, when opposite to the sun, is twice as near as the sun is; his parallax, therefore, will be twice as great as that of the sun; and Venus, when in inferior conjunction with the sun, is sometimes nearer than he is; her parallax, therefore, is greater in the same proportion. Thus, from the parallaxes of Mars and Venus, Caffini found the sun's parallax to be ten seconds; which implies his distance to be 19,000 semidiameters of the earth.

The most accurate method of determining the parallaxes of these planets, and deducing from thence the true parallax of the sun, is that of observing their transit: however, Mercury, though frequently to be seen on the sun, is not fit for this purpose; because it is so near the sun, that the difference of their parallaxes is always less than the solar parallax required. But the parallax of Venus, being almost four times as great as the solar parallax, will cause very sensible differences between the times in which she will seem to be passing over the sun at different parts of the earth. With a view of engaging the attention of astronomers to this method of determining the sun's parallax, Dr. Halley communicated to the Royal Society in 1691, a paper containing an account of the several years in which such a transit may happen, computed from the tables which were then in use: those at the ascending node occur in the month of November, O. S. in the years 918, 1161, 1396, 1631, 1874, 2109, 2117; and at the descending node in May, O. S. in the years 1048, 1253, 1891, 1518, 1526, 1761, 1769, 1960, 2004. Phil. Trans. Abrv. l. p. 435, &c.

Dr. Halley even then concluded, that if the interval in time between the two interior contacts of Venus with the sun could be measured to the exactness of a second, in two places properly situated, the sun's parallax might be determined within its 500th part. But this conclusion was explained more fully in a subsequent paper, (Phil. Trans. N. 348, or Abr. vol. iv. p. 213.) concerning the transit of Venus in the year 1761. It does not appear that any of the preceding transits had been observed except that of 1600, by our illustrious countryman Mr. Horrox, and his friend Mr. Crabtree, of Manchester. But Mr. Horrox died on the 3d of January, 1640—1, about the age of twenty-five, just after he had finished his treatise, intitled "Venus in Sole Vindas," in which he discovered a more accurate knowledge of the dimensions of the solar system than his learned commentator Hevelius.

In order to give our readers, not much conversant with subjects of this kind, a general idea of this method of determining the horizontal parallax of Venus, and from thence, by analogy, the parallax and distance of the sun, and of all the planets from him; it may be briefly illustrated in the following manner: let D B A, (Plate XVIII. Almanomy. fig. 15.) be the earth, V, Venus, and T S R the eastern limb of the sun. To an observer at B the point \( t \) of that limb will be on the meridian, its place referred to the heaven will be at A, and Venus will appear just within it at S. But, at the same instant, to an observer at A, Venus is east of the sun, in the right line A V F; the point \( t \) of the sun's limb appears at \( e \) in the heavens, and if Venus were then visible, she would appear at F. The angle C V A is the horizontal parallax of Venus; and is equal to the opposite angle \( D E B \), measured by the arc \( D E \). A S C is the sun's horizontal parallax, equal to the opposite angle \( E S E \), measured by the arc \( E S \); and \( F A c \), or \( V A v \), is Venus's horizontal parallax from the sun, which may be found by observing how much later in absolute time her total ingress on the sun is, as seen from A, than as seen from B, which is the time she takes to move from \( V \) to \( V \), in her orbit \( O V \). If Venus were nearer the earth, as at U, her horizontal parallax from the sun would be the arc \( F A c \), which measures the angle \( F A c \); and this angle is greater than the angle \( F A c \), by the difference of their measures \( F F \). So that as the distance of the celestial object from the earth is less, its parallax is the greater. Now it has been already observed, that the horizontal parallaxes of the planets are inversely as their distances from the earth's centre; therefore as the sun's distance at the time of the transit is to Venus's distance, so is her horizontal parallax to that of the sun; and as the sun's mean distance from the earth's centre is to his distance on the day of the transit, so is his horizontal parallax on that day to his horizontal parallax at the time of his mean distance from the earth's centre.
centre. Hence his true distance in semidiameters of the earth may be obtained by the following analogy: as the line of the sun's parallax is to radius, so is unity or the earth's semidiameter to the number of semidiameters of the earth in the sun's distance from the centre; which number multiplied by 3083, the number of miles in the earth's semidiameter, will give the number of miles in the sun's distance. Then from the proportioned distances of the planets, determined by the theory of gravity (see Distance), we may find their true distances. And from their apparent diameters at these known distances, their real diameters and bulks may be found. See Planets.

Mr. Short, with great labour, deduced the quantity of the sun's parallax from the observations that were made of the transits of June 6th, 1761, (for which see Phil. Trans. vol. li. and lii.) both in Britain and abroad, and found it to have been 8°.52 on the day of the transit, when the sun was very nearly at his greatest distance from the earth; and, consequently, 8°.65 when the sun is at his mean distance from the earth. (See Phil. Trans. vol. lii. art. 100. p. 611, &c.) Whence we shall have radius, or 10,000,000 = 5,621,914, or fine of 8°.65 taken out of Gardiner's tables = 4,378,080, the logarithm of the number 23828.84, or the number of semidiameters of the earth contained in its distance from the sun: and multiplying 23828.84 by 3083, the number of English miles contained in the earth's semidiameter, we shall have 95,713,177 miles for the earth's mean distance from the sun. And from the analogies under the article Distance, we shall find the mean distances of all the rest of the planets from the sun in miles as to be as follows, viz. Mercury's distance, 36,841,468; Venus's distance, 68,891,536; Mars's distance, 145,014,148; Jupiter's distance, 494,000,976; and Saturn's distance, 907,956,136. In another paper, (Phil. Trans. vol. liii. p. 169.) Mr. Short rates the mean horizontal parallax of the sun at 8°.69. Mr. Hornby, from several observations of the transit of June 30, 1769, (for which see Phil. Trans. vol. lix. &c.) deduces the sun's parallax for that day equal to 8°.65, and the mean parallax 8°.78, whence he makes the mean distance of the earth from the sun to be 95,736,680 English miles; Mercury's distance, 35,821,700; Venus's distance, 67,795,590; Mars's distance, 143,818,000; Jupiter's distance, 497,172,000; and Saturn's distance, 894,162,000 miles. (Phil. Trans. vol. lix. part ii. p. 579.) Others, however, by taking the results of those observations which were most to be depended on, have made the sun's parallax at his mean distance from the earth to be 8°.6045; and others again make it 8°.54. According to the former of these, the sun's mean distance from the earth is 95,109,936 miles; and, according to the latter, it is 95,834,742 miles. Upon the whole, there seems reason to conclude, that it may be fairly reckoned at more than ninety-five millions of miles, and less than ninety-six. Ferguson's Afrt. p. 354. See Planets.

The Parallax of the Stars, with regard to the Earth's Natural Orbit; called their annual parallax. The stars have no parallax, with regard to the earth's semidiameter; yet, with regard to the earth's annual orbit, it is justly expected, that some parallax may be found.

The axis of the earth, in its natural motion, describes a kind of cylinder, which, being prolonged to the heaven of the fixed stars, there draws a circular circumference; each point of which is the pole of the world for its respective day: so that the inclination of the apparent pole, with regard to any of the fixed stars, changes very considerably in the course of a year.

Could this be found by observation, it would irrefragably evince the annual motion of the earth round the sun, and remove that only objection which lies against it, urged by Riccioli, from no such parallax being observed.

Accordingly, Dr. Hook attempted to find it by observing the various distances of a fixed star from the zenith, in different parts of the earth's orbit; and Mr. Flamfled, from the accents and recedes of a fixed star from the equator at different times of the year, and with imagined fudces; the result of his observations being, that a fixed star, near the pole, was found 40 or 45 seconds nearer it at the winter solstice, than at the summer one, for seven years successively.

Mr. Caffini the younger allows the observations of Flamfled to agree with those made at the Royal Observatory; but he denies the consequences: he says that the variations in the distance of the pole-star are not such as they should be, supposing the motion of the earth. Fontenelle accounts for them from a supposition, that the stars, like the fun, turn or revolve on their centres; and that some of them have their hemispheres equally luminous: whence, when the more shining hemisphere is turned towards us, the stars appear bigger, consequently nearer the neighbouring stars, than when the darker is towards us.

Dr. Bradley has accounted for this supposed parallax in another way; and conceives it to proceed from the progressive motion of the star's light. (See Motion of the Earth and Light.) For the result of later observations, see Stars.

Parallax is also used, in Levelling, for the angle contained between the line of true level, and that of apparent level.

Parallaxis, among Medical Writers, expresses a natural change in the situation of the parts of a broken bone, as when the two fragments flip to the sides of one another.

Parallel, in Geometry, is applied to lines, figures, and bodies, which are every where equidistant from each other; or which, though infinitely produced, would never either approach nearer, or recede farther from each other.

Parallel Right Lines, are those which, though infinitely produced in the same plane, shall never meet.

Thus the line OP, (Plate X. Geometry, fig. 10.) is parallel to QR.

Parallel lines stand opposed to lines converging, and diverging.

Some define an inclining or converging line which will meet another at a finite distance; and a parallel line, that which will only meet it at an infinite distance.

A perpendicular is by some said to be the shortest of all lines that can be drawn to another; and a parallel the longest.

Geometricians demonstrate, that two right lines, perpendicular to one and the same right line, are parallel to each other, and hence they infer the possibility of parallel lines: that perpendiculars to one of two parallel lines, terminated by those lines, are equal to each other, and also perpendicular to the other of the two parallels; that two lines, parallel to the same third line, are also parallel to one another; and if two parallels, OP and QR, be cut by a transversal line ST in A and B; 1. The alternate angles α and γ are equal. 2. The external angle ω is equal to the internal opposite one θ; 3. That a line intersecting two parallel lines, make the angles on the same side equal to each other; and,
4. That the two internal opposite ones, \( z \) and \( y \), are also equal to two right ones.

It is shown, on the principles of optics, that if the eye be placed between two parallel lines, they will appear to converge towards a point opposite to the eye, because the apparent magnitudes of their perpendicular intervals are perpetually diminished; for the same reason they appear to converge towards an imaginary line, drawn parallel to them from the eye: and if they run to such a length, as that the distance between them be but as a point thereto, they will then appear to coincide.

This is the reason that the removable parts of a walk or floor appear to ascend gradually, and the ceiling to descend towards the horizontal line: and that the surface of the sea, seen from an eminence, appears to ascend gradually in going from the shore; and that the upper parts of very high buildings seem to lean forward over the eye below.

Parallel lines are described by letting fall equal perpendiculars, and drawing lines through their extremities, by sliding the compasses open to the desired width, along a line, &c. or, by drawing two lines, which shall make the alternate angles with a line intersecting them equal.

**Parallel Motion.** is a term used among practical mechanics to denote the rectilinear motion of a piston-rod, &c. in the direction of its length; and contrivances, by which such alternate rectilinear motions are converted into continuous rotatory ones, or *nice seriatim* for pumps, steam-engines, saw-mills, &c. are usually called parallel motions, or parallel levers. In the modern improved steam-engines and pumps, close cylinders are generally used for the pistons to act in, which being worked by polished rods sliding through collars or *slipping-boxes* in the lids of the cylinders, it has become necessary to contrive methods for causing the piston-rod to move accurately up and down in the same right line. The different combinations of levers used to produce this effect are worthy of our notice, as exhibiting some ingenious applications of geometrical principles. The object of the parallel motion is, to convert the motion of the end of a reciprocating beam or lever, into a vertical or rectilinear motion; or the continuous motion of a crank at once into a reciprocating motion.

The simplest and most obvious method of producing either of these effects, is to connect the end of the piston-rod to the beam, or the crank, by means of joints, with a connecting rod of a proper length between them, and confine the former, to preserve its rectilinear movement, by sliding through a collar, or in grooves. Friction-wheels may be used to make it work easily; but in machines which have great strains, the constant wear of the grooves or wheels would soon produce looseness, and destroy the parallelism of the motion: recourse must, therefore, be had to parallel levers.

**Plate 111. of Steam engines.** contains three different constructions of levers, which are in common use in steam-engines, to produce parallel motions. Two of them, figs. 1, 2, 3, and 4, were, we believe, first introduced by Mr. Black. Boulton and Watt, as appendages to their patent steam-engine, in lieu of the levers, or arch heads with chains, formerly applied to the beams of the old atmosphere engines. The most simple of these two is represented in figs. 3 and 4, where the pump, or piston-rod \( T \), is required to move always in the line \( T T \), when actuated by the beam, or lever, \( H B \), whose centre of motion is \( A \), and the point \( I \), from which the rod receives its motion, of course moves in an arc of a circle. To this point, one end of a bar, or link \( I L \), of any convenient length, is joined, and to the opposite end, \( K \), the extremity of a lever, \( K L \), is attached by the joint or centre-pin \( K \), the other end, \( L \), moving on a fixed centre of motion. The lever, \( K L \), is exactly equal in length to the acting radius, \( A I \), of the beam, and its centre of motion, \( L \), is attached to a fixed support, so situated, that when the beam, \( A I \), is horizontal, or at right angles to the line \( T T \), the lever, \( K L \), will also be horizontal, and therefore parallel to \( A I \); at the same time the link, \( I K \), which connects them, must hang perpendicular. A centre-pin is fixed at \( M \), exactly in the middle of \( I K \), and to this centre the top of the piston-rod, \( T \), is attached. Now the effect of the combination is, that the point, \( M \), will always move in the vertical line \( T T \), when the beam or the point, \( I \), describes an arc of a circle round the centre \( A \); for it is evident, that when the levers, by the motion of the beam on its centre, are brought into the position shewn by the dotted lines \( A I, K L \), fig. 3, either above or below the horizontal, the upper end of the link, \( I K \), is drawn as much out of the line, \( T T \), on one side, by the curved motion, or sweep of the beam, as the lower end is drawn out of that line, on the opposite side, by the sweep of the lever \( K L \); consequently, its middle point, \( M \), continues always in that line, and prevents the piston-rod deviating from it. The movement may be readily traced by inspection of the diagram, fig. 3, which exhibits the levers in three different positions.

Figs. 1 and 2 represent another of Boulton and Watt's parallel motions, and is that now most commonly used by themselves and other engine-makers. This, as before described, has two fixed centres, \( A \) and \( F \), and rods connected by moveable joints \( C \), \( B \), \( D \), and \( E \), forming a parallelogram.

In setting out of these centres, the line \( G G \), in which the piston is to move, should fall as much short of the end of the beam, or point \( B \), when in the horizontal position, as it will be between the end of the fames at the two extremes of the movement; which positions are represented by dotted lines, fig. 1: the link, \( B D \), connects the end of the beam with the top of the piston-rod, and about half way to the centre of the beam, another link, \( C E \), of the same length, is joined, being always kept parallel to the former by a connecting rod, \( D E \), which is equal in length to \( C B \), so that \( C B \), \( D E \), may form a parallelogram, in whatever position it may be placed by the motion of the beam, and the consequent motion of the links and coupling-rod on their moveable centres.

The parallelogram of the point, \( D \), is produced by means of the lever, \( E F \), which is connected to the point, \( E \), of the parallelogram, and the other end moves on the fixed centre, \( F \); therefore the end, \( E \), of the rod, \( E D \), moves in an arc of a circle, round the centre \( E \); the other end, \( D \), will be found to traverse the right line \( G G \).

The proportions of the levers of this motion admit of great variation; the simplest case is, when the radius, \( A C \), is exactly half of \( A B \), then \( E F \) must be equal to \( A C \) or \( C B \). Considerable latitude is allowed to the workman in the length of the links \( B D \) and \( C E \), without feebly deranging the parallelism of the point \( D \), and piston-rod attached to it. With these proportions, the centre, \( F \), will fall upon the line \( G G \), which is often inconvenient; for as there are two of the parallelograms, \( C E \) and \( D B \), one on each side of the beam, the centres of the lever, \( E F \), cannot be made on one common axis. Eleven different proportions for these levers will appear by the following table of dimensions, in inches, taken from some of the best steam-engines, by various makers in or near the metropolis.

Figs.
The principle on which parallel motion, or what is sufficiently near to one, is produced in all these different cases, will appear, after explaining a different construction for the same purpose by Mr. Freeman.

Fig. 6. represents this parallel motion, which is effected by means of two fixed centres, D and E, and the two moveable ones B and A. In this case the beam-centre, A, is not stationary, but has a small motion on its support DA, which is moveable on the fixed centre D: the centre C, which unites the lever, EC, to the beam, is in the middle of the beam, (i.e. BC = CA, and EC is also of the same length,) the support DA, being of any convenient length; but the longer the better, since the construction requires, in strictness, that the point, A, should slide horizontally in the dotted lines EA, instead of descending in each end of its course in the arc of the radius DA. The pin-on-rod, G, is moved immediately to the end of the beam at B. The parallelism of the motion in this contrivance is effected by the lever, EC, compelling the middle point of the beam, A B, to move upon the arc CC, as it liberates upon its centre, whilst that point traverses upon the top of the bar, AD, to such an extent that the extremity, B, will always traverse upon the line GG, and of course carry the pin-on-rod with it. This may be demonstrated thus: supposing EA to be a horizontal line, let the dotted line, BA, represent any position whatever of the beam, and EC the corresponding position of the lever; then B C E and C A E will form two isosceles triangles, because of the equal sides B C and C E, and E C and C A: their opposite angles are equal, as E B C = B E C, and C E A = C A E; and because the angle, B E A, is made up of the angles B E C and C E A, the same, (B E A,) is equal to the sum of the two angles, B and A, of the triangle B A E, which flew the third angle, E, to be a right angle; therefore the point, B, will be perpendicular over E, or perpendicular beneath it, as a similar construction, below the line EA, would shew. As the demonstration is equally true of every other part of the movement, as well as its extremes, the angle, B E A, will in all cases be a right angle, and consequently produce a parallel motion. We have here supposed the centre, A, to be confined to slide along the line EA; but in practice it has been found, that the point, A, may be allowed to move in the arc of a circle, described on the centre D, instead of the right line EA, without producing sensible deviation in the parallelism of the point B, and the pin-on-rod, G, attached to it. The fixed centre, E, may also be moved out of the line BB, either towards or from the centre A, within certain limits, making proportionate alteration in the lengths of the lever EC, and radius AC, as will be evident on making the following comparison between the constructions in fig. 2. and fig. 6. If in fig. 1. and 2. we produce the line DE, and from A draw a line parallel to CE and BD, intersecting it in Y, then supposing the figures turned upside down, and end for end, we can compare the fixed centre D, fig. 6, with A, fig. 2; and the fixed centre E, fig. 6, with F; also the beam A B, fig. 6, with the produced coupling rod Y D; the support D A, fig. 6, with A Y; and the lever E C, fig. 6, with F E: it will then appear that the two constructions are essentially the same in principle, supposing the fixed centre, E, moved out beyond the line BB, as has been mentioned above to be practicable.

The dimensions, given in our table above, will shew what considerable variations in the proportion of lengths, particularly with regard to the lever E F, fig. 2, may be made in practice, without sensibly impairing this admirable contrivance for producing a vertical motion from a power moving up and down, in the arc of a circle described by the end of the beam.

A very ingenious parallel motion is represented in fig. 5, which converts the rectilinear motion of a pinion-rod at once to a rotatory motion for a crank or axis. This contrivance has been ascribed to an American, named White; and has been adopted in steam-engines by Mr. Murray, of Leeds. It is founded on a well-known property of epicycloidal curves, viz. that if within any given fixed circle another circle rolls round, which is just half the diameter of the fixed circle, any point in the circumference of the rolling circle describes a right line, which crosses the longer circle, as a diameter thereto. The mode of construction is easily understood from the figure, in which A B is a fixed circle, or hoop of cast iron, whose internal diameter is equal to the stroke of the pinion; it is supported externally by standards G and H, and furnished with small teeth all round the interior part of its circumference; C is a toothed wheel, whose diameter is only half that of the ring; the axis of the wheel, which is to have the rotatory motion, passes through the centre of the ring, and has a circular iron plate, or wheel E, fixed upon the extremity of it; from this plate, a pin or bolt, R, projects, and is by the motion of the axis carried round in a circle, in the manner of a crank. This pin forms the centre-pin of the small wheel C, and therefore compels it to roll round within the great circle, and keep the teeth always in contact. The upper extremity of the pinion-rod is attached to a pin, F, fixed on the circumference of the small wheel, at the point where the two wheels will be in contact, when at the lowest and highest points of the motion.

The pin F, at the circumference of the small wheel, is adjustable by a slider and screw, so as exactly to suit the diameter of the outer circle; and the pinion-rod, being attached to it, is moved truly up and down in the line I K, in a very regular manner, when the axis of the plate, E, is turned round; or vice versa, if the impelling power is applied to the pinion-rod, in which case a fly-wheel must be applied upon the central axis to regulate the motion.

The extremity of the pinion-rod will be confined to move in the vertical diameter of the ring, because it is made to describe an epicycloid of that kind, which is formed by a circle rolling round within the inside of another circle of double diameter, in which case, it is well known the epicycloid becomes a diameter of the larger circle, and the smaller circle makes two complete revolutions, while it is revolving from any one point of the larger circle to the same point again.

In all the motions we have described, the conversion of the reciprocating motion to a rotative, is effected by means
of a crank, which communicates with the beam by a connecting rod at the opposite end of the beam, in the manner of HK, fig. 4; usually at the end opposite to the parallel levers. Some mechanics have supposed it definable, in a parallel motion, to give the pinion-rod, the saw, or the like, an uniform velocity through the whole of its progress; then to bring it at once to rest again, and to give it instantaneously its intended velocity in the opposite direction, and so on. This the crank will not do, as its motion, at the point where the change or reciprocation of motion takes place, is imperceptible; they have therefore sought other means.

One method of producing this effect is, to make the pinion-rod consist of two parallel bars, having teeth in the side, which front each other. Let a toothed wheel be placed between them, having only the half of its circumference furnished with teeth. It is evident, without any further description, that if this wheel be turned uniformly round its axis, the pinion-rod will be moved uniformly up and down without intermission. This has often been put in practice, and the pinion-rod made to work between grooved rollers, but the machine always went by jolts, and seldom last a few days. Unskilful mechanics attributed this to defects in the execution, but the fault is essential, and lies in the principle. The machine could not perform a single stroke without breaking, if the first mover did not flacken a little, or the different parts of the machine did not yield by bending, or by compression, and no strength of materials could withstand the violence of the strains at every reciprocation of the motion. This is chiefly experienced in great works, which are put in motion by a water-wheel, or some other equal power, exerted on the mass of matter of which the machine consists. The water-wheel, being of great weight, moves with considerable steadiness, or uniformity; and when an additional resiliency is opposed to it by the beginning of a new stroke of the pinion, its great quantity of motion is but little affected by this addition, and it proceeds with very little loss of motion. The machine must either yield a little by bending, or compression, or go to pieces, which is the common event. Cranks are free from this inconvenience, because they accelerate the pinion gradually, and bring it gradually to rest, while the water-wheel moves round with almost perfect uniformity. The only inconvenience attending this slow motion of a pinion at the beginning of its stroke, is, that the valves do not shut with rapidity, so that some water gets back through them. But when they are properly formed and loaded, this is but trifling.

**Parallel Planes** are those planes which have all the perpendiculars drawn betwixt them equal to each other. And it is demonstrated, that two right lines perpendicular to the same plane are parallel to each other; and that if one of two parallel right lines be perpendicular to any plane, the other will also be perpendicular to the same plane; that planes, to which one and the same right line is perpendicular, are parallel to each other; that all right lines, perpendicular to one of two parallel planes, are perpendicular to the other; that right lines parallel to one and the same right line, though not in the same plane with it, are also parallel to each other; that if two right lines, meeting each other, be respectively parallel to two other right lines, also meeting each other, and not being in the same plane with them, the angles contained by the lines will be equal; that if two right lines, meeting each other, be respectively parallel to two other right lines, also meeting each other, and not being in the same plane with them, the planes extended by those lines will be parallel; and that the sections, made by a plane cutting two parallel planes, are also parallel to the other: and hence parallel lines, terminated by the same parallel planes, are equal to each other.

**Parallel Rays**, in Optics, are those which keep at an equal distance in respect to each other, from the visible object to the eye, which is supposed to be indefinitely remote from the object.

**Parallel Ruler**, called also **Parallelism**, an instrument consisting of two wooden, brass, or steel rulers, A B and CD, (Plate X. Geom. fig. 11,) equally broad every where, and so joined together by the cross blades E F and G H, as to open to different intervals, and accede and recede, yet still retain their parallelism. The use of this instrument is obvious; for one of the rulers being applied to R S, and the other withdrawn to a given point V, a right line A B, drawn by its edge through V, is a parallel to R S; and thus, having given only one line, and erecting a perpendicular upon it, we may draw any number of parallel lines, or perpendiculars to them; by only observing to set off the exact distance of every line with the point of the compasses.

But the belt parallel rulers are those whose bars cross each other, and turn on a joint at their intersection; one end of each bar moving on a centre, and the other ends sliding in grooves as the rulers recede. See fig. 12.

**Parallels**, or **Places of Arms**, in a siege, are deep trenches fifteen or eighteen feet wide, joining the several attacks together; and serving to place the guard of the trenches in, to be at hand to support the workmen when attacked. There are generally three in an attack; the first is about three hundred toises from the covert-way; the second one hundred and sixty, and the third near or on the glacis. They are laid to have been first invented or used by M. Vauban.

Thus, in **Plate VII. Fortification**, fig. 2, let A, B be the bastions to be attacked, whose capitals, as well as that of the ravelin C, being indefinitely produced towards the field, lie off three hundred fathoms from the flanant angles, r s, of the covert-way to the points 1, m; and from the centre, o, of the place, describe an arc of a circle through the points 1, m, whose interferences with the capitals will terminate the several parts of the first parallel E, which is terminated at twenty fathoms beyond the faces produced of the two adjacent ravelins z, X, next to the front attacked. Take f, n, m q, each equal to one hundred and forty fathoms, and describe from the centre, o, another part of a circle through the points n, q; and its interference with these capitals will terminate the several parts of the second parallel F, which extends only ten fathoms beyond the faces of the ravelins z, X. Lastly, draw lines through the flanant angles of the glacis, and they will give the third parallel G. When this is done, take the points d, e, in the capitals of the bastions, at about eight hundred fathoms from the flanant angles, r s, of the covert-way, and join them by a right line, which will express the beginnings of the attacks. From the point j, in d e, at about twenty-four or twenty-six fathoms from the point e, draw a line jf g or H of any length, as one hundred and twenty or one hundred and twenty-six fathoms, for the first approach; but fo as, when produced, to fall ten or twelve fathoms from the farthest flanant angle of the covert-way; from the point g draw g b, so as to fall as much from the farthest flanant angle on the other side of the place g, and the point b is taken, fo as to be nearly at the same distance from the capital t e as the point g; and from the point b draw the line b t, so as to fall again as far from the farthest flanant angle in the first side, and that the point i be equally as distant from the capital t e as the point b; and thus continue the approaches to the third parallel. The approaches are traced after the same manner as the capital d e, and also...
on the capital of the ravelin C, from the second parallel to
the third; always observing that no part of them is to be
seen or entailed from any part of the fortification, nor to
defile too much, which would occasion unnecessary labour.
As the approaches advance nearer the place, they become
shorter, as they make smaller angles with each other. Be-
tween the second and third paralels, at the returns of the
approaches, are made places of arms, such as I, about thirty
or forty fathoms long, nearly parallel to the third parallel,
which serve to receive the troops that are to cover the
workmen, till the third parallel is quite finished. When the
principal or outline of the trenches are thus traced, paralels
are drawn to them on the side towards the field, at twelve
feet distance in the approaches, fifteen in the first and second
paralels, and at eighteen in the third; and the intervals be-
tween these and the former lines will express the width
of the trenches. At the ends of the second parallel are
made square redouts, as K, K, of about ten or twelve
fathoms on each side, to protect it more effectually from the
fallies of the besieged. The first part, d, of the trenches is
an embankment of about ten feet high to c over the horse
defended to guard the trenches. Muller's Attack and Def.
of Fortified Places, p. 21, &c.

Parallels, or Paralel Circles, in Geography, called also
paralels of latitude, and circles of latitude, are like circles
of the sphere, inclosed to pass through every degree and minute
of the colures.

They are represented on the globe by the divisions of the
quadrant of altitude, in its motion round the globe, when
screwed over the poles of the ecliptic.

Parallels of Altitude, or Almucantars, are circles par-
allel to the horizon, imagined to pass through every degree
and minute of the meridian, between the horizon and zenith;
their poles in the zenith.

On the globe these are represented by the divisions on the
quadrant of altitude, in its motion about the body of the
globe, when screwed to the zenith.

Parallels of Declination, are the same with parallels of
latitude in geography.

Parallels, Ant. See Anti-Paralels.

Parallel Sphere, that situation of the sphere in which
the equator coincides with the horizon, and the poles with
the zenith and nadir.

In this sphere, all the paralels of the equator become par-
allels of the horizon; consequently no tides ever rise or set,
but all turn round in circles parallel to the horizon; and the
sun, when in the equinoctial, wheels round the horizon the
whole day.

After his rising to the elevated pole, he never sets for fix
months; and after his entering again on the other side of the
line, he never rises for fix months longer.

This position of the sphere is then's of the earth's axis of
rotation, if any such there be; their sun being never above
23° 26' high.

Parallel, Sailing, in Navigation, is the falling under a
parallel of latitude.

Of this there are but three cases. 1. Given the depart-
ure, and distance; required the latitude. The canon for
Vol. XXVI.

which is, as the difference of longitude is to the radius, 30
the distance to the cosine of latitude.

2. Given the difference of longitude between two places
under the same parallel; required their distance. The
canon is, as radius to difference of longitude, so is cosine
of latitudes to distance.

3. Given the distance between two places in the same
latitude; required their difference of longitude. The
canon is, as the cosine of latitude to distance, so is radius
to difference of longitude. See Sailing.

Parallel Cut, in Inland Navigation, is a counter-drain
to carry off water, and prevent the adjoining lands from
being flooded.

ParallelEla, a word used by medical writers to ex-
press a fret of scurf or leprous appearance, affecting only
the palms of the hands. It is a symptom of the pox.

ParallelEped, in Geometry, one of the regu-
lar bodies, or solid, comprehended under six par-
alelomcgs, the opposite ones of which are similar, parallel,
and equal; as in Plate X, Geometry, fig. 13.

A paralelEped is by some defined an upright prism,
whose base is a parallelepiped, and the planes of whose fides
are perpendicular to the plane of the base. A rectangular
paralelEped is that which bounding planes are all rect-
angles, and which stand at right angles one to another; and
every rectangular parallelepiped is said to be contained
under the planes that are its length, breadth, and alti-
itude.

It is demonstrated, that if from one of the angular points
of any parallelogram, a right line be elevated above the
plane of the parallelogram, fo as to make any angles with
the contiguous sides of it, and there be also drawn, from the
three remaining angular points, three other right lines
parallel and equal to the former, and the extremities of these
lines be joined, the figure thus described will be a paral-
lelepiped. If the angle of the parallelogram be right, and
the elevated line be erected perpendicular to the plane of
the base, then will the parallelepiped be a rectangular one.

Parallelepiped, Properties of the. All parallelepiped,
prisms, and cylinders, &c. whose bases and heights are
equal, are themselves equal.

Every upright prism is equal to a rectangular paral-
lelepiped of equal base and altitude.

A diagonal plane divides the parallelepiped into two equal
prisms: a rectangular prism, therefore, is half a paral-
lelepiped upon the same base, and of the same altitude.

All parallelepiped, prisms, cylinders, &c. are in a ratio
compounded of their bases and altitudes: wherefore, if their
bases be equal, they are in proportion to their altitudes;
and conversely.

All parallelepiped, cylinders, cones, &c. are in a tripli-
cate ratio of the homologous fides; and also of their
altitudes.

Equal parallelepiped, prisms, cones, cylinders, &c. are
in the reciprocal ratio of their bases and altitudes.

Rectangular parallelepiped, contained under the corre-
sponding lines of three ranks of proportionals, are themselves
proportionals.

To measure the Surface and Solidity of a Parallelepiped.—Find
the areas of the parallelograms I LM K, L MN, and
O M K P (see ParallelElogram); add these into one sum, and
multiply that sum by 2; the product will be the surface
of the parallelepiped.

If, then, the base I L M K be multiplied by the altitude
M O, the product will be the solidity.

Suppose, v. gr. L M = 36, M K = 15, M O = 12. Then
L I K M = 36 × 15 = 540; L M O N = 36 × 12 = 432; 3
M M K P
PAR

MOKP = 15 \times 12 = 180. The sum of which is = 1152, which multiplied by 2, gives the superficies equal to 2304. And 540 \times 12 gives the solidity equal to 6480. Or the solid content of a parallelepiped may be obtained by multiplying the area of the base by the altitude of the parallelepiped.

E.g. If the two dimensions of the base be 16 and 12 inches, and the height of the solid 10 inches; then the area of the base being 192, the content of the solid will be 1920 cubic inches.

The parallelepiped with oblique angles is a figure very common to many kinds of stones, especially of the softer sort. The common crystallizations of grottos break naturally into fragments of this shape; and the flatlets which hang down from their roofs in form of icicles, are originally small hollow pipes formed by the water which continually trickles down drop by drop; and whose outer surfaces, fixing themselves by their small bases, form by degrees a fort of blunted pyramids, which like so many rays from the axis, which is the hollow pipe, grow hollow at last. This axis seems to be composed of plates, almost cylindrical, laid one over another; but, if broken, the whole divides into fragments of a parallelepiped figure: the blunted pyramids that are about the axis divide themselves at first into other blunted pyramids; but afterwards almost all these fragments divide of themselves into other fragments of a parallelepiped figure, this seeming everywhere the ultimate shape of the particles.

In the mountain of Berea there is found a vast quantity of abellos: the stone upon which this grows, though in itself of no determinate figure externally, always breaks into regular parallelepipeds: nor is this peculiar to these stones found naturally concreted on the surface or within the bowels of the earth, but it is also found in such as are concreted by means of art out of the water in which they are originally suspended.

The water of the fountain de Salut, near Bagneres in Gascony, when evaporated to a certain degree, yields a scum on the surface, which also adheres to the sides of the vessel; and this scum, examined by the microscope, is found to be composed of many regular parallelepipeds. If the same waters, and those of several other springs, be evaporated to a dryness, there remains a white foming powder, out of which the microscope can direct us to several the regular figures. Phil. Trans. N.'472. p. 32.

PARALLELISM, the quality of a parallel, or that which denominates it such: or it is that whereby two things, e.g. lines, rays, or the like, become equidistant from one another.

Thus, we say, remote objects are fearcely perceptible, by reason of the parallelism of their rays.

PARALLELISM of the Earth's Axis, in Astronomy, or motion of parallelism, is that invariable situation of the earth's axis, in its progress through its orbit, whereby it still looks nearly to the same point of the heavens, viz. towards the pole-star; so that if a line be drawn parallel to its axis, while in any one position; the axis, in all other positions or parts of the orbit, will always be nearly parallel to the same line. This parallelism is the necessary result of the earth's double motion; the one round the sun, the other round its own axis. Nor is there any necessity to imagine a third motion, as some have done, to account for this parallelism.

It is to this parallelism that we owe the vicissitudes of seasons, and the inequality of day and night.

PARALLELISM of Rows of Trees. The eye placed at the end of an alley bounded by two rows of trees, planted in parallel lines, never sees them parallel, but always inclining to each other, towards the farther extreme.

Hence mathematicians have taken occasion to enquire, in what lines the trees must be disposed, to correct this effect of the perspective, and make the rows still appear parallel?

To this purpose parallel they must not be, but diverging; but according to what law must they diverge? The two rows, in fine, must be such, as that the unequal intervals of any two opposite or corresponding trees may be seen under equal visual angles.

On this principle, F. Fabry has asserted, without any demonstration; and F. Tacquet, after him, has demonstrated by a long and intricate synthesis, that the two rows of trees must be two opposite semi-hyperbolas.

M. Varignon has since, in the Memoirs of the Royal Academy, ann. 1717, found the same solution by an easy and simple analysis. But he renders the problem much more general, and requires not only that the visual angles be equal, but to have them increase, or decrease, in any given ratio: provided the greatest do not exceed a right angle. The eye requires to be placed in any point either just at the beginning of the ranges, or beyond, or on this side.

All this laid down, he supposes the first row to be a right line, and seeks what line the other must be, which he calls the curve of the range. This he finds must be an hyperbola, to have the visual angles equal. The straight and hyperbolical rows will be seen parallel to infinity; and if the opposite semi-hyperbola be added, we shall have three rows of trees (the straight one in the middle), and all three parallel.

Nor is it required this second hyperbola be the opposite of the first, i.e. of the same kind, or have the same transverse axis: it is enough, if it have the same centre, its vertex in the same right line, and the same conjugate axis. Thus the two hyperbolas may be of all the different kinds possible; yet all have the same effect.

Again, the straight line being laid down as before; if it be required to have the trees appear under decreasing angles, M. Varignon shows, that if the decrease be a certain ratio, which he determines, the other line must be a parallel straight line.

But he goes yet farther, and supposing the first row any curve whatever, he seeks for another that shall make the rows have any effect desired, i.e. to be seen under any angles equal, increasing, or decreasing.

Notwithstanding the ingenuity of this speculation, it has been satisfactorily demonstrated by M. D'Alembert, and M. Bouguer, that in order to produce the effect proposed, the trees are to be ranged merely in two diverging right lines. Encyclopedie.

PARALLELISM, in Hebrew Poetry, is a term used by bishop Lowth for expressing the correspontence of one verse, or line, with another. When a proposition is delivered, and a second is subjunctive to it, or drawn under it, equivalent, or contrasted with it in sense, or similar to it in the form of grammatical construction: the learned prelate calls parallel lines; and the words, or phrases, answering one to another in the corresponding lines, are denominated parallel terms. Parallel lines, he says, may be reduced to three forts; parallels synonymous, parallels antithetic, and parallels synthetic. Of these the author has given a variety of examples, exhibiting their various forms, from the books universally acknowledged to be poetical; the correspondent examples from the prophet Isaiah; and sometimes also from the other prophets; in order to shew, that the form and character of the composition are in all the same. It is observed, that the several forts of parallels are perpetually mixed
mixed with one another; and that this mixture gives a variety and beauty to the composition.

Parallel lines synonymous are those which correspond one to another by expressing the same sense in different, but equivalent terms; when a proposition is delivered, and is immediately repeated, in the whole or in part, the expression being varied, but the sense entirely or nearly the same. Examples occur in the following passages: viz. Pf. xxi. 1, 2. Prov. i. 24—32. Psalms, lv. 6, 7. If. liv. 4. If. li. 7, 8. Joel, xi. 7. Pf. cxii. 1. If. xlvii. 3. Prov. iii. 9. If. lv. 3.

In the foregoing examples there are different degrees of synonymous parallelism. The parallel lines sometimes consist of three or more synonymous terms; sometimes of two, which is generally the case, when the verb, or the nominative case of the first sentence, is to be carried on to the second, or understood there; sometimes of one only, as in the four last examples. Among the foregoing there are a few instances, in which the lines consist of double numbers, or two propositions. The author has subjoined one or two more perfect examples of this kind, occurring in Pf. clxxxiv. 5. 6. If. lxv. 21, 22.

Parallels are also sometimes formed by a repetition of part of the first sentence, as in Pf. lxxxvii. 3. 11. 16. If. xxvi. 5. 6. Hosea, vi. 4.

Sometimes in the latter line a part is to be supplied from the former to complete the sentence; as in 2 Sam. xxii. 41. Job, xxxvi. 5. If. xli. 28.

There are also parallel triplets; when three lines correspond together, and form a kind of stanza, of which, however, only two commonly are synonymous: Pf. cxii. 10. Job, iii. 4. 6. 9. If. ix. 20. Joel, iii. 13. There are likewise parallels consisting of four lines; two different being so connected together, by the sense and the construction, as to make one stanza. Such is the form of the xxxviii. Psalms. See particularly Pf. clxxxvii. 1, 2. If. i. 3. If. xlix. 4. Amos, i. 2.

Some periods may be considered as making stanzas of five lines, in which the odd line, or number, either comes in between two dithyrambs, or after two dithyrambs making a full close: as in Job, viii. 5, 6. If. xlvii. 7. Hos. xiv. 9. Joel, ix. 16. If. xxxvii. 20. In stanzas of four lines sometimes the parallel lines answer to one another alternately; the first to the third, and the second to the fourth; as in Pf. xi. 11, 12. If. xxx. 16. If. i. 16.

The second parallels are the antithetic; when two lines correspond with one another by an opposition of terms and sentences; when the second is contraled with the first, sometimes in expressions, sometimes in sense only. Accordingly the degrees of antithesis are various, examples of which occur in Prov. x. 1. Prov. x. 7. Prov. xi. 24. Prov. xx. 26. Prov. xvi. 33. See also Pf. xx. 7. 8. Pf. xxx. 5. Pf. clxxxvii. 10, 11. If. liv. 10. If. ix. 10.

The third form of parallels comprehends those, which are called synthetic, or constructive; where the parallelism consists only in the similar form of construction; in which word does not answer to word, and sentence to sentence, as equivalent or opposite; but there is a correspondence and equality between different propositions, in respect of the shape and turn of the whole sentence, and of the constructive parts; such as anisms anwering to noun, verb to verb, number to number, negative to negative, interrogative to interrogative. See Pf. clxxxviii. 7—13. Job, xii. 17—16. If. lv. 5, 7—8. The following passages are constructively parallel, viz. Pf. cxxxv. 6—7. If. ii. 56. Micah, vi. 1. See also Prov. xxx. Prov. xvi. 16—19. Eccl. ii. 2. If. li. 19. Cant. i. 5. If. xv. 3.

Of the three different sorts of parallels, above-enumerated, every one has its peculiar character and proper effect; and therefore they are differently employed on different occasions; and that fort of parallelism is chiefly made use of, which is best adapted to the nature of the subject and of the poem. Synonymous parallels have the appearance of art and concinnity, and a studied elegance; they prevail chiefly in shorter poems; in many of the psalms; in Baal's prophecies; frequently in those of Isaiah, which are most of them distinct poems of no great length. The antithetic parallelism gives an accuteness and force to adages and moral sentences; and therefore abounds in Solomon's proverbs, and elsewhere is not often to be met with. The poem of Job, being on a large plan, and in a high tragical style, though very exact in the division of the lines, and in the parallelism, and affording many fine examples of the synonymous kind, yet conflits chiefly of the constructive. A happy mixture of the several forts gives an agreeable variety; and they serve mutually to recommend and set off one another. Lowth's Preliminary Dissertation to his "New Translation of Isaiah."

PARALLELOGRAM, in Geometry, a quadrilateral right-lined figure, whose opposite sides are parallel, and equal to each other.

A parallelogram is generated by the equable motion of a right line always parallel to itself.

When the parallelogram has all its four angles right, and only its opposite fides equal, it is called a rectangle, or an oblong.

When the angles are all right, and the sdes are all equal, it is called a square, whence make a species of parallelogram, others not.

If all the sides are equal, and the angles unequal, it is called a rhombus, or lozenge.

If both the sides and angles be unequal, it is called a rhomboid.

Every other quadrilateral whose opposite sides are neither parallel nor equal, is called a trapezium. See each of these, under their respective names.

PARALLELOGRAM, Properties of the. In every parallelogram, what kind ever it be ex. e. g. A B C D, Plate X. Geometry, fig. 14. a diagonal DA divides it into two equal parts; the angles diagonally opposite B C, and A, D are equal; the opposite angles of the same side, C, D, and A, B, &c. are, together, equal to two right angles; and each two sides together are greater than the diagonal. Every quadrilateral whose opposite sides are equal, is a parallelogram.

Two parallelograms A B C D, and E C D F, on the same side, or on an equal base C D, and of the same height A C, or between the same parallels A F, C D, are equal. And hence two triangles C D A, and C D F, on the same base, and of the same height, are also equal; and all parallelograms or triangles whatever, whose bases and altitudes are equal among themselves.

Hence, also, every triangle C D F is half a parallelogram A C D B upon the same base, or an equal base C D, and of the same altitude, or between the same parallels. Hence also a triangle is equal to a parallelogram, having the same base, and half the altitude, or half the base, and the same altitude.

Parallelograms, therefore, are in a given ratio, compounded of their bases and altitudes. If then the altitudes are equal, they are as the bases; and conversely.

In similar parallelograms and triangles, the altitudes are proportional to the homologous sides; and the bases are cut proportionally thereby. Hence, similar parallelograms and triangles are in a duplicate ratio of their homologous sides, also of their altitudes, and the segments of their bases; they are,
are, therefore, as the squares of the sides, altitudes, and homologous segments of the bales.

In every parallelogram, the sum of the squares of the two diagonals is equal to the sum of the squares of the four sides; and the two diagonals bisect each other. For the triangles AEB, DEC, (fig. 15.) being equiangular, on account of the equal vertical and alternate angles, and having one side AEB = one side DCE, will have AEC = CED, and ECD = ECD. Moreover, because the double of the square of a line drawn from the vertex to the middle of the base of any triangle, together with the double of the square of the femi-bale, is equal to the squares of both the sides taken together, 2AE\^2 + 2ED\^2 = AD\^2 + CD\^2, and by doubling these, we shall have, because four times the square on half a line is equal to the square on the whole line (see Squares), 4AE\^2 + 4ED\^2 = (AD + BC)^2 + (CD - AB)^2.

This proposition, M. de Lagney takes to be one of the most important in all geometry; he even ranks it with the celebrated forty-fourth of Euclid, and with that of the similitude of triangles; and adds, that the whole first book of Euclid is only a particular case of it. For if the parallelogram be rectangular, it follows, that the two diagonals are equal; and, of consequence, the square of a diagonal, or, which comes to the same thing, the square of the hypotenuse of a right angle, is equal to the squares of the sides.

If the parallelogram be not rectangular, and of consequence, the two diagonals be not equal, which is the most general case, the proposition becomes of vast extent; it may serve, for instance, in the whole theory of compound motions, &c.

There are three ways of demonstrating this proposition; the first by trigonometry, which requires twenty-one operations; the second geometrical and analytical, which requires fifteen. M. de Lagney gives a more concise one, in the Mémoires de l'Acad., which only requires seven.

To find the area of the right-angled parallelogram A B C D, (fig. 14.) Find the length of the sides A B and A C; multiply A B into A C, the product will be the area of the parallelogram. Suppose, e.g. A B to be 3 4 5; A C 1 2 3; the area will be 4 2 4 3 5.

Hence. 1. Rectangles are in a ratio compounded of their sides A B and A C. 2. If, therefore, there are three lines continually proportional; the square of the middle one is equal to the rectangle of the two extremes; and if there be four proportional lines, the rectangle under the two extremes is equal to that under the two middle terms.

Other parallelograms, not rectangular, have their areas found by resolving them by diagonals, into two triangles, and adding the areas of the separate triangles into one sum; or by multiplying their bales into their altitudes.

Parallelogram, Complement of a. See Complement.

Parallelogram, Newtonian or Analytic, in Algebra, an appellation used for an invention of sir Isaac Newton, to find the first term of an infinite converging series.

This is sometimes called the method of the parallelogram and ruler; because a ruler or right line is also used in it.

This analytic parallelogram is formed by dividing any parallelogram into equal squares or parallelograms, by lines drawn horizontally and perpendicularly through the equal divisions of the sides of the parallelogram. The cells, thus formed, are filled with the dimensions of the quantities x and y, and their products.

The powers, y^0 = 1, y, y', y'', &c. of y, for instance being placed in the lowest horizontal range of cells, and the powers of x, or x^2 = 1, x, x', x'', &c. in the vertical column to the left, or vice vers; so that these powers and their products will stand as in Plate X.11. Analyt., fig. 4.

Thus, when any literal equation is proposed, mark such of the parallelograms or cells as correspond to all its terms; and let a ruler be applied to two or perhaps more of the parallelograms so marked, of which let one be the lowest in the left-hand column at A B, the other touching the ruler towards the right hand; and let all the red not touching the ruler lie above it. Then erect those terms of the equation which are represented by the parallelograms that touch the ruler, and from them find the quantity to be put in the quotient.

This is sir Isaac Newton's famous rule, of the application of which he has left us some examples in his Method of Fluxions and Infinite Series, p. 9 and 10, but without demonstration; which has been since supplied by others. See Mr. Colfon's Comment on that treatise, p. 192, seq. Macaulain's Algebra, p. 251, seq. and particularly Monti. Cramer's Analyt. des Lignes Courbes. chap. vii. p. 148, seq.

This learned author observes, that this invention, which is the true foundation of the method of series, was but imperfectly understood, and not valued as it deserved for a long time. He thinks it more convenient in practice to use the analytic triangle of the abbé de Gua, which takes in no more than the diagonal cells lying between A and C, and those which lie between them and B.

Parallelogram, or Parallelism, also denotes a machine used for the ready and exact reduction or copying of designs, schemes, prints, &c. in any proportion; which is done hereby without any knowledge or habit of designing; which see.

The parallelogram is also called pentagraph. See its description and use under Pentagraph.

Parallelogram of the Hyperbola, in Geometry, is used for the parallelogram formed by the two asymptotes of a hyperbola, and the parallels to them, drawn from any point of the curve. A parallelogram thus formed is of an invariable magnitude in the same hyperbola; and the rectangle of its sides is equal to the power of the hyperbola. I. Hospital, Sect. Conic. Art. 69-101. See Power.

This parallelogram is the modulus of the logarithmic system; and if we take it as unity, the hyperbolic factors and segments will correspond to Napier's, or the natural logarithms. If the parallelogram be taken = 0.43429; &c. these factors and segments will represent Briggs's logarithms. See Logarithm.

Huygens has made use of this term, De Cauf. Gravitation in fin. See Logarithmic Curve.

Parallelogram Præsidium, a mathematical instrument, consisting of a semicircle of brass, with four rulers in form of a parallelogram, made to move to any angle; one of these rulers is an index, which shows on the semicircle the quantity of any inward or outward angle.

Parallelopipedia, in Natural History, the name of a genus of spars, thus called, because regularly of a parallelopiped or parallelepiped form.

They are pulcru crystalline spars, externally of a determinate and regular figure, always found loose, detached, and separate from all other bodies, and in form an oblique parallelepiped, with six parallelogram sides and eight solid angles, easily fitted, either in a horizontal or perpendicular direction, being composed of numbers of thin plates, and those of very elegantly and regularly arranged bodies, each of the same form with the whole mass, except that they are thinner in proportion to their horizontal planes; and naturally
PAR

rally fall into these and no other figures, on being broken with a slight blow.

Of this genus Hill has enumerated fourteen known species.
1. The hard, pellucid, and colourless one, called the island crystal of authors. (See Island Crystal.)
2. A dull and whitish kind, found in France, Germany, and England, particularly in the Derbyshire and Yorkshire lead-mines, and about Scarborough. This has the same property with the former, of giving a double refraction; but it is so dull and opake, that it does not shew it so elegantly.
3. A soft, white, and very bright one, found principally in the lead-mines of Yorkshire, and about the lead-houses of that county. And, 4. A dull, hard, and pale brown one: this is found in the lead-mines of the face county, and in some parts of Ireland. All these species have the same power of double refraction with the first, but are too opaque to shew it so beautifully, and often have not transparence enough to make it at all distinguishable.

PARALLELOPLEURON, a term used by some writers for an imperfect parallelogram, or a kind of trapezium, having unequal angles and sides, but which obliterates a certain regularity and proportion.

PARALOGISM, αραλογίας, in Logic, a false reasoning, or a fault committed in demonstration, when a consequence is drawn from principles that are false, or, though true, are not proved; or when a proposition is passed over, which should have been proved by the way.

A paralogism differs from a sophism in this, that the sophism is committed out of design and subtlety; and paralogism out of mistake, and for want of sufficient light and application.

Yet Messieurs du Port Royal do not seem to make any difference between them.

PARALOPHIA, a word used by Keil, and some other anatomical writers, to express the lower and lateral part of the neck.

PARALOURGES, αραλογίστης, among the ancients, a kind of garment, with a purple clavis on each side. See CLAVIS.

PARALYSIS, in Botany. See Primrose.

PARALYSIS, in Medicine. See Palsy.

PARALYTIC, a perfon afflicted with the paralysis, or palsy.

PARAMARIBO, or Paramaripama, in Geography, a confiderable town of South America, and capital of Surinam, or Dutch Guiana, occupying a pleafant gravelly situation, on the banks of the river Surinam, which is here about a mile in breadth. The number of houses, chiefly conftructed of timber, is about 1400: and that of the inhabitants is about 9000: the town contains two churches, and two Jewish synagogues: the streets are all perfectly ftraight, and lined with trees, fuch as oranges, lemons, fladdocks, and tamarinds. It is about 18 miles from the sea, and has a good harbour. N. lat. 5° 46'. W. long. 55° 11'.

PARAMBAB, a town of Hindooflan, in Bahr; 17 miles E. of Bahar.

PARAMECUM, in Verneology, a genus of worms of the order Infusoria, of which the generic character is this: an invisible, flimsy, pellucid, flattened worm. There are seven species mentioned by Gmelin, which are as follow:

Specie

* Aurelia. This is compressed, longitudinally plicated towards the fore part, behind it is acute. This, says Mr. Adams, is rather a large animalcule, four times longer than it is broad; the fore part is obtuse, transparent, and apparently without intestines; the hind part is filled with molecules of various sizes: the fold that goes from the middle to the apex is a flaring characteristic of the species, forming a kind of triangular aperture, and giving it somewhat the appearance of a gimblet. Its motion is rectilinear, reeling, or flitting, and generally vehement. This species is frequently found in ditch-water, and in infusions, coahring litharge; the lateral edges of both bodies appear bright. They may sometimes be seen lying on one another alternately, at others adhering by the middle. They will live many months in the same water, without its being renewed. They are to be found in the month of June, in ditches where there is plenty of duck-weed.

* Chrysalis. This is cylindrical, longitudinally plicated on the fore part, and obtuse behind. It is an inhabitant of hot water, very like the last, but is more obtuse behind. The margins are filled with black globules.

* Oviferum. Depressed, with a large oval molecule within; the body is oval, pellucid, with black grains towards one end.

MARGINATUM. This is depressed, is grey, and has a double margin. It is, says Mr. Adams, one of the largest of the genus, flat, elliptical, and every part filled with molecules, except in the lower end, where there is a pellucid vehicle. This animalcule is surrounded by a broad double margin, and at the moment of its expiring, a bright spiral intelease is observable.

CAUDATUM. This species is pointed at both ends, the middle is the broader, and filled with molecules. It is found in waters among duck-weed; its motion is very slow.

ANCUS. The tail of this species is two-edged, and the head is obtuse. The motion of this animalcule is very slow; it is found in the water, in which the plant hydrocharis is produced.

ACUTUM. Tail two-edged, head acute; inhabits flagrant water; is slow in its motions, continually agitating its tail.

VERSUTUM. This species, mentioned by Adams, is cylindrical, the lower part thick, and both ends very obtuse. It has an oblong green gelatinous body, filled with molecules; the lower part is thick, the fore part is smaller, both ends are obtuse, and they may be seen to propagate by division. It is found in ditches.

PARAMES, αραμός, in the Ancient Myth., the ninth chord or found in the diagramma, or scale of music.

The word is Greek, and signifies justa medietem, next to the middle; its situation in the first rate of the scale, being next the mele, or middle chord.

It was the note above the mele, which answers to elia-mire of Guido’s scale. Hence, as the parameæ was the first of the diazeugmenon tetrachord, it will be equivalent to Guido’s highest mi. See Diagram.

PARAMESOS, a word used by some to express the sin, or that next the little one.

PARAMESVARA, in Mythology, a name given to the Hindoo deity Siva by his sectaries. Hindoos of some sects give this name exclusively to Brahman, the supreme ruler; others apply it to the deity whom they more particularly worship. In one of the Puranas, Lakshmi is invoked under the name of Paramasiva-rupini, meaning with the countenance of Paramesvara; but in another he seems more applicable to the supreme ruler, as noticed under the article LAKSHMI.

PARAMETER, in Geometry, a confident right line in each of the three conic sections; called also latum rectum. In the parabola the rectangle of the parameter, and an abscissa, is equal to the square of the correpodent semi-ordinate. See PARABOLA.
In an ellipse and hyperbola, the parameter is a third proportional to a conjugate, and transverse axis. See Ellipsis and Hyperbola.

PARAMO, Luiz de, in Biography, a native of Borox, in the diocese of Toledo, archdeacon and canon of Leon, and afterwards inquisitor in Sicily, is author of a most extraordinary work, entitled "De Origine et Progresso Officii Sancie Inquisitionis, ejusque Dignitate et Utilitate," which was undertaken under the patronage of D. Gaspar de Quiroga, then archbishop of Toledo, and inquisitor-general, and which was pronounced by Nicholas Antonio, to be a work full of various learning. It was printed in folio at Madrid in 1598, and afterwards at Antwerp, in 1614, and a copy of the first edition is in Mr. Williams' library in Redcros-street, London. Mr. Southey, in the General Biography, has given an analysis of this book, from whose account we shall give a short extract, to shew the inquisitor's mode of reasoning.

Paramo begins by proving God to have been the first inquisitor, who convicts Adam and Eve of heresy, infidelity, apostacy, and blasphemy. God cited Adam, otherwise the process would have been null. On Adam's appearance, he made inquisition into the crime. The man accused his wife, and then the judge questioned her: he did not examine the serpent, because of his obstinacy. The examinations were secret and separate, that there might be no collusion lying. He calls no witnesses, and affirms that confidence and confession are as a thousand witnesses, and save the judge all the trouble, except that of condemning. The whole, he says, was done secretly, that it might be a precedent for the holy office; and closely does this holy office observe the precedent, that they make the dregs of penitent offenders after the very pattern of the clothes which God made for Adam and Eve, and conficate all the property of a heretic, because Adam and Eve were turned out of paradise. The author then goes on to shew that Abraham was an inquisitor, so were David and Solomon, Chrifi, and a multitude of others, but our readers will easily believe, after the specimen we have given, he can prove any thing. It had been well had Paramo stopped here, but he was one of the most savage practical inquisitors that ever existed. In proof of this it is sufficient to observe, that, he himself says, in the course of one hundred and fifty years, the inquisition had burnt thirty-thousand witches, and he claims great part of the merit for himself, saying he had punished very many of them. We cannot help saying, that unless the British government infallibly upon the allegation, not only of the existing inquisition in Spain, but also of the laws (which we know on good authority still remain) which function to savage a court, they cannot with any degree of propriety be said to be contending for the liberties of mankind. We hope the noble marquis, the hero of the times, will immortalize his name by destroying every vestige of it.

PARAMORES, in Geography, a small island in the Atlantic, near the coast of Virginia. N. lat. 37° 36'. W. long. 75° 44'.

PARAMOUNT, in our Law, signifies the supreme lord of the fee.

There may be a tenant to a lord, who holdeth himself of another lord; in respect whereof the former lord is called lord mojne (i.e. Mesne), and the latter lord paramount.

All honours, which have manors under them, have the lord paramount.

But even the term lord paramount is only comparative; for as one man may be great, compared to a less; and little, being compared with a greater; so none truly seems to be lord paramount but the king, who is patron paramount to all the benefices in England. See Manor and Tenant.

PARAMOURS, or Paromashir, in Geography, the second of the Kurile or Kurilskoi islands; between which and Shoomshu, the latt is but two verds broad. It extends from N.E. to S.W., and is twice as large as Shoomshu, and, according to Capt. Cook, is the largest of the Kuriles under the dominion of Russia. The land is very high, and when visited by Capt. Cook's navigators, in his Third Voyage, Oct. 13, 1779, it was entirely covered with snow. It is richly furnished with roots and minerals, but deficient of wood. Here is no scarcity of red foxes, wolves, and all kind of mice. Mr. King places the S. end of this island in N. lat. 49° 58', and the N. end in lat. 50° 46'. E. long. 156° 14'.

PARAMUTTY, a town of Hindoostan, in the Carnatic, taken by the British in 1790; 10 miles S.W. of Coveri- porum.

PARANA, the longest and most considerable stream of the Rio de la Plata, which rises in the grand mineral mountains of Brazil, S. lat. 15°, and bending S., then W. till it receives the Iba Parana, after which it bends S.W. till it is joined by the Paraguay; while the conjunct rivers are still called the Parana by the natives, and the Rio de la Plata by the Spaniards. Yet the length of the Paraguay, according to the maps of La Cruz, does not yield above half a degree to that of the Parana; and the breadth of its course gives it the appearance of the principal river. The grand cataract of the Parana is in lat. 24°, not far from the ruined town of Cuaya; but it rather a series of rapids, for a space of 12 leagues, amidst rocks of tremendous and singular forms. Dobrizhofer afferts that the Parana is the chief stream, which receives the Paraguay and Urugay. The inundations are chiefly in December and January, rising about five or six yards above the iflets. This noble river is flushed with numerous islands; and Spanish vessels navigate to the town of Assumption, about 400 leagues from the sea. On the shores are often found goods, including crystals; but the natural history of the Parana is almost as obscure as that of the true Maranon. The breadth of the estuary is such, that the land cannot be discovered from a ship in the middle of the stream. Pinkerton.

PARANA, a town on the W. coast of the island of Samar. N. lat. 11° 54'. W. long. 124° 48'.—Also, a town of Brazil, on the coast of the island of Marajo. S. lat. 6° 12'. W. long. 57° 36'.

PARANAGUA, a river of Brazil, which runs into the Atlantic, S. lat. 25° 30'.

PARANAMERIN, a river of Brazil, which runs into the Atlantic, S. lat. 2° 50'. W. long. 42° 40'.

PARANAPANEMA, a river of Paraguay, which runs into the Parana.

PARANETE, in the Ancient Music, was a name sometimes used to signify the next note or chord to the note, or last note of a tetrachord. Hence it might be called the penultimate chord. It was otherwise, and more properly called the hibonas, or index.

PARANETE Diezeugmenon, in the Greek Music, was the penultimate note of the diezeugmenon tetrachord, and answers to Guido's de la folia. See Diagram.

PARANETE, Hyperboleon, was the penultimate note of the hyperboeion tetrachord, and answers to Guido's foli- e-uit. See Diagram.

PARANOMASIA, is a figure that occurs when two words, very near in sound, but different in sense, respect each
each other in the same sentence; this is usually called a pun.

PARANOEE, in Geography, a river of Malacca, which runs into the sea, N. lat. 4° 40'. E. long. 123° 25'.

PARANYPHES, or PARANYPHUS, among the ancients, the person who waited on the bride-groom, and directed the nuptial solemnities; called also prominbus and auxipes, because the ceremony began with taking auxpicia.

In strictures, the paranymph, παραγωγὴς, only officiated on the part of the bride-groom; on the part of the bride a woman officiated, who was called promuna.

The Jews had likewise a kind of paranymphs, which the Talmud and rabbins call דבכטש, מנהטביה, q. d. companions of the bride.

The fourth council of Carthage appoints, that when the married couple come to ask the priest's blessing, they be presented either by their fathers and mothers, or by their paranymphs.

PARAPET, Breastwork, in Fortification, a defence, or screen, on the extreme of a rampart, or other work, serving to cover the formidable and the cannon from the enemy's fire. See Plate VII. Fortification, fig. 3.

Borel gives us, from Jof. Maria Subreitius, a curious collection of names, which the ancients and moderns have given to this kind of parapet: the Latins call them subcarra, and balleine, whence the names balleine and battaille. They also call them paginemata, loricae, and antemuralia. The Spaniards call them barricanas; the Italians, parapeti, because of their defending the breach, pette; whence our parapet.

Parapets are railed on all works, where it is necessary to cover the men from the enemy's fire; both within and without the place, and even in the approaches. See Mr. Vanban's Method of Fortification, under the article Military Construction.

The thickness of the parapet should be about eighteen or twenty feet, in order to be cannon-proof, and it should be about seven or eight feet high, when the enemy has no command above the battery; otherwise it should be raised high enough to cover the men while they load the guns. Its length depends on the number of guns to be employed in the battery; for one gun, it is common to allow eight yards in length, and fix yards more for every other gun. The parapet consists of two parts, the wall contained in one piece from end to end, and about two and a half or three feet high, and the merlons, which are detached pieces of the parapet, leaving openings, called embrasures, through which the cannon deliver their shot.

The parapet of the wall is sometimes of stone. The parapet of the trenches is either made of the earth dug up; or of gabions, fatines, barrels, sacks of earth, or the like.

PARAPET is also a little wall, breast-high, railed on the brinks of bridges, quays, or high buildings; to serve as a stay, and prevent people's falling over.

PARAPH, a particular character, knot, or flourish, which people habitation themselves to make always in the same manner at the end of their name, to prevent their signature from being counterfeited.

The parapet of the kings of France used to be a grate, which the secretaries always place before their own, in all letters, &c. Ménage derives the word from paragraphus. See Paragraph.

PARAPHERNALIA, or PARAPHERNA, in the Civil Law, those goods which a wife brought her husband, besides her dower, and which were still to remain at her disposal, exclusive of her husband, unless there was some provision made to the contrary in the marriage-contract.

The word is formed from the Greek παραπάνω, beyond, or over, and αὐτον, dōs, dower. "In his rebus quas extra dotem mulier habet, & quas Greci παραπάνω vocant, nullam, uxore prohibente, vir habet communem." Cod. du Pacis.

The Grand Council of Normandy gives a different sense to the word; it calls paraphernalia the moveables, linen, and other female necessaries, which are adjudged to a wife, in prejudice to the creditors, when she renounces the succession of her husband's goods.

Some of our English lawyers give a still different sense to the word paraphernalia, defining it to be such goods as a wife challenges over and above her dower, or jointure after her husband's death; as furniture for her chamber, wearing apparel, and jewels, which are not to be put in the inventory of her husband's goods.

Accordingly the apparel and ornaments of a wife, suitable to her rank and degree, are paraphernalia; and even the jewels of a peeress, usually worn by her, have been held to be paraphernalia. (Moor, 213.) These he becomes entitled to at the death of her husband, over and above her jointure or dower, and preferably to all other representatives. (Cro. Carr. 347.1 Roll. Abr. 911.2 Leon. 166.) Neither can the husband devise by his will such ornaments and jewels of his wife; though during his life he hath the power if (unkindly inclined to exert it) to sell them or give them away. (Noy's Max. c. 49. Grahme v. Lord Londonderry, 24 Nov. 1744. Calt.) But if he continues in the use of them till his death, the shall afterwards retain them against his executors and administrators, and all other persons except creditors, where there is a deficiency of affets. (1 P. Wms. 730.) And her necessary apparel is protected even against the claim of creditors. Noy's Max. c. 49.

PARAPHIMOSIS, or PARAPHRIMOSIS, from παρά, back, and φιμωμένος, to bridle. This term, in Surgery, is applied to the cæs, in which the prepuce is drawn backward, behind the glans penis, and cannot be brought forward again. The complaint is the very reverse of phymos, which is attended with a contraction of the opening of the prepuce, so that the glans cannot be uncovered. Both these diseases are mostly the consequence of an inflammatory thickening of the prepuce, arising from the irritation of gonorrhoea, a chancre, or simple excoriations. Paraphymos very frequently follows phymos, by the thickened prepuce being very improperly drawn back behind the glans. In this circumstance, the constricted part of the prepuce acts as a ligature round the body of the penis, and retards the return of blood from the glans, and the portion of the prepuce beyond the stricture. Hence, edematous inflammation attacks the latter part, while the former becomes prodigiously distended, and, it is evident, that mortification of the glans and part of the prepuce may be produced by the complaint.

Paraphymos frequently admits of being expeditiously relieved, by compressing as much of the blood as possible out of the glans penis, and then pushing this part back again through the stricture. In order to perform this operation skilfully, the surgeon should first make continued pressure on the glans, by placing it between the ends of the thumb, index, and middle fingers of each hand. The whole surface of the part should thus be gradually compressed at the same time for the space of four or five minutes. Then the two thumbs are to be employed, both in pushing backward the diminished glans, and, together with the fingers, in drawing forward the prepuce. The caes, which cannot thus be relieved, are extremely few. When the plan fails, however, leeches should be applied to the glans, and the flow of blood be afterwards promoted by immersing the part in warm water.
In almost every case, the preceding method will now be found completely effectual. But, if it should not do so, as much blood must be taken away by venepction, as the state of the patient will well bear, and the part is either to be covered with a cold turban, poultice, or the lotio plumbi superacetatis. When, notwithstanding every exertion, and the strict observance of antiphlogistic means, the edematous swelling increases instead of subsiding, the only way to prevent a mortification of the glass and prepare to make an incision, cut deep behind the former part, through that portion of the prepuc which forms the constrictio. A small scalpel is the best instrument, and care must be taken to cut to a sufficient depth. In most surgical books, paraphymosis is represented as a venereal complaint, and demanding the exhibition of mercury; but the history, which we have here given of it, must convey a different, and, we trust, a more accurate notion of the complaint. When paraphymosis originates from the irritation of a chancre, mercury is indeed necessary for the cure of the sore; but the paraphymosis does not itself absolutely require this medicine, and may be at once cured by compressing the glass and pushing it back through the constricted part of the prepuc. Paraphymosis from gonorrhœa never stands in need of mercury. See Full Lines of Practice of Surgery, by S. Cooper, edit. 3.

PARAPHONIA, from παρά, and φωνή, the voice, signifies a depraved sound of the voice in speaking, and of course is not applicable to dumbness. Dr. Cullen makes fix species of morbid voice, viz. 1. Paraphonia puerorum, or the harsh and rough voice of males about the period of puberty. 2. P. rauca, or hoarse, occasioned by dryness or swelling in the fauces. 3. P. raonans, or nasal tone, from obstructions of the narial. 4. P. palatinus, or the change of voice arising from a lefs or division of the uvula, or pendulous palate. 5. P. clangens, when the voice acquires a harsh, acute, and small sound. And, 6. P. comatus; when, from relaxation of the palate and glottis, a flertorious found is made during inspiration. Cullen, Nofol. Gen. 112.

PARAPHONIA, in Mafic, is that species of concord which results from different sounds, as the fifth and fourth, and thus it differs from homophonia, which is produced by the same sounds, as in the unison, and from antiphonia, or the repetition of the same sounds, as in the octave.

PARAPHRASE, a word used by the ancients to express a flight kind of delirium, or light-headedness in a fever: some have made it to signify a delirium in general.

PARAPHRASE, from παρά, and phrasis, an explanation of some text in clearer and more ample terms, whereby we supply what the author might have said or thought on the subject. See TEXT.

Colomeus looks on Erasmus's Paraphrase on the New Testament as an extraordinary work, that he makes so scruple to declare, he thinks the author to have been divinely inspired when he penned it.

PARAPHRASE, Chaldee, is a phrase frequent among the critics and divines, denoting an ancient version of the Bible, in Chaldee. There are three Chaldee paraphrases on the Pentateuch: that of Onkelos, whom some take to be the same with Aquila, and whom others take to have been Onkelos whom the Talmudists, in the treatise "Gittin," make a nephew of the emperor Titus. The second is the paraphrase of Jonathan. The third is called the Targum of Jerusalem. See TARGUM.

The Chaldee paraphrase on the prophets is that of Jonathan son of Uziel, whom some confound with Theodotius.

The author of the Chaldee paraphrase on the Hagiographers is unknown. Some attribute it to one Jophath, further named the Squinter; others to Rabbi Akiba. Others say there is so much difference in the style, that no one person can have been the author of the whole.

The paraphrase of Onkelos is that which is most esteemed by the modern Jews, and read in their Synagogues. See Walton Pref. Polyglott.

PARAPHRENITIS, from παρά, and φρένος, or the mind, signifies a deprived sound of the voice in speaking, and of course is not applicable to dumbness. Dr. Cullen makes six species of morbid voice, viz. 1. Paraphymosis puerorum, or the harsh and rough voice of males about the period of puberty. 2. P. rauca, or hoarse, occasioned by dryness or swelling in the fauces. 3. P. raonans, or nasal tone, from obstructions of the narial. 4. P. palatinus, or the change of voice arising from a lefs or division of the uvula, or pendulous palate. 5. P. clangens, when the voice acquires a harsh, acute, and small sound. And, 6. P. comatus; when, from relaxation of the palate and glottis, a flertorious found is made during inspiration. Cullen, Nofol. Gen. 112.

PARAPHRENITIS, in Medicine, sometimes written paraphrenes, is not derived, it would appear, from φρένος, mind, and therefore synonymous with phrenitis, or phreny, from φρένος προσεχεται; and it is synonymous with diphragnitis, which signifies an inflammation of the diaphragm. The disease, indeed, is described as accompanied by feverish delirium, but its seat is in the diaphragm, and consequently the pain and most distressing symptoms are referred to the precordia.

Authors who have described the paraphrenitis, have mentioned the symptoms attendant upon pleurisy, together with conflant delirium and a rufus fardanicius, or convulsive laughter, as characterizing the disease. They describe the respiration as exceedingly short and quick, being performed entirely by the motion of the ribs, the tender flate of the diaphragm not admitting of its motion, and therefore preventing the expansion of the cavity of the chest in that direction. They mention also other symptoms, indicative of the inflammatory foref Rem of the diaphragm, especially an extreme increase of the pain of the chest upon coughing, sneezing, reaching, vomiting, straining at stool, &c. See Boerhaave, Aphorism 900.

But there appears to have been some mistake, in referring such a fever, with delirium, and convulsive laughter, to an inflammation of the diaphragm: and every practitioner will now accord with the observance of Dr. Cullen, when he observes, (First Lines, par. cccclx.) "an inflammation of the pleura covering the upper surface of the diaphragm has been distinguished by the appellation of paraphrenitis, as supposed to be attended with the peculiar symptoms of delirium, rufus fardanicus, and other convulsive motions; but it is certain, that an inflammation of that portion of the pleura, affecting also the muscular substance of the diaphragm, has often taken place without any of these symptoms; and I have not met with either diphthongies, or any account of diphthongies, which support the opinion, that an inflammation of the pleura covering the diaphragm is attended with delirium more commonly than other pulmonary inflammations." The result of modern investigation of disease, by diphthong after death, is in fact demonstrative of the error of referring such a fever to inflammation of the diaphragm; and when it does occur, m it must be obviously ascribed to a morbid affection of the fenilatorium itself. See Fever and Pleurisy.

PARAPHRYSIS, or Attention of Mind, signifies, in the writings of some physicians, a flight and transitory derangement of the intellect, or non-fibrile delirium, especially the temporary delirium occasioned by intoxicating and narcotic substances, such as spirituous liquors, opium, stramonium, hyoscyamus, hemp or bang, nightshade, hemlock, the betel leaf, &c. &c. Sauvages Nofol. Meth. clasi viii. gen. 17.

PARAPHRASE, in Geography. See MADEIRA.

PARAPLEGIA, and PARAPLEXIA, from παρά, and πλήξ, signify, in the writings of the older authors, a palsy affecting the whole body below the neck. Dr. Cullen and the moderns confine it to a palsy, affecting half the body transversely, in contradistinction from the hemiplegia, which affects one side, or half the body longitudinally. See Palsy.

PARAPOTAMIA, in the Materia Medica of the Ancients, a word used at first as an epithet of distillation for a kind
kind of cænane, from which the cænalanise ointment of the
Greeks was made; but afterwards used simply as the name
of that plant. This kind of cænane was the most fragrant of
all the kinds, and was therefore used for making the
ointment preferably to the rest.
Theophrastus makes a very great difference in the cænane
of different places, observing that the Cyprian kind was
fragrant, and fit for making this sweet ointment; but that
the Grecian had no smell at all: and thence it probably
arose, that the Greeks used afterwards the flowers of the
wild vine for this purpose, and called them by the same
name.

Pliny's account of this ointment is by no means to be de-
depended upon. The whole passage where he names it, and
the others of the like kind, is taken from the account
of Apollodorus, in Athenæus; but it is so carelessly translated
by Pliny, that the author's sense can scarcely any where be
made out.

PARAPROSDOCIA, ἡ παραπρόσωπος, in Rhetoric, the
name with paradox. See Paradox.

PARARYTHMOS, an epithet used by the ancients to
express any kind of pulse, which did not seem suitable to the
age and state of the person.

PARASANG, παρασάγαν, or FARSAING, an ancient Per-
ian measure different at different times, and in different
places; being usually thirty, sometimes forty, and sometimes
fifty stadia or furlongs.
The word, according to Littleton, has its rise from parasch,
angarius, q. d. the space a pullman rides from one station,
angaria, to another.
Cafaubon cites a fragment of the architect Julian, who
says, that the most common measure of the parafang, in his
time, was forty stadia; and reckoning each stadium at one
hundred and twenty-five geometrical paces, they would hereby
avoid fractions in the computation of distances; forty
stadia, of one hundred and twenty-five paces each, making
two thousand Roman paces. The authors of the Universal
Dictionary, vol. ii. p. 19, fol. ascribe the introduction of this
measure to Keykobad, one of the Persian kings of the
second race, who employed his soldiers in making great roads
through the empire, setting up public marks at the end, as
they say, of every four thousand paces, which space was
called by the Persians, phefengis, and from thence by the
Greeks, parafang.

PARASAOLI, in Geography, a town of Hindostan,
in the circuit of Irunur; 15 miles N.N.E. of Jeypour.
N. lat. 27° 10'. E. long. 76° 48'.

PARASCENIUM, among the Romans, was a place be-
hind the theatre, where the actors withdrew to dress, und-
ders, &c. more frequently called ps phosphium.

PARASCAYE, παρασκαυα, the sixth day of the la-
ft week of Lent, popularly called Good Friday.
St. John says, our Saviour was crucified on the parafce of
the Passover, i. e. on the eve or day of preparation of the
Passover; for Hidore and Papius observe, that the word in
the original Greek signifies preparation, and was applied
among the Jews to Friday, because on that day they used to
prepare what was necessary for the celebration of the
fabbath. Exod. xv. 23. xxxv. 2, 3.

Hence, whatever our translation of the New Testament ren-
ders preparation of the Passover, M. Simon, and some others,
call parafceos.

PARASCHE, from ἄρα to divide, a name which the
Jews give to that portion of the Pentateuch which they read
every Sabbath. They divide their five books of the law, not
into chapters, as we do, but into fifty-four parts, which they
call parafceos: and thus go through the whole in a
year. To these they have added some verses of the pro-
phets, which they made use of under the perdition of
Antichus Epiphanes, when they were prohibited the use of
the law.

PARASCHIDES, a word used by chirurgical writers
to express the splinters of fractured bones, or the fragments
of bones corroded by sharp humours.

PARASEISMA, a fort of exercice prescribed by the
Greek physicians in many cases. It was a general concu-
ion of the, body.

PARASELENE, formed from παρα, near, and σέλη
moon, in Physiology, a mock moon: a meteor, or pheno-
menon encluding or adjacent to the moon, in form of a
luminous ring; in which are sometimes observed one, some-
times two apparent images of the moon.
The paraleknes are formed after the same manner as the
parhelia, or mock-suns, by reflections of the moon from
zones of dense vapours that happen to be collected in the
skies.

Pliny mentions three moons, which were seen in the year
of Rome 632. Eutropius also informs us, that he saw
three moons at Rimini, in the year 234 before Christ.
Helvius also saw three moons at Dantzie, in 1660. And
similar phenomena have been observed at different times, by
many others. These paraleknes have been seen, accompa-
nied with tails and coloured circles, like those which accom-
pany the parhelia. An account of several, and a particular
description of a fine appearance of this kind, may be found
in Muhchenbroeck's Introduction, p. 1046. See Halo and
Parhelium.

PARASEMUM, παρασεμον, among the ancients, a sign
painted or carved on the prow of ships, by which they were
distinguished from one another. The sign was com-
monly the figure or picture of some animal, as the bull, lion,
&c. or of any other thing, as a mountain, tree, flower, &c.

PARASIOPEISIS, παρασιοπεισις, in Rhetoric. See Pa-
ralepis.

PARASITE, παρασιτης, among the Greeks, was origi-
inally a very reputable title: the parasites being a kind of
priests, or at least ministers of the gods; in the same
manner, as at Rome were the epulones.
They took care of the fered corn; or the corn destined
for the service of the temples, and the gods; &c. They had
even the hintance over sacrifices, and took care that they were duly performed. At
Athens there was a kind of college of twelve parasites; each people of Attica furnishing one, who was always chosen out of one of the best families.

Polybius adds, that parasite was also an honourable name
among the ancient Gauls, and was given to their poets; but
of late it has been made a term of reproach, and used for a
flatterer and mean dependant.

PARASITE Plants, in Gardening, are all those which are
produced upon the trunks, branches, or any other parts of
other plants or roots: and which, in some instances, will
not take their growth in the ground, as in the cafes of
mistletoe, various mollies, and the fungus tribe in general,
but not always.

The particular manner in which these sorts of plants at-
tach themselves to thoe of other kinds is not by any means
confant or uniform. Some, such as the mistletoe, mollies, and
fungi, are produced originally upon the plants on which
they are found growing; the fritt of which grows upon
the branches of large trees, principally from the under fides
of them multiplying and extending its roots underneath the
bark; and its top branches or fprads out into a large head,
which, for the most part, grows downwards in a hanging
position,
position, being nourished wholly at the expense of the tree
or plant upon which it grows: the mosses, on the contrary,
are in general diffused all over the surfaces of the stems
and branches; and the fungi sometimes fix themselves upon
the upper roots of old trees, and at others upon their trunks
or stems.

There are other plants of this nature which arise from
the ground, and the stems of which fix on said attach them-
selves to the first plants which they meet with, or that come
in their way, into which they strike root, in consequence of
which the first or ground roots die, or as decayed, the
plants continuing to live and nourish themselves upon the
plants into which they have stricken, and in which they are
fixed.

And there are still other kinds of this sort of plants, which
first root in the ground, their stems attaching themselves to
the bodies of trees or other substances within their reach,
striking their roots into their barks, or other matters, as
they rise or grow upon them; but still continuing their
ground roots, and drawing their chief nourishment from the
earth. This is the case in the ivy kind of plants, and some
others of a similar nature and habit of growth.

Several of these plants are highly injurious and mis-
chievous to garden, fruit, and other trees, as the mistletoe
and mofs, to those of the apple kind; and the ivy, as
well as sometimes the fungulose, both to fruit and forest
trees. They should therefore be constantly removed from
them by the gardener as soon as they are perceived to have
fixed or established themselves on them.

This, in the first or mistletoe kind, should be done by cut-
ting away the top parts, and then completely destroying
the roots, while the plants are in an early state of growth. And,
in the mofe sorts, by means of rubbing and scraping them of
the trunks and branches in a complete manner by a
flint brush, or some other way, afterwards washing them
well with soot and water, then keeping the trees suffi-
ciently thinned out in their different parts.

The fungi about the roots of trees may be easily removed
and destroyed by any sort of flight digging of the ground
near them.

PARASITEUM, among the ancients, a granary or
place where the sacred corn, designed for religious purpofes,
was preserved. See Parasite.

PARASO, in Geography, a town of France, in the
department of Golo (or isle of Corfica,) and chief place of
a canton in the district of Calvi. The canton contains 2471
inhabitants.

PARASOL, a little moveable, in manner of a canopy,
borne in the hand to screen the head from the sun, rain, &c.
more usually called umbrella.

It is made of leather, taffety, oil-cloth, &c. mounted on a
stick, and opened or shut at pleasure, by means of pieces of
whalebone that fulfill it. The East Indians never fir-with
out a parasol.

The word is French; and that ufed against rains is some-
times called parapluie.

PARASOPIAS, in Ancient Geography, a country of
Greece, in Thessaly, between Aepus and Sparuchus, and
above Heraclia. Strabo.

PARASPHAGIS, a word ufed by some anatomical
writers to express that part of the neck which is contiguous
to the clavicles.

PARASTATA, in Ancient Architecture, a kind of pier,
or piliast, serving as a defence or support to a column
or arch.

Mr. Evelyn makes the parastata the fame with pilaftcr.

Barbaro, and others, the fame with anta; and Davier,
the fame with piliastcr. See Pilaster.

PARASTATE, in Anatomy. See Generation.

PARASTREMMMA, a name given by medical writers
to a convulsive dilatation of the mouth, or of any part of
the face.

PARASU RAMA, in Hindoo Mythology, is one of the
ten grand incarnations of their deity Vithuna. On this occa-
ion he was born the son of a pious Brahman named Ja-
madagni, and his wife Runeka. (See these articles.) This
incarnation or avatara is said to have taken place in Agra,
for the purpose of relieving mankind from a military go-
vernment, which has become insupportably oppreffive. Pa-
rafu Rama fought twenty battles with one of the superfi-
rious rajas, slew him, and extirpated the race. After a life
spent in mighty and holy deeds, Rama gave his whole
property in alms, and retired to the Kokan, or Concan, the
low country between Surat and the Southern Cape, though
not the whole extent of this land, (see Concan,) where the
Hindoos say he is still living. In pictures, this Rama
(for there are three of this name whose exploits form the
subject of the Ramayana, to which article, and to Rama,
the reader is referred,) is usually represented two-armed,
holding a battle axe and a lotus, combating his twenty-
armed foe Raja Diruj. The epithet parasu, diftinguishingly
prefixed to the name of this hero, means a sword, and
denotes his warlike character. Some authorities say that
Rama was educated by Siva, and going one day to pay his
repects on Kailafa, he was prevented from entering by
Ganefa, whom he knew not. Enraged at his insobience, he
wrenched a fecimeter from his hand, and cut of his head,
and was hence furnamed Parasu, the cutter-off. Ganefa is
a name of Pollcar. See the latter article.

PARETECA, in Geography, a town of Brazil, in the
Francisco; 240 miles W. of St. Salvador.

PARETTELA, a town of Hindooflan, in the cercar
of Condappily; 5 miles N. of Condappily.

PARETHENAR, in Anatomy, a name given by Win-
low to two muscles of the foot. His parthenar major is that
part of the abductor minimi digit, which arises from the
os calcis; the parathenar minor is the flexor brevis min-
imi digit.

PARETHESIS, in the Greek Church, the prayer which
the bishop reheafes over the catechumen, stretching his
hands over them to give them benediction; and which they
receive, bowing their heads under his hands.

Parethesis (popularly called brackets or crochets) is also
the name of a kind of point or mark, as [ ], ufed in writing,
chiefly to include synonyma, explicatives, and the like mat-
ters, not essential to the difcourfe. See Parenthesis.

PARETHESIS, in Grammar, opposition; or a figure whereby
two or more flultivates are put in the fame cafe.

PARETHREMA, from παράτρημα, and αφένειον, a joint,
in Surgery, a luxation, or dilocation. Also, a tumour caused
by a protrusion of parts; a rupture, or hernia.

PARETI, in Ichthyology, the name of a Brasillian fish
of the mulet kind, much reembling that species called cul-
rema, or tainira, in all respects but size, and in the colour of
its eyes, the iris of which, instead of the filver colour it
has in the cewma, is in fine yellow. Its flesh also, when
dried, is drier than that of the cewma, which fee.

PARETIANÆ, in Ancient Geography, a town of Africa,
in Mauritania Caxariensis, on the route from Lema to Hip-
pone, between Ruficades and Calucitena, according to the
Tin. of Antoneine.

PARETILMUS, in the Ancient Greek Jurisprudence,
a name
a name given to a sort of punishment imposed on adulterers, who were poor, and unable to stand the common penalty.

It consisted either in making them run a horse-raddle up the anus, which they called παραθύρωσις; or in tearing up by the roots the hair about the pudenda, which they called παραστερομετρήσας, to tear, pluck up.

PARATINGA, in Geography. See Xingou.

PARATITLES, PARAVAIL, in Jurisprudence, short notes, or summaries of the titles of the Digest and Code; which have been made by several lawyers, in order to compare and examine the connexion of the several parts with one another.

We have paraitiles of Cuias, of Maran, &c. Chaffiennes has a second comment on the paraitiles of Cuias.

PARATOLA, in Geography, a town of Bengal; 8 miles S.S.E. of Illamadab.

PARATOUNKA, an ostrog of Kametchatka, on a river which runs into the Avatcha; 10 miles W. of St. Peter and St. Paul.

PARAVAIL, PARAVAILLE, in Law, the lowest tenant of a fee; or he that is immediate tenant to the land.

He is called tenant paravail, because, it is prefixed, he hath profit and avail by the land. See TENANT.

PARAVANGAH, in Geography, two small islands near the coast of Bengal. N. lat. 22° 50'. E. long. 89° 35'.

PARAVANI, a town of Turkih Armenia; 50 miles S.-S.E. of Akalkizé.

PARAU'TE, a town of South America, in the province of Venezuela, on lake Maracaybo; 80 miles S. of Venezuela.

PARAWA, a town of India, on the route from Agra to Oujiin; 14½ miles N.W. from Suoouneer. The soil in its vicinity is black andpongy, like moat of Malava or Malva, but little cultivated. The district dependent on this town yields one lack of rupees annually. Asiat. Ref. vol. vi. p. 62.

PARAY-le-Moniat, a town of France, in the department of the Saone and Loire, and chief place of a canton, in the district of Charolles, near the river Bourbince; 6 miles W. of Charolles. The place contains 2848, and the canton 7258 inhabitants, on a territory of 2335 kilometres, in 12 communes. N. lat. 46° 27'. E. long. 4° 12'.

PARAZONIUM, παράζωνιον, or Scipia, among Medallas, a feepot rounded at the two ends in manner of a tube, or commander's flag; or a kind of poignard, or short sword, represented as worn at the girdle, on several ancient medals.

Antiquaries are much divided on the explanation of the parazonium; as, indeed, the form and manner of bearing it are very different. It is sometimes thrown across the shoulders in manner of a quiver.

PARBOILING, in Pharmacy, &c. a term applied to fruits, herbs, &c. which are boiled a little while, to draw out the first juices, in order to be afterwards infipitated or thickened. See Boiling.

PARBOSENA, in Ancient Geography, a town of Asia, in the environs of Cappadocia, upon the route from Tavia to Sebaste, between Sibora and Carnians, according to the Itinerary of Antonine.

PARBUCKLE, in Seamen's, a contrivance used by sailors as a substitute for a crane or tackle. It is formed by fastening the light of a rope to the place from whence the weight, such as a cask or bale, is to be raised or lowered; the two parts of the rope are then passed under the quarters of the cask, and bringing them back again over it, the ends of the rope are hauled upon to raise the weight, or gradually flackened together, and the cask or bale suffered to roll easily downwards to whatever may receive it below.

PARCE, so called, fays Servius, on the fourth eclogue of Virgil, by antithesis, because they spare nobody, quad runimi parant, goddefles who, according to the ancient Pagan theology, preside over the periods or durations of human lives. These the ancients frequently confounded with the Fates, or Deities; and, in effect, the Parce, according to Plato, were the daughters of Necessity and Deftiny. According to Hesiod, they were the daughters of Jupiter and Themis, by whom he had also the Seasons; but in another place he says, they were the offspring of Night and Erebus.

The Parce were three, Clotho, Lachesis, and Atropos; because, forsooth, all things have their beginning, progress, and end. Hence the poets tell us, the Parce spin the thread of men's lives; that Clotho held the distaff, and drew the thread; Lachesis twirled the spindle, and spun it; and Atropos cut it:

"Clotho column retention, Lachesis net, & Atropos osct."

The ancients represent the Parce divers ways: Lucian, in the shape of three poor old women, having large locks of wool, mixed with daffodils, on their heads; one of which holds a distaff, the other a wheel, and the third a pair of scissors, with which to cut off the thread of life. Others represent them ourselves; Clotho appearing in a long robe of divers colours, wearing a crown upon her head, adorned with seven stars, and holding the distaff in her hand; Lachesis in a robe befit with flars, with several spindles in her hand; and Atropos clad in black, cutting the thread with large scissors.

The ancients imagined, that the Parce used white wool for a long and happy life; and black for a short and unfortunate one.

Pausanias says, that these goddefles had some temples in Greece, and statues in several places. He informs us, that in the city of Olympia, there was an altar consecrated to Jupiter, the inventor of the Parce, near which these goddefles had another; and from the same author we learn, that among the other figures upon Cypselus's cchef, was to be seen that of a kind of monifier, with a wild and savage air, great tuffs, and crooked hands, which was known to be a Parce from an inscription upon it.

PARCAS, in Geography, a town of Walachia; 16 miles S. of Brancovani.

PARCAY, a town of France, in the department of the Mayne and Loire; 12 miles S.E. of Baugé.

PARCE', a town of France, in the department of the Sarthe; 6 miles E. of Sable.

PARCEL-MAKERS, two officers in the exchequer, who make parcels of the exchequer's accounts, wherein they charge them with every thing that they have levied for the king's use, within the time of their office, and deliver the same to one of the auditors of the court to make their accounts therewith.

PARCELS, Bill of. See BILL.

PARCELLING, RIGGING, in Ship Building, long narrow slips of canvas payed or dipt in loft tar, which are bound round the surface of ropes in spiral turns, as smoothly as possible, before it is served, that the rope may not be uneven, or full of ridges, and to further preserve it from the injuries of weather, &c.

PARCELLING a Seam, is laying a slip of canvas, prepared as above, over the seam, first paying under it, and then over it, with loft tar or melted pitch. This should be always per...
formed when seams are covered by the cheeks of the leads, &c. or, what is better, covered with sheet copper.

PARCELOR, in Geography, a mountain of Asia, on the coast of Salengore, near the straits of Malacca. N. lat. 2° 45'. E. long. 101° 29'.

PARCENERS, quasi Parcellers. See Co-parceners.

Parcellers are so called, says Littleton (§ 300.), because they may be constrained to make partition, of which there are several kinds. (See Partition.) The properties of parcellers are, in some respects, like those of joint-tenants (see that article); as they have the sameunities of interest, title, and possession. They may sue and be sued jointly for matters relating to their own lands (Co. Litt. 164); and the entry of one of them shall, in some cases, enure to the entry of them all. (Ibid. 188, 243.) They cannot have an action of trespass against each other; but herein they differ from joint-tenants, that they are also excluded from maintaining an action of wapal (2 Inst. 405); for co-parcellers could at all times put a stop to any wapal by writ of partition, but till the statute of Henry VIII. joint-tenants had no such power. Parcellers also differ materially from joint-tenants in other points. 1. They always claim by decent, whereas joint-tenants always claim by purchase. 2. There is no unity of time necessary to an estate in co-parcenary. 3. Parcellers, though they have an unity, have not entirety, of interest.

PARCHIM, in Geography, a town of the duchy of Mecklenburg, on the Elde, which divides it into New and Old Town, in each of which is a church. The number of inhabitants is about 3000; 34 miles S. of Wismar. N. lat. 53° 28'. E. long. 11° 55'.

PARCHMENT, in Commerce, &c. sheep or goats' skin prepared after a peculiar manner, which renders it proper for several uses; particularly for writing on, and for the covering of books, &c.

The word comes from the Latin Pergamentum, the ancient name of this manufacture; which it is said to have taken from the city of Pergamos, to Eumenes, king whereof, its invention is usually ascribed; though, in reality, that prince appears rather to have been the improver than the inventor of parchment. In the Persians of old, according to Diodorus, wrote all their records on skins; and the ancient Tonians, as we are told by Herodotus, made use of sheep-skins and goat-skins in writing, many ages before Eumenes's time. Nor need we doubt, that such skins were prepared and dressed for that purpose, after a manner not unlike that of our parchment, though, probably, not so artificially. Vide Diod. Sicul. lib. ii. p. 84. Herodot. lib. v. Prid. Connec. part i. lib. vii. p. 708.

Dr. Prideaux is a strenuous advocate for the antiquity of parchment; and he imagines that the authentic copy of the law which Hilkiah found in the Temple, and sent to king Josiah, was formed of this material; because no other used for writing, parchment excepted, could be so durable a nature as to last from the time of Moses till that period, for eight hundred and thirty years. But it has been replied to this argument, that the Egyptians wrote on linen those things which they defiled for long duration; and those who have examined mummies with attention, affirme us, that the characters so written continue to this day. It is not, therefore, improbable, that a copy of the law of Moses, written after this manner, might have lasted eight hundred and thirty years. Besides, it is not very likely that those skins which were used, according to the testimony of Diodorus and Herodotus, by the Persians and Romans for writing, long before the time of Eumenes, were dressed like parchment. They must have been prepared in a much ruder manner, and have little resembled the parchment, of which Eumenes is said to be the inventor; because, if it had been found out before, it would have rendered the want of the Egyptian papyrus no inconvenience to that prince. Such skins might do for records, and for some occasional writings, but would have been by no means proper for books. Hence some writers have concluded, that parchment was a later invention than the Egyptian paper.

Parchment constitutes a very considerable article in the French commerce; it is made in most of their cities; and, besides the consumption at home, they send vast quantities abroad, particularly to England, Flanders, Holland, Spain, and Portugal.

That called virgin parchment is somewhat thinner and finer than the rest; and is most proper for certain purposes, as fans, &c. and made of the skin of an abortive lamb, or kid.

PARCHMENT, Manufacture of. The skin having been tretched of its wool, and having puled the lime-pit (after the manner desribed under the article SHAMMY), the skinner stretches it on a kind of frame, confilling of four pieces of wood, mortified into each other at the four angles, and perforated lengthways from distance to distance, with holes furnished with wooden pins, that may be turned at pleasure, like those of a violin.

To stretch the skin on this frame, they make little holes all around it, and through every two holes draw a little fkewer; to this fkewer they tie a small piece of pack-thread, and tie that over the pins; so that coming to turn the pins equally the skin is strained tight every way, like that of a drum.

The fkin being thus sufficiently stretched on the frame, the flesh is pared off with a sharp instrument for that purpose; this done, it is moistened with a rag; and a kind of white flour, or chalk, reduced to a fine dust, is threw over it: then, with a large pumice-stone, flat at bottom, much after the manner of a mullet for grinding colours, they rub over the skin as if about to grind the chalk; and thus they scour off the remains of the flesh. Then they go over it again with the iron instrument; again moisten it as before, and again rub it with the pumice-stone without any chalk underneath; this softens and softens the flesh-side very considerably. They then drain it again, by passing over it, the iron instrument as before.

The flesh-side being thus drained, they pass the iron on the wool or hair-side; then stretch it tight on the frame, by means of the pins, and go over the flesh-side again with the iron; this finishes its draining; and the more the skin is drained, the whiter it always becomes.

They now throw on more chalk, sweeping it over with a piece of lamb-skin that has the wool on; this softens it still farther, and gives it a white down or nap. It is now left to dry, and when dried it is taken off the frame, by cutting it all round.

The skin, thus far prepared by the skinner, is taken out of his hands by the parchment-maker, who first ferapes or pares it dry on the summer with an iron instrument like that above-mentioned, only finer and sharper; with this, worked with the arm from top to bottom of the skin, he takes away about one-half of its thickness. The skin, thus equally pared on both sides, they pass the pumice-stone over both sides, to smooth it. This last preparation is performed on a kind of bench covered with a sack stuffed with books, and it leaves the parchment in a condition for writing on.

The paring of the skin dry on the summer is the most difficult preparation in the whole process of parchment-making; for which reason, the skinners seldom dare meddle with
with it, but usually leave it to those more experienced in it; the fummer, whereon it is performed, is a calf-skin well-stretched on a frame, serving as a support to the skin, which is softened a top of it with a wooden instrument, that has a notch cut in it. Lastly, that the iron knife may pass the cather between the fummer and the skin to be pared, they put another skin, which they call the counter-fummer. The parings, thus taken off the skin, are used in making glue, size, &c.

What we call vellum, is only parchment made of the skins of abortive calves, or, at least, of sucking calves; it is finer, whiter, and smoother, than the common parchment; but it is prepared in the same manner as that, except that it is not passed through the lime-pit.

Parchment, To make a green transparent. Wash the parchment in cold ley, till it come clear from it; then squeeze out the liquor as much as possible; and if you would have it of a fine green colour, take ditilled verdigris, ground with vinegar, and add a little sap-green to it; temper it neither too thick nor too thin; then soak your parchment in this colour thoroughly a whole night; rinse it afterwards in water, strain it immediately on a frame, and let it dry; take clear varnish, lay it on both sides, let it in the fun to dry; after this cut the parchment out of the frame into leaves, as large as you please, and lay them in a book under prefs, to keep them thin and straight. The effect of this parchment is to make a small letter, when put over it, appear as big again; and it is a great preferer of the eyes, especially to those that read much by candle-light. The varnish must be prepared of linseed-oil, and boiled with frankincense, mastic, and foxdara.

If you would have the parchment of a clear, transparent, and white colour, only wash, strain, and varnish it, as above. If you would colour it yellow, steep your parchment, after it has been washed, in a yellow liquid, made of saffron; for which purpose, tie saffron in a thin linen rag, hang it in a weak ley, and warm it over a slow fire; and when you see the ley tintured yellow, it is fit for use.

For a transparent red. — Take brazil, as much as you will, put it into a hot ley, which is clear, and not too strong, and it will tincture the ley of a fine red; then pour to it about half an egg-shell full of clean wine; draw the parchment through the colour; and when it is as deep as you would have it, strain it as before.

For a blue. — Take Lombard indigo, grind it with vinegar on a stone, and mix fal ammoniac among it, to the quantity of a pea; with this wet your parchment, and proceed as has been directed for the green.

For a violet or purple Colour. — Temper two-thirds of the above red, and one-third of the blue, and use it as before directed.

For a black Colour. — Take Roman alum, beat it into powder, and boil it in rain-water to a fourth part; add Roman vitriol, or strament, with some Roman galls, and boil them together: with this stain your parchment twice or three times over; and, when dry, lay the Spanish varnish over it.

N. B. With these transparent parchments you may make curious bindings. One fort, used at Rome, is made thus: lay the board or pasteboard over with leaf-gold, leaf-silver, flanial, metal-leaves, &c. then binding the parchment over it, it will give it an uncommon luster and beauty.

Dr Lewis informs us, that, in order to render the ink durable on parchment, a thick piece of it should be steeped in water, with some oak-bark, for three or four days, and then pressed smooth and dried. When the surface of this parchment was pared off, and the internal part written upon, the characters continued of a good black, while those made with the same ink, on unprepared parchment, were changed into a yellow-brown. Vellum may also be treated in the same manner.

It is said, that writing upon parchments decayed by time, may be recovered, and rendered legible, by dipping the obliterated parchment into a vessel of cold water, fresh drawn from the well; let it be taken out in about a minute, and prefixed between two papers, in order to prevent its crumbling up in drying. As soon as it is moderately dry, if it be not legible, repeat the operation two or three times.

PARCHMENT, Roll of. See Roll.

PARCHOUR, in Geography, a town of Hindooftan, in the cinema of Gunnor; 18 miles S. of Gunnoor.
PARCHWITZ, a town of Silisia, in the principality of Liegnitz, and capital of a prefecture, containing two Lutheran churches, and a Roman Catholic chapel, and also a manufacture of cloth; 10 miles N.E. of Liegnitz. N. lat. 51° 15'. E. long. 16° 20'.

PARCIEUX, Anthony de, in Biography, a French mathematician, and member of the Academy of Sciences, was born in the diocese of Uzes in 1703. He taught the mathematics at Paris with great reputation, and died there in 1768. His works are "A Treatise of Trigonometry," "Essays on the Probability of the Duration of Life," and Memoirs on the Practicability of bringing to Paris the Water of the River d'Yvette." Of the tables of M. Parcieux on the probability of life, great use has been made by the writers on the doctrine of annuities. He had a nephew of the same name, who was educated at the college of Navarre at Paris, where he studied mathematics and philosophy, and, at the age of 24, gave public lectures. In 1770 he began a course of experimental philosophy, in the military school of Brienne; after which, he occupied the philosophical professorship at the Lycee in Paris, where he died in 1798. He wrote an elementary book on Geometrical and Astronomical Calculations; and in his youth he is said to have composed a tragedy, entitled "Ozorio."

PARCO FRACTO, or Pound-breach, in Law, a writ which lies against him who violently breaks open a pound, and takes out beasts thence, which, for some trefpads done, were lawfully impounded. See Pound.

PARCOL, or PARCOUL, in Geography, a lake of Thibet; 25 miles in circumference. N. lat. 43° 22'. E. long. 92° 42'.

PARCO, a town of Peru, in the diocese of Guamanga; 25 miles N.E. of Guanavelica.

PARCOUS, a town of France, in the department of the Lower Charente; 12 miles E. of Montlial.

PARCOW, a town of Austrian Poland, in Galicia; 36 miles N.N.E. of Lublin.

PARDALIS, in Zoology. See Felis Pardalis.

PARDALUS, in Ornithology. See Tringa Squatarola.

Gen. Ch. Cal. none, unlefs the bractea be taken for fpathas. Cor. of one petal, superior, wheel-shaped, regular, divided to the base into five equal segments, spirally twistedit in decay. Stam. Filaments three, shorter than the corolla, inserted into the base of three of its segments, nearly straight, spreading; anthers oblong, vertical, somewhat approaching each
each other. Puff. German roundish: style thread-shaped, ascending, the length of the filaments; stigma three, spreading, dilated, involute, two-lipped. Peric. Capsule obovate-oblong, conicose, obscurely triangular, of three cells and three valves, the valves at length revolutioned. Seeds numerous, globose, pulpy, inserted in three double rows upon the edges of a triangular, central, unconnected receptacle.

Euf. Ch. Corolla regular, divided into six equal spreading segments. Capsule with many globose, pulpy seeds, inserted into a central, unconnected, triangular receptacle.

PARDON, in Roy, a remission or forgiveness of a felo-

nity or other offence, against the king, or the laws.

This, our lawyers make twofold: the one, ex gratia regis; the other, per cours de ley. The first is that which the king, out of some special regard to the person, or some other circumstance, grants, by his absolute prerogative or power, either before conviction of the offender, or after.

This power of pardoning is the most amiable prerogative of the crown. It was said by our Saxon ancestors, (L.L. Edw. Conf. c. 18.) to be derived "a lege fuz dignitatis;" and it is declared in parliament by statute 27 Hen. VIII. c. 24, that no other person hath power to pardon or remit any treason or felonies whatsoever: but that the king hath the whole and sole power thereof, united and knit to the imperial crown of this realm.

Judge Blackstone observes, that this is one of the great advantages of monarchy in general, above other form of government: that there is a magistrate, who has it in his power to extend mercy, wherever he thinks it is deferred; holding a court of equity in his own breast, to soften the rigour of the general laws, in such criminal cases as merit exemption from punishment. Some theories, however, maintain, that pardons should be excluded in a perfect legislation, where punishments are mild, but certain; because the clemency of the prince seems to be a tacit disapprobation of the laws. But the exclusion of pardons must necessaril introduce a very dangerous power in the judge or jury, that of confounding the criminal law by the spirit instead of the letter (see Bocaccia, ch. 4. and 46.); or else it must be held, what no man will seriously avow, that the situation and circumstances of the offender, though they alter not the essence of the crime, ought to make no distinction in the punishment. In democracies, however, this power of pardon can never subsist; for there nothing higher is acknowledged than the magistrate who administers the laws; and it would be impolitic for the power of judging and of pardoning to centre in one and the same person. This, as Montesquieu observes, (Sp. of Laws, book vi. c. 5. would oblige him very often to contradict himself, to make and unmake his decisions: it would tend to confound all ideas of right among the mass of the people; as they would find it difficult to tell, whether a prisoner were discharged by his innocence, or obtained a pardon through favour.

In monarchies, the king acts in a superior sphere; and though he regulates the whole government as the first mover, yet he does not appear in any of the disagreeable or invidious parts of it. Whenever the nation fees him personally engaged, it is only in works of legislation, magnificence, or compassion. To him, therefore, the people look up as the fountain merely of bounty and grace; and these repeated acts of goodness, proceeding immediately from himself, endear the sovereign to his subjects, and contribute more than any thing to root in their hearts that filial affection, and personal loyalty, which are the sure establishment of a prince. In the exercise of this prerogative, however, the sovereign should be directed by a sound diseretion and impartial judgment, and also by wise and upright coun-

fellors.
fellors; and the occasions for the exercise of it should be rendered as few and unfrequent as possible, by mitigating the severity of our criminal laws, and lessening their number, and making the penalties annexed to the violation of them more definite and certain.

A pardon may be pleaded in arrest of judgment; in which case it has the same advantage, as when pleaded upon arraignment, viz. the saving the attainder, and of course the corruption of blood, which nothing can restore but parliament, when a pardon is not pleaded till after sentence. And certainly, on all accounts, when a man hath obtained a pardon, he is in the right to plead it as soon as possible.

With regard to the object of pardon, judge Blackstone observes, that the king may pardon all offenses merely against the crown, or the public; excepting, 1. That, to preserve the liberty of the subject, the committing any man to prision out of the realm is, by the habeas corpus act, made a praemunire, unpardonable even by the king. Nor, 2. Can the king pardon, where private justice is principally concerned in the prosecution of offenders; therefore, in general, (except of all kinds, which are the fault not of the king, but of the party injured,) the prosecutor may refuse, but the king cannot pardon. (3 Inst. 237.) Neither can he pardon a common nuisance, while it remains unredressed, or so as to prevent an abatement of it; though afterwards he may remit the fine. (2 Hawk. P. C. 391.)

Neither, lastly, can the king pardon an offence against a popular or public statute, after information brought; for thereby the informer hath acquired a private property in his part of the penalty. (3 Inst. 238.) Nor, farther, can the king's pardon be pleaded to any parliamentary impeachment, or so as to impede the enquiry, and stop the prosecution of great and notorious offenders. It was enacted by the act of settlement (12 & 13 W. III. c. 2.), that no pardon under the great seal of England shall be pleaded to an impeachment by the commons in parliament. But after the impeachment has been solemnly heard and determined, it is not unfounded, that the king's royal grace is farther restrained and abridged.

As to the manner of pardoning, it must be under the great seal, and it is a general rule, that wherever it may be reasonably presumed the king is deceived, the pardon is void; so that any suppression of truth, or ignition of falsehood, in a charter of pardon, will vitiate the whole; for the king's signature must be innumerable. (3 Inst. 238.) Generally, words have also a very imperfect effect in pardons. A pardon of all felonies will not pardon a conviction or attainder of felony, but these must be particularly mentioned. (2 Hawk. P. C. 383.) Nor will a pardon of felonies include piracy, which is not punishable at the common law. (1 Hawk. P. C. 94.)

It is also enacted by 13 Ric. II. st. 2. c. 1. that no pardon for treason, murder, or rape, shall be allowed, unless the offence be particularly specified; and in murder it shall be expressed, whether it was committed by lying in wait, assault, or malice prencipe.

A pardon may be conditional, or the king may extend his mercy upon what terms he pleases. (2 Hawk. P. C. 394.) It may also be observed, that a pardon, by act of parliament, is more beneficial than by the king's charter; for a man is not bound to plead it, but the court must ex officio take notice of it (Inst. 43.) neither can he lose the benefit of it by his own laches or negligence, as he may of the king's charter or pardon. (2 Hawk. P. C. 397.)

The effect of such a pardon by the king, is to make the offender a new man; to acquit him of all corporal penalties and forfeitures annexed to that offence, for which he obtained pardon, and to give him a new credit and capacity. Blacklt. Com. book iv.

PARDON by course of Law, is that which the king grants as the law and equity persuades, for a flight offence; as homicide, casual, &c.

PARDON, Charter of. See Charter.

PARDON for discovering Accomplizes, &c. See Approver and Discovery of Accomplizes.

PARDON, in the Canon Law, is an indulgence which the pope grants to supphsed penitents, for remission of the pains of purgatory, which they have merited for the punishment of their sins.

The grand time for the dispensation of pardons is the jubilee.

In this sense, pardon is properly the angelic salutation, said to the Virgin at the found of three little strokes of a bell, rung in the morning, at noon, and night, in order for the person to be entitled to indulgences.

PARDONERS, in our Ancient Costumes, were persons who carried about the pope's indulgences, and fold them to the bell bidders.

PARDOS, or POMPENY, in Geography, a town of Africa, in the diocrit of Anta, on the Gold Coast.

PARDOUX, Sr., a town of France, in the department of the two Sevres; five miles S.S.W. of Partheny.

PARDOUX la Riviere, Sr., a town of France, in the department of the Dordogne, and chief place of a canton, in the diocrit of Nontron; four miles S.E. of Nontron.

The place contains 1273, and the canton 7860 inhabitants, on a territory of 217 § square kilometres, in seven communes.

PARDUBITZ, a town of Bohemia, in the circle of Chrudim, situated on the Elbe, well-built and fortified, in which is a manufacture of knives and sword-blades; five miles N. of Chrudim. N. lat. 49° 55'. E. long. 15° 40'.

PARDUS, in Zoology. See Felis Pardus.

PARDUS, in Conchology, a name given by authors to a kind of shells, of the genus of the volute. We have three kinds of this shell. 1. A voluta spotted with black. 2. Another spotted with yellow. And, 3. A very elegant one spotted with a reddish-colour. They are called pardis, or leopard-sheals, from their distinct spots resembling those on the skin of a leopard.

PARE', Ambrose, in Biography, a French surgeon of eminence, was born at Laval, in the diocrit of Maine, in the year 1509. He commenced the study of his profession early in life, and practised it with great zeal both in hospitals and in the army; in the latter he held an appointment, under the captain-general of infantry, in 1556. Subsequently his reputation rose very high, and he was appointed surgeon in ordinary to king Henry II. in 1552; and he held the same office under the succeeding kings, Francis II., Charles IX., and Hen. III. To Charles IX. especially he is said to have conferred great professional benefits, especially on one occasion, when some formidable symptoms had been produced by the accidental wound of a tendon in venalectia, which he speedily removed. His services appear to have been amply acknowledged by the king; for as Pari was a Huguenot, he would have been included in the horrible massacre of St. Bartholomew's, had not the king sent for him on the preceding night, and ordered him not to leave the royal chamber. After having been long esteemed as the first surgeon of his time, and beloved for his private virtues, he died in the year 1590, at the age of eighty-one.

Pare was not a man of learning, and was even obliged to request a physician to make a French translation of some of the books of Galen, which he wished to consult. NeverthelesS...
there is an affection of much learned reference, and numerous quotations from the ancients, in his writings, which have added nothing to his reputation. There is some justice in the remark of Van Hoorne, that Paré would have done better, if he had limited his publication to a small volume, containing only the records of his own observation and experience. He must be considered, however, as a man of original mind, and a real improver of his art; and as having greatly facilitated and extended the application of several principles of practice, which, according to his own acknowledgment, he derived from the Italian writers and practitioners. Though he did not invent, he greatly promoted the practice of cutting divided arteries, which he effected by drawing them out naked, and passing a ligature over them. He was the author of a great improvement in the treatment of gun-shot wounds, by adopting a lenient method, and rejecting irritants and cauterizations, which were employed by his contemporaries. He was also a bold and successful operator, and records many instructive cases, in which he displayed all the resources of an enlightened surgeon. He did not, however, greatly excel in anatomy, though he had practised dissections; and was chiefly a borrower from the works of Vesalius in this department of science, though not without some observations of his own.

Paré was the author of some works, which were universally read and translated into most of the languages of Europe. His first treatise, "Manière de traiter les plaies faites par harquebused, fleches, c. c." was published at Paris in 1545, and again in 1552 and 1564. He afterwards laboured strenuously to put his brethren in possession of a body of surgical science in their native tongue; and in 1561 published the first edition of his works, in folio. Numerous editions were afterwards printed at Paris and also at Lyons; and his pupil, Guillemeau, who was also surgeon to Charles IX. and Henry IV., translated these works into Latin. This translation has been frequently reprinted at various places, with the title of "Ambroli Paréi, Opera, novis iicombus elegantissimis illustrata, et Latinitate donata." This volume contains twenty-six treatises, and there is no branch of surgery which is not touched upon in the collection. Elyot Dict. Hist. Gen. Biog.

PARÉ, or PARÉZ, DAVID, a celebrated German Protestant divine of the reformed communion, was born at Francoflein, in Silesia, in the year 1548. He was put apprentice to a shoe-maker, but this situation did not repress the early inclination which the youth had discovered for learning, and at length his father permitted him to follow the bent of his inclination. At the age of sixteen years he was sent to Hirschberg, where was a college, of which Christopher Schilling was the principal. By his tutor he was converted from Lutheranism, in which he had been educated, to the principles of the reformed church, on the subject of the real presence, a circumstance that involved the matter and the pupil in considerable difficulties. In 1566 he was sent, with ten of his schoolfellows, to Heidelberg, and they carried with them such effectual recommendations from their college of Wiidom, of which Zachary Ursinus, prosector of divinity, was director. At Heidelberg, Paré made great proficiency in all the branches of learning taught in that place, and in 1571 he was admitted to the ministry, in which he officiated many years with great reputation. In 1598, he was nominated divinity professor of Heidelberg. He died in June 1622, and was buried with all the funeral honours which the universities of Germany are accustomed to bestow on their most distinguished members. He wrote several treatises against Bellamine; and commentaries on the scriptures. That on the epistle to the Romans, being translated into English, was burnt by order of James I. for containing seditious principles. He had a son, John Philip, who was born in 1576, at Hembach, in the diocese of Worms; and who studied at Neulandt and Heidelberg. In 1610 he was made rector of the college at Neulandt, where he continued till the town fell into the hands of the Spaniards in 1622, on which occasion his library was plundered. He died in 1670. He was author of "Lexicon Criticum?" "Lexicon Plautianum, or a Vocabulary to the Comedies of Plautus?" "Calligraphia Romana?" and other works. He left a son, Daniel, who published "Mellificium Atticum?" "Hitoria Palatina?" "Medulla Historiae Ecclesiasticae.

Paré, in the Blanq. To pare a horse's foot is to cut his nails; i.e. the horn and sole of his foot; which is done with a buttrifer in order to shoe him.

In England, the smith or farrier holds the horse's foot between his knees, in which position he pares the foot, sets on the shoe, drives the nails, and rivets them, and this all alone, without any assistance from the groom.

PARECULA, in Geography, a fertile province of the island of Lucon, rich in mines of gold and precious stones. The Spaniards receive tribute from about 7000 persons.

PARECABASIS, παρακατάσκοι, in Rhetoric, is used to signify the exaggeration of a crime, and not a digression from the question in hand, as some have thought.

PARECHAMPA, in Geography, a town of Bootsan; five miles N. of Taifaludon.

PARECHESIS, παραχεσία, in Rhetoric, the too frequent repetition of the same syllable, thus perire me multa mala morta.

PARECHIA, in Geography, a small town of the island of Paros, built on the ruins of the ancient Paros, on the W. coast of the island, facing Antiparos; but it presents no idea of the ancient city, unless by the beautiful ruins, which are employed equally without reverence and without taste in its construction. Of Parechia, the sea forms a bight, and a harbour, whose entrance is difficult, on account of the shoals by which it is obstructed on the opposite coast. N. lat. 35° 7'. E. long. 25° 10'.

PAREDES, a town of Spain, in Alfora; 25 miles N. W. of Oviedo.—Alfo, a town of Spain, in Leon; 13 miles N. W. of Leon.—Alfo, a town of Spain, in New Catalonia; eight miles N. of Siguenza.

PAREDES, a town of Portugal, in Estramadura; 12 miles N. W. of Ray.ia.

PAREDÓN del Eldío, a small island near the N. coast of Cuba. N. lat. 22° 16'. W. long. 77° 30'.

Paredon del Medio, a small island near the N. coast of Cuba. N. lat. 22° 16'. W. long. 77° 50'.

PAREDRI, the Athenians. When the archon, basilicus, or polemarchus, by reason of their youth happened not to be so well skilled in the laws and customs of their country as might have been wished, it was customary for each of them to make choice of two persons of age, gravity, and reputation, to sit with them upon the bench, and direct them as there was occasion. And these aiffessors, or paredri, were obliged to undergo the same probation in the senate-house and public forum with the other magistrates; and like them too, to give an account how they had behaved themselves in their respective trusts, when their office was expired.

PAREDRIA, a term used by Hippocrates to express an affection of two or more diseases in the same patient, making what we call, a complicated illness.

PAREGORIES, παραγραφικύς, formed of παράγομαι, ἰδιω-
proph, or mitigat], in Medicine, remedies which allay pain. The same with what we otherwise call anodynes and aborters.

PAREJA, Juan de, see ELENIKH PARGOURIMAS.

PAREIRA BRAVA, the root of a plant which is a species of Cissampelos, growing in the West Indies, chiefly in Mexico and Brazil; formerly esteemed a specific for the cure of the stone and gravel.

The name, which, in the original Portuguese, signifies wild wine, or bastard wine, bears a good deal of analogy to the plant which bears branches laden with leaves perfectly like those of the vine; and which, like them, creep along walls and trees. The Portuguese value this root on an equal footing with the ipecacuanha. Some druggists call it, by corruption, paraida prava.

This root has no remarkable smell, but to the taste it manifests a remarkable sweetness of the liquorice kind, together with a considerable bitterness, and a slight roughness covered by the sweet matter. It gives out great part both of the bitter and sweet substanee to watery and Spirituous medicines; in evaporating the watery decoction, a considerable quantity of resinous matter separates, which does not mingle with the remaining extract, nor dissolve in water, but is readily taken up by spirit; whence spirit appears to be the most perfect dis solvent of its active parts. Both the spirituous tincture and extract are in taste stronger than the watery.

The Portuguese were informed of the virtues of this root by the natives of the Brahis, who infused it in water, which they drank freely in all obstructions of the urinary passages; and on trial extolled it above all the medicines in use. According to Browne, it is still used with this intention by the negroes in Jamaica. Towards the end of the 17th century, some of these roots were brought over to Europe by the Portuguese, who recommended them to physicians as the most effectual remedy hitherto discovered in all calciuous and gravelly complaints, and various accounts of their efficacy were soon after published. The Portuguese accounts were too exaggerated to gain credit with the judicious part of the world; but Mr. Geoffroy's experiments set its virtues in a much modeller light, and yet shewed them to be very great; and that the root deferred to be ever continued in use in medicine, and reckoned among the most valuable simples. The Portuguese pretended that it dissolves the stone in the bladder; but though this is not true, Mr. Geoffroy found that it was admirable for breaking the common weaker fabulous concretions in the kidneys and ureters; and that the taking it was always attended with the voiding of large quantities of gravel. He gave it also with great success to persons afflicted with ulcers in the kidneys and bladder, and whose urine was purulent, and at many times totally suppurated; these suppurations of urine were always cured by it, and their urine became less thick and purulent; many also were perfectly cured of these complaints by a course of it, with the addition of balsam of capivi toward the end of the course.

This property of the pareira brava, of dissolving thick humours, gave Mr. Geoffroy an opinion of trying it in lumbarous affections; and these obliturate cates often were greatly abated, and sometimes perfectly cured by it. The usual way of taking it was in decoction, sweetening it in the manner of tea. Of the root in substanee he prescribed from twelve grains to half a dram, and in decoction or infusion, two or three drams; this quantity of the root bruised he directed to be boiled in a pint and a half of water, till only a pint remains, which is to be strained off, sweetened with a little sugar, divided into three portions, and drank as tea at intervals of half an hour. Mem. Acad. Par. 1710.

The facts alleged to evince the utility of the radix pareira brava in nephritic and calculous cases, were principally those of Geoffroy, Helvetius, and Lochner. It has also been recommended in iuduria, jaundice, asthma, and some other chronic diseases. The accounts given of the successful employment of this root by French writers induced physicians to try its effects in this country; but British practitioners have recorded no remarkable instances of its efficacy; and as a proof of its being funk into disrepute, it has no place in our pharmacopoeas. Lewis's Mat. Med. Woodville's Med. Bot.

The following is an instance of the parenthesis:

"Aecas (sequo enim patrius consiliiere mentem
Paffus amor) rapidum ad naves praeemitt Achatem."

See PARENTHESIS.

PARENCHELIS, a name given by some authors to the cerebellum.

PARENCHYMA, in Anatomy, is generally applied to the substanee of glands, and denotes that part of them, which constitutes the peculiarity of the organ, the basis, which would remain, if the vessels and nerves were removed. It is often used more generally, and in application to other parts, and signifies the arrangement of the general tissuess, which is common to all the body, and in which the peculiar matter producing the differences of the organs is deposited. See FIBRE.

PARENCHYMA of Plants. Dr. Grew gives the name parenchyma to the pith or pulp, or that inner part of a fruit or plant, through which the juice is supposed to be distributed.

This, when viewed with a microscope, appears to resemble marrow, or rather a sponge, being a porous, flexible, dilatable substance.

Its pores are innumerable, and exceedingly small; receiving as much humour as is requisite to fill and extend them; which disposition of pores it is, that is supposed to fit the plant for vegetation and growth.

The parenchyma of roots is white at first; but it changes its colour, in proportion as the root grows thicker. Thus
it becomes yellow in the root of the bastard rhubarb, and red in that of the bilwort.

PARENT, PARENTS, a term of relation, applicable to those from whom we immediately receive our being. See Father and Mother.

The duties of parents to legitimate children confit in three particulars: viz. their maintenance, their protection, and their education.

The first of these duties is a principle of natural law; its obligation refults from their having been voluntarily instrumental in giving them existence, which existence they should endeavour, as far as in them lies, to support and preserve. Children have, therefore, a perfect right of receiving maintenance from their parents. Montefiquien observes (Sp. of Laws, b. xxiii. c. 3.) that the establishment of marriage in all civilized states is founded on this natural obligation of the father to provide for his children; for that averts and makes known the person who is bound to fulfill this obligation. Moreover, the affection of parents to their children, which is so powerful to be totally suppressed or extinguished by any deformity of person or mind, or by the ingratitude, rebellion, and wickedness of children, and the provision which nature has prepared in the person of the mother for the sustentation of the infant, concerning the existence and defense of which there can be no doubt, are manifest indications of the divine will. We may hence infer the guilt of those, who run away from their families, and by mere idleness or drunkenness, throw them upon a parish, or leave them, at their death, destitute of that provision for their subsistence, which, by diligence and frugality, they might have laid up for them; and also of those, who refuse or neglect the care of their bastard offspring, abandoning them to a condition, in which they must either perish, or become burdenome to others; for, though it be often not properly regarded, the duty of maintenance, like the reason upon which it is founded, extends to ballards, as well as to legitimate children. The Christian scriptures have declared, in explicit terms, the obligation of this duty: "If any provide not for his own, especially for those of his own house, he hath denied the faith, and is worse than an infidel" (1 Tim. v. 8). that is, he hath disgraced the Christian profession, and fallen short in a duty which even inidels acknowledge. We may further observe, that the municipal laws of all well-regulated states have taken care to enforce this duty. The civil law (Fl. 25. 3. 5.) obliges the parent to provide maintenance for his child; and if he refuses, "judex decenae cognoscat." It even carries this matter so far, that it will not suffer a parent at his death totally to disinherit his child, without expressly giving his reason for so doing, and there are fourteen such reasons enumerated (Nov. 115), which may justify such disinherison. If the parent alleged no reason, or a bad, or a false one, the child might set the will aside, "tanquam sellamentum inofficium," a testament contrary to the natural duty of the parent.

It is also a principle of law, as well as of nature, that every man is obliged to provide for those defended from his own limits. By 43 Eliz. cap. 2. the father, mother, grandfather, and grand-mother of poor impotent persons, shall maintain them at their own charges, if of sufficient ability, according as the quarter-fees shall direct; and by 5 Geo. I. cap. 8. if a parent runs away, and leaves his children, the churchwardens and overseers of the parish shall seize his rents, goods, and chattels, and dispose of them towards their relief. But no person is bound to provide a maintenance for his issue, unless where the children are unable to work, through infancy, diseafe, or accident; and then is only obliged to find them with necessaries, the penalty on refusal being no more than 20s. a month. (See Laws.) Our law has made no provision to prevent the disinheriting of children by will; but by the custom of London, formerly universal, the children of freemen are entitled to one third of their father's effects, to be equally divided between them; of which he cannot deprive them. Further, a parent, by our laws, may protect his children by supporting them in their law-suits, without being guilty of the legal crime of maintaining quarrels (2 Inst. 564.); and a man may justify assault and battery in defense of the persons of his children. (1 Hawk. P. C. 131.) With regard to the education of children, parents are bound to perform this part of their duty in a manner suitable to their station in life. This is a duty obviously reasonable, and unquestionably important. If this duty be not discharged with proper attention and fidelity, children must be miserable, and probably will be vicious, when they grow up, either from want of the means of subsistence, or from want of rational and inoffensive occupation. Besides, a person left in this condition will be useless, and at the same time he will be generally mischiefous to the community. So that to launch an uneducated child into the world, is injurious to the rest of mankind; it is little better than to turn out a mad dog, or a wild beast into the streets. In the inferior classes of the community, this kind of reasoning condemns the neglect of parents, who do not betimes inure their children to labour and restraint, and fit them, as they have ability and opportunity, for some honest employment, by which they may be preferred from beggary, vice, and infamy. The municipal laws of most countries seem to be defective in this point, by not constraining the parent to belowe a proper education upon his children. The charity of the well-disposed has provided sufficiency for those parents, whose lot is so hard, that they cannot by labour provide for their children the means both of subsistence and education; and although our laws are defective, yet in one instance, they have made a wise provision for breeding up the rising generation; since by the statutes for apprenticing poor children, such children may be apprenticed out by the overseer, &c. (See Apprentices.) And, in the case of religion, all parents are under peculiar restrictions.

Among the Athenians, if the parent did not put his child into a way of getting a livelihood, the child was not bound to make provision for the parent when old and necessitous. In the middle orders of society, those parents are most reprehensible, who neither qualify their children for a profession, nor enable them to live without one; and those in the highest, who, from indolence, indulgence, or avarice, omit to procure for their children those liberal attainments, which are necessary to make them useful in the stations to which they are destined. A man of fortune, who permits his son to confume the feafon of education, in hunting, hunting, or frequenting horse-rcases, assemblies, or other unedifying, if not vicious diversions, defrauds the community of a benefactor, and bequeaths them a nuisance. As some preparation for future life is necessary for youth of every description, those who leave the education of their ballards to chance, contenting themselves with making provision for their subsistence, defert half their duty. Archdeacon Pely observes, that a reasonable provision for the happiness of a child in respect of outward condition, requires three things; a situation suited to his habits and reasonable expectations; a competent provision for the exigencies of that situation; and a probable security for his virtue. The two first articles will vary with the condition of the parent. A situation somewhat approaching in rank and condition to the parent's own; or, if that be not practicable,
ble, similar to what other parents of like condition provide for their children, bounds the reasonable, as well as (generally speaking) the actual expectations of the child, and therefore contains the extent of the parent's obligation. By virtue of this rule, a parent is justified in making a difference between his children, according as they stand in greater or less need of the assistance of his fortune, in consequence of the difference of their age or sex, or of the situations in which they are placed, or the various success which they have met with. Daughters, on account of their peculiar circumstance, which it is needless to specify, should be the particular objects of a parent's care and foresight; and as an option of marriage is not precluded to every female who defers it, especially in a country at a period of time in which a licentious celibacy is fashionable with the men, a father should endeavour to enable his daughter to lead a single life with independency and decorum, even though he subtract more from the portions of his sons, than is agreeable to modern usage, or than they expect. A parent, having provided for the exigencies of his children's conditions, next considers how to satisfy their just expectations; and upon this principle he prefers the eldest son to the rest, and the sons to daughters; which constitutes the right, and the whole right of primogeniture, as well as the only reasons for the preference of one sex to the other. The preference of the first born, indeed, has one public good effect: that if the estate were divided equally among the sons, it would probably make them all idle; whereas, by the present rule of descent, it makes only one fit; which is the less evil of the two. And on the part of sons it may be observed, that if the rest of the community make it a rule to prefer sons to daughters, an individual of that community ought to guide himself by the same rule, upon principles of mere equity. For as the son suffers by the rule in fortune he may expect in marriage, it is but reasonable, that he should receive the advantage of it in his own inheritance. Indeed, whatever the rule be, as to the preference of one sex to the other, marriage restores the equality. And as money is generally more convertible to profit, and more likely to promote industry in the hands of men than of women, the custom of this country may properly be complied with, when it does not interfere with the very plain reason already explained. The actual expectations of children, together with the expediency of subjecting the illicit commerce of the sexes to every discouragement which it can receive, makes the difference between the claims of legitimate children and of bastards. But neither reason will, in any case, justify the leaving of bastards to the world, without provision, education, or profession; or, what is more cruel, without the means of continuing in the situation to which the parent has introduced them; which last is to leave them to inevitable misery.

After the exigencies of a child's situation are provided for, a parent may diminish his portion, in order to punish any flagrant crime, or to punish contumacy and want of filial duty in instances not otherwise criminal; for a child who is conscious of bad behaviour, or of contempt or his parent's will and happiness, cannot reasonably expect the same indulgences of his misconduct. In case of vicious habits that are incorrigible, or of such a disposition to waste or misemploy the fortune put into his power, as if he were made an idiot, the parent may treat the child as such; and provide for his support by an annuity equal to his wants and innocent enjoyments, and which he may be restrained from alienating; and this, says Dr. Paley, is the only case in which a disinherit, nearly absolute, is justifiable. But in order to justify an inofficious disposition of his fortune, no parent should be allowed to plead, that "every man may do what he will with his own." For though his will, in this case, however capricious, will be valid; yet his conscience will not be absolved from the obligations of a parent. Nor, on the other hand, when he sits down to make his will, should any partialities for a favourite child over-rule and mislead more many deliberations. When a parent, in order to make suitable provision for his children by frugality and industry, has gained a sufficiency for this purpose, the plea of children furnishes no just excuse for parsimony. A parent should consider, that children gain not so much as we are apt to imagine, in the chance of this world's happiness, or even of its external prosperity, by getting it in it with large capitals. With respect to those who have died rich, many began with little; and with regard to enjoyment, there is no comparison between a fortune, which a man acquires himself by a fruitful industry, or a series of successes in his business, and one found in his possession, or received from another. It remains to mention another principal part of a parent's duty, which is that of using proper precautions and expedients, in order to foresee and preserve his children's virtue. But this is a subject which is amply discussed under the several articles of Education.

The rights of parents result from their duties; and the authority with which they are invested, is given them, partly to enable them more effectually to perform these duties, and partly as a recompense for their care and trouble in the faithful discharge of them. The relation between a parent and his children infers no property in their persons, or natural dominion over them.

By the ancient Roman laws, the father had a power of life and death over his children; but the rigor of these laws was softened by subsequent constitutions. By our English laws, parental authority is much more moderate, but still sufficient to maintain order and obedience. A parent may lawfully correct his child, being under age, in a reasonable manner. The consent or concurrence of the parent to the marriage of his child under age was also directed by our ancient law to be obtained; but now it is absolutely necessary, and without it the contract is void. A father has no other power over his son's estate than as a trustee or guardian; for though he may receive the profits during the child's minority, yet he must account for them when he comes of age. He may, indeed, have the benefit of his children's labour while they live with him, and are maintained by him: but this is no more than he is intitled to from his apprentices or servants. Moreover, the legal power of a father (for a mother, as such, is entitled to no power, but only to reverence and respect) over the persons of his children ceases at the age of twenty-one. Yet, till that age arrives, this empire of the father continues even after his death; for he may by his will appoint a guardian to his children. He may also delegate part of his authority, during his life, to tutors and school-masters.

As it is necessary to determine the delination of children, before they are capable of judging of their own happiness, parents have a right to elect professions for them: Parents, having no natural dominion over their children, or property in their persons, have no right to sell them into slavery. Accordingly, the children of slaves are not, by the law of nature, born slaves; for as the master's right is derived to him through the parent, it can never be greater than the parent's own. Parents not only pervert, but exceed their just authority, when they consult their own ambition, interest, or prejudice, at the manifest expense of their children's happiness. Many instances might be mentioned of this abuse of parental power;
Great I. Geography, (hort view a the and be of See 3J facrifice his See a manufcript His verfe, dif-
Paley's Prius of Moral and Political Philosophy, vol. i. ch. 9 and 10. See Child.

Parent, Anthony, in Biography, was born at Paris in the year 1665. Great care was taken of his education, and at a very early period he discovered a strong propensity to the study of mathematics. At the age of fourteen, he accidentally met with a dodecahedron, upon every face of which was delineated a sun-dial, excepting the lowest, upon which it stood. Struck with the curiosity of these dials, he attempted to imitate them, and was led from the practice to investigate the theory, and in a short time he wrote a treatise upon "Gnomonics," which, though said to be extremely rude and unpolished, had the merit of being his own invention, as was a work on "Geometry," which he wrote about the same time. At the earnest desire of his relations, he entered upon the study of the law, as a profession for his life, but he no sooner completed his studies in that faculty, than he betook himself, with increased ardor, to those pursuits which accorded best with his genius and inclination. He attended very diligently the lectures of M. de la Hire and M. Sauvage, and as soon as he felt himself capable of teaching others, he took pupils; and fortification being a branch of study which the war had brought into particular notice, he was called upon frequently to teach the principles of that science. After some time, he began to entertain speculations about undertaking to teach a subject of which he had no practical knowledge, and communicated them to Sauvage, through whose interest he made two campaigns with the marquis d'Alegre, during which he had many opportunities to inform himself with respect to every species of knowledge on the subject. Upon his return to the metropolis, he spent his time in a continual application to the study of natural philosophy, and all the branches of the mathematics, both speculative and practical, to which he added that of anatomy, botany, and chemistry. His great talents, and indefatigable industry, enabled him to surmount the difficulties attendant on the acquisition of any science. In 1699, M. Fillau des Billettes having been admitted a member of the Academy of Sciences at Paris, with the title of their academican, nominated M. Parent for his eleve, who particularly excelled in that branch of knowledge. It was soon discovered that he directed his attention to all the subjects that came before the academy, and that he was competent to the investigation of every topic which was recommended to their notice. His temper was however very bad, and he exposed himself to many disputes, which he carried on in a very acrimonious manner, and which was the cause, together with the want of perspicuity in his compositions, of the very limited circulation of his various pieces. In the year 1710, the king abdicated the class of eleves, and on this occasion he made M. Parent an adjutant, or affiliated member of the class of geometry. He lived, however, but a short time to enjoy the honour, being in the same year cut off by the small-pxox, when he was about fifty years of age. Although he was of a very irritable disposition, he is said to have possessed great good-natured heart, and though his means were extremely limited, he devoted much of his income to acts of beneficence. He was author of a work entitled "Elements of Mechanics and Natural Philosophy; " "Mathematical and Physical Researches," a sort of journal, which first appeared in 1705, and which in 1712 was greatly enlarged, and published in three vols. 4to; and "A Treatise on Arithmetic." Besides these, he was author of a great number of papers in the different French "Journals," and in the volumes of the "Memoirs of the Academy of Sciences," from the year 1760 to 1714, and he left behind him in manuscript many works of considerable research; among these were some complete treatises on diverse branches of mathematics, and a work containing proofs of the divinity of Jesus Christ, in four parts. Moreri.

Parent, in Geography, a town of Prussia, in Pomorania: 10 miles N. of Marienburg.

Parentalia, in Antiquity, funeral obsequies: or the last duties paid by children to their deceased parents.

Parentela, also used for a sacrifice or solemn service offered annually to the manes of the dead.

Parentela—Dr. parentela se tolere, in Ancient Customs, signified a renunciation of one's kindred and family.

This was done in open court, before the judge, and in the presence of twelve men, who made oath, they believed it was done for a just cause.

We read of it in the laws of Henry I. After such abjuration, the person was incapable of inheriting anything from any of his relations, &c.

Parenthesis, parenthesis, formed of parenthesis, inter, between, and others, position, q. d. putting between, in Grammar, intercalary words interret in a discourse, which interrupt the sense or thread, but which seem necessary for the fuller understanding of the subject. The politef of our modern writers avoid all parentheticals, as keeping the mind in suspense, embarrasing it, and rendering the discourse less clear, uniform, and agreeable. Long and frequent parentheticals are intolerable, especially in verse, which they ever render dull and languid, and like to profe.

The proper characteristic of a parenthesis is, that it may be either taken in, or left out, the enfe and grammar remaining entire.

In speaking, parentheticals are to be pronounced in a different tone; and in writing they are included between brackets, ( ), to distinguish them from the rest of the discourse.

The character itself, whereby they are distinguished, is also called a parenthesis. See Parembole.

Parentis-de-Born, in Geography, a town of France, in the department of the Landes, and chief place of a canton, in the district of Mont-de-Marlan; 33 miles N. of Tarcas. The place contains 1440, and the canton 4213 inhabitants, on a territory of 6324 kilometres, in four communes.

Parenza, a sea-port town of Ifria, and fee of a bishop. The town is well built on a rock, and has a harbour for large vessels; 35 miles S. of Triage. N. lat. 45° 18'. E. long. 13° 40'.

Pareola, in Ornithology, a species of Pipra; which see.

Parer, in the Meige, a term formerly used as a command to flop, but now exploded; all the riding-masters, when they have a mind the scholar should flop the horse, calling out hola. See Stop.

Parere, in Commerce, an Italian term, which signifies the advice or counsel of a merchant, or negociant; because such a person, being consulted on any point, introduces his answer, in Italian, with mi pare, i.e. I think, it forms to me. The method of negociating, especially that of bills of exchange, being borrowed from the Italians, most trading cities, especially Lyons, retain the use of pareer; which are...
are the advice or opinions of merchants and negociants, and which serve as acts before notaries, when given by authority of a judge conservator, or at a particular consultation, for maintaining the right of the consuls.

M. Savary has a Collection of scarce and important works of the most difficult questions relating to bankruptcies in trade, bills of exchange, orders without date, and expirations of value, bank-linings, renewing of bills of exchange, tho' drawn or accepted by women in behalf of their husbands, or during the minority of the drawer, &c.

**PARGA**, a term sometimes used in architecture, for facades, or appendages, made by way of ornament to a principal work. It is sometimes also used in painting, for little pieces, or compartments, on the sides, or in the corners, of the principal pieces.

**PARES CURTIS**, or *Pares Curie*, peers of the court, an appellation which, in all the feudal institutions, both here and on the continent, distinguished the vassals of the inferior lords, who were bound by their fealty to attend their domestic courts baron (which were instituted in every manor, or barony, for doing speedy and effectual justice to all the tenants), in order as well to answer such complaints as might be alleged against themselves, as to form a jury or homage for the trial of their fellow tenants.

**PARESIS**, from *pargyia*, to relax, in Surgery, a palsy of the bladder, attended either with retention of the urine, or involuntary discharge of it.

**PARESEUX**, in Zoology, a name given by Gautier to the *Bradyus tridentatus*; which fee.

**PARENTION**, in Natural History, the name of an earth, chiefly found on the shores of Egypt, Cyrene, and the island of Crete, and used by the ancients in painting. It had its name either from a part of Egypt, near which it was gathered, or from the name of a town in that kingdom, where it was usually found.

**Vitruvius** is of the first opinion, and Volaternus of the other. Of late we have been taught to think it lost; but it is still common on most of the shores of the islands of the Archipelago, though not observed or regarded; and is truly a very heavy and tough clay, of a fine white colour, found in masses of different sizes, generally as soft as the softer clays within the strata; and, by rolling about on the beach in this state, it gathers up the sand, small shells, and other foulnesses we always find about it. It is most probable, that there are strata of it fine and pure in the cliffs; and that the sea washes off masses of them in storms and high tides, which are what we find.

**PAREWAH**, in Geography, a town of Hindooftan, in Oude; 8 miles N. of Bahrairacht.

**PARGAS**, in Geography, a small island in the gulf of Finland, near the coast of Sweden, with a town. N. lat. 60° 19' E. long. 22° 7'.

**PARGET**, in Natural History, a name given to the several kinds of gypsum or plaster-flour, which, when slightly calcined, make what is called *plaster of Paris*, used in casting statues, in flockcoings floors and ceilings, and on many other like occasions.

The word parget, though generally understood of all the gypsums, is, however, by the workman principally applied to the two species which make up the first genus of that class, called by Dr. Hill *phulos*. These are the Montmartre kind, and that of Verfhyre. See Pholis.

**PARGETING**, in Building, is used for the plattiering of walls; sometimes for the plaster itself.

Pargeting is of various kinds: 1. White lime and hair mortar laid on bare walls. 2. On bare laths, as in partitioning, and plain railing. 3. Rendering the inside of walls, or double partition-walls. 4. Rough-casting on hearth-laths. 5. Plattering on brick-work, with finishing mortar, in imitation of stone-work; and the like upon hearth-laths. 6. Rendering the surface of brick or stone, as in the building of fireplaces, &c.

**PARGOIRE**, St., in Geography, a town of France, in the department of the Herault; 14 miles S. E. of Lodove.

**PARROW**, a town of Hindooftan, in the circur of Gohud; 9 miles S. W. of Kooch.

**PARHAM**, a town of the island of Antigua, and legal port of entry; 5 miles W. of St. John's.

**PARHELION**, or *Parhelion*, formed from *parhelion*, near, and *helion*, sun, in Physics, a mock sun or meteor, being a part of the heavens strongly illuminated by the image of the sun, and appearing like another sun, but often coloured and drawn out to a considerable length, in the form of a tail.

The parhelions usually accompany the coronas, or luminous circles, and are placed in the same circumference, and at the fame height. Their colours resemble those of the rainbow; the red and yellow are on the side towards the sun, and the blue and violet on the other. Though there are coronas sometimes seen entire, without any parhelion; and sometimes parhelion without corona.

The apparent size of parhelion is the same as that of the true sun; but they are not always round, nor always of bright as the sun; and when several appear, some are more bright than others. They are tinged externally with colours like the rainbow, and many of them have a long fiery tail opposite to the sun, but paler towards the extremity. Some parhelions have been observed with two, and others with three tails. These tails appear for the most part in a white horizontal circle, which generally passes through all the parhelions; and if it were entire, would go through the centre of the sun. Sometimes there are arcs of lesser circles, concentric to this, touching those coloured circles which surround the sun. They are also tinged with colours, and contain other parhelions. Parhelions are generally situated in the interections of circles; but Callini says, that those which he saw in 1653, were on the outside of the coloured circle, though the tails were in the circle that was parallel to the horizon. M. Epton apprehends, that parhelions with elliptical coronae are more frequent in the northern regions, and those with circular ones in the southern. They have been visible for one, two, three, and four hours together; and in North America they are said to continue some days, and to be visible from one-aft to sun-set. When the parhelion disappears, it sometimes rains, or there falls snow in the form of oblong spicules, as Malardé, Weidler, Kraft, and others, have observed; and because the air in North America abounds with such frozen spicules, which are even visible to the eye, according to Ellis and Middleton, such particles have been thought to be the cause of all coronae and parhelions.

Parhelions are sometimes double, triple, &c.

Arrildtze observes, that two were seen in Bosphorus from morning to evening, though, in general, he observes, they are not seen, except when the sun is near the horizon.

Pley}
Pliny relates under what confus this phenomenon was ever
seen at Rome.
In the year 1629, was seen at Rome, by Scheiner, a
parhelion of four funs, and the fame number was seen by
M. Mutchenbroek at Utrecht; Gaffendi says, that in 1635
and 1636, he often saw one mock fun; in 1661, Hevelius
observed at Danzig one of seven funs; and in 1666, another
was seen at Arles, of fix.
Phenomena of this kind have also been observed by M.
de la Hire at Paris, in 1689, and by M. Cuffini, in 1693;
by Mr. Grey, in 1700; by Halley, in 1702; and Maraldi,
in 1721.
The Roman phenomenon observed by Scheiner, is re-
presented Plate XVII. Optics, fig. 8, in which A is the
place of the observer, B his zenith, C the true fun, A B a
plane paffing through the obferver's eye, the true fun,
and the zenith. About the fun C, there appeared two
concentric rings, not complete, but diversified with colours.
The leifer of them, D E F, was fuller, and more perfect;
and though it was open from D to F, yet thofe ends were
perpetually endeavouring to unite, and sometimes they did
fo. The outer of thefe rings was much fainter, fo as
dareably to be difcernable. It had, however, a variety of
colours, but was very inconstant. The third circle,
K L M N, was very large, and all over white paffing through,
the middle of the fun, and every where parallel to the
horizon. At firft this circle was entire; but towards the
end of the appearance it was weak and ragged, fo as
hardly to be perceived from M towards N.
In the intercefion of this circle, and the outward iris
G K I, there broke out two parhelion, or mock funs, N and
K, not quite perfect; K being rather weak, but N fome
brighter and ftronger. The brightnefs of the middle of
them was something like that of the fun, but towards the
edges they were tinged with colours, like thofe of the
rainbow, and they were uneven and ragged. The parhelion
N was a little wavering, and fent out a spiked tail N P, of a
colour somewhat fiery, the length of which was continually
changing.
The parhelion at L and M, in the horizontal ring, were
not fo bright as the former, but were rounder, and white,
like the circle in which they were placed. The parhelion
N disappeared before K; and while M grew fainter, K
grew brighter, and vanifhed the laft of all.
It is to be observed, farther, that the orders of the colours
in the circles D E F, G K N, was the fame as in the
common halos, namely, red next the fun; and the diameter
of the inner circle was alfo about 45 degrees; which is the
ufual fize of a halo.
Aristotle (Meteor. cap. 3.) was of opinion, that rainbows,
halos, and mock funs, were all occasioned by the refleffion
of the fun beams in different circumftances, by which an
imperfect image of his body was produced, the colour only
being exhibited, and not his proper figure. The image,
he fays, is not fingle, as in a mirror; for each drop of rain
is too fmall to reflefl a visible image; but the conjunction
of all the images is visible.
M. Mariotte accounts for the appearance of parhelion from
an infinity of little particles of ice floating in the air, which
multiply the image of the fun, either by refracting or break-
ing his rays, and thus making him appear where he is not;
or by reflecting them, and ferving as mirrors.
The known laws of refleflion and refraction have given a
handle for geometrizing on these phenomena; and M.
Mariotte has determined the precise figure of the little icles,
and their fipation in the air, the fize of the corones, or cir-
cles, which accompany the parhelion, and the colours with
which they are painted, by a geometrical calculus.
The hypothesis of DeCaries, to account for this hori-
Zontal circle in which mock funs appear, has less pro-
ability than any of his conjectures. He fuppofes that a
great quantity of frozen vapours, crowded together by
contrary winds, form a prodigious cylinder, which refleffes
the light that falls from it on all sides, fo as to exhibit that
lucid appearance in all the surrounding clouds. M. Huy-
gen, on applying his attention to these appearances, was
foon fenfible that they could not arise from fuch globules
as formed the halos; yet fince parhelion are always attended
with halos, he was fatisfied that their caufes muft be much
alike. Confering, then, what other figures hall-foines
might possibly have, besides a fpherical one, he could find
no other fo fimple as that of a cylinder; and, indeed, he
had often obferved, that funow did confift of feveral fnder
oblong particles, mixed with thofe of other fapes; and
feeing that small globules were fufficient for the production
of halos, he imagined that a great number of fmall cylinders,
floting in the air, might produce similar appearances. He
also remembered that Defcartes had taken notice of certain
small columns, or cylinders, which he had feen lying on the
ground, the extremities of which were bounded with flat
flars, confifting of fix rays or points.
The large and white horifontal circle, in the Roman
phenomenon, M. Huygens fuppofed to be produced by the
reflection of the fun's rays from the outides of the up-
right cylinders, which, when the fun fhines upon a great
number of fuch cylinders, fuspended in the air, a white
circle mult neceflarily appear to pass through the fun, pa-
rallel to the horizon, and of the fame breadth with that of
the fun. This he fhes very diftinflly by a large figure of a
cylinder, and by pointing out the progress of the fun's
rays refleffed from it. For every point of the fun's ver-
tical diameter, as well as his centre, will illuminate a circle
of cylinders, of the fame apparent height as the illuminating
point. It is obfervable that no thick clouds are feen in the
air when these circles appear, but only fuch as are very thin,
and feafably visible. For in moft of these obfervations the
sky is faid to have been very clear and fereine, which very
well agrees with this hypofethis; fince thofe minute cylinders
must confitute a very thin cloud, uniformly extended;
through which the fun, and even the blue colour of the sky,
may be feen.
M. Huygens fuppofes that the parhelion at K and N,
(fig. 8.) are produced by the fame upright cylinders which
produce the great white circle; but not in the fame manner
as that was caufed, viz. by simple reflection, but by means
of two refraffions, exactly in the fame manner as halos are
produced; the centre of the cylinder being funow, and the
outer part ice. The interval between thofe parhelia, he
fays, will be greater, as the cylinder of funow is thicker in
proportion to the whole cylinder; and becaufe the fun
appears brightefh through thofe cylinders which are on the
outfides of the arch K N; and as this brightnefs decays
gradually to a certain distance, it exhibits the appearance
of a parhelion, with a tail always tending towards the white
circle, and making it brighter as far as it extends. The
tail N P, of the parhelion at N, is drawn out of this circle;
but this was a miftake, as Hevelius obferves; and though
it is not faid that the parhelion at K had any tail, yet it is
plain that a certain part of the white circle was its tail,
though hut a dull one; becaufe this parhelion is faid to have
been fainter than the other; and it appears, by the obferra-
tions of Hevelius, and his own, that thofe parhelia, or
mock funs, as well as parafelenze, or mock moons, always
have
have tails. Lastly, the extraordinary brightness of the parhelia, which was said to rival that of the sun, he supposed, might easily be accounted for, by considering that every cylinder shines through its whole length; whereas, the round grains in the halo, or the rainbow, emit but little light; so that the cylinder may probably afford more light than ten of those round grains; and if there be great plenty of cylinders in the air, it is no wonder that those images of the sun should appear so bright.

He then proceeds to demonstrate his hypothesis, by an accurate consideration of the refraction of the rays of light through the sides of such cylinders as have been described; and he investigates the distance at which the parhelia must appear from the sun; shewing that it is so much the greater, as the internal cylinder of snow is thicker in proportion to the whole cylinder; and that this distance must become greater as the fun rises higher; and he submits a table of these distances, in proportion to any given altitude of the sun; from which it appears, that if a sufficient number of cylinders be placed one above another, one of which may be melted more and some left, besides the collateral parhelia next the fun, two or more may appear farther from him, but still in the same white circle, which was also confirmed by the observations of Hevelius in 1661, and of Scheiner in 1630. It appears also, from the fame tables, that while the cylinders remain in the same situation, as the fun rises higher the intervals between him and the two parhelia will increase, which was the very thing which he himself had observed.

But a greater alteration of these intervals may happen, if the cylinders be more melted; and from hence might arise that very remarkable phenomenon, which is said to have appeared in the time of Augustus, when three funs were seen at the same time, all of which were foon contracted into one; which, he observes, would be effected by the warmth of the air melting the snow in the cylinders; by which means both the parhelia would draw nearer to the sun, till they coincided with it; at which time all the cylinders would be melted, and changed into round drops.

In the next place, our author proceeds to explain the cause of that corona in the Roman phenomenon, of which the fun is the centre. And here his former hypothesis concerning halos, he acknowledges, will not answer the purpose. For though, when small cylinders are produced in the air, it is probable that half-thawed globules are lodged there at the same time, for the production of coronas; yet it is difficult to conceive how they can be thawed in so exact a proportion, as to produce a corona that shall pass precisely through those very parhelia.

Neither, as he observes, can this appearance be produced by cylinders obliquely situated, but only by the round ends of upright cylinders. And to suppose the above-mentioned cylinders to be always terminated by plain bases, he says, is by no means agreeable to nature; for, since their tops and bottoms will be thawed, as well as their sides, and to the same degree quite round, the water at their extremities will necessarily assume a round figure; so that not only those upright cylinders which lie on each side of the fun, and produce the collateral parhelia, will transmit his rays to the eye; but also those that lie quite round beyond him, to a certain distance, which will, therefore, produce a corona.

To verify this hypothesis by experiment, he ordered a glass cylinder to be made with round ends; and, inclining it in an opaque body of the same shape, he found that it did, in reality, refract the light in such a manner as would produce this appearance. Considering, therefore, the necessity there is for the cylinders being of this particular shape, in order that the rays, passing through their extremities, may produce coloured circles, he did not doubt, but that these circles are those very coronas. Otherwise some irregular and ill-shaped circles would be seen.

Hevelius had remarked, that the circle which passes through the parhelia, frequently appears fainter above and below, and brightens next the parhelia. The reason of this M. Huygens thought to be very plain from his glass cylinder, since the rays which pass through the round tops and bottoms of them produced only a small round image of the sun, as round grains do; whereas those which passed towards the ends of the cylindrical surfaces, where they just began to turn round, were formed into a broader and brighter pencil, like those which produce the parhelia; and this must make the corona grow gradually brighter and brighter towards the parhelia, both above and below, and to be more intensely coloured.

Having explained the cause of this corona, he proceeds to account for the two parhelia L and M, which appeared in the back part of the great white circle. And these, he thought, were produced, not by the reflection, but by the refraction of the fun's rays in the upright cylinders. The inner opaque cylinders, he observes, are so far from contributing to the production of these parhelia, that they sometimes hinder their appearance. But yet this inner cylinder of snow is absolutely necessary, whether the outward shell that contains it be made of water or of ice; for, without the snow, the watery cylinders would be immediately changed into round drops, and the whole cylinders could not be ice, because then they could not be everywhere transparent, without supposing them to have been quite liquid before they were frozen, which is inconsistent with a cylindrical figure.

He then shews, that these back parhelia must be in the large white circle; and determines, geometrically, that the distance between them must be sixty degrees. Indeed, in Scheiner's scheme, the distance of these parhelia exceeds ninety degrees; but it was neither measured, nor estimated, nor, indeed, so much as mentioned, and therefore M. Huygens does not doubt but that it is drawn much too large. In the Roman phenomenon these parhelia are said to have been white, whereas, according to this hypothesis, they ought to have been coloured. M. Huygens supposes that the whitened arose from the weakness of their light; on which account halos sometimes appear white, and sometimes also the lateral parhelia, as appears by the accurate observations of Keelhuis. But that these back parhelia do sometimes appear coloured, is evident from the account we have of one in Mat. Paris's history; in which we are told, that, besides the true fun, four mock funs appeared red, in a great circle, of the colour of crysalt. That two of these were back parhelia, is evident from the figure, though it may be faultly in other respects.

The scarcity of cylinders. M. Huygens supposes, may be the reason that, in many observations, these parhelia have not appeared, though the white circle was plain enough to be seen. But there is another circumstance which may hinder their appearance, viz. the inner cylinders of the back part of the white circle being too thick in proportion to the water that surrounds them. For the rays, which should produce the parhelia, will be flopped; and he found, by calculation, that when the sun is twenty degrees high, if the diameter of the opaque cylinder bear a greater proportion to that of the whole, than 590 to 1000, no back parhelia can appear.

That the back parhelia in the Roman phenomenon appeared rounder than the lateral ones, M. Huygens supposes to arise from this circumstance, that though some cylinders
cylinders in the arc L M, which lie not far from L and M, do send some refracted rays to the eye, yet they are so numerous as those which come from the cylinders at L and M; and, therefore, that these parhelia can have no tails that are far extended, like the lateral ones. Besides, the refractions through the cylinders that produced the back parhelia are more regular; for the rays are not scattered in their course by the opaque cylinders within, but receive their directions from the refractions at the most exact figure and polish of the outward watery surface of the cylinders. For the dark cylinders within, not being exactly equal to one another, are the cause of the irregular and inconstant shape of the lateral parhelia. The reason of the fluctuating motion of the tail of the parhelion N, he supposes to be, that sometimes fewer, and sometimes more cylinders were carried into that place; which also accounts for the corona D E F being sometimes entire, and sometimes open below, and that the parhelion K grew brighter while N grew duller. The phenomenon observed in 1661 by Hevelius, exhibited in fig. 9, seems to comprise all the real varieties of this most magnificent spectacle, parts of which have often been seen separately. The greatest difference between this appearance and that at Rome, consists in the arcs O R and T, which are convex towards the sun, and which Huygens accounts for by cylinders lying in a horizontal situation. The parhelia in these inverted arcs have rays, are nothing more than the brightest parts of them; and therefore they never appear quite distinct, nor much brighter than the adjoining parts of the arcs. Accordingly, Hevelius, in all his observations of this kind, took notice, that they appeared rather dull, heavy, and faint; and he was not sure whether there was a parhelion at H or not. The reason why the middle part of the arc should appear a little distinct from the rest, he supposed to be this, that though there be great plenty of horizontal cylinders in the air, yet they may be so short, as to have but little of a cylindrical surface, or perhaps may be like oblong spiculæ. Besides, it is perfectly agreeable to the observations of Hevelius, that the higher the sun or moon, and consequently the more the coronas are elevated above the horizon, the flatter these inverted arcs appear. It is confided by M. Huygens, that the upper parts of these arcs are represented by Hevelius, as being much less than his calculations require them to be; but he imagines that the figure of the observer was imposed upon, by the arcs being so much elevated above the horizon; in consequence of which they would appear to be parts of much lesser circles than they really are.

M. Mufchenbroeck says, that nothing has been advanced concerning the cause of parhelia, more probable than the hypothesis of M. Huygens, except that frozen cylinders or spiculae are always found transparent, and are never opaque at the centre. The coloured arcs that accompany parhelia, he thinks, to be not at all different from the common corona, so that if there be a quantity of icy spiculae in a thin fog, the whole of this appearance will be produced, the corona being formed in the fog, and the parhelia in the spiculae. See Huygen's Dissertation on this subject in Smith's Optics, book i. chap. 11. See also Pneehley's Hist. of Light, &c. p. 613; &c. and Mufchenbroeck's Introduction, &c. vol. n. p. 1638, &c. quarto.

PARHOMOLOGY, αἰπαρομοιοσ, in Retorics, a figure wherein a part is yielded to the opponent, and the reff denied: thus, "Sume hoc ab judiciis nostris volantibus; nominem illi propriorem cognatum quam tu usufisse, concedimus: officia tua nonnulla in illum extinisse, utpendia vos unâ secilice aliquamdiu nemo negat; sed quid contra testamentum dicis, in quo scriptus hic est."

PARA, or NEW ANDALUSIA, in Geography, a province of South America, in the government of Caracas, formerly a part of Spanish Guiana, situated E. of Cumara, on the N. coast of the continent of South America. Between it and the island of Trinidad is a large bay, called the "Gulf of Para;" 100 miles long, and from 30 to 40 broad.

PARA, a town of South America, and capital of a district in the viceroyalty of Buenos Ayres, commencing 210 miles N.W. of that city, and about 120 miles in extent. The air is so cold, that the country produces little grain, but this deficiency is compensated by its abundance of all kinds of cattle: the cheese that is made here, from the milk both of sheep and cows, is in high estimation, and sent into every part of Peru. Here are also some silver mines; 18 miles S. of Oruro. S. lat. 18° 50'. W. long. 68° 20'.

PARIAN CHRONICLE. This venerable relic of Greek literature is occasionally called, Marmor Chronicum, Marmor Chronologicum, Parium Chronicum, Marmor Epicharum, Stela Epicharum, or the Arundel Marble. (See ARUNDEL MARBLES.) It was found in a square tablet of coarse marble, five inches thick; and when Selden first inspected it, measured three feet seven inches, by two feet seven. The upper part was then imperfect, the lower corner on the right hand having been broken off, which reduced that side of the marble to two feet eleven inches. On this stone were engraved some of the principal events in the history of ancient Greece, forming a compendium of chronology during a series of 1318 years, which commenced with the reign of Cecrops, the first king of Athens, B. C. 1582, and ended with the archonship of Diogetus.

It originally contained about one hundred lines, each consisting, on an average, of sixteen words, or one hundred and thirty letters; so that the whole might have been comprised in five octavo pages. This venerable monument of antiquity was purchased, with many others, by Mr. W. Petty, who was employed by the earl of Arundel, in the year 1624, for the purpose of collecting marbles, books, statues, and other curiosities, in Italy, Greece, and Asia Minor, that was afterwards given up in the island of Paros, and was purchased at Smyrna. When brought to England in 1627, it was placed in the gardens belonging to Arundel-House, the site of which is now occupied by Arundel, Norfolk, Surry, and Howard-streets in the Strand. The next morning, it was examined, with eager curiosity, by some of the most distinguished literati of that time. These were Sir R. Cotton, Selden, Patrick Young, and Richard James. After much labour it was deciphered, and a copy of it published by the learned Selden in the year 1628, accompanied with a Latin translation and commentary.

During the civil wars, and the subsequent usurpation of Cromwell, this rare monument of ancient literature was unfortunately broken into smaller fragments, and almost entirely defaced. The upper part, containing nearly half the original tablet, is said to have been used in repairing a chimney-piece, or hearth, in Arundel-House; but luckily the inscription, or at least as much of it as could be made out, was preserved in the copy which Selden had previously taken and published. In the year 1667 the remaining fragments were presented by the Hon. Henry Howard, grandson of the first collector, to the university of Oxford, and deposited in the public schools, where they still remain. The genuineness of this valuable relic of antiquity was universally acknowledged throughout all Europe, as soon
as its contents were made known; its authority has been considered as equal, if not superior, to any other, and writers of the first importance have derived the greatest advantage from it in their historical and chronological researches. It was not till the year 1788, that its authenticity was impeached by a man of considerable learning and industry, in an elaborate volume, called "A Dissertation on the Authenticity of the Parian Chronicle." The author was the Rev. John Robertson, who founded his doubts and objections on the following considerations:

1. The characters have no certain, or unequivocal marks of antiquity.
2. It is not probable that the Chronicle was engraved for private use.
3. It does not appear to have been engraved by public authority.
4. The Greek and Roman writers, for a long time after the date of this work, complain that they had no chronological account of the affairs of ancient Greece.
5. This chronicle is not once mentioned by any writer of antiquity.
6. Some of the facts seem to have been taken from authors of a later date.
7. Parachronisms appear in some of the epochs, which we can scarcely suppose a Greek chronologist, in the 129th Olympiad, would be liable to commit.
8. The history of the discovery of the marbles is obscure and unsatisfactory; and
9. The literary world has been frequently imposed upon by spurious books and inscriptions; and therefore we should be extremely cautious with regard to what we receive under the venerable name of antiquity.

These observations are made the subject of separate chapters and disquisitions, and are illustrated with an appearance of much candour and extensive erudition; and, for a short time, the credit of the Parian Chronicle was shaken in the public opinion: but early in the following year, a vindication of it was undertaken by a writer of equal learning and certainly of superior judgment. This was the Rev. J. Hewlett, B.D., who is well known to the public as the author of three volumes of sermons, which have been much approved, and as the editor of a classical and elaborate edition of the Bible, with a comment and notes, which will afford very important and useful instruction to every person who wishes to acquaint himself with the sacred writings.

Other writers followed Mr. Hewlett on the same side; but their arguments had for the most part been anticipated by him, or illustrated with additional learning and facility of criticism. It would exceed our limits to enter minutely into this controversy; but our readers may expect to have the summary arguments of the vindication laid before them in the correspondent order of the differtator's doubts and objections.

With respect to the first, it is truly said, that mere characters can have no certain, or unequivocal marks of antiquity; but that those of the Parian Chronicle bear a general resemblance to such as appear on the coins of that age, and the most genuine monuments of antiquity, without being a slavish imitation of any; and that a singular mode of notation is adopted, which is explained only in an obscure tract of Herodian; but which occurs in no other author.

With respect to the second observation, it is remarked, that there is no improbability in supposing the Parian Chronicle to have been engraved by a private person. Monuments on different subjects have been engraved and erected by individuals; such are the Apostrophe of Homer; the Tabula Iliaca; and, particularly, the Marble Tables discovered at Paestumina, on which Verrius Flaccus had a corrected calendarium engraved.

As to the third remark, it is only necessary to observe, with Mr. Hewlett, it does not appear that the Parian Chronicle was not engraved by public authority, and that, in either case, its authenticity cannot be affected by the present supposition.

In answer to the fourth, it is shewn that the Greek and Roman writers, for a long time after the date of this work, do not complain of their having no chronological account of the affairs of ancient Greece: they only complain, that there was not any authentic or consistent chronology of those ages, a complaint which still exists.

In reply to the fifth article, Mr. Hewlett observes, that though this Chronicle is not mentioned by any writer of antiquity, yet there are abundant reasons to prove, that the ancients could have no motive, or fair opportunity, for mentioning it. The remains of ancient literature, in which any notice of a small chronological table could be expected, are extremely few and imperfect; besides, it was not the practice of the ancient writers, as we learn from Pliny and others, to quote authorities, with any accuracy; and no writer who flourished before the Christian era, would appeal to fo short a compendium of chronology as the Parian Chronicle was, cut on stone, and erected in the little island of Paros, when he could refer to the voluminous collections of Timaeus Siculo, Eratosthenes, Apollodorus, Julius Africanus, and others. Much more has been laid on the omission of Archilochus, who was a native of Paros, in a chronological monument, that was evidently calculated to mark and record the progress of literature and science; but professor Wagner has shewn, that the name of the Parian fartiff ought to have been inserted under the proper epochs, where the commentators have arbitrarily filled up the lacuna on the marble with an event of no importance. Vide Epoch.

P. 44.

With regard to the sixth assertion of the dissertator, it is confidently affirmed, after a minute and critical investigation of the subject, that there are no facts in the Parian Chronicle, which seem to have been taken from authors of a later date.

On the seventh, the result of Mr. Hewlett's disquisition is, that if there really are parachronisms in some of the epochs, the authorities opposed to the Parian Chronicle are extremely doubtful; and that the circumstance of its differing from the few remaining authors of antiquity, in some particulars, is rather an internal proof of its authenticity. After all, no one in vindicating the genuineness of this venerable relic of Grecian literature, ever dreamed of proving its infallibility, any more than that of any other chronologists.

In answer to the eighth objection, it is remarked, that the history of the discovery of the Parian Chronicle, upon the whole, is not unsatisfactory, or obscure; since the commentators, critics, and historians, who have had occasion to mention it, and who had a clear idea of what it was, agree as to the time and place of its discovery, and with regard to the person who procured it. And though we are not precisely informed of the sum which was paid for it, (because it formed a part of a collection,) nor are furnished with a full account of the particular circumstances under which it was purchased; yet this must necessarily have proceeded from the negligence and inadvertence, and not the ignorance, or doubts, of the first editor. It is sufficient, that no just ground of fraud, or suspicion, attaches to any of the parties in the whole of the transaction.

With respect to the ninth remark, it is laid, that though the literary world has frequently been imposed on by spurious books and inscriptions, yet spurious books apply not to the preface.
prefect question; and as to inscriptions, there is nothing to be found in the whole history of impostures, that bears the least resemblance in point of learning, labour, and expense, to the Parian Chronicle.

In addition to these remarks, let it be observed, says Mr. Hewlett, that very few men, since the revival of learning, have been capable of executing such a literary monument as the Parian Chronicle. Of these few, not many, it is hoped, would have had the benefit to attempt it; and others might have been justly withheld from doing it, by the labour of the undertaking, and the danger of detection; since it would require three months to cut the characters only; and, in executing such a project, it is scarcely possible, that many persons should not be privy to it, and that the author should not be guilty of some error, or meet with some untoward circumstance, that would have betrayed the imposture to such a man as Mr. Petty, who purchased it, and who is represented by Selden, Dr. Chandler, and others, as a perfom of the greatest judgment and discernment, and no less distinguished for his learning.

Farther, on the supposition of its being a forgery, it does not appear that the impostor received any adequate compensation for his trouble; and, as no oftenable author was held forth, the vanity of learning could not be gratified, for a moment, by the excellence of imitation, or any successful competition with works of departed genius; motives which appear to have been general with the impostors of antiquity, and no less prevalent among those of modern times. Besides, it is not at all probable, that the fabricator of such an inscription would have broken it to pieces and defaced it, in the manner that it was when Mr. Petty purchased it, unless, like the rest of his fraternity, he had contrived some prudent means of being the refiner of his own monument, and the interpreter of his own mysteries.

Such are the mere heads of the arguments advanced by the learned and successful vindicator of this valuable monument of ancient literature; arguments which are illustrated and enforced with varied and extensive erudition, and great diligence of research, combined with much critical acumen, that is displayed in detecting fallacies, exposing errors, and refuting objections. It is remarkable, that on the appearance of this matterly vindication, the controversy has flamed into a flame; and the respectable author of it has had the satisfaction of seeing the Parian Chronicle re-established on the fame fold basis, on which it had always relied from the time of its first discovery.

Parian Marble. See Marble.

Pariana, in Botany, a name of Aublet's, which, as Professor Martyn remarks, seems to have been suggested by the flowers growing in pairs upon the spike. Aubl. Guian. v. 2. 876. Schreb. 650. Willd. Sp. Pl. v. 4. 492. Mart. Mill. Dict. v. 3. Juill. 44. Lamarck Dict. v. 5. 13. Illust. t. 776.—Clas and order, Monocota Polyandra. Nat. Ord. Gramina. Gen. Ch. Male. Cal. Glume of two short acute valves, containing a single floret. Cor. of two ovate acute valves, larger than the calyx; one of them narrower than the other. Stam. Filaments about forty, capillary, inserted into the base of the corolla; anthers linear.

Female, solitary in the same whorl, Cal. Glume of two ovate, concave, acute valves, containing a single floret. Cor. of two acute valves, hairy at the summit, smaller than the calyx. Plf. German superior, triangular; style long, hairy; stigmas two, villous. Peric. none, except the permanent corolla. Seed solitary, triangular, invested with the glumes.

Eff. Ch. Male, Calyx of two valves. Corolla of two larger valves. Stamens forty, inserted into the base of the corolla.

Female, Calyx of two valves. Corolla of two smaller valves. Style hairy. Stigmatic two. Seed one, triangular.

1. F. campylitis. Aubl. Guian. 877. t. 337.—Gathered by Aublet in woods and by way-fides in Cayenne, flowering in January. The root is perennial. Stem several, reedy, a foot or two in height, densely, knotty, leuc. Lemons foliary at each joint, ova, broad, pointed, entire, many-ribbed, smooth; paler beneath; leaves long, fringed, closely enveloping the stem, bearded at the summit with copious long reddish hairs, and contracted suddenly below the leaf, into a fort of slender, short footstalk, accompanied by a pair of membraneous fringed spilei. Spike terminal, foliary, erect, about two inches long, dense, whorled, each whorl consisting of two pairs of male flowers, with a solitary one, and a single female flower in the centre between them. The great number of flaments is very extraordinary in the natural order of graminés, to which this plant belongs.

Paria-Tuba, in Geography, a town of Brazil, in the government of Para, on the river Amazonas; 35 miles S.W. of Pauixi.

Paridson, or Phari, a strong town and mountain of Boatan, on the borders of Thibet; 40 miles N.W. of Taflisndon. N. lat. 28. E. long. 89° 13'. The fortresses of Phari is a strong stone building, situated on high ground; and on the N. and W. sides of it is an extensive suburb; on the S. is a large basin of water; and on the E. a bank of earth projected to a considerable distance, and falling with an easy slope from a level with the rampart into the plain. The valley of Phari is very extensive, being not less than ten miles long and four broad, surrounded on all sides with rocky hills. At the foot of the rocks, on the well border of the plain, is a large brook, flowing towards the south, called "Mahatchie," which is said to have a passage, through the hills of Nipal, into Benggal. This is the situation of Phari Lama, a dependant of Teshoo Loomboo, who is here a little potentate, being superintendent of a gomtbah, or monastery, and governor of a most extensive range of rocks and deferts, which yield produce only in the mildest season of the year, when his neighbourhood is frequented by large herds of the long-haired, bulky-tailed cattle. From his character and station, he has great influence among the herdmen. The mukt-deer, which produce a valuable article of revenue, abound in the vicinity of these mountains. The mukt-deer are deemed the property of the flate, and hunted only by the permission of government; and of course a great part of the mukt, which is a recreation formed in a little bag, or tumour, resembling a wen, situated at the navel, and found only in the males, passes through the hands of its agents. It is liable to much adulteration; but that which bears the regent's seal may be regarded as genuine. The mukt-deer, the language of Thibet, is called "La," and the vacular covering of the mukt, "Latcha." Turner's Tibet.

Pariesovatz, a town of Croatia; 15 miles S. of Bihacs.

Parietalia Osea, in Anatomy, two bones of the cranium. See Cranium.

Parietaria.

Obf. The clafs Polygania having been much curtailed by Dr. Smith, we have followed him in removing this genus to Tetrandria. It may be remarked however that some of the flowers are female, and in these the calyx undergoes no change.

1. P. indica. Indian Pellitory. Linn. Mant. 128. Syfl. Veg. ed. 14. 908. (Cratatozegnon major; Rumph. Amb. v. 6. book 10. 25. t. 10?)—Leaves lanceolate. Stem erect.—Native of India. The appearance of this species is very similar to the following one, but the whole herb is more naked. Leaves with much longer points, three-nerved and naked. Flowers in smaller heads. Bractea awl-shaped, not ovate. Styles longer. Fruit sessile, furrowed. Linnæus once took the plant of Rumphius above quoted for a Spermacoce, but the description of the feed seems to prove it to be a Parietaria, though the opposite, nearly sessile leaves make us rather suspect that this synonyym belongs to P. scylla, which is now, as well as P. microphylla, referred to Urtica.

2. P. officinalis. Pellitory of the Wall. Linn. Sp. Pl. 1492. Engl. Bot. t. 879. Curt. Lond. facic. 4. t. 63. Fl. Dan. t. 521. ('E?&v; Dioec.)—Leaves lanceolate, without lateral ribs at the base. Segments of the involucrum ovate. Stem ascending.—Native of Britain, on mouldering walls, chiefly in sheltered places, being rather impatient of cold; common in the south of Europe. It flowers abundantly through the summer and autumn. Root perennial. Stem branched, spreading, reddish, shining, leafy, juicy. Leaves alternate, elliptic-lanceolate, obtuse, pointed, pale beneath, the lateral nerves all springing from the main rib considerably above the base of the leaf, in which it especially differs from judaica and indica. Each involucrum is cut into seven ovate segments, and contains three fertile flowers; the central one female. The clastic stamens, which spring from the calyx forcibly when touched, scatter the pollen by that means all around.

The mucilaginous qualities of this plant have led some writers on the materia medica, to regard it as an emollient, but in this respect it is inferior to the Mallow tribe. Curtis remarks, on the authority of Aurelius Victor, that Constantine bestowed on the emperor Trajan the name of Parietarius, because he embellished his statues and inscriptions, like that herb, were found on all the walls of Rome. Bradley recommends the Pellitory to be laid on the corn in granaries, for the purpose of driving away that destructive insect the weevil.

4. P. lufitanica. Chickweed-leaved Pellitory. Linn. Sp. Pl. 1492. (P. lufitanica annua, minima; Tournef. Inft. 509. P. ficula, alizes folio; Bocc. Sicic. 47. t. 24. f. B.)—Leaves ovate, obtuse. Stems thread-shaped, fimbriated, even, procumbent.—Native of Spain and Portugal. Introduced at Kew in 1771, by M. Richard, where it flowers in July. Root annual, according to Tournefort, though Boccone says it differs only from the last, and officinalis, in the leaves, which are very much smaller, and of the form and fize of Chickweed.

7. P. capenifis. Cape Pellitory. Thunb. Prodr. 31.—Leaves opposite, ovate, serrated. Branches diffuse.—Native of the Cape, and adopted entirely on the authority of Thunberg's Prodromus. We are not acquainted with either a figure or description of this species.

9. P. cochinichena. Cochinichina Pellitory. Lour. Cochinich. 654.—Leaves ovate, three-nerved, hairy. Stem tufted, diffuse.—Native of China and Cochinchina, in neglected gardens. Root perennial. Stem herbaceous, a foot and half high, slender. Leaves opposite, entire, small, hairy. Flowers axillary, whorled, in little heads. Loureiro says that the natives use this plant to put at the mouths of vessels containing salt provisions, for that it attracts such vermin as would otherwise destroy the salted meat, or fish. It is also esteemed an emollient, refrigerant, and diuretic herb.

10. P. arboria. Tree Pellitory. L'Herit. in Journ. de Rozier. v. 33. 55. Ait. Hort Kew. ed. 1. v. 3. 429. (Urtica arboria; Linn. Suppl. 417. L'Herit. Stirp. Nov. 39. t. 20.)—Leaves elliptical, pointed, flightly three- nerved. Stem arborescent.—Native of the Canary Islands, whence it was sent to Kew by M. F. Maffon in 1779. It flowers from February to May. Root woody, branched, fibrous, reddish. Stem flabby, five or six feet high, upright, round, branched, ash-coloured. Branches villous; red when young with hoary hairs. Leaves alternate, spreading, entire, veiny, bright green, soft and downy; rather paler beneath; the younger ones much wrinkled. Flowers in terminal panicles, composed of simple, axillary, erect, villous spikes. L'Heritier originally made this species an Urtica, but, upon further examination, referred it to the present genus.

Parietaria, in Gardening, contains a plant of P. p 2

shrubby
A PAR

The shrubby kind for the greenhouse, of which the species cultivated is tree pellitory (P. arboea).

Method of Culture.—This plant may be increased by planting cuttings of the young shoots in the summer season, watering them occasionally till they have formed root. When the plants are well rooted, they may be removed with balls about their roots into separate pots, and have the constant protection of the greenhouse, in which they afford variety.

PARIETES is often used, in anatomical descriptions, to denote the silex or sculls of a cavity; thus we speak of the parietes of the chest or abdomen, &c.

PARIGNE, L'Evesque, in Geography, a town of France, in the department of the Sarthe, and chief place of a canton, in the district of Le Mans; nine miles S.E. of Le Mans. The place contains 2636, and the canton 14,712 inhabitants, on a territory of 310 kilometres, in 12 communes.

PARILUM, in Botany, Gartn. v. i. 234. t. 51. f. 1, appears to have received that appellation because the capsule consists of two equal parts, clapsed closely together, in an advanced late easily separable from each other. So the garments of the Romans made of a double stuff, were called parilia, from par, a pair. The genus thus denominated nevertheless retains the name of Nyctanthes, and its histology is curious. The only species known is the Arbor trifis, which Linnaeus forced into his original Nyctanthes, notwithstanding its capsular fruit; that genus, as at first constituted, having a berry, and differing from Jasminum only in having eight instead of five segments to its corolla. (See JASMINEUM and NYCTANTEST.) He afterwards entirely forgot the plant, having no specimen in his herbarium, that when he subsequently received one, he described it as fresh in its Manfisena, by the name of Scabria triloba, which was somehow changed in the Syll. Veg. to S. jasina. He was the more readily led into this error, by finding four flaments in the flowers; so that he placed Scabria in his class Tricandria. This character seems to be variable, for the plant is described with two flaments in the Hortus Malabaricus, which nobody has contradicted. But it has been found proper to remove all the berry-bearing species of Nyctanthes to Jasminum, there being no certainty in the number of segments in the corolla, which in the common J. officinalis vary from four to six, and in others are five, six, seven, or eight. When the Linnaean herbarium arrived in England, Scabria, which had always been a mystery, proved, on inspection, the identical Arbor trifis, for which the generic name of Nyctanthes is peculiarly appropriate. Even Jussieu, to whom Vahl had, rather surreptitiously as on many other occasions, communicated this intelligence, thought proper to let that name go remain, establishing a new genus, under the title of Magnorium, for the Jasmines with eight segments to the corolla; which however has not been adopted. (See MAGNORIUM.) Vahl in his Enum. Plant. v. i. 255, has acceded to the decision of Banks and Solander on this point.

PARILLA, in Geography, a town of South America, in the province of Panama; 70 miles N.W. of Panama.—Alto, a town of Peru; 50 miles S. of Trujillo.

PARILOVA, a town of Ruffia, in the government of Irukiti, on the Angara; 68 miles N. of Balaganikot.

PARIMA, called also Paraquapinae, or the White sea, a lake of South America, in Spanish Guiana, is represented by La Cruz, as more than 100 British miles in length, b. y. 50 in breadth. Its extent, and even its existence, have been doubted, as it was the noted seat of the city El Dorado, (which see,) the streets of which were paved with gold; a fable, which seems to have arisen from a rock of tale reflecting, like a mirror, the golden rays of the sun. N. lat.

3° 40'. W. long. 45° 20'.—Alto, a large river, likewise called the Rio Blenco, which has its source in the above-mentioned lake, and which joins the river Negro, and great river Maranon.

PARIMA, Mountains of. See Andes.

PARINA CAUCHA, or Caba, or Caca, a town of Peru, and capital of a jurisdiction in the bishopric of Guanaga, fertile in cattle, corn, and fruit, but receiving its principal riches from its silver and gold mines.

PARINARIUM, in Botany, Juss. 243, a name formed by the author from the Peruvians Aucis, see Petrocarya; also Mamipara and Neoc.

PARING and Burning, in Agriculture, the process of paring off the surface of lands in the flate of graves, in order to convert them into tillage, by means of fire. It is a practice for the most part employed on rough coarse grounds that are over-run with strong plants of the graves, mofs, or heath kinds, and on some mossy or peaty lands.

The author of a late practical work states, that "the practice of bringing land into a suitable condition for the growth of grain or other crops by means of fire, by paring and burning the surface or flame, is probably a method of cultivation that was adopted at a very early period. It is a process by which various changes are produced in the materials of the soils on which it is employed; some of which would seem to lessen rather than improve their fertility, while others have obviously the power of promoting and augmenting it in a very considerable degree." And that "the action of the fire during the time of the combustion, especially when carried to a great height, by forcing off and diffusing much of the moisture and elastic principles that they contain, as well as by reducing the proportions of vegetable and animal matters, which may be mixed and incorporated with them, must have the effect of producing some degree of deterioration; while, by its conversion of the fresh vegetable products, as the different kinds of coarse plants and grasses, into ashes of an alkaline, saline nature, which proceeds has the property of quickly rendering the portions of vegetable materials which may remain, proper for supplying the nutrition of plants; and by combining oxygen with the argillaceous, earthy, or other particles contained in them, in such a manner as to be easily parted with during the insipid stages of vegetation, great advantage and improvement must unquestionably in many cases be produced. It would seem to be chiefly on the former principle, that the crops are generally found to be so abundant after land has undergone this process; as the saline fulness contained in the ashes, though frequently small in quantity, by bringing such parts of the soils as were not before in a lit state for the purpose of being applied to the support of vegetables, suddenly into that situation in which they may be taken up by the absorbent roots of the plants, a vital immediate fertility may be given, but which must soon have the effect of exhausting the ground, if grafs or some other kind of green crops do not cultivated in due rotation upon it. That some effect of this sort takes place in such cases, is shown by the general experience of the most correct practical agriculturists." But besides this, there is also another way, in which the saline or other matters thus formed may be conducive to the purposes of vegetation, which is, by the great stimulus which it is known to afford to the roots of growing plants, by which they may be induced to take up a larger proportion of nutrient matters from the soils on which they grow. And on lands prepared in this manner, especially where they are of the clayey kinds, it is probable, that in some instances so much oxygen may be combined, by means of the fire, with the particles of clay, as, in particular situations and circumstances,
PARING.

circumstances, to render it capable of forming nitrous acid; as is the case with imperfectly-baked bricks, according to Dr. Darwin, which, where lime is made use of at the same time with the ashes, may constitute a fort of calcareous nitre; a substance which experiment has shewn to be highly favourable to the process of vegetable growth.

Further, that "in the method of cultivating lands, by means of paring and burning the surface, such loaves or deteriorations of soil as may be unfilled, must evidently be produced by the quantity of vegetable or animal materials, which may have been consumed or dispersed in the state of carbonic acid or other aerial forms; as it is sufficiently known, that not a particle of the real earthy matter of the land can be destroyed or carried away by the process; it being left in most cases where the business has been properly performed, probably in a much more mellow and friable condition, than it was before the commencement of the operation, and perhaps more suited to the absorption of elasic principles from the surrounding atmosphere." It has, however, been flouted by the earl of Dunford, that "the disadvantage in respect to vegetable matter, is nineteen parts out of twenty; but the above author fuggels that, as he has not informed us what is the degree of loss of such matter by this process, where it is incorporated in the state of fale, or the nature of the experiment from which his conclusion was drawn, we are at liberty to believe, that in the mode of preparation it is not by any means so great, whatever it may be where the vegetable matters are themselves simply submitted to the action of the fire; especially as in the trials which he has made by burning such soils as contained a large proportion of vegetable materials, so as nearly to resemble that of garden mould, consequently, having considerably more than is usual with in the lands that are subjected to the operations of paring and burning, it has not been nearly in such a proportion even under a high degree of heat, which ought in every case to be as much as possible avoided."

"Experience has, however, shewn, the first writer observes, that whatever may be the proportion of soil matter which is formed in this way, a great deal depends upon the ashes which are produced; as it has been found by those who have been largely engaged in the practice of this husbandry, that on those parts where the ashes were spread out upon the land as soon as the process was finished, the crops were highly luxuriant and productive; while on those where they had been from necessity taken away, they were very mean and inferior, not being worth more than from an eighth to a tenth of the value of the others."

In respect to the nature of the fale substances that are formed during the process of paring and burning, they have been found to be fixed vegetable alkali, and vitriolated tartar; in the latter case, the alkali of the consumed vegetable matters uniting with the sulphuric or vitriolic acid, which is frequently found to exist in some state of combination or other in soils. These substances have been found, by the experiments of Dr. Home, to be capable of promoting the growth of vegetables in a considerable degree.

And in addition to these modes, in which the practice of paring and burning may be beneficially employed in the cultivation of land, there are some others which seem of a more mechanical nature; such as its reducing the various kinds of coarse vegetable productions, as heath, furze, different sorts of dwarf shrubby plants, tough bony grasses, rushes, and many other aquatics, into such a powdery carbonaceous state, as that, by the ready action of other substances upon them when thus reduced in the soils, they may become useful in promoting the growth of proper kinds of vegetables; but which, without undergoing this process, could not, by any means, from their great elasticity, and almost indestructible properties, be prevented, for a very considerable length of time at least, from rendering the ground too light and porous for growing any sort of grain crops. And the state and condition of the soils, in so far as respects their textures, as already suggested, must likewise, in many cases, be greatly improved, being, by such means, when properly performed, rendered much more mellow and powdery, and thereby more proper for the admiss of the fibrous roots of the growing plants, as well as more capable of minutely dividing the particles of the manures, of whatever kind they may be, that are afterwards applied to them, and consequently affording a more full and equable supply of nourishment to the crops that may be cultivated. And from the process radically destroying, in most instances, when well performed, all sorts of plants of the weed kind that may have established themselves in the soils which are subjected to the operation, the lands are left perfectly clean, and therefore in the most proper situation for affording the whole of the nutritious properties which they contain to the support of the crops that may be grown upon them.

From this view of the manner in which this process may contribute to the improvement of land, the nature of the products that are formed by it, and the effects which they produce on the soils, it would appear to be a mode of cultivation more adapted to some sorts of land than others; as where they are light or thin, and there is much vegetable matter accumulated within the soil, whether from the decay of succicive crops or different sorts of plants, for a great length of time, or the repeated applications of manures, without their having much fward or coarse vegetable products, such as have been mentioned, growing upon the surface, it may do harm, especially when a great degree of heat is not carefully guarded against, and judicious modes of cropping introduced, by lessening the quantity of useful vegetable matter which they contain, without supplying any thing as a compensation. But where they are more fluff and heavy, and there is a thick matted fward, disposed to the production of moes, or covered with any sort of rough four plants, whether of the grass or other kinds; it must, when cautiously practiced, be a highly beneficial, and perhaps, in many cases, an indispensable mode of cultivation; not only by rendering them more open and porous in their textures, and reducing the coarse vegetable mufs into that sort of form in which it can be readily turned down and incorporated with the earthy materials, but also by supplying a portion of fahle or other matter, that may operate still further in promoting their fertility and productivity. These are considered as the effects of the process, and the canes in which it should be made use of, or rejected, is as fully shewn by the experience of the most exact and careful practical farmers. Mr. Donaldson, an intelligent inquirer, who seems to have paid great attention to the effects of the different modes of practice that are employed in different tricths in the cultivation of land, it is remarked, he observes, that such fous as are light and friable, are everywhere considered as unfit or improper for being treated by means of this process. And an experienced writer, who appears to have consequently examined the nature and effects of the operation, affirns us, he
he says, that he has many doubts about the propriety of extending the practice to such foils as have been already fertilized and brought into a proper state of tilth, by the application of manures.

It is fupposed, that there is also another sort of foil on which the procefs of paring and burning must be practifed with equal caution, or perhaps in some cafes be wholly rejected, from the danger there is of its reducing the materials of which it is constituted to too great a degree. This is that of the peat or mossy kind. In this cafe, the author mentioned above fuppofes, it is not the plants which grew upon it, but the very fubfance itself, that ferved as a foil on which the plants grew, that is totally deftroyed by incineration. This fubfance is, by burn-baking, amazingly diminished in quantity; and the little that remains, instead of foil, after this deftructive procfs, is an inert earth, which is more unfit for the purpofes of vegetation than any other that has ever fallen under bis obfervation. There cannot, however, be any doubt but that, in fome cafes, mossy foils may be subjected to the procefs of paring and burning with much benefit to the cultivator, provided that it be performed with proper care and attention. And it is unquestionably practiced in various districts without any injury being produced by the deftruction of the materials that constitute such foils.

In cafes where the foils are of the four, heavy, light, and fenny kinds, and where overgrown with fuch coarsel vegetable productions as have been already mentioned, there cannot be the leaft doubt of the propriety of adopting fuch a method of practice in breaking them up and bringing them into a flate of cultivation.

Mr. Young has well observed in his Calendar of Farming, in regard to the contradictory opinions held on this practice, that by one fett it is pronounced, contrary to every principle, that it is a wafteful, extravagant operation, which difpares what fhould be retained; annihilates oils and mucilage; calcines falt, and reduces fertile organic matter into ashes of very weak efficacy; that the vegetable particles which are brought into play at once, for the production of a fingle crop, by lefs delicate management might be hufbandfed to the support of many. On the contrary, the advocates for this management affert, that these objections are all grounded on vain reafoning, and philosophical theory; that practice the moft decided, and experience the moft extended, pronounce it to be an admirable fystem; and that the mischiefs often quoted as flowing from it, are to be attributed merely to the abuse of the method, and by no means necelfarly connected with it. And he fultan, without the leaft hesitation, declare, that the latter of these opinions is that to which he muft fubcribe. To trufl to reafoning in matters of agriculture, is a moft dangerouf reliance. He fhall leave others to detail their philosophical fpeculations, and reft what he has to offer folely on the practice, various and extensive, of numerous agriculturalists, and on the common hufbandry of many fpacious districts. Thafe agree in declaring, and it is most particularly to be had in remembrance, for the enemies of the practice admit it, that by paring and burning you may command two or three good corn crops in fucceffion. The fact cannot be denied; for whether you examine the peat of the Cambridge fens, or the shallow chalk foils of the downs and wolds of Hampshire, Gloucefter, and the East Riding, it is known, that bad farmers do act thus abfurdl. They get great crops, but they too often take them in fucceffion, to the injury of the foil, though not to its ruin, unlefs that can be efecled the ruin of land, which enables the tenant to pay a double rent for it. Such farmers have been in the habit of burning for wheat, and then taking two crops of spring corn; all good. Now, it might be asked, how is it possible that that hufbandry can have all the philosophical evils detailed above, of annihilation, dijperflon, conversion, and deftruction, which enables a foil, naturally poor and weak, to give two or three good crops of corn? Their argument evidently proves too much. The effect fhews that there is a powerful cance or agent in burning, which they do not understand; which escapes from the retort of the chemift, and from the rationale of the theolog. That operation on manure which will give a good crop of wheat, will give a good crop of turnips or cabbage; and he, who having made this commencement for the food of sheep on the land, and knows not how to go on preferring the advantage he has gained, is a tyro in the art of hufbandry. The farmers that are rafed at, know it as well as their philoſophical inftruétors; but avarice, united with the baneful effect of short, or no leaves, may produce them paralysed against their judgments. It is maintained, that paring and burning will, on all foils, give turnips or cabbage; thefe fed on the land by sheep, will feurce barley or oats, and feeds; the feeds fed with sheep, whether for a short or a longer duration, will fecure another crop of corn adapted to the foil; and in this stage of the progress the foil will have gained much more than it has lost. To infance cafes which he has seen, and to quote authorities for thefe affertions, would be tiresome. He could produce infances from more than half the counties of the kingdom in support of it.

But further, it has been often contended, that burning lefrens the foil. If this happens any where it muft be in peat; yet in the fens in Cambridge, this hufbandry has been repeated once in eight years for a century and a half, and the proofs of a fols of depth are extremely vague, in every infance he has met with, and hardly to be distinguished from that undoubted fubfidence which takes place in drained bogs of every defcription. In all other foils the affertion may be safely and positively denied. He has calcined pared turf, not calcareouf, after careful feparation and weighing, and in a heat far exceeding what is ever given in defhiring heaps, and on re-weighing, found the fols too minute to be attributed to any thing but fols of water intimately combined, but driven off by heat, and re-exposing the earth to the atmosphere, free from rain, found an increafe rather than a diminution of weight. The vegetable particles only are reduced to ashes. Thafe, in any method of putrefcation, would difolve, and combining with water, be exhaled by heat, or absorbed by the veftels of plants. In afhes, thafe are in a more fixed flate, relatively to the influence of the atmosphere. That plants feed on them, the great crops that fucceed offer abundant proof. In conclusion, it is noticed that there are men who are timid in acknowledging truth, who admit the practice to be good, in poor foils, and in peat, and feedly bottoms, but fear it on better land. Experiment is againft them, for in Yorkshire, land of 20s. and 30s. an acre, has been thus broken up with great succed; but in what manner do thay reafon? Rich foils are full of vegetable fibres. Then there will be the more afhes. Thafe are in proportion to the organic matter. Peat, which these men admit to be burnt, is the richest foil in the world, and therefore burning the moft univerfally practifed on it. The foil itself is not reduced; if it was rich before burning, it will be rich after it. And in addition to these circumftances, is the capital one, of deftroying infects, grubs, and weeds. Thafe are apt to abound moft in the richer foils, no reafon for abjuring from this hufbandry on fuch. He ventures therefore to conclude, that paring and burning, with a proper couple of crops, is safe on any foil; and effentially necessary on some. He however well remarks, that very rich ones will do exceedingly well in many cafes without it. This distinction,
PARING.

distinction, therefore, should be made. There is, in some 
causes, no necessity for it; there is in others.

It is observed in the twelfth volume of the Annals of Agricu-
lulture, that on inclining the waste lands in the parish of 
Bows, in Yorkshire, large portions of the ground were sub-
jected to the processes of paring and burning; and the few 
persons who ploughed up the ground without previously 
employing this method, had reason to regret it. And it has 
been itated by a writer, in speaking of bringing into 
cultivation the chalk lands in the county of Middlesex, that 
the impurity of breaking up this kind of land, without 
paring and burning, is manifested in the neighbourhood of 
Beech-hill, where land, after twenty years inclosure and 
cultivation, is in a worse state than it was originally. Well 
would it be for the owners of such allotments, if they could 
now plough and burn it; but it has been ploughed, and not 
reducing more than what the vermin destroyed, laid down in 
slowly a flat to graze, as to be incapable of being pared 
and burnt; the original wiry bent and dwarf shrubs are now 
growing in full vigour; and that on the incline of Stanwell, 
in the same county, the allotments on Hounsdown-success-
ceded well under the perfect practice of paring and burning, 
and all where the turf was ploughed without the application 
of fire. In the former case the land was immediately fit for 
turnips, tares, barley, and clover; in the latter, the tough, 
wiry bent, heath, and dwarf furze, kept the land too light 
and spongy for any crop. Even rolling, he afferts, cannot 
keep it down, for its elasticity raises the soil soon after 
the roller has passed over it, and it is of imperishable na-
ture, that it is likely to plague the farmer for many years. 
The difference between the two methods of breaking up 
rough ground, is more than the value of the freethrow in fa-
vour of paring and burning, whereas the other proceeding 
leads to nothing but expense and disappointment. It is like-
wise added that paring and burning has more merit than any 
other manure, in its property of converting heath, furze, 
shrubs, and wiry bent, into coal, most fitly prepared for the 
food of plants; and that it will pulverize such a soil as much 
in two years as all other means can effect in twenty. And 
others contend, that on any part of soil which has not before 
been reclaimed from a state of waste, and where furze, 
broom, brambles, ferns, rurfee, &c. abound, these operations, 
when properly performed, are productive of the most 
beneficial consequences. That there is perhaps no other 
method that could be devised, so well adapted for preparing 
land in a state of nature, and incubemerced with such produc-
tions, for valuable crops with expedition and certainty; and 
that, on this account, paring and burning might well be 
considered by Virgil, and other ancient writers, as a sure 
means of improvement. And that, in such cases, they are 
not at this period, may, it is thought, be proved by the con-
curring testimony of those to whom this latter fails to cultivate 
the common or waste lands in many of the new inclosed 
districts of the kingdom. It is further stated, that instances 
are frequently met with of great advantage, resulting from 
this mode of management; and that wherever land is ren-
dered unfit for cultivation by the inclemencies that have 
been mentioned, the Devonshire maitlock and the paring-
frame may be used with the greatest propriety, and the best 
effects.

In the Agricultural Survey of Suffolk, it is stated, that in 
that district they could not cultivate without this capital 
assistant. It is scarcely possible, profitably, to bring boggy, 
moory, and peat foils, from a state of nature into cultivation, 
without the assistance of fire, which is the most effective 
destruétion of the spontaneous growth, and never fails, 
unless the men employed do not pare deep. However, of 
late years an opinion against it has prevailed much in some 
counties. Several of the nobility and gentry of very large 
estates have interdicted the practice, not allowing their 
tenants to pare and burn under any pretence whatever. The 
reason alluded for this conduct is an apprehension, that the 
depth of the foil decreases from it, that you burn the land, 
and reduce half an inch to half a line, a great evil when the 
land is perhaps only three or four inches deep on a lime- 
stone rock. But this reasoning, many very inéfible and experi-
farmers know to be false. They, on the contrary, urge the 
universal circumstance of no land ever being pared till it has 
acquired a turf, which with natural gravelies will be from seven 
to twenty years, and with fainfes the duration of the crop, 
which is from ten to twenty years; that it is not the foil 
which is burnt, but the bulbs of the plants, the roots and 
met-work of grass roots; the earth which is intermixed is not 
burnt, it is calcined but not reduced to ashes, all of which arise 
from bulbs and roots: hence the fact that the flapple of the 
foil rarely sufffers from paring and burning. If this reason-
ning be not true, whence the known fact that soils not four 
thickness, which have remained at the same thickness as 
long as the oldest man can remember, have yet been pared 
and burnt regularly four or five times in a century? and as 
the fame husbandry is known by record to have been practised 
for ages in the same land, the flapple must have left three 
ices every hundred years; in other words, it must have been 
totally gone long ago, and nothing but rock remained; 
which is evidently false, the foil at this day being as thick 
as ever. We may hence conclude, what such farmers assert 
to be true, that the earth suffers no diminution, thoé roots 
and bulbs only being reduced to ashes, which in breaking 
up by the plough alone would rot away.

In speaking of the objectious which have been made to this 
practice in fen districts, from the idea that it has the tendency 
of rediving the soil greatly, as is shown by the linking of 
drained lands that have been pared, the same writer adds, 
that it has been found that a series of ploughing and cropping 
shiftens, concentrates, and diminishes the lighter kinds of fen 
soils; and that the stratum of black peat earth, which on 
their first breaking up was considerably deeper than the 
plough run, has been within the memory of the present occu-
piers, without any fresh paring or burning, so far reduced, 
that without taking more mould, or ploughing deeper than 
they formerly had been accustomed to do, they have not only 
pared the whole of the black peat stratum, but have ploughed 
up two or three inches of the clay beneath it; and that if it 
be granted, which will scarcely be denied, that the surface 
of the adjacent depaupilated fen lands, from the decay of vegetable, 
dung of animals, and the soil brought thither by the waters 
from the neighbouring high lands, has been continually, 
though slowly, increasing, there will then appear other 
reasons for their present different level than mere paring 
and burning. It is well known, that earth is not to be dif-
figured by combustion; it is more likely this appearance pro-
cceeds, in the first place, from the light peaty earth of a fen 
foil being gradually conñediated by alternate cultivation and 
paturation, so as to sink below the level it formerly preferred 
in its uncultivated state; and in the next place, may it not 
proceed from the commons gradually rising higher by the 
accumulation of mud and foil deposited by the adjacent land 
waters? All these facts, which obviously rest upon the founda-
tion of practical experience, sufficiently demonstrate that 
little danger is to be apprehended from the destruction of the 
foil, when the process is properly performed, and a correct 
method of management pursued with the land.

The
The effects of the process may, however, be examined a little further, as they stand in respect to the different forts of soil.

Clayey Soils.—Mr. Young supposes that many appropriate reasons have not been brought against the practice on this part of land; the only one that merits the least attention, is the assertion, that it converts what is properly soil, into pieces of infertile brick. The fact is not so, for every one that ever burnt clay for manure, knows that though there are many heaps of the substance which they allude to, yet, that the mass of the heaps consists of ashes, properly so called; but when the tenacity of this soil, which is one of its greatest evils, is considered, it will be found that bricks are an excellent addition to the soil, to loosen and open its stubborn adhesion. He has seen and examined carefully heaps of clay ashes, amounting to many hundreds of loads, that have been burnt and applied to great profit on this soil. By paring and burning you have, therefore, on it the common manure found in vegetable ashes, and you have in addition a substance which acts mechanically. Hitherto, he says, who wrote from practice, and whose writings abound with many just observations, remarks: I recommend burning of the surface as the cheapest manure, and most effectual of any; for it not only adds salts to the soil, which the burning of grays-roots produces, but it opens part of the stratum of clay next the soil, so much, that the roots of vegetables can afterwards feed therein; for when the turf of a piece of land has been burnt in heaps, at four or five yards apart, though all the ashes be taken away with some of the clay, and spread over the other parts of the land, yet neither corn nor turnips will grow so vigorously there, as on those places that were only opened by heat.

Almost near Guildford, Mr. Birbeck has found this practice highly useful on clayey soils. After remarking that by the process, that portion of the turf, which contains from three-fourths to four-fifths of the undecayed fibres, is at once converted into a substance the most favourable to vegetation; he has had the most decisive proofs of the preference of paring and burning, as he states, to following and toowing on the fresh turf on both clays and loams, and that he has never had occasion to notice the impoverishment from the former, which he had suspected; on the contrary, the reverie has been so obvious, as to amount, in his judgment, to very strong evidence, if not demonstration. And he believes, that if the crops on equal quantities of land subjected to these different processes, were accurately weighed for two, or perhaps three years, it would be found that the produce of the pared and burnt land would exceed that of the fallowed, by more than the amount of the whole turf consumed.

Near Beverley in Yorkshire, Mr. Mofs likewise gives an instance, within his own knowledge, of a farmer breaking up several cloths of old sward, one of the belt of which, about twelve acres, he ploughed out, and pared and burnt the soil. The first year he took 100l., the second 10l., and the third 50l. for want of paring and burning; the whole lots 250l., being more than 20l. per acre, at that time about three-tenths the value of the land. This was a fine sweet sward, and has not been superior since to the pared and burnt land, on account of cropping about twenty years. And on poor clay near Horncastle, Mr. Elmhurst, after properly draining such as wanted it, parcs an inch, or an inch and a half thick, about Lady day, a d gets it well burnt. So soon as all or a good part of the piece is burnt, he spreads all the ant-hills at a level as possible upon the ground between the ant-hills. He then has the ashes all evenly spread, and as soon as a tolerable rain comes, he has the whole well harrowed, and ploughed shallow furrow for turnips; and for the most part has had very good crops; which he always eats off with sheep. As the land is not broken up too deep, as soon as the turnips are eaten off, and the land is dry enough, he has it ploughed up again into small lands, about two inches and a half, not more than three deep; and with two more ploughings and harrowings in good time for fowing it with cloe-feed, and then barley. He has often had more than six quarters per acre, and the next year from five to six quarters per acre of wheat, upon poor land by this process; and in various parts of the country, where he has for many years occupied such lands, paring and burning such fort of land is the very best practice that can be used, as it tends to the enriching of it, by the greatest quantity of manure that can be obtained.

Also on poor cold clay, the same thing has been experienced by Mr. Maxey, in Bedfordshire. Thirty years back he broke up a piece of sward of this description, one part of which he pared and burnt, another he ploughed with hores, and a common plough, ground sharp, as thin as it could be, which part he also burnt; the remaining part was fallowed the succeeding winter. The part that he had ploughed by hores, which was about five acres, abounding with ant-hills which consisted entirely of clay, he was under the necessity of burning in large heaps, whereby a large portion of the offence was destroyed. On this he had more ashes than could be used to advantage thereon, and from which, after spreading a double portion, he manured eight acres in an adjacent field. Now, were burning fo prejudicial as it has been represented, this piece must have been utterly ruined. The two pieces thus burnt were prepared for wheat, and in due season fown therewith; the other with oats, which was a very poor crop, mowing in some measure to the grub and other insects, to which this kind of land is subject; and which in a great measure are destroyed by the preceding process; the wheat on both pieces was very thin, but that which was ploughed by hand was somewhat better, which he ascribed to the superior quality of the ashes, they being the product of the surface only, and burnt in small heaps. In the course of cropping that followed, the parts burnt were so much inferior to the other, that he shall not exaggerate if he says, he had more profit from an acre of that burnt in three years, than in five from the other part. It is worthy of remark, that those spots where the large heaps were burnt, on which was sown the face an acre, to the clay was comfumed to ashes, yet by their situation not to that degree as was the bulk of the heaps, the fire not being strong next to the ground, but so as to retain its efficacy, not only produced the most luxuriant crops at first, infomuch that he has been under the necessity of mowing them down twice, and yet has had so much at harvest; but continued for a number of years superior to any part of the field. When he has manured this field, he has avoided laying any dung thereon, and yet it is at this time, after a lapse of thirty years, equal to any part of the land. This confirmed him many years back in the propriety of burning, as it is a de.

PARING.
PARING.

the better. For the above reasons, he recommends paring by hand in preference to that by the plough. In further proof of the advantage of burning, he relates a recent experiment of two neighbours in an adjacent parish where an inclosure took place five years back, at which time they had each a portion of waste or common laid to their allotments adjoining to each other of equal quality: the one who is the proprietor par ed and burnt, and sowed in succession with cole,

barley wheat, wheat, barley: all of which were good crops. The land is at this time under water-ears, which he proposes feeding off with sheep, and fowing it with wheat again in the autumn. Although he cannot recommend such a course of cropping, yet he doubts not, as ‘the prices of the produce hath been so high, that he will profit very much thereby; and that its own produce of dung will more than compensate the expense. The other farmer, who is a reaper, (probably like the majority of reapers, under some injudicious restraints laid down by some farmer’s land taper), followed his land in the winter, sowed barley, oats, col-led feed, and barley, all of which were very poor crops. The former calculates that he has made a profit from fifteen to twenty pounds an acre more than the latter, and that his land is in a far superior state for any succeeding crop. It is objected that land which is burnt will not bear clover, the fallacy of which he has proved in many instances, having always found the clover on such land to be equal to that on land which is not burnt; but this he has also discovered, that no land of this description will live, either burnt or not, will bear clover to advantage; it must first go through a course of cropping of at least five or fix years, when it will be of a better texture for that purpose.

Loamy Soils.—These are, Mr. Young says, especially when good, those upon which the practice has been most confined; but here we have some experiments to recite, which, in his estimation, let the matter in its clear light, that nothing more is necessary than to recite them very shortly. Mr. Wilkes, of Measham, in Derbyshire, has for many years been in the practice of ploughing old rough pastures, the soil a stiffish loam, eight or nine inches deep, and burning the old furrow in heaps of thirty or forty bushels each, the fires lighted by a few coals, and coal-flack: the effect was very great, and the improvement immense and durable. Mr. Wilkes is of opinion, from the experience of many years, that even this burning, which is twenty times the depth of common paring, does not waste the soil in the leaf, but does not more than break the texture of stiff soils, expelling a great quantity of water; that by expostition to the atmosphere the land re-aborsits its water, and by the great immediate fertility, fills itself presently with more vegetable particks than it had before. Thirty years ago his father burnt at Overlake, exactly in the manner described, a field of ten acres, which was not then, and has not since been treated with any more favour than the fields adjoining, yet it has ever since retained a superiority. And the writer, in 1790, in his renamed old-grafs-field of four acres and a half, of cold, wet, poor loam, on a clay-marle bottom; the rent, 9s. an acre, and not worth more in its then state, perhaps, than 7s. In 1791 he ploughed four acres of it four inches deep, which was the whole depth of the soil or surface, of different colour from the jtratum beneath, between that surface and the clay-mark, and burnt the whole furrow of the part so ploughed. Having no coal-flack, and wood being dear, he made but four heaps in the field; the consequence was, the heat and degree of calcination were far beyond what is ever practised in common, and many persons who knew and approved of paring and burning in the common way, pronounced the field completely ruined. The aires were sowed, and ploughed in with a shallow furrow, and turnip-feed sown, and very slightly buf-harrowed. The crop was very fine, worth, to sell for feeding on the land, at least 50s. an acre. The crop on the burnt part double to that of the half acre.

And after feeding them with sheep, the land was ploughed thrice, and sown with oats and grars. The oats produced above seven quarters an acre, and the grars has ever since been much better worth 20s. an acre than it was worth 5s. before. The oats on the half acre were not threshed separately, but judged by those that viewed them to be much inferior to the rest. About half the field have since been dressed with earth and road fallage, and once turned slightly. It is remarkable, that in three years after, an extensive growth, common in the country, the feed heavy, and which, therefore, could not be carried by the wind, began to appear, and has been increasing ever since. There is at present no perceptible difference between the part burnt and the other not burnt; if any thing, the burnt is best. These two experiments prove, if any thing can, that paring and burning does not lessen the oil, in its most efficacive application, and that it works a very great improvement on loams.

Likewise upon stony-braft and light loams, near Bristol, the Rev. Mr. Swayne has experienced the advantage of this process: he, indeed, has remarked, in more instances than one, the beneficial effects of combustion, in promoting the growth of vegetables on red or yellow ferruginous clay or till, which have long been ranked among the most unfertile of soils. It is that the mineral oil, with which these soils abound, and which in its natural state may be the cause of infertility, is by the action of the fire wholly diffilled, in the case of the clay being burnt red, and converted into carbonaceous matters, when that is burnt to a black cinder; or, is this effect, he asks, produced chiefly from the mere till, or from other grars, common in the country, the feed heavy, and which, therefore, could not be carried by the wind, began to appear, and has been increasing ever since. There is at present no perceptible difference between the part burnt and the other not burnt; if any thing, the burnt is best. These two experiments prove, if any thing can, that paring and burning does not lessen the oil, in its most efficacive application, and that it works a very great improvement on loams.

But the following detail of a field par ed and burnt, may possibly be thought of more confectious to the present inquiry, than the before-mentioned small and unfinished experiment. A small close of old grafs lay of between two and three acres, the soil a lightish hazel loam, of about eight inches stape, upon a clay subsoil, beneath which, at the depth of two or three feet, several strata of clays, which will burn to brown lime, was let, in the year 1796, to a common labourer, for the term of five years, at the rate of five guineas per acre per annum, to be ploughed up for potatoes, or any other crop he might choose to raise. In the month of February the turf was par ed with a bread-plough, and burnt in the month of March, the aires then sowed, and the ground immediately ploughed. In the months of April and May it was planted with potatoes. The summer being rainy, it was found that the potatoes had been planted too thick. The strength of the fresh ground mantled with the water flowing, caufed them to rot much to his haum. However, fifty-six aires of potatoes were dug from fifty perches of ground. The second year it was again planted, the greater part with potatoes, some part with wheat. The produce was not ascertained. After the potatoes were dug up, part of the ground, exactly half an acre, was sown with wheat in the beginning of December. The wheat was hoed in; that is, drills were opened with the potato-hoes, at about nine inches apart. When one drill was opened, the seeds were scattered therein as evenly as possibly by hand, after the rate of about one bushel to an acre. In making a second drill, the earth hoed thereout covered the wheat sown in the firft, and so on. The crop of wheat, owing to the
the uncommonly wet season, run much to straw, but its produce was sixteen bushels, or after the rate of thirty-two bushels an acre; a very bare crop in that unpropitious season. The rest of the field was planted with potatoes; no account taken of their produce. The fourth season, two roods and a half were tawn with wheat, the fort red lammas, in the same manner as in the former year; the produce nineteen bushels. A better crop, by fifteen bushels an acre, than any farmer's in the neighbourhood. The straw was purchased by the writer at two guineas and a half.

Sandy Soils.—In regard to sandy soils, it is remarked by Mr. Young, that Hitt, a practifer of this husbandry, observes, that it improves sandy soils as much as any other; and he has seen some fields thus worked in Suffolk and in Cambridgeshire, and improved by it, though under a course of crops by no means ammissible. There is not the least reason, from analogy, to doubt the effect on this, or indeed on any soil.

And in Sussex, Mr. Baldock found vart advantage from the use of this mode of breaking up poor sandy soils on an extensive scale. In the course of twelve years, the land broken up in this manner has coll. 40. per acre, but the produce which has been afforded has been fairly estimated at 200. per acre in the former years.

Also, on this skinned warren land, near Spilby, Lincolnshire, Mr. Kerthaw has found this practice beneficial. In the year 1782, he entered upon a farm of nearly seven hundred acres of land, which had chiefly been in a warren, and was at that time of very small annual value. A considerable portion of this land was pared and burnt, and found to answer his most fanguine expectation. The crops were full as much more as from the land which was broken up and tawn in the common course of husbandry. In order to prove this assertion, he mentions two or three circumstances of the proceeds and conduct. At Michaelmas 1782, he entered on the largest part of the farm; he had, amongst other lands, a walk containing forty-five acres, valued to him by the quitting tenant, from that time till Michaelmas 1783, at forty shillings. He mentions this to have the poverty of the land, which was so thin skinned, that to have pared and burnt it was not practicable; he therefore, the year following, ploughed it up and fowed it with oats, the crop of which was scarcely worth the labour. The fummer after, working it well, and getting it into good condition, he fowed it with coltsfoot, and it produced but a scanty crop. The spring following he laid thirty acres of it down with fainfain, of which he had good crows for several years. When it was worn out, having a good deal of rough grasses up on it, he pared and burnt it, and got a good crop of turnips, considering it was a very dry seasion; after which, he fowed it with oats, and had a remarkably good crop for the kind of land, more than fix quarters per acre. The year following he fowed it with turnips and cole, which were decent crops; cut them off at Michaelmas, and fowed the land with wheat. The middle of February he laid about three quarters of foot per acre, and the latter end of April laid it down with a none of white clover, and two bushels of rye-grafs per acre, and harrowed the feeds in upon the wheat; the latter yielded near a chaldron per acre, and a finer crop of Feeds could not be seen. He has continued them ever since, and the land has kept three times the flock it was ever known to do before. This early fews the utility of paring and burning; in proof of which the thirty acres so cultivated, part of the forty-five valued at forty shillings, are now worth from fix to eighty shillings per acre, for the fame period of time.

The other fifteen acres of the best land he worked in the common way, without being able to get any turnips; the crops of corn were scanty, and the feeds did not afford more than a proportion of two-thirds for the feed of sheep. In the year 1791, he pared and burnt another piece of fainfain, about eighteen acres; also a piece of grass feeds twenty-five acres, on both of which he had remarkably fine crops of turnips.

Likewise on poor, gravelly heath land, Mr. Wright, in Rutlandshire, has found this practice to answer perfectly. In March 1799, he began grubbing, paring, and burning a twenty-four acre piece of this heathy land; in June, fowed it with turnips, on one ploughing, not suffering the plough to exceed the depth of two inches, left the ashes should be buried, and out of reach of the turnip to take. As harrowing this tough sod would have made it lie worse instead of better, the feed was tawn, and only bush-harrowed. The plants came up true and well; but, after hoeing, the places where the fires had been, grew, if possible, ten times as fast as those where there had been none, notwithstanding there were no ashes left on those spots. This shews the amazing fertility of fire, and is a lesson to him and all future burners, to make their heaps as small as possible, so as to enable the fires to cover as much of the surface as may be; for, if all the ashes be swept off, and even some of the surface pared off, it will still be superior to the ashes, as he fully experienced. Another advantage arises from making the heaps small, which is the quality of the ashes; the larger the heaps, the more intense the fire, and the centres of such heaps get too much burned, as may be seen by the redness of the ashes; those on the outside being perfectly black, and very little inferior to foot. This ground produced a most excellent quality of turnips (as indeed all burnt ground does), 21. 10s. per acre. He afterwards sowed with barley on one ploughing, in March; a finer crop he never saw (quality of land considered); it was estimated at five quarters per acre, throughout the piece, but not yet threshed; clearing to him as much in one year (and consequentlly a proportionate benefit must accrue to the nation), as it would have done by pailourage, in its original state, in a century.

Chalky Soils.—Mr. Young observes, that in respect to thefe, we have a much more ample field of experience, for it has been, and is the common method of breaking up downs in every part of England. On the Cotifield hills, in Gloucefelterfide, it is the common husbandry, and often repeated. The deep walks and warrens on the downs of the east riding of York, and of Lincs, have thus been brought most profitably into culture, though not with the attention in cropping that ought to have been given. In Hampshire and Wilts, the fame husbandry prevails. In these countries, he has been fewn lands that have been pronounced ruined by this husbandry. The cropping was bad, but still the rent had been doubled by the practice. It is stated in his Eastern Tour, that, in the well riding, colonel St. Ledger remarks, that if burning waffe the foil, his lime-fonne lands, only four inches deep, would have been gone long ago, as it had been pared and burnt for ages.

In Kent, he lets Mr. Boys speak for himself: who observes, that if any persons who condemn paring and burnings should come into Kent this summer (1795), he can shew them several scores of acres of wheat, barley, oats, and fainfain, now growing on land which has several times undergone that operation. The crops of sufficiency value to buy the land at more than forty years' purchase, at a fairly estimated rent before the improvement. It is humbly presumed, that Mr. Hairs. Kent, Claridge, and Pearce, the great enemies of paring and burning, will not pronounce this land ruined by that extreame practice.
PARING.

And in the experience of Mr. Birbeck, near Guildford, in Surrey, on a chalky soil, two fields, making together about fifty acres, were laid down in an exhausted state. When they had acquired a turf, one received a farmer's winter's fallow, the other was pared and burnt; and both were sown with barley and beans. The effect was strikingly in favour of the latter, both in the barley and beans which followed.

And another field of the same quality, twenty-two acres, was pared by the plough in the spring of 1799; and about half of it was harrowed repeatedly during the summer; the weeds of the season prevented the burning; but as the turf was completely killed, and much broken by the harrow, this part of the field became good fallow. The remainder was not being disturbed, set again; and, the following spring was nearly as green as before. In the succeeding summer, the operation of burning was thoroughly performed: where it had not been previously broken by the harrow, the entire turf, down to the chalk, was subjected to the fire; and in the other, that newly decomposed by two years' fallowing, enough was burnt to produce a tolerable sprinkling of ashes, to stimulate vegetation, if that were their property. This field afforded a fair opportunity of deciding between the two modes of reducing old turf to tillage. He expected that, in this instance, the fallow would have taken the lead by the help of the ashes; but in the turnips now growing, the seeds are very much in favour of the pared and burnt land.

佩蒂土.—Mr. Young states, that whatever variety of sentiments there are on this method, for other soils, here there can be none. The universal practice, from the flat fens of Cambridgeshire to the swelling bogs of Ireland, the mountainous moors of the north of England, the rough fedy bottoms, in almost every part of the kingdom, where they are broken up by men of real practice and observation, are always done by paring and burning. Regulated experiments of doing it by fallowing, are to be met with in various works. The Board's reports of the North Riding of York, and of Somerset, detail some; others are to be found in his Tours; and the result is either loose, or a profit so very inferior, that the question ought to be considered as settled and done with. Let it sleep for ever, except for the wrong-headed individuals who will, upon every question, arise in every age to contradict the common sense of mankind.

Paring.—In the method of performing the process there are some slight differences in the practice of different districts; and perhaps in managing this business, an attention to the nature of the lands may be as necessary as in other cafes of husbandry: as it would seem that, as those of the more clayey and heavy kinds, would be most benefited, by having the fire to come as much as possible into contact with the whole of the superficial parts of them, without being carried too far; as by that means they may be rendered more proper for the reception of the roots of vegetables, after being lightly burned, as well as more suitable for supplying nourishment to them; while in others, as those of the more light and thin descriptions, it might be most advantageous to merely confine the thin paring of fward after being piled up for the purpose; without permitting the fire to exert its influence upon the mould or foil immediately below, as in this way there would not probably be so much danger of injuring the花费 by destroying the vegetable matters contained in such soils. Of course, that in the drift of these modes of burning the fward, the sods or parings should be piled up as little as possible into heaps, the advantage of a suitable feland being taken to apply the fire to them in the state in which they lie, or are set at first after being cut up, or after a few only have been placed together, as happens in some instances, where they are, immediately after being cut, set on edge to dry, and placed in perpendicular directions, in order to prevent them from falling over; but in the latter cases they should be formed or built up in little circular heaps or piles, some what in the form and size of the little cocks made in hayfields, the sods being placed in a side downwards, in order to admit air; but the openings both at the bottoms and tops, after they have been fully set on fire by some combustible substance, such as straw, &c. are to be closed up, as is the case in others, and the fire allowed to proceed by the addition of sods; so that the combustion may proceed in a slow, furthering manner, such as is practiced in the making of charcoal.

When the whole of the earth in each of the piles has been acted upon by the fire, the heaps may be suffered to extinguish themselves by slowly burning out.

And there is another method of practice of this kind, which is much in use in some districts, as in Devonshire and Cornwall, for breaking up and preparing grass lands for the reception of what have been termed fallow crops, which is that of flaiting, in performing which, a part of the fward or surface is alternately left unturned, upon which the next thin furrow slie is constantly turned, so that the fwards of each come in contact, by which means the putrefactive fermentation is speedily excited, and the greenest part of the grassy vegetable matter converted into manure: what ultimately remains undestroyed being, after repeated crofs-cuttings with the plough, and harrowings, all the mould or earthy matter having been previously well removed from the roots of the plants by flaiting, collected into small heaps, which is done either by the hand, or with iron-headed rakes, coUecting them from the surface, and burning the ashes being then spread evenly over the land. The operation, when managed in this way, is termed beat-burning, and would appear to be the most proper and useful on land, where the turf or fward is not very tough or matted together, and where there is little or no coarse vegetable products growing upon the surface of it.

In separating the fward from the surface of the soil, different implements are made use of in different parts of the island: that which was the most employed in the infancy of the art, was a kind of curved mattock or adze, about seven or eight inches in length, and five or six inches in breadth; and which, from its shape, would appear to have been better adapted for cutting up the roots of brufh-wood, furze, broom, or other coarse shrubs, than for paring off the surface of a field free from such incumbrances. This instrument is, however, it is said, common in the south; western districts; and that, though it no doubt retains in a great measure the shape of the instruments livid used for the purpose in that part of the country, when the lands were in very different state; yet the labours, who are in the practice of using it, are able to pare off the sod with great dexterity and dispatch. But in other districts, where the sod is pared off by manual labour, the ordinary breakspade, (in some places called the break-plough, and in Scotland the flaughter-spade,) is mostly employed. The iron, or cutting part of this implement, is about eight or nine inches in length, and from ten to twelve inches in breadth, having frequently a kind of edge rising up a few inches at the right-hand side of the turf, next the unmov'd fward. This instrument, which is formed with a fine edge, is forced forward by the strength of the arms of the person using it and by pressing the break against that part of the frame or shaft which is held in the hand. In working the tool, the...
the labourer generally cuts the sods at about an inch or an inch and a half thick, and from ten to twelve inches broad; and when the spade has run under the sod to the length of about three feet, he throws it off by turning the instrument to one side, and proceeds in the same way, cutting and throwing over the sods, the whole length of the ridge. In this way of performing the operation, the labourers, by following each other with a slice of the spade or surface of the land, accomplish the business with much ease.

There is another implement that is sometimes used for paring the sod, which is the horse-paring-plough, and is made of different contrivances, according to the circumstances of the ground to be pared. In the feney districts on the eastern coasts, where paring and burning are practiced on a large scale, they have ploughs constructed for the purpose of a particular form, but which vary from the common ploughs chiefly in the breadth and sharpness of the share or fock. They are admirably calculated for paring off the sward or sod of such grounds as are level, and where neither stones, bruish-wood, ant-hills, nor other impediments obstruct their progress; but where such obstructions present themselves, the broad-spade, or common team-plough, with a small alteration of the share, will be found preferable, both in respect to the extent of ground that can be pared, and the superior manner in which the work in such cafes can be performed. Ploughs, from their great expedition and regularity of performing the business, should always be made use of where the nature and situation of the land will admit them, in preference to such tools as require manual labour. In some of the western counties the common plough only is used. There the old grafs field, when it is proposed to burn the sward, are rib or slob-furrowed about the beginning of winter; and being again crofs-ploughed the following spring, the sods are collected and managed in the manner mentioned in speaking of sifting. In those cafes the plough has, however, a wing turned up on the furrow-side of the plough-share, by which the furrow is cut any breadth required, the work is also sometimes done by means of the spade, mattock, and broad-plough, in such cafes.

Mr. Young states, that in the fens of Cambridgeshire, upon a peat soil, free from large roots and stones, the work of paring is always done with a plough, which they make on purpose for the work, and which executes it in the completest manner that can be imagined. It turns off a furrow, from 12 to 16 or even 18 inches broad, and not more than an inch deep. The use of this admirable tool brings down the whole expense of paring, burning, and spreading the ashes, to 9s. or 10s. per acre. But upon those soils, when they have not been in a state of cultivation, such a plough would not work.

But in old meadows and pastures, this sort of work is done with the break-plough, as it is called, which is pushed on by strength of body, the thighs being armed with wooden guards. It is hard work, and now commonly paid for, including burning and spreading, from 25s. to 40s. per acre. An inch, or an inch and a half, is the common depth; but some farmers prefer two inches, for the sake of more ashes. The thinner it is pared, the more certain the burning, should the weather prove unfavourable. Considerable tracts of heath and down-land, on a weak, thin, loamy land, with a calcareous bottom, have, within the last five years, been thus broken upon Newmarket-Heath, at the expense of 30s. per acre, and immense crops the consequence. And the moors and mountains of the north of England, Wales, Devonshire, &c. when broken up for cultivation, are often, and ought always to be reduced by this practice. It has long been common husbandry in those counties, and is, therefore, done cheaper, from 24s. to 30s. per acre. However, draining should precede it.

The months in which the greatest quantity of land is pared and burnt, are April, May, and June. The particular period must, however, always depend much on the state of the weather, the nature of the crop, and the farmer's convenience. When the east winds prevail, in February and March, this sort of business may sometimes be carried on. But for accomplishing the work with the greatest dispatch, and also with the least trouble and expense, a dry season is obviously the best. The prudent farmer should not embark in the undertaking, unless there be a reasonable probability of his accomplishing it while the weather keeps dry and favourable. The latter end of May, or the beginning of June, when the hurry of the spring feed time is over, in the more northern districts, when a number of hands can be most easily procured, may upon the whole be considered as the best and most convenient season; as at this period the green vegetable products are in their most succulent and full states, and of course may probably afford more saline matter; but in the more southern counties either a much earlier season must be taken, or the interval between the hay season and the harvest time must be fixed upon, the latter of which is, on the principle just stated, evidently the best, where the extent of ground to be burnt is not too large. In other seasons it would frequently be impossible to procure a sufficient number of hands for performing the business. In bringing waste lands into cultivation, where an extensive tract of ground is to undergo this process, the autumn may, in many cafes, afford a convenient opportunity for the operation.

As the crops, that are sown after paring and burning, are various, and as the season for performing the process, in many cafes, depends, in some measure, on their nature, it may be observed, that when rape or turnips, which are the most prevailing crops in such circumstancies, are to be cultivated, the end of May or the beginning of June will be the most proper time: but if barley or oats are to be sown, the paring and burning must be completed as early in spring as the nature of the season will admit; and when lands are pared and burned as a preparation for a crop of wheat, July, or even the beginning of August, may, in favourable seasons, answer; but it is better to have the ground ready sooner if possible.

The depth to which lands of different qualities may be pared with the most advantage differs much; but as it can hardly be proper to pare light, thin, stapled soils, to the same depths as those of the more deep and heavy kinds, it should, in some degree, be regulated by their particular nature, and their differences in respect to depth and heaviness. Mr. Boys, however, who is in the habit of breaking up thin chalky soils, and such as have been in tillage this way, observes, that in Kent, where the method of paring mott in use is with down-shares or break-ploughs, they take off turfs as thick as the nature of the soil will admit, from half an inch to two inches; the thicker the better, provided there be a sufficient portion of vegetable matter contained within them to make them burn well. The most usual depths of paring are from about one to three inches.

**Burning.**—When the season is not very wet, the turfs will commonly be sufficiently dried in about a fortnight or three weeks, even without being turned; but in rainy weather they require a longer time, and must be turned more than
Paring.

than once to prevent their flaking out roots and shoots, which might hinder them from burning. And that as soon as the turfs have fully undergone the processes of burning, and are reduced to the state of ashes and a powdery earthy matter, the whole should, as soon as possible, be spread out over the land in as regular and equal a manner as the nature of the work will admit of; for without great attention in this respect, great inequality in the crops may take place; besides, the foil will be made lighter in some places than in others, which may be disadvantageous in the same way. The spreading, where it can by any means be accomplished, should always be performed before any rain falls; as where this point is not attended to, a great loss may be sustained by the faine matter being carried down in a state of solution, and their beneficial effects in a great measure lost before the crops are in a condition to receive them. In order to secure the full influence of the ashes, the land is frequently lightly ploughed over immediately after the ashes are spread out. And Mr. Donaldson states, that those, who are more than ordinarily attentive in this respect, only rib or shallow furrow the field, so that the ashes may be got covered up with the greater expedition and dispatch. By this mode they cannot probably, however, be so equally mixed with the soil as by that of ploughing the whole field with a very light furrow, so as just to cover them. It is remarked by Mr. Young, that in this business, the heaps should not be made large, twelve or fifteen bushels of ashes are large enough; twenty may be admitted, but if much larger, the turfs will be too much burned. This must, however, depend, in some measure, on the weather; for the worse that is, the larger the heaps must be. It will also depend on the thickness of the turf. Thin flags will burn in smaller heaps than thick ones.

It is evident that the expence of the operation of paring and burning must vary according to the nature and situation of the land, the method in which it is performed, and the customs of the district in regard to the price of labour. On the thin sort of chalky soils it is flated by Mr. Boys, who is accustomed to have such land prepared by this means, that the expence for paring at a moderate thickness, where the land is not very flinty, is twenty shillings per acre; for laying it up in heaps and burning, ten shillings; and for spreading the ashes, three shillings; and that a coat of manure is thus produced on the land of from eighty to one hundred and fifty cart loads per acre, for the trifling expence of thirty-three shillings. A hundred cart-loads of dung purchased from neighbouring towns and villages, at the distance of three miles from the land, would cost, carriage home included, ten times the price of down-hairing, and yet would not improve the land more. But that, where the land is well covered with turf, it may be ploughed for burning about two inches deep, with a common plough, drawn by a pair of horses, early in the spring, and as soon as a drying wind sets in, the turf be laid in heaps, and burnt by labourers for one pound one shilling per acre, which will produce near two hundred cart loads.

In some few districts, where the original surface is rough and unequal, from great tufts of rushes, &c., called haflocks, Mr. Young states, that some persons cut them with spades at the expense of five or ten shillings an acre, and others with the plough. Paths for the horses are in that case to be cut by hand, and the plough made on purpose, and called a haflock plough, cuts laterally much beyond the line of its draught. But opinions are said to be in general, that the hand-work is the cheaper; in either case, the haflocks are dried, heaped, burnt, and the ashes spread. After this they go over it again with a very complete and effective tool, called a fen-paring plough, the furrow of which is burnt: the expence of this business in different cases has been given above.

Cropping.—In the management of land by this process, it is necessary to attend to such a mode of cropping as will tend to its improvement, whatever may have been the manner or kind of foil in which the process was performed. Without a nice and exact attention in this respect, much injury may frequently be done, and a useful practice be brought into disrepute. Where the nature and situation of the land will admit of them, as in the lighter sorts of soils, the growing of turf crops, to be consumed on the ground, would seem to be more proper for the first year; then white or grain crop, as oats, or wheat; after that turnips again, or, in some cases, peas, beans, or some form of green crop, to be eaten off, if possible, by sheep; and lastly, a grain crop with grasses seen: but on the heavier sorts of lands, where the turnip husbandry cannot be so well introduced, cole, clover, and bean crops, may often be interposed between those of the grain kinds with the most propriety and advantage. And it would seem that the interposition of green crops ought on the whole to be more frequent in the former sorts of soil than in those of the latter, on account of their containing, in general, a less proportion of vegetable matter. It is often attended with great advantage to apply some sort of manure, such as lime, with the second crop of turnips in cases of these kinds. It has been observed by Mr. Young, that upon high moors, in undertaking new improvements, it may be of singular importance to gain straw. In that case, to sow oats upon the first burnt lands may be admitted, but in general it is much more correct to leave the ashes ploughed in for sowing turnips upon all the land burnt in March, April, or May. This preparation is unexceptionable for potatoes, so that if this root be wanted, it may be planted in April on the land burnt in March.
