In writing the article Escapement, which is that portion of a clock that transmits the maintaining power, in a modified way, to the pendulum, we found it necessary to explain at some length, how the natural scale of forces, arising from gravity alone, is disturbed by the accessional of any external force, such as is derived from the maintaining power; and by a reference to figs. 1. and 2. of Plate XXXI. of Escapements, we proved that this scale is most deranged, when the external force is applied at the extremity of the arc of excursion; and least, at the lowest point of the said arc. We also showed how to estimate, in any point of the arc, both the force applied at that point, and the velocity with which the pendulum is moving there; as well as determined the total arc corresponding to the maximum of velocity, and other particulars of essential importance both in the theory and practice of clock-making. We will, therefore, request the reader to consult our introduction to the article Escapement, so far as it relates to the pendulum, before he proceeds to peruse the remainder of our present article. Indeed, the different parts of a clock are so intimately and mutually connected, that the action of one frequently cannot be clearly explained, without at least a partial explanation of the properties of the other; which is the reason why we have anticipated several particulars relating to the motion of the pendulum, before we arrived at our present article.

Of the Simple Pendulum in Horology.—When a pendulum was first applied to be the regulator of a clock, the crown-wheel escapement was used with it by Huygens, and the pendulum was necessarily made to vibrate in long arcs; but it was soon found that it had at least three defects: 1st, the maintaining power acted on the wheel, and consequently on the pendulum, by means of the fork, almost constantly, thereby producing an alternate acceleration and retardation of motion beyond what gravity alone would produce; 2ndly, the times of vibration in the longest arcs were found
to be slower than in the shorter arcs, in the proportion of about 34 to 29; and, daily, the verge of the pendulum itself was found to have its total length increased or decreased by variations of atmospheric temperature. Hence arose the necessity of new ecafements, and of different modifications of the pendulum, to make it act as an uniform regulator of mean time under all circumstances. As we have had occasion to describe different pendulums, and also the parts connected with them, such as the fork that gives it motion, the cock by which it is suspended, the spring of suspension, the verge, the bob, and screw of adjustment, &c. (see Clock, and Clock-Making,) a repetition of what we have before said would be superfluous. We will, therefore, take it for granted that every one, that has been an ordinary clock with a seconds pendulum, which, with Dr. Hooke's anchor ecafement, is called the royal pendulum, knows its parts and construction. The true length between the centre of oscillation and axis of suspension of any pendulum is best ascertained by adjustment for rate, first, from hour to hour roughly, and then from day to day, either by the going of a good clock already adjusted, or by a transit of one of the heavenly bodies. (See Chronometer, prob. vii, viii, and ix.) But from what we have said under our article Escapement, it will be seen that the length of any pendulum will require to be a trifle more or less, accordingly as the external impulfs, derived from the maintaining power, is great or small, permanent or temporary, gradual or intcraneous; or, which is to the same effect, accordingly as the ecafement has a recoil, is of the dead-bolt fort, is detached, or has a rempintoire. When, therefore, we speak of the acting length of a pendulum, we must always have a reference to both the quantity and quality of the auxiliary force that perpetuates its motion. In ordinary cafes, an additional force applied in aid of gravity accelerates the pendulum, and requires a compensation by adjustment, as will be seen presently, for additional length. This adjustment was made by Huygens, by a small ball moving along the verge above the bob, but is generally effected by a tapped nut at the inferior end. This method is, however, inconvenient, inasmuch as it requires the pendulum to be flopped; for which reason, in many regulators, or astronomical clocks, the adjustment for rate is made at the superior end, above the cock. For the shape and size of the bob of a given pendulum, we must refer to our term Bon, in its proper place, where we have entered into a minute detail of the particulars relating to its shape and size, with a given maintaining power and ecafement, both which must be considered at the same time; but further experiments are perhaps wanting, in this department of horology, to determine the best possible combination of all the requisite agents in a moving pendulum, including the suspension. The metal of which the verge is usually composed is iron or steel; but their expansion by heat, and contraction in cold, render them improper substances for an accurate pendulum: for, in the extremes of temperature, the rate will alter by an iron pendulum more than 20" in the 24 hours. Straight-grained deal or fapadillo, well fished, is better for the verge than metal; though these, and indeed all sorts of wood, are subject to changes, from moisture, if not from heat, and therefore cannot be entirely depended on, in all seasons of the year, where great accuracy is required.

From what we have here had occasion to state respecting the motion of an attached pendulum, it will be evident to our readers, that our deductions with respect to the exact length of the detached one, where the accelerative force was considered constant and uniform, will not be strictly accurate when that force is variable, which it is more or less in its attached state: we will therefore conclude our remarks on the simple attached pendulum, by shewing in what degree the length of such pendulum is affected by any accelerative force. Whatever this force (F) may be, the time of a body's falling down half the length of the pendulum, by the laws of acceleration, will be

$$T = \sqrt{\frac{\sqrt{\frac{S}{m}}}{2 m F}}$$

where \(m = 16\frac{1}{2}\) feet, and \(L = \) the length of the pendulum, and \(\pi = 3 1416\); therefore \(T = \sqrt{\frac{L}{2 m F}}\). If \(T\) be given, then \(L \propto \frac{1}{T^2}\); that is, the times of vibration of pendulums of the same length vary inversely as the square roots of the accelerative forces; and if \(L\) be given, then \(T \propto \frac{1}{\sqrt{F}}\); namely, the lengths of pendulums vibrating in the same time vary as the forces which accelerate them.

The accelerative force, added to the natural force of gravity in a clock, is usually called the maintaining power, and may be derived either from an appended weight immediately through the ecafement, or from a spring or springs wound up by a weight at short intervals; and in either case the quantity and mode of its action will be limited by the nature of the ecafement adopted; and frequently the spring of suspension is so tapered upwards or downwards, as to become a moddier of the maintaining power, in conjunction with the ecafement, all which circumstances must be taken into the account when the nature and quantity of the extraneous force is estimated.

Before we conclude our account of the simple pendulum, we will just mention that such pendulum vibrating in a given time, in a given situation on the Earth's surface, has been propounded as a perpetual standard of linear measure. Hutton, we understand, first propounded this subject for the consideration of the Society of Arts at the Adelphi buildings, (vol. i.) and Mr. Whitehurst took up the subject after him, and contrived a method of ascertaining the difference between the lengths of a seconds and half-seconds pendulums, by means of an apparatus, which afterwards came into the possession of Dr. George Fordyce, who improved it, by adding a compensation to the pendulum, and gave an account of it, with drawings, in the Philosophical Transactions of London, of the year 1794.

We may also mention here, that Huygens, in his "Horologium Oscillatorium," proposed a circular or circling pendulum, to move in the concave side of a parabolic conoid, the circuits of which would be performed, be laid, in equal times, when the mechanism is properly adjusted; but it would lead us beyond our mark in this place, to pursue this part of the subject further. See Horol. Oicil.

Of compound or compensating Pendulums.—If any substance, sufficiently long for a pendulum, could be found in nature, that has not its dimensions enlarged or diminished by heat or cold, such substance would be the most suitable for a simple attached pendulum; but all attempts to discover such a substance have hitherto been ineffectual. (See Expansion.) Hence different contrivances have been devised by ingenious
men, to counteract the effects of variable temperature in the pendulum, and some of them have succeeded in effecting this desirable purpose. So long ago as the year 1648, the different expansibilities of various metals was known by Wendelin to exult, and in 1715 that ingenious artist George Graham made several experiments with the pyrometer, invented by Mulochenbrock, to ascertain the relative quantities of expansions of different metals, with a view of availing himself of the difference of the expansions of some two or more metals, when opposed to each other, in the construction of a compensating pendulum, but the difference which he detected, between iron and brass, for instance, was so small, that he relinquished all hope of being able to accomplish his object in this way, and therefore gave up the project. (Phil. Trans. London, 1726.) However, it occurred to the same artist, that mercury was affected by changes of heat and cold sufficiently to answer the purpose of keeping the centre of oscillation of a pendulum always equi-distant from the point of suspension, provided the mercury could be made to ascend while the verge of the pendulum descended, or elongated, by any degree of heat; and vice versa. In 1721, the trial was made in a pendulum, which we shall presently describe, and in which the compensation, after some adjustment, was found so complete, that its error in the extremes of temperature was reduced to ⅛th of the quantity observable in an ordinary simple pendulum. In the mean time, the idea of arranging metallic bars of different expansibilities in such a manner, so as to constitute a good compensating pendulum, being once suggested by Graham’s paper on the subject, roused the ingenuity of different mechanics, and Harrifon, a carpenter of Burton in Lincolnshire, in the year 1726, succeeded in completing the requisite arrangement. His rods of metal were placed in such parallel situations as to resemble those of a grid-iron, from which circumstance the pendulum, so constructed, has been denominated the grid-iron pendulum. Since Harrifon’s time, there have been various modifications of the compensating pendulums, both in England and France, the principal of which we shall describe in their order of time, but none of them have been found to excel the prototypes of Graham and Harrifon, which are still used, one or other of them, in the principal observatories. If any improvement has been made on the original pendulums, it is in the external appearance, and in the fuller modes of adjustment.

**Graham's Mercurial Pendulum.**—Graham’s mercurial pendulum, which may be considered as the first compensating pendulum, is represented in fig. 4, of Plate XXXIX. of Horology; A B is the verge confining of a rod of steel, carrying at its lower extremity a stirrup, B C, of the same metal, holding the glass cylindrical vessel, E F, on a circular plate, surrounded by a rim, to keep the vessel from falling out; this vessel was filled with pure mercury up to the letter F, near the top; and above there was space enough to receive more, in case the compensation should not prove on trial to be sufficient. The filling piece of metal, D, was adjustable to any part of the verge, for fixing the rate of going, and the compensation could be made more or less by adding to or deducting from the mercury. It does not appear certain, whether the glass vessel was chosen by conjecture, as to its size and shape, or was calculated previously, from a confederation of the relative expansibility and absolute specific gravity of mercury; but we are disposed to think, that it must have been from calculation, because it very much resembles the vessel calculated by Mr. Lowe of Iffington, for the mercurial pendulum recently made for the Royal Observatory of Greenwich, by Hardy. In this pendulum, as now made by Hardy, and others, the lower end of the verge is tapped, and descends through the top of the stirrup, where a milled and divided nut screws on, by means of which the adjustment for rate is made, without the sliding piece D, which is now rejected. One peculiarity of this pendulum is, that the mercury which is used as the means of compensation, constitutes also the weight of the bob. We are not made acquainted with the quantity of mercury used by Graham; nor yet with the particulars of Mr. Lowe’s calculation; but the vessel which the latter determined, as the most suitable, was cylindrical, seven inches and a half long, and two inches in diameter, exclusively of the thickness of the glass, which was one-eighth of an inch; the capacity proposed was for twelve pounds, but by eliminating the solid contents of such a vessel, and trying its bulk of mercury, from a table of specific gravities, we find that it will not hold more than ten pounds of this fluid, if so much. The depth to which Hardy’s vessel was proposed to be filled was 6 ¾ inches, but on trial at the Royal Observatory, it was found necessary to add 1 ¼ th more, and 6 ¾ inches are now found to compensate the steel verge so admirably, that the greatest deviation in the rate, during winter and summer, has never yet exceeded 3 ⅝ths of a second per day. The exasperation that acts with Hardy’s pendulum is of the remonstrate sort, acting almost constantly on the pendulum, and therefore requiring it to be somewhat longer than an exact standard.

**Harrifon’s Grid-Iron Pendulum.**—Though we have given a general description of Harrifon’s grid-iron pendulum, as made by Reid of Edinburgh, under the article Clock, (see Astronomical Clock by Mr. Thor. Reid of Edinburgh) to which we refer our readers, as well as to Plate XXI. of Horology, where it is represented; yet we feel it due to this ingenious artist, to resume our observations on his contrivance in this place. When Harrifon had determined the relative expansions of steel and brass to be very nearly as 3 to 5, it is probable that he realigned on the subject in some such way as this; let a rod of steel be suspended by its upper end on a fixed point, and let it hang freely in a vertical position, then to the lower end rivet the lower end of a brass rod, fo as to ascend parallel and contiguous to the iron rod, while it is supported by the rivet; if the iron rod be divided into five equal portions, and the brass rod be made just equal to the sum of those portions, what will be the consequence? Why the tops of the two rods will always preserve the same distance from each other, because the downward expansion of the longer iron rod will always be equal to the upward expansion of the shorter brass rod, consequently, if the vertex of the iron rod be made stationary, by being fixed to a wall or otherwise, the vertex of the brass rod will also be stationary as it respects the other. Let now the vertex of the iron rod be assumed as the point of a pendulum’s suspension, and let the vertex of the brass rod be the place for the centre of oscillation, then the centre of oscillation of a single rod, or of any number of similar rods, of uniform metal, is at 3/4 of the length from the point of suspension; but the common centre of oscillation will be still lower in a compound pendulum that has another rod, not of the same length attached to its lower end; therefore two rods fo united cannot produce a proper compensation, and at the same time have the immovable point at the common centre of oscillation. But the rods may be cut into any number of lengths that the due arrangement may require; we have seen that if the long iron rod be cut in two between the second and third portion, we shall have three lengths, one of iron ⅓ths of the long rod, one of brass ⅘ths, and another of iron ⅗ths, or equal to the one of brass; in every arrangement of the various lengths to form a compound pendulum, the
the rods of least expansion must necessarily expand downwards, and those of greater expansion must expand upwards, because these rods will be fewer in number, and the difference of the total expansions must compensate the last rod of the combination, by which the ball is suspended; accordingly the length of the verge must be \( \frac{1}{3} \) of the longer rod, and the other two each \( \frac{2}{3} \); but \( \frac{3}{4} \) longer than the required pendulum; this arrangement therefore in a seconds pendulum is inconvenient, making the pendulum too long; let the iron rod then have three lengths and the brass rod two, so that there may be two pairs of equal length and one to spare for the verge, to be compensated by the surplus of expansion of the brass over the iron; equal pairs of rods; this division in due proportions will make a pendulum of the requisite length, and will also prefer the centre of oscillation unchanged as it regards the axis of suspension; but there is yet an inconvenience to be surmounted; the two pairs of alternate iron and brass rods are to be united at both their extremities, each to the next contiguous rod, first below and then above, till they are all attached to each other, and the ball of the pendulum must in this case be suspended by the extreme rod, which will therefore make the vertical line fall diagonally across the parallel rods, and pull them to a distance from each other; but to prevent this evil the ball must hang from the middle rod, and also the rods must be braced to prevent their flying out; these requisites may be effected by employing two pairs more of similar iron and brass rods, at the opposite side of the iron rod, that carries the ball, for these additional pairs of bars will not otherwise affect the compensation, than do the same thing over again which the others did without them; and they will thus constitute a counterpoise by their weight, afford the means of a longer horizontal bracing piece, and prefer the coincidence of the vertical line with the middle rod at the quiescent position. Thus nine rods became necessary to constitute the grid-iron pendulum; and when they are well proportioned and nicely fitted into the holes of the connecting pieces, so as not to touch one another, nor to have friction in the holes, the pendulum completely answers its purpose in all variations of temperature, and may be brought to time, like the simple pendulum, by a few of adjustment either at the cock of suspension under the ball, or at the point of oscillation. But the proportions of the alternate rods may not produce the exact compensation; that is, the pendulum may be either over-compensated or under-compensated; the adjustment for compensation, when that is necessary, is usually made by altering the position of one of the horizontal connecting pieces of brass, by taking out the pins and inflicting them again into other holes, drilled in some of the bars to answer this purpose. This adjustment, however, is troublesome, as it cannot be made without detaching the pendulum, and putting it probably out of its rate of going; and this inconvenience constitutes one of the principal objections to this construction of the pendulum, for which there appears to be no remedy yet devised. For the construction of a grid-iron pendulum rods, drawn into wire, are preferable to square rods, both on account of their having less friction, and of their being more exposed to the air, when not quite in contact. To Harrison’s pamphlet, published in 1763, it is stated that one of his clocks did not deviate from its rate, as measured by his grid-iron pendulum, more than one second in a month, for ten years together; and Berthoud has expressed his regret that all the particulars of Harrison’s construction of a clock, have not been divulged, that the public may benefit from his contrivances. It should seem that notwithstanding the objections that have been made to the cycloidal cheeks, Harrison, while unacquainted with Huygens’s invention, introduced the use of them into at least one of his clocks. But their excellence did not confit of this addition. About the year 1798 the composer of this article saw, in a back lane at Lincoln, and purchased one of Harrison’s clocks, which he recollects had wheels and pinions of hard wood; and that the teeth of the pinions were cylindrical rollers turning loosely on as many pins of steel; but he could not examine the escape ment. The old woman, who was the possessor, was a lineal descendent from Harrison, and some of her neighbours persuaded her, that if she parted with Harrison’s clock, his ghost would haunt her, which persuasion made such an impression on the good woman’s spirits, that she begged the might be allowed to retain her clock; which request was accordingly granted.

Regnault’s Pendulum.—In the year 1753, Regnault, a clock-maker of Chalons in France, contrived a metallic pendulum of brass and steel, the expansions of which were opposed to each other in such a way, that they constituted a partial compensation. This pendulum is represented by fig. 5 of the same plate that contains Graham’s mercurial pendulum, and probably derived its origin from the experiments mentioned in his paper on the Philosophical Transactions of London of the year 1726. The pendulum in question was made before Harrison’s account was published; it was composed of three parallel rods, two of steel and one of brass; the middle rod was of steel, and carried the horizontal cross-piece EA attached to its lower extremity; one end of this cross-piece supported the brass rod AB, to the top of which, at B, was riveted the horizontal pin which paffes through an oblong hole in the middle rod; the third rod, DE, which was of steel, was suspended by the pin B, and carried the bob L, attached to it by a tapped nut of adjustment for rate beneath; the whole pendulum must have been suspended by the top of the middle rod. The action is thus; while the middle rod elongates downward by increased heat, the brass rod of greater expanpibility, AB, elongates upwards, and carries with it the pin B, by which the third rod DE is suspended; and this rod passing through the cross-piece EA, again elongates as much as its fellow, or rod AB of the same metal; therefore the compensation is effected on a supposition that one rod of brass will compensate for two of steel, or that brass expands double the quantity of steel with the same degree of heat, and also contracts in the same ratio, neither of which assumptions is true. The relative expansions being in fact as 17 to 10, according to Berthoud, or, according to others, as 113 to 68, or very nearly as 5 to 3.

Deparcieux’s Improvement of Regnault’s Pendulum.—In the year 1739, Deparcieux, a teacher of mathematics, and a distingushed member of the Academy of Sciences at Paris, examined the construction of Regnault’s pendulum, and proposed an improvement in its construction, which rendered it capable of adjustment for compensation as well as for time. This pendulum is given in fig. 6 of the same plate, and may be thus described: AB and EF are two bars of steel passing through the perforated piece of metal ST, which forms a clamping-piece to hold them in their places; CD is a bar of brass rifting with its inferior end on the toe, F, of the bar EF, so as to be supported by it. QR is another clamping-piece, fast either at Q or R to one of the steel bars, but so adjusted, that the other two may not be restrained from passing without friction whenever they elongate. Through the clamping-piece, ST, passes a flat lever rifting at the end S, as a centre of motion, in a notch, or otherwise made moveable round a fixed pin.
pin, in the clamping-piece; this lever has a triangular point relling on the top of the brafs bar CD in such a way, that it is at liberty to ascend with the bar whenever it elongates; at the other end of the said lever the rod AR is fufpenfed, which therefore has more or lefs motion upwards produced by the expansion of CD, accordingly to the triangular point on the lever is nearer to S, the centre of motion, or T, the point of the third bar’s fufpenfion; for when the rod EF elongates, the rod of brafs CD elongates more in the proportion of 17 to 10, and the turpuf 7 acts on bar AR, and, by the aid of the lever, compenfates it.

This pendulum was afterwards still further improved by Berthoud, who made the triangular point of hearing in the lever adjustable for distance from the centre of motion, by a screw that acted on it, and altered its situation a little. (See Essai fur l’Horlogerie, tom ii. p. 123.) Berthoud afercered the relative expansions of feveral different metals by a pyrometer that indicated the 17th part of a French line, and according to his experiments, made the 17th of March 1760, when he was contriving the alteration in Deparcieux’s improved pendulum, the following Table was constructed; in which the verge was taken at 3 feet 2 inches and 5 lines French, or 461 lines, in each experiment.

Berthoud’s Table of Metallic Expansions.

In this table the whole fraction of each metal gives its absolute expansion, and the numerators the relative expansions, as the denominator is common to all. These experiments were first made with fimple rods, and again with 35 pounds fufpenfed to each, without any variation in the expansions, though it appeared that the fubfrequent contractions were not exactly correffponding when the weight was fufpenfed and when there was no weight; and it is to be regretted, that the author did not repeat his observations on the comparative contractions under different circumstances, as he has done the comparative expansions, in order that the reffults might have been afercered as they relate to the pendulum’s verge fletcher by a weight; for in all the experiments we have reported under our article Expansion, the fubfrequent contractions are considered as being exactly proportional to the expansions in the fame degrees of oppofite temperature. In compofing a pendulum of rods of any two of these metals, it is perhaps unneccesary to remark, that the rods of each metal must have their total lengths in an inverse ratio of their expansibilities, unlefs indeed aome mechanical advantage by a lever, or otherwife, be given in aid of the difference of the absolute expansions, as is done in the infancy before us.

Deparcieux’s Compenfation of a Simple Pendulum.—In the

fame year in which Deparcieux afercered an improvement of Regnauld’s pendulum, he invented a compound compenfation frame to be fubstituted for the common cock of fufpenfion, without altering the fimple pendulum, which mechaanism comes next to be deferibed.

This contrivance is repreffented by fig. 7, of our laft named plate, where A B D F is a feele bar bent into the fhape of a two-pronged fork with the ends pointing upwards, and fixed to a folid wall at the points A and E. G E T H is another fork, femed, fmalie, of brafs, and is defcribed, or made to lend with its ends relling on the horizontal part, B D, of the outer, or feele fork. The horizontal, or upper part, E, of the brafs fork, conflitutes the cock of fufpenfion, and has a fquared hole in the middle, which juft admits the fapped wire K, from which the fufpenfion-spring depends; in order that the nut of this fapped wire may give the adjustment for time. Underneath this crosf-piece of the fork of brafs is a detached cock, not fhewn, near C, which has a flit cut through it in the direffion of the vertical line of the fpring of fufpenfion, through which the fpring passes without play, and from the under fide of which the length of the pendulum is reckoned. This cock of limitation is frewed to the frame of the wheel-work, and therefore remains unmove. It is easy to fee, in this difpofition of the bars of fteel and copper, that if the expansions of thefe two metals be as 10 to 17, the length of the feele verge of the pendulum added to the length, A B, of the outer fork, must be to E G, the length of the inner fork above, as 17 to 10, to make the compenfation complete; and accordingly the length of the brafs fork was made 54; French inches, the fun of the other two being very nearly 93.

About the fame time that this pendulum was made, Caffini propofed fome different contructions, fome with three, and fome with five rods, feele and brafs alterntely, in the pendulum itself, which he gave in a memoir in the History of the Academy of Sciences at Paris in the year 1741.

Compenfating Tube and Reel of Julien le Roy, applied to the Simple Pendulum.—According to Thiout, Julien le Roy afercered a mode of compenfating the fimple pendulum in the fame year as Deparcieux, above flated, and on the fame principle, though the compenfating mechanism of Le Roy was altogether above the pendulum. This contrivance, exhibited in fig. 8, of the fame plate, confifts of a vertical brafs tube, 42 French inches long, denoted by the letters a b c d, relling at its lower end on A B, the cock of fufpenfion, which is also the cock of limitation of the pendulum’s length, by having a flit made in it juft large enough to admit the fpring of fufpenfion without play, which fpring hangs from the lower end of a feele rod, at- tended to the top part or cap, a b, of the brafs tube; therefore, in this contrivance also, the fun of the feele rods, i.e. of the verge of the pendulum, including its fpring, and of that included in the tube, should be to the tube alone as 17 to 10. Thiout has given the length of the tube only at 42 inches, but Berthoud has remar ked, that it either is, or ought to be, 54; like the brafs fork of Deparcieux. A pendulum of Le Roy’s contrivance was fpoen well of in Caffini’s Memoir of 1741, and was adopted in the observatory of Cluny about 1748, after which time the clock, to which it was applied, was fpoen of with great eulogium.

The principal objections that we conceive, apply to either of these two falt pendulums, are, that the fpring of fufpenfion is conftantly altering its length and strength; that the flit in the cock of limitation muft have the effect of
of lengthening the pendulum in proportion to the play that the spring has in it, to the right and left of the vertical line, as the pendulum is vibrating; and that the pendulum rod in motion will cool faster than the compensating parts remaining at rest.

Elliot's Compensating Pendulum.—We have stated under our article Expansion, that Elliot, of London, made very accurate experiments on the relative expansions of seven different metals, which, on a comparison, we find to differ, more or less, from Berthoud’s table, as well as from the determinations of Smeaton, Ramsden, Julien Le Roy, Borda, and others; so that when a compensation pendulum is constructed of any description, it seems proper, that the relative expansions of the metal used should not be taken from any table of results, but from an examination of the identical materials of which the pendulum is to be constructed, and that after tempering, hammering, filing, polishing, &c. in order to gain the due proportions in their state as prepared for use. Elliot, we doubt not, used this precaution, and his experiments were made, most probably, with a view to the construction of the pendulum we are now going to describe. It had been objected to Har- rison’s grid-iron pendulum, that the adjustment of the rods for temperature was inconvenient, and accompanied by a considerable change in the rate, and that the expansion of the ball supported at its lower edge was in the wrong upward direction, to avoid which objections, as well as the impeded jerks during the elongation, was probably Elliot’s object, at the time of his contriving a new pendulum; whether or not he had seen the application of the lever in Depar- cieux’s pendulum is not certain, but his contrivance is nearly allied to that, the principal difference being that in Elliot’s pendulum the two levers are adopted instead of one, and are applied at the bob instead of the superior end of the verge. In describing Elliot’s pendulum we shall avail ourselves of the inventor’s own account, and then subjoin our own remarks.

Fig. 1, of Plate XL. of Horology, represents the pendulum; in which $ab$ is a bar of brafs made quite flat at the upper end by pins, and held contiguous at several equal distances, by the screws $1, 2$, &c. to the rod of the pendulum, which is a bar of iron; and, so far as the bras bar reaches, is filed of the same size and shape, though it does not appear so in the figure, but, a little below the end of the bras, the iron is left broader, as at $dd$, for the conveniency of fixing the work to it, and is made of a sufficient length to pass quite through the ball of the pendulum to $c$. The holes $1, 2$, &c. in the bras, through which the screws pass into the iron rod of the pendulum, are filed, as in the drawing, of a sufficient length to suffer the bras to contract and dilate freely by heat and cold under the heads of the screws; $ef$ represent the ball of the pendulum; $f, f$, two strong pieces of flecl, or levers, whose inner centres, or pivots, turn in two holes drilled in the broad part of the pendulum rod, and their outer ones in a strong bridge, or cock, screwed upon the same part of the rod, but omitted in the figure, to shew the mechanism: $gg$, are two screws entering at the edges, and reaching into the cavity near the centre of the ball. The ends of the screws next the centre are turned into the form seen in the figure, which, precluding with the weight of the ball against the longer arms of the levers, cause the short ends to press against the bras bar at $b$. Things being in this situation, let us suppose that the rod of the pendulum, and the bras annexed to it grow longer by heat, and that the bras lengthens more than the iron of the same length; then the bras, by the excess of its dilatation, will press the short ends of the levers downwards at $b$, and at the same time necessarily lift up the ball, which rests on the long ends of the same lever, at $f$, to any proportion necessary for due compensations. The calculated proportion of the short arms of the levers must be to the long ones, as the excess in the expansion of bras is to that of the whole length of iron; and if this calculation be found on trial not perfectly accurate, the idle screws $g, g$, will produce the exact compensation at a few adjustments. At $i, k$, the inferior end of the iron verge, a strong double spring is fixed to bear the major part of the ball’s weight, by its prealire upwards against two points of the ball, equidistant from the vertical line. This is the description of the first pendulum made in this way, and the only alteration that the inventor made afterwards was placing the idle screws in the body of the ball.

Cunning, after describing this pendulum in his Elements of Clock and Watch-work, proposes that the bras bar should elongate between two iron bars, in order to keep it straight, and to prevent the jerks to which he conceives Elliot’s construc- tion is illibar, from friction impeding the free elongation of the bras bar, and from a consequent tendency to curvature before each jerk: he has also proposed to alter the structure of the short arms of the levers, by making them turn each on an axis of motion, and to change their places of prealire mutually, in order that their united action might be equally applied in the same point, at the centre of the bras bar, in direct opposition to the line of downward expansion; and we entertain no doubt but that the proposed alterations, once adopted, would be found to be real improvements in Elliot’s pendulum. See Cumming’s Elements, page 106, and plate xi.

Rhomboidal Pendulum.—Mr. Hooke proposed to make a compensating pendulum of rods of flecl and bras arranged into the form of a rhombus, or rhomboid, the four sides of which were of flecl and the long diagonal of bras; this construction, requiring the pendulum to be broader than long, was found to be very inconvenient, and was therefore never applied to a clock. But the principle was afterwards taken up by a clock-maker at Ulverston in Lancashire, named Williamson, or Williams, who, about the time that Elliot contrived his pendulum, made several pendulums, not however of one rhombus each, but of five united by joints at the angular points, opposed to the diagonals of bras; so that as the bras elongated more than the flecl, the angles opened and kept the diagonals always at the same distance from the said angular points, and from each other. Mr. Edward Troughton also, without knowing what had been done by Williamson in this way, contrived and made a pendulum similar to his in all respects, except that seven rhombi were adopted instead of five, which nar- rowed the pendulum still more than Williamson’s construc- tion, and which answered its intended purpose very well. We believe this construction is very little known at the present day; and, therefore, we beg leave to give a sketch of its arrangement in fig 2, of Plate XL., which will be suffi- ciently understood from inspection. We have not calculated the proportions necessary for the sides and common bafe of the triangles which compose these rhombi, so that the compensation may be complete; but any one competent to construe this pendulum will easily ascertain by calculation the due proportions.

Compensating Pendulum of F. Berthoud by Frames.—When Berthoud had finished his experiments on the relative expansions of metals in 1760, which was three years before Har- rison had published his pamphlet relating to his pendulum, he contrived a compound pendulum, much resembling Har- rison’s grid-iron at the first appearance, and which is con- structed to answer the same purpose. He had previously noticed
Pendulum.

noticed that Dparcieux's improvement of Regnault's pendulum, and also his own, where the lever was introduced, were not calculated to support a heavy pendulum with head-nets; he therefore employed his mind in contriving one, by which any weight might be suspended, that might be found desirable to move in small arcs. This pendulum, or rather a sketch of it, is contained in fig. 3. of Plate XL., in which the oblong frame, surrounding the other parts, and denoted by the letters a, b, c, d, is of steel; the upper end of which carries the knife edge suspension at 2; e f g h is a second frame, open at the top, and made of brass; the horizontal portion, e f, rests on the interior part of the lower end of the steel frame above the ball; the upper ends do not reach the whole length of the surrounding frame, but allow another frame of steel, i n m n, to rest on them, by means of their chin-pieces, at their upper extremities; again, o and p are two rods of brass resting on the inferior part of the horizontal connecting piece, i n, of the second steel frame, and at their upper ends support a single steel rod, with a chin at each side, which rod defends in the middle of the pendulum, and holds on its lower end the ball, after it has passed through holes made in the three frames above described. In this construction, as in Harrison's, it is easy to see, that the difference of the ascending expansions of the brass frame and rod, and of the descending expansions of the steel frames and middle rod, constitutes the compensation for the effects of variable temperature; and if the sum of the lengths of steel are to the sum of the lengths of brass inversely as their expansions, the compensation will be perfect.

For the particulars relating to the suspension, and metallic thermometer of a pendulum, made agreeably to this arrangement, we beg to refer our readers to Berthoud's own account, and to the corresponding engravings. See fig. 1. of plate 28. of Essai sur l'Horologerie, and fig. 1. of plate 10. Histoire de la Mefure du Temps.

Troughton's Mercurial Pendulum.—When Graham's mercurial pendulum had been many years in use, and had performed in the most satisfactory manner, some prejudices were without reason raised against it, originating more in fancy than from experience, and Mr. Edward Troughton, about the year 1790, with a view of doing away the most material prejudice, contrived a modification of the mercurial pendulum, which may be considered as a distinct pendulum, inasmuch as that the materials are differently arranged both as to quantity, quality, and situation. An idea prevailed that the metallic rod of Graham, and the vessel of mercury, would not be affected by changes of temperature in a contemporaneous manner, but that the mercury being below the rod, and having on that account a quicker motion, would cool sooner than the metallic rod, and be moreover liable to more frequent changes from its greater fincceptibility, notwithstanding the testimony of a long trial to the contrary; Mr. E. Troughton therefore substituted a strong glass tube with a bulb at the lower extremity, to be filled to a certain height with mercury, which should rise and fall precisely as in a thermometer, which instrument, in fact, his tube is; and to make it useful as such, it carries a graduated scale. The tube in question is about the size of a barometer tube, and the bulb large enough to contain 45 ounces of pure mercury, by the aid of one-half the tube. Fig. 4. of Plate XL. will explain Mr. Troughton's arrangement more clearly than a mere verbal description. A B is the mercurial rod filled with mercury to the middle point of the rod; at A the suspension is similar to that described in Meffrs. Brockbank's astronomical clock, (see Clock,) where Troughton's tubular pendulum is described, with a reference to Plate XXIII. and XXVII.; C D is the bulb guarded by the surrounding lenticular bob of brass and lead made in the usual way, except that it is made hollow at the centre; the metallic parts of the pendulum weigh about nine pounds exclusively of the mercury; the rim that surrounds the bulb, and by which the weight of the lenticular bob is supported, projects into two notches cut in the interior edges of the metallic lens, at each side of the cavity, and produces a nice fitting of the bulb to its rim, renders the glass capable of bearing the weight of metal supported by it. The compensation of this pendulum is effected entirely by the aseent and descent, alternately, of the mercury up and down the glass tube as the heat varies, and as the expansion of glass is much less than that of any of the metals, the small column of mercury contained in the tube is found sufficient to answer its purpose completely, after a trial of more than twenty years. Indeed this pendulum has proved itself equal, if not superior, to any of its predecessors, and the difficulty of the construction is perhaps the only objection why it is not more generally adopted, particularly in situations where there is no risk of carriage. We cannot dismiss our account of this pendulum, of which fort only a small number has been constructed, and of which no account has been before publicly given, without mentioning a curious property in it, known only perhaps to the constructor and to the writer of this account, which is, that if the column of mercury be made to reach either above or below the middle of the pendulum, at a mean temperature, the pendulum in either case will be under-compensated; but when the column reaches to the middle exactly, at a mean temperature, the compensation is exact; that is, the compensation has the greatest effect when the column reaches to the middle of the pendulum, which the inventor, we understand, would be the case, and calculated his dimensions accordingly.

Dr. G. Fordyce's Compensation of the Simple Pendulum, and others of a similar Conformation.—The compensation described in the Philosophical Transactions of 1774, as the invention of Dr. G. Fordyce, is not attached to the pendulum, but to the cock of suspension, in this respect like that of Dparcieux, contrived in 1759, from which it probably was borrowed. The original pendulum of Dr. Fordyce, as altered from Whitechurch's, is now in the possession of Gen. Bentham, from which an universal standard of linear measure was attempted to be taken, and from which, as a model, some few others have been made. In fig. 5. of our last plate, let A B represent the back of the clock cafe, to which a tube of brass may be attached at its lower end, of such length as to compensate the verge of the pendulum, which is a long flender spring. Near the top of this tube is a bracing piece, C, in form of a clamping tube, through which it passes without play or friction, and by which it is kept fast to the back of the cafe. The upper end, A, carries the cock of suspension and a counterpoise to the pendulum, and under it is fixed fast to the clock frame a second cock of limitation, for the spring of suspension to be received in, and by which the effective length of the pendulum is limited. (For a minute account of this apparatus, see Nicholson's Journal, 40. ed. vol. iii. p. 20.) The theory of this pendulum is, that as the fixed rod behind the clock cafe lengthens by expansion in heat, the steel pendulum, though more expanded, will be shortened in the fame proportion by the upward motion of its spring and cock of suspension above the cock of limitation; and if the wood of the clock cafe were unalterable by heat or moisture, this theory would be a good one, but as it takes no notice of the material to which the fixed rod is attached at its lower end, the actual compensation amounts to no more than the difference between the expansion of metal and wood gives; or
or in other words, it does no more so circumstances than a wooden pendulum would do applied in the common way. But inaccurate as the compensation we have described must necessarily be, where the compensation tube is resting on another body not taken into the account; yet Mr. John Crosthwaite of Dublin has described a pendulum of his invention, in the Transactions of the Royal Irish Academy, as being a superior pendulum which differs in no respect from Dr. Fordyce’s, except that the fixed rod of compensation is solid as well as the verge, and is supported by a bracket carried by a large piece of marble, and like Whitehurst’s clock, has cycloidal checks near its spring of suspension. Likewise the Rev. J. Pine of Eastdown, near Barnstaple in Devonshire, has described in the 3d vol. of the Repertory of Arts, &c. a pendulum similar in all respects to Mr. Crosthwaite’s, except that the cycloidal checks are omitted, and spiral springs applied to raise and lower the cock of suspension as the rod of compensation directs, which must be left freely than the original method of Dr. Fordyce.

Berthoud has described a method of compensating a simple pendulum in his “Histoire de la Mesure du Temps,” tome ii. p. 84. fig. 2. plate 11, which is not liable to the same objection as the preceding ones; for he has not allowed any subsidence to be a part of his mechanism, if it is his own that he describes, but what is taken into the account; a frame of three bars, the middle one of steel, and the two extreme ones of brass, all fastened at the bottom to a cros piece, and the brass ones also at their tops to another cros piece, confines the compensation in quietness; the upper cros piece, or end of the frame, is fixed to the back plate of the frame that holds the wheels, and consequently the brass rods elongate downwards, while the single steel rod elongates upwards in a smaller quantity; it is not however fail to the cros piece, but passes through it, and carries a pin acting against one end of a double lever, that has its centre of motion on the cock of suspension, while the other end of the double lever bears the pendulum. The consequence is, that while the brass rods lengthen downwards, they take the steel rod with them as far as is equal to the difference of their respective expansions, and the contiguous end of the lever, which has a counterpoise for the pendulum, falls with it, and lifts the pendulum verge at the remote end of the double lever the requisite quantity for compensation of the simple rod: and this quantity is determined by an adjusting screw, altering the centre of motion between the two opposite ends of the double lever. This construction seems to profess all the requisites of a good compensation, except that the frame is not in motion.

Troughton’s Tubular Pendulum of different Metals.—We have already described two pendulums of Troughton’s contrivance, both of which answered their purpose of being good regulators, and hence it may be matter of surprise, why the same man should contrive a third, very different in its construction from either of the former. But pendulums which may be equally good regulators of a clock, when properly adjusted, are not equally capable of ready adjustment, particularly for variations of temperature, after they are brought to a mean time. All the pendulums which we have hitherto described required their adjustments for temperature to be made from a trial of their going in summer and winter, and eight or nine months waiting between each adjustment was an interval inconveniently long for an astronomer, who was anxious to pursue his observations; Mr. Troughton therefore, who has numerous contrivances in general so many improvements in the mechanical arts, converted the grid-iron pendulum into a tubular one, which has all the accuracy of the old pendulum, and at the same time all the simplicity of the external shape of the simple pendulum. This pendulum has its compensation examined, and its compensating mechanism adjusted by means of the inventor’s new spirit-level pyrometer, without any trial for rate in the opposite extremes of temperature, and that as soon as it has been roughly adjusted to mean time. This saving of time, and of a repetition of adjustments, is a great improvement in the art of clock-making, and when generally known and adopted will enable the maker to send home his machine perfectly adjusted in the short space of a few days, whereas the old method of adjusting for temperature, from observations repeated at diurnal intervals, required as many months, and in some cases even years. Our Plate XXVII. of Horology, exhibits a variety of figures illustrative of the arrangement of the different parts of Troughton’s tubular pendulum, and in our description of An Astronomical Clock with Troughton’s Pendulum, under the head Clock, a minute account is given of the construction, to which our readers are refered to revert. It is asserted in the British Encyclopaedia, that Finny of Liverpool, and Chandler of Seven Dials, London, both constructed tubular pendulums, very similar to Troughton’s, many years before 1804, which is the date of Mr. Troughton’s publication of his, in Nicholson’s Journal; but as the arrangement of the two metals is not the same as in Troughton’s construction, nor was known to him previously, this circumstance, if true, does not detract from his merit, as it regards the invention in question. Indeed we happen to know, that no tubular pendulum is at present, nor ever was, at the Richmond observatory, formerly superintended by M. de Mainbray, as stated in the article above referred to.

Ward’s Compensation Pendulum.—In March of the year 1806, Mr. Henry Ward, of Blandford in Dorsetshire, communicated to the Society of Arts at the Adelphi, an account of a new compensation pendulum, accompanied by a model, which gained him the silver medal from the society. This pendulum consisted of three bars, two of iron and one of zinc, arranged in a manner very similar to Deparcieux’s improvement of Regnault’s old French pendulum, but without the lever of adjustment. The representation is given in fig. 6. of our last plate, where h and ii are two flat rods of iron or steel, about half an inch wide and an eighth of an inch thick each; and k k is a rod of zinc, of nearly a quarter of an inch thick, interpolated; the two extreme or iron rods are cranked, one at the top to receive the suspension spring, and the other at the bottom to hold the ball in the same vertical line with the zinc rod. These three parallel rods are united by four screws l, l, l, l, which passing through oblong holes in the bars h k and k k, screw into the rod i, while the rod, h, is fastened to the zinc one, k k, by the single screw m, near its lower extremity, which screw is the screw of adjustment for temperature, and requires several holes to be made in the bar h, and also in k k, that the length of the zinc bar may be limited to its due proportion for exact compensation. The iron bar, i, rests by a chimpiece on the upper end of the zinc bar, and therefore the ball supported by its lower tapped end stretches all the bars equally. If the zinc bar had rested on the crank at the bottom of the bar h, instead of being held by the screw m, the arrangement would have been the same as in Deparcieux’s, but with zinc substituted for brass, which consequently would not require the aid of a lever to increase its effect. The proportional expansions of zinc and iron were taken for this pendulum from Smeaton’s table in the 48th vol. of the Phil. Trans. of London, and were made for hammered zinc as 373:151; but subsequent observations on the rate of the clock, to which the pendulum was applied, proved
proved that the expansion of the hammered zinc was greater than Smeaton's table gives it, though the quantity was within the reach of the adjustment.

In Nicholson's Journal, 8vo edit. (vol. vii. page 500.) there is a notice of a similar pendulum by Benzeiherg, where one rod of lead is introduced to compensate two rods of iron, but no drawing is given. For the original see Voigt's Magazine, vol. iv. page 787.

Compensation Pendulum by Adam Reid—Another compensation pendulum, made by Mr. Adam Reid of Woolwich, was presented to the Society of Arts in April 1809, and the inventor was rewarded with fifteen guineas for his contrivance and model. This pendulum is given in fig. 7. of our last plate, and has its compensation in a tube of zinc acting on the ball, from the lower end of the steel verge thus; A B is the steel verge, made a little thicker where it enters the ball C, and also of a lozenge shape, to prevent the ball's turning, but above and below it is cylindric; near the centre of the ball is a shoulder in the verge, against which the upper end of the zinc tube D presses the cross piece of the ball when the nut E is turned up close to its lower extremity, but when the nut is turned back, in adjusting for rate, the tube defends a little, and the ball with it: while it rests on the upper extremity of the tube. When the compensation is too much, the tube may be shortened till it is found of the exact length, by a trial of the rate in extremes of temperature. In the figure before us the length of the zinc tube does not appear sufficiently long to compensate an entire verge of steel. The inventor observes that plating might be substituted for steel, and zinc for the formation of this kind of pendulum, but that the expense would be enhanced by the dearth of plating.

Doughty's Compensation Pendulum.—Mr. Thomas Doughty, of Charles-street, Somer's-town, favoured us, in January 1811, with a sketch and short description of a compensation pendulum invented by him on the principle of flexure, by a compound bar that is applied to draw up the pendulum's ball in hot weather, after the manner of Mr. W. Nichol-son's, which we shall notice presently. Fig. 8. of the same plate to which we have lately referred, represents this pendulum in its reduced state; A is a compound bar of steel and brasses folded together, with the steel uppermost; the length of which is ten inches, the breadth half an inch, and thickness four-tenths; the steel portion being 1/8 the whole, and curved with the convex face downwards, the point E above the ball being the centre of curvature. Above this bar, and connected with it at the middle, rides the brass bar B, six inches long, to which the spring of suspensions is fast, and which receives the impulse from the clock at the point 8. C, C, are two similar flinging heads of brass, tapped to receive each a screw and saddle-piece to fix them in any given part of the compound bar; by means of two clock springs these heads are attached to the six rods D, D, of steel, each 3/4ths of an inch wide, and 7/8ths thick, which rods are again attached to the iron flat piece E by similar springs, while the flat piece passes through the ball and receives the nut of adjustment for rate. The compensation is effected thus; while the brass piece B, and the steel flat rods D, D, elongate by heat, the curve of the compound bar, A, becomes more and more approaching towards a straight line, by the superior expansion of the steel portion, and this alteration of figure lifts up the ball of the pendulum a corresponding quantity; which quantity is regulated by the distance of the heads C, C, from the middle of the compound bar; the greater distance being always accompanied by a greater effect of the compensation, and vice versa; but in making this adjustment care must be taken that the clock be not put out of heat, by moving one head more than the other; but if the clock is already cut of heat, this adjustment may be used also as an adjustment for heat, at the time of adjusting for temperature. The springs are used for the purpose of preventing friction during the variations of temperature, but we suppose that there will be another consequence, not so favourable to the regular motion of the pendulum as might be wished; which is, that when the impulse is given from the maintaining power at the point 8 of the brass bar B, the springs, both near C and E, will yield, or bend a little, before the heavy ball will be urged, and thereby require a greater power to keep the pendulum in motion than would be necessary without such springs; and also the ball and the rods will not beeg n and end their vibrations exactly in a contemporaneous manner, which circumstance, without very nice equipoise of the side rods, will produce a vacillation in the ball Ritchie's pendulum, however, which follows, and which was intended to remedy the faults of this, is liable to the same objection, though his adjusting for temperature will not interfere with the adjustment for rate, as must be the case with the pendulum before us; for bringing the upper ends C, C, of Doughty's side rods nearer together lengthens the effective length of the pendulum, thereby requiring a new adjustment for rate. The inventor heated a small room with steam till the adjusting for temperature was found complete, which turned out to require eight out of the ten inches of the compound bar to make this adjustment perfect.

Ritchie's Compensation Pendulum, and Nicholson's—In March of the year 1812, Mr. David Ritchie, of Clerkenwell, laid before the Adelphi Society, also, a model of a compensation pendulum, for which he received, as a reward, twenty guineas. The compensation in this pendulum was effected by means of the flexure of two compound horizontal bars interpolated between the verge and the ball, which, like Doughty's, act on the same principle as the compound bars in the ordinary compensation balances of a chronometer. Fig. 9. represents the pendulum at present before us, in which A is the spring of suspensions, B the ball, and C the steel verge as usual, with the nut of adjustment for rate at E, below the ball. The compensating bars are E and G, the upper part of E and the lower part of G being steel, and the other parts brass; so that any additional heat may bring the bars nearer together by the convexity of the brass faces of the compound bars being contiguous. These compound bars have each a sliding piece above and below e and f respectively, by the sliding of which the bars may have their effective lengths altered, in the adjustment for temperature; and are connected by the slender springs e and f, which bear a portion of the ball's weight; the remainder being borne by the springs l and m attached by screws at b, one to the verge piece d and the other to the ball piece b, while they themselves are united by screws at l and m. The compensation frame, so contrived, is adjusted by sliding the compound bars, before they are fixed, till the centre of the ball falls in the vertical line of the verge, where the screws at b fix it for trial. The impression on our mind, from a contemplation of this construction, is, that when the crank of the clock urges the verge, the ball will not move with it till the springs e and f are bent a little, for when the ball is heavy, as is now customary in pendulums, its weight will place a great stress on the slender springs that connect it with the verge, and produce, probably, a vacillation, as in Doughty's, that must be very unfavourable to isochronism.
Pendulum.

Iochronism, even allowing the compensation to be perfect. It was to avoid this evil, that Mr. Nicholson placed a similar compensation bar on the clock of suspension above the verge of his pendulum, and also above the cock of limitation, as seen in fig. 10, but without any spring, and in this situation the varying curvature of the horizontal compound bar, E E, altering the length of the suspension spring, produced the alternation of rising and falling of the ball, and thus carried it in an opposite direction, so that the centre of oscillation was comparatively stationary. (See Phil. Journal, vol. i. 4to. ed. plate 5, fig. 3.) The alteration in the length and strength of the spring of suspension is, however, an objection to Nicholson’s construction. The same author also contrived a compensation pendulum composed of four rods; of steel and one of a compound, or alloy, of zinc and silver, which is described in vol. ii. of his 4to. Phil. Journal. (See page 205, and plate 9.) But as there are eight figures necessary to explain the fittings of the different parts, and as the work is in every one’s hands, we will satisfy ourselves by referring our readers to the author’s own description.

Hardy’s Compensation Pendulum.—Mr. Hardy of Clerkenwell, whose ingenuity and good workmanship have given him a high rank among chronometer makers, has lately contrived a compensation pendulum that parts partly of the gridiron class, and partly of Ellicott’s, and that promises to be exempted from the jerks that have been imputed to the other constructions during the elongations and flexure of the bars. It was our intention to have given a drawing of this pendulum, but our plates of pendulums are fall; and as the pendulum before us has not yet been applied to a clock, we will consider it as a project rather than as an approved pendulum. It is, however, completed in shape.

It consists of five parallel bars, the three middle ones of steel, and the two extreme ones of brass; there are two brass pieces at top, and as many at bottom, to connect the longitudinal bars, and the lower carries a pair of small levers, on the remote ends of which the brass bars act as they elongate downwards, but the centres of their motions are springs, like those in the inventors’ compensation balance, which balance performs very well; the ball is attached to the interior ends of the said levers by other springs, and a spiral spring acts near the top of the middle lever to carry a part of the ball’s weight, in order to let the springs near the ball act without having too much spring on them. The excellence or defect of this pendulum must be proved by future trials.

Recapitulation of the principal Properties of a Pendulum.—As the various properties of, and circumstances relating to, the pendulum, have been treated of under different heads in this work, we will conclude our present account by recapitulating the principal of them in a succinct manner, thereby condensing the substance that is necessarily diffused over our work into regular order and a narrow compass.

1. The theory of a pendulum’s motion is derived from the uniformly accelerative force of the gravity of its bob, considered as having all its weight concentrated into one point.

2. If such bob could be made to descend down the chord of its semi-arc of vibration, and to ascend up the chord of the other half, its long and short semi-vibrations would be performed in the same time, namely, in the time that would be taken up in falling through half the length of the pendulum, and the velocity at the lowest point would be as the length of the chord.

3. A pendulum cannot be made to move in the chords of a circle, but will necessarily move in the arcs when suspended by a cord or rod.

4. The longer arcs of vibration require more time than the shorter ones; when those arcs are circular.

5. In that peculiar curve called a cycloid, or by the French a roulette, a semi-vibration is performed in the same time, whatever be the length of the arc, namely, in the time that would be taken up in descending down the chord of a corresponding arc of the generating circle.

6. The axis of a cycloid is equal to the diameter of the generating circle; the straight line passed over in the generation is equal to the circumference; and the whole cycloid equal to twice the circumference of the said circle.

7. The time of a semi-vibration in a cycloidal arc is to the time of the bob’s descent down the axis of the cycloid, as a quadrant of a circle is to its radius; therefore the time of a whole cycloidal vibration is to the time of the fall down the axis as a semi-circle is to radius; or as the circumference of a circle is to its diameter.

8. The involution of a cycloid is itself a cycloid in every respect similar to the cycloid evolved.

9. Any cycloidal arc is equal to twice the corresponding chord of the generating circle; and therefore the axis of the generating circle is equal to half the arc of the whole semi-cycloid; hence a cord representing the length of a pendulum, evolved from contact with a semi-cycloid, till it rests at the vertex, must be double the length of the axis of the generating circle, and will move in a semi-cycloid.

10. Therefore the time of a pendulum’s vibrating in a cycloidal curve is to the time of its bob’s descent down one-half of its length, as the circumference of a circle is to its diameter.

11. Hence Huygens placed two portions of separate semi-cycloids, with their curves opposed to each other, and with their vertices nearly in contact at the point of suspension, that the thread of suspension might be evolved, from one, and then from the other alternately, in each semi-vibration, in order to make all the vibrations, of whatever length, isochronous.

12. The theory of this contrivance was admirable; but it supposed the action of the pendulum’s gravity to be sufficient to maintain the continuance of the vibrations, as well as all the ponderous matter collected into one point; likewise the centre of oscillation to be in the same point with all lengths of the cycloidal cord; and also the cord itself to be invariable in length, as well as perfectly free from rigidity; all which suppositions, not founded in nature, proved to many impediments to the practical adoption of the cycloidal checks for an attached or going pendulum, where external force is necessarily superadded to that of gravity, and where the centre of oscillation does not coincide with the centre of gravity.

13. But small circular arcs are so nearly coincident with cycloidal arcs near the vertical line, or line of quiescence, that they may be substituted for the latter, where they do not exceed 4°, without sensible error.

14. Hence the time of a vibration in small circular arcs, is to the time of the bob’s falling down half the pendulum’s length, very nearly as the circumference of a circle is to its diameter, which, in cycloidal arcs, has been shewn to be exactly so.

15. An escapement for short arcs, therefore, became necessary, when the cycloidal checks were laid aside, which acted with the crown-wheel escapement (an escapement adapted for long arcs), and Clement or Hooke contrived the anchor-escapement, which gave the pendulum, vibrating...
vibrating in short arcs, the name of the royal pendulum, from the noble property it possesses as a regulator. [Query, was not the sign of the crown and anchor of horological origin?]

16. As the momentum of a pendulum is composed partly of ponderous matter, and partly of velocity, the reduction of the arc of vibration produced a necessary addition to the weight of the bob.

17. The times of vibration of pendulums of different lengths will be always directly to each other as the square roots of their respective lengths, where the accelerative force is constant and unaltered.

18. When pendulums of the same length vibrate with different forces, the times will vary inversely as the square roots of the accelerative forces.

19. The lengths of pendulums, vibrating in the same times, vary directly as the forces which accelerate them.

20. The times of vibration of pendulums of different lengths, acted upon by different accelerative forces, will vary as the square roots of the lengths directly, and the square roots of the forces inversely.

21. Hence the same pendulum will not vibrate in precisely the same time in all latitudes, where the force of gravity varies.

22. Nor will an attached pendulum, continuing to vibrate by the aid of some external force added to gravity, vibrate, even in the same latitude, in the same time as a detached pendulum vibrating by the force of gravity alone for a limited period.

23. Pendulums acting with different escapements, or having otherwise different maintaining powers, will therefore vary a little in their lengths, though they measure the same time, and even move in the same arcs.

24. External force, from the maintaining power, may be added to gravity, either instantly or gradually, for a longer or a shorter time, uniformly or variably, and commencing or ceasing to act at any given point of the vibration; or it may be applied to act in conjunction with gravity during the whole vibration; all which modes will require so many corresponding lengths of pendulum to vibrate in the same time.

25. Hence originated all the variety of escapements that act with the pendulum, and modify the maintaining power, by giving their impulses differently, as to place, quantity, quality, and duration.

26. That mode of giving the impulse is best, which either deranges the action of gravity least, or acts most in conformity with it.

27. When the same pendulum is by any cause made to vibrate in different arcs, the daily error, or difference, in seconds of time, will be 

28. A vibrating pendulum may have its arcs altered, not only by a variation in the additional force, or maintaining power, but may be so attracted by a contiguous heavy body, particularly if homogeneous, that its arc of vibration may be either enlarged or diminished by the position of the said body: if placed near the line of quietness, the arc may be shortened; but if placed beyond the extremity of the arc, it may be enlarged.

29. If the point of suspension be not firmly and immovably fixed, a slight motion in it will have the same effect on the time, as lengthening the pendulum, though the maintaining power be the same; and if the points of suspension of two pendulums be contiguous, and be attached to the same shelf or yielding substance, they will continue to vibrate together, though they are not exactly of the same length, nor adjusted precisely to the same time. This curious property is observable in either the detached or attached pendulums.

30. When the pendulum is taken as an universal standard of linear measure, as well as of time, the experiments to ascertain the exact length of a second, or half-seconds pendulum, must be made always in the same latitude, on the same level, and in a detached state if possible, or otherwise the result will be affected by all or several of the variety of circumstances, which we have had occasion to consider as influencing the length of the vibrating pendulum.

31. That compensation-pendulum may be accounted the belt, that changes its rate least throughout the year, provided that its adjustments can be conveniently made.

Pendulum Level. See Level.

Pendulum Watch. See Watch.

Penedon, in Geography, a town of Portugal, in the province of Beira; 19 miles N.E. of Viseu.

Penedia, a town of Portugal, in the province of Beira; 15 miles S.E. of Coimbra.

Penelope, in Mythology, the mother of Pan (see his article) by the god Mercury. She was the daughter of Icarus, who lived at Athens in the time of Pandion II., and had offers of marriage from several princes of Greece. Her father, to prevent quarrels that might have happened, obliged them to contend for her in the games, which he caused them to celebrate. Ulysses was the conqueror, and gained the lady for his prize. (Paulan. in Laco.) After this marriage had been solemnized, Icarus used his utmost efforts to prevail with his son-in-law to stay with him at Sparta, where he was fet, and despairing of being able to persuade him, he conjured his daughter not to forfake him. Ulysses, tired of these importunities, referred the matter to the determination of his wife, leaving her at liberty either to accompany him to Ithaca, or to remain with her father. Penelope blushed at this speech, and answered only by covering her face with a veil. Icarus, understanding this dumb language, confented to her going with her husband; but moved by her graceful confusion, consecrated a statue to "Modelly," on the spot where Penelope had put a veil over her face. Penelope has been always considered as the most perfect model of conjugal love; but Bayle and some other authors have ridiculed the idea of her having been made a model of chastity, when it is alleged, that she suffered herself to be debauched by some of her lovers, who were always about her during the absence of her husband, and that she was expelled by him from Ithaca, whence she repaired first to Sparta, and afterwards to Martinea, where she ended her days.

Penelope, in Ornithology, a genus of birds of the order Gallin. The generic character is this; bill naked at the base; head covered with feathers; chin naked; tail with twelve feathers; legs without spurs. There are four species.

Cristata, or Guan. Head with an erect crest, temples violet. It inhabits Brazil and Guiana, and is about 30 inches long. It is frequently tamed, and its flesh is reckoned very delicate. It utters a sound something like the word Jact. The other characteristics of this species are, a black bill; irides orange; nostrils reaching from the middle of the bill to the front; orbit violet; caruncle on the chin compressed, red, covered with a few hairs; crest oblong; body black-
black-green; back brown; neck, breast, and belly, spotted with white; legs red.

**Cumanensis**; Jacou or Yacon. Blackish; crell and first quill-feathers white. It is about the size of a hen turkey. It is found in Cayenne and Guiana. It creeds its eggs, expands its tail, and cries in a mournful tone, like a young turkey. It builds on the ground, is easily tamed, and is often domesticated.

**Pipile**; Piping Curallow. Carmine on the chin blue; belly black; back brown, spotted with black. Like the last it is found in Cayenne and other parts of South America. The voice is weak and piping.

**Marahl**; Marahl Turkey. Greenish-black; naked orbits and legs red; throat naked; speckled with white. It is the size of a common fowl, and not dissimilar in shape. Though not much known to naturalists, it is common in the woods of Guiana, at a distance from the sea. It is generally seen in small flocks, excepting at breeding time, when it is often met with in pairs, and then frequently on the ground, or on low shrubs, at other times on high trees, on which it roosts during the night. The female builds her nest on some low bushy tree, as near the trunk as possible, and lays three or four eggs. When the young have been hatched for ten or twelve days, they defend with the mother, which scratches on the ground like a hen, and broods them, till they can shift for themselves. They breed twice a year. The young birds are easily tamed, and seldom forsake the places in which they have been brought up. Their cry is not unharmonious, unless they are irritated, when it is harsh and loud. Their flesh is good for food, and highly esteemed.

**Penelope**, a species of Anas. See DUCK.

**Peneo**, in Geography, a river of Thesaly, which runs into the Aegean sea; 20 miles E. of Larifia.

**Penetrability.** See Impermeability.

**Penetrale**, among the Romans, properly denoted the chapel consecrated to the penates, or household gods.

**Penetration, Penetratio**, the act whereby one thing enters another, or takes up the place already occupied by another.

The schoolmen define penetration the co-existence of two or more bodies, so that one is present, or has its extension in the same place as the other.

Philosophers hold the penetration of bodies absurd, i.e. that two bodies should be at the same time in the same place; and accordingly, impermeability is laid down as one of the essential properties of matter. See Matter.

What we popularly call penetration only amounts to the matter of one body's being admitted into the vacuity of another. Such is the penetration of water through the substance of gold.

The theory of the penetration of bodies is of great importance in military and naval affairs, the object in all cases of battery being to communicate the greatest possible momentum to the obstacle intended to be destroyed, whether it be the gates of a fortress, or the sides of a vessel; or rather we would say, that the effect to be produced should be the greatest possible, and which, it is well known, depends in a great measure upon the proper charges employed. If the charge be too small, the velocity being also proportionally small, the momentum thus communicated may fail to produce the desired effect; and again, if the charge and velocity be too great, that is, if it be such that the impinging ball passes quite through the opposing obstacle, the momentum communicated to it in this case will also be less than if the ball had lodged within it. This may be illustrated by letting up a thin deal board upon its edge, and firing a ball through it from a musket or pistol, which if the charge be at all considerable, may be done without throwing down the board, whereas the same ball cast from the hand against it would infallibly produce that effect. The reason for which is, that notwithstanding the great momentum of the ball in the former case, the time of its passage is so short, that the product of the momentum into the time (which is the measure of the effect) is so small, as not to be sufficient to overcome the natural gravity of the plane. The same thing is observed in naval actions, many balls palling completely through the sides of the vessel, the shocks of which are by far less than those which lodge within them, or than those which barely pass through, and similar effects are observed in the practice of land artillery, particularly when the opposing obstacle is wood, as in the gates, &c. of fortified places. See Moore's "Treatise on Military Rockets, &c."

These circumstances have induced most authors on gunnery, to consider the penetration of bodies as part of their subjects, and various experiments have been instituted in order to furnish dates for this purpose. Of these authors, Robins and Dr. Hutton have made the greatest number of experiments, and particularly the latter, an ample account of which is given in vol. i. of his Tracts, from which we have selected the following small table, exhibiting the velocity and diameter of the ball, the penetration, &c., each case, as stated below, being a mean of a great many experiments made with the same ball, or with equal balls, and with equal charges.

In all these experiments, the gun was placed within such a distance of the obstacle as to not affect the initial velocity of the ball, and the penetration was made in the direction of the fibres, the wood perfectly found, and cut off near the root of the tree. Now in order to make this table applicable to other cases, viz. when the diameter and density of the ball, and the projectile velocity are different from those above stated, we may proceed as follows.

Let $d$ represent the diameter of the ball.

$f$ the height of a column of water equal to the resisting force of the obstacle, considering it as uniform.

$a$, the specific gravity of the ball, that of water being 1.

$v$, the velocity of projection.

$a = \pi r^2$, the area of a circle to diameter $r$.

Then $a d^2$ will be the area of the section, $a d^3$ the resistance, and $\frac{a}{2} v$ the weight of the ball; so that the resistance will be to the weight of the ball as $a d^2$ to $\frac{a}{2} v$, or as $\frac{a}{2} v$ to $\frac{3}{2} d$; that is, as $\frac{3 f}{2 n d}$ to 1, or gravity. Now the velocity generated or destroyed by gravity in describing any space $s$, is $\sqrt{\frac{2 s}{f}}$, as $\sqrt{\frac{10}{2}} = \sqrt{2} = \sqrt{\frac{10}{2}}$ and when the space is a sphere, the velocities generated or destroyed, are as the square roots of the forces, or the forces are as the squares of the velocities, and the velocity destroyed by the force $\frac{3 f}{2 n d}$ in describing the space $s$. 

$\pi = \frac{1}{2}$, being
$s$, being $v$; therefore $s = \frac{3f}{2n d} = 64 s : v'$; hence $s = \frac{3f}{2n d} = \frac{v^3}{64}$; consequently $f = \frac{n d v^3}{32 s}$; and $s = \frac{n d v^3}{96 f}$.

Hence it appears, that the depth penetrated is as the density and diameter of the ball, and the square of the velocity, divided by the strength or resisting force of the obstacle. So that if equal balls be discharged against the same obstacle, then shall the depths of penetrations be as the squares of the velocities, which pretty nearly agree with the experiments above stated. Hence also it follows, that if unequal balls, but of the same density, be discharged with equal velocity, the depths of penetration will be as the diameters of the balls; so that a greater ball will not only make a wider aperture, but will penetrate farther into the obstacle than a smaller ball, all other circumstances being the same in both. Again, if it be known from experiment, how far a given ball will penetrate into any substance with a given velocity, the force of resistance may be determined from the above formula $f = \frac{n d v^3}{32 s}$, and hence the depth of penetration with any other ball, and with any other velocity, may be determined while the obstacle remains the same.

This however is upon a supposition, that the resistance of the obstacle is constant, like the force of gravity, which cannot in fact be the case, as it is obvious, that the farther a ball penetrates into any obstacle, the greater will be the resistance, in consequence of the increased density arising from the parts of the obstacle driven before the ball; but it is extremely difficult to establish any law of resistance that will answer in all cases, we must therefore adopt the hypothesis of uniform resistance, till farther experiments enable us to proceed with greater certainty; the resisting force of eln on this supposition, according to the first four results in the above tables, will be as follows.

1. $f = \frac{n d v^3}{32 s} = \frac{71}{2} \times 1.96 \times 1600 = 20000$.
2. $f = \frac{n d v^3}{32 s} = \frac{71}{2} \times 2.78 \times 1500 = 15000$.
3. $f = \frac{n d v^3}{32 s} = \frac{71}{2} \times 2.78 \times 1600 = 16452$.
4. $f = \frac{n d v^3}{32 s} = \frac{71}{2} \times 2.78 \times 2000 = 15362$.

The mean of these four results is 16692, which expresses the resisting force of eln, on the hypothesis of an uniform resistance, the force of gravity being assumed as unity; and now this value of $f$ being established for eln, the formula $s = \frac{n d v^3}{96 f}$ will obviously furnish the means of determining $s$, or the depth of penetration in any other cafe that may be proposed. Also the resisting force being supposed uniform, we have, according to the doctrine of forces, $t = \frac{2 f}{v}$ for the time of penetration.

In the second of the above recited experiments, the velocity of the ball is 1200 feet, and the depth of penetration 15 inches; let it hence be required to find the time of penetration, and the time of passing through each successive inch of the 15, and the velocity last at each of them.

Here $v = 1200$ feet = 14400 inches, also $s = 15$ inches, whence $t = \frac{2 \times 15}{14400} = \frac{2}{9}$ of a second the time of penetration. Again, the velocities and times being as the square roots of the spaces, we have
Hence, as the motion lost at the beginning is very small, and consequently the motion communicated to any body, as an inch plank, in pulling through it, very small also; we may conceive how such a plank may be shot through when standing upright without overfetting it. For more on this subject, see Hutton's Tracks, vol. iii. p. 288.

PENUS, in Ancient Geography, and Mythology, a river of Thessaly, which ran from W. to E., its source being in mount Pindus, and its mouth at the entrance of the Thersian gulf. Some doubts have been suggested concerning the course of this river. The ancients thought that the breach by which it discharged itself into the sea, was occasioned by an earthquake, that separated the mountains. Hence it has been sometimes called "Araxes," from *agare", scindo, to cleave. The modern name of "Salampria" is ancient, as, according to Euhathius, this river was in his time called "Salimprias," a name, according to Hefychius, of Greek origin, *ελαμπρία* and *ελαμπρίων*, signifying the openings of gates.

Most authors are of opinion, that Deucalion's deluge was occasioned by the river Peneus. (See Deucalion.) To this purpose, Herodotus observes, (l. i.) "It is said that Thessaly once was nothing but a lake, being environed on all sides with hills. The country which lies between those hills is what they call Thessaly, which is watered with plenty of rivers, the chief of which are the Peneus, the Apoës, the Onichones, the Eripus, and the Panito. These five rivers, falling down from the neighbouring mountains, after having run through the low country, disengaged themselves into the sea by a very narrow canal, where they all unite, and make but one great river, which retains the name of Peneus. They tell us farther, that before the canal was made, these rivers flooded the whole country, and turned it into a great lake; but that Neptune having formed that great canal, all the waters retired." Peneus, on account of its beauty, was an object of worship.

Peneus, a river of the Elide, in the northern part of the country, which flowed from its source eastward towards mount Scollis by Elis, and discharged itself into the sea to the west of Ephrya. — Alfo, a name given to the Araxes, a river of Armenia, on account of its resemblance to the Peneus of Thessaly, according to Strabo.

PENGEBUR, a town of Persia, in the province of Meceran; 30 miles N. of Kidge.

PENGHIOUM, a town of the Birman empire, at the confluence of a small river with the Irrawaddy; near Yanyangheoum, or Earth-oil creek.

PENGUIN, in Ornithology, a name given by sailors of different nations to two different species of water-fowl, both web-footed, and both wanting the hinder toe.

The penguin of the English is the bird more commonly known by the name of the goefugel, or the alca impennis of Linnaeus. See Alca.

The penguin of the Dutch is the anser Magellanicus of Clusius. See Pinguin.

PENGUIN, or Wild Ananas, Karatass, in Botany. See Bromelia.

PENGUIN Island, in Geography, a small island near the coast of New Holland, at the entrance into Adventure bay. N. lat. 43° 21'. E. long. 14° 31'. — Alfo, a small island near the Cape of Good Hope, a little to the north of Table bay. — Alfo, an island near the S. coast of Newfoundland. N. lat. 47° 22'. W. long. 56° 45'. — Alfo, a small island near the coast of Patagonia, nine miles S.E. of Port Defrie.

PENIA, in Mythology, the goddess of Poverty, and mother of Love.

PENICHE, in Geography, a sea-port town of Portugal, in Eßaramamura, situated on a peninsula, which runs into the Atlantic; fortified and defended by a citadel; containing three parishes, and about 2800 inhabitants. This town is sometimes called "New Libon." 39 miles N.N.W. of Libon. N. lat. 30° 20'. W. long. 9° 5'.

PENICILLA, thus called from penicillus, a pencil, which it is supposed to resemble in shape, in Pharmacy, a lozenge; or form of medicine made round by rolling.

PENICILLI MARINII, in Natural History, a fort of marine tubuli, or cafes of sea-worms, making a distinct genus of those shells. They are defined to be felly tubes, very fender, and terminating in the shape of a painter's pencil; many of them in their native shape adhering to stones, &c. on the sea-shores, by means of a soft and lax subfultance. Some of these are white and pellucid, others yellowish or brown; and the more common fort are about a finger's length, and about the thicknes of a wheat straw; and some are of a fort of funnel-like shape, and have their mouths surrounded by a fort of hairs, or filaments. These are called by some *proboscidians*, others are called *cadi* and others *ostifia*.

PENICILLUS, among Surgeons, is used for a tent, to be put in wounds, or ulcers.

PENIDIUM, in Pharmacy, barley-fugar.

Dr. Quincey uses the word penidium for a kind of clarified fugar, with a mixture of tarch, made up into little lumps.

PENJEKORCH, in Geography, a river of Asia, which runs into the Sewad, about five miles S. of the town of the same name. This river joins another S.E. of the town of Bijoe, and in its course separates the province of that name on the W., from Sewad, on the E.

PENJEKORCH, a river of Candchar, in Cabulifan; eight miles W. of Mafhanger.

PENIGK, or PENIO, a town of Saxony, and capital of
of a lordship, in the principality of Schonburg, on the Mulda. In this place are a manufacture of woolen fluffs, and a pottery; 38 miles W. of Dresden. N. lat. 56° 52'. E. long. 12° 35'.

Penning, a town of Bavaria, in the principality of Aichelstatt; nine miles E.N.E. of Aichelstatt.

Peninsula, or Penninsula, in Geography, a portion or extent of land, joining to the continent by a narrow neck or isthmus; the sea being encompassed with water.

The word is compounded of the Latin penis and insula, q. d. almoγf islant, which the French pertinently enough render presque ille.

Such is Peloponnesus, or the Morea; such also are Africa, Jutland, &c.

Peninsula is the name with what is otherwise called cherso-

nesus.

Peninsula Point, a cape on the W. coast of the island of Mindoro. N. lat. 12° 45'. E. long. 120° 56'.

Peninsus, or Pennin, in Mythology, a god acknowledged by the Penini, inhabitants of the Alps, from whom that chain of mountains derived its name; as we learn from Livy, Dec. 3. 1. xi. n. 38. Guichenon, in his History of Savoy, has preserved the inscription that was upon the pedetal of a fine statue, that represented this god under the figure of a young man naked, in these terms, "L. Lucilius Dec. Peninus optimo Maximo dominum dedit." Cato and Servius (in 3 Ed.) say, that this was not a god, but a goddes whom the one calls Penicus, and the other Apennina; but both the figure and the inscription express the contrary. The statue of that god was afterwards carried off, and that of Jupiter put in its place. Nevertheless, the worship of Peninus was not abolished, but the mountaineers continued to pay adoration to him. Some say this god was Jupiter himself, which they infer from the epithets "Optimus Maximus;" but others say that he was the Sun; and that the carbuncle upon the statue, called Peninus's eye, was the name with that of Obris, who, in Egypt, represented the sun.

Penis, in Anatomy;

Penis, Arteria dorsofla et profunda;
Penis erector, a muscle of the organ;
Penis glandula, or secretory gland;
Penis glandulae, or secretors; Penis, Vena magna;

Penis, Amputation of, in Surgery. This operation is sometimes rendered indispensible by carcinomatous diseases, in which the mischief has not as yet extended itself either too far towards the pubes, or to the glands in the groin. It is also very erroneously recommended to be practiced in cases of mortification; but every judicious surgeon will be of opinion, with Sabatier, that here it is entirely unnecessary, because if the disorder has ceased to spread, the dead part will be thrown off by a spontaneous process, and if the gangrene is still spreading, the operation is not likely to check its progress. The manner of operating is as follows: Sabatier advises the surgeon to take hold of the part with his left hand, and draw the integuments forwards, while with one swise of the knife he makes the requisite division. A catheter is then to be introduced into the bladder. Were this precaution neglected, the corpora cavernosa and urethra might become retracted towards the pubes, and the orifice of the urethra be covered with the redundant skin, so as to obstruct the passage of the urine. Le Dran saw such an accident happen, and was obliged to puncture the skin, in order to enable the patient to make water.

This operation is occasionally followed by a considerable degree of hemorrhage. The blood sometimes gushes out of the middle pudendal vein, and the arteries which ramify at the lateral and upper parts of the corpora cavernosa, while there is also a general flow of it from the spongy sublimation of the corpora cavernosa and urethra. This sort of bleeding is, in general, to be stopped like other hemorrhages. If the veins appear large, they should be immediately tied. When they seem to be of more moderate size, and the blood only oozes from the corpora cavernosa, hypodermics and compression will answer.

After suppuration has taken place, Sabatier conceives that the catheter is no longer needed. Towards the completion of the healing, care must be taken to keep the orifice of the urethra from becoming contracted, should any tendency of this kind show itself.

Penis of Birds. See Anatomy of Birds.

Penisaari, in Geography, an island of the Baltic, three versts long, and distant six versts from Lavenaari, which is. It is inhabited only by a few families, and has no water-springs.

Peniscula, a town of Spain, in Valencia, situated on the coast of the Mediterranean, surrounded on three sides by the sea, and difficult of access by land; 24 miles S. of Tortosa. N. lat. 41° 1'. E. long. 5° 24'.

Penishehr, or Pennieshehr, a town of Candahar, and capital of a district in the Cabulistan, on the E. side of the Hindoo Kto mountains; 46 miles N. of Cabul. N. lat. 35° 16'. E. long. 68° 24'.

Penistone, or Penniston, a small market-town in the wapentake of Stainefors, and liberty of the honor of Pontefract, West Riding of Yorkshire, England, is situated eight miles W.S.W. from Barnley. The market is on Thursday, but it is little frequented. Here are four annual fairs, which are chiefly noted for the sale of mule sheep. The town is environed with dreary moors, especially to the westward, where nothing presents itself to the eye but bleak and barren mountains, covered with heath or ling. Penistone, according to the population returns of 1811, contains 115 houses, and 515 inhabitants. The church here is a large structure, and near the centre of the town is a well endowed grammar school.

Penitence, or Penitentia, is sometimes used for a state of repentance, and sometimes for the act of repenting. See Repentance and Impenitence.

Penitence is also used for a discipline, or punishment attending repentance; more usually called penance.

Penitence also gives the title to several religious orders, confiting either of converted debauchees, and reformed profittites; or of persons who devote themselves to the office of reclaiming them. Of this latter kind is Penitence, Order of, of St. Magdalens, established about the year 1275, by one Bernard, a citizen of Marcellis, who devoted himself to the work of converting the courtezans of that city.

Bernard was seconded by several others; who, forming a kind of society, were at length erected into a religious order by pope Nicholas III. under the rule of St. Auguflin. F. Grisay adds, that they also made a religious order of the penitents, or women they converted, giving them the same rules and observances which they themselves kept.

Penitence, Congregation of, of St. Magdalens, at Paris, owed its rise to the preaching of F. Tilletan, a Franciscan, who converted a great number of courtezans about the year 1492. Louis, duke of Orleans, gave them his house for a monastery; or rather, as appears by their constitutions,
Charles VIII. gave them the hotel, called Bochaigue, whence they were removed to St. George's chapel, in 1572. By virtue of a brief of pope Alexander, Simon, bishop of Paris, in 1497, drew them up a body of statutes, and gave them the rule of St. Augustine.

To qualify a woman for admission, it was required, that she had committed the sin of the flesh. None were admitted who were above thirty-five years of age.

Till the beginning of the last century, none but penitents were admitted; but since its reformation by Mary Alvequin, in 1616, none have been admitted but maids, who, however, still retain the ancient name penitents.

PETENTIAL. PETENTIALL, an ecclesiastical book, retained among the Romanists; wherein is preferred what relates to the imposition of penance, and the reconciliation of penitents.

In the Capitularies of Charlemagne, the priests are enjoined to study well their Penitential. There are various Penitentials: the Roman Penitential, that of Venncrable Bede, that of pope Gregory III. &c.

PETENTIARITY, PETENTIARIUS, an office, or tribunal, in the court of Rome, wherein are examined, and delivered out, the secret bulls, graces, or dispensations, relating to conscience, confession, &c.

The expeditions of the penitentary are sealed up with red wax, and sent close; directed to the confessors.

Penitentiary is also an officer or dignitary, in some cathedrals, vested with power from the bishop to absolve in cases referred to him; on which account he is also called the bishop's ear.

In some places there is a grand penitentiary, and a sub-penitentiary. Anastasius says, that pope Simplicius chose some among the Roman priests to preside over penances. At present the pope has his grand penitentiary, who is a cardinal, and the chief of the other penitentiary priests established in the patriarchal churches of Rome, who confute him in all difficult cases.

He prelides in the penitentiary, dispatches dispensations, abolutions, &c. and has under him a regent, and twenty-four proctors, or advocates of the sacred penitentiary.

PETENTIARY HOUSES, for the punishment of convicts.

See Transportation.

PETENTES, in the church of Rome. See Penitentes.

Penitents, an appellation given to certain fraternities, or societies of persons who assemble together for prayers, make processions bare-footed, their faces covered with linen, and give themselves discipline, &c.

There are White Penitents in Italy, at Avignon, and at Lyons. There are also Blue Penitents, and Black Penitents, which last afflict criminals at their death, and give them burial.

PETENTES, or Conversi of the name of Jesus, a congregation of religious at Seville, confounding of women, who had led a licentious life, founded in 1550.

This monastery is divided into three quarters: one for professed religious; another for novices; a third for those under correction.

When these last give signs of a real repentance, they are removed into the quarter of the novices, where, if they do not behave themselves well, they are remanded to their correction. They observe the rule of St. Augustine.

Penitents of Orietio, are an order of nuns, instituted by Antony Simoncelli, a gentleman of Orietio. The monastery he built was at first destined for the reception of poor girls, abandoned by their parents, and in danger of losing their virtue.

In 1662 it was erected into a monastery, for the reception of such as, having abandoned themselves to impurity, were willing to take up, and consecrate themselves to God by solemn vows. Their rule is that of the Carmelites.

These religious have this in peculiar, that they undergo no noviciate. All required is, that they continue a few months in the monastery in a sequestered habit; after which they are admitted to the vows.

PENKEMAS POINT, in Geography, a cape or headland of South Wales, on the N. point of the county of Pembroke, at the mouth of the Tivy, four miles below Cardigan.

PENKRIDGE, a market-town in the hundred of Cuddlen, and shire of Stafford, England, is seated on the river Penk, whence its name is feepoed to have been derived, at the distance of six miles to the south of Stafford. It is of very great antiquity, and, according to Camden, was the seat of the Roman station, Penneoricum, mentioned in the Itinerary of Antoninus; but Plot, Stukeley, and Horley, place that station at the neighbouring village of Stretton; and Salmon transfers it to Oldkury, in Warwickshire. But though thus entertaining different opinions respecting the actual position of Penneoricum, all these authors agree in considering the present town of Penkrige as the immediate offspring of the deserted station. Some Roman remains were discovered here about the middle of the last century, and among other smaller articles, a brass head of the bolt of a catapult.

Penkrige is but a small town, consisting, according to the late population returns, 204 houses, and 925 inhabitants, who are principally engaged in different departments of the iron trade. The market day is Tuesday; and there are, besides, two fairs annually, which are reported to be faddle and draught horsfes. Here is an excellent charity school for the clothing and education of twelve boys and eight girls. The church is an old edifice, with a square tower at the west end. In the reign of King Stephen it was collegiate, and belonged to the united sees of Lichfield and Coventry; but it was afterwards bequeathed to John, archbishop of Dublin, and his successors, who were perpetual deans of the college, and had the collation of all the prebendaries, who were thirteen in number. The revenue of this college was estimated at £67l. 15s. at the time of the dissolution. The lands in Penkrige and its vicinity benefited according to the rule of 'Borough English.'

Lapley, a small village to the south of this town, is distinguished as the seat of an alien priory for black monks, which was annexed as a cell to the abbey of St. Remigius at Rheims, on whom it was bestowed by Aylmer, earl of Chester and Mercia, in the time of Edward the Confessor. At its suppression by Henry V. its site and-polletions were given to the college of Tong. The church belonging to this priory is still standing, and is now the parochial place of worship. It has a handsome tower, which rises between the chancel and the body of the church.

Near this village is Stretton, above-mentioned, as the supposed seat of Penneoricum. An elegant feat here, belonging to the family of Monckton, was anciently the property of the Congreves, ancestors to the celebrated dramatic poet of that name. The Roman road, called the Wasing street, pales close to the south side of the village. Tanner's Notitia Monastica; Camden's Britannia; and Beauties of England and Wales, vol. xiii. by Mr. Nightingale.

PENKUM, a town of Anterior Pomerania, which has suffered greatly by war and fire; 15 miles S.W. of New Stettin, lat. 53° 19', E. long. 14° 32'.

PENLAU LEDGAD, a river of Aquitania, which flows from
PEN

from lake Alben, and runs into the Traun; four miles S.W. of Wels.

PENLEE POINT, a cape in the English channel, on the S. coast of the county of Cornwall.

PENLLYN, William, in Biography, one of the successful champions on the harp, at the Eisteddfod, or feation of the bards and minstrels, appointed in the ninth year of queen Elizabeth, at Caerwy in North Wales, where he was elected one of the chief bards and teachers of Instrumental Song. Pennant's Tour in North Wales, 1773; printed 1778.

PENMAEN MAUR, in Geography, a large and lofty mountain of Caernarvonshire, North Wales, rises with a rapid ascent from the southern shore of the Menai river. The summit is about 1540 feet above the level of the sea. On the top is an ancient Britifh cairn, called "Braich y Dinas," also a barbied, or drum-shaped circle of upright and proffet flakes. Near the base of the mountain, on the north side, is a turnpike road, from Aber-Conway to Bangor, &c., which has been formed with much difficulty and expense. In some parts it is constructed on arches, thrown across fiffures, and in other parts it hangs over a deep and lofty precipice, at 300 feet above the sea, and presents a terrific appearance to the traveller. A wall has been built to guard against dangers. "The summit," says Mr. Aikin, "is a rude mass of shattered rock, covered with heath, difficult of ascent, and the defcent even far greater than at any time we had before experienced." See Pennant's Tour in North Wales.

PENMAN HEAD, a cape of Scotland, on the N. coast of Aberdeen. N. lat. 57° 37'. W. long. 2° 9'.

PENMARCK POINT, a cape on the W. coast of France, S. of a bay which takes its name from the town of Audierne; 15 miles S.S.E. of Audierne. N. lat. 47° 48'. W. long. 4° 17'. Exit of this point are Penmarck rocks.

PENN, Sir WILLIAM, Knelt, in Biography, an admiral of England, and one of the commanders at the taking of Jamaica, was born at Bristoll, 1621. Being addicted from his youth to the sea, he became a captain at twenty-one, and after several intermediate promotions was made admiral in the first Dutch war, at thirty-two years of age. In 1655 he came home, and was chosen member of parliament for Weymouth, not without hereby incurring the displeasure of the republican government, by which he was committed for a while to the Tower, on a charge of quitting his command without leave to the hazard of the army. Upon the restoration of the monarchy, he was made a commissioner of the admiralty and navy, governor of the town and fort of Kinlale, vice-admiral of Munster, and one of the council of that province. After fulfilling the chief command, under the duke of York, in the victory over the Dutch in 1665, he took leave of the sea, but continued in his other employments till 1669, when, growing infirm, he retired to Wandlead, in Essex, and died there the year following. He is said to have acquifited himself, in his liberal high offices, with honour and fidelity.

PENN, William, an illuftrious perfon among the Quakers, and founder of the colony of Pennsylvania, was the fon of the admiral above-mentioned, by his wife Margaret, daughter of John Jaifer, merchant of Rotterdam. He was born in London, in the vicinitv of the Tower, 14th October, 1644. His father gave him a liberal education, induced, no doubt, to greater care in the finifhing of it, by prospects of his fon's advancement at court, where he himself was in high favour. But the mind of the fon was formed for other pursuits, and before he had paffed his twelfth year, was already glowing with a fefullity to religion, which eventually unftined him for the employments of a corrupt court; and gave him to others of a more honourable and beneficent nature. He was placed first at Chigwell, and afterwards at Exeter, then at a private academy on Tower Hill, with the advantage besides of a tutor; and finally, in 1660, entered a gentleman commoner of Christ-Church college. He continued at Oxford two years, and was intimated with Robert Spencer, afterwards earl of Sunderland, and with John Locke. Though fond at this time of youthful sports, he had ftrong religious imprefions; and, together with fome other students, withdrew from the national way of worship to hold private meetings, at which they preached and prayed among themselves. This conduct gave great offence to the heads of his college; the parties were lined for nonconformity; and, proceeding after this to fome public acts of imprudent zeal, Penn and feveral others were expelled the college. Returning home, he continued to affect the company of religious perfon; from which his father, feering the obfacles it would throw in his way to preferment, endeavoured both by words and blows to deter him; and, finding all methods ineffuclial, became at length fo incenfed, that he turned him out of doors. The patience of young Penn held out under this rough treatment; until (parental afention taking place of anger, and poffibly fuggeling the expedient) his father concluded to fend him, in company with fome perfon of rank, on a tour to France. This took place in 1662. Here, though he spent fome time in study under the celebrated Protestant preacher, Mofes Amyrault, the very different conversation of other associates at length diverted his thoughts from religion. He had however acquired the language, together with the polished manners of the French, when, in 1664, he was recalled by his father from Turin, to which place he had proceeded from Saumur, the residence of Amyrault. The admiral joyfully received his fon, concluding the main point (of his fitneas for promotion) was now gained. He was admitted of Lincoln's Inn to ftudy the law, where he continued till the breaking out of the pefilence, soon after which, being now twenty-two years of age, his father put under his management a confiderable estate in Ireland, and he went to reside in that kingdom.

In folitude, the religious ftuggle in Penn's breast revived. On the one hand, natural vivacity, personal accomplishments, and the refpect and favour of his friends attracted his regard to the prefent world; on the other, devotion, and an infedible lefse of duty, fixed his contemplations on the next. He had been affected, about ten years before this time, by the preaching of Thomas Loe, a Quaker; and, being at Cork, was informed of a meeting for worship, then about to be convened, as it feems, by defire of the fame perfon. Penn attended it, and Loe delivered a discourse, beginning with the words, "There is a fath, that overcomes the world; and there is a faith, that is overcome by the world;" on which he is faid to have expatiated with much clearnefs and energy. His doctrine agreeing with the previous experience and prefent disposition of Penn, he now inclined to enter into communication with the Quakers, and from this time contantly attended their meetings. At one of these, held at Cork, November 1667, he, with many others, was apprehended by order of the mayor, who would have liberated Penn upon his giving bond for his good behaviour; but the latter, deeming the meeting no midlemanour, refused bond, and was fent to prifon with the rest. He wrote a few lines to the earl of Orrery, containing exceptions to the mayor's proceedings, an argument againft perfection, and a requelt "for the speedy reaflemblc of all" who had been
be committed on the occasion. The earl contented himself with ordering Penn's discharge.

His father, being informed by a nobleman of his acquaintance of the danger his son was in of being prosecuted to Quakerism, remanded him home, and was readily obeyed. Penn had now again to pass through the ordeal of parental displeasure, and in this a principal object seems to have been, his continuance in the exterior of his education, or, as his biographer has it, in the customs and fashions of the age. But to fixed was he in the resolution to follow what he esteemed a manifestation of the will of God in his conscience to the contrary, that, although he beheld on these occasions with Christian meekness and filial affection, neither threats nor entreaties could move his constancy. The honour of the hat (in these times a matter of no light esteem) was especially contended for by the pontifical admiral; who, at last, would have tolerated his son in other instances of nonconformity, on condition that he should be uncovered before the king, the duke of York, and himself. Penn took time to consider of this proposal in secret, he even made it a subject of fasting and supplication to God to be directed aright, and he deliberately refused the terms. This was sacrificing much to sincerity and constancy in his profession, for his father, upon this, finding his hopes of the courtier at an end, could no longer endure the son in his preference, and he was a second time driven from paternal mansion. His integrity was now put to a severe proof: it appears, that he found a shelter among his adopted friends the Quakers, while his mother privately supplied his wants. At length the admiral relented, so far as to wink at his return to the family; and when in consequence of being found at religious meetings (by the flate then called seditionary conventicles) he was at any time imprisoned, would privately use his influence to get him released.

The talents of Penn were soon devoted to the support of the doctrine he had espoused. He became a preacher among the Quakers, and published in 1668, on their behalf, a piece entitled "Truth exalted;" another occasion, however, more important in its consequences, presently occurred. A preacher, named Thomas Vincent, irritated by the going over of two of his hearers to the Quakers, accused the latter of holding erroneous doctrine concerning the Trinity. A dispute was held in consequence, in a meeting-house belonging to a Presbyterian congregation in London, chiefly between Vincent on the one part, and George Whitehead, an eminent Quaker, on the other. Vincent began by laying (in the gentle phrase of the time) that the Quakers held "damnable doctrines;" which being denied, he followed up his charge with a question, whether they owned "one Godhead subsisting in three distinct and separate persons." Whitehead, and those with him, rejected these terms as unscriptural, Vincent framed the following sylllogism: "There are three that bear record in heaven, the Father, the Word, and the Holy Ghost, and these three are one. There are either three manifestations, three operations, three subsistences, or three somethings else befides subsistences: but they are not three manifestations, three operations, three subsistences, nor three any things else but subsistences: ergo, three subsistences."—Whitehead again rejected the terms, as not to be found in scripture, nor deducible from the text; and observing "that God did not use to wrap up his truths in heathenish metaphysics, but to reveal them in plain language," he defined an explanation. This was safe ground, though likely to prove barren of scholastic argument; but Penn, either not aware of its advantage, or as yet too full of Arifletete, chose to deny the minor of the sylllogism, and went into some dilutions, using the rejected terms sub-

flunce and subsistence. After much of this fort of logic, and some abuse bel lowed on the Quakers, the dispute ended, for the present, to the satisfaction of neither side. In prosecution of the controversy thus raised, Penn wrote a piece with the following title: "The fundy Foundation shaken, or those so generally believed and applauded Doctrines, of one God, subsisting in three distinct and separate Persons: the Impossibility of God's pardoning Sinners: a plenary Satisfaction: the Justification of impure Persons by an imputative Righteousness; refuted from the Authority of Scripture and right Reason." The dispute with Vincent had excited much attention. This publication did more; it raised up the vindictive spirit of intolerance. It was evil spoken of, says Sewell, the historian of the Quakers, and not long after Penn was committed to the Tower; and, as some thought, not without his father's being acquainted with it, perhaps to prevent a worse treatment. From what quarter this was apprehended, we shall see presently; for Penn being thus secured in the Tower, and denied the access of his friends, his servant one day brought him word (as it seems, from the admiral) that the life of London was resolved he should either publicly recant, or die a prisoner. His reply evinced a mind un tertified at the prospect of fullings, which he considered as inflicted for conscience sake: and he began to occupy his solitude with religious compositions, the most considerable among which was a practical treatise on the Christian religion, entitled "No Crosses No Crown." In this work, his contemporary, Dr. Henry More, says, he has treated the subject of a future life, and the immortality of the soul, with a force and spirit equal to most writers. It has passed through many editions.

After near seven months' durance, Penn wrote to the secretary of state, lord Arlington, requesting to be heard in his own defence before the king, and complaining warmly of the manner in which his sentiments had been misrepresented by his enemies. In this letter several just and noble sentiments occur. He tells his lordship, "that he is at a loss to imagine how a diversity of religious opinions can affect the safety of the state, feeing that kingdoms and commonwealths have lived under the balance of divers parties. He concedes that they only are safe for political society, who maintain principles subseive of indiglory, fidelity, justice, and obedience; but to say that men must form their faith of things proper to another world, according to the prescriptions of other mortal men in this, and, if they do not, that they have no right to be at liberty, or to live in this, is both ridiculous and dangerous. He maintains that the understanding can never be convinced by other arguments than what are adequate to its own nature. Force may make hypocrites, but can make no converts, &c. &c." He now likewise published a short piece, entitled "Innocency with her open Face, preented by way of Apology for the Book, entitled The fundy Foundation shaken." He here says, "that which I clamorously informed to be the greatest reason of my imprisonment, and of that noise of blasphemy which hath pierced so many ears of late, is my denying the divinity of Christ, and divesting him of his eternal Godhead; which most busily has been fuggelled, as well to those in authority, as maliciously inflamed among the people." In confusion of which charges, he proceeds to prove from scripture the Godhead of Christ. Both of these tracts were republished in the collection of his works, in folio, 1771; and the reader, who desires to obtain a just view of his sentiments on the several controverted points, will do well to compare them with each other, and with his doctrinal works at large. Soon after this explanatory defence, Penn was liberated from the Tower, and went to Ireland, where he seems to have been
occupied for twelve months in the care of his father's estate, and in various services to his friends, the Quakers; after which he returned to England.

In the year 1670, the Quakers being persecuted by some magistrates, after the act against conventicles, were forcibly kept out of their meeting-houses in Gracechurch-street. They met as near it as they could, in the streets, agreeably to their practice in such cases; and their fines and fines hereon eventually procured them the free exercise of their right. On the occasion alluded to, Penn, preaching in the street, was apprehended by warrant from Sir Samuel Starling, lord mayor, and committed to Newgate. At the next sessions at the Old Bailey he was indicted, along with William Mead, another eminent Quaker, for meeting in, and conspiring to preach to an unlawful and tumultuous assembly. He made, says his biographer, a brave defence, discovering both the free spirit of an Englishman, and the undaunted magnanimity of a Christian, inasmuch that notwithstanding the m. partial frowns and menaces of the bench, the jury acquitted them both. It ought to be added, that this jury exhibited an instance of firm, perceiving justice, under most tyrannical and indecorous treatment by the court, worthy of the notice and remembrance of every Englishman. They were fined for the verdict which they had brought in, and ordered to be imprisoned till the fines were paid. But this dangerous assumption of power was afterwards adjudged illegal by the court of common pleas, on which occasion the chief justice Vaughan distinguished himself by a very able speech in vindication of the rights of jurors. The trial of Penn and Mead is inserted in the collection of Penn's works, and has been also published separately.

Nor was this event the least signalised. For this event as an admiral Penn died, perfectly reconciled to his son, to whom he left an estate of 1500l. per annum. Penn engaged about this time in a public dispute, at Wycombe, with Jeremy Ives, a celebrated Baptist, on the universality of a divine light in the minds of men; which doctrine Ives undertook to dispute, but seems to have quitted the field to his antagonist immediately after flating his argument. In the month called February 1460-1, Penn was again committed on the pretext of preaching publicly, to Newgate, where he remained six months. It is observable that he had recently published a piece in favour of liberty of conscience, and another entitled "A Feasible Caution against Popery," the one probably offensive to the interests of the other. This event, on the other hand, he held a spirited dialogue on persecution with Sir John Robinson, lieutenant of the Tower; at the close of which, the latter calling for an officer with a file of musketeers, "No, no," said Penn, "fend thy lacquey, I know the way to Newgate."

Early in 1672 he married Gulielma Maria, daughter of Sir William Springett, formerly of Darling in Sussex. He settled at Rickmansworth, Herts, continuing to render service, both by preaching and writing, to the religious cause in which he was now engaged for life. Nor did he neglect an attention to the interests of his country, but published, in this year, a pamphlet entitled "The Proposed Comprehension foberly and not uneaasonably considered," and in 1675, a larger work, the title of which is "Penn's patent Interest considered, with Honour to the Prince, and Safety to the People," in answer to this one Question, What is most fit, easy, and safe, at this Juncture of Affairs, to be done, for quieting of Differences, allaying the Heat of contrary Interests, and making them subserve to the Interest of the Government, and consistent with the Prosperity of the Kingdom?" The answer to this, and the argument of the piece, is in three things: 1. An inviolable and impartial maintenance of English rights. 2. Our superiors governing themselves upon a balance (as near as may be) towards the several religious interests. 3. A sincere promotion of general and particular religion...
in time to winter; the third was detained till spring in the
West India islands. Thus was the settlement begun,
the proprietor being occupied meantime in providing a
government for the colony, and in concerted measures for its
security. The native Americans, or Indians, having experi-
cenced, in some provinces on that continent, much injustice,
had made the most terrible reprisals: found policy, there-
fore, conforming with his own temper and principles, made
it Penn's care to have them treated with candour, justice,
and humanity; and his relation, W. Markham, failing with
the first fleet, he joined him with others in a commission
to open a friendly intercourse with the natives, to whom he
sent out considerable presents, and a letter couched in plain
conciliatory terms. In the beginning of 1682 he published
"The Frame of the Government of the Province of Penn-
sylvania in America, together with certain Laws agreed upon
in England, by the Governor and divers Freemen of the
 aforesaid Province, to be further explained and confirmed
thereby by the first provincial council that shall be held, if they
seem meet. In the preface to this work we have a sketch of
his sentiments on the forms and subsistence of civil govern-
ment. "That," he observes, "which makes a good govern-
ment, must keep it foci: 1. An unchangeable and
virtuous form; 2. Laws suited to the temper and
worldly inheritances, must be carefully propagated by a virtuous education of youth"; and in order to give effect where he had power,
to that great principle of good government, liberty of con-
science, in behalf of which he and his friends at home to deeply
suffered, he recognized it in the first article of his "Constitu-
tutions," and proceeded to establish it by the following
"Law." "All persons living in the province who shall confess and acknowledge the one Almighty and Eternal
God, to be the creator, upholder, and ruler of the world,
and that hold themselves obliged in conscience to live peace-
ably and justly in civil society, shall in no wise be molested or
prejudiced for their religious persuasion, or practice in
matters of faith and worship, nor shall they be compelled, at
any time, to frequent or maintain any religious worship,
place, or ministry whatsoever." Having completed his pre-
parations, the governor, early in the autumn of 1682, failed
for Pennsylvania; his family (of whom he took leave in a
pathetic and instructive letter) remaining behind. He was
accompanied by about an hundred persons, mostly Quakers,
from his own neighbourhood: but of these the small-pox,
which had been inadvertently carried on board, swept off no
less than thirty. In other respects the voyage was pro-
spersous, and pausing at the Delaware, he was met by the
colonists, consisting of English, Dutch, and Swedes, with
manifestations of satisfaction. Having landed at Newcastle
on October 24, he convened and addressed the inhabitants,
received legal possession of the country, and renewed the magis-
trates' commissions. After paying a visit to New York, he
met the first provincial assembly at Chelfer, on the Delaware,
then called Upland. Here, in a session of three days, the ter-
ritory ceded by the duke of York was annexed to the province;
an act of settlement was confirmed; resident foreigners natural-
ized; and the laws, which had been formed in England, after
some revision, passed in form. Penn now visited lord Baltimore
in his government of Maryland; whence he returned to Co-
quannock (the future site of Philadelphia), and began to
purchase lands of the natives. He now likewise first entered
personally with them into that firm alliance of peace and good
offices, and formed (to use their own symbol) that chain of
friendship, which was to last as long as fun and moon endure.
Certainly, he framed schemes of justice in paying
them for the soil (which was their inheritance), and the
interest he manifested, during many successive treaties, in their
real welfare, not only operated to secure this colony, for a
long series of years, from hostile attacks, but implanted in
the generous, though uncultivated mind of the American,
a regard for Penn (Penn), and his children (the Quakers),
which bids fair to be transmitted to the latest remains of the
race.

Philadelphia, the capital of the province, was next to be
laid out, of which, at the time of Penn's arrival, not a
house was completed; the colonists having, in general,
no better lodgings than caves, hollowed out of the high
banks of the river; the very plot fixed on for the city was
claimed by some Swedes, to whom the governor allowed a
greater quantity of land in exchange. This city extending
two miles in length and one in breadth, and abutting at each
end on a navigable river, was now planned, with admirable
boldness, convenience, and regularity, and laid out under
the inspection of Thomas Holmes, surveyor-general to the
province. Ere twelve months had elapsed, the rudiments of
the future metropolis shewed themselves in about fourscore
dwellings, the feats of freedom, peace, and industry. The
governor dispatched his plan to the committee of the Free
Society of Traders, accompanied with a description (the best
of the times) of the vessels of (the countries) of its natural
resources and aborigines: this description is inserted in the collection
of his works before-mentioned. The first jury was impan-
nelled here early in 1683; and one Pickering was tried, with
others his accusers, before the governor and council, and
convicted of counterfeiting the Spanish silver money current
in the province. His sentence discovers the fame spirit of mild-
nesses and equity, which, at this day, constitutes the praise
and the efficacy of the criminal code of Pennsylvania. He
was to pay a fine of forty pounds towards the building of
a court-house, landing committed till payment; find securities
for his good behaviour; and make reparation, in good silver,
to the holders of his base coin, which being first melted down,
can be restored to him. Various legislative, economical, and
religious measures, together with a tedious dispute with lord
Baltimore, on the subject of the boundary line between this
province and Maryland, continued to occupy Penn till about
Midsummer 1684; when he found it needful, on various con-
fidations, to return to England. His interest at court had
declined during his absence; but it was now restored, upon
the death of Charles II, by the accension of his more im-
mediate patron James II. He made use of his influence for
the relief of his friends, the Quakers, who still lay under the
scourge of penal statutes; and for the gratuitous service of
many others. In particular he exerted himself in favour of the
measure at that time so much, though so indirectly, held
out by the court, of universal liberty of religion, by
1686 (as we learn from bishop Burnet), being in Holland,
in the course of a tour to Germany, &c. he had several inter-
views on this subject with the prince of Orange, on behalf
(though not as an accredited minister) of king James; but
his proposal going so far as to abolish the tithes, it was re-
jected, probably by Burnet's advice, who was then with the
prince, and in his confidence. However freely we may excuse
Penn, on the fair plea of gratitude, for his attachment to
James, it is to be lamented that he gave implicit credit to
preferred schemes of religious liberty, the duplicity of which
was so fully penetrated by others. His intimate reception
at court, and the appearance of being in some way trusted
or employed by the king, now subjected him to the
general imputation of being a courtier himself. Even his
old acquaintance, Dr. Tillotson (afterwards archbishop of
Canterbury), suspected him; but some expressions of Tillot-
son's on the subject coming to Penn's ears, a correspondence
ensued between them, at the close of which Tillotson acknow-
ledged
ledg'd himself fully satisfy'd that there existed no just grounds for the fornicate. About this time (besides a further account of his province) Penn published several pieces on his favourite topic, liberty of conscience, one of which was entitled "Good Advice to the Church of England, Roman Catholic, and Protestant Dissenter, in which it is endeavoured to be made appear, that it is their duty, principle, and interest to abolish the penal laws and tellest.

The last occasion in which we have to view Penn in connexion with the court of James, is in an occasional attendance on the movements of the latter, this year, through several of the midland counties. Penn seems to have made use of several intervals in this progress, to pay religious visits to his friends, and to preach to the people. On some of the latter occasions the king, too, was present to hear him. At Oxford he remonstrated with James on his arbitrary treatment of the fellows of Magdalen college, and attempted a mediation between them and the king, which he farther proceeded afterwards at Windsor; but it proved abortive.

The revolution brought Penn again into difficulties, as a suspected Papist, or Jesuit, and a secret agent for the old government. On the 10th of December 1688, walking in Whitehall, he was sent for by the lords of the council, then sitting, who, though nothing was laid to his charge, obliged him to give sureties for his appearance on the first day of the next term: he was continued on these to the Easter term following, on the last day of which he was cleared in open court. In 1690 he was again brought before the council, on an accusation of holding correspondence with the late king James; he appealed to king William, who, after a conference near two hours, inclined to acquit him; but to please some of the council he was held upon bail for a while, and in Trinity term, of the same year, again discharged. He was yet a third time attacked, and his name inserted in a proclamation, dated July 18th this year, wherein (among divers of the nobility, and others, to the number of eighteen) he was charged with adhering to the king's enemies, but proof failing respecting him, he was again cleared by order of the court of king's bench. He now purposed to go again to his province, and gave out proposals for a new settlement there. It appears that though his stay in England might be necessary to the security of his title as proprietary, it was highly detrimental both to his interests in America, and, through deficiency hitherto of revenue from it, to his private estate. His order for convoy had already paid the secretary of state, when the voyage was prevented by a new charge against him, backed by the oath of one Fuller, a wratchet who was afterwards declared by parliament an imposter: the charge, however, being that of partaking in a plot to restore the late king, a warrant was granted for his apprehension, which he narrowly escaped at his return from George Fox's burial, the 16th of the month called January 1690.

Seeing now no probability of fair treatment, he retired (or, as Burnet chuses to say, abconded) for two or three years: during which time, besides a preface to the collected works of Barley, he wrote the following pieces: 1. "Just Measures," an epistle to the Quakers in vindication of religious discipline: 2. "A Key," or a treatise explanatory of their principles and practice: 3. "Reflections and Maxims relating to the Conduct of Human Life;" the second of these latter have gone through many editions. At the close of 1693, being admitted through the intercession of some of the nobility to appear before the king and council, he now effectually repre- fended his innocence, and got clear of this long political persecution.

About this time his wife, who was an amiable and accomplished woman, died, and he married, after two years, Hannah, daughter of Thomas Callowhill, of Bristol; and soon after loth, by a consumption, his eldest son, a promising youth, just of age. The interval from his appearing again in public, to the year 1699, appears to have been chiefly devoted to religious labours and controversies: he also prefixed to parliament some arguments for exempting Quakers from oaths; and some remarks on a bill against blasphemy, in which he very rationally proposed that the term should be so defined as to preclude malicious interpretations: this bill was dropped.

On the prevalence of Penn's enemies at court, he had been deprived of his government of Pennsylvania, which was annexed, in October 1692, to that of New York, under colonel Fletcher. The onlenable reasons for this step were mal-administration, and danger of the loss of the province thereupon: the real one probably was a jealousy excited by the growing prosperity of the colony, and by principles and practices in its jurisprudence too liberal for the age. Penn's rights were restored to him by an instru- ment of William and Mary, dated in August 1694, but it was not till five years after this, that he embarked a second time for the province, accompanied by his family. The vessel, being three months at sea, did not arrive at Phila- delphia "until the beginning of the tenth month, 1699, when a dangerous and contagious distemper, called the yellow fever, having raged in the province, and carried off great numbers of people, had ceased." Penn seems now to have intended to spend the remainder of his life in America, and he applied himself diligently to the offices of government; in which the inevitable difficulties arising from a mixed population, of various dispositions and interests, and enjoying a great share of liberty, required the exercise of both skill and patience. His administration was successful, and the colony is rated to have been at this period, when compared with others of the same standing on the continent, in an easy and flourishing condition. His old allies, the natives, were not overlooked, and religion being ever a predominant consideration with Penn, he engaged his friends at a monthly meeting for discipline, held the beginning of 1700, in a plan for the instruction of the natives and of the negroes, who had now been introduced among them, in the principles of the Christian faith. Later experience has shown that Christianity, to obtain a cordial and general reception among these people, should be preceded by her handmaid, civilization. A public school, (free to the children of the poor,) had been already founded here. In the second month 1701, a treaty was held between the go- vernor and about forty of the chief persons among the natives, in which, Besides renewing former covenants, the parties established some regulations on the subject of trade between them: a principal care of the governor, on this occasion, seems to have been to prevent the abominable practice, already used by some unworthy colonists, of drawing the natives into a ruinous traffic, by offering them spirituous liquors.

During these transactions an attempt was making, at home, under pretence of advancing the prerogatives of the crown, and of national benefit, to invade the several proprietary governments in America, and reduce them to regal ones. A bill for this purpose was already before the lords, when the land-owners of Pennsylvania, present in England, petitioned the house, and gained time for the governor's return; who, on notice of the measure, forthwith embarked, and arrived at Portsmouth in December 1701. The bill which had been postponed, was now entirely dropped, and the accission of queen Anne, soon after, placed Penn once more in the sunshine at court. His estate, however, had now suffered much, by liberal disbursements, by inadequate returns,
returns, and by the continual political impediments thrown in his way. He was moreover involved, in 1707, in a suit at law with the executors of a person who had been his fellow; and his cause not admitting of relief by the court of chancery, he was obliged to live within the rules of the Fleet, until the dispute could be adjusted. Advantage was now taken of his embarrassments by the ministry, to endeavour to buy what was before to have been taken by an act of power. He demanded for his province 20,000l. and, after some discussion, had agreed to accept of 12,000l. when he was incapacitated by illness from completing the sale. This defect was to have been supplied by an act of parliament, and by the queen's order one was prepared. It now appeared, on the petition of Henry Gouldney and others, that Pennsylvania had actually been mortgaged to them by its proprietor in 1708, for the sum of 6000l. Let us turn from this prospect: it is thickening to see public spirit and liberal enterprize reduced to the necessity of pawning and selling to sake its honourable fruits. The estate, however, was not fold, but continued in the hands of Penn, and the proprietaries, after the revolution in America, received from the legislature of Pennsylvania the sum of 130,000l. in lieu of their quit-rents, besides retaining many valuable tracts of land. They also received, by an act of the British parliament, a remuneration of 4000l. per annum, in consideration of their losses, and of the "meritorious services" of their ancestor.

For ten years after his return to Europe, Penn lived mostly near London, and was still active in religious and civil society. He wrote, in 1709, "Some Account of the Life and Writings of Bulstrode Whitelocke, esq." This was published along with the "Memorials of English Affairs," written by that excellent man and statesman, with whom Penn had been for many years acquainted. In 1710, his health declining, he took a handifoet at Ruhcomer, near Twyford, Bucks. Here, in 1712, he was attacked with fits, supposed to be apoplexy, by which his understanding and memory were much impaired, and he became, in consequence, unfit for public action, though not infensible, as it appears, to the sympathy of his friends and the comforts of religion in a peaceful confidence. He died, after a gradual declension of six years, the 30th of the month called July 1718, and was interred at the Quaker's burial-ground, at Jordans, near Beaconsfield.

One of the ablest and best informed of Penn's contemporaries, Burnet, in his history of his own times, has exhibited him, on several occasions, to some disadvantage, both as a man and a citizen. That he should no where report any good of a perfon so eminent might juftly excite our surprize; but was not apparent that Penn was, on several accounts, odious to this historian: we must therefore receive the little he is pleased to say concerning him, with due allowance for the effect of party prejudice. That Penn was a perfect, or a faultlefs character, will not, by his warmest friends, be pretended. He appears to have wanted deference in his estimate of affairs at home: but in his policy abroad, where he moved without shackles, there is a soundnes of principle, and a dignity of feeling, that make ample amends for this defect: his integrity was evinced through many severe trials: his errors may be pronounced a fraction of no moment, when set against the great sum of good, of which, under the Author of every good gift, he was the conscious and the willing donor to mankind. Penn's Life, prefixed to his Works, in folio. Sewell's Histoty of the Quakers. Proud's History of Pennsylvania.
prepare his British Zoology, in 132 coloured plates, im-
perial folio, with explanations. This work he afterwards
published for the benefit of the Welsh charity-school in
London. In 1765 he came into possession of the estate of
Downing, and with it a rich mine of lead-ore, which en-
abled him to make great improvements. The death of
his wife interrupted his domestic enjoyments, and in the spring
of 1766 he made a tour to the continent, and visited Swit-
zerland, part of Germany, and Holland, and acquired an
intimacy and friendship with several persons of great sci-
cient knowledge, among whom were Buffon, Haller, the
Gefneri, Groovonius, and Pallas. His conference with the
latter at the Hague gave rise to the plan of his "Synopsis
of Quadrupeds." In 1767 he was elected a fellow of the
Royal Society of London, and in the next year he repub-
lished his British Zoology, in two vols. 8vo., and in 1769 a
third was added, including fishes and reptiles. In the same
year he took a journey to the remote point of Scotland,
and the observations which he made were afterwards the
basis of a very interesting publication. In 1770 he published
three additional plates to his British Zoology, with several
new descriptions, and in the following year he printed his
Synopsis of Quadrupeds, in one volume 8vo. His well-
earned reputation caused him to be preferred, by his Alma
Mater, with the compliment of the degree of Doctor of
Laws. The account of his first Tour to Scotland was well
received by the literary world, for previously to this little
was known of Scotland by the people of England; and the
valuable and well-arranged facts given by this excellent
traveller, were highly prized by persons on both sides of
the Tweed. In 1772 he repeated his northern tour, extending
it to the Hebrides, the result of which was a rich harvest of
valuable and entertaining observations. In the following year
he published "Genera of Birds," in one volume, and
employed himself in a journey through the northern counties
of England.

Mr. Pennant was now become an habitual traveller, and
he found his excursions equally conducive to the health of
his body and vigour of his mind. In all his tours he laid
up new stores of information, and he found even the most
frequent tracts fertile of those topographical memoranda
to which his attention was principally directed. In 1776 he
gave the public an account of his native country, Wales, in
a work entitled "A Tour in North Wales," and in addition,
with the title of "A Journey to Snowdon." These are particularly interesting, on account of
the many anecdotes interpered illustrative of the manners
and history of that part of the island. He did not neglect
his original object of pursuit, Natural History. He had,
in the year 1777, added a volume to his British Zoology,
containing the Verms, Tellocaeus and Crucilaceus animals.
In 1781 he published his "History of Quadrupeds," and
in the same year his "History and Natural History of the
Turkey" was inserted in the Philosophical Transactions.
His "Arctic Zoology," in two vols. 4to. appeared in 1785.
To this there was a copious introduction, which is thought
to be the most interresting and original of all his writings.
It is a kind of survey of all the coasts of the arctic region,
beginning from the Straits of Dover, and proceeding to the
remoted north, on the east and west, and filled with a great
variety of geographical, historical, and physical facts, afford-
ing a series of the most animated pictures. In 1782 he
published "A Journey from Chester to London," and also
an account of the antiquities of the capital itself, entitled
"London." Several smaller pieces of the political and
miscellaneous kind filled up the intervals of his greater
works, and proved the continued activity of his mind.

These facts are chiefly taken from the history of his literary
life by himself, which was printed in the year 1793. After
which he published a natural history of the parishes of
Holywell and Dawning, within the latter of which he re-
plied more than 50 years. Not long before his death ap-
ppeared another work, in two volumes 4to., which was en-
titled "A View of Hindoosan," which was executed in an
able manner, and which bears a strong resemblance to the
introduction to the "Arctic Zoology." He died at his
seat at Downing in the year 1798, in the 72d year of his age.
He inherited from nature a strong and vigorous con-
stitution; his countenance was open and intelligent; his dis-
position active and cheerful; and his vivacity, both in writing and
conversation, rendered him, at all times, an entertain-
ing companion. He was exemplary in the relations of
domestic life, zealously attached to the interests of his coun-
try, both local and general, and kindly attentive to the
wants of his poor neighbours. As an author his dyle is
lively, and well adapted to convey the ideas which he in-
tended to express, but it is not always correct. In the
department of natural history he is clear and judicious in his
principles of arrangement, concise, energetic, and exact in
his dcriptions. His facts are regarded as of good au-
thority.

PENNANT, or Pendant, in a Ship. See PENDANT.

PENNANTIA, in Botany, was so named by Forster,
in honour of his friend and patron the late Thomas Pennant
eq. of Downing, F.R.S., the great British zoologist,
who in his various publications has incidentally touched
on botany in many places, and who published in his various
toues the first British figures of some of our rarest plants.
Jaff. 428. Lamarck Illustr. t. 574.-Clasf and order, Poly-
uncertain; perhaps akin to the Utica of Jullieu.

Gen. Ch. Cal. none, unless the corolla be taken for
fuch. Cor. Petals five, equal. lanceolate, acute, concave,
widely spreading. Stam. Filaments five, capillary, the
length of the petals; authors oblong, incumbent. Filj.
Germen superior, obutely triangular; style none; stigma
flat, petale, obfuscely three-lobed. Peric. Capsule? trian-
gular, of two cells. Seeds solitary, somewhat triangular.

Some flowers, on a separate plant, have the filaments
larger, as long as in the above, with ovate anthers, but no
pilifer.

Capsule? of two cells. Seeds solitary.

1. P. corvulofla. Forti. Prodr. 75.-Native of New Zea-
land. 1. A tree or shrub, with round leafy branches, dotted,
and somewhat downy, when young. Leaves alternate,
flaked, two inches or rather more in length, obovate, either
quite entire, or with two or three broad, blunt, shallow
teeth or small lobes; furnished with a mid-rib, and many
transverse interbranching veins; dark green above, nearly
smooth, except the rib, which is on both sides minutely
hairy; pale and smooth beneath. Folia not half an
inch long, channelled, hairy. Stapular minute, oblong,
containing the membrane very soon falling off. Caryms ter-
minal, much branched, many-flowered, hairy; the branch-
early alternate. Flowers about the base of Laurus-tinus;
as far as can be judged of them in a dry state, they seem
to be pale green or yellowish-white. The whole specimen
bears a general resemblance to some kind of Viburnum, but
the absence of a calyx is a striking difference. Such is
Forster's original specimen before us. The younger Lin-
neus however obtained in England, if we mistake not, a
specimen under the name of Pennantia, which is a very dif-
ferent
ferent thing. The leaves are ovate, four inches long, green
on both sides, undivided and entire. Branches and footstalks
smooth, with a solitary flaked gland at a little distance
above each of the latter, and no flabell. Flowers numerous,
in a terminal, compound, smooth chilum; their style as long
as the corolla, their filaments longer, and, what is most
remarkable, each flower has a calyx, deeply divided into five
ovate fringed segments, and rather elongated at its base.
This plant therefore is unquestionably altogether different
from Forler's Pennatia; it may be an Æbreia, but we know
nothing of the fruit, nor is it to our present purpose
to investigate this question. The true Pennatia above
described has so much resemblance in some points to the order of
Urtice, that we venture to hint its probable affinity thereto.
Possibly the supposed corolla of five petals may be a
deeply divided calyx. As to the true nature of the fruit,
nothing certain is known. Forler examined the germen
only, and hence we allow that the rudiments of two cells
is a circumstance much against our conjecture, we conceive
there are not sufficient materials to lead us to any other false
conclusion.

Pennar, in Geography, a river of Hindooftan, which
rises in Myfore, traverses the carch of Cuddapa and the
Carnatic, and runs into the bay of Bengal, 12 miles E. of
Nellore. N. lat. 12° 26'. E. long. 80° 13'.

Pennar Point, a cape in the English channel, on the
S. coast of Cornwall; 6 miles W.S.W. of Dedman's
point. N. lat. 50° 12'. W. long. 4° 46'.

Pennarth Bay, a bay on the S. coast of Wales, in
the Severn, at the mouth of the Taf, below Cardiff. A
point of land, called Penarth point, bounds it on the
S.W.

Pennas, Lus. a town of Peru, in the diocese of La
Paz; 70 miles N. of Potosi.

Pennata Folia, winged leaves, among Butanii, are
such leaves of plants as grow directly one against another,
on the same rib or stalk: as those of the ash, walnut-tree,
&c. See Leaf.

Pennatula, or Sea-pen, in Natural History, a ge-
nus of the class and order Verme Zoophyta. The generic
character is as follows: animal not affixed, of various
shapes, supported by a bony part within, naked at the
base, the upper part with generally lateral ramifications, fur-
nished with rows of tubular denticles, producing radiate
polypes from each tube. There are eighteen
Species.

Coccinea. The stem is round, radiating, with papillos-
ous polype-bearing sides, and clavate at the top. It inhabits
the deeps of the White sea, and unites the two genera Aleyoniumm
and Pennatula; it is soft, red, an inch and half high, and as
thick as the little finger; it is wrinkled, with the papille
deposed in rows.

Grysea. Stem fleshy, with a smooth midrib and imbric-
ate plaited spiny ramifications. It is found in the Adriatic,
and is about eight inches long; its leaves by night;
back of the midrib lanceolate, smoothish; rays imbricate,
and uninate on the anterior margin, the lobules are armed
with a spine, and obtusely crenate at the margin.

Pseudophorina. Stem fleshy, with a rough midrib and
imbricate ramifications. It inhabits most seas, and emits
a strong phosphoric light in the dark; it is about four inches
long and red; the stem is villous, with a lanceate rough
midrib, and nearly incumbent rays, the tubes pointing
all one way.

Filosa. The stem is a little fleshy, with a rib feathered
on each side, and furnished with two fimbriate tentacula at the
base. It inhabits European seas, and is from four to six
inches long.

Rupira. Stem fleshy, with a broad, tuberculate mid-
rib, the ramifications are imbricate, with each a short spine
at the base. It inhabits the Mediterranean, is about four
inches long; in colour it is whitish, varied with red dots and
faffron lines.

Mirabilis. Stem fimbriate, with lunate, dilatant, alter-
native ramifications. It inhabits the American, the Atlan-
tic, and Norwegian seas; is about three or four inches long,
and is fulvous; the tubes are round, with a fimbriate tip.

Sacittia. Stem fimbriate, with close-fet ramifications,
and naked at the tip. It inhabits the ocean, and is thought
not to be a distinct species.

Antennaria. Stem nearly quadrangular, falcate,
with polype-fuckers, on three sides. It inhabits the Me-
diterranean; is two feet ten inches high, and with regard
to colour it is yellowish dotted with red.

Stellifera. Simple, equal, with solitary polypes to-
wards the tip. It inhabits the Norway seas, and is about
four inches long.

Phalloides. Simple, with a cylindrical midrib every
where covered with polypes. It inhabits the Indian ocean,
is six inches long, and grey.

Arundinacea. Stem quadrangular and very long.
It inhabits the Norway seas, and is four feet long; the
stem is linear, with cylindrical rays of solitary tubes, which
are deciduous, erect, crowded, and feasted on a thin pe-
dicle.

Searpea. This is simple, linear, tapering, with a round
midrib producing polypes on one side. It inhabits the
ocean, and is eighteen inches long; the stem is fleshy, thicker
and longer than the midrib; the bone is somewhat flexile.

Juncea. Simple, linear, with a truncate rib, and trans-
verse polype bearing wrinkles on each side. This is found
in the Indian ocean, is two feet long, white, beneath horuly,
the rays mixed, fulvous and white.

Grandis. Pen-shaped, linear-lanceolate, with a smooth
round item, and jagged toothed ramifications. It inhabits
the Indian ocean; is a foot long, greenish grey, shines
with a cerimiceous light in the dark, and sometimes things the
hand if it be touched.

Argentea. Pen-shaped, lanceolate, with a smooth
round item, and very close-fet imbricate, fimbriate ramifica-
tions. This alio is found in the Indian ocean, and is about
a foot long; in colour it is a rich, silver white, elegantly
fimbriate along the ramifications with lines of black; like
many of the tribe it is luminous in the dark.

Encrinus. Stem quadrangular, taper, very long, bony,
covered with a callous membrane, with an umbellate clus-
ter of polypes from the top. It inhabits the Greenland
seas, is about six feet long, and when taken fresh from the
sea, appears like a nosegay of yellow flowers.

Cynomorium. Cylindrical, fleshy, somewhat clavate,
bearing polypes on the whole upper surface. It inhabits the
Mediterranean, is reddish, and about four inches long.

Reniformis. Stem round, vermicular, supporting a
kidney-shaped leaf-like head, producing polypes on one sur-
face, and is found in South Carolina. The body is expand-
ed, kidney-shaped, flat, rising from a short item, and
covered on the upper surface with numerous tubular orifaces,
through which the polypes are protruded at pleasure; the
upper surface is of a rich purple, the under side less brilli-
ant, and sometimes yellowish.

Penne, in Geography, a town of France, in the de-
partment of the Lot and Garonne, and chief place of a can-
ton, in the district of Villeneuve d'Agen; 3 miles E. of it.
The place contains 8,34, and the canton 10,621 inhabitants, on a territory of 1625 square kilometres, in 22 communes.

**PENNEDO** de St. Pedro, a small island in the Atlantic. N. lat. 0° 53'. W. long. 27° 10'.

**PENNEVISCH.** In Ichthyology, a name given by some to the half-fish common species of the fish called **bagger**, caught in the East and West Indies.

**PENNEWANG,** in Geography, a town of Austria; three miles N. of Schwanauadt.

**PENNI,** Giovanni Francesco, called **Il Fattore,** or the steward, from having been entrusted with the domestic concerns of Raphael, in Biography, soon became one of his principal affiliates. He more than any other helped him in the execution of the cartoons of the Arazzi, and in the Loggii of the Vatican painted the histories of Abraham and Isaac. After the death of his master, he executed the fresco of the coronation in the Stanza of Confrontante. The upper part of the Assumption of the Virgin at Monte Lupi, in Perugia, is ascribed to him, but the lower part was painted by Giulio Romano. Few of his own works remain.

Facility of conception, grace of execution, and a singular felicity in landscape, are mentioned as his characteristics.

Penne wished much to have united himself with his co-heir Giulio, but being coldly received by him at Mantua, went to Naples, where his works and principles might have contributed much towards the renown of his name, had he not been intercepted by death, in the year 1528, at the age of 45. Fufelli's Pilkinson.

**PENNIGONDA,** in Geography, a town of Hindoostan, in the circuit of Rajamundry; 38 miles E. of Rajamundry.

**PENNING, in Commerce,** a money of account in Holland. The gilder, or florin, contains 20 rivers, and each of these is subdivided into 16 pennings; the rix-dollar is = 800 pennings; 2 pennings = a duit, and 8 duits = 2 gros of Flemish = a River.

**PENNINGTON, Isaac,** in Biography, a member of the society of friends, and a considerable writer among that people, was the son of an alderman of London, who repeatedly filled the office of chief magistrate, was a noted member of the Long Parliament, and nominated one of the judges of king Charles I., though he did not take his seat among them. Ifaac was born about the year 1617, and having the prospect of succeeding to a large estate, he was furnished with the means of obtaining the best education. As he grew up, he had, from his father's situation in life, opportunities of mixing with some of the most considerable men of the age, and if he had been of an ambitious turn of mind, he might have occasionally indulged hopes of rising very high in the world. But from a very early age he was under strong religious impressions, and as he grew up to manhood, discovered an incalculable attachment to retirement, fervent contemplation, and the reading of the scriptures. While he was in this state of mind, he met with some of the writings of the Friends, "which," says he, "I cast an eye upon and disdained, as falling very short of that wisdom, light, life, and power which I was seeking after." There was, however, something in them that roused his attention, and he went to one of their public meetings, at which George Fox preached, whose discourse produced on him a sudden and complete conversion to the principles of the new sect. From this time he joined the society in opposition to the influence of his connections, as well as unmoved at the prospect of reproaches and loss of which his profession would unquestionably expose him. In the years 1661 and 1662, Mr. Pennington was called forth to be a confessor for the profession which he had embraced. For the crime, as it was called, of holding meetings of Friends for the worship of God in his own house, he was committed to Aylebury gaol, where he was kept in close custody for seventeen weeks, great part of which was in the winter season; and to aggravate the severity of his treatment, he was confined in a cold and very inconvenient room, without a chimney, by which cruel usage he contracted so violent a disorder, that for several weeks after his release he was not able to turn himself in his bed. From this time till the year 1679, he suffered six different imprisonments. These repeated calamities, together with heavy pecuniary losses, arising, in many instances, from the confiscation of his property, to discharge the oppressive fines which were levied upon him, Mr. Pennington sustained with firmness and serenity, believing himself to be a sufferer for obeying God rather than man. With the same equanimity and fortitude he bore the attacks of a painful distemper, which terminated his life in the year 1679, in the 63rd year of his age. His character procured him the respect and esteem of all good men, as it exhibited an excellent pattern of piety, virtue, and the highest morality. He was most faithful in the discharge of all the duties of life, and was author of numerous writings, which were highly prized by the people with whom he associated. They were collected and published in a folio volume in 1681. They have since been reprinted in 4to. and 8vo., and in the year 1766, some of his "Letters" were published.

**PENNINGTON,** or Pennsburg, in Geography, a pleasant and flourishing village in Hunterdon county, New Jersey; 9 miles W. of Princeton, containing a church and about 42 houses.

**PENNISTUM,** in Botany, so called by Richard, from **penna,** a feather, and **fita,** a bristle; Richard in Perf. Syn. v. 1. 72. Brown Prod. Nov. Holl. v. 1. 195. (See Panicum.) The name alludes to the feathery structure of the bristles which compose the involucrum.

**PENN, or Pennox,** a standard with a triangular tail, anciently borne before knights bachelors, who brought a certain number of followers into the field. Some instances occur of pennons being carried before esquires, but they were only such as poissell certain eftates or fields; or who could bring a sufficient suite of vaflals into the field. The pennon was in figure and size like a banner, which was small and of a square figure, with the addition of a triangular point. They were charged with armorial bearing of their own. On the performance of any gallant action by the knight and his followers, the pennon was converted into a banner by the king, or commander-in-chief, cutting off the point, by which the knight was raised to the degree of a banneret. Both knights and bannerets were bound to appear in the field at the head of a certain number of men, whence ancient historians frequently express the strength of an army by the number of banners and pennons of which it consisted.

**PENSIBEROU**GH, West, in Geography, a town of America, in Cumberland county, Pennsylvania; famous for a remarkable flow of water from a ridge of lime-stone, called "The Big Spring," which, after turning fix mills, discharges itself through Conodoguinet creek into the Susquehannah.

**Pensiborough, Eng.,** a township in the same county.

**PENSIBURY,** a small town of Pennsylvania, in Buck's county, on a small creek of Delaware river. This was a manor which Mr. Penn referved for himself, where he built a house, and planted orchards and gardens; which, with many additional buildings and improvements, still continue.

**PENNSYLVANIA,** one of the principal provinces of the United States of America, extending in length 228, and
and in breadth 156 miles, between 39° 43' and 42° N. lat. and 74° 48' and 80° 8' W. long, and comprehending 46,000 square miles. It is bounded E. by Delaware river, which divides it from New Jersey; N. by New York and lake Erie; W. by the state of Ohio and a part of Virginia; S. by Virginia, Maryland, and Delaware. The figure of this state is a parallelogram, if we except the N.W. corner of this state, containing about 202,000 acres, lately purchased of Congress by the state. In the year 1800 Pennsylvania was divided into thirty-five counties, as in the following Table:

* The suburbs contain 39,789 inhabitants.

A new census having taken place since the above table was formed, some of the statements admit of considerable alteration. The interruption of intercourse between the two countries has prevented our obtaining this census; but as soon as it is received, the necessary corrections shall be made.

The total number of acres in all the counties is reckoned at 29,624,840; and a great portion of the state is divided into townships, in each of which the freemens assemble annually to chuse overseers of the poor, a collector of taxes for roads, and a constable. The number of inhabitants, which is 632,545, includes 1766 slaves. In this state are fix considerable rivers, viz. the Delaware, Schuylkill, Susquehannah, Youghiogeny, Monongahela, and Allegany. The only swamps, worthy of notice, are the Great Swamp, between Northampton and Luzerne counties, and Buffalo Swamp, near the head waters of the Susquehannah. These swamps are found, upon examination, to be bodies of firm land, thickly covered with beech and sugar maple. A considerable proportion of this state may be reckoned mountainous. The principal ridges, in the great range of Allegheny mountains, comprehended in Pennsylvania, are the Kittatteny, or Blue mountains. Behind these, and nearly parallel to them, are Peters, Tuscarora, and Nefcopek mountains, on the E. of the Susquehannah; and on the W. Shuremon's hills, Siddering hills, Ragged, Great warriors, Evits and Will's mountains; then the great Alleghany ridge, which being the largest gives name to the whole range; and W. of this are the Chefnut ridges. Between the Jumata and the W. branch of the Susquehannah are Jacks, Tuffys, Nittingy, and Bald Eagle mountains. The vales between these mountains are generally of a rich, black soil, suited to the various kinds of grains and grains. Some of the mountains admit of cultivation almost to their summits. The other parts of the state are generally level, or agreeably variegated with hils and valleys.

The soil of Pennsylvania is of various kinds; in some parts it is barren; but a great proportion of the state is good land, and no inconsiderable part of it is very good. In general, however, the soil is more fit for grain than for grases. This state includes the greater part of the kinds of trees, shrubs, and plants, that grow within the United States. Oaks of several species form the chief bulk of the woods. Hickory and walnut are also more abundant than in the northern states. Saffrares, mulberry, and tulip or poplar trees are frequent and thriving. The Magnolia grandiæ grows in low grounds; and the acuminate attuks to great height about the western mountains. Grapes are common; and some of them, mellowed by frost, with the addition of sugar, make good wine. The white pine and white cedar grow well in some parts; and also red cedars are not rare in high grounds. The sugar maple is plentiful in the western and northern parts of the state, and inhabitants are supplied from them with a considerable quantity of sugar.

Iron ore is distributed in large quantities through various parts of the state; and in some places appear copper, lead, and alum. Here are also limestone quarries, and various kinds of marble. In the middle and western country is abundance of coal. In the new settlements of the country there are large flocks of wild turkeys. Partridges are numerous; pheasants are dear; and grouse are found in some districts. In the cold seafon pigeons migrate from the north in large numbers. In spring and autumn, severl kinds of ducks, and some wild geese, are found on the rivers. The fissing birds migrate to Pennsylvania from the north and south in certain seasons, and are numerous. In the rivulet swams are common; in the eastern rivers the principal fish are roch, shad, and herring, which, in the spring, come from the sea in large shoals. In the western waters are a species of catfish, weighing from 50 to 100 pounds, and also yellow perch and pike, which are large and numerous.

Among the useful quadrupeds in the new districts are deer in great number, beavers, otters, racoons, and monies. Buffaloes rarely cross the Ohio, and elk's seldom advance from the north. Panthiers, wild cats, bears, foxes, wolverines, are not rare; the fowl of all which is valuable. In the north settlements rabbits and squirrels are frequent; in the marshes are minks and musk-rats; but opossums and ground hogs are rare. The best settled land is on the south
of Pennsylvania; which is owing to the roads that have been formed in this part of the country and adjacent districts. The principal article of agricultural cultivation is wheat. The next in value is Indian corn. Buck-wheat, rye, barley, and oats, are also cultivated. As are also German spelt, chiefly as food for horses. Potatoes are plentiful; and also turnips, cabbage, parsnips, and carrots, and the small oval pea. The culture of meadows is a considerable object in this state; those on the rivers are banked, drained, trenched, fenced, and harrowed; and fown with Timothy grass and clover. The summer is long enough to admit of two mowings, and even three in rich ground. On farms that have springs and streams, dairies are built over them so as to place the milk-yellets in the water, which is necessary to avoid the injurious effects of heat. Horses, it is said, are reared beyond the proper use, as oxen might more generally supply their place. The belt for teams are bred in Lancaster county; and the elegant saddle and coach horses have more or less of the blood of stallions imported from England. The number of sheep is considerable, and increases. Hogs, supplied with food from the woods of oak and beech, exceed home consumption. Mules and asses are hitherto very rare. Poultry are abundant, and turkeys are cheap. Flax and hemp are cultivated; the growth of hops is inconsiderable: bees are objects of attention. In favourable seasons, cherries, apples, and cider abound. Some attempts have been lately made about eleven miles from Philadelphia for the plantation of vineyards. Improved farms and roomy lots in the country towns have gardens which supply common vegetables, fruits, and flowers.

The general style of architecture in this state is neat and solid. Stone buildings are most common in the old settlements; log and frame-houses in the new. Towns have a considerable proportion of brick houses; shingles cover the roofs. Necessary tradesmen and mechanics are settled on small farms or lots throughout the improved country, and also in villages. Manufacturers dwell chiefly in towns, though many of them are scattered through the country. The product of domestic female industry is considerable. The wives and daughters of even opulent farmers knit and spin; and in the towns, some females of higher rank do the same. Woollen flockings are made in sufficient quantity for home use, and hemp, which is used in several places for coarse wearing apparel, bags, lines and nets. &c. is manufactured, in large quantities, into curdage, cables, and ropes. Iron works are of long standing, and are in an improving condition. The furnaces are 16, and the forges 37. The flitting and rolling-mills are paid to cut and roll 1,500 tons per annum. The fabricated articles are numerous, and of all the common kinds. Manufactures of leather, flints, and fur, are very extensive and good. The most respectable trades employed in materials of wood are cabinet-making, house-carpentry, coach-making, and ship-building. The port of Philadelphia is said to be among the finest in the world for naval architecture. Paper of most kinds form a beneficial branch of manufacture, in which are employed above 50 mills, the annual product of which is computed at 25,000 dollars. Manufactures in flax, clay, and oilfish, are bricks, and various pieces of marble, common earthen ware, grind-floines, and mill-flones. Pot and pearl-ashes are gradually advancing; tin-wares are well executed for various domestic purposes. Copper, brass, lead, and pewters are also the materials of various manufactures. A considerable quantity of cotton is wrought in families; linens imported are now printed; sugar refineries, and distilleries of molasses, and various preparations of tobacco, furnish employment for many hands. The manufactures of Pennsylvania are said to have greatly increased within a few years, partly by the immigration of workmen from abroad, as well as by the skill and industry of the natives. Several new machineries have been lately set up at Philadelphia, and in some other places.

The commerce of Pennsylvania with the eastern and northern states, is, in great part, an exchange of staple commodities; which are too numerous to be recited. The commerce of Pennsylvania with the west is carried on by the Ohio with the Spaniards, and by the lakes with the British, dominions; and both ways with the Indian tribes. At present nearly the whole foreign commerce is carried on by the port of Philadelphia. The value of the exports from this state in the year ending September 30, 1791, was 3,136,692 dollars, 56 cents; in 1792, 3,820,662 dollars; in 1793, 6,698,836 dollars; in 1794, 6,642,902 dollars; in 1795, 11,518,260 dollars; in 1796, 12,431,957 dollars; in 1801, 17,438,193 dollars; in 1804, 11,030,157 dollars.

The importation is very great, both for the consumption of Pennsylvania, and of the districts supplied from Philadelphia: common and fine imported linens and woolens are used to a great amount, notwithstanding the quantity of home-made; much Swedish iron and Russian hemp is imported; and English hard-ware is in great demand. The tonnage of this state amounted, in 1796, to 98,237 tons; in 1799, to 93,824 tons.

The population of this state (for which see the Table) is, according to the census of 1800, more than 13 for every square mile. The inhabitants are principally the descendants of English, Irish, and Germans, with some Scotch, Welsh, Swedes, and a few Dutch. The Friends and Episcopalians are chiefly of English extraction, and compose about one-third of the inhabitants. The Germans compose about one-quarter of the inhabitants of Pennsylvania: they confide of Lutherans (who are the most numerous), Calvinists or the Reformed church, Moravians, Catholics, Mennonists, Dutch Baptists (corruptly called Tunkers and Dunkers, by way of reproach), and Zwingfelters, who are a species of Quakers. They are all distinguished for their temperance, industry, and economy. The Baptists (except the Mennonists and Dutch Baptists) are chiefly the descendants of emigrants from Wales, and are not numerous. The original Swedes went over in the year 1638, as a colony, under the name of New Sweden, for the protection of Sweden. Few Swedes have since settled in America; and their language is nearly extinct. These people uniformly had the character of probity, mildness and hospitality; but have been careless of their lands and interest. A privilege, almost peculiar to this state, has been granted to foreigners by the legislature; viz. that of buying and holding lands and houses within this commonwealth, without relinquishing their allegiance to the country in which they were born.

The character of the Pennsylvanians is naturally diversified by difference of extraction, various degrees of education, and of opulence.

The congregations of the different denominations of Christians in Pennsylvania are as follow; viz. Presbyterians, 96 congregations; German Calvinists, 84; German Lutherans, 84; Friends or Quakers, 54; Episcopalians, 26; Baptists, 15; Roman Catholics, 11; Scotch Presbyterians, 8; Moravians, 8; Free Quaker, 1; Universalists, 1; Congregations, 1; Methodists, several; besides a Jewish synagogue; amounting in all to about 400 religious societies. Religious liberty was formerly on a more respectable establishment in this state than in the other parts of America. But even here it was imperfect till the late revolution; for Roman Catholics and Jews were excluded from a share in the governemt. The latter continued under this disadvan-
The military strength of this country consisted, in 1799, of 93,221 men.

Pennsylvania abounds with literary, humane, and other useful institutions more than any other of the American states. We shall here merely enumerate them, and mention the time of their institution. They are the American Philosophical Society, founded in 1769; the Society for promoting Political Inquiries, instituted in February 1787; the College of Physicians, instituted in the same year, and incorporated in 1789; the Pennsylvania Hospital, established in 1751; Philadelphia Dispensary, instituted in 1786; the Pennsylvania Society for the Abolition of Slavery and the Relief of free Negroes unlawfully held in bondage, begun in 1774 and enlarged in 1787; the Society for alleviating the Miseries of Prisons, which is become a regular work-house with an annexed place of confinement; the Society of United Brethren for propagating the Gospel among the Heathens, instituted in 1757; the Pennsylvania Society for the Encouragement of Manufactures and useful Arts, instituted in 1787; the Philadelphia Society for the Information and Affiliation of Persons emigrating from foreign Countries, instituted in 1794. Beside these there are two insurance companies, an humane society, for the recovery of drowned persons, instituted in 1770; an agricultural society, a society for the relief of German, and another for the relief of Irish emigrants, a marine society, a charitable society for the support of widows and families of Presbyterian clergymen, and St. George's and St. Andrew's charitable societies. Most of these societies are in the city of Philadelphia.

Under the head of colleges, &c., we may enumerate the University of Pennsylvania, founded and endowed by the legislature during the late war, and lately united with the college of Philadelphia; Dickinson college, at Carlisle; Franklin college, at Lancaster; and the college at Washington (see College); the academy of the Episcopalian, at York-town; the academies at German-town, Pittsburgh, Allen's-town, and other places; the schools of the Moravians, and other private schools in different parts of the state. The principal cities and towns of Pennsylvania are Philadelphia, the metropolis, the borough of Lancaster, Pittsburgh, Bethlehem, Nazareth, Carlisle, Harrisburg, York-town, Washington, Sunbury, &c. See the Table at the beginning of this article, and an account of each town under its respective name.

As to the constitution of this state, we may observe, that the supreme executive power of the commonwealth is vested in a governor; the legislative, in a general assembly, consisting of a senate and a house of representatives. The governor is chosen for three years, but cannot hold his office more than nine years in twelve. A plurality of votes makes a choice. The representatives are elected for one year; the senators for four. The latter are divided into four classes. The time of one clafs expires each year, whose seats are then filled by new elections. Each county chooses its representatives separately. The senators are chosen in districts formed by the legislature. There is to be an enumeration of the inhabitants once in seven years. The number of senators and representatives is, after each enumeration, to be fixed by the legislature, and apportioned among the several counties and districts, according to the number of taxable inhabitants. There can never be fewer than sixty, nor more than one hundred representatives. The number of senators cannot be less than one-fourth, nor greater than one-third of the representatives. The elections are made on the second Tuesday of October. The general assembly meets on the first Tuesday of December, in each year, unless sooner convened by the governor. A majority of each house makes a quorum to do business, and a less number may adjourn from day to day and compel the attendance of members. Each house chooses its speaker and other officers, judges of the qualifications of its members, and establishes the rules of its proceedings. Impeachments are made by the house of representatives, and tried by the senate. All bills for raising revenue originate in the lower house, but the senate may propose amendments. The senators and representatives are free from arrest, while attending the public business, except in cases of treason, felony, and breach of the peace; and are not liable to be questioned concerning any thing said in public debate. They are compensated out of the public treasury, from which no money can be drawn but in consequence of appropriation by law. The journals of both houses are published weekly, and their doors kept open, unless the business requires secrecy. All bills which have passed both houses, must be presented to the governor. If he approve he must sign them, but if he does not approve he must return them, within ten days, with his objections, to the house in which they originated. No bills so returned shall become a law, unless it be repassed by two-thirds of both houses. The governor is commander-in-chief of the military forces; may remit fines and forfeitures, and grant reprievs and pardons, except in cases of impeachment; may require information from all executive officers; may, on extraordinary occasion, convene the general assembly, and adjourn it, for any term not exceeding four months, in case the two branches cannot agree on the time themselves. He must inform the general assembly of the state of the commonwealth; recommend such measures as he shall judge expedient; and see that the laws are faithfully executed. In case of vacancy in the office of governor, the speaker of the senate exercises that office. The judicial power is vested in a supreme and inferior court, the judges of which pay and salaries of the peace, are appointed by the governor, and commissioned during good behaviour; but are removable on the address of both houses. The other officers of the state are appointed, some by the governor, some by the general assembly, and some by the people. The qualifications for an elector are 21 years of age, two years' residence, and payment of taxes. They are privileged from arrests in civil actions, while attending elections. Those for a representative are 21 years of age, and three years inhabitation. For a senator, 25 years of age, and four years inhabitation. For a governor, 30 years of age, and seven years inhabitation. The governor can hold no other office. The senators and representatives none, but of attorney at law, and in the militia. No person, holding an office of trust, or profit, under the United States, can hold any office in this state, to which a salary is by law annexed. All the officers of the state are liable to impeachment, and are bound by oath, or affirmation, to support the constitution, and perform the duties of their offices.

The declaration of rights affords the natural freedom and equality of all; liberty of conscience; freedom of election, and of the press; subordination of the military to the civil powers; trial by jury; security from unreasonable searches and seizures; a right to an equal distribution of justice, to be heard in criminal prosecutions; to petition for the redress of grievances; to bear arms; and to emigrate from the state. It declares that all power is inherent in the people, and that they may, at any time, alter their form of government; that no person shall be obliged to maintain religious worship,
worship, or support any ministry; that all persons, believing in the being of a God, and a future state of rewards and punishments, are eligible to office; that laws cannot be suspended but by the legislature; that all persons shall be bailable, unless for capital offences, when the proof is evident, or pre- sumption strong; that every debtor shall be released from prison, on delivering his estate to his creditors, according to law, except there be false pretences of fraud; that the privileges of the writ of habeas corpus shall not be suspended but in time of rebellion, or public danger; that no ex post facto law shall be made; that no person shall be attainted by the legislature, or forfeit his estate for a longer term than his own life; that no title of nobility, or hereditary distinction, shall ever be granted. The constitution above described was ratified in 1790.

Under the head of the history of this state it is not necessary to enlarge. Pennsylvania was granted by King Charles II. to Mr. William Penn, son of the famous admiral Penn, in consideration of his father’s services to the crown (see his biographical article); and the charters received the royal sanction on the 4th of March 1681. To secure his title against all claims, and prevent future altercation, Mr. Penn procured a quit-claim deed from the duke of York, of all the lands covered by his own patent, to which the duke could have the leaf pretensions. This deed bears date Aug. 21, 1682. In the same month he obtained, by deed of feu-faitment, Newcastle, with 12 miles of the adjacent territory, and the land south to the Hoarkills. In December following, Mr. Penn effected an union of the lower counties with the province of Pennsylvania. The first frame of government for Pennsylvania is dated in 1682; another was proposed by Mr. Penn in 1683; in 1699, while Mr. Penn remained in Pennsylvania, the last charter of privilege, or frame of government, which continued till the revolution, was agreed upon and established. It was delivered to the people in October 1701. In 1700, 1701 and 1708, Mr. Penn obtained from different denominations of Indians some portion of territory. By the favourable terms which Mr. Penn offered to settlers, and an unlimited toleration of all religious denominations, the population of the province was extremely rapid. At the revolution the government was abolished; and the people, by their representatives, formed a new constitution on republican principles. The proprietaries were excluded from all share in the government, and the legislature offered them 120,000 in lieu of all quit-rents, which was finally accepted. The proprietaries, however, still poffessed in Pennsylvania many large tracts of excellent land. After many disputes the proprietors acquired the ascendency, and the constitution underwent an alteration, that affiliated it nearly to the federal constitution. The federal constitution was ratified by Pennsylvania December 13, 1787. Moree’s Geography, 1806.

PENNY, or PEN, in Commerce, an ancient English coin, which had formerly considerable course; but is now dwindled into an imaginary money, or money of account.

It is derived by Camden from pecunia; but others suppose that the word is formed from penos, to weigh, and it was sometimes written, according to this origin, pendens.

The ancient English penny, penige, or penning, was the first silver coin struck in England; and, and the only one current among our Saxon ancestors; as is agreed by Camden, Spelman, Dr. Hickey, &c.

Of the heptarchic penceys we have given an account under the article MEdaLS, &c.; Modern; and we have there given a brief history of the penny, as a silver coin, both before and after the Conquest.

The penny, which in Ethelred’s time was the 20th part of the troy ounce, was equal in weight to our three-pence; five of them made one shilling, or calling Saxon; and thirty a mark or muncie, equal to our 71 6d. It was the largest silver coin in England, and retained this value till the reign of Edward III.

Till the time of king Edward I. the penny was struck with a crofs so deeply indented in it, that it might be easily broke, and parted, on occasion, into two parts; thence called half-pennies; or into four, thence called fourthings, or farthings. But that prince coined it without indenture; in lieu of which he first struck round half-pence and farthings.

Stow, in his Annals, p. 209, observes, that half-pennies were first coined round, A.D. 1279, in the reign of Edward I. But historians have since discovered, that half-pennies of this kind were coined by Henry I., and that though the usual way in the reign of the two first Williams was to cut the penny into two for making of half-pennies, &c. yet it has been suppos’d that some few half-pennies might even then be coined round. Some few pieces of this kind are preserved in the cabinets of the curious. See Mr. Pegge’s remarks on this subject in Gent. Mag. vol. xxviii. p. 64. &c.

Edward I. also reduced the weight of the penny to a standard; ordering that it should weigh thirty-two grains of wheat, taken out of the middle of the ear. (Stat. 13 Edw. I.) This penny was called the penny sterling. Twenty of these pence were to weigh an ounce; whence the penny became a weight, as well as a coin.

By Edw. III. it was diminished to the twenty-sixth part of the troy ounce; by 2 Henry VI. it was the thirty-second part; by 5 Edw. IV. it became the fortith, and also by 36 Hen. VIII. and afterwards the forty-fifth; but by 2 Eliz. sixty pence were coined out of the ounce, and during her reign sixty-two, which proportion is observed in our times.

The penny sterling is now diffused as a coin; and freely subsists, but as a money of account, containing the twelfth part of a shilling, or the two hundred and fourtieth part of a pound.

The course of exchange between England and France is settled on the foot of so many pence sterling, for a French crown of three livres. See ExChANGEx.

For an account of the French penny, or denier, in the old system, see Denier. For the Dutch penny, see PENKING. For the German penny, see PfENKING.

The penny Flemish, called "grote," or "groat," is a money of exchange in Flanders, Holland, and Hamburgh. Accounts are sometimes kept in Brabant and Flanders in pounds Flemish of 20 shillings Flemish, subdivided into twelve groats or pence Flemish; but mostly in florins or gilders of 20 liuvres or AVers, called also pates, each of which was formerly subdivided into 16 pennies, but for a long time they have been divided into twelve parts or deniers. The pound Flemish, or pound Vlams, is reckoned at 2 1/2 rix-dollars, 6 florins, 20 shillings, 120 liuvres, 240 groats, or 1920 Brabant pennings. The rix-dollar, or patacon, is worth 2 1/2 florins, 8 shillings Flemish, 48 liuvres, or 56 pence Flemish. The Brabant penning contains three mites. See PfENKING.

PENNY, in Ancient Statutes, &c. is used for all silver money.

And hence the word-penny, aver-penny, hundred penny, tilling-penny, and brothal-penny. See PENCE, &c.
PEN

PENNY, in Geography, a town of Bengal; 15 miles S.E. of Purneath.

Penny-earth, in Agriculture, a term used by the farmers for a hard, loamy, or sandy earth, with a very large quantity of sea-shells intermixed in it, some of which being round and flat, and in some measure resembling pieces of money, have occasioned the earth's being called by this name. It is an earth not easily dug, but is usually undermined with pick-axes, and then falls in large lumps: which, with the frosts, break to pieces, and leave the shells loose. It is prepared by breaking and mixing well with water, and then makes very desirable floors. The Jerky combers' comb-pots are also made of it, and the sides and roofs of ovens are plastered with it; and being rightly managed, it combines into a floor almost as strong as platter of Paris.

Penny, bord. Half. See Bord Half-penny.

Penny, half. See Half penny.

Penny, Retro. See Retro-print.

Penny, Sebar. See Scarab.

Penny, Ward. See Ward-penny.

Penny or Twopenny Foll. See Post.

Penny-Royal, in Botany, &c. See Mentha Pulegium.

Penny-Royal, Virginia, a species of Satureja; which fee.

Penny-Weed, in Agriculture, a troublesome weed, known sometimes by the name of nettle.

Penny-Port, in Botany. See Cotyledon.

Penny-Port, Marth and Water. See Hydrocotyle.

Penny-weight, a Troy weight, containing twenty-four grains; each grain weighing a gram of wheat, gathered out of the middle of the ear, well dried.

The name took its rise hence, that this was actually the weight of one of our ancient silver pennies.

Twelve of these penny-weights make an ounce troy.

See Weight.

Penobscot, in Geography, a river of America, which is the most considerable in the district of Maine, and rises by two branches in the high lands. Between the source of the W. fork, and its junction with the E., is Moosehead lake, 30 or 40 miles long, and 15 wide. The E. branch passes through several smaller lakes. From the Forks, as they are called, the Penobscot Indians pass to Canada, along either branch, principally the W., the source of which, as they say, is more than 20 miles from the waters which empty into the St. Lawrence.

At the Forks is a remarkable high mountain: and from thence down to Indian Old Town, situated on an island in this river, the distance is about 60 miles, and in the interval the river widens and embraces a great number of islands. Just below Indian town are the Great Falls, where is a carrying place of about 20 rods, and thence for 12 miles to the head of the tide there are no falls to obstruct boats. From thence for 35 miles to the head of Penobscot bay, or to the site of old fort Pownal, the river flows in a pretty straight course, and is easily navigated. Passing by Mahone Bay on the E. seven miles, and Owl's head twenty miles farther, you enter the ocean. The Indians have a communication from this river to Scudlack river, by a portage of three miles. This river was the eastern limit of Nova Scotia or Acadia, by the treaty of Utrecht. Within about twenty miles there are more than sixty islands, of various sizes, comprehending in the whole about 12,000 acres. Fifty-four of these the Indians have referred to their own use.

Penobscot, a bay on the coast of Hancock county, in the state of Maine, and called by the first discoverer "No-rembeaga," about sixteen leagues wide from Naftaeg point and Burnt-coat island on the E., to the point on which Thomstown stands, on the W. side of the bay. The chief islands it includes are Fox, Haut, Long and Deer islands; besides a number of small islands, rocks, and ledges. On a fine peninsula on the E. side of the bay, the British built a fort, and made a settlement, which is now the fine town of the county of Hancock, and is a commodious place for the lumber trade. Haut island, or the isle of Holt, lies in N. lat. 43° 23', and W. long. 68° 16', and is the fouthermost of the large islands.

Penobscot, a port-town of Maine, on the E. side of the bay of its name, which is a port of entry, and carries on a small trade in fish and lumber. In 1796 it was divided into two towns; the one retaining the name of Penobscot, containing 935 inhabitants, and the other named "Caffin," which fee.

Penobscots, a small tribe of Indians who live in Indian Old Town, on an island in Penobscot river, and who say, that they have for five hundred years possessed the island on which their towns stands. (See Indian Old Town.) In a former war, this tribe lost its lands; but at the commencement of the last war, some new restrictions were felt, and they consider that, notwithstanding these, they have a right to haul and fish as far as the mouth of the bay of Penobscot extends. This was their original right, in opposition to any other tribe, and they now enjoy it.

Penomin, a town of Siam; 60 miles S. of Te-naffeerim.

Penon. See Pennon.

Penon, El, in Geography, a town of South America, in the province of Carthagine; 46 miles S. of Mompos.

Penowal, a town of Hindostan, in the circe of Oudeypour; 20 miles S.E. of Chitoure.

Penrhy, a sea-port of North Wales, in the county of Caernarvon, on the Menai, from which great quantities of slate are exported; two miles S.W. of Bangor.

Penrhyon, a cape on the W. coast of Wales, and county of Caernarvon; 10 miles S. of Pwllhele.

Penrhy, or Penrice. See Oxwich.

Penrith, a town of South Wales, in the county of Glamorgan, on the W. side of a bay in the Bristol channel, having a cattle and a weekly market on Thursday; 14 miles W.N.W. of Swansea. N. lat. 51° 46'. W. long. 4° 10'. See Oxwich.

Penrith, New, a market town in Leath ward, and county of Cumberland, England, is situated in a vale within the district called Inglewood Forest, 18 miles north of Carlisle, and 283 from London. It is a place of considerable antiquity, and was successively in possession of the English and Scotch sovereigns; during whose contentsions it suffered by the depredations of the Scots, by whom it was burned in the 18th of Edward III., and again in the following reign. About that period the plague raged in Penrith: and in the year 1597, a second visitation of this dreadful disorder nearly depopulated the parish; for 2260 persons fell victims to it within a year and a half. The fear of infection prevented the continuance of the regular markets; and places were appointed, without the town, for purchasing the provisions brought by the country people. Penrith is built in a very irregular manner: the houses are, in general, composed of red stone, and covered with blue slate. The population, in the year 1811, amounted to 4328, occupying 938 houses. The inhabitants are chiefly employed in agriculture, and in weaving checks and fancy cloths for waistcoats. A weekly market is kept on Tuesday, and here are five annual fairs. The flations for marketable commodities are disposed in a singular manner: the wheat market is in one part of the town, barley is sold in
in another part, rye and potatoes in a third: cattle, hogs, and horses, have also disinclined places of idleness. The church is a neat, but plain structure: the body was rebuilt of red bricks, in the year 1712, at the expense of 125l., and connected with the ancient tower. In the churchyard is a singular monument of antiquity, called the Giant's Grave, the origin of which has frequently exercised the sagacity and speculations of antiquarians. It consists of two stone pillars, standing at the opposite ends of a grave, about the distance of fifteen feet asunder, eleven feet six inches in height, and nearly five feet in circumference at the bottom, where they are mortified into round stones embedded in the earth. The space between them is two feet in breadth, and is inclosed by four thin semi-circular stones, two on each side, of unequal lengths, but little more than twenty inches in height. Three of these stones have an ornament of foliage, rudely sculptured, remaining round their upper edges; the fourth is plain, of a different kind, and seems to have been placed in the room of one decayed. The pillars taper upwards; their lower parts are rounded to about the height of seven feet, where they assume a square form, and appear to have terminated in a point; but the tops are broken. On the square parts are some traces of ornamental fretwork; and the interior side of one pillar has a rude delineation of some animal, resembling the wolf. Near the summit of each pillar are the velliges of a raised croslet, now almost obliterated. Bishop Lyttleton, in his remarks on this monument (published in the Archæologia) inclines to the opinion of its being the sepulchre of some British prince interred here subsequent to the introduction of Christianity; and tradition ascribes it to the British king Ewan, a warrior of gigantic size, who reigned in this county in the time of Athelstan, or Ida. That this Ewan was actually buried at Penrith, appears in the highest degree probable, from the notice of his sepulchre in the "Veris of the Graves of the British Warriors," written about the close of the sixth century. At a small distance from this monument, with which, however, it does not appear to have any connexion, is a single stone, called the Giant's Thumb, five feet eight inches in height, about fourteen inches broad at the lower part, but contracting upwards to ten inches: the head, which appears to have been circular, expands to the diameter of about eighteen inches. This seems to have been an ancient stone croslet.

Previous to the year 1490, the inhabitants of Penrith were frequently differefed for fresh water: but about that time, Strickland, bishop of Carlisle, purchased a sufficiency of the water of the river Peter, which he conveyed to the town at his own expense. He also founded a chantry here, and endowed it with fix pounds annually for the support of a priest. The revenues of this establishment were given by queen Elizabeth to an ancient school (instituted so early as the year 1340,) which she refounded, by the title of "The Free Grammar School of Queen Elizabeth in Penrith."

Weltward of this town are the ruins of a castle, which appears to have been built of an oblong form, and fortified with a very deep outward fos, and a walled rampart. This fortress was dismantled in the time of the commonwealth: the principal remains are the outside walls and arched vaults.

On the heights, to the north of Penrith, is a square stone building, called the Beacon, difficult of access, but affording a variety of delightful views of the surrounding country. History and Antiquities of Westmoreland and Cumberland, by Nicholson and Burn, 2 vols. 4to. 1777. Beauties of England and Wales, vol. iii. by Britton and Brayley.

PENRY, AP-HENRY, JOHN, in Biography, a victim to persecution and tyranny in the reign of queen Elizabeth, was born in some part of the county of Brecknock in the year 1559. When he was about the age of nineteen, he became a sub-bi-zer of Peter-Houfe, in the university of Cambridge, where he was admitted to the degree of B.A. about the year 1583. After he had finished his college studies he took holy orders, and preached several times at Oxford, as he did afterwards at Cambridge, with much reputation, but he soon rendered himself obnoxious to the ruling party in the church, by adopting the sentiments of that body of the clergy who were distinguished by the name of Puritans. Having chosen his lot with this proscribed party, he travelled into Wales, and he is said to have been the first who preached the gospel publicly in Welch, and fowed the good seed among his countrymen. In the year 1588 he published "A View of some Part of such Public Wants and Disorders as are in the Service of God, within her Majesty's Country of Wales, with an humble Petition to speedy Redrefs," in which he undertook to shew, not only the necessity of reforming the flate of religion among the Welsh, but also the most proper means of bringing about that work. He likewise published, about the same time, "An Exhortation to the Governors and People of her Majesty's Country of Wales, to labour earnestly to have the preaching of the Gospel planted among them." Both these pieces were written upon Puritanical principles, and were attacked by some zealous friends to the established hierarchy.

As the public printing-presses were shut against the Puritans, some of them purchased a private one, and carried it about from one part of the country to another to prevent discovery. The publications which excites the greatest attention, were supposed to be the productions of a club of writers, of whom Mr. Penry was esteemed one of the most active. Among the tracts which were printed and dispersed by them all over the kingdom, one that gave the most offence bore the title of "Martin Mar-Prelate," which contained a violent and bitter satire against the hierarchy, and all its supporters, and was soon followed by other pieces of the same description. When these pieces were known, a special warrant was issued by the privy-council in 1590, with the signatures of archbishop Whitgift and other members, for the apprehension of Mr. Penry as an enemy of the state, and calling upon all the queen's good subjects to consider him in that light. Penry withdrew into Scotland, where he drew up many observations on subjects relating to religion for his own private use; and he prepared the heads of a petition to the queen, intended to lay before her the true state of religion, and the many abuses in the church of England, especially in the management of ecclesiastical matters, of which her majesty was ignorant. One object of it was that he might be allowed to return to Wales, to preach the gospel in his native country. With the intention of finishing the petition above-mentioned, when opportunity should offer, and of delivering it afterwards to the queen with his own hands, Mr. Penry ventured back to England in the year 1593, and lived in concealment at Stepney, near London, till he was discovered, seized, and thrown into prison. Having obtained his papers, the privy-council determined to prosecute him without delay for a capital offence. No evidence could be brought against him but what his own private papers afforded; nevertheless, upon the trial his enemies succeeded in giving him such a handle, that it was soon resolved that he should be put to death. He pleaded against the sentence as totally contrary to the law of the land: he defied his persecutors to prove against him a single
a single act of disloyalty, but he had attacked the hierarchy, and could not be forgiven. Archbishop Whitgift was the first person who signed the warrant for his execution. As soon as the warrant was signed, it was sent to the sheriff, who, on the same day, gave orders to erect a gallows at St. Waterings, and while the prisoner was at dinner, sent his officers to bid him prepare to die that afternoon. He was accordingly carried, without delay, to the place of execution, and so vigorous was the conduct of the sheriff that he refused him the opportunity of addressing his friends, but was turned off in a hurry on the 29th of May 1593, when he was in the 54th year of his age. His learning and piety were highly extolled by his friends; and Mr. Strype says of him, "that he was well disposed to religion, but mistaken in his principles, and so very hot in his temper, and became so busy in church controversies, to his own destruction." He had connected himself with that branch of the Brownists, who maintained the discipline of the church of England to be popish and anti-christian, and all her ordinances and sacraments invalid. (See Brownists.) Before the articles already noticed, Mr. Penry was author of "An Appellation to the High Court of Parliament, from the bad and injurious Dealing of the Archbishop of Canterbury, &c.," "A Dialogue on the injurious Dealing of the Bishops," and "A Treatise to show that Retention, and those that sincerely favour the same, are unjustly charged to be Enemies to her Majesty and the State." The editor of this Cyclopaedia traces his genealogy, by the maternal branch, to the family of Mr. Penry.

PENRYN, in Geography, a borough and market-town in the parish of St. Gluvias, hundred of Kerriar, and county of Cornwall, England, is situated three miles from Falmouth, and 256 from London, on the side of a hill, and bank of a river, called the King's road, which unites with Falmouth harbour. The town formerly possessed a college, which, according to Leland, was calculated, and had three strong towers. Parts of this were lately to be seen, but are now enveloped by modern buildings. The manor was an appendage to the fee of Exeter, and the town appears to have been made a borough by one of the bishops towards the end of the reign of Edward I. The town was incorporated in the 18th year of James I. and is governed by a mayor, recorder, steward, portreeve, twelve aldermen, twelve common-councilmen, a town clerk, and other officers. Two members are returned to parliament; the right of election is in the mayor, aldermen, and inhabitants paying feot and lot. Three weekly markets are held on Wednesday, Friday, and Saturday, and three fairs annually. The market-house, which is also used as a town-hall, stands near the middle of the principal street, from which others diverge at right angles. From the peculiar situation of the town, it possesses an extensive airfield. In the population returns of the year 1811, Penryn is rated to contain 362 houses, inhabited by 2134 persons. On the opposite side of the river is the village of St. Gluvias, the church and parsonage house of which are placed in very beautiful situations. Polwhele's History, &c. of Cornwall. Beauties of England and Wales, vol. ii.

PENS, a town of the island of Cuba; 32 miles S.W. of Bayamo.

PENSACOLA, in Geography, the capital of West Florida, situated on the W. side of a bay, to which it gives name. The harbour is on the N. shore of the gulf of Mexico; 11 leagues E. of Port Lewis and Mobile, and 158 W. of the islands of Tortuga. It is spacious, and le-

cure from all winds, and has four fathoms of water at its entrance, deepening gradually to seven or eight. The bay lies in N. lat. 30° 15' and W. long. 87° 14', and admits of vessels drawing no more than 21 feet of water. The town is of an oblong form, healthfully, as well as delightfully situated, about one mile in length, and a quarter of a mile in breadth. While the British nation possessed it, it contained several hundred habitations, and many of the houses and public buildings were spacious and elegant. But since the Spaniards took possession of it, it has been upon the decline. The exports from this town, consisting of skins, logwood, dyeyielding, and silver dollars, amounted, while it belonged to Britain, to 63,000 annually; and the average value of imports from Great Britain was 97,000.

The town and fort of Pensacola surrendered, after a spirited defense, to the Spaniards in 1781; and with them the whole province. The entrance into the bay is defended by a small fort and the W. end of Rofe's island, and a battery nearly opposite, on the main land. Eufambia Coenecuh river is the largest stream which falls into the bay; it admits slallops some miles up, and boats upwards of 50 miles. N. lat. 30° 18'. W. long. 87° 17'.

PENSEN, a town of Germany, in the principality of Cuninich; 6 miles E. of Bayreuth.

PENSFORST ST. THOMAS, or ST. THOMAS, a small market town in the hundred of Keyoutham, and county of Somerset, England, is seated on the river Chew, which here flows through a fine wooded vale environed by small hills, the acclivities of which are covered with orchards. It is a town of high antiquity, and is conjectured by Dr. Stukeley to have derived its name from the British words Pen Ife, signifying the head of the river, being near the source of the Chew. In the time of Leland it seems to have been a very flourishing place, for it is mentioned by that affiduous antiquary as "a pretty townlet, occupied with clothmaking." This buffets is now, however, much declined, and the town is nearly bereft of all its former trade. None of its buildings deceive notice except the church, which is a handsome, modern structure, with a tower at the west end, apparently of more ancient date than its other portions. The market day here is Tuesday, and there are two fairs annually. An old stone bridge of three arches is thrown over the river, and connects the town with the village of Publow, to the church of which that of Pensford is a chapel, though in other respects it is parochial.

PENSILES HORTI, in Antiquity, gardens raised on arches by Nebuchadnezzar, king of Babylon, in order to gratify his wife Amytis, daughter of Alyages, king of Media. Q. Curtius makes them equal in height to the walls of the city, viz. fifty feet. They contained a square of four hundred feet on every side, and were carried up into the air in several terrasses, laid above one another, and the ascent from terras to terras was by stairs ten feet wide. The arches sustaining the whole pie were raised above one another, and it was strengthened by a wall, surrounding it on every side, of twenty-two feet in thickness. The flars of each of the terrasses were laid in the following manner: on the top of the arches were first laid large flat stones sixteen feet long and four broad, and over them was a layer of reed, mixed with a great quantity of bitumen, over which were two rows of bricks closely cemented together by plaster,
plaiter, and over all were laid thick sheets of lead; and, lastly, upon the lead was laid the mould of the garden. The mould or earth was of such a depth, as to admit the largest trees to take root and grow; and it was covered with various kinds of trees, plants, and flowers. In the upper terras there was an aqueduct or engine, whereby water was drawn up out of the river, for watering the whole garden. Divid. Sic. lib. ii. Strab. lib. xvi. Q. Curtius. lib. v. c. 1. or Fricid. Conn. vol. i. p. 144.

**PENSION.** Pension, a yearly appointment, or sum of money paid any one for services or considerations already past. Of this kind are pensions from the crown, which disquifify those, on whom they are conferred, for being elected members of the house of commons. (See Parlia-

ment.) Those pensions exceeding the value of 100l. per annum are subject to a duty consisting in an annual payment of one penny in the pound, (over and above all other duties.) A perfon, who takes a pension from any foreign prince without the consent of the king, is chargeable with the crime of contempt against the king’s prerogative. See Contem-

Pensionary, or Pensioner, a perfon who has a pension, appointment, or yearly sum, payable during life, by way of acknowledgment: charged on the estate of a prince, company, particular perfon, or the like.

In the Roman countries it is frequent to have pensions or benefits; these were anciently granted with a great deal of care, under pretence of infirmities, poverty, &c. But since the twelfth century, these pretences were carried so far, that the incumbents, or titularies, of benefits, were little more than farmers.

This obliged the spiritual powers to fix the causes, and the quantities, of pensions. Pensions are now only creatable by the pope, and are never to exceed one-third of the revenue; two-thirds being still to remain to the incumbent.

**PENSIONARY was also the appellation of the first minister of the flates of the province of Holland; under the old sytem.**

The pensionary was chairman in assemblies of the flates of that province; he propofed the matters to be confulted on, collected the votes, formed and pronounced the refo-
lutions of the flates; he also opened letters, conferred with foreign ministers, &c.

He was charged with inspecting the finances, preferring the rights of the province, maintaining the authority of the flates, and feeing to the observation of the laws, &c., for the good of the flate. He affided in the college of deputy-counsellors of the province, who represented the sovereignty in the abfence of the flates; and he was perpetual deputy of the flates-general of the United Provinces. His com-
miffion was only given for five years; after which it was deliberated whether or no it should be renewed. Indeed there was no infatiation of its having been revoked. Death only put a period to the functions of this important minister. Formerly he was called the advocate of the province: the title pensionary was only given at the time Barnevelt had the office. Grotius calls him in Latin advocatus jurisprudentius; Merula, advocatus generalis; and Mathiæus, prolocutor at Leyden, confilturn pensionarius, which is the quality the flates gave him in their inftitutions.

**PENSIONARY was also the first minister of the regency of each city, in the province of Holland.**

His office was, to give his advice in matters relating to the government, either of the city in particular, or of the flate in general; and in assemblies of the flates of the province he was speaker in behalf of his city.

Yet the function of these pensionaries was not alike every where; in some cities they only gave their advice; and were never found in assemblies of the magistrates, except when expressly called thither; in others they attended con-

stantly; and in others they even made the propositions on the part of the burgher-masters, drew up their conclusions, &c. They were called pensionaries, because they received an appointment or pension.

**PENSIONERS, GENTLEMEN, a band of gentlemen, whose busines is it to guard the king’s perfon in his own houfe; and who for that end wait in the presence-chamber.**

They were first set on foot by king Henry VII.; the number is forty; and each is obliged to keep three double horses, and a fervant, who is to be armed; so that they properly
properly make a troop of guards, and have accordingly been muster’d by their own officers; but this part of duty, to which they are sworn, the king usually dispenses with.

Their officers are a captain, whose salary is 1000l. a year, lieutenant, with 500l. a year; ilandard-bearer, with 310l. a year; and clerk of the cheques, whose annual appointment is 150l. Their ordinary arms are gilt pole-axes, with which they attend the king to and from the chapel royal; receiving him in the presence-chamber, or coming out of his private lodging; as also at all great solemnities. Their pension 100l. per annum.

To this band belong also a pay-master, harbinger, ake-keeper, and messenger.

PENSTOCK. See Pen.

PENTA, in Geography, a town of the island of Corfica; seven miles N.E. of La Porta.

PENTACEROS, in Natural History, a name given by Linckius, and some other authors, to a kind of Stellaria marina, or Stell are-fish, composed of five principal rays, with several transfere hairy or downy proceffes.

Gen. Ch. Cal. Perianth inferior, double; the innermost of five equal, lanceolate, concave leaves; outermost of four or more, much smaller, imbricat ones. Cor. of one petal, funnel-shaped; limb in five spreading equal segments, longitudinally bearded on the upper side with downy hairs. Nectar of five scales, at the base of the germen. Stam. Filaments five, thread-shaped, equal, inserted into the tube; anthers incumbent, oblong, Fil. Germen superior, roundish, of five cells; style short, columnar; stigma obtuse. Pefic. Berry with five feeds.

Eff. Ch. Outer calyx of four or more leaves. Corolla funnel-shaped; its limb spreading, longitudinally bearded. Berry with five feeds.

Obs. This genus might perhaps, without impropriety, be referred to Lycogon. See that article; it being very difficult in this tribe to define the limits between a deupa and a berry, at least in some cafes.—The species are dwarf mountain herbs, with scattered stalked leaves, and solitary, terminal, ereth, white flowers.—They are natives of Van Diemen’s land and New Zealand.

1. P. involucrata.—Filaments projecting beyond the tube. Calyx fringed; the outer one of eight scales. Leaves elliptic-lanceolate, flattish, many-ribbed. Young branches downy. Stem ereth.—Gathered by Mr. Brown, in Van Diemen’s land.

Pentachord, in Ancient Myth, an instrument of five strings invented by the Scythians, played with the jaw-bone of a dog, instead of a plectrum. Labore. The concord of the fifth is sometimes called pentachord.

Pentacrostic, a set or series of verses, so disposed as that there are always found five acrostics of the same name, in five divisions of each verse. See Acrostic.

Pentactinodos, in Natural History, a name given by some authors to those species of Stellare-fish which are composed of a body divided into five rays.

Pentadactylon, Five-Fingers, in Botany, a name given by some authors to the ricinus, or palma Christi, from the figure of its leaf.

Pentactylotos Precis, the Five-fingered Fish in Ichthyology, the name of a fish common in all the seas about the East Indies, and called by the Dutch there vijf viniger vish.

It has this name from five black streaks which it has on each side, resembling the prints of five fingers. It grows to about a foot and half long; its head is small in proportion to its body; its snout is long, and its fins large, and reaching almost to its tail; its general colour is very bright and elegant, a yellow, with an admixture of purple, and of a silverish sheen; it has no scales, and is a dry but ill-tasted fish.

Pentadactylotos-aster, in Natural History, a name given by Linkius, and some other authors, to a species of Stellare-fish, composed of a small body, and five principal rays, which have each several proceffes coming from them, covered with down.

Pentadaldostyla, the name of a genus of spars. The word is derived from the Greek πεντά, five, and αὔθης, a column.

The body of the genus are spars, in form of pentangular columns, terminated by pentangular pyramids at one end, and irregularly fixed at the other to some solid body.

Of this genus there are three known species.

Pentaglossum, in Botany, from πεντά, five, and γλώς, the tongue, in allusion probably to the shape of the five red petals, is a genus founded by Forkall, Fl. Egypt. Arab. 11. upon the Lythrum thymifolium of Linnaeus, which having but two flaments, was not recognized by its finder, as a Lythrum, though its whole habit, and every character besides, precisely accord with that well-known genus. See Lythrum.

Pentagon, from πεντάγωνον, quinquagangular, compounded of πεντά, five, and γωνία, angle, in Geometry, a figure of five sides and five angles.

If the five sides are equal, the angles are fo too; and the figure is called a regular pentagon, as Plate X. Geometry, fig. 17. Most citadels are regular pentagons.

The most considerable property of a pentagon is, that one of its sides, v. gr. DE, is equal in power to the sides of a hexagon and a decagon inscribed in the same circle ABCDE; that is, the square of the side DE is equal to the sum of the squares of the sides DA and DB.

A pentagon, and also a decagon, may be inscribed in a circle, by drawing the two diameters AP, mn (fig. 18.) perpendicular to each other, and bisecting the radius an at q. With the centre q, and distance q A, describe the arc AR, and with the centre A, and radius AR, describe the arc RB. Then AB is one-fifth of the circumference, and AB carried five times over will form the pentagon; and the arc AB bisected in s will give A, the 10th part of the circumference, or the side of the decagon. See Decagon.

If tangents be drawn through the angular points, they will form the circumcirculing pentagon or decagon. See Polygon, and Regular Figure.

Pappus has also demonstrated, that twelve regular pentagons contain more than twenty triangles inscribed in the same circle, lib. v. probl. 45.

The dododecagram, which is the fourth regular body, consists of twelve pentagons.

Pentagon-aster, in Natural History, a name given by Linkius, and other authors, to a kind of Stellaria marina, or Stellare-fish, composed of five rays, with a number of 4 L transverse
transverse processes issuing from them, covered with hairs.

It is one of the general classes of the \textit{stella crinata}, so called from this hairiness.

\textbf{PENAGO}nia, in Botany, from πεν, five, and γον, an angle, because of the figure of the corolla, a name given by some old writers to those species of \textit{Campanula} that have a wheel-shaped corolla, with five angles, of which \textit{C. Speculum}, or Venus's looking-glass, is an example. \textit{L'Heritier} once intended to form a separate genus of these plants, by the name of \textit{Prinacetarcius}; but on due consideration of the great variety of figure, in the corolla, of other species of the very natural genus \textit{Campanula}, he gave up his design.

\textbf{Pentagonotheca}, from πεν, five, γον, an angle, and σεθ, a cafe or cell, a name given by \textit{Vaillant} to the \textit{Pisonia}, (see that article,) on account of the form of its seed-veil.

\textbf{Pentograph}, an instrument whereby designs, prints, &c. of any kind, may be copied in any proportion, without a person's being skilled in drawing.

The instrument is otherwise called a \textit{parallelogram}.

The common pentagrsph (represented Plate XXIII. \textit{Méth. fig. 5}) consists of four brass or wooden rulers, two of them from fifteen to eighteen inches long, the other two half that length. At the middle of the longer rulers, as also at the ends of the shorter, are holes, upon the exact fixing of which the perfection of the instrument chiefly depends. Those in the middle of the long rulers are to be at the same distance from those at the end of the long ones, and those of the short ones; so that, when put together, they may always make a parallelogram.

The instrument is fitted together for use by several little pieces, particularly a little pillar, \textit{N} 1, having at one end a screw and a nut, whereby the two long rulers are joined; and at the other a little knot for the instrument to slide on. The piece, \textit{N} 2, is a rivet with a screw and nut, with which each short ruler is fastened to the middle of each long one. The piece, \textit{N} 3, is a pillar; one end of which, being hollowed into a screw, has a nut fitted to it. At the other end is a worm to screw into the table; when the instrument is to be used, it joins the ends of the two short rulers. The piece, \textit{N} 4, is a pen, porc interracial, or pencil, screwed into a little pillar. Lastly, the piece, \textit{N} 5, is a brass point, moderately blunt, screwed likewise into a little pillar.

\textbf{Use of the Pentograph, or Parallelogram.}—1. To copy a design in the same scale or bigness as the original: screw the worm, \textit{N} 3, into the table; lay a paper under the pencil, \textit{N} 4, and the design under the point, \textit{N} 5. This done, conducting the point over the several lines and parts of the design, the pencil will draw or repeat the same on the paper.

2. If the design be to be reduced, \textit{i.e.} gr. into half the pace, the worm must be placed at the end of the long ruler, \textit{N} 4, and the paper and pencil in the middle. In this situation conduct the brass point over the several lines of the design, as before; and the pencil at the same time will draw its copy in the proportion required; the pencil here only moving half the lengths, and the point moves. Hence, on the contrary, if the design be to be enlarged by one half, the brass point, with the design, must be placed in the middle at \textit{N} 3, the pencil and paper at the end of the long ruler, and the worm at the other.

3. To enlarge or reduce in other proportions, there are holes drilled at equal distances on each ruler: \textit{i.e.} all along the four ones, and half way of the long ones, in order for placing the brass point, pencil, and worm, in a right line therein; \textit{i.e.} if the piece carrying the point be put in the third hole, the two other pieces must be put in its third hole.

If, then, the point and design be placed at any hole of the great rulers, and the pencil with the paper at any hole of the short ruler, which forms the angle therewith, the copy will be less than half the original. On the contrary, if it be placed at one of the holes of that short ruler, which is parallel to the long ruler, the copy will be greater than half the original.

The construction of this instrument requires a very considerable degree of accuracy; for which reason there are very few of the instruments that succeed. Few will do anything tolerably but straight lines; and many of them not even those. In order to prove that the figure described by a pentograph is similar to the given figure; let \textit{C} (fig. 6) be the fixed centre of motion; \textit{P} the pencil for tracing the given figure \textit{PP}, and \textit{p} the pencil which traces the other figure \textit{pp}; \textit{p} &c. must be so adjusted, that \textit{p}, \textit{C}, and \textit{P}, may lie in one straight line; then, since \textit{BP} : \textit{AP} :: \textit{AC}, whatever is the situation of the pentograph, the angles \textit{PCP} and \textit{PCP}, are vertical; and, therefore, \textit{PCP} will in every position of the instrument be a right line; but \textit{PC} : \textit{PC} :: \textit{BA} : \textit{AP}, in each of the two positions in the figure, and therefore the triangles \textit{CPC}, \textit{PCP}, are similar; and \textit{PP} :: \textit{PP} :: \textit{PC} : \textit{PC}. Hence it appears, that by moving the pencil \textit{p}, \textit{A}\textit{P} may be equal to \textit{BA}, or less in any proportion; and consequently \textit{PP} may be equal to \textit{PP}, or less in the same proportion.

\textbf{Pentagyria}, in Botany, from πεν, five, and γον, a female, the name of an order which occurs in the 5th, 10th, 11th, 12th, and 15th classes of the Linnaean artificial system. Its character depends, as the name expresses, on the presence of five stamens, or, if stamens be wanting, of so many leaf-like stigmas. In the 12th class however, \textit{Iceofandria}, it is necessary to take this character with considerable latitude. Plants of the natural tribe of pomaces, which make an important part of that class, are very uncertain as to the number of their stamens in the same genus, and even variable in the same species. Hence the writer of the present article has, in his Introduction to Botany, chap. 24, presumed to advise that the order in question should admit flowers with from two to five stamens, or even a few more occasionally. In the 13th class, \textit{Polyandria}, the order \textit{Pen-}

tagryia separates some genera, from others, to which they are closely allied, in the \textit{Trigeina}, and admits \textit{Nigella}, some species of which have ten stamens. Hence it is no less eligible to adopt the same latitude here as in \textit{Iceofandria}. Perhaps the definition of the order, in both these classes, might most conveniently be "stamens from two to ten.

Some genera in other classes may have five stamens; but the orders of such classes being marked by other characters, the number of stamens usually becomes a part of the generic definition.

Gen. Ch. \textit{Cal.} Perianth inferior, of five lanceolate, erect, hairy leaves. \textit{Cor.} Petals five, lanceolate, erect, cohering by their lower part, somewhat reflexed at their summits. Nectary tubular, erect, with five teeth. \textit{Stam.} Filaments five, thread-shaped, flatish, infected into the incisions of the nectary, about as long as the petals; anthers ovate, erect. \textit{Pilf.} Germen roundish, hairy, with five furrows; style short, thick, hairy; stigma simple. \textit{Peric.} Berry roundish, fivelobed, of one cell. \textit{Seeds} five, ovate. Eff. Ch. Corolla of five petals, bell-shaped. Nectary tubular,

PENTAPETALUS PLANTS, are such whole flowers consist of five leaves.

PENTAPETES, in Botany, having five leaves, an ancient name for Cinquefoil, adopted for a very different plant by Linnaeus. Though he declines any explanation of it, the five leafy expansions, which, in his Pentapetes, accompany the flamas, seem so well to account for this appellation, that one cannot but think the idea of such an adaptation of the word had occurred to him, though he might have forgotten it when he wrote the Philosophia Botanica, p. 175. There seems otherwise no possibility of accounting for his choice of the name, for the particular genus in question; of which indeed what is now separated under the denomination of Pterospermum, see that article, was the original type, but the above character is common to that and the present genus. — Linn. Gen. 351. Schreb. 459. Wild. Sp. Pl. v. 3. 727. Mart. Mill. Dict. v. 3. Juff. 276. Lamarck Illustr. t. 576. Garin. t. 54. — Clasf

Gen. Ch. Cal. Perianth inferior, double; the outer a little remote, of three lanceolate, pointed, deciduous leaves; inner of one leaf, in five deep, lanceolate, pointed, spreading segments, permanent. Cor. Petals five, roundish, spreading, oblique, affixed by their claws to the tube of the flowers. Stam. Filaments 15, thread-shaped, erect, shorter than the corolla, united below into an oblong pentagonal tube, but separable above; anthers arrow-shaped, erect. Between every parcel of three flamas itands a linear-lanceolate, obtuse, erect, petal-like leaf, originating from the tube, and much longer than the flamas, being five in all. Pifl. German superior, ovate, with five furrows; style thread-shaped, rather longer than the five leaf-like appendages, swelling upwards, flattened; stigma with five flight segments. Peric. Capulse membranous, nearly globose, pointed, of five cells and five valves, the partitions from the centre of each valve. Seeds eight in each cell, inserted in two rows into the central column, obovate, angular, abrupt, without wings.

1. P. phcenicea. Scarlet Pentapetes. Linn. Sp. Pl. 978. 6. 6. P. phcenicea. Ktze. ed. 1. v. 376. I. Mill. Illust. t. 98. Mill. Ic. t. 200. (Dobhaya phcenicea; Cavan. Diff. 129. t. 43. f. 1). Blattaria cyclanica, flora ampo coccineo; Comm. Hort. v. 7. t. 6. Flos impius; Rumph. Amph. 5. 288. 100. f. 1.) — Native of various parts of the East Indies, sometimes cultivated for its beauty in our flowers, where it has been known considerably above a century. It flowers in July, and is annual. The stem is two or three feet high, round, branched, leafy, besprinkled with a few close-peddled flary bristles, indicative of its natural order. Leaves alternate, filiform, lanceolate, taper-pointed, strongly crenate, smoothish, more or less haitate at the base. Stipulae in pairs, linear. Flowers axillary, solitary, drooping, on rough stalks shorter than the footstalks; they are only but the scarlet colour, and have an io, in diameter; the five leafy appendages are externally rough or hairy. The fooplike name by which Rumplius has dignified this flower, and which is said to be a translation of its Indian appellation, alludes to its "profane or impious nature, in never looking towards heaven." So may flowers, as well

4 L 2
as men, be sometimes cumulated! The all-wise Creator, rich in infinite resources, has caused this and many more blossoms to droop, that their flames may be sheltered from rain; whilst the same end is accomplished in others by their courting the full blaze of day, in an erect expanded position. In the spring of our damp climate, drooping or cloathed flowers abound; in India perhaps a different economy is generally best suited to the nature of the country.  

Pentaphetes, in Gardening, comprises a plant of the exotic kind, for the fiove, of which the species cultivated is the scarlet-flowered Penapotis (P. phoenicea).

Method of Culture.—This plant may be increased by foying the seeds upon a good hot-bed early in March; and when the plants are fit to remove, shoule be a new hot-bed prepared to receive them, into which must be plunged some small pots filled with good kitchen garden earth; into each of which one plant should be put, giving them a little water to settle the earth to their roots, shading them from the sun till they have taken new root; when they should be treated in the same way as other tender exotic plants, admitting the free air to them every day in proportion to the warmth of the seaon, and covering the glaflles with mats every evening. When the plants are advanced in their growth, so as to fill the pots with their roots, they shoule be shifted into larger pots, filled with the fame port of earth as before, and plunged into another hot-bed, where they may remain as long as they can stand under the glaflles of the bed without being injured; and afterwards they must be removed either into a fiove or glafs-cave, where they may be fereeneed from the cold, and in warm weather have plenty of fresh air admitted to them. These plants are sometimes turned out of the pots when they are young, and planted in warm borders; where, if the feson prove very warm, the plants will flower tolerably.

Pentapharmacum, a medicine confifling of five ingredients: it has also been applied in the fame fenes to aliments. Adrian the emperor was, as we are informed, particular fond of a difh of five ingredients, called by this name. The ingredients were the udder of a fow, lam, peacock, brown, and a fort of pafle.

Pentaphyloides, in Botany. See Potentilla and Pentaphyllium.

Pentaphyllum, an old name, synonymous with Quinaefchium, and applied, like that, by fome of the old writers to fixh species of Potentilla as have five, or fometimes more, radiating leaflets upon one flake, forming a digitale leaf. Thofe species that are furnished with leaves otherwise conftructed, make Tournefort’s genus of Pentaphyloides.

Pentapleurum, a name given by fome botanical writers to the common small plantain, ufually called ribwort and pantago quinquenervia, from its leaves always having juft five ribs running along them.

Pentapogon, from πέντην, five, and νόμον, a beard, was fo named by M. R. Brown, in allusion to the five beards, or awns, of the fultk.—Brown Prædr. Nov. Holl. v. 1. 173.—Clafs and order, Triandra Digenia. Nat. Ord. Gra- 

mina. Gen. Ch. Cal. Glume of two oblong, acute, equal, bearded flaves, containing one flaked fiove. Cor. of two flaves; the outermost rather longer than the calyx, ovate, bearing five awns at the fummit, of which the middle one is much the longest, and spirally twilled; inner half the fize of the outer, ovate, acute, concave, membranous, bearded. Stam Filaments three, capillary, fhorter than the corolla; anthers oblong, pendulous. Pfyl. German superior, roundiñh, styles none; Rigmas two, spreading, feathery. Peric. none, except the permanent corolla. Seed one, oblong, pointed.

Eff. Ch. Calyx of two equal, bearded flaves, containing one flaked fiove. Outer valve of the corolla with five terminal awns; the middle one longiñ, and spiral.

P. Billardierii. (Agrollis quadrifida; Labill. Nov. Holl. v. 1. 20. t. 23.)—Native of Van Diemen’s land. A small and tender graft, scarce a fpan high. Root fibrous. Stems feveral, round, flirated, with one bent joint near the bottom, and one fhort leaf, with a long hairy fheath. Radial leaves numerous, tufted, short and fetaeous. Panicle erect, about two inches long, not much branched, of 15 or 20 upright fowers. Valves of the calyx ferrated at the keel. Flora hairy at its base.

Pentapolis, in Botany, a country wherein are five cities.

The Pentapolis of the faked writings comprehended Sodom, Gomorrah, Adama, Seboim, and Segor; and of thefe the laft only excefed the flames which destroyed the others.

The most celebrated was the Pentapolis Cyrenaica, or Pentapolis of Egypt, whose five cities were Berenicene, Arino, Philemon, Cyrene, and Apollonia.

Among the ancient geographers and historians we likewise read of the Pentapolis of Lybia, now called Misfrata; the Pentapolis of Italy; and the Pentapolis of Afia Minor, which contained Lindus, Jalyfios, Camiros, Cos, and Cirdus. This country once bore the name of Hexapolis, when it fo plaintiffed Halicarnassius.

Pentapterophyllum, in Botany, a name by which Billienius has called the meriophyllum of other authors, characterised under that name in the Genera Plantarum of Linnaeus, p. 459.

Pentaptoton, in Grammar, a noun which has only five cafes.

Pentastich, Pentastichon, in Poetry, a flana, or divifion of a poem confifling of five verses.

Pentastyle, in Architecture, a work wherein are five rows of columns.

Such was the portico begun by the emperor Gallienus, and which was to have been continued from the Flaminian gate to the bridge Milvius, i. e. from the Porto del Popolo to the Porte Mole.

Pentateuch, in Sacred Literature, the five books of Moses at the head of the Old Teftament; viz. Genesis, Exodus, Leviticus, Numbers, and Deuteronomy. See each of these books under its respective title.

The word is formed from πέντε, five, and στιχος, a verse; compounded of πέντε, five, and στιχος, volume.

Pere Simon, in his Hist. Crit. du Vet. Teft. produces a great number of passages to prove, that Moses was not wholly the author of the Pentateuch, as we now have it.

Indeed, those apparent interpolations at the end are fufficient to determine that point; it being abfurd to fuppofe Moses the author of the account of his own death and burial, and of the comparison between him and the fucceeding prophets in Israel.

These interpolated passages are ufually attributed to Ef- 

dras, or Ezra; who, on his return from the Babylonifh captivity, is fuppofed to have published the Old Teftament, or at leaft a part of it, corrected and enlarged. See Bible and Canon.

There are two famous Pentateuchs, or editions of the Pentateuch, which have a long time disputed the preference, both as to antiquity, and as to character; viz. that of the Jews, called the Jewifh, or Hebrew Pentateuch, written in the Chaldean or Arabian character; and that of the Samaritans, written in the Samaritan or Phoenician character. Each is maintained to be the ancient Hebrew; whereas both feem to be different copies of the fame Hebrew original, written
written in different characters. The Samaritan Pentateuch was well known to many of the fathers, who have quoted it; and these quotations are all older than the year 600. From that time, for 1000 years, we have no record of this Pentateuch until about the beginning of the 17th century; when Scaliger, having had notice that it was still preferred by some of his contemporaries, and perhaps with some reason, procured a copy, at Aleppo, probably chaplain to the factory there, obtained two or three copies of it out of the East. Not long after, Sancius Harley, a priest of the oratory at Paris, and afterwards bishop of St. Malo's in Brittany, brought another copy into Europe, which he deposited in the library belonging to that order in Paris; from which copy, Morinus, another priest of that order, published it in the Paris Polyglot. The Samaritans, beside the Pentateuch in the original Hebrew, have also a translation of it into the language which was vulgarly spoken among them. This is also published, together with the original, in the Paris Polyglot; and it is so exactly literal, that Morinus thought that one Latin translation might serve for both. Bishop Walton has followed the same method in his Polyglot; only when there are any variations, they are marked at the bottom of the page. This Samaritan Pentateuch has some additions, variations, and transpositions, by which it differs from the present Jewish copies. But it is lefs a matter of wonder, that there should be some differences, than that there should not be more; considering that those who adhered to the one, and those who adhered to the other, had not only broken off all manner of communication, but had confiemente been at the bitterest variance for more than 2000 years: for such an interval had elapsed from the apostacy of Manasseh (see Samaritans) to the time when these copies were first brought into Europe. In so many ages, many differences might happen by the errors of transcribers; and most of those that occur in these two copies are of this fort. See the sequel of this article.

But the grand difference is in the letter or character; the Jewish being in the Chaldean or Assyrian character, and the Samaritans in the Phoenician, i.e. the Canaanish character; this latter seems to have an advantage over the vulgar Jewish Pentateuch. Yet Prideaux is of opinion, that the latter is only a transcript from the former out of the Chaldean into the old Hebrew character.

One great reason he gives is, that there are many variations in the Samaritan, manifestly occasioned by mistaking the similiar letters in the Hebrew alphabet; which letters having no similitude in the Samaritan character, it is evident the variations must have arisen in transcribing from the vulgar Hebrew into the Samaritan; and not the contrary way.

Add to this, that Sismon, Allix, and many other learned men, take the Chaldean or Assyrian character to have been the character always in use among the Jews; and the Samaritan or Canaanish, as it is also called, the old Hebrew character, to have never been used by the Jews before the captivity, in any manner, either on books or on medals.

Hence the Pentateuch must have been transcribed into that character; and that, probably, to render it legible to the inhabitants of Samaria, who, upon their introduction of the Pentateuch, might probably be versed in no other character.

Uher takes the Samaritan Pentateuch to have been compiled by Dofithes, a Samaritan, mentioned by Origen to have adulterated the Pentateuch. Dupin supposes it the work of some modern Samaritan, whom he imagines to have compiled it chiefly out of the different copies of the Palestinian and Babylonian Jews, and the Septuagint, because it sometimes agrees with one, and sometimes with another.

Although, as we have already said, the Hebrew and the Samaritan copies of the Pentateuch agree in the main, they neverthelwes differ in many places from one another; and as some of these differences are very considerable, in respect to particular letters and single words, and besides, as several whole verses are now found in the latter, but not in the former, Dr. Kennicott has attempted to establish, as to some of these differences, the superior authority of the Samaritan Pentateuch. One text, in particular, (Deut. xxxvii. 4.) has constantly been objected to the favourers of this Pentateuch; a text which the advocates for the Hebrew copies have inferred upon as decisive against the Samaritans, and which has been almost invariably admitted to contain a shock ing a corruption made voluntarily by the Samaritans, that even the most equitable judges have joined warmly on the Jews on this occasion, and have manifested an inclination to give up the whole Samaritan Pentateuch as of no authority, on account of this one (as they apprehend) notorious and undeniable corruption. Among those who have exclaimed loudly on this occasion have been, not only Boeotus and the younger Buxtorf, Carpzovius and Leusden, with all their brother advocates for the integrity of the printed Hebrew text, but Hottinger and Lightfoot, Patrick and Calmet, Uher and Du Pin, Prideaux and Watson, father Simons and father Houbigant. To these names we may add that of Mr. Anthony Collins, in his "Grounds and Reasons of the Christian Religion." Against this host of learned men, Dr. Kennicott has appeared as an able advocate for the cause of the Samaritans.

In order to understand the ground of this dispute, we may observe, that God, by Moses, commands the Israelites, when they shall have passed over Jordan into the land of Canaan, "to put the blessing upon Gerizim, and the curse upon Ebal:" two mountains situated in the centre of the promised land between Dan and Beerheeba; two mountains near each other, and having between them (at the foot of Gerizim) a small town, anciently called Sichem or Schechem, but afterwards Neapolis, and now Napole. The mount, which was to be dignified with the "law" and the "altar," (Deut. xxxvii. 4.) is in the Hebrew text Ebal, and in the Samaritan Gerizim. About 1000 years afterwards, the Samaritans built a temple upon mount Gerizim, as one of the principal causes of the inveterate hatred that subsisted between the Jews and Samaritans. The text, it has been said, has been wilfully corrupted, either by the Samaritans, who, in their copies, put Gerizim, instead of Ebal, in order to recommend their temple, or by the Jews, who have, in their copies, put Ebal, instead of Gerizim, from opposition to it. That this corruption was made by the Samaritans, Walton, with whom join expressly Hottinger and Prideaux, affirm to be undeniable, for the following reasons: "cum omnibus codicibus Hebreis, omnibusque versionibus antiquis, legatur Ebal, non Gerizim." The learned Kennicott has examined these reasons, and finds, it is said, "is the word in all the Hebrew copies;" and therefore Ebal is the original word. But this is almost taking the point for granted; for it might as well be said, Gerizim is the original word, because it occurs in the present Samaritan copies. Moreover, "Ebal," it is alleged, "is the word in all the ancient versions." But as the point in dispute relates to a corruption, introduced about 400 years B.C., these versions, being all too late, can be of no use: they can only serve as evidence for the state of the Hebrew
Hebrew copies from which they were translated, and not for copies five, or six, or seven hundred years later. The Greek version of the Pentateuch was made about 280 years B.C.; but such a version can be no proof, that this text of the Jews had not been altered by themselves, 100 years before. This corruption was made, without doubt, either by the Samaritans in favour of their temple, or by the Jews in opposition to it, soon after that temple was built; and it was built, as Prideaux allows, during the reign of Darius Nothus, about 400 years B.C. Hence it is concluded, that all the ancient versions, which have been made from the Hebrew text, being made after the corruption had been introduced, are too late to be admitted as evidences, that can acquaint the Jews, or convict the Samaritans. It is true, but by no means true, that "all the ancient versions read Ebal in the text under consideration." For we have an ancient version of the Samaritan Pentateuch, expressed in Samaritan letters, and written in the Samaritian dialect, where is a mixture of Chaldee and Hebrew. This ancient version is of equal, nay, superior antiquity to the version of the LXX.; and this very ancient version reads Gerizim, in the disputed text. In some Arabic versions from the Samaritan Pentateuch MSS. preferred in the Bodleian library, the reading is the same. The authority of versions may, therefore, be adduced to oppose the authority of versions. Dr. Kennicott urges several presumptive and positive arguments in vindication of the Samaritans. Gerizim, he alleges, is universally allowed to have been the mount of blessings; and it seems very improbable, that the sacrificers of peace offerings, which implied a plate of favour with God, should by divine command sacrifice upon Ebal, confederally the mount of cursings. Moreover, when the Samaritans were determined to erect a temple for themselves, after being forbidden to join in rebuilding the temple of Jerusalem, they would, without doubt, choose some place signally honoured by God or his prophets, the more effectually to oppose the fame of the Jewish temple, and the more easily to vindicate their separate worship. Gerizim and Ebal were two mountains, on the former of which a form of blessings was to be pronounced, and on the latter a form of cursings; and one of these was to be honoured with the "Law of God," and "an altar for divine worship." This altar must have continued there for some hundred years, and the memory and fame of it continued in the country for many hundred years longer. But as both these mountains were near one another, both in the tribe of Ephraim, and both consecrated in the possession of the Samaritans, so that either might be the object of their election for the site of the temple, it is natural to imagine, that they would prefer that mountain, which had been, of old and by God's command, the place of his worship. Hence it is inferred, with strong probability, that Gerizim was the mountain of worship formerly, and not Ebal, which they rejected. Again, the different nature of these mountains furnishes another strong argument for the preference of Gerizim. For this mountain standing on the south, with its surface declining towards the north, is sheltered from the heat of the sun by its own shade; whereas Ebal, looking southward, is more open to the sun falling directly upon it: the former was therefore clothed with a beautiful verdure, while the latter was more scorched up and unfruitful. Besides, about 240 years before one of these mountains had been thus consecrated, when Jotham made that beautiful and solemn oration, recorded Judges ix. 7, he mutil at that time know, which mountain had the law and the altar. Accordingly, he spoke from mount Gerizim, with a view of giving greater weight to his address. It is added, that the Samaritans would have been less likely to have willfully corrupted the law of Moses, if it be allowed, as ample testimonies prove, that they had a great veneration for it. In the interview recorded in the 4th chapter of St. John's gospel between our blessed Saviour and a Samaritan woman, near this mountain, he does not charge the Samaritans with having arrogated to mount Gerizim honours which did not belong to it: much less does he say, that Ebal had been the mount really honoured by God; and not Gerizim, as the fathers falsely pretended. We may also observe, that several instances occur in which our blessed Lord pays a general tribute of respect, either directly or indirectly, to the character of the Samaritans; as in the story of the "Good Samaritan," and also in the fact recorded Luke, ch. xvii. But if the Samaritans, on account of their good disposition and general character, he excusated from the charge of willful corruption, a charge of this kind against the Jews would not be the jest that has been brought against them. Instances of this nature have been adduced by Dr. Kennicott, grounded upon the most unexceptionable testimonies. If we recur to the subsisting hatred of the Samaritans with respect to the Jews, and conceive that they might be thus urged to commit any crime from opposition to them, it might be retorted that the hatred of the Jews is at least equally notorious. It is further pleaded, that Josephus, the Jewish historian, afferts that the altar to be erected was not to be upon Ebal, but between this mountain and Gerizim, and rather nearer to the latter; and as he was the declared enemy of the Samaritans, it is not likely that he would have expressly given up the honour of Ebal, if he could have supported it. As Josephus does not charge the Samaritans with corrupting the text in question, so neither did other ancient Jews. If then the Samaritans, in this celebrated article, it must be admitted that the Jews have corrupted it, and corrupted not only this text in their Pentateuch, but the corresponding text in Joshua, xvi. 30. For other answers to the objections of Mr. Collins against the Pentateuch, we refer to Dr. Kennicott, ubi infra. Our author concludes a learned and elaborate dissertation on the Samaritan Pentateuch with the following observation. "It is by no means here intended to recommend the adoption of the Samaritan, in the place of the Hebrew Pentateuch: or to establish the pretensions of the former as to exclude the latter. One ancient copy has been received from the Jews; and we are truly thankful for it. Another ancient copy is offered by the Samaritans; let us thankfully accept that like with. Both have been often transcribed; both therefore may contain errors. They differ in many insubstantial errors; therefore the errors must be many. Let the two parties be heard without prejudice; let their evidences be weighed with impartiality; and let the genuine words of Moses be asceritored by their joint assilnace. Let the variations of all the MSS. on each side be carefully collected; and then critically examined by the context, and the ancient version. If the Samaritan copy shall be found, in some places, to correct the Hebrew: yet with the Hebrew copy, in other places, correct the Samaritan. Each copy therefore is invaluable. Each copy therefore demands our pious veneration, and attentive study. And I am firmly persuaded, that the Pentateuch will never be underflood perfectly, till we admit the authority of both." Kennicott's Second Dissertation.

The Jews read the whole Pentateuch every year; and for this purpose they divide it into paragraphs or sections, which they distinguish into great and small. The great are those which they read in a week, of which there are fifty-four (see Parascia); and the small regard particular matters. Each greater section, which is denominated by the word with which it begins, is divided into seven parts, because they are read
read by so many different persons: the priest begins, afterwards a Levite; and in the choice of the other readers, respect is paid to the rank of the people. After the text of Moses, they read a paragraph of the paraphrase of Onkelos. The books of the prophets are also divided in the same manner.

PENTATHLON, πεντάθλος, in Antiquity, the five exercises performed at the Grecian games, and for which prizes were proposed.

These exercises were wrestling, darts, leaping, running, and quoit-playing. He who bore away the prize in them all was called pentathletes; by the Latin, quinquerius; as the five exercises themselves were by those latter people called quinquerium.

Some have pretended that by the word pentathlon no more is to be understood than a game, or trial of skill, consisting of five, and of any five exercises; but however this be, the context was not of that nature. It is probable, that the pentathlon did not always consist of the five exercises above-mentioned, because Paufanias informs us (lib. v.), that the Eleusins from time to time made frequent changes in the Olympic games. The race in the pentathlon was of the same length with the stadion or simple foot-race, and regulated by the same laws. (See Race and Running.) The wrestling was subject to the same regulations with the simple palæ, or wrestling. (See Pala.) In the exercize of leaping, in which the competitors endeavour to leap beyond one another in length, the height of the leap not being taken into the account, the athletes carried in their hands pieces of lead, or some other metal, made in the form of a half circle, not exactly round, but inclining to an oval. In thee there was a place made for the fingers to pass through, in the same manner as through the handle of a shield; and with these weights, called andes. Halteres, the athletes were accustomed to poise their bodies, and swing themselves forward in the leap. Some assistance of this kind seems to have been necessary to enable them to perform any thing like what is related of Phaëus of Crotona, whose leap is said to have been 52 (or, as others say, 55) feet long. For the exercize of quoiting, see Discus and Quoiting. In the exercize of darting, the victory was awarded to him who threw his javelin farther than the rest of his antagonists. However, there were certain limits prescribed, beyond which it was a forfeiture of the prize for an athlete to call his javelin; and to this custom Pindar himself has frequent allusions. The javelin was sometimes thrown with the bare hand, and sometimes with the help of a thong, wound round the middle. The exercize of leaping in the pentathlon was accompanied by festes playing Pythian airs, as we are informed by Paufanias.

The candidates in the pentathlon, as well as those in all the other gymnastic exercizes, contended naked, and were also anointed with oil. Although some doubts have been suggested with regard to the conditions upon which the victory was awarded in the pentathlon, it is certain, that he who vanquished his antagonist in every one of the five exercizes was alone entitled to the crown. If all hopes of gaining the pentathletic crown were lost to him who was vanquished in any one trial, it has been queried why the vanquished should contend any longer? The reply to this question is, that the pentathletes were probably obliged by the laws of the olympic games to go through all the five exercizes. Although all the competitors, except one, must have depairned of gaining the crown, even from the first trial, yet they might still be dearious of carrying on the contest through the four remaining exercizes, if they had not been required to do it by the olympic laws, either with a view of equalizing themselves in some of the other contests, or the hopes of ravishing the crown from him, by whose victory they had been excluded from the prospect of obtaining it. Pindar, in his thirteenth Olympian ode, congratulates Xenophon of Corinth upon his having gained in one day two olympic crowns; one in the stadion, or simple foot-race, the other in the pentathlon, which, as he says, never happened to any man before. The reason is, that the regimen of a pentathlete, as we are informed by both Epictetus and Arrian, was very different from that of an athlete, who qualified himself for a single exercize alone, as running, wresting, or any other, whence, as both Plato and Longinus assure us, it seldom happened that a pentathlete, though very eminent in his profession, was able to contend with an athlete in that exercize, as, e.g., running, or wresting, to which alone he had applied himself altogether. The same observation is applicable to all the athletes in general; who differed from each other in their respective regimens and diets, as much or more than in the several exercizes to which they peculiarly applied themselves. Well's Pindar, vol. iii.

PENTATONON, in the Ancient Musick, a concord, by us called the redundant sixth.

It consists of four tones, and a major and minor semi-tone; whence the name, pentatonon, q. d. five tones.

PENTAJREAN, a name given by some fabulous authors to a flute sped to have been first found by Apollonius Tyanaeus, and to possess the virtues of all the other flutes, and to attract them all to it, as the magnet does iron.

PENTECOSTARCHA, among the Ancients, the captain or commander of a galley, called penteconters.

PENTECOSTERS, πεντακταρχήν, a vessel with fifty oars.

PENTECOST, Ἔπτομα, Whit-sunday; a solemn feast of the church, held in commemoration of the descent of the Holy Ghost on the Apostles; as described in the Acts. See Whit-sunday.

It has its name from the Greek, επτάκτης, q. d. quinquagesimus, fiftieth, because held on the fiftieth day after Easter.

In the ancient church, Ponceost effihed the Paschal time, or Easter season; wherein, as Tertullian, St. Jerom, &c. observe, Hallelujah was sung every where, the office celebrated standing, no falling allowed, &c.

The Jews likewise had a feast they called Pentecost, or Quinquagesimus; solemnized in memory of the laws being given to Moses, fifty days after their departure out of Egypt.

This was the second of the three grand festivals in the ecclesiastical year, at which all the males were to appear before the Lord at the national altar. This feast lasted but one day, and was kept with great mirth and rejoicing. It is called by several names in the Old Testament; as the Feast of Weeks, because it was celebrated seven weeks, or a week of weeks, after the Passover, or rather, after the first day of the feast of unleavened bread; the Feast of Harvest, according to Mede and Bochart, because, as the harvest begun at the Passover, it ended at Penteost: or, according to others, because at this feast the first fruits of their wheat harvest were brought and offered to God; and the Feast of First Fruits.

PENTECOSTALS, PENTECOSTALIA, anciently were pious obligations made at the feast of Penteost, by the parishioners to their parish-priest; and sometimes by inferior churches or parishes to the principal or mother church. These parish Pentecostals were also called Whitsun-farthings, and their sum was divided into four parts, of which one went to the priest, one to the poor, one towards the repair of the church, and one to the bishop of the dioceze. These are paid still in some few dioceses: being now only

5 a charge
a charge on particular churches, where by custom they have been paid. And if they are denied where they are due, they are recoverable in the spiritual court.

PENTECOSTE, in Geography, a river of Canada, which runs into the river St. Lawrence, N. lat. 45° 45'. W. long. 66° 45'.

PENTECOSTE, or Whitsunday Island, a small island in the South Pacific ocean, and one of the archipelago of the Great Cyclades, or New Hebrides discovered by M. Bougainville in 1768.

PENTEKILIS, or Pent Elelis, a town of Attic Turkey, on the S. coast of Natolia; 30 miles W.S.W. of Mectre.

PENTELASMSI, in the Hiftory of Shell-fish, the name of the conchæ antafiera of some writers.

The pentelasmis is a genus of animals, composed of a shelly body, affixed to a flabby and soft pedicle; the body is composed of five valves, and the pedicle is sometimes short, and sometimes long. The animal itself belongs to the tritons.

PENTELICUM, Marmor, in the Works of the Ancients, a name given to a very beautiful and glossy species of white marble, of which many of the columns and statues of larger size of the ancients were made: the Parian marble, from certain cracks and fissures in the slabs, seldom affording blocks of more than five feet in length.

PENTELICUS, in Geography, a mountain of Greece; six miles N.W. of Athens.

PENTSXYRINGUS, in Antiquity, a sort of pillory, with five holes; wherein were fastened the legs, arms, and heads of criminals, to prevent their fleeing.

PENTEXOCHES, a name given by authors to a species of echinates, resembling the ripe fruit of the medlar, and thence called also melosperm lapsus.

PENTHEMIMERIS, compounded of πενθης, five, μιμεσίς, half, and μηρός, part, in the Greek and Latin Poetry, part of a verse, confiting of two feet and one long syllable.

PENTHIER POINT, in Geography, a cape on the W. coast of France; six miles S.E. of Point St. Matthew. N. lat. 48° 15'. W. long. 3° 17'.

PENTHIEVRE, a town of France, in the department of the Morbihan, situated on the peninsula of Quiberon, on the E. and W. sides washed by the sea; seven miles N. of Quiberon.

Eff. Ch. Calyx in five or ten segments. Petals five, minute. Capsule of five cells, with five points. Seeds numerous.

Linneas fays Penthorum is distinguished from Sedum, by wanting the nectariferous fowl proper to that genus. But the fruit also differs, though indeed only as that of some species of Nigella differs from others. Jussieu has strangely mistaken the structure of the fruit, whose cells, he says, split horizontally; and thence he was led to doubt whether the genus could properly belong to his order of Semperiwae. The seed-refel however opens exactly like those of Sedum, Semperivum, Crassula, &c., nor can there be a question of the genus before us belonging to the same natural order.

1. P. ferdnites. Linn. Sp. Pl. 620. (Penthorum; Linn. A. T. Suppl. ann. 1744. 12. t. 2.—Native of moist flady situations, in North America; Michaux fays from Canada to Carolina. It is a hardy perennial in our botanical gardens, flowering in July and August. Root fibrous, throwing out creeping feyons. Stems numerous, diffuse, twelve or eighteen inches long, leafy, slightly branched: their opposite angles rough with minute bristles. Leaves alternate, nearly fiddle, lanceolate, acute, serrated, smooth, scarcely succulent. Spikes several, terminal, recurved, collected into a fort of corymb. Petals white, fome or all of them frequently wanting, while the segments of the calyx are preternaturally multiplied. The plant has no smell, nor any thing more than an herbaceous tafe.

PENTICOTTA, in Geography, a town of Hindaooan, in the circuit of Cicatele; 32 miles S.W. of Coffimucotta.

PENTIDATELO, a town of Naples, in Calabria Ultra; 12 miles S.E. of Reggio.

PENTIMA, a town of Naples, in Abruzzo Cita; five miles N.W. of Salomona.

PENTLAND Frith, the fraft which separates the main land of Scotland from the Orkney islands. It is sometimes called Piéland Frith; and indeed the latter is considered by many writers to be its proper and original appellation. This frith is about twelve miles across, and is remarkable for the impetuosity and opposition of its currents, from the meeting tides of the Atlantic and Northern oceans. So strong are thee currents at times, that no vessel can navigate against them, however favourable the wind may be. Hence the navigation of this frith is so peculiarly dangerous and difficult, that few vessels attempt to pass it without the assistance of an experienced pilot. Its dangers are also greatly augmented by several whirlpools, of which those most usually fatal are the "Wells of Swinna" and the "Swellie of Stromfa," near the northern side of that island. On its southern shore is another very hazardous spot, called the "Merry Men of Mey," from the name of a gentleman's residence on the opposite coast of Caithness. Here, from the concurrence of the opposing tides, the sea is agitated in a very violent manner, even in the finest weather. From these concurrent causes, it is impossible at any time to cast anchor in any part of this frith; which, notwithstanding, is annually entered by between three and four thousand vesels. The number, however, will no doubt rapidly decrease as soon as the Caledonian canal is opened for navigation. Many of the natives of the Caithness coast, and of the islands, are said to derive their livelihood solely from the produce of the numerous ships which are founedered, or dashed to pieces in their passage through this frith. Barry's Orkney Islands, 440.

PENTLAND Skerries, three small islets, or holms, at the eastern entrance to the Pentland frith; four miles N.E. from Dungby head. Being from their situation extremely dangerous to mariners, a lighthouse is placed upon the largest of them. It was erected in 1794.

PENTLAND Hills, a range or ridge of eminences, which extend from a place about four miles S.W. of Edinburgh, towards
towards the confines of Peebleshire and Lanarkshire. Some of these hills are of considerable elevation; particularly the western summits, two of which, called Capelaw and Cearkan-craig, rise to the height of nearly fifteen hundred feet above the level of the sea. Logan-hope hill even exceeds seventeen hundred feet above the same level. The eastern division, near Edinburgh, however, seldom reaches much above one-half that elevation; in some places it is nearly flat on the top, and affords excellent pasturage for large flocks of sheep. Several streams, noted in fong, take their rife among these hills; as the North Esk, Glencofre, and Logan water; the two latter of which disfigure the honour of being the scene of Allan Ramsay’s “Gentle Shepherd.” Each of these waters is accordingly distinguished by the name of “Habby’s Howff,” and both are frequently visited by poetical parties from the Scotch metropolis during the summer months. The composition of the Pentland hills is principally granite, but on the north side of the Logan summit is a rock of a very singular character, which has obtained the appellation of “Pentum Pentlandica,” from its resemblance to the substance employed in the manufacture of Chinese porcelain. It is the only specimen of the kind in Great Britain, and probably in Europe.

PENTODRYON, in Botany, a name given first by the Greek writers, and after that by the Romans, to a kind of Hyssopus or nightshade, which caused madness in those who eat of it. This was called by others manichum erychnum, and by some fimpliciter manicum.

PENTOPHYTHALMOS, in Ichthyology, the name of an East Indian fish, approaching to the European Liparis, or butterfly, but larger, and called by the Dutch there Visjing. It has these names from five round spots in the tail-fin, resembling five eyes; it is of a yellowish colour, and is covered with a smooth skin, having no scales; its body is thick, its head small, its body long, it has the head fins, and the tail is bluish; it is an inhabitant of the fresh waters, and is a very well-tailed fish.

PENTOROBOS, in Botany, a name recorded in Pliny as belonging to the Peony. It is formed of πεντα, five, and ροβος, a rod or leg, evidently alluding to the fruit of that plant, which, when perfect, consists of five feed-vellets, that have very much the appearance of legumes. See PEONY.

PENTOWEN POINT, in Geography, a cape on the S. coast of Wales, in the Britol channel. N. lat. 51° 45’. W. long. 4° 15’.

Gen. Ch. Cal. Perianth inferior, of one leaf, in five deep, lacinolate, nearly equal, permanent segments. Cor. of one petal, two-lipped; tube longer than the calyx, gibbous at the base on the upper side, dilated upwards, and there most inflated at the lower side, or front; upper lip erect, in two ovate obtuse segments; lower lip obtuse, in three deep, ovate, obtrude, deflexed segments, shorter than the tube. Stam. Filaments four, thread-shaped, diverging at the summit, inserted into the tube and not extending beyond it, the two inferior ones longer; anthers roundish, vol. XXVI. dilant, inclosed within the tube, cleft, their lobes divaricated. The rudiment of a fifth filament is inserted into the tube, between the two uppermost flaments, about equal to them in length, thread-shaped, straight, bearded at the upper part. Pfl. Germ. superior, ovate; style thread-shaped, the length of the tube, deflexed at the top; stigma abrupt. Peric. Capsule ovate, acute, comprefTed, of two cells and two divided valves, with inflexed margins. Seeds numerous, orbicular, bordered. Receptacle large, flattish, meeting the inflexed margins of the valves.

Obt. We cannot perceive the necessity of separating this genus from Chelone, nor should we here have done any thing more than refer to the labours of our learned and judicious predecessor, the late Rev. Mr. Wood, under that article, had not Pentstemnon been now so generally adopted. We must remark however, that Juffien, who hints at its establishment under Chelone, Gen. 137, errs in attributing to the latter a capsule with partitions from the centre of each valve, and a receptacle contrary to the valves. There is no difference between the fruit of these genera in that respect, nor in any other, except the trivial circumstance of the valves of Pentstemnon being split vertically, which is not the case with Chelone glabra at least, if we may rely on Gartner, t. 54; for this plant does not, under our observation, perfect its fruit. The seeds are bordered in Pentstemmon as well as Chelone.

Pentstemon in Gardening, contains plants of the hardy, herbaceous, flowering kind, of which the species cultivated is, the smooth pentstemon (P. levigata.)

Method of Culture.—This plant may be increased by sowing the seeds either in the autumn or early spring in the places where they are to remain, or in beds, to be removed in the beginning of the summer to the borders or clumps of the pleasure-grounds.

They afford variety among other plants of familiar growth in these situations.

Gen. Ch. Common calyx hemispherical, of many imbricated, oblong, obtuse, membranous-edged scales. Cor. compound, dicotylæ. Florets all fertile, numerous, uniform, level-topped, tubular, funnel-shaped; the limb erect, in five flight segments. Stam. Filaments five, capillary; anthers united into a cylindrical tube. Pfl. Germ. oblong: style thread-shaped, the length of the flaments; stigmas two, 4 M.
The membranous, unevenly lobed, border. Calyx imbricated, hemi-phileral. Florets all tubular, five-clft.

1. P. flabellaris. Willd. n. 1. (T. crenata; Thunb. Prodr. 145. Tanacetum flabelliforme; L'Hert. Seri. Angl. 21. t. 27. Ait. Hort. Kew. ed. 1. v. 3. 165. Graphium dentatum; Linn. Sp. Pl. 1194. Coma aurea indica, foliis oblongis, capitulis oblongis; Burm. Afric. 185. t. 68. f. 2.)—Native of the Cape of Good Hope. Mr. Maffon sent it to Kew in 1774. This is a bushy much branched florba, altogether of a hoary silvery aspect, remarkable for its little alternate, fan-shaped, long-tailed leaves, furnished with prominent longitudinal ribs, and strongly toothed at their abrupt termination. Corollas simple, terminal, but soon surmounted by young branches. Flowers the fize of a pea, yellow, with a downy somewhat shining calyx. The plant is slightly aromatic. It might perhaps have been allowed to remain in Tanacetum, the very conspicuous white seed crown being little more than a dilatation, of what always exits, in some degree, in that genus, and the want of a few female three-clft, florets, fully termed obsolete, in the radius, being at an inconsiderable, if not variable character.

PENUKONDA, in Geography a town of Hindoostan, in MyFORE; 65 miles N. of Bangalore.

PENULA. See P. ENULA.

PENULTIMA, or Penultimate, formed from Pena, and ultimus, almost last. In Grammar, denotes the syllable, or foot, immediately before the last.

Hence antepenultimate is that before the penultimate, or the last but two.

PENULTIMATE, in Music. M. Broiardi will have it the same with what the Greeks call paramete; though others will not allow the paramete to be the penultimate chord, but the next to it.

Penultimate of the Separate, paramete diazegmenon, is a name the ancients gave to one of the chords of their lyre or sytem; corresponding to the , la, re, of the third octave of the modern sytem.

Penultimate of the Acute, paramete hyperboleon, a chord of the ancien sytem, answering to the , sol, of the third octave of the modern sytem.

PENUMBRA, in Astronomy, a faint or partial shade, observed between the perfect shadow and the full light in an eclipse.

The penumbra arises from the magnitude of the sun's body; were he only a luminous point, the shadow would be all perfect; but by reason of the diameter of the sun, it happens that a place which is not illuminated by the whole body of the sun, does yet receive rays from a part thereof.

Thus, suppose S the sun (Plate XVIII. Aftron. fig. 17.) and T the moon, and the shadow of the latter to be projected on a plane, as G H. The true proper shadow of T, viz. G H, will be encompassed with an imperfect shadow, or penumbra, H L and G E, each portion whereof is illuminated by an entire hemisphere of the sun.

The degree of light or shadow of the penumbra will be different in different parts, as those parts lie open to the rays of a greater or lesser part of the sun's body; thus from L to H, and from E to G the light continually diminishes; and in the confines of G and H, the penumbra becomes lost and confounded with the total shade; as near E and L, it is confounded with the total light.

A penumbra must be found in all eclipses, whether of the sun, the moon, or the other planets, primary or secondary; but it is most confusible with us in eclipses of the sun; as in the case here referred to.

In eclipses of the moon, the earth is encompassed indeed with a penumbra; but it is only feasible to us on the earth near the total shadow: as otherwise placed on a plane, whereon the shadow falls, might observe the whole penumbra, as in eclipses of the sun. Thus an eye placed at I or F, would only see the semidiameter of the sun; the rest being hid behind the moon. Going from I towards H, more and more of the fun is hid, till it be lost in the shadow itself,

Hence we have eclipses of the sun when the shadow never touches the earth; provided the penumbra do but reach it; and hence there is a difference observed in eclipses of the sun, as the shadow itself, or a greater or less degree of the penumbra, passes over a place. But eclipses of the moon appear the same in all places where they are visible.

When the shadow itself falls on the earth, the eclipse is said to be total or central; when only the penumbra falls on it, the eclipse is said to be partial.

The penumbra extends infinitely in length, inasmuch as to each point of the diameter of the sun, there answers a space infinite in length, into which no rays enter from that point, though there do from others. Two rays drawn from the two extremities of the earth's diameter, and which proceed still diverging, form the two edges of the penumbra; which, of consequence, is continually growing in width, and is infinite also in this sense. All that infinite space is the penumbra; except the triangle of the shadow included in it.

The figure of this space comprehending the shadow, is a trapezium, one of whose sides is the diameter of the earth; the opposite side parallel thereto is an infinite line, i.e. the width of the penumbra projected to infinity, and the other two sides are two rays drawn from the two extremities of the diameter of the sun, through those of the diameter of the earth, and which, prolonged back beyond the sun, will intersect in a certain point, making an angle equal to the apparent diameter of the sun; which angle may be called the angle of the penumbra.

Now the penumbra will be the greater, as this angle, or, which is the same thing, as the ilum is greater, the planet remaining the same; and if the diameter of the planet be increased, the ilum remaining the same, it will be the same as if the diameter still reeded from the angle of the penumbra.

In order to determine how much of the surface of the earth can be involved in the penumbra, let us suppose the apparent semidiameter of the sun to be the greatest, or about 16° 23', which is when the earth is in her perihelion. Let A B D (fig. 18.) be the earth, L the moon, and A M B half the angle of the cone, which is equal to 16° 23'; whence we shall find its height $L M = 58^\circ$ semidiameters of the earth. (See Shadow.) Let the moon be in her apogee, and, therefore, at her greatest distance from the earth, which is 64 semidiameters of the earth, and $T M = T L + L M = 122^\circ$ semidiameters. But $T B : T M = \text{line of } T M B : \text{line of } M B N$ or $M B T$; and $T B : T M :: 1 : 122^\circ$, and the angle $T M B = 16^\circ 23'$, therefore the angle $M B N = 58^\circ = 25^\circ 42' = T M B + M T B$.

Consequently $M B N = T M B (58^\circ 42' - 16^\circ 23' =)$ $M T B = 58^\circ 23^\circ$, which is the measure of the arc $A B$; whole
whole double 70° 51' is equal to the arc C A B, or about 4900 English miles. See Eclipse.

M. de la Hire examines the different degrees of the penumbra, and represents them geometrically by the ordinates of a curve, which shall be among themselves, as the several parts of the sun’s disc, with which a body placed in the penumbra is enlightened.

PENURIE, in Geography, a town of Hindooftan, in Bahar; 23 miles S. of Bahar.

PENUTURA, a town of Hindooftan, in the circur of Cicacole; 25 miles N. of Cicacole.

PENY, a town of Hindooftan, in Bahar; 24 miles S. of Bahar.

PENYCUIK, is the name of a village and parish in the county of Mid-Lothian, or Edinburghshire, Scotland. The village is situated nine miles S. from the northern metropolis, and is adorned with a very handsome church, the living of which was formerly a rectory. This edifice is placed on the site of an older structure, which was dedicated to Kentingern, popularly called St. Mungo. The parish is twelve miles in length and six in breadth. Its surface is extremely various, and exhibits almost every kind of soil, from clay and mors to the poorest gravelly loam. A great number of sheep are bred in this parish; but the greater proportion of it is under tillage. It is watered throughout its whole extent by the river North Elk, and abounds with coal and peat. It also possesses several objects entitled to the attention of the topographer and the antiquary. Near the village is the elegant seat of Sir James Clerk, bart. M. P. for the county of Edinburgh. The situation of this mansion is delightful, and its prospects are both picturesque and extensive. In the library here is an excellent collection of books and paintings; and in another room is a large assemblage of Roman antiquities, principally from the wall of Antoninus, and the neighbouring encampments. Close to the river, within the “policy,” is Offian’s Hall, the much-admired work of Runciman; and behind the house is an exact model of the celebrated Roman temple, called by Buchanan Templum Terminis, which formerly stood on the banks of the Carron, and which was known to the vulgar by the appellation of Arthur’s Oon. Here is likewise an obelisk, in honour of Ramlay the poet, who frequently resided at Peny- cuik, and is supposed to have laid the scene of “The Gentle Shepherd” on the confines of this parish and Glessers. About two miles from this seat, lower down the river, the ancient castle of bruntone, the baronial mansion of the Crietchouns, some ruins of which still remain. New-Hall, another residence of the same family, stands three miles N.W. from the village. It is supposed to have derived its appellation of New from the circumstance of its occupying the site of an old religious house. The name of New-House, an inn on the lands of Spittal here, holds a similar derivation, having been erected to supply the place of an ancient hospitium, for the accommodation of travellers. Even at the present day the weary and benighted traveller is considered as entitled to shelter and protection; and accordingly one of the out-houses, at the Old Spittal, is usually appropriated to that purpose. Traces of several encampments of different forms and eras are yet visible in this parish. Raven-Neck-Castle, situated on the Elk, belonged to the Sinclair of Roslay. Government has lately converted the buildings of two large paper manufactories here into depots for preserving war.

According to the parliamentary returns of 1811, the houses in this parish amount to 309 in number, and the inhabitants to 1827. Beauties of Scotland. Carlyle’s Topographical Dictionary of Scotland, and of the Islands of the British Seas. 4th. 1813.

PENZA, a town of Russia, and capital of a government, near the Sum; 644 miles S.E. of Petersburg. N. lat. 53° 30'. E. long. 45° 42'.

PENZANCE, a sea-port and market town in the west division of the hundred of Penwith, county of Cornwall, and the most westerly town in England, is situated on the N.W. side of Mount’s bay, 287 miles W.S.W. from London, and 10 miles from the Land’s End. It is particularly distinguished for the cheapness of its fish market, the mildness of its climate, and the fertility of the neighbourhood lands: these circumstances have occasioned a considerable increase of population, by the influx of inhabitants from the adjacent villages. In the year 1595, the Spaniards dispatched four vessels from Bretagne, (of which they were then masters,) to invade the English coast. They landed near Mousehole, which they burnt, together with the church of St. Paul. Meeting with little resistance, the enemy proceeded to Penzance, and the inhabitants deporting it, they entered the town in three places, and set it on fire, after which they returned to their galleys. The returning courage and increased numbers of the Corsairs, prevented the Spaniards from re-landing, and Penzance has since remained undisturbed by foreign foes. The parish church is situated nearly at Maderv, two miles from the town; but there is a chapel of ease nearer home, dedicated to St. Mary. There are various religious denominations residing here; Presbyterians, Quakers, Methodists, and Jews, who have separate places of worship. The government is vested in a corporation, consisting of a mayor, recorder, twelve aldermen, and twenty-four common-councilmen. Penzance is one of the four Stannary towns of the Cornish tin mines, and the petty feoffments for the west division of the hundred of Penwith are held here. There is a charity school endowed by John Bulker, esq. of Morvall, in 1711. The town is very pleasant, many of the houses large and respectable, and most of the streets are paved. A new pier, which was erected by the corporation some years since, affords much convenience to the considerable trade carried on here, consisting chiefly of tin, and the pilchard fishery. The packets which form the principal mode of conveyance to the Scilly islands, sail from Penzance. Thursday is the market day, and there are three annual fairs. By the census of 1811, Penzance contained 794 houses, and a population of 4022 inhabitants.

At the distance of half a mile from Penzance, are some remains of the celebrated Wherry Mine. They are situated in part of the bay, which is dry at low water, but covered by every returning tide to the depth of several feet. The peculiar situation of this mine rendered it an object of curiosity, although the shaft is filled up, and the frame-work nearly annihilated. When the works were in operation, the labour became extremely adventurous; the miners working at the depth of seventeen fathoms below the waves, nearly 120 fathoms from the shore, and momentarily menaced with an inundation of the sea, which roared above them. The dangerous situation of the shaft, the injurious effect of storms and tides, and a partial failure of the lode, induced the proprietors to discontinue its working in 1798. A large tract of marsh-land, adjacent to Penzance, subject to occasional inundations of the sea, has been partly fenced from helter from the tide, through the laudable exertions of Dr. Samuel Myole of Marazion. It was effected by means of an aqueduct or pipe, communicating with the sea, which carried off all the drainage water from the marsh. Several crops of corn and potatoes have been obtained from the parts so faved, and it promises to reward the adventurer for his expense.
and perseverance. In cutting one of the drains, an earthen pot was discovered, containing nearly one thousand Roman copper coins, which the impressions shew to have been minted between the years A.D. 260 and 300.

Well of, and contiguous to, Penzance are several small villages and antiquarian objects deserving notice. Meudon, on the western side of Mount's bay, is celebrated among antiquaries for having been the residence of Dolly Pentreath, one of the late persons known to speak the Cornish language. She lived to the great age of 102, and was buried in the parish church-yard of St. Paul's. St. Buriens is the name of a parish, which, though at present consisting only of a few wretched cottages, was formerly distinguished by a college of Augustinian canons, founded and endowed by Athelstan about the year 930. It is now in the patronage of the prince of Wales. The deanery includes the parishes of Burcan, Senner, and St. Levan. At the Norman conquest there were secular canons here, and in the 20th of Edward I. a dean and three prebends. The church is built on a high spot of ground; it consists wholly of granite, and its tower forms a conspicuous object from the Land's End, the Scilly isles, and the North and South channels. The greater part of the district round St. Buriens, though wild and unsheltered, is interesting to the antiquary, it being intersected by cairns, circles, cromlechs and other Druidical remains. In the parish of St. Paul is a circular inclosure of stones, called the "Roundago," fifty-two paces from north to south, and thirty-four from east to west. Some of the stones are erect, others piled in a wall-like form, but without mortar. In the parish of Senner is a circle of similar shape and character, and at Tredineck another of the same kind. In the parish of Burien is a small circle of nineteen upright stones, called the "Dance Main," or the Merry Maidens. The stones are about four feet above the ground, and five feet distant from each other; the diameter of the circle is about twenty-five feet, and at some distance north-west from it are two taller upright stones, called the Pipers. Another of these Druidical circles is named Boscawen-un, which also consists of 19 upright stones, and is about 25 feet in diameter, having a single leaning stone in the centre. In the parish of Gullval is Bolkednan-Circle, consisting also of 19 stones, but of smaller diameter than the two former. In the parish of St. Juft is a considerable structure of this kind, known by the name of the Botallach circles, composed of four circles of upright stones intersecting each other. Lanyon Quoit is a cromlech, consisting of four upright stones, three of which support the other, a broad flat stone, 28 feet long, by 14 wide. In the parish of Morval is a cromlech, similar to this last, but of smaller dimensions, called Chân Quoit; and half a mile east of Senner church is another, the quoit of which is supported by a barrow heaped round it, 14 yards in diameter. In the parish of Madern stand three stones erect, on a triangular plane, the middle one of which is perforated with a large hole near the base, nine inches in diameter. Dr. Borlase conjectures that this perforation was appropriated to superstitious rites, in the days of Druidism.

The same antiquity is observed in various logan or rock-forming stones, as formerly extant in this part of Cornwall; the most considerable and curious of which was at Treryn-Caithle, in the parish of St. Levan. The chief stone is an immense granite block, supposed to weigh nearly 90 tons, placed on the top of a vast pile of rocks which project into the sea. This enormous mass, it is flatted and believed, was once hauled, from a peculiarity of position, to be moved to and fro. The Treryn-Caithle is a large piece of rocky ground, projecting into the sea, and inclosed by two formidable ramparts and ditches, one within the other, stretching in a semicircular form from the sides of the cliffs: the perpendicular rocks form three sides of this fortification, and the land side is guarded by the thick and high embankments. About a mile and a half west of this, the cape, called Tolzpen-penwith, is divided from the main land by a stone wall. The cairns, Karnijeck and Bofcaule, in the parish of St. Juft, are also of the same kind, as well as many others on the sea-coast.

The Land's End is the most westerly promontory in England. It is a point of huge and rugged rocks, forming a barrier to the tumultuous sea, of the most awful and wildly \*\*\*...
French history, who was surnamed d'Herijal from the place of his birth, on the river Meuse, near Liège. He governed Austrasia after the death of Dagobert II. in 689, and was defeated in the following year by Ebroin, the powerful mayor of the palace of Neustria. He, however, levied new troops, and, after the death of Ebroin, defeated king Thierry, gained possession of Paris, and became master of the king and kingdom, with the title of mayor of the palace of Neustria and Burgundy. He was a man of extraordinary qualities, extremely brave, prudent, and politic; and one who was able to conceal his ambition under the mask of moderation, and a very mild and affable demeanour. When he had seized the reins of government, he employed himself with vigour and industry to correct abuses, restore law and order, repair the finances, and secure the obedience of all ranks of the state. He suffered Thierry to act the pageant of a king, and in public paid him all possible respect, while he excluded him from any share in the administration. After the death of Thierry, he placed the crown successively upon the heads of his sons, Clovis and Childerbert, and his grandson Dagobert, who in French history are denominated, from their insignificance, "Les Rois Faîcans." In the mean time, Pepin was engaged in wars with the Frifons and Germans, over whom he was constantly victorious. His executive power excited the envy of some lords, who, while he was labouring under a dangerous illness, took up arms and assassinated his son Grimoald. He, however, recovered, and took severe vengeance on his foes. Shortly after this he died, having had the administration of the government in his hands nearly 30 years. This was in the year 714, and he left his authority so well established, that he nominated his young grandson, Theobald, mayor of the palace, under the guardianship of his widow. Pepin was father of Charles Martel, the founder of the Carolingian line of French kings. Univer. Hist. History of France, 1790.

Pepin, surnamed Le Brei, first king of France of the second race of kings, was the second son of Charles Martel. (See FRANCE.) His father, in his last illness, divided his dominions between his sons, Carloman and Pepin: assigning to the former Austrasia, to the latter Neustria and Burgundy. They united in suppressing an insurrection, and afterwards turned their arms against Odilon, duke of Bavaria, and other German princes and nations, whom they reduced to subjection. In the midst of this prosperity, Carloman, disdaining the world, retired to a monastery in 746, and resigned his possessions to Pepin. This prince had hitherto exercised the royal authority in the name of king Childeric; but finding himself perfectly established in his power, beloved by his people, respected by the nobles, and favoured by the clergy, to whom he had restored part of the property which his father had taken from them, he resolved, in the year 751, openly to assume the title, as well as the office, of king. The elder historians unanimously affirm, that the assembly of the states sent a deputation to pope Zachary, to ask whether it were not right that he who exercised all the functions of royalty should be king, rather than he who was fó only in name; and that the pope pronounced in the affirmative. From this time it is probable that king Childeric was flayed, and that up to a monastery, where he soon died; his queen was put into a convent; and their son, Thierry, passed his life in the character of a monk: and thus ended the race of Merovingian kings of France.

Pepin, soon after being proclaimed king, was consecrated at Soissons by Boniface, bishop of Mentz, the pope's legate, and is said to have been the first French king on whom this ceremonial was performed. The solemnity was, without doubt, intended to give an additional sanctity to his character. With the same view he undertook, on various occasions, to be the champion of the church. He severely chastised the heathen Saxons, who had taken up arms, and expelled the millionaries. He attacked the Saracens in the southern provinces of France, and, after a long siege, made himself master of the important city of Narbonne. Of such importance was Pepin now in the world, that pope Stephen III. implored his protection against the enemies that pressed upon him, and even came in person to his court. He was received with all possible respect; and in return for his kindness, the holy pontiff crowned him and his queen in the church of St. Denis, belotted the royal insignia upon his sons Charles and Carloman, and conferred upon the father and his sons the title of Roman patrician. Pepin re-conducted the pope to Italy with an army, befought the king of the Lombards in Pavia, and obliged him to make a treaty, by which he relinquished the sovereignty of Rome, and all his conquests. As soon as Pepin had recrossed the Alps, the Lombard monarch broke the treaty, and invaded Rome. Pepin passed again into Italy, and constrained him to accept of peace a second time, but on much harder conditions than before. He visited Rome, where he was received with great honour as its deliverer, and cauèd the keys of Ravenna and the other cities of the exarchate to be offered on the throne of St. Peter. As soon as he returned, he employed himself in regulating the internal affairs of his kingdom, and receiving the homage of the duke of Bavaria, and of the king of the Selcivians. A general revolt of the Saracens again gave occasion to him to exercise his arms, and he reduced them to submition. While he was thus engaged, the Lombards, under king Desiderius, attacked the pope, who applied to Pepin for his assistance, which in this and other influences he readily afforded. Pepin died in 768, at the age of 53, after having reigned with glory and succees nearly 17 years. No author of a revolution ever met with less disturbance in maintaining his power, which was owing to his great prudence, and the moderation with which he exercised his authority; confuting the general assembly of the nation on all important occasions, and paffing his laws by the medium of their assent. In perfon Pepin was very short, but he possessed extraordinary vigour and activity, as well as intrepidity. The fame of Pepin, like that of Philip of Macedon, has been in some degree impaired by the superior renown of his son, Charlemagne; but his eminent qualities sufficiently entitle him to a place among the great men of his age and nation. Univer. Hist. History of France, 1796.

Pepin Lake, in Geography, an expansion of the Missippii, where it receives the Chipeway from the north-east, in N. lat. 44° 5', and W. long. 93° 42', below the Falls of St. Anthony.

PEPIÀ, in the Materia Medica, a name given by some authors to the fæba fancil Ignatio, or St. Ignatius's bean.

PEPLION, or PEPLOS, names given by the ancients to medicines which they used as brilk cathartics to purge off the bile and other humours.

PEP

Gen. Ch. Cal. Perianth of one leaf, bell-shaped, pointed, permanent, large; its border in two small segments, alternately reflexed. Cor. Petals six, ovate, very minute, inserted into the border of the calyx, often wanting. Stam. Filaments six, sometimes but four, awl-shaped, short; anthers roundish. Pist. German ovary, in the bottom of the calyx; style very short; stigma orbicular. Peric. Capsule nearly globofo, with two longitudinal furrows, membranous, not buttering, of two cells, the portion opposite to the furrows. Seeds numerous, minute, obovate. Receptacle rather comprised, in the middle of the partition.

Eff. Ch. Calyx bell-shaped; its border in twelve segments. Petals six, inserted into the calyx. Capsule superior, of two cells, not buttering.

The modern Greeks call it Λαμπρακτό, or ακρογλυφο, and eat it in fallads, or in fousps. The root is annual. Herb smooth, pellucid and somewhat succulent. Stems prostrate, or floating, weak, fimple, leafy. Leaves opposite, flaked, obovate, obtuse, entire, a quarter or half an inch long. Flowers axillary, solitary, sessile, small, reddish. Petals fugacious, and often wanting. Capsule pellucid.

Willdenow says the *P. tetrandra* of Linnaeus is a *Hygios*, of which indeed it has all the appearance. He adds, in its stead, the following new species, for the genus of which we must depend on him, not having seen the plant ourselves.

2. P. *indica*. Willd. n. 2.—Flowers spikel, bracteated. Leaves fimple.—Native of the East Indies. "Stem ascend- ing, square smooth, six inches or more in height. Leaves opposite, oblong-obovate, abrupt, entire, sciny, smooth. Spikes axillary, simple, longer than the leaves. Flowers lefible, opposite, each accompanied by a lanceolate bract, twice its own length. Calyx with only eight teeth. Petals wanting. *Stamens four.*" Willd.

PEPLUM, a name given by the ancient Greek writers to a shrub which had pinnate leaves and papilionaceous flowers. It is translated by many *fena*; but this does not appear certainly to be right: the several species of *colutea* agree as well with this description as the *fena*, and they have indeed been called *fena* by many; probably it was one of thefe.

PEPLON. in Geography, a town of Hindoostan, in the Candeih country; 80 miles S. of Indore. N. lat. 21° 41'. E. long. 76° 45'.

PEPLUS, σπήλαιον, among the ancients, a kind of garment worn by women.

The peplos was a long robe that reached to the feet, without any sleeves, and so exceeding fine, that the shape of the body could easily be discovered through it.

The peplos of Minerva is very famous among ancient mythologies. The Athenians used a great deal of ceremony in making the peplos, and dressing the statue of the goddess with it.

The peplos was worked over with gold, on which were represented the combats and grand achievements of Minerva, Jupiter, and the Hermes. On the feast of the *Panathenaei*, (which see.) this was carried about in procession, formed of Perfons of all sexes, ages, and ranks; the young bringing up the rear, and the aged bearing an olive branch in their hands, the young virgins baskets, and the blooming boys crowned with millets, and singing hymns known by the name of "Peans," while those who were called "Rhapodoris" recited verses of Homer. The procession advanced from the Ceramicus to the temple of Ceres Eleusina. The peplos was fastened to a barge, which was moved along by machinery.

PEPLUS, in Botany, πεπλος of Dioscorides, appears by his description to be the same kind of Spurge, or *Euphorbio*. Linnaeus believed it the common European weed, which he denominated, for that reason, *E. pephus*. Dr. Sibthorp was induced to think the *E. foliata* of Linnaeus was rather the plant of Dioscorides; not only "because it is frequent in vineyards and other cultivated ground, in Greece and the Greek islands; but because the precumbent mode of growth of this species, and the thick bulk it forms, answer much better to the description of that ancient author, than the more upright growth of *E. pephus*.

PEPO, a Gourd or Pumpkin. See CUCURBITA.

PEPO, in Vegetable Physiognomy, is adapted, as a technical term, by Garriñer and Wildenow, for a particular kind of succulent fruit, exemplified in the natural order of *Cucurbitaceae*, in which the seeds are attached to the inner surface of the rind. This sort of fruit differs, in different plants, with respect to the thickrese or hardness of the rind, and the more or less pulpy nature of the internal subsidence, as well as the number of cells into which that subsidence, at an early period, is usually divided. The writer of this article, as well as Garriñer, considers the *pepo* as no other than one of the numerous forms of a *Bacca*, the infusion of the seeds differing in no respect from that of a Gooseberry. Wildenow alone has described it as a distinct kind of fruit, ranging after the *Pumma*, or Apple, with which last Linnaeus has, very unaccountably, confounded it, in his generic descriptions of Trichosanthes, Momordica, Cucurbita, and Cucurquis.

PEPPER, or *Lizard's Tail*, in Botany. See PIPER.

PEPER, or *Black, Piper nigrum*, is an aromatic fruit, obtained from a species of piper, which grows spontaneously in the East Indies, but does not arrive at perfection without the aid of culture. It is cultivated with much success at Malacca, Java, and especially at Sumatra, that from these islands pepper is exported to every part of the world, where a regular commerce has been established. According to Mr. Marlden, (Hist. of Sumatra,) the ground chiefly by which the Sumatrans for a pepper garden, is marked out into regular squares of fix feet, the intended distance of the plants, of which there are usually a thousand in each garden. The next advantage is to plant the chinkareens, which serve as props to the pepper vines, and are cuttings of a tree of that name, which is of quick growth. When the chinkareen has been some months planted, the most promising perpendicular shoot is reserved for growth, and the others lopped off; this shoot, after it has acquired two fathoms in height, is decked sufficiently high, and its top is cut off. Two pepper vines are usually planted to one chinkareen, round which the vines twist for support; and after being suffered to grow three years (by which time they acquire eight or twelve feet in height) they are cut off about three feet from the ground, and being loosened from the prop, are bent into the earth in such a manner that the upper end is returned to the root. This operation gives fresh vigour to the plants, and they bear fruit plentifully the ensuing season. The fruit, which is produced in long spikes, is four or five months in coming to maturity: the berries are at first green, turn to a bright red when ripe and in perfection, and soon fall off if not gathered in proper time. As the whole cluster does not ripen at the same time, part of the berries would be left in waiting for
PEPPER.

for the latter ones; the Sumatrans therefore pluck the
bunches as soon as any of the berries ripen, and spread them
to dry upon mats, or upon the ground. By drying they be-
come black, and more or less shrivelled, according to their
degree of maturity. These are imported here under the
name of black pepper.

Pepper is also cultivated to a considerable extent in
India. Dr. Roxburgh began the cultivation of black pepper
in the cirears in 1787; using for prop trees the
Mouchly woodtree, or Erythrina corallodendron. One
thousand plants yield from 500lbs. to 1000lbs. of pepper.

Pepper, White, Piper album, is the fruit of the same
plant with the black, though some have erroneously thought
it to be a different species. Accordingly it has been fold at
the fales of the East India company, who have the monopoly
of the Sumatran pepper trade, for treble the price of
the black. Whereas white pepper is the ripe and perfect
berries of the same species stripped of their outer coats. For
this purpose the berries are steeped for about a fortnight in
water, Gill by swirling their outer coverings burst; after
which they are easily separated, and the pepper is carefully
dried by exposure to the sun. Or, the berries are freed from
their outer coats by means of a preparation of lime and
mullard, called "Chinum," applied before it is dried. Pepper
which has fallen to the ground over-ripe loses its outer
cost, and is sold as an inferior sort of white pepper.

Of these pungent hot spices the black is the hottest
and strongest, and most commonly made ufe of for medicinal
as well as culinary purposes. Its virtues are entirely ex-
tracted by ether and alcohol, and partially by water. The
aqueous infusion has a brown colour, and redness vegetable
blues; and the decoction of the ground pepper forms a pre-
cipitate with infusion of galls, which dissolves again when
the fluid is heated to 170°. When the alcoholic infusion is
diluted, a green, rhenous, oily matter is left, which
appears to be the source of the odour and taffe of the pepper.
Its principal constituents are supposed to be larch, the
above oily matter, and extracutive. Ether digested on powdered
pepper takes up three parts in ten; and when evaporated
on water, departs an intensely hot, biting, yellowish resin,
with the odour of the pepper, and an almost limpid extracutive
matter. It has been said, that these spices differ from most
others in this, that their pungency resides not in the volatile
parts, or essential oil, but in a sublimation of a more fixed
kind, which does not rise in the heat of boiling water; and
that this fixed substance is probably the rhenous part; the
aromatic odorous matter seeming to depend upon the essen-
tial oil. The dilutted oil has a strong smell of the pepper,
with little acrimony; the remaining decoction, infallible,
yields an extract of considerable pungency. The quantity
of extract from both kinds of pepper is nearly the fame;
that by rectified spirit amounting to about one-eighth,
and the watery to nearly one-half their weight; but those of
the white are weaker than the other sort. A tincture made in
rectified spirit is extremely hot and fiery; a few drops of it
set the mouth as it were, in a flame.

Black pepper is fluent and carminative: its ufe as a
condiment is well known, and though, in general, it is not
hurtful, but useful to those whose digestion is weak, yet,
even in small quantities, it proves injurious, where the inflam-
matory diathesis is present, and to those who are subject
to piles. Some have supposed pepper to be lefs heating to
the sytem than other aromatic; and Gaubius afferts that,
when taken in large quantities, he never found it to warm his
fomach, nor to increase the frequency of his pulse.
Whereas Dr. Cullen affirms, that when he took this spice,
even in a small quantity, it felt warm in his fomach, and

heated his whole body; and he supposes, that Gaubius did
not feel its effects from the frequent ufe of it. As a medicine,
pepper is sometimes found serviceable in checking nausea
and vomiting, and removing biliousness. It has been also
successfully employed in some cases of vertigo, and in para-
litic and arthritic disorders. In large doses it has been found
useful as a remedy for intermittent fevers; and such ufe of it has,
in some instances, produced fatal confequences. The watery infufion
forms an useful gargle in relaxation of the uvula. The dose
of black pepper may be from x gr. to 3 gr.

The officinal preparations are the "Euphrasii melisses velifat-rii
compositum" of Edinb., and the "Unguentum piperis nigri"

Pepper that is fold ground is very apt to be forfhificated;
the black with burnt crout of bread, &c., and the white
with beaten rice.

Pepper, Long, Piper longum, is thus denominated from
its form, which is cylindrical, and about an inch and a half
in length; it consists of an affembly of grains, or seeds,
joined close to one another, of a brownifh colour, bordering
without on red, and within on black; and grows by a long
pedicle to a plant, like that of the black pepper, and of
the fame genus, but lower, and its leaves smaller and greener.

It is a native of the East Indies, especially Java, Malabar,
and Bengal. The berries, or grains, are very small, and
lodged in a pulpy matter; like those of the black pepper,
they are fird green, and become red when ripe. This fruit
is hotter to the taffe in its immature state, and is therefore
gathered while green, and dried by the heat of the sun,
when it changes to a blackifh or dark grey colour. Dr.
Cullen obferves, that long pepper has precisely the fame
qualities with those of black, but in a weaker degree; and
Bergius fays that black pepper is hotter than this species,
whereas the contrary is the fact, and is afferted both by
Lewis and Murray. Its confulent parts appear to be
similar to those of black pepper. Either digested on pow-
dered long pepper takes up 2½ parts in 10, and when evapo-
rated on water deposits a thin lefs hot than that of black
pepper, but more permanent; and a smaller proportion of
extracutive. Its officinal preparations are "Confeftio opii"
Loud., "Pulvis cinamomii comp." L. D., "Pulvis crete
comp." L., and "Tinctura cinamomi compota," L. E.D.
Woodville. Thomson.

Some have mentioned three kinds of this pepper, that of
the East Indies, that of America, and that of Ethiopia, called
also grain of Zelin; though the first alone is the proper long
pepper, the reft resembling it but little.

Pepper, Barbary, Belt, Bird, Bonnet, and Cayenne. See
Capsicum.

Pepper, Guinea, piper indicum, obtained from a species
of the capsicum, is a reddifh pod, of a coral colour, much
feemmed by the Americans, from among whom it is brought,
and by them called cible, and by the French, garden coral.
See Capsicum.

Under the article Capsicum we have mentioned the die-
tric and medicinal ufe of the fruit of the capsicum, or of
Cayenne pepper. We shall here add some other particulars.

It has been found beneficial in lethargic affections; in dropsies,
and other cachectic complaints, when chalybeates are
indicated, a small portion of powdered capsicum is recommended
as an excellent addition by Dr. Wright; and in the diseases
cynanche maligna, and sciaratica maligna, it has been found
highly useful, both given internally, and ufed as a gargle.

Capsasms of capsicum operate as a powerful rubefacient
without blighting the skin, and are ufed in the West Indies
to relieve the coma and delirium, which almost constantly
attend tropical fevers. The diftuted juice of the fruit is said

10
to be a sovereign remedy in ophthalmia from relaxation. Capsicum may be given in the form of pills in doses from gr. 1/2 to gr. 1; or fij to fij, in a glass of water, of a tincture made with 3iv of capsiicum and 5iv of alcohol. The gargle usually employed is made by heating into a paste fij of Cayenne pepper and 3ij of common salt; then adding fiv of boiling water; and to the solution, strained when cold, 3iv of vinegar. But a simple infusion in the proportion of gr. j of the pepper to fj of boiling water, answers equally well. Thomson.

Pepper, Jamaica, called by the Dutch annomi, by the Spaniards pimenta de Jamaica, is the fruit of a tree, the myrtus falsis alternis of Linnæus, growing plentifully in Jamaica, and other American islands.

It is a real aromatic, and may supply the defect of cloves, nutmeg, and cinnamon; whence it is called also by the English, allspice. The French call it the round clove, from its round shape, and its taste resembling that spice. See MYRTUS and PIMENTA.

Pepper, Caja, pimenta de Caja, a name given by the Spaniards to a fort of spice which they discovered in Caja, a province of Guatimala, in New Spain, and of which they were at first very fond, both in food and medicine.

In medicine it is a very good cephalic and tonick. It is recommended very strongly also by some of the Spanish writers, as a cure for the epilepsy and gouta ferena; but those who tried it in these cafes do not consider such accounts.

The descriptions we have of it are, that it has the taste of cloves, pepper, cinnamon, and ginger, all blended together; and Redi is of opinion, that it is no other than our pimenta, or Jamaica pepper.

Pepper, Indian. See Guinae Pepper and Capsicum.

Pepper, Poor man's, a name sometimes given to the distander, or lepidium; which see.

Pepper, Wall, a name sometimes given to a species of sedum, or leffer house-leek. See SEDUM.

Pepper, Water, a species of polygonum; which see. Miller and others make it a species of the persicaria; which see. Pepper graps. See PILLARIA.

Pepper-mint, the name of a species of mint. See MENTHA.

Pepper-wort, a name by which some call the lepidium; which see.

Pepper-bird, in Ornisology, the English name of the rhamphallos with a yellow rump, otherwise called tocan.

Pepper-mushroom, in Botany, a name given by Dr. Liitler to a new species of fungus, discovered by him in the woods of Yorkshire, whose juice is acrid and hot as pepper. This is somewhat larger than the common efficient mushroom, but of the same shape with that, having a round head and open gills underneath. The head is very fleshy, and the pedicle also is folt, not hollow, as in most other of the large funguses: any part of this mushroom being cut or broken, it bleeds very freely a white milky juice, like that of the thymals. This juice tastes like pepper, only that it is much hotter. It is not viscid or clammy to the touch, and the air does not much discolor it; nor does it render the blade of the knife, with which it is cut, black, as most other vegetable juices do. When let out of the plant it very soon concretes into a firm and dry mass, making a sort of cake; and when thus dried into a solid substance, it retains its white colour and pungent taste. It is very remarkable, that this mushroom, though so hot to our tongues as not to be endured, yet is so well suited to the palates and nature of certain insects, that they can not only feed on it, but live comfortably in the midst of it. The yellow naked fainl feeds greedily on the plant while growing, and the flanks of it at such times as the juice is sharpest of all, that is, while it is growing to the full size, are full of the maggots and worms hatched from the eggs of flies, deposited there for a nidsus and food for them in that state. The juice has a great affinity with esphorhum, and may be brought into medicinal use, perhaps, to very good purpose.

John Bauhine describes a mushroom much resembling this, but smaller and less fleshy; and the Prussians and Polanders have a sort of great mushroom, which they call groosbytus, which agrees with this in many particulars; but it is larger and thicker. Phil. Trans. N° 89.

Pepper-water, a liquor prepared by the curious for examination by the microscope, as always affording a great number of small animals.

The method of preparing it is: thus put common black pepper, groosly powdered, into an open vessel so as to cover the bottom of it half an inch thick, and put to it rain or river water, till it covers it an inch; shake or stir the whole well together, at first mixing, but never disturb it afterwards: let the vessel be exposed to the air, uncovered; and in a few days there will be seen a pellicle or thin skin swimming on the surface of the liquor, appearing of several colours.

This is a congeries of multitudes of small animals; and being examined by the microscope, will be seen all in motion: the animals, at first sight, are so small as not to be distinguishable, unless to the greatest magnifiers; but they grow daily till they arrive at their full size. Their numbers are also continually increasing, till the whole surface of the liquor is full of them, to a considerable depth. When disturbed, they will sometimes all dart down to the bottom, but they soon after come up to the surface again. The film appears soonest in warm weather, and the animals grow the quickest; but in the severest cold it will succeed, unless the water freezes. Baker's Microscope, p. 71.

About the quantity of a pin's head of this feum, taken upon the nib of a new pen, or the tip of a hair-pencil, is to be laid on a plate of clear glass; and if first applied to the third magnifier, then to a second, and finally to the first, will show the different animalcles it contains, of several kinds and shapes, as well as sizes. Phil. Trans. N° 284.

The animalcles discoverable in this liquor are principally of six kinds. 1. The largest kind of all is in length about the diameter of a hair, and scarcely a fourth part of that measure in breadth; they are very thin and transparent, but their back is darker than their belly; they turn about very frequently and nimbly in the water: their fides are fringed with a great number of minute feet, which are seen principally at the two ends; and at one end there are also some brittles longer than the feet, which make a sort of tail. They are very nimble, and walk as well as swim, and will climb up a hair, if put in among them.

2. There is a smaller sort, whose length is about the third of a hair's breadth; but their tail is five or six times as long as their body. This they either carry straight, or in a spiral form; and at the other end they thrust out a sort of bearded tongue: these make a constant current of water towards them.

3. There is a smaller sort than thefe, which arc sometimes seen of an oval figure, and sometimes long and flat, like a flounder: these also have feet, which are faintly seen when the water is evaporating.

4. A fourth may appear like slender worms, fifty times as long as broad: their thickens is not above the hundredth part of a hair's breadth; and they move with equal ease either forward or backward.

5. There
5. There is a fifth fort extremely minute and round; and
6. A fifth kind, which are longer than these, but not larger;
and probably there may be yet many kinds not discovered.
These small animals are easily destroyed; a little diffused
fart or sugar, or spirit of vitriol, or even spirit, will kill them;
and in the drying away of the waters many of them burn.

Phili. Trans. No. 203.

P E P P E R B E R G, a town of the island of Java, on the
S. coast, 75 miles S. of Batavia.

P E P P E R E L B O R O U G H, a township of America,
in York county, and State of Maine, on the N. side of Saco
river, near the mouth, which separates it from Biddeford
to the south. A bank by the name of "Saco Bank" was
established here in 1803; about 12 miles S.W. of Portland.
It was incorporated in 1772, and contains 18,42 inhabitants.

E. branch of Nahway river, and on the N. line of Middle-
sex county, 40 miles N. by W. of Boston; incorporated in
1773, and containing 1,913 inhabitants.

P E P S I Q U A C H P O I N T lies on the northern side of
Chaleur bay, now called "Paspabiac Point;" about three
leagues W.N.W. of East Nouvelle. It is a barren plain,
like a large long, where is carried on a very extensive
fishery.

P E P T I C, in Medicine. See PEPTIC.

P E P U N G, in Geography, two small islands of the East
Indian sea, near the coast of China. N. lat. 23° 22'. E.
long. 107°.

P E P U S C H, John Christopher, in Biography, doctor
in music, Oxford, a very learned musician, who was born
at Berlin in 1667, and had made fo great a progress in music at
the age of fourteen, that he was sent to court, where
he gave such proofs of his abilities that he was appointed
to teach the prince, father of the late king of Prussia.
He remained at Berlin till he was about twenty, when he went
into Holland, where he first began to publish his composi-
tions; but after continuing there about a year, he came to
England soon after the Revolution. His first employment
in London was playing the tenor in the band at Drury-lane
play-house; but having convinced the managers that he
deferved a better place, he was advanced to the harpischord
about 1700. In 1705 he had acquired English sufficient to
adapt Motteaux's translation of the Italian opera of
"Thomyria" to airs of Scarlatti and Bononcini, and to new-
let the recitatives. In 1709 and 1710, several of his works
were inserted in the first edition of the Tarlers, partic-
sularly a set of sonatas for a flute and baffe, and his first book
of cantatas. In 1713 he obtained, at the same time as
Crofts, the degree of doctor of music at the university of
Oxford. And soon after this, upon the establishment of a
choral chapel at Cannons, he was employed by the duke of
Chandos as maestro di capella; in which capacity he com-
posed anthems and morning and evening services, which
are still preferred in the Academy of Ancient Music. In
1715 he composed the masque of "Venus and Adonis," written
by Cibber; and in 1716 "The Death of Dido," by Booth,
both for Drury-lane. These pieces, though not very suc-
cessful, were more frequently performed than any of his
original dramatic compositions. In 1723 he published an
ode for St. Cecilia's day, which he had set for the concert
in York-buildings. And about the year 1724, Dr. Ber-
kley, dean of Londonderry, afterwards bishop of Cloyne,
having formed a plan for erecting a college in one of the
Summer isles, or Bermudas, among the several perfons of
Vol. XXVI.

distinguished abilities whom he had engaged to accompany
him thither, fixed on Dr. Pepusch. But having embarked
with his associates for the intended settlement, the ship was
wrecked, and the undertaking frustrated.

Being returned to England after this accident, Dr. Pe-
pusch married Margarita de l'Epine, who had quitted the
flag, where she had acquired a fortune that was estimated
at 1,000,000 ducats. These possessions, however, did not incline
the doctor to relax in his musical studies or pursuits. He had
always been a diligent collector of ancient music and musical
tracts, and he was now enabled to gratify this passion
without imprudence. He still continued to compose for
the play-house in Lincolns-Inn-Fields, and had the "Squire
of Alsatia" for his benefit there in 1726, "with singing by
Mrs Chambers, also singing in Italian and English by
Mrs Forfryth, Mrs Davies, and Mrs Grimaldi, being the
first time of their respective appearances on the flage." Soon
after this, he was very judiciously chosen by Gay, to help
him to select the tunes for the "Beggar's Opera," for
which he composed an original overture, the subject
of which was "an original" (I'm like a type), and furnished the wild,
rude, and often vulgar melodies, with balance and
excellence, that no judicious contrapunctist will ever attempt
to alter them for the theatrical purpose for which they
were originally designed. It would be easy to multiply
notes, and make the base more important than the treble,
at the expense of the finger, the vocal part, and of pro-
priety; and we will venture to say that the ineffectual and
accompaniment that robs the finger of the attention of the
audience by being too loud, or too busy (if the finger is
worth hearing), is much more defearing of sense than
praise.

After this period, he composed but little, applying him-
selt chiefly to the theory of music, and explaining the mys-
teries of composition to young professors. He had always
been extremely anxious for the prosperity of the Academy
of Ancient Music, of which he was one of the first founders,
and continued very active in its service to the time of his
death. As a consequence of his musical erudition and zeal
for the advancement of his art, he published, in 1731, a
correct edition of a short "Treatise on Harmony," which
the late earl of Abercorn is supposed to have offered to
put it into English. This nobleman had fo long studied
composition under Dr. Pepusch, and so frequently conversed
with him on the subject, that he was supposed to be able
to explain his principles in English than the doctor himself.
The second edition of this small tract appeared without the
plates or the contents of the author. This work contains
many elementary rules for composition that are practical
and useful; but it likewise contains many prejudices and
explored doctrines, which, to reviwe, would shackle genius
and throw the art back into Gothic times.

In 1737 he was appointed organist of the Charter-house,
which afforded him a tranquil retreat well suited to his time
of life and love of study; and he was visited and consulted
as an oracle, not only by young musical students, to whom
he was always kind and communicative, but by every
master who modestly supposed he had fill something to
learn. Here he greatly augmented his library, which
consisted of musical curiosities, theoretical and practical,
of all kinds.

In 1739 he left a son, his only child, upon whose genius
and disposition there was every reason to found the greatest
expectations; and in 1740 Mrs Pepusch died; after which,
his time seems to have been chiefly devoted to the study of
the genera and fytens of the ancient Greek music, concern-
ing which he presented a paper to the Royal Society in
1749.
1726, N° 481, and Martin's Abridg, vol. x. and was soon after elected a member of that learned body.

From this period till the year 1752, when he died at the age of eighty-five, he perfisted in the study of Greek music; and having dispatched the "Genera," was trying to illustrate the doctrines and prejudices of Isaea Voffius concerning the "Rhythmus" of the ancients, but left no papers behind him on the subject, that were either useful or intelligible to those who had the possession of them after his decease.

This profound musician was buried in the chapel of the Charter-house, where a tablet was placed, and inscribed to his memory, by his friends and associates of the Academy of Ancient Music.

As a practical musician, though so excellent a harmonist, he was possessed of so little invention, that few of his compositions were ever in general use and favour, except one of his twelve cantatas, "Alexis," and his airs for two flutes or violins, consisting of simple easy themes or grounds with variations, each part echoing the other in common divisions for the improvement of the hand. Indeed, though only one cantata of the two books he published was ever much noticed. there is considerable harmonical merit in them all; the recitatives are in general good, and the counterpoint perfectly correct and merrily. The fifth cantata of the second book seems much superior to the rest: the first air would admit of modern taste and expression, the harmony is rich, and the parts are well arranged; and the second air, with a trumpet accompaniment, is spirited, and if sung by a powerful and cultivated voice, would have a good effect. But these cantatas are by no means in the style of Alef. Scarlatti, as has been suggested; they rather resemble the cantatas of Gasparini, whose melodies were simple and modulation tine; the original cantilena and extraneous modulation of Scarlatti. Among all the publications of Pepusch, the most useful to musical students was, perhaps, his correct edition of Corelli's sonatas and concertos in score, published in 1732.

He treated all other music in which there was fancy or invention with sovereign contempt. Nor is it true, as has been alleged, that he readily acquiesced in Handel's superior merit." Handel defpised the pedantry of Pepusch, and Pepusch, in return, confantly refused to join in the general chorus of Handel's praise.

The sole ambition of Pepusch, during the last years of his life, seems to have been the obtaining the reputation of a profound theorist, perfectly skilful in the music of the ancients; and attaching himself to the mathematician De Moivre and Geo. Lewis Scot, who helped him to calculate ratios, and to continue the Greek writers on music, he bewildered himself and some of his scholars with the Greek genera, scales, diagrams, geometrical, arithmetical, and harmonical proportions, furd quantities, apotomes, lemmas, and every thing concerning ancient harmonics, that was dark, unintelligible, and foreign to common and useful practice. But with all his pedantry and ideal admiration of the music of the ancients, he certainly had read more books on the theory of modern music, and examined more curious compositions, than any of the musicians of his time; and though totally devoid of fancy and invention, he was able to correct the productions of his contemporaries, and to assign reasons for whatever had been done by the greatest merriers who preceded him. But when he is called the most learned musician of his time, it should be said, in the music of the 16th century. Indeed, he had at last such a partiality for musical mysteries, and a spirit so truly antiquarian, that he allowed no composition to be music but what was old and obscure. Yet, though he fettered the genius of his scholars by antiquated rules, he knew the mechanical laws of harmony so well, that in glancing his eye over a score, he could by a stroke of his pen smooth the wildest and most incoherent notes into melody, and make them submissive to harmony; infantly seeing the superfluous or deficient notes, and fugging a base from which there was no appeal.

His admirable library, the most curious and complete in scarce musical authors, theoretical and practical, was dispersed after his death. He bequeathed a considerable part of his books and manuscripts to Keimer, an old German friend, who played the double-bass in the theatres and concerts of the time; fome to Travers, and thefe and the reft were at large, dispersed, and embezzled, in a manner difficult to describe or understand. For an analysis of Dr. Pepusch's "Treatise on Harmony," see Counterpoint.

There never was a great man in any art or science who had not his opponents: and there have always been two opinions concerning the merit of Pepusch. He was respected and revered by the exclusive lovers of old music, and students in harmony, for his profound erudition and knowledge in harmony; while the admirers of Handel, and of modern Italian composition, regarded him as a pedant totally devoid of genius. It seemed, therefore, but just and equitable, after the decease of his friends and his foes, to point out, with the utmost truth and candour, the real merit and deficiencies in this little valuable work.

PEPUZAJ, in Ancient Geography, a town of Asia, in Phrygia Pacatiana.

PEPUZJANS, in Ecclesiastical History, a fect of ancient heretics; otherwise called Phrygians, or Caphrygians.

They had their name Pepuzians, from a pretence that Jesus Christ appeared to one of their prophetesses in the city of Pepuza in Phrygia, which was their holy city. See Quintilians.

PEPULLCHNUS, in Ancient Geography, a river which bounded Macedonia.

PEPUS'S ISLANDS, in Geography. See Falkland Islands.

PEQUANACK, a township of America, in Morris county, New Jersey, separated from Bergen county N. by Pequannock river.

PEQUANNOCK Point or River. The river is a small stream which runs S. through the towns of Huntington and Stratford in Fairfield county, Connecticut, and discharges itself into a bay in the found, where vessels may anchor. The point forms the western extremity of the bay, near which are some rocks; 5 miles S.W. of Stratford river.

PEQUEA CREEK, a river of Pennsylvania, which runs into the Susquehannah, N. lat. 39° 54'. W. long. 76° 22'.

PEQUESIGEAUGEM, or Bear Lake, the source of a river of the same name, which is the north-branch of Maggakadawra river: it is of an irregular form, about three miles long, and two wide.

PEQUEST CREEK, a river of New Jersey, which runs into the Delaware, N. lat. 40° 45'. W. long. 75° 10'.

PER, a Latin preposition of en ued before the two words Ars and Theif. Per thesis means, in beating time, the first note or portion of a bar, when the hand or foot is beaten down. Per arsin implies the second or fourth portion of a bar, when the hand or foot is lifted up. It is also said of a melody, counterpoint, or fugue, &c. that the notes move per thesis, when they descend from the acute to the grave; and that their motion is per arsin, when, on the contrary, the notes remain from the grave to the acute.

PER
PER is also an Italian preposition which has many acceptations in the musical compositions of Italy.

1. Before the name of authors, when it is meant to signify by in English; but this is bad Italian.
2. It is confusingly found in tables of contents to motets, indicating the occasion, the subject, and day of festivals, on which it was intended to be sung: and then it means for. Per la Beata Virgini, or the initials B. M. Y. for, or in honour of, the bleffed Virgin. Per li, or gli defunti; for the dead, &c.
3. Per alto often signifies A, or per diritto, straight on. Per rovescio, by inversion, &c.

PERAM, in Botany. See Mattuschka.

PERAMBULATION of the Foreft, the surveying, or walking about a foreft, or the limits of it, by justices or other officers appointed for this purpose, to set down the metes and bounds thereof, and what is within the foreft, and what without.

PERAMBULATION of Parifhes is annually performed in order to preserve those bounds of parifhes, which have been long settled by custom; and because these perambulations were performed in the rotation week, the rotation days were anciently called gange-days, from the Saxon gan, or gangen, to go.

In the perambulation of a parifh, no refreshments can be claimed by the parifhioners, as due of right from any houfe or lands in virtue of custom.

These perambulations were, in the times of popery, accompanied with great abufes, viz. with feaftings and superftition; being performed in the nature of processions, with banners, hand-bells, lights, flaying at crofles, and the like: and, therefore, when processions were forbidden, in the reign of queen Elizabeth, it was required, that, for the retaining of the perambulations of the circuits of parifhes, the people fhould, once a-year, at the ufual time, with the curate and the fubftantial men of the parifh, walk about the parifhes, and at their return to church make their common prayers, &c.

PERAMBULATIONE FACIENDO, is a writ commanding the sheriff to make perambulation, and set down the bounds of two or more manors, whose limits are not fo well known.

The writ de perambulatione facienda is only iffued, where the lords of both manors agree to have such perambulation. If one of them refufe, the other muft feck his remedy by a writ de rationabilibus divis.

PERAMBULATOR, in Surveying, an instrument for the meafuring of distances; called also pedemeter, way-wifer, and surveying-wheel.

Its advantages are its handines and expedition: its contrivance is fuch, that it may be fitted to the wheel of a coach; in which it feizes its office, and meafures the road without any trouble at all.

There is none difference in its make; that now moft ufual, and moft convenient, is as follows.

PERAMBULATOR, or Way-wifer, conftitution of the. The perambulator (reprefented Plate VI. Surveying, fig. 9.) conftits of a wheel two feet seven inches and a half in diameter; confequently half a pole, or eight feet and three inches in circumference. On one end of the axis is a nut, three quarters of an inch in diameter, divided into eight teeth, which, upon moving the wheel round, fall into the eight teeth of another nut, and then turn the rod once round, in the time the wheel makes one revolution. This rod lying along a groove, in the fide of a carriage of the instrument, has at its other end a fquare hole, into which fits the end b of the little cylinder P. This cylinder is dipofed under the dial-plate of a movement, at the end of the carriage B, in fuch manner as to be moveable about its axis. Its end a is cut into a perforated refew; which falling into the thirty-two teeth of a wheel perpendicular to it, upon driving the instrument forward, that wheel makes a revolution, each sixteen poles. On the axis of this wheel is a pinion with fix teeth, which, falling into

4 N 2
the teeth of another wheel of sixty teeth, carries it round every hundred and sixtieth pole, or half a mile.

This last wheel then carrying a hand or index round with it, over the divisions of the dial-plate, whose outer limb is divided into one hundred and sixty parts, corresponding to the one hundred and sixty poles, points out the number of poles passed over. Again, on the axis of this last wheel is a pinion containing twenty teeth, which, falling into the teeth of a third wheel, that has forty teeth, drives it once round in three hundred and twenty poles, or a mile. On the axis of this wheel is a pinion of twelve teeth, which, falling into the teeth of a fourth wheel, that has seventy-two teeth, drives it once round in twelve miles.

This fourth wheel carrying another index over the inner limb of the dial-plate, divided into twelve, for miles, and each mile subdivided into halves, quarters, and furlongs, serves to register the revolutions of the other hand, and to keep account of the half-miles and miles passed over, as far as twelve miles.

**Perambulator, or Way-wiser, used by the.** The application of this instrument is obvious from its construction. Its proper office is in the surveying of roads, and large distances, where a great deal of expedition, and not much accuracy, is required. It is evident, that driving it along, and observing the hands, has the same effect as dragging the chain, and taking account of the chains and links. See Chain.

Long distances, fays major Rennell, may be accurately measured by a perambulator; and he fays, that during the Bengal survey, he measured a meridian line of three degrees with this instrument; and found it to agree minutely with the observations of latitude. An allowance, however, was made for the irregularities of the ground, whenever they occurred.

**Perames, in Geography, a town of America, in Bergen county, New Jersey, lying on the point of land formed by the branches of the Saddle river, a N. branch of the Passaic; about 18 miles N. of Bergen.**

**Perami, a town of the island of Cuba; 25 miles S.E. of Villa del Principe.**

**Peranema, in Ichthyology, the name of a Brazilian fish, of the size of the perch, being ten or eleven fingers in length, and about three fingers broad in the broadest part.**

Its mouth is large and round, and has no teeth, but several very rough and sharp prominences; its eyes are large, and it has a long fin running down the back, which is supported by rigid and prickly rays; its tail is not forked; its whole body is a silver white, with a faint bluish spot; its scales are extremely small, and of a triangular figure, and its belly is very white: it is a sea-fish, and is wholesome and well-taught.

**Peranites, the name of a stone mentioned with many idle stories of its origin, by the writers of the middle ages.**

It seems originally to have been only a corruption of the word peanitids, a name by which the ancients seem to have called our flatfishes or drogphine.

**Peraralo, in Geography, a town of Italy, in the Cadorin; two miles S. of Cadora.**

**Peraror, a town of Hindooftan, in the Carnatic; 10 miles S. of Tiagar.**

**Perarsin, and Thesin, in Mafic. See Per, &c.**

**Perasemajoki, in Geography, a town of Sweden, in the province of Wafa; 50 miles E.N.E. of Chritlinefladt.**

**Perashacotta, a town of Hindooftan; 13 miles W.N.W. of Combatore.**

**Perasta, a town of Albania, on the Cattaro.—Also, a town of European Turkey, in Romania, on the coast of the Sea of Marmora; 12 miles N.E. of Gallipoll.**

**Perastorff, a town of Austria; five miles S.S.W. of Ias.**

**Pera, an town of Hindooftan, in Bahar; 45 miles S.S.W. of Patna.**

**Perbatour, a town of Hindooftan, in Allahabad; 45 miles N.E. of Gazipour.**

**Perca, the Perch, in Ichthyology, a genus of fishes of the order Thoracic, one of which the generic character is, jaws unequal; teeth sharp, incurved; gill-covers scaly, of three laminae, the upper fork; gill-membrane seven-rayed; lateral line arched with the back; scales hard, rough; fins spiny; vent nearer the head than the tail. The name perca is of Greek origin, and is derived from the word πέρας, which signifies variegated with black or dusky spots; a character common to most of the species of this fish. About sixty species are enumerated in Gmelin's last edition of Linnaeus; these are divided into three sections according as they have one dorsal fin or two.**

A. Dorval Fins two, distinct.

Species.

* Fluvatilis, or Common Perch. The second dorsal fin has sixteen soft rays; the eyes are large; the iris blueish, edged within with yellow; the nostrils are double, near the eyes, with four pores before them; the mouth is large; jaws nearly equal; teeth small, in the jaws; and on the roof; the tongue is smooth and short; aperture of the gills large; dorsal fins violet, the first with fimbriated and a black spot at the end; pectoral reddish, the rest are red; the tail is a little forked. This well-known fish measures from eight to ten inches, to nearly two feet in length. It inhabits the clear streams of Europe and Siberia; the back, and part of the sides, are of a deep green, with five broad black bars, which are sometimes dark green or blue, and very rarely wanting; belly white tinged with red; it swims with great swiftness at a certain height in the water. It is tenacious of life, and may be carried sixty miles in a row, and yet survive the journey; eagerly takes a bait: it feeds on aquatic insects and smaller fish, spawns in May and June, and is very prolific; it has no real air-bladder. Its flesh is firm and delicate, and was held in high repute at the table of the ancient Romans. In some of the northern countries, a sort of lumpfish is made from the skin. It is preyed upon by the pike, eel, &c.**

* Americanus. Red; second dorsal fin with thirteen rays. It is found in the brackish waters of North America; the lower lip, chin, gill-membrane, and upper edge of the covers red.**

**Lucipepera. Second dorsal fin with twenty-three rays. This species inhabits the clear waters of Europe and northern Persia. It grows to four feet long; is very voracious, feeds on other fish, even of its own tribe; spawns in May, and is extremely prolific; the flesh is tender and good.**

**Volonensis. Green-gold; second dorsal fin with twenty-three rays. It is found chiefly in the Volga and neighbour-
PERCA.

ing rivers, and is an intermediate species between the fluvialtilis and the lucioperca.

ASPER. Yellowfish, with three or four transverse bands; second dorsal fin with thirteen rays. This species inhabits the clear waters of southern Europe, is from six to eight inches long. The body above is blackish, but it is whitish beneath; it feeds on insects and worms; the flesh is delicious.

ZINGEL. Second dorsal fin with nineteen rays; the lower jaw is by much the shorter of the two. It is found in the rivers of Germany. It resembles the last, except that it is much larger; the head more pointed; the gape large; the colour less dusky, and the tail longer, truncate, and somewhat rounded.

*LABRAX; the Balfi. Second dorsal fin with fourteen rays; the back is dusky, tinged with blue; the belly is white. It inhabits Europe and Egypt. It sometimes grows to the weight of twelve or fourteen pounds; is strong, active, and voracious; the body is shaped like a salmon.

ALBURNUS. Doral fins unarmed; the gill-membrane is three-rayed; the tail entire. It inhabits Carolina; the body is oblong, with numerous oblique brown bands.

PESSILLA. Body oval, compressed, rough. It inhabits the Mediterranean, is only an inch and a half long; the body is of a reddish-silver hue, covered with very minute prickles. The head is armed with prickles; the lower jaw a little longer, very rough beneath; the iris is white; the ventral fins with a strong spine, and serrate on the anterior edge.

LOPHII. Silvery; ventral fins compressed. It inhabits Constan tinople; it is about the size and shape of a herring; the back is greenish-brown; it is thought by some naturalists not to be of the perca tribe.

ARABICA. Body silvery, with longitudinal black lines; tail with a golden spot, and black in the middle. It inhabits Arabia, the body is oblong-lanceolate, truncate, beneath without spots or lines; the scales are lax, broad, deciduous, denticulate, dispersed in ten rows; it has sixteen or seventeen black lines on each side.

NILOTICA. Doral fins hardly distinct; tail entire. It is found in the river Nile, and also in the Caspian sea.

B. Dorval Fins Single; Tail Undivided.

Species.

UNDULATA. Doral fins sub-united; body brown, waved, a brown spot at the pectoral fins. It inhabits Carolina, and is there called the croaker. The anterior gill-covers have five short teeth; the tail is entire.

OCELLATA. Doral fins sub-united; tail with a black ociclate spot at the base. It inhabits Carolina, and is there called the baffe. The first ray of the dorval fin very short, the fifth of the ventral is shorter and unarmed; the spot on the tail is encircled with white.

ARGUS. Silvery-blueish, with numerous ociclate brown spots. It grows to about a foot in length, and is reckoned a very beautiful fish. The spots on the body have white centres; those on the head, pectoral and ventral fins, are smaller and without white centres.

MARINA; Sea Pearch. This species is red, with dusky lines on the sides; gill-covers with a black spot; it has fifteen dorsal spines. It is found in many parts of Europe, is about a foot long, and the flesh is very good. The head is large and deformed; the eyes are large; the teeth are small, numerous, and on the head and gill-covers are strong spines.

SCANDENS. The dorval fin of this species has seventeen spinos and eight soft rays; the scales are rough, with a whitish denticulate edge. It inhabits rivulets in Tranquebar; is about four inches long; has the very singular habit of crawling up trees, whence it takes its specific name, which it effects by means of the spines on the gill-covers, and spinous rays of the other fins. It is described in the Linnaean Transacciones. The body is covered with a black slidy mucous; above it is of dusky-green, lighter on the sides, and beneath it is of a pale golden colour.

NOBILIS. Body silvery, with eight brown bands. It inhabits North America. The spinous rays of the dorval fin are silvery at the sides.

POLYMNA. Body black, with three white bands. It inhabits South America and some parts of India. The middle band passes through the hind part of the dorval fin.

MEERA. Body white, with numerous sub-hexagonal brown spots. It inhabits Japan, and is about a foot long. The lower jaw longer; pectoral gill-cover spinous, tail rounded.

COTTOIDES. All the fins of the fifth of this species are marked with two dotted lines. It is found in India.

PHILADELPHIUS. The dorval fin has a black spot in the middle; the scales and gill-covers are ciliate. It inhabits South America.

PALPEROSA. The eyelids of this species are marked with a brown spot; the lateral line is curved. It is a small fish, and inhabits America.

ARABIA. The body of this species is black, the fins are spotted with white. It is found in Carolina.

CHRYSOPTERA. The lower fins are yellow, spotted with brown. It inhabits Carolina. The gill-covers are very finely toothed; the lateral line is straight.

MEDITERRANEAE. All the fins of this species, except the dorval, are tawny; the pectoral is marked with a pectoral black spot. It inhabits the Mediterranean. The body is green, with dusky lines parallel with a lateral line on the upper part; those on the lower part are broader, and of a fine blue; about a foot long; compressed, oblong.

VITTATA. The body with five white and brown transverse lines; there is a variety of this species, in which the lines are widened into bands; the first inhabits America; the second Japan. They are about eight inches long.

GUTTATA. Body sprinkled with bloody coloured dots. This and the next are natives of America.

PUNCTATA. Body dotted with blue.

SCIRPA. Pectoral and caudal fins yellow; the head with irregular zigzag marks.

GIGAS. Body clouded; gill-covers three-spined; eleven dorval spines. It inhabits the Mediterranean, and is about three feet long. The body is oval, compressed at the sides, whitish-yellow, with dusky-brown waves.

ROGAA. Reddish-black; tail equal; fins black; gill-membrane dusky-red. It is found in divers parts of Arabia.

LUNARIA. Rusty black; pectoral fins black, behind yellow; dorval and caudal behind of a palish hyaline. It inhabits Arabia, and is a good deal like the lat.

TAUVINA. Body oblong linear, brown, with rusty black dots; the tail is rounded. It inhabits Arabia. The scales are small and denticulate.

FASCIATA. This is red, with broad whitish transverse bands. It inhabits the Red Sea; is above a yard long, and the scales are small.

MINIATA. This species is scarlet, covered with blue dots; the tail is rounded; there are two varieties: 1. Brown, with ociclate blue spots. 2. Red, with blue dots. It inhabits
bits Arabia, and feeds on fish; the scales are very small, round, carinate; the flesh is very good.

**Summary.** Of this species there are three varieties.  
1. Tail rounded; body ash-brown, covered with white spots.  
2. Body bluish, with brown dots.  
3. Whitish-suff, with yellowish-brown dots. These are natives of Arabia.

**Sixnus.** Yellowish; tail oval; lower jaw shorter. It inhabits China, and resembles the P. fluviatilis, but is smaller.

**C. Doras Fin Single: Tail forked.**

**Species.**

**Ascensionis.** Above reddish, beneath whitish. It is found in Ascension In. The body is narrower, covered with oblong narrow scales, denticulate on the fore-part.

**Louti.** Oblong-lanceolate, carmine, with pale violet dots; hind edge of all the fins yellow. It inhabits Arabia, and is about three feet long.

**Venera.** Pectoral fins tint with yellow; the tail is lunate; the body is marked with blood-red dots. It is a native of America, and infested of being poisonous.

**Melanura.** Tail black, edged with white; the body is marked with yellow lines. It inhabits America, as does the next.

**Stolatrina.** Tail forked, red on the hind-part; the belly is of a pale yellow, with grey lines.

**Stigma.** Doras fin filamentous; gill-covers banded. It is a native of India.

**Diagramma.** The body of this fish is white, with longitudinal stripes; it has eleven dorsal spines. It inhabits India, in fresh waters; grows to ten inches long, and preys on smaller fishes.

**Striata.** The body of this species is striate. It inhabits North America, and differs from the P. melanura, chiefly in not having the tail black.

**Lineata.** Doras fin filamentous; the body with five alternate white and brown lines.

**Carinata, or Ruffe.** The dorsal fin of this species is twenty-seven-rayed; the spines are fifteen. It inhabits the clear streams of Europe, and is from six to eight inches long; the body is round, mucous, sides yellowish, dirty-green, spotted with black, breast white, nape and back blackish; it feeds on lesser fishes, and is the prey of larger, and also of various aquatic birds; it is a very fertile fish, and spawns in March or April; the flesh is reckoned very good.

***Nigra; Black Fish.** The body of this is narrow, with small thin scales. It is found in Cornwall, and is a very indifferant species.

**Aecrana.** The dorsal fin of this species has thirty-one rays and seventeen spines. It inhabits the Euxine sea, and the rivers running into it; it refleems, in its figure, colour, and habits, the P. carinata, but its head is longer.

**Schreter.** Body with longitudinal black lines on each side. It is found in many parts of the south of Europe; the head is aculate.

**Argentea.** Nostril tubular; a black spot on the spinous part of the dorsal fin. It inhabits America.

**Cabrilla.** Body marked with four longitudinal blood-red stripes. A variety of this species is varied with yellow and violet blotches. It inhabits the Mediterranean.

**Radula.** Body with white dots disposed in lines. It is found in India.

**Foramia; Squirrel Fish.** Tail lunate; head marked with blue lines, and blotches. It inhabits Carolina. The gill-covers are toothed; the anterior part of the dorsal fin abbreviate towards the hind part.

**Sacer.** Body rose-coloured; secondary of the dorsal fin very long. It inhabits the Mediterranean, and is about a foot long. The posterior gill-cover ends in a spine; the tail is lunate.

**Lunulata.** Reddish; tail with a black lunule at the base. It inhabits Sumatra.

**Aurata.** Whitish, with a longitudinal yellow stripe. It inhabits Sumatra, as does the next.

**Sumatrensis.** Body dark-silver; fins longitudinally striate. It inhabits in shoals the coasts of Sumatra; it has about three inches long; scales small, denticulate, and dotted with brown. It is described in the Linnaean Trans.

**Triphurca.** The tail is trifid; and the body has seven blue bands. It inhabits Carolina, and is very finely variegated.

The common perch, or perca fluviatilis of Linnaeus, is much admired as a firm and delicate fish; and the Dutch are particularly fond of it when made into a dish called water-foordy.

Mr. Pennant mentions a singular variety of the perch, the back of which is quite hunched, and the lower part of the back bone, next the tail, strangely distorted; in colour and other respects it resembles the common kind. It is found in a lake called Llyn Raithlyn, in Merionethshire, and also in the Thames near Marlow.

The common perch affords good sport for the angler. The best time for their biting is, when the spring is over, and before the heats of summer come on. At this time they are very greedy, and the angler, with good management, may take at one landing all that are in the hole, be they ever so many.

The perch will bite all day long, if the weather be cloudy; but the best time is from eight to ten in the morning, and from three to fix in the afternoo0n. The perch is very ablemister in winter, and will seldom bite in this season of the year; if he does at all, it is in the middle of the day: at which time indeed all fish bite best at that season. See Fishing.

**Perca Amboinensis.** The name of a fresh water fish, somewhat resembling our perch, but differing in that it is of a brown colour, and has several blue lines under its snout, and some blueeats in the adjoining fins, but its back and belly fins are green. It is caught in the lakes and rivers of fresh water, at Ambonuha, and is a very delicately tasted fish. See Scorpena Volutans.

**Perca Rhomboides.** See Sparus Rhomboides. See also Sparus Marmoratus.

**Percee, L'Isle, in Geography, a small but remarkable island on the W. side of the gulf of St. Lawrence, being a perpendicular rock, pierced with two natural arches, through which the sea flows. One of these arches is large enough to admit a large boat to pass through it; 15 miles S. of Cape Gaspee.**

**Perceiana, in Ancient Geography, a town of Spain, in the route from the mouth of the river Anato Emerita, according to the Itinerary of Antonine.**

**Percepi, in Botany, a name attributed by Lobel, in his Adversaria 524, to the Aphanes of Linnaeus, Alchmilla arvenis, Eng. Bot. 1.1011; see Aphanes. From the manner in which Lobel is always quoted, it would seem that he considered the above name as English; but he merely declares the plant was very commonly sold about Bristol for promoting the urinary secretion. Gerarde says "our herbe women in Cheape-side know it by the name of Parley broke-\(r\)."**
..." PERO

stone." Lobel's word seems a French corruption of the latter, which expresses the appearance of the plant, and its reputed lithrientric virtues. Purfley-Pier's English appellation in Ray's Synopsis is, but a little further corruption, partly typographical, in the third edition. Baumann, in his Pinax 153, has Perekhiper Anglorum, and he explains it by Saxifrages, or Freshstones. One would suppose, that amid all the jumble of nomenclature, there might be some foundation for the reputed qualities of this plant. Ray says "it is believed violently and suddenly to promote urine, and to break down the calculus. It is eaten raw, as a salald, or preserved with salt, and a diluted water is extracted from it for the above purposes." All this we fear is illusive, and has certainly not been confirmed by experience. The herb in question is indeed slightly astringent, and more slightly mucilaginous; qualities useful in the disease alluded to. But we cannot but observe that it came into use, in times of ignorance, from its partial resemblance to some of those various diminutive herbs, that have obtained the name of Saxifrages, Saxifraga or Breakstone, from their growing on stones or walls, which their roots, by the force of vegetation, penetrate and break down. Hence such herbs were preserved likely to have an effect on the stone in the bladder; for if the old writers do not expressly declare this, the manner in which they speak of the quality of the plants, and of their places of growth, tacitly implies such an opinion. By tracing these by-ethical properties of plants to their fources, the Materis Medicae is diversified much from trash, and implicit faith in the affections of herbalists is considerably weakened. Perhaps we may be able to discuss the subject to a greater extent hereafter, in treating of the Virtues of Plants.

PERCEPTION, Perceptio, in Logic, the act of perceiving, or apprehending a thing, without making any affirmation or negation. See APPREHENSION and CONCEPTION.

Some writers have confounded idea and perception, whereas these are clearly distinguisable as the cause and effect: the one is an operation of the mind, and the other the refult of that operation. See IDEA.

The faculty or power of perception constitutes what we call the understanding.

The faculty of perception seems to be that which constitutes the distinction between the animal and inanimate parts of the creation. Vegetables, some of them, have some degree of motion, and, upon different applications of other bodies, alter their figures and motions; so as hence to obtain the name of senitive plants; which, however, is the result of mere mechanism, and no otherwise produced than the shortening of a rope by the effusion of water. But perception is a metaphysical principle, and is found in some degree in all animals; and in them alone.

Perception is a principle or power, the existence of which can only be known by consciousness, or the experience which every man has of what passes within himself: and it has been long ago observed (see Cic. Tusc. Quæst. lib. i. § 28.), that the mind is as incapable of comprehending the nature of perception, as the eye is of seeing itself. Nevertheles of all the operations of our minds, the perception of external objects is the most familiar. It is one main link of that mysterious chain which connects the mortal world with the intellectual. In this operation, many things are unaccountable; and there are sufficient to convince us, that we know but little of our own frame, and that a perfect comprehension of our mental powers, and of the manner of their operation, is beyond the reach of our understanding. In perception there are impressions upon the organs of fenfe, the nerves, and brain, which, by the laws of our nature, are followed by certain operations of the mind. These two things, thoug apt to be confounded, ought to be carefully distinguished. Some philosophers have, without found reason, concluded, that the impressions made upon the body are the proper efficace cause of perception; whilst others have, with as little reason, concluded, that impressions are made on the mind similar to these made on the body. It is universally allowed, that we perceive no external object but by means of certain bodily organs which God has given us for that purpose. This is so well known from experience, that it needs no proof; and, indeed, we can give no reason for it, but that such is the will of our maker. But, as we have reason to believe that the Supreme Being perceives everything in a much more perfect manner than we can do, without bodily organs, and that there are other created beings endowed with powers of perception more perfect and extensive than ours, without such organs, we ought not to conclude, that such bodily organs are, in their own nature, necessary to perception; but rather that, by the will of God, our power of perceiving external objects is limited and circumscribed by our organs of senfe; so that we perceive objects in a certain manner, and in certain circumstances, and in no other. We ought also to be cautioned against confounding the organs of perception with the being that perceives. Perception must be the act of some being that perceives. It is another law of our nature, that we perceive no object, unless some impression is made upon the organ of senfe, either by the immediate application of the object, or by some medium which passes between the object and the organ: and in conformation of this law, well known and capable of the most familiar illustration, our powers of perceiving external objects are further limited and circumscribed. It is likewise a law of our nature, that, in order to our perception of objects, the impressions made upon the organs of senfe must be communicated to the nerves, and by them to the brain. From such impressions some philosophers, both ancient and modern, have deduced conclusions, that are very doubtful, if not absolutely erroneous. Hence some have inferred, that man is nothing but a piece of matter so curiously organized, that the impressions of external objects produce in it senfation, perception, remembrance, and all the other operations of which we are conscious; or, because the Author of nature has established a constant connection between certain impressions on our senfes and our perception of the objects by which the impression is made, that these impressions were the proper efficace causes of the corresponding perception. But this kind of reasoning supposes, that because two things are always conformed, one is caused therefore to be the cause of another (see CAUSE); and it supposes also that matter, by any motion or modification of which it is capable, may produce thought. Another conclusion, very generally deduced by philosophers from the facts above stated, is, that in perception an impression is made upon the mind, as well as upon the organ, nerves, and brain. They seem to think, that the object perceived acts upon the mind in some way similar to that in which one body acts upon another, by making an impression upon it; and this impression upon the mind is conceived to be something with regard to which the mind is altogether passive, and has some effect produced on it by the object. But this, says Dr. Reid, is an hypothesis which we make of our own, and which ought not to be admitted without proof. Another conclusion drawn from the impressions made upon the brain in perception, which the author just named conceives to have no solid foundation, though it has been very generally adopted by philosophers, is
PERCEPTION.

is this; that by the impressions made on the brain, images are formed of the object perceived; and that the mind, being feated in the brain as its chamber of preception, immediately perceives those images only, and has no perception of the external object but by them. (See Idea and Soul.) But whether the brain be the seat of the soul or not, it is alleged by our author, that there is no proof nor probability of the opinion that images of all the objects of sense are formed in the brain, with regard to any of them; and that with regard to the greater part of them, these are words without any meaning. Although it be allowed, that external objects make some impression on the organs of sense, and by them on the nerves and brain; yet it is most improbable, that these impressions resemble the objects by which they are made, so as that they may be called images of the objects; not to add, that the brain itself, being a f Holt, most meditary substance, is altogether improper for receiving and retaining such images. It is added, that the word "image," when applied to all objects of sense, except figure and colour, has absolutely no meaning. Our author further observes, with respect to another part of the hypothesis just stated, viz. that the mind perceives the images in the brain, and external objects only by means of them; that this is as improbable as that there are such images to be perceived. If our powers of perception, he says, be not altogether fallacious, the objects we perceive are not in our brain, but without us. Dr. Reid sums up what he has said, with regard to the organs of perception, and the impressions made upon our nerves and brain, in the following manner. "It is a law of our nature, establisht by the will of the Supreme Being, that we perceive no external object but by means of the organs given us for that purpose. But these organs do not perceive. The eye is the organ of sight, but it does not. A telescope is an artificial organ of sight; the eye is a natural organ of sight, but it does as little as the telescope. We know how the eye forms a picture of the visible object upon the retina; but how this picture makes us see the object we know not; and if experience had not informed us that such a picture is necessary to vision, we should never have known it. We can give no reason why the picture on the retina should be followed by vision, while a like picture on any other part of the body produces nothing like vision."

"It is likewise a law of our nature, that we perceive not external objects, unless certain impressions be made by the object upon the organ, and by means of the organ on the nerves and brain. But of the nature of these impressions we are perfectly ignorant; and though they are conjoined by the will of our Maker, yet it does not appear that they have any necessary connection with it in their own nature, far less that they can be the proper efficient cause of it. We perceive, because God has given us the power of perceiving, and not because we have impressions from objects. We perceive nothing without those impressions, because our Maker has limited and circumscribed our powers of perception by such laws of nature as to his wisdom seemed meet, and such as suited our rank in his creation."

Dr. Reid, having discarded the old ideal system, proceeds to the consideration of that of the mind, of which we are all conscious, and which is denominated perception. If we attend to it, we shall find in it, he says, these three things: 1st, some conception or notion of the object perceived; 2dly, a strong and irresistible conviction and belief of its present existence; and, 3dly, that this conviction and belief are firm and settled, and not the effect of reasoning. After the illustration of these circumstances attending perception, and observing that thys he intended the account which he has
given of our perception of external objects as a faithful delineation of what every man come to years of understanding, and capable of giving attention to what passes in his own mind, may feel in himself, our author acknowledges that he is not able to flew, nor does he pretend to flew, in what manner the notion of external objects, and the immediate belief of their existence, are produced by means of our senses. "If the power of perceiving external objects, in certain circumstances, be a part of the original constitution of the human mind, all attempts to account for it will be vain. No other account can be given of the constitution of things but the will of him that made them: as we can give no reason why matter is extended and inert, why the mind thinks and is conscious of its thoughts, but the will of him who made both; so I suspect, we can give no other reason why, in certain circumstances, we perceive external objects, and in others do not." As to the manner in which the mind exercises its powers of perception, our author professes to give no theory of his own, though he has lurked at the root of all the commonly received theories on this subject. Plato conceived that by our senses we perceived the shadows of things only, and not things themselves. He seems to have borrowed his notions on this subject from the Pythagoreans, as they probably derived theirs from Pythagoras himself. Allowing for Plato's allegorical genius, his sentiments correspond very well with those of his scholar Aristotle, and of the Peripatetick. The shadows of Plato may represent the species and phantasmis of the Peripatetic school, and the ideas and impressions of modern philosophers. Two thousand years after Plato, Mr. Locke, who studied the operations of the human mind so much, and with so great success, represents our manner of perceiving external objects by a limbdire very much resembling Plato's cave; and both the subterraneous cave of the ancient philosopher, and the dark closet of Mr. Locke, may be easily applied to all the systems of perception that have been invented. "For," as Dr. Reid states the matter, "they all suppose that we perceive not external objects immediately, and that the immediate objects of perception are only certain shadows of the external objects. Those shadows or images, which we immediately perceive, were by the ancients called species, forms, phantasmis. Since the time of Des Cartes, they have commonly been called ideas, and by Mr Hume impressions. But all philosophers, from Plato to Mr. Hume, agree in this, that we do not perceive external objects immediately, and that the immediate object of perception must be some image present to the mind. So far there appears an unanimity rarely to be found among philosophers on such abstruse points."

Philosophers, Berkeley and Hume excepted, believe the existence of external objects of sense, and call them objects of perception, though not immediate objects. But what they mean by a mediate object of perception they have not clearly explained. It seems to be their opinion, that we do not really perceive the external object, but the internal only; and that when they speak of perceiving external objects, they mean to express themselves in a popular or in a figurative sense, intimating that we perceive such objects as we perceive an absent friend when we look on his picture.

Besides what is common to philosophers in accounting for our perception of external objects, as above stated, some differences subsist among them. The ideas by which we perceive external objects are said by some to be the ideas of the Deity; but it has been more generally thought, that every man's ideas are produced by himself, and not in his mind, or in his periculum, where the mind is immediately present. The err is the theory of Malebranche; the second may be called the common theory. (See Cartesian Philosophy, I. c.)
LEIBNITZISM, MALEBRANCHISM, PERIPATECTICS, PLATONISTS, AND PYTHAGOREANS. SEC also CONCEPTION, IDEA, QUALITY, REFLECTION, AND SENSATION.) Dr. Reid, after giving a long account of the different theories advanced by philosophers, in order to account for our perception of external objects, closes with observing "that neither Aristotle's theory of sensible species, nor Malebranch's of our feeling things in God, nor the common supposed of our perceiving ideas in our own mind, nor Leibnitz's theory of monads, and a pre-established harmony, give any satisfactory account of the power of the mind, or make it more intelligible than it is without their aid. They are conjectures, and if they were true, would solve no difficulty, but raise many new ones. It is therefore more agreeable to good sense, and to found philosophy, to rest satisfied with what our own consciousness and attentive reflection discover to us of the nature of perception, than by inventing hypothesis, to attempt to explain things which are above the reach of human understanding. I believe no man is able to explain how we perceive external objects, any more than how we are conscious of those that are internal. Perception, consciousness, memory, and imagination, are all original and simple powers of the mind, and part of its constitution. For this reason, though I have endeavored to shew that the theories of philosophers on this subject are ill grounded and insufficient, I do not attempt to substitute any other theory in their place. Every man feels that perception gives him an invincible belief of the existence of that which he perceives; and that this belief is not the effect of reasoning, but the immediate consequence of perception. If philosophers have wearied themselves and their readers with their speculations upon this subject, they can neither strengthen this belief nor weaken it; nor can they shew how it is produced. It is the philosopher and the peasant upon a level; and neither of them can give any other reason for believing his fancies, than that he finds it impossible for him to do otherwise." The objects of perception are the primary and secondary qualities of bodies (i.e., quality); and besides these, certain states and conditions of our own bodies; mechanical powers or forces; chemical powers; medical powers or virtues; and vegetable and animal powers; to one or other of which classes all the objects of perception may be referred. Reid's Essays on the Intellectual Powers of Man. Stewart's Elements of the Philosophy of the Human Mind.

PERCEVAL, Spencer, in Biography, born Nov. 1, 1762, was son of John, the late earl of Egmont, by Catharine Compton, sister to Spencer, earl of Northampton, from whom he took the Christian name of Spencer. His mother was, in the year 1770, created a peeress of Ireland, in her own right, with the title of baroness Arden; and dying in 1784, she was succeeded by her eldest son Charles George, who, in July 1808, was raised to the peerage of England. Mr. Perceval's infancy was spent at Charlton, in Kent, the seat of his family, where he received the elements of his education. After this he went to Harrow school, where he was distingushed for the gentleness of his manners, the benevolence of his disposition, and the good-nets of his heart. Those who knew him in early life were not surprized at the good fortune which distingushed him in his future prospects, nor at the warm attachment which his political and personal friends felt for him. At Harrow he was contemporary with Sir William Jones; after having passed the usual time at this school, he was sent to Trinity college, Cambridge, where he formed some of the most valuable connections of his future life. As soon as he had completed his collegiate studies, he entered himself a member of Lincoln's Inn, and pursued the study of the law as a profession. He was remarkable for close and regular application: he was aware that eminence was not to be obtained in the law without industry and perseverance, and in these he studied to excel. While employed as a barrister, he was particularly noticed for his mild and gentlemanly behaviour, which he displayed in an high degree when he became prime minister, and which in the senate called forth the well-merited encomiums of his warmest political opponents.

At an early period he was appointed counsel to the admiralty, in the year 1799 he was honoured with a filk gown, and about this time he was elected counsel for the university of Cambridge. In consequence of his uncle's death a vacancy was created in the borough of Northampton, which introduced Mr. Perceval into parliamentary life. He immediately gave his support to Mr. Pitt, and pursued the same line of politics regularly and efficiently through the remainder of his life.

Mr. Perceval had not been long in parliament before he attracted the marked attention of the minisler, who it is said, being asked by his second, Mr. Ryder, now lord Harrowby, when about to engage in a duel with Mr. Tierney, who was the fittest person to succeed him if he should fall in the contest, replied Mr. Perceval is that man. At this period he endeavored to become thoroughly master of every branch of policy, dedicating his time and talents to the study of finance. In 1801, at the formation of the Addington administration, Mr. Perceval, then in his 39th year, was appointed solicitor-general, and in 1802 he was promoted to the situation of attorney-general, become vacant by the elevation of Sir Edward Law, now lord Ellenborough, to the chief-justicehip of the court of king's bench. The only prosecution instituted by Mr. Perceval, in his character of attorney-general, worthy of notice, was that against Peltier, the editor of a French journal, printed in London, for a libel on Bonaparte.

Mr. Perceval retained his situation when Mr. Pitt resumed the reins of government, and continued to distinguish himself as a ready and instant supporter of his measures. On the death of Mr. Pitt, Mr. Perceval, for the first time, appeared in the ranks of opposition, and it has been assumed, by those who were the witnesses of his parliamentary career at that period, that his talents were most conspicuous and marked when he rofe as an opposition-speaker: in this character he was animated without affectation, earnest without overstatement, attached to his own party, without an indiscriminate contention with his adversaries.

When the Fox administration quitted office, towards the beginning of the year 1807, Mr. Perceval was appointed chancellor of the exchequer; but as the duke of Portland, who was first lord of the treasury, was very old and infirm, and feldom took an active or decided part in the administration of public affairs, Mr. Perceval was unquestionably, even then, the prime-minister of Great Britain, and upon the death of that nobleman he became so nominally as well as virtually. The situation of the country and of Europe at this period was very difficult: it required great talents, exercised with uncommon delicacy, as well as decision and vigour. The talents of Mr. Perceval can hardly be said to be of the first order; and it cannot be denied that the decision and vigour which he undoubtedly possessed, were not unfrequently mixed with something like precipitation and obstinacy. He seemed to have imbibed and acted upon a most dangerous idea, which a prime minister should never admit into his thoughts; viz., that a measure once openly avowed, ought, on no account, and under no circumstances, to be abandoned. The relative circumstances of Great Britain and of Europe most undoubtedly required political bravery;
they required that the prime minister of this country should have a mind above fear and embarrassing scruples: in short, that he should be able to take a comprehensive, profound, and cool view of the ideas of man, and of all the events which Britain had been involved in, and of the principles on which Britain professed to prefer her honour and independence in Europe. When this view was once taken, then decided, firm, and prompt conduct corresponding to it was equally requisite. But it is obvious, that if decision, firmness, and promptitude are not preceded by thorough political knowledge, as well as the founded political principles and views, they are capable of much mischief. This sort of knowledge Mr. Perceval did not possess in a degree which either the state of Europe required, or which could justify the pertinacity with which he adhered to measures that he had once adopted. The events of his administration are too near to render it necessary to refer to them seriatim. He was avowedly an enemy to those concessions to the Roman Catholics, which many of his subjects, at least as wife, and possessing more powerful talents, regard as essential to the safety of the state. To his unyielding and unconsidered temper, the American war in which we have been plunged has been imputed. His death was occasioned by the hand of an affidavit, who was unquestionably mad. On Monday the 11th of May, 1812, about five o'clock in the evening, Mr. Perceval having walked from his house in Downing-street, was entering the lobby of the house of commons, where a number of persons were flanging; he was shot by a person named Bellingham, formerly a merchant, but whose diffidences had probably deranged his mind. Having committed the deed, he made no effort to escape. Being asked if he was the villain who had shot the minister, who replied, "I am, indeed, the unhappy man;" and at the bar of the house, during a short examination, being cautioned not to criminate himself, he said "I have admitted the fact: I do admit it: I have been denied the redress of my grievances by government: I have been ill treated. They all know who I am, and what I am; through the secretary of state and Mr. Becket, with whom I have had frequent communications. They knew of my intention six weeks ago, through the Bow-street magistrates. I have fought redress in vain. I am a most unfortunate man, and feel here," pointing to his heart, "sufficient justification for what I have done." No serious attempt was, however, made on his trial to prove insanity: indeed time was not allowed for his friends to appear in his behalf. The deed was committed on Monday evening; he was tried and convicted on the following Friday, which was as soon as it could be known in Liverpool that his trial would come on at the sessions then in its course.ample provision was made for Mr. Perceval’s family by parliament.

As a public speaker, Mr. Perceval rove much in reputation and excellence, after he became minister: as the leading man in the house of commons, it was necessary that he should be able to explain and defend all his measures; and this duty, arduous under all circumstances, was particularly so in his sphere of influence, as there was scarcely any other member of administration in that house, competent to the task of relieving or supporting him. In a short time, proved that he stood in need of no assistance: he made himself so completely acquainted with every topic that was likely to be regularly discussed, that he was never taken unawares or at a loss. In the statement of his measures, he was remarkably methodical and perspicacious. By many persons he was deemed particularly to excel in his replies; in rebutting any fevere remark that came unexpectedly upon him, and in turning the fact adduced, or the argument used, against his opponent. "His speeches," says one of his biographers, "if carefully examined, will let us completely into the nature and extent of his talents: they display no large and comprehensive views; the arguments that illustrate those that they contain do not proceed from any philosophical and luminous principles: but they are distinguished by their detail, by taking up a detached argument, and groundning it on the particular circumstances of the cafe, rather than upon any general maxim. This species of public speaking, however, was well adapted to his audience, for in a mixed and numerous assembly, such as the house of commons, there will always be found many more persons who can comprehend particular arguments, than general reasoning, and who will deem the special pleader a man of much greater abilities, than a comprehenfive and philosophical statesman." In domestic life, few men were more amiable and more respected than Mr. Perceval, and few men, even in the private walks of society, can pass the greater portion of time with their family, than did this prime minister of England. Gent. Mag. Month Mag. New Ann. Register for the year 1812.

PERCH, Pole, or Rod, a long measure, much used in surveying and measuring of land.

Among the old Romans, and still among geomancers, the perica, perch, is ten feet; and they otherwise call it the catena, fanus, and decempa.

In England, the statute perch contains five yards and a half, or sixteen feet and a half; and for coppice-woods, &c., eighteen feet. A square perch is thirty square yards and a quarter. Forty square perches make a rood, and one hundred and fifty an acre.

The outmost furch is various in various counties: in Staffordshire it is twenty-four feet; in the forest of Sherwood twenty-one, the foot there being eighteen inches, the measure of which is marked in the chancel wall of Edwynd-flo\n, and in the church of St. Mary in Nottingham.

In Herefordshire, a perch of walking is sixteen feet and a half; a perch of ditching twenty-one feet, &c. In France, according to the old systém, the perch is from eighteen to twenty-three, and even twenty-seven, of their feet.

The arpent, or acre, of land contains, in general, 100 square perches, but the perch varies in different parts of the country. The arpent of wood-land, however, is the same all over France, the perch being 22 feet long; this arpent, therefore, contains 46,400 French square feet = 6108 square yards, 100 square yards, 1 rood, 1 perch. The arpent for cultivated land, in the neighbourhood of Paris, contains 900 square toises, or 4088 English yards; hence, 45 such arpents equal 38 English acres nearly. See Measure.

Perch, or Pole, of a wheel carriage, is fastened to the middle of the hind axle-tree, and paffes between the fore axle-tree and its bolster, being secured by the pole-pin, so as to move about it, and connecting the fore and hind carriages together. Thus A B (Plate XXIII. Miscellany, fig. 7.) represents the perch paffing under the body of a coach, and fastened to the hinder axle at C. D E represents the fore axle, and W, W, the fections of the wheels. It is plain, that in turning a carriage of this construction, the larger the wheel, the sooner it will strike against the perch; and in the cafe represented in the figure, the wheel strikes against the perch when the axle makes the angle described by the dotted lines D, D. On this account, the fore wheels are usually made smaller than the hind ones; and notwithstanding this diminution of size, the turning of such carriages is attended with great inconvenience. In order to remedy this, many expedients have been adopted, particularly in coaches, chariots, and other light vehicles, to which the crane-necked perch could be conveniently applied.
plied. But as this could not be adapted to the heavier kinds of carriages, and is, besides, attended with a very considerable expense, Mr. Jacob has contrived a more simple and less expensive method of attaining the proposed end. For this purpose, instead of fixing the pin, passing through the perch at F, in the centre of the axle, he brings a projection backwards from it, as in fig. 8, and makes the axle with the wheels turn round the pin passing through that projection at P; in which case the angle, which the wheel makes with the perch, becomes considerably less, before the wheel strikes against it. So that the conftruction, in a carriage of this conftitution, will not touch the perch fo foon as a smaller wheel in a carriage of the ordinary conftitution; and whatever be the size of the wheels, the carriage will turn shorter than if it were conftrueted in the former method, with the centre-pin in the centre of the axle. This conftitution is attended with no additional expence, is applicable to all kinds of carriages, and is stronger than the usual mode of conftitution. Jacob's Obf. on the Structure and Draught of Wheel Carriages, 4to. 1773, p. 79.

PERCHANT, among Fowlers, a decoy-bird, which the Fowler has fattened by the foot, and which flutters about the place where it is tied, to draw other birds to it, and give the owner the advantage of catching them. See BIRDS.

PERCHE, in Geography, a country of France, before the revolution, which had formerly courts of its own, and enjoyed its own laws, subjunct to the parliament of Paris. It at present forms the department of the Orne.

PERCIPANY, a town, or rather village, of America, in Morris county, New Jersey, on a branch of Passaic river; six miles N. of Morristown.

PERCIVAL, in Ichthyology. See COTTUS Gobio.

PERCIVAL THOMAS, M.D., in Biography, an eminent physician, was born at Warrington, in September 1740. Having left both his parents in one day, he was placed at the age of four years under the protection of his uncle, Dr. Thomas Percival, a learned and respectable physician, resident at the same place; but of his parental guidance he was also deprived at the age of ten, after which his education was directed with the most kind and judicious attention by his eldest sister. His literary pursuits commenced at a private school in the neighbourhood of Warrington, whence he was removed, at the age of eleven, to the free grammar-school of that town, where he exhibited great promise of talent, and much industry. On the institution of the Warrington academy in 1757, under the direction of the Rev. Dr. Aitkin, the Rev. John Holt, and the venerable Dr. Taylor, he was enrolled the first student of that well-famed seminary. After prosecuting his studies there with diligence and reputation for the space of upwards of three years, he removed to the university of Edinburgh, at which place he employed the winters of 1761, and the two following years, in close application to the study of phylisc. In farther pursuit of medical improvement, he visited London in the winter of 1764; and, during his residence in the metropolis, he had the opportunity of pursing with greater intimacy a connection, which had subsisted some time, with Hugh lord Willoughby of Parham. Having, through the medium of their common friend, the Rev. John Seddon of Warrington, been honoured with the friendship of that excellent and accomplished nobleman, he became the constant companion of his walks, and the familiar partaker of his social and literary entertainments. The warm attachment of his noble patron, the uncommon advantages he derived from his freedom of access to a mansion, which was the reft of the most celebrated literati of the day, and the occasions thereby offered of conciliating the esteem and confidence of persons of the first confluence and rank, all conspired to suggest to him the resolution of fixing his residence in the metropolis. This project, however, was relinquished on the sudden death of his highly valued friend; an event, which, to his last moments, he never recollected, but with the tenderest expressions of regret. During the course of this winter, he was elected a fellow of the Royal Society.

The following year, 1765, he spent in visiting Paris, Hamburgh, and various other places on the continent; and having graduated at Leyden, he returned to his native town, where he resided a few months; and in March 1766 he married the only daughter of Nathaniel Baillie, esq. a merchant in London. He now determined to make Manchester the theatre of his professional practice, and settled there in the year 1767, where he continued until his death, which happened in August 1804, in the unremiting exercise of his medical duties.

The character of Dr. Percival was in every way calculated to secure for him that eminence in his profession, and that general respect, esteem, and attachment, which he everywhere obtained. A quick penetration, a discriminating judgment, a patient attention, a comprehensive knowledge, and, above all, a solemn sense of responsibility, were the endowments which fitted him at once to discharge the duties, and to extend the boundaries, of the healing art; and his external accomplishments and manners were alike happily adapted to the offices of his profession. In social discourses, he possessed powers of a very uncommon stamp, combining the accuracy of science, and the strictest precision of method, with the graces of a copious and unctuous elocution; and to these was superadded the polish of a refined urbanity, the joint result of innate benevolence, and of early and habitual intercourse with the most improved clafhes of society. In few words, he was an author without vanity, a philosopher without pride, a scholar without pedantry, and a Critic without guile. Affable in his manners, courteous in his conversation, dignified in his deportment, cheerful in his temper, warm in his affections, steady in his friendships, mild in his refentments, and unshaken in his principles; the grand object of his life was usefulness, and the grand spring of all his actions was religion.

As a literary character, Dr. Percival held a distinguished rank. His earlier publications were devoted to medical, chemical, and philosophical inquiries, which he pursued extensively, combining the cautious but affidious employment of experiment, with scientific observation, and much literary research. His papers were published collectively, under the title of "Essays Medical and Experimental," of which the first volume appeared in 1771, the second in 1773, and a third was subsequsntly added. These volumes obtained for the author a considerable reputation in the philosophical world, and have gone through many editions. The subjects which occupied his pen, in later years, were of a nature most congenial to his feelings; and in the several volumes of "A Father's Instructions to his Children," and of "Moral Differtations," which appeared at different periods, through a space of twenty-five years, and which were originally conceived with the design of exciting in the hearts of his children a desire of knowledge and a love of virtue; there is to be found as much of pure fyle, genuine feeling, refined taste, apt illustration, and pious reflection, as can eafily be discovered, in the same compass, in any didactic composition. His last work, which he expressly dedicated as a "parental legacy" to a much-loved son, under the title of "Medical Ethics, or a Code of Institutes and Precepts, adapted to the professional conduct of Physicians and Surgeons," published in 1803, is a monument of his professional integrity.
integrity, in which, while he depicted those excellences of the medical character which he approved in theory, he unconsciously drew the portrait of himself, and described those which he every day exemplified in practice.

In addition to the works already mentioned, numerous papers on various subjects, all having the impress of the clearest understanding, and of the most peripatetic style, are to be found in the publications of the Literary and Philosophical Society of Manchester, an institution to the establishment and reputation of which, he eminently contributed, and which did not cease to manifest its grateful sense of his merits, by the continued appointment of him to the presidency, from the date of its incorporation. See Monthly Magazine, September 1804. Duncan's Annals of Medicine, vol. viii, and Percival's Essays.

PERCKAM, in Geography, a town of Audria; 18 miles S.W. of Freylund.

PERCOLATION. See Filtration.

Many have attempted the condensing of wines by percolation, or separating from them that superfluous moisture or water, which dilutes them below the true spirit of vinous liquors, in order to make them richer, and fitter for keeping; but it does not appear that such attempts have as yet succeeded.

PERCOTE, in Ancient Geography, a town which belonged to Dardania, at a small distance S.W. of Lampfus.

PERCUNOS, the name of an ancient Prussian idol. See Potrimos.

PERCUSSION, in Physics, the impression a body makes in falling or striking upon another; or the shock or collision of the two moving bodies; which meeting, alter each other's motion. See Motion.

Percussion is either direct or oblique.

In bodies either perfectly hard, or perfectly soft, and fo void of all elasticity, the laws of percussion are easily determined; but since even the hardest bodies have their share of elasticity, and in elastic bodies the laws are very different, and much more intricate, having been first ascertained in the Philosophical Transactions, by Sir Christopher Wren, Dr. Wallis, and Mr. Huygens, we shall lay down each apart; referring for another mode of illustrating the same subject to the article Collision.

Percussion: Laws of, in Bodies not Elastic. 1. If a body in motion, as A (Plate XXXIV. Mechanics, fig. 12.) strike directly against another at rest, B, the first will lose just as much of its motion as it communicates to the second; so that the two will proceed thence with an equal velocity, as if collected into one mass.

If A therefore be triple of B, A will lose one-fourth of its motion; so that if before it moved through a line of twenty-four feet in a minute, it will now only move eighteen.

2. If a moving body, A, strike against another already in motion, B; the first will increase the velocity of the latter, but will lose less of its own motion than if the latter had been at rest; since all here required is, that some degrees of motion be added to the latter already had, to make them both proceed with an equal velocity.

Suppose, e.g., the body A, with twelve degrees of motion, to strike against the other B, left by half, and at rest, the first will transfer four degrees of its motion to the latter, and retain eight to itself; but if it strike with twelve degrees of motion on the other already moving with three degrees, it will only communicate two degrees; for A being double of B, this needs only half the motion to make it proceed with the same velocity.

3. If a moving body, A, strike on another, B, either at rest, or moving more slowly, and either in the same direction or in a contrary one; the sum of the moments, if the bodies move in the same direction, or their difference, if they move in a contrary one, will be the same after the percussion as before.

4. If two equal bodies, A and B, meet each other with equal velocities; after the congruence, they will both remain at rest.

5. If a body, A, strike directly on another at rest, B; its celerity after the stroke is to its celerity before it, as the weight of A is to the sum of the weights of A and B: if therefore, the weights were equal, the celerity after the shock will be half of what it was before it.

Thus if A = Q, and its velocity before the stroke be denominated C, and B = q, then Q C would express the whole quantity of motion before and after the stroke, and \( \frac{Q C}{Q + q} \) or, the quantity of motion divided by the weights or quantities of matter, will be equal to V, the common velocity: hence we shall have \( Q C = V \times Q + q \); and, therefore, \( C : V :: Q + q : Q \). If \( Q = q \), it will be \( C : V :: 2 \).

6. If a body in motion, A, strike directly on another moving more slowly, but in the same direction; the velocity, after the shock, will be equal to the sum of the momenta, divided by the sum of the weights.

For the sum of the momenta both before and after the stroke is \( Q C + q \); e= being the velocity of q or B; therefore \( V = \frac{Q C + q}{Q + q} \). Hence if \( Q = q \), \( V = \frac{Q \times C + q}{Q + q} \).

\[ \frac{C + \epsilon}{2} \], or half the sum of the former velocities.

7. If two equal bodies, moving with different velocities, strike directly against each other; after the conflict, they will proceed with the semi-difference of the velocities with which they were moved before it.

For the quantity of motion is \( Q C - q \); and, therefore,

\[ V = \frac{Q C - q}{Q + q} \]; and if \( Q = q \), \( V = \frac{Q C - q}{Q + q} = \frac{C - \epsilon}{2} \).

And if \( C = \epsilon \), \( V = \epsilon \), and, therefore, the quantity of motion is not always the same, as the Cartesian maintain.

8. If two bodies, A and B, meet directly with velocities that are reciprocally as their weights; after the conflict, they will both remain at rest: i.e. if \( Q : q :: \epsilon : C \), \( Q C = q \epsilon \), and \( V = \frac{Q C - q \epsilon}{Q + q} \).

9. If two bodies, A and B, meet directly with the same velocity; the celerity, after the impulsion, will be that before it, as the difference of the weights to their sum.

For \( Q C - q \epsilon = V \times Q + q \); therefore, \( V = \frac{Q C - q \epsilon}{Q + q} \).

10. If two bodies meet directly, with any velocity whatever; the celerity after the stroke will be equal to the difference of the momenta, divided by the sum of the weights.

For \( V = \frac{Q C - q \epsilon}{Q + q} \).

To determine the momentum left by the conflict: multiply the celerity which the body had before the conflict, into its mass; thus you have the momentum before the conflict. In like manner, multiply the celerity after the conflict into the mass; thus you have the momentum after the conflict. The latter momentum, therefore, being subtracted from the former,
Thus in the three cases already recited, the momentum before the collision is \( QC, QC + q, \) and \( QC - q \); and

\[
\frac{QC}{Q + q}, \quad \frac{QC + q}{Q + q}, \quad \frac{QC - q}{Q + q}
\]

the quantities of motion lost by \( Q \) will be respectively

\[
\frac{QC - q}{Q + q}, \quad \frac{QC + q}{Q + q}, \quad \frac{QC - q}{Q + q}
\]

therefore the moments of the stroke lost by \( Q \) will be respectively

\[
\frac{QC - q}{Q + q}, \quad \frac{QC + q}{Q + q}, \quad \frac{QC - q}{Q + q}
\]

Hence it appears, in the first case, that the magnitude of the stroke, which is as the motion lost, will be as the velocity of the striking body ; for if its velocity were \( C \), the motion lost would be \( \frac{QC}{Q + q} \); but if it were \( v \), the motion lost would be \( \frac{QCV}{Q + q} \); and \( QC \cdot \frac{QCV}{Q + q} = \frac{QC - q}{Q + q} \).

In the second case, the magnitude of the stroke will be the same as if \( v \) had been at rest, and \( Q \) had struck it with the difference of their velocities; for the motion lost is \( \frac{QC}{Q + q} \); but in the case now supposed, the motion lost would be \( \frac{QCV}{Q + q} \); and \( QC \cdot \frac{QCV}{Q + q} = \frac{QC - q}{Q + q} \).

In the third case, the magnitude of the stroke will be the same as if \( v \) had been at rest, and the other, as \( Q \), had struck it with the sum of their velocities: for the motion lost is \( \frac{QC + q}{Q + q} \); and in the case now supposed it would be \( \frac{QCV + q}{Q + q} \) equal to the former. Hence it appears, that the magnitude of the stroke between two given bodies is always proportional to their relative, and not to their absolute velocities.

11. A direct or perpendicular stroke is to an oblique one as the whole line is to the sine of the angle of incidence. For let \( BC \) (fig. 13.) be the body struck, \( A \) the striking body, \( AC \) the oblique stroke, \( aC \) the perpendicular stroke, and the magnitude of the perpendicular stroke \( aC \) will be to that of the oblique stroke in the direction \( AC \) as \( aC \) to \( AB \), or as \( AC : AB \). For resolving the force in \( AC \) into \( AB \) and \( BC \) as \( AC \) and \( AB \), and it is evident that the force in the direction \( AB \) is the only part of \( AC \) that strikes \( BC \), the other part being parallel to it; and the magnitude of a perpendicular stroke of the same body moving with the same force is to be measured by the line \( aC = AC \); and therefore it is to the magnitude of the oblique stroke as \( aC \) to \( AB \), i.e. as \( AC \) to \( AB \), or as radius to sine of the angle of incidence.

Percussion, Law of, in Elastic Bodies. In bodies perfectly elastic, the force of elasticity is equal to the force with which they are compressed; that is, the collision of two such bodies on each other is equivalent to the motion which either of them would acquire, or lose, by mere simple impulse. This force exerting itself contrary ways, a motion equivalent to it must be subtracted from the motion in the impelling body, and added to that in the body impelled by mere impulse, to find their velocities after percussion. See Elasticity.

12. If a body strike directly on an immoveable obstacle, either one or both of them being elastic, the body will be reflected with the same velocity with which it struck, and in the same line. For if the elasticity were away, the whole force of the striking body would be spent in overcoming the resistance of the obstacle; and consequently all the motion would cease; it follows, that the whole force is employed in compressing the elastic body; by which means it acquires an elastic force equal thereto; once the elasticity, when the comppring force is spent, reduces the body into its former state, it repels the other with the same force with which it struck; consequently, it will rebound with the same velocity. And because an elastic body restores itself in the same direction in which it was compressed (there being no reason why it should change its direction) the body will rebound in the same right time.

13. If an elastic body strike obliquely on an immoveable obstacle, it will rebound in such manner as to make the angle of reflection equal to the angle of incidence. See this demonstrated with regard to light; by a method which applies to all impinging elastic bodies, under Reflection.

14. If an elastic body, \( A \), strike directly against another at rest, \( B \), equal to it; after percussion \( A \) will remain at rest, and \( B \) will proceed with the same velocity which \( A \) had before the shock, and in the same direction.

For if the bodies were not elastic, each would proceed, after the stroke, in the same direction, and with half the velocity; but since the elastic force acts in the same direction in which the compression is made, and is equal to the compressing force; it repels \( A \) with half its velocity, and therefore stops its motion; but it drives \( B \) farther with half its velocity, and therefore accelerates its motion. It is therefore carried after the shock, with the whole velocity with which \( A \) was carried before it, and \( A \) remains at rest.

The quantity of motion before the stroke is \( QC \), and the motion lost by percussion, being the double of that lost between non-elastic bodies, is \( \frac{2QC}{Q + q} \); therefore the momentum after the stroke will be \( Q + \frac{2C}{Q + q} = \frac{QC}{Q + q} \); and \( V = \frac{QC - CQ}{Q + q} \); and the velocity of \( q \), whole motion is equal to that lost by \( Q \), is equal to \( \frac{2QC}{Q + q} \); and \( V = \frac{QC - CQ}{Q + q} \). If \( Q = q \), \( V = \frac{QC - CQ}{Q + q} = 0 \); and \( v = C \).

Hence, since \( A \) (fig. 14.) transfers all its force to \( B \); \( B \), in like manner, will transfer it to \( C \), and again to \( D \), and \( D \) to \( E \). Wherefore, if there be several equal elastic bodies, mutually touching each other, and \( A \) be struck against \( B \), all the intermediate ones remaining at rest, the last alone, \( E \), will be moved, and that with the velocity with which \( A \) struck against \( B \).

15. If an elastic body, \( A \), strike directly on another at rest, \( B \); its velocity, after percussion, will be to its velocity before it, as the difference of weights is to their sum; but the velocity it communicates to \( B \), is to the same, as double the weight of \( A \) to the sum of the weights.

After percussion, therefore, the velocity of \( A \) is to the velocity
velocity of \( B \), as the difference of weights to the double of \( A \).

Thus, \( V = \frac{Q C - C q}{Q + q} = \frac{Q - q \times C}{Q + q} \); therefore, \( V \times Q + q \)

\[= \frac{Q - q \times C}{Q + q} \times C \text{; consequently, } V : C =: Q - q : Q + q. \]

And because \( v = \frac{2 Q C}{Q + q} \), \( v : C =: 2 Q : Q + g \). Consequently

\[V : v =: Q - g : 2 Q.\]

16. If a greater body strike a less body at rest, the velocity given to it will be less than the double of its own velocity.

For \( Q > g \), let \( Q = m q \), then \( v = \frac{2 Q C}{Q + q} \) will be
equal to \( \frac{2 m q C}{m q + q} = \frac{2 C}{1 + \frac{1}{m}} \).

17. The velocity which a greater body gives to a less body at rest, is to that which the less body moved with the same velocity that would communicate to the greater body at rest, as the magnitude of the greater to the magnitude of the less body. If \( Q > g \) is supposed to be at rest, then

\[v = \frac{2 Q C}{Q + q}, \text{ but if } Q \text{ be at rest, and } q \text{ strike it with the velocity } C, \text{ the velocity of } Q \text{ after the stroke would be } \frac{2 q C}{Q + q}; \text{ therefore the velocity given by the greater body is to that given by the less as } \frac{2 Q C}{Q + q} : \frac{2 q C}{Q + q} =: Q : q.\]

18. If a greater body strikes against a less, the greater body will not come to rest, but move more slowly: for since \( Q > g \), \( Q - g \) will be positive, and therefore, in the proportion \( Q + q : Q - g =: Q - g : C, V \) will be positive but less than \( C \), because \( Q - g < Q + g \).

19. Again, if an elastic body strike a larger elastic body at rest, the smaller body will always rebound, and move in a contrary direction to what it did at first, and also give the larger body a greater quantity of motion than what was originally in the smaller body. For as \( g > Q \), \( Q - g \) will be a negative quantity, and, therefore, \( V \) will be negative, or \( Q \) will move backwards. And this quantity of motion communicated, may be greater than the original motion in any ratio less than that of \( x \) to \( 1 \). For supposing the small body and its velocity to be denoted by unity, and the larger body at rest by \( x \), the velocity of \( x \) after the shock will be \( \frac{x}{1 + x} \), and its quantity of motion will be \( \frac{2 x}{1 + x} \). But though the proportion of \( 2 x \) to \( 1 + x \) increases when \( x \) increases, yet its limit will be the proportion of \( 2 \) to \( 1 \); which is the limit to which the motion of \( x \) may approach indefinitely near.

Hence it follows, that if the force of moving bodies be measured by their quantity of motion, a body may, by percussion, immediately communicate a greater force than itself has to another, and this in any proportion less than double.

But if other elastic bodies be interposed, a body may mediate communicate a greater force than its own to another larger body \( x \), in any proportion less than that of \( x : x \) to \( 1 \). Thus, if \( x = 1000000 \), the body \( 1 \), with the velocity \( 1 \), may, by the means of intermediate bodies, give it the force \( 9999999 \); and the sum of the absolute forces of all these bodies taken together, arising from the percussion, may exceed the force of the first or unity, in any ratio less than \( 2 \times \sqrt{x} / x \) to \( 1 \), or \( 200000000 \) to \( 1 \), although the relative force in all cases remains as at first \( = 1 \).

These are paradoxes which cannot be urged against those who maintain the forces of bodies to be measured by their masses and the squares of their velocities.

It is also to be observed, that those who measure force by the quantity of motion, will deny that there is any force felt by the impressions, made on soft bodies, or by the bending of elastic bodies; for if any were felt from such causes, the sum of the quantities of motion of bodies moving the same way, could not remain the same before, during, and after the shock, which is an universal rule admitted by the Newtonians. But they admit that a spring bent between two bodies may, by unbounding itself, generate motion in these bodies. Hence it follows that, according to this doctrine, though a spring may give motion to bodies, it cannot, by a contrary action, take it away; which seems no small paradox. See Force.

20. If a body, \( A \), moves towards the body \( C \), at rest, and an intermediate body, \( B \), of a mean magnitude, be placed at rest between them, so that \( A \) first impels \( B \), and then \( B \) impels \( C \), a greater motion will be given to \( C \) than if \( A \) had struck it directly. And if \( B \) be a mean proportional between \( A \) and \( C \), the velocity communicated to \( C \) will be the greatest that can be. Huygens, de Mot. Corp. ex Percus. prop. 12.

In the preceding series of proportional magnitudes, \( B + \frac{AC}{B} < A + C \). For \( A : B :: B : C \), therefore \( A - B :: B - C :: B - C :: B :: C \); but \( C \), \( B < B - C < A - B \); and therefore \( B < A - B + C \), and \( 2 B < A + C \); but \( B = \frac{AC}{B} \); therefore \( B + \frac{AC}{B} < A + C \). The same proposition might be demonstrated, if \( C \) were the greatest body, and \( A \) the least.

Now it is plain, that the velocity of the body \( C \), struck only by \( A \), would be \( \frac{2 A a}{A + C} = \frac{2 A a}{2 A + 2 C} \), in which the velocity of \( A \) : the velocity of \( B \), struck immediately by \( A \), would be \( \frac{2 A a}{A + B} = b \); in which the velocity of \( B \) : and, therefore, the velocity of \( C \), struck by \( B \), moved with the velocity \( b \), would be \( \frac{2 B b}{B + C} = \frac{2 B \times 2 A a}{B + C \times A + B} \).

\[\frac{4 B A a}{C + A + B} = \frac{4 A a}{A + B + C} = \frac{4 A a}{A + B + C} \]

\[\frac{4 A a}{A + B + C} = \frac{4 A a}{2 A + 2 C} = \frac{4 A a}{2 A + 2 C} \]

But \( A + B + C \), and \( A + B + C \), and \( A + B + C \). And the second antecedent is evidently greater than the second consequent; therefore the first antecedent is greater than the first consequent. But if \( B \) were
a mean proportional between A and C, \( B + \frac{AC}{B} \) would be
less than in any other case. For if \( B = m \) the mean proportional,
\( B + \frac{AC}{B} = m + \frac{m'}{m} = 2m \); but if \( B = m + D \),
then \( B + \frac{AC}{B} = m + D + \frac{m'}{m + D} \); i.e., \( m' + 2mD \)
\( + D^2 + \frac{AC}{B} = 2m^2 + 2mD \).

If more bodies be interposed between A and C, the motion
of C will be greater; and it will be the greatest when
the bodies interposed constitute a series of mean proportionals
between A and C. Ibid. prop. 13.

21. If there be a series of a hundred bodies in the proportion
of 1, 2, 4, 8, 16, &c. and the motion begins by
the greatest body, the velocity communicated to the smallest
will be to that with which the greatest moved nearly as
2,338,500,000,000 to 1. And, if the motion begins by
the least body, the quantity of motion will be increased on
the whole nearly as 1 to 4,077,000,000,000. But it is to
be observed, that there is a mistake in the impreffion of
Huygens's Book, which is there printed 1,476,000,000,000, instead of 2,338, &c., fo that the
velocity thus given to the smallest body is 150 times greater
than what the printed copy of Huygens affigns. Bernoulli,
Difc. fur le Mouv. Oper. tom iii. p. 34. and s'Gravefande,

This stupendous augmentation of the quantity of motion
is a remarkable instance of the falsity of the Cartesian
principle, that the fame quantity of motion is always preferred
in the world.

Some have thought this augmentation no small difficulty
against those who maintain the moving force or power of
action in bodies, to be proportional to their quantities of
motion. This difficulty does not preclude the Leibnizians; for
it is to be observed, that notwithstanding the prodigious
increase of motion here assigned, yet there is no increment of
the viv a viva of this fylem of bodies. See Forfe and VIS
Viva.

A learned author has urged, that if the force of bodies
were in proportion to their quantities of motion, the increafe
in the motion here mentioned might be employed to restore
the motion of the firft body, and hence make a perpetual
motion. But it is anfwered, that as the motion of the laft
is increafed in the fame direction with the firft, the motion
of all the reft will be in the contrary direction, and equal to
that of the laft diminished by unity: hence the fum of
the motions in the fame direction remains as it did, equal to
that of the firft and laft body, which we fuppofe unity.
See Maclaurin's Demontrat. de Loix du Choc des Corps,
p. 21, Paris, 1724; and s'Gravefande, Rem. fur la Possibilite
du Mouvement perpetuel, in Journ. Liter.

It is to be obferved, that there is a limit which the
velocity communicated to the laft body never amounts to, (fuppofing the firft and laft bodies, and the velocity of the firft
before the stroke, to be given,) but to which it approaches
continually, while the number of fuch bodies interpofted be-
tween the firft and laft is always increafed. And this limit is
to the velocity of the firft body before the stroke, in the
subduplicate ratio of the firft body to the laft.

Mr. Huygens has not mentioned this limit, but the
curious may fee the determination of it in Mr. Maclaurin's
Fluxions, art. 514.

22. If two equal elastic bodies, A and B, meet di-
rectly, and with equal force; each will rebound with the
fame velocity with which it struck, and also in the fame
direction.

For fetting aside the elafiity, both would remain at reft:
their whole force, therefore, is spent in the compreflion;
but their elafiic force, whereby they rebound in the former
direction, is equal thereto. This force, therefore, acting
equally on each body, A and B, will produce the fame
celerity in each; and that equal to the former. So that
they will rebound with the celerity with which they
strike.

23. If two equal elastic bodies, A and B, strike directly
against each other with unequal velocities; after the stroke,
they will rebound with interchanged velocities.

For suppose the bodies to concur with the velocities
\( A + c \) and \( C \); if they meet with the fame velocity \( C \),
after the stroke, they would both move with the fame
velocity \( C \).

If \( B \) were at reft, and \( A \) should strike upon it with the
celerity \( c \); after the stroke, \( A \) would remain at reft, and \( B 
\)
be moved with the celerity \( c \). Therefore the excess of the
celerity \( c \), with which \( A \) is carried, is transferred wholly by
the conflict to \( B \); \( A \), therefore, is moved with the
celerity \( C \) and \( B \) to the celerity \( C + c \).

Hence, after percussion, they recede from each other with
the fame velocity as before they concurred.

The two propositions in these two laft articles may be
proved otherwise, thus: the momentum of \( Q \) before the
stroke is \( QC \); the motion loft by it is \( \frac{2QCq}{Q+q} + 2Qe^c \),
therefore, its quantity of motion after the stroke will
be \( QC - \frac{2QCq}{Q+q} + 2Qe^c = \frac{QC - QC - 2QCq}{Q+q} \),
Confequently \( V = \frac{QC - QC - 2QCq}{Q+q} \).

The quantity of motion in \( Q \) before the stroke is \(-q\),
and that loft by \( Q \) and acquired by \( q \) is \( \frac{2QCq}{Q+q} + 2Qe^c \),
and, therefore, its momentum after the stroke will be \(-q\)
\( + \frac{2QCq}{Q+q} = \frac{2QCq - q^c + Qe^c}{Q+q} \); and
\( v = \frac{2QCq - q^c + Qe^c}{Q+q} \). But when \( Q = q \), \( V = \frac{QC - QC - 2QCq}{2Q} \)
\( = C \).

24. If two elafiic bodies, A and B, strike directly on
each other with velocities that are reciprocally proportional
to their weights; after collision, they will rebound with the
fame velocity with which they met.

For \( Q : q :: c : C \), therefore \( CQ = eq \); and \( V = \frac{QC - 2QC - Cq}{Q+q} = \frac{QC - Cq = Q+q}{Q+q} \)
\( = C \); and \( v = \frac{2QCq - q^c + Qe^c}{Q+q} = \frac{q^c + Qe^c}{Q+q} \).

25. If an elafiic body, \( A \), strike on another equal one
induced with a lefs degree of motion \( B \); after percussion,
both will proceed in the fame, viz., in the former direction,
and with interchanged velocities.

For suppose \( A \) to strike with the velocity \( C + e \), upon
\( B \) moving with the velocity \( C \). Since by reafon of the
equal
equal velocities $C$ and $C$, there arises no impulse: it is the same thing as if $A$ struck on $B$, with the sole velocity $c$, on $B$ at rest. But in that case $A$ would remain at rest, and $B$ would move with the velocity $c$: therefore, after percussion, $A$ will move with the sole velocity $C$, and $B$ with the velocity $C + c$, both according to the former direction, there being nothing to change that direction.

For in this case, the quantity of motion in $Q$ before the stroke is $Q C$, the motion lost by it is $\frac{2 Q C Q - 2 Q C}{Q + q}$, and the quantity of motion after the stroke will be $Q C - \frac{2 Q C Q - 2 Q C}{Q + q}$, and therefore $V = \frac{Q C + 2 C C - Q C}{Q + q}$.

The momentum of $q$ before the stroke is $q$, that lost by $Q$ and acquired by $q$ is $\frac{2 Q C Q - 2 Q C}{Q + q}$; therefore the momentum of $q$ after the stroke will be $q + \frac{2 Q C Q - 2 Q C}{Q + q}$, and $v = \frac{Q C + 2 C C - Q C}{Q + q}$.

In the case here supposed $Q = q$, therefore $V = Q C + 2 Q C = C$, and $v = \frac{2 Q C + Q C - C C}{Q + q}$.

26. If a moving body, $A$, strike on another, $B$; the stroke will be the same as would be made by the body $A$ striking on $B$ at rest, with the difference of their velocities.

Hence, since the elastic force is equal to the percussion; it acts on the bodies $A$ and $B$ with the difference of the velocities they had before the congrs.

27. To determine the velocities of any two elastic bodies, $A$ and $B$, after striking directly on each other with any velocities.

If the elastic body $A$ strike on $B$, either at rest, or moving faster than $A$; the velocity, $v$, gr. of $A$ after percussion is found thus: if the sum of the weights is too double of either of them, supposing, in this case, of $B$, $f$ is the difference of the velocities before the congrs, to a velocity, which subtracted from the velocity of $A$ before the impulse (the other case added to it) leaves the velocity of $A$ after the congrs.

If the two elastic bodies, $A$ and $B$, meet each other; the velocity of $A$, after the impulse, is found thus: as the sum of the weights is to the double of either of them, supposing of $B$, fo is the sum of the velocities before collision, to a velocity which, subtracted from the velocity of $A$ before collision, leaves its celerity after collision.

28. In the direct collision of bodies the same respective velocity is preferred, i.e. in a direct concurrence, the difference of velocities is the same before and after the shock; and in a direct mutual encounter, the difference of velocities after the shock is the same with their sum before it.

Hence they retire from each other, after the impulse, with the same velocity with which they met.

Thus $v - V = C + c$, For $v = \frac{2 Q C + q + Q C}{Q + q}$, and $V = \frac{Q C + 2 q - C C}{Q + q}$; therefore $v - V = 3 Q C + g Q - Q C + 2 Q C + C C = 2 Q C + q C + Q C + C C = Q C + q C + Q C + C C = \frac{Q + q}{Q + q}$.

29. In the collision of elastic bodies there is not always preferred the same momentum, or, as the Cartesians express it, the same quantity of motion; and this is sometimes increased, and sometimes diminished.

It is a mistake, therefore, of Deferraries, and his followers, that the same quantity of motion is still preferred in the world.

Thus, let $q$ at rest be greater than the impinging body $Q$; and the quantity of motion will be increased by collision: let $q \equiv Q + x$, and $C$ the velocity of $Q$: the velocity of the body $q$ after the stroke will be $2 Q C = 2 Q + x$; but the velocity of the body $Q$ will be $Q C + \frac{x C}{2 Q + x}$; therefore the absolute momentum of $q$ after the stroke will be $\frac{x C}{2 Q + x}$.

But the momentum of the body $Q$ is $Q \times -\frac{x C}{2 Q + x}$; and the quantity of motion in both bodies will be $2 Q C + 2 Q \times x + Q \times x C = 2 Q C + 3 Q \times x C = 2 Q + x$.

And $\frac{Q + q \times x C}{Q + q} = 2 Q + x$; but the quantity of motion before the stroke was $Q C$, which is less than the former quantity, because $\frac{x C}{2 Q + x} < x C$; for $\frac{x C}{2 Q + x} = x C$. If the bodies return to a second stroke with the velocities acquired by the first, they will recover their first velocities, in which case the quantity of motion will be diminished.

30. If two elastic bodies, $A$ and $B$, meet or overtake each other directly; the sum of the elements into the squares of the velocities remains the same, before and after the congrs; hence the same quantity of force is likewise preferred in the congrs.

31. To determine the motion of two bodies, $A$ and $B$, (fig. 15.) striking obliquely against each other, whether they be elastic or not elastic. The motion of the body $A$ along $A C$ is resoluble into two others, in the directions $A E$ and $A D$; and the motion of $B$ along $B C$ into two others according to $B F$ and $B G$: and the velocities through $A D$ and $B F$ are to the velocities through $A C$ and $B C$ as the right lines $A D$, $B F$, $A C$, $B C$: now since the right lines $A E$ and $B G$ are parallel, the forces acting according to these directions are not mutually opposite, and must therefore he confedered in the congrs.

But since the lines $A D$ and $B F$, or, which is the same, $E C$ and $G C$, constitute the same right line perpendicular to $D C$; it is the same as if the bodies $A$ and $B$ should meet directly with velocities that are as $E C$ and
and G C. Find, therefore, the velocity of A and B according to the rules above laid down.

Suppose, r. gr. the velocity of the rebundant body A to be as CH; since the motion along A E is not changed by the conres, make CK = AE, and complete the parallelogram HCK; the diagonal CI will represent the motion of A after the conres: for, after percusion, the body will move according to the direction C I, and with a velocity as C I. In the same manner it will be found, that the rebundant body B will move along the diagonal of the parallelogram C M; in which L M = B G. These velocities, therefore, after percusion, are as C I to C M.

PERCUSION, Centre of. See Center of Percussion.

PERCY, in Geography, a town of France, in the department of the Channel, and chief place of a canton, in the district of St. Lo; 12 miles S. of St. Lo. The place contains 2052, and the canton 9580 inhabitants, on a territory of 160 kilometres, in 13 communes.

Percy, an extensive township of America, in Grafton county, New Hampshire, watered by the several branches of Upper Amoskeag river, bounded W. by Northumberland, on Connecticut river; incorporated in 1774, and containing 148 inhabitants.

PERDICAS, in Biography, one of the captains of Alexander the Great, was a Macedonian of noble birth, and rose to high favour with his master, in whole conques he bore a considerable part. Alexander, in his lall iilnes, entrusted his ring to Perdiccas, who, at a meeting of the great officers after the death of the conqueror, refined the ring, together with any authority it might be supposed to convey. When Ariduces, the brother of Alexander, was appointed to the succession, Perdiccas gained a considerable ascendency over him, and procured the death of Meleager, the commander of the Macedonian phalanx, of whom he was jealous. At the division of honours and provinces among the great officers, he was nominated general of the household troops, and exercised the protectorate of the Macedonian princes, Ariduces, and the new-born son of Alexander by Roxana, though Craterus had the title of protector. In conjunction with Roxana, he removed all who could be competitors for the crown, and conducted the government with great cruelty. Ambitious of extending his power, he repudiated his wife Nicca, the daughter of Antipater, and married Cleopatra, the daughter of Philip, and sister of Alexander, at the proposal of Olympus, her mother. A league being formed against him, between Ptolemy, Antipater, and Craterus, he resolved to march into Egypt against the first, while Eumenes, who adhered to him as guardian of the royal family, should make head against the others. Perdiccas, on entering Egypt, found some symptoms of disaffection in his troops, which he was at first disposed to treat with severity, but finding that this method would not succeed, he changed his conduct, and behaved to them with great clemency, insomuch that they were induced to cross the Nile, and atack Ptolemy in his intrenchments. After a bloody action, they were repulsed, and great numbers of them were drowned in repelling the river. At length their discontents were so high, that they mutinied; and a party of horse, surrounding the tent of Perdiccas, murdered him in the year B.C. 321, two years after the death of Alexander. Univ. Hist.

PERDICUM, in Botany, appears to have been so called by Linnaeus, on account of a considerable resemblance between his original species, semiflosculare, and his Lantodon (now Hieracium) bulbosum. The latter was thought by some to be the πτεροκες of Theophratus, which received that appellation, as the Greek writer expressly mentions, because partridges frequented the plant and scratched its roots out of the ground. Various other tuberous-rooted herbs have indeed been taken for the ancient πτεροκες, but these are not to our present purpose. The roots of the Linnean Perdicum semiflosculare are copious, long and fluffy, and we cannot doubt that hence arose the scarcely warrantable assumption of an old Greek name, for a Cape and American genus, though that name had hitherto not been, with any certainty, appropriated. Linn. Gen. 428. Schreb. 559. Wildl. Sp. Pl. v. 3. 2116. Mart. Mill. Dict. v. 3. Vahl. in Copenh. Tran. v. 1. falc. 2. 8. Ait. Hort. Kew. ed. 2. v. 5. 84. Jull. 181. Lamarck Illust. t. 677. Garrr. in v. 2. 450. t. 170. (Trixxi; Browne Jam. 312?) — Claf and order, Synagelia Polygacta-superflua. Nat. Ord. Composite dicotul., Linn. Corydobyora, Jull. Gen. Ch. Common Calyx oblong, of many lanceolate imbricated leaves; the innermost scarcely longer than the corolla. Cor. compound, imbricated, radiated. Flowers of the dftk perfect, tubular, cloven half way down; their inner lhp deeply divided, sharp-pointed, equal; outer three- left half way down, linear, equal; those of the radius female, linear, tongue-shaped, three-toothed, with two teeth at the base on the inner side. Stam. in the perfect florets, filaments five, short; anthers forming a cylindrical tube, with five teeth. Pfil. in the same, germinate small; file simple; Agama cloven, obtuse: in the female ones, germin female; file cloven half way down; Agama obtuse. Petr. more, except the unchaged calyx. Seeds solitary, obovate. Dowm capillary, fiddle, rough, very abundant, the length of the calyx, level-topped. Recept. naked.

Obs. The flower resembles a ferraliusculus one, though it is truly radiated. The characters were taken from the first species, P. semiflosculare; the radiata, though agreeing in the character of the two-lipped florets, differs entirely in habit. Linn. Vahl considers the florets as all uniform, and therefore places this genus in the order Polygacta equalis.

1. P. semiflosculare. Linn. Sp. Pl. 1248. Amoen. Acad. v. 6. P. Thumb. Prodr. 160. (P. Taraxici; Vahl. n. t. t. 1. Wildl. n. 1.) — Stalks radical, fiddle-flowered. Leaves runcinate, smooth, with rounded lobes — Native of the Cape of Good Hope, in muddy places. The root is perennial, long and tuberous, with numerous, long, cylindrical, thick, fleshy fibres, running deep into the ground, totally misrepresented in Vahl's plate. Stem none. Leaves numerous, radical, spreading, stalked, three or four inches long, runcinate, obtuse, smooth; their numerous lobes short, broad, rounded, slightly toothed. Flowers linear, their permanent ribereus remaining crowning the root, and surrounding the present leaves. Flower flokkes one or two, ascending, simple, round, wolly, rather longer than the leaves, each usually bearing one linear bract, towards the top. Flower somewhat drooping, large. Calyx like a Scorzonera. Seed down very copious and dense, shining, rather tawny, an inch long. This plant has indeed much of the aspect of a Dandelion, but we cannot submit to the change of a good Linnean name, expressive of the habit of the flower, for a new one of a very faulty construction.

May. Smaller and more downy than the former, with lyrate leaves, whose terminal lobe is heart-shaped and wavy, with flight teeth. Flowers much smaller, with a purple radius and yellow disk.

—Native of Siberia, in mountainous fields. Cultivated by Miller in 1759. It flowers in March and is perennial, but has nothing to recommend it as a garden plant, except botanical singularity. The root, according to Gmelin, confits of many fleshy spreading fibres, like that of Asphodel. Leaves radical, stalked, lyrate, minutely toothed; when young cottony beneath, but becoming naked and smooth, on both sides, when fully grown; their terminal lobe larger, more ovate, and acute, than in the lal. Flower-stalk a foot high, much taller than the leaves, cottony, with several awl-shaped bracteas. Flower nearly globose; its calyx downy, closed, rising much above the florets, which appear to have the proper characters of Perdicium, as was first pointed out by Mr. Brown. The whole habit of the plant, compared with the two preceding species, confirms his determination of the genus.

4. P. popopifolium. (Tuliflago icaco imbricato, unifloro, foliis ovatis, oblongis, ex linneo dentatis; Gmel. Sib. v. 2. 141. t. 67. f. 1.)—Stalk radical, single-flowered, with several fleshy bracteas. Leaves ovate, wavy, toothed; densely woolly beneath. Root creeping.—Native of Siberia, in flomy places. We cannot but think this must be a distinct species from the lal. The root creeps among fions, and is not thicker than a crow's quill. Leaves simple, (not lyrate,) wavy or coarsely toothed; cottony beneath at all times; clothed with deciduous down on the upper side when young, but afterwards smooth and shining, of a dark purplish hue. Flower-stalk invested with three or four broad, fheathing, finally smooth bracteas. Flowers white. Calyx chiefly downy at the base, scarcely more than half the length of the spreading radicis, which is white.

With respect to Gmelin's Tuliflago n. 124. t. 67. f. 2, it differs from this in having somewhat lyrate leaves, for his cottony beneath, and a very long linear bracteas. This appears to be what Linnaeus has figured in Hort. Upsl. t. 2. under the name of Bellidigra. He speaks of it as a variety of Anandra, with elongated radiant florets, caused by being planted in a pot, or an open dry situation. Gmelin seems not to have been satisfied with this decision, and advised the cultivation of both plants, from seed. We are also well aware of the fallibility of cultivators, and think it not impossible, that Linnaeus might have received the roots of both the plants in question, without distinguishing them, and thus have been led to consider the subfrequent difference in their produce as accidental. We will not however presume to decide this question, any further than that we have no doubt of the permanent difference between our P. popopifolium and Gmelin's t. 67. f. 2; which, if not distinct, must be a variety of Anandra, with which its bracteas and habit most nearly agree. Gmelin's original specimens are all before us in the Linnaean herbarium. In the moment of writing this article, the fourth and fifth volumes of the Hortus Kewensis have reached us, and have led to the above investigation. This valuable publication being now complete, we need not in future note the edition to which we refer, except when we may occasionally want to cite the first.

—Gathered by Commerfon in the latins of Magellan. The root is perennial, with long slender fibres. Stems several, ascending three or four inches high, simple or rarely divided, loosely woolly, bearing ulually one pinnatifid leaf near the base, and several alternate, linear, undivided ones higher up. Leaves mostly radical, thickf, clothed with fine, long, lax, deciduous wool, deeply pinnatifid; their segments ovate or wedge-shaped, deeply and irregularly cut; their margins generally entire and smooth, but now and then minutely pinnate. Flowers terminal, solitary, about an inch wide. Radiant florets ovate, entire, revolute, purple. Down more feathery than in the rest. Our specimen was given by Thomson to the younger Linnaeus.

6. P. magellanicum. Linn. Suppl. 376. Wild. n. 4.—Vahl n. 4. t. 4.—Stems simple, single-flowered, liliput, nearly leafless. Leaves pinnatifid; their segments rounded, undivided, fringed. Radius spreading. —Gathered by Forster and Commerfon in the latins of Magellan. Root much like the lal. Stem solitary, from two to five inches high, slightly leafy, reddish, rough all over with minute, prominent, glanular points. Leaves chiefly radical, numerous, spreading, about two inches long including their footstalks, deeply pinnatifid, and somewhat lyrate, with numerous, opposite, rounded, entire segments, smooth on both sides, but densely bordered with minute brilliages. Flower solitary, twice the size of the lal, white, with spreading oblong radiant florets, toothed at the end. Leaves of the calyx bordered with purple, roughish, partly fringed. Stem-down rough, not feathery. This is a very elegant plant, on account of the regularity of its leaves, which resemble those of a Lapidium, and the size as well as beauty of the flower.

7. P. nerofo. Thum. Prod. 160. Wild. n. 5. —"Leaves simple; downy and ribbed beneath."—Native of the Cape of Good Hope. We have seen no specimen of this or the next.

8. P. chinense. Wild. n. 6. —"Stem leafy, single-flowered Leaves linear-lanceolate, stalked, fervated at the extremity."—Native of Chili. Root perennial. Stems several, a span long, ascending, smooth, leafy, fingle-flowered. Leaves half an inch long, linear-lanceolate, tapering at each end, very narrow, sharply serrated at the apex. Footstalks longer than the leaves. Bracteas numerous, somewhat flaked, of the shape of the leaves, surrounding the flower, which is radially.

9. P. latissimica. Vahl n. 5. t. 5. Wild. n. 7. (After magellanicaus; Lamarack Dict. v. 1. 305. n. 26. Illust. t. 681. f. 3.)—Stem leafy, single-flowered. Radical leaves elliptic-lanceolate, on long stalks; the leaf simple, clasping the stem.—Gathered at the latins of Magellan, by Commerfon, who having marked his specimens as an After, the plant was described as such by Lamarack. The whole herb is destitute of pubescence. Stem from one to nearly two feet high, slender, quite fimple, round, leafy. Radical leaves several, an inch or two long, entire, on slender, almost capillary, footstalks, three or four times their own length; the in the items numerous, alternate, alternate, linear-lanceolate, entire, about an inch long, embracing the item with their ovate base. Flower solitary, rather drooping, not unlike that of P. magellanicum, but scarcely half so large.

PER

A very handsome species. The stem is above a foot high, leafy, corymbose, bipinnatifid in the manner of the fifth species. Leaves sessile, two or three inches long, linear, shining, rough with minute points, deeply pinnatifid; their segments acute, toothed, each point and tooth tipped with a pale bristle; the radical leaves most numerous, somewhat flattened, their segments rather folded or imbricated. Flowers solitary at the top of each branch, from four to eight in all, an inch broad. Calyx rough, pointed, its outer leaves fringed, Radius purple, revolute.

11. P. brasilienfi. Linn. Mutt. 115. Willd. n. 9. Vahl n. 7.—Stem many-flowered. Leaves rough; radical ones obovate, runcinate; the rest oblong; uppermost entire. —Gathered in Brazil, by Father Paredes an almoner, who sent it to Arduino. Commerson also found it at Monte Video. The root has many thick fleshy fibres. Herb rough in every part, with minute bristly hairs, a foot or more in height. Radical leaves flat, near three inches long, obtuse, with many shallow, runcinate, toothed segments; those on the stem fleshy, oblong, undivided, the lower ones toothed, the upper gradually smaller and entire. Flowers four or five at the top of the stem, corymbose, the size of the leaf, but yellow, or pale sulphur-coloured.

12. P. levigatum. Berg. in Stockh. Trans. for 1772. 229. t. 7. Willd. n. 10.—Stem rather shrubby. Leaves flaked, lanceolate, entire, fringed. Flower-stalk terminal, softly in pairs. —Native of Porto Bello. We have seen no specimen, nor even that volume of the Stockholm Transactions, in which alone this species is described.

14. P. recurvatum. Vahl n. 9. t. 7. Willd. n. 12.—Stem somewhat shrubby. Leaves linear-lanceolate, recurved, revolute, bordered with minute spines. Flowers terminal, solitary. —Gathered by Commerson at the Strait of Magellan. This seems to be a low, tufted, much branched shrub, with crowded, recurved, shining, linear-lanceolate leaves, an inch long, corrugated on the upper side, reflexed at the margin, the prominent edges beget with little spines. Flower-stalk broad, fringed, imbricated. Flowering branches terminal, erect, roughish upward, each bearing a few alternate, fringed, elafining leaves, and one erect purple flower, about an inch wide, whose outer calyx-leaves are fringed with small spines. A very pretty and singular species, which though different in its first aspect, displays, when examined, abundant marks of affinity to the rest.

Perhaps Vahl may be right in removing Perdix to the order of Symphyotrichum Aegyptiaca, there being, apparently, in most of the species, no more difference between the florets, than a gradual diminution as they approach the centre, like what is seen in Hieracium and others. In habit some of the species agree with the ligulate, others with the capitulate, genera of that order. Notwithstanding all this, as the various species have not been examined living, and as Linnaeus has described a difference in structure, between the florets of the radius and of the disk, we rather prefer leaving the genus where he placed it. The thirteenth species is so different in habit, that we cannot but suppose it to belong to some other tribe. Browne's figure of the different flower disfigures with his description, which says the florets are all uniform. In the plate the radiant ones are as they ought to be in Perdixium; while the disk is made to consist of such as are equally five-cleft.

PERDIDO, in Geography, a river and bay on the coast of West Florida. The mouth of the river is about ten leagues E. of Mobile point and four W. of the line of Pensacola. It has a narrow entrance, with a bar of six feet, but afterwards widens considerably. This was formerly the boundary between Florida and Louisiana, separating the French and Spanish dominions, and is now considered as the eastern boundary of Louisiana, as lately ceded to the United States. The river stretches in one place N.E. where it pales within a mile of the great lagoon W. of the entrance of Pensacola harbour.

PERDIX, in Conchology, a name given by authors to a genus of shell, supposed to resemble the partridge in the shades and disposition of the colours.

The partridge-shell is of the dolium, or conch globoide claus. and is striated and spotted in a peculiarly elegant and regular manner. See Conchology.

PERDIX, in Ornithology. See Tetrao.

PERDIX Rufica. See Scopolarix Ruficala.

PERDIX Major Brasilienfi. See Psophia Crepsiota.

PERDIX Montana. See Colomba Montana.

PERDOLI, in Geography, a town of Itfria; four miles N.N.W. of Pola.

P.E. DONATIO at lagarias, in Lava, a pardon for one who is outlawed.

PERDRIX de Mer, in Ornithology. See Glareola and Tetrao.

PERDU, Mont, in Geography, the loftiest mountain of the Pyrenees, and the most elevated in which any marine remains have been found in Europe. M. Ramond observed that this mountain was calcareous, and contained shells and other organized bodies, in a fossil slate, at an elevation of about 3000 metres. As he ascended this mountain, in August 1802, by passing the Col de Fanlo, or Nifele, he constantly found frata of compact carbonated lime in a position nearly vertical. They include frata of calcareous sandstone, and these frata sometimes cover the fossiliferous angles of the vertical frata, nearly in a horizontal direction. This calcareous frata falls off spontaneously in little irregular fragments; and on the first friction, or disdissed in acids, it emits a nauseous fætid smell, probably owing to the animal matter it contains. Some of the frata of this frata contain nodules of flint; others such considerable masses of "Camermines," that the flint appears entirely composed of them. The fummit is formed of a fætid limestone, contaminated with quartz, and containing a little iron, and 4'/th of carbon, without alumine. The elevation of this fummit is the fame as that of the Col du Geant in the Alps, or 3426 metres = 3727 yards.

M. Ramond has ascertained the limits of permanent snow, and of vegetation, for this lofty part of the Pyrænean chain. The snow terminates at 3440 metres. The laft trees are Scotch firs, which reach 2150 metres. Next come the herbs, of which the juniper is the highest. At 2760 metres were found the "Ranunculus paranoia folia," the "Santræfra Groenlandica," &c.; then the "Artemisia raprifia" of Lamarck; and lastly round the very peak of Mont Perdu, on rocks too sloping to retain the snow, grow the "cæralium," perhaps the "alpinum" of Linnaeus, and the rose- flowering "Aretis alpin."
PERDUE, a soldier placed in a dangerous, and almost desperate poll. Thus we say, estufiort perdu, for the forlorn hope of an army.

The word is French, and literally signifies lost.

To he perdu, is to lie flat on the belly, or to lie closely in wait.

Perdune Bay, in Geography, a bay on the S.W. coast of the island of St. Vincent; 71 miles N.W. of Kingston bay.

Peria, a small island near the coast of Brazil. S. lat. 20° 22'. W. long. 45° 5'.

Parébea, in Botany, Audub. Guiana. 952. t. 361. Juff. 402, a Guiana plant, whose botanical characters are not fully known. Aublet describes it as a middling-sized tree, throwing up from the root many straight flexible trunks, about four or five inches in diameter, which bear fringed leafy branches. Leaves alternate, nearly sessile, elliptic-oblong, pointed, wavy and somewhat toothed, a foot or more in length; and about five inches wide, green, smooth and shining, with one principal rib, and many transverse ones. When held against the light, these leaves appear full of transparent drops. Stapel foliario, large, men-branched, deciduous. Flowers axillary, on short flasks, foliary, each consisting of a flat flaky receptacle, toothed at the edge, two inches or more in diameter, its upper surface covered with about 30 crowded florets, and at length becoming convex. Each floret consists of a tubular calyx, with four teeth, embracing a roundish herm, a flaky columnar style, and cloven stigma. Aublet saw nothing of the flowers, which he supposed are in separate flowers, on a distinct tree. The calyx becomes a flaky fruit, of a coral red, containing a single seed, as in the Mulberry; but each fruit falls off separate, leaving the receptacle bare. Every part of the tree yields a milky juice. The bark serves for cordage.

This genus is justly ranged by Jussieu in his natural order of Urtica, being evidently allied to Fitus, Morus, Broussonetia, &c. See PAPAUR.

Peréen-Retz, St., in Geography, a town of France, in the department of the Lower Loire, and chief place of a canton, in the district of Paimboeuf. The place contains 1973; and the canton 5988 inhabitants, on a territory of 2525 kilometres, in four communes.

Peresfixe, Hardouin de Beaumont, in Biography, a prelate and historian, descended from an ancient family in Poitou, was the son of cardinal Richelieu's maître d'hôtel. That minister took care of his education, and being brought up to the church, he was made a doctor of the Sorbonne, and preached with applause. He was chosen preceptor to the prince; afterwards Louis XIV.; and in 1654 he was admitted into the French academy. By command of the king he composed an abridgment of French history, from which he detached the life of Henry IV. which was published separately at Amsterdam in 1661, and again with additions at Paris the year after. Though negligently written, it is accounted an excellent work, and one which gives a better picture of that amiable monarch than the fuller history of father Daniel. It omits many circumstances of his life, the purpose being to collect those only which might serve for lefions to a great prince. This author published likewise a small piece entitled "Institution Principis," being a plan of royal education during the peri of childhood. In 1664 he was created archbishop of Paris; and had the fortune to be deeply involved in the disputes of Janenfin. He died at an advanced age in 1676. His private character has been represented as mild and amiable. Moreri.

Perégrinary, Perégrinarius, in the Ancient Monastery, a monk to whom was committed the care of receiving and entertaining strangers, or visitors.

Perégrinatores, in Botany, a name for such students in that science as have taken long journeys, and visited the remotest regions, in search of plants.

Perégrine, Perégrinus, a term applied among Astrologers, to a planet, when found in a sign where it has none of its essential dignities.

Perégrinus, surnamed Proteus, in Biography, a cynic philosopher in the second century, was a native of Parium in Pontus. If we are to credit the account which Lucian has given of him, his conduct in early life was extremely profligate. Being obliged to fly by his country, he went to Palestine, where he made profession of Christianity, and gained some credit with the Christians by his firmness in submitting to imprisonment under Trajan's persecution, sooner than renounce his avowed principles. During his confinement, he was visited by the deputies from the churches of Asia, who administered to him alms sufficed to his wants and sufferings, and in the character of a persecuted believer, he contrived to amass a considerable sum of money. At length he was set at liberty by the governor of Syria, who was a lover of philosophy, and admired the contempt of death which Perégrinus displayed. Upon his return to Parium, he acquired reputation in the character of a disinterested philosopher. By the charity of the Christians, whom he continued to deceive, he was furnished with all necessaries, till, having been detected in the commission of some crime, he was dismission their society, and fell into indigence. He now endeavoured to recover the possession of his citates from the city, but failing in the attempt, he went into Egypt. Here, in the character of a mendicant cyncic, he practised the most extravagant exploits of fanaticism, in order to swell his contempt for the opinions of the world. From Egypt he went into Italy, where he behaved extremely ill, so that he was driven away by the government. Palling over into Greece he attracted the admiration of the crowd at Athens, by the severity of his cynical manners, and the lectures which he delivered. Finding their enthusiasm in his favour becoming less ardent, he determined to procure an immortal name by burning himself at the Olympic games, in imitation of Hercules. This design he announced throughout the whole of Greece, and, at the appointed time, went to Olympia, where, in the presence of a vast concourse of spectators, he raised a funeral pile, and devoted himself to a voluntary death. Such is the account given of Perégrinus by Lucian, but Aulus Gallus speaks of him as a philosopher of reputation at Athens, who was admired for his confluence, and whose moral lectures were much frequented. According to Eusebius he committed himself to the flames in the year 168. Lucian. Enfield's Hist. Phil.

Pétra, Bartholome, a Portuguese Jesuit, and one of the many epic poets which that extraordinary society has produced. The work which he published is entitled Paccidio's 'libri vii. Coimbra 1640; it was written in honour of a Jesuit who suffered Martyrdom in Japan, and to whom the poet was related. Except the names of idols, and the bronze, there is no allusion to any rite or custom of the country. There are, however, says Mr. Southey, some curious passages in the poem, particularly a perfonification of Amor Vite, and some of real merit.

Peréia de Sufa, in Geography, a town of Portugal, in the province of Beira; 18 miles S.E. of Oporto.

Perék, a town of Perú, in the province of Tarapacá; 14 miles N. of Daireghend.

Perékop, a fortress of Russia, in the province of Tauria,
Tauris, on the isthmus which joins the peninsula to the continent, and which has been always reckoned the key to the whole country. Its name is Scylavont, denoting a cut made through a place, and applicable to the ditch dug here, in remote ages, across the neck of land at the entrance of the Crimea, for the security of the city. For the fame reason the Greeks called it "Taphiros" or "Taphirz," and the Romans and Tartars "Or." The heavens here are mean. After often changing mailers, it was finally ceded, in 1783, to the Russians, with the rest of the Crimea, by the abdication of the khan. N. lat. 46° 4′. E. long. 33° 26′.

PEREKOPSKAIA, a town of Ruffia, in the county of the Cossacks, on the Don; 48 miles S. of Archedin-

skia.

PERELMOV, a town of Ruffia, in the government of Irkutsk, on the Amor; 56 miles N.E. of Strastinsk.

PEREMSHAL, a town of Ruffia, in the government of Kaluga, on the Oka; 16 miles S.S.W. of Kaluga. N. lat. 53° 15′. E. long. 35° 44′.

PEREMTORY, in Law, an epithet applied to an action, exception, &c. signifying them to be absolute, final, and determinate; and not to be altered, renewed, or re-

fused, ratified.

Thus in our law books we find: peremptory action, peremptory non-suital, peremptory exemption, &c.

PERENDORE, or Perentolay, in Geography, a town of Hindoostan, in the Mymore; 10 miles S.W. of E-road.

PERENE, a river of Peru, which rises about two leagues from Tarma, runs through that town, and receives many streams from the heights of Bomboh and Pafco; the Pe-

erene joins the Maranon, on the western side, at 11° 18′.

PERENNIAL PLANTS, in Gardening, are such as are of long duration. Such plants as are perpetuated by the roots, whether the leaves and stalks decay annuually in winter, or always remain, provided the roots are of many years duration, are perennial. All plants, therefore, with abiding roots, both of the herbaceous, shrub, and tree kinds, are perennials; though in the general acceptation of the word perennial, it is most commonly applied to herbaceous ve-

tables with durable roots, more especially those of the flowery kind, which among gardeners are commonly called simply perennials, particularly the fibrous-rooted tribe; but it is equally applicable to fibrous, tuberous, and bulbous-rooted plants, whose roots are of several years duration; likewise all shrubs and trees of every denomination, as having abiding roots, are perennial plants.

And these sorts of plants confilt both of deciduous and ever-green kinds; those that call their leaves, &c. in winter being termed deciduous perennials, and those which retain their leaves, ever-greens.

The herbaceous perennials, of the fibrous, tuberous, and bulbous rooted kinds, for the greater part, have annual stalks, rising in spring, and decaying in winter; and a great many lose their leaves entirely also in that season, such as the per-

ennial sun-flower, alders, and numerous other sorts; and many retain their leaves all the year, but not their stalks; as is exemplified in the auricula, polyanthus, fome campa-

nulas, pinks, carnations, and many other plants.

Numbers of the herbaceous perennials multiply exceedingly by off-lets of the root, by which they are readily pro-

pagated. See Offset.

All the tree and shrub perennials are durable in root, item, and branch; but renew their leaves annually. Even the ever-green kinds, although they are in leaf the year round, put forth new leaves every year, to which the old ones gradually give place. See Deciduous and Ever-Green Trees.

PERENNIAL WINDS. See Winds.
of Perez had every advantage which a most captivating and perfect execution could give them.

The operas by which he acquired the greatest fame in Portugal were "Demetrio" and "Solimano," with which, as they were to be alternately performed with the operas of "Valorgado" and "Ero a Latio" that Juxelli had been requested by his most faithful majesty to compose for his theatre, were produced with a degree of exertion and emulation, which rendered him superior to himself. Jomelli on this occasion was chiefly admired for the ingenious and learned texture of the instrumental parts; and Perez for the elegance and grace of his melodies, and expression of the words.

His music for the church, of which a specimen has been printed in England, "Matutino de i Morti," published by Bremner, in four, is grave, ingenious, and expressive.

But though Perez has composed a "Te Deum," which is greatly esteemed at Lisbon, and his "Lezione prima para il Giovendi santo," mentioned above, has considerable merit, yet it appears, on examining his scores, that this matter had not, like Jomelli, much exercised his pen in the composition of fugues or learned counterpoint for the church, to the perfection of which, genius alone can contribute but little, without the assistance of great study and experience.

There is, however, an original spirit and elegance in all his productions; in which, if any defect appears, it is the want of symmetry in the phrasing of his melodies, in which there may sometimes be found what the French call "phrases manques," and "contre-tens," to which critical ears, in modern times, are much less accustomed than formerly. An ear for measure, and an ear for harmony and the accuracy of tones, seem to be totally different gifts of nature; and it frequently happens that a person who dances perfectly well in time, knows not one tone or tune from another.

Perez, like Handel, was corpulent and gourmand, a propensity which has been supposed to have somewhat shortened his days. After living much admired, beloved, and respected, twenty-seven years in Portugal, where he was maestro di capella to his most faithful majesty, and maestro to the royal family, at a salary exceeding 3,000l. per annum, he died extremely regretted at the age of sixty-seven. Like Handel, he was likewise blind during the latter years of his life; but after this calamity, when confined to his bed he frequently dictated, without an instrument, compositions, in parts, to an amanuensis. His remains were deposited in the church of the Italian Barbadinos, and a solemn dirge of his own composition was performed at his funeral, by aconcerto of the best musicians in Lisbon.

Perez, Antonio, whose father was forty years sole secretary of state to Charles V. and Philip II., in which office he was succeeded by the subject of the present article, was also made secretary of war, and demeaned himself so well, as to enjoy, at the same time, the favour of the king and of the people. While in office he was commanded by the king to obtain the affiancement of Don Juan de Ecevedo. He unfortunately obeyed the orders of his sovereign; and supposing that the deed would be considered as a common accident, the murder was perpetrated in the streets of Madrid. Perez appears never to have suspected that he committed a very great crime. He represented Ecevedo's death as necessary, and the forms of justice he thought might readily be dispensed with on extraordinary occasions. Spanishmen fell on him and the princes Eboî; it had been formed that Philip was an unsuccessful suitor to this lady, and jealous of Perez's intimacy with her. Be this, however, as it may, he took the opportunity, occasioned by the fugitio, to throw them both into prison, and suffered the accusation to hang over the secretary's head for many years, still continuing to employ him, and promising him his protection and favour. At length he got possession of the papers which alone could have established his own charge in the murder, and then suffered Antonio to be put to the rack. It was the intention of this unfortunate man to bear the tortures inflicted on him without confessing, but the violence of the pain overcame his resolution, and he declared that he had procured Ecevedo's affiancement, but that it was by Philip's orders. Happily for his own character, he had till by him papers sufficient to prove this, and with these he escaped to Arragon. "That kingdom," said Mr. Southey, in writing the life of Perez only a year or two since, "was still by its constitution a free country, but confusions are nothing in the way of power, and no country has any other security for its freedom than the spirit and strength of the people." He appealed to the tribunal del justiza de Arragon, a free tribunal, to whose decision Philip did not chuse to attend, and, therefore, removed the cause to the Enquista, a sort of star-chamber of his own, in which any wickedness that it pleased him to direct would receive the form of legality. "But," says the writer already alluded to, "the Arragonefe had now espoused the cause of their injured countryman, and it was thought: that the most effectual method of destroying him would be to deliver him over to the inquisition. That accused tribunal, which had lately been established in Saragossa, laid hands on him, on a charge of witchcraft: blinded and befuddled with superflition as the Arragonefe were, in common with all the Spaniards, their love of liberty was not at this time to be thus betrayed. They refused him from the holy office. In consequence of this and other tumults an army was marched into Arragon. The justiza, as he was bound to do, called upon his countrymen to resist this invasion of their rights; but he, and the nobles with him, aware of their inability to oppose veteran troops, let the example of flight. Better had it been to have died in the field, even had the cause been utterly hopeless, as he deemed it, which possibly it might not have been. He and the other chiefs were secured and beheaded. Perez made his escape into France, and the forms of liberty in Arragon were extinguished."

Antonio found the protection that he implored; he published a narrative of his sufferings, and it is certain, by the great names which appear in his correspondence, that he was highly esteemed and respected both in France and England. Several unsuccessful attempts were made to murder him. He died miserably poor in the year 1611, and endured to the last the heavy affliction of being separated from his wife and children. No interest could avail to procure their liberation, and he imputes the death of his eldest daughter to grief on his account. Gen. Bigg.

**PER**

**PER**

PERFECT, something to which nothing is wanting; or that has all the requisites of its nature and kind.

PERFECT, **perfect** in Church History, a designation which the followers of Valentimins assumed to themselves.

PERFECT, **perfect** in Grammar. Preter or pretent-**perfect** tense, is an inflection, marking a time perfectly past; as I have **heard**; pluquam-**perfect** is an inflection, expressing the time more than perfectly past; as I had **heard**, &c. See TENSE.

PERFECT, in Music, denotes something that fills and satisfies the mind, and the ear. In which sense we say, perfect cadence, perfect concord, &c.

The ancients had two kinds of modes, the major and minor; and each of these, again, was either **perfect** or imperfect.

The word **perfect**, when joined by the words **mode** and **time**, usually expresses triple time, or measure; in opposition
position to double time, which they call imperfect. See
Time.
Perfect, in Physiology. A perfect animal is used, by
some writers, for that which is born by univoval generation;
in opposition to infects, which they pretend to be produced
by equivocal generation.
Perfect Flowers, in Botany, and Vegetable Physiology,
are such as have the stamens and pistils both perfect in the
same flower. They are the flera fructiferae of Linnæus,
and are sometimes called united flowers.
Perfect Mixts. See Mixts.
Perfect Number, in Arithmetic, is one that is equal to
the sum of all its divisors, or aliquot parts (Euclid, book vii.
def. 22): thus,
\[6 = \frac{2}{3} + \frac{2}{3} + \frac{2}{3}\]
\[28 = \frac{2}{7} + \frac{2}{7} + \frac{2}{7} + \frac{14}{7} + \frac{14}{7} + \frac{14}{7}\]
are both perfect numbers.
To find Perfect Numbers—Find \(2^n - 1\), a prime number,
then will \(2^n - 1\) \((2^n - 1)\) be a perfect number: for \(2^n - 1 = 1 + 2 + 2^2 + 2^3 + \ldots + 2^n - 1\), and it is demonstrated by Euclid, in the last proposition of book ix, that if the
above series he continued till the sum be a prime, then that
sum multiplied by the last term of the series will be a perfect
number, which, therefore, is identically the same as the above
formula, and the truth of the theorem under its analytical
form may be demonstrated as follows. Since \(2^n - 1\) is a
prime, put it \(b\), and \(2^n - 1 = 2^n = a^n\), then the above
is reduced to \(\frac{a^n - b}{a - 1}\).
Now the sum of the divisors of \(a^n b = \frac{a^n + 1 - 1}{a - 1}\times
\frac{b + 1 - 1}{b - 1}\). See Numbers.
But in this formula the number itself is considered as a
divisor, which is excluded in perfect numbers; therefore the
sum of the divisors, exclusive of the number itself, is
\[\frac{a^n + 1 - 1}{a - 1} \times \frac{b + 1 - 1}{b - 1} a^n - b;\]
and it only remains to be shown that this is equal to \(a^n b\), or that
\[\frac{a^n + 1 - 1}{a - 1} \times \frac{b + 1 - 1}{b - 1} = 2 a^n b;\]
and this will be obvious by re-establishing again the values of
\(a\) and \(b\), as above: for then
\[2^n - 1 = 2^n - 1 = \frac{(2n - 1) - 1}{(2n - 1) - 1}\]
\[(2^n - 1) (2^n - 1) = 2^n - 1,\]
\[2^n - 1 = 2^n - 1,\]
are identical.
Consequently, every number of the form \(2^n - 1\) \((2^n - 1)\)
when the latter factor is a prime, is a perfect number, the
sum of its divisors being equal to the number itself.
If \(n = 2\) then \(2 (2 - 1) = 6\)
\(n = 3\) \(2^3 (2 - 1) = 28\)
\(n = 5\) \(2^5 (2 - 1) = 496\)
\(n = 7\) \(2^7 (2 - 1) = 8128\)
\(n = 11\) \(2^{11} (2 - 1) = 8589869056\)
\(n = 19\) \(2^{19} (2 - 1) = 137438691328\)
\(n = 31\) \(2^{31} (2 - 1) = 2305843008409952128\)
which are all the perfect numbers at present known.
The difficulty, therefore, of finding perfect numbers arises
out of that of finding prime numbers of the form \(2^n - 1,\)
which is a very laborious operation. Euler ascertained that
\(2^{11} - 1 = 2147483647\) is a prime number, and this is the
greatest at present known to be such, and consequently the
last of the above perfect numbers, which depends upon it,
is the greatest perfect number at present known, and in all
probability the greatest that ever will be known; for being
merely matters of curiosity, it is not likely that any one
will ever attempt to find one beyond it. See Barlow's
Theory of Numbers.
Perfect Plants. See Plants.
Perfection, the state or quality of a thing
perfect. This is of divers kinds: physical, moral, and
metaphysical.
Perfection, Physical, or Natural, is that by which a
thing has all its powers or faculties, and those too in their
full vigour; and all its parts both principal andsecondary,
and those in due proportion, constitution, &c. In
which sense a man is said to be perfect, when he has a found
mind in a found body.
This perfection is by the schoolmen frequently called
enginse, because a thing is thus enabled to perform all its
operations.
Perfection, Moral, is an eminent degree of virtue, or
moral goodness; to which men arrive by often repeated acts
of piety, beneficence, &c.
This some subdivide into absolute or inherent, which is
actually in him to whom we attribute it; and imputative,
which exists in some other, and not in him to whom it is
attributed.
Perfection, Metaphysical, or Transcendental, or Essential,
is the possession of all the essential attributes, or of all the
parts necessary to the integrity of a subsistence: or it is
that by which a thing has, or is provided of, every thing be-
longing to its nature.
This is either absolute, where all imperfection is excluded;
such is the perfection of God: or secundum quid, and in its
kind.
Perfectissimae, Perfectissimae, a quality, or dignity, mentioned in the Code. Perfectissimi were
thefo to whom the emperors trusted the presidentship of any
provinces; Alcian imagined the name had been only given
to the governors of Hispania Tarraconensis, and Noricum;
but Calvin has shown the contrary in his Lexicon Juridici-
um.
The perfectissimi were inferior to the clarissimi, though the
former word implyd most perfect.
Perfecto, as in the old time-table, when perfecto
implied triple time, confonante perfecta, a perfect concord.
Perfeid, in Italian Music, implies a certain tendency
to repeat the same thing, as in Rosalia, to repeat the same
passages, or purue the same design, perfet in the same
movement, the same character of air or melody, the same passion
in the same kind of notes. (See chant, design, and
movement.) Such are the ground bases, in chaces, and
an infinite number of constrained accompaniments, or perfects,
or perfidii, which depend on the caprice of the
composers.
Perfoliata Folia, in Botany, Perfoliate Leaves, are
such as have the same or branch running through them,
as in Buculorum perfoliatus, thence termed Thorough-wax,
from the old word wax, to grow. See Leaf.
Perforans, Perforatus, in Anatomy, two muscles
of the fingers, called also flexor digitorum profundus
dul卑ji, See Flexor.
Perforans Gaffcris, a name given to the external cuta-
necous nerve of the arm, which penetrates the coraco-brachial
chials mucle, from an Italian anatomist who described it. See Nervae.

**PERFORATA**, in **Botany**, a name given by some authors to the *Hypericum*, or St. John's wort, from the small holes seen all over its leaves, if held up to the light.

**PERFORATIS**. See **Perforata**.

**PERFORATOR**. in **Midwifery**, an instrument used to open the heads of children, when from some error, or desire of the pelvis of the mother, it is impossible to bring them through without mutilating them. (See *Labour, Difficult*.) The perforator introduced by Smellie, and which is now generally used, is of that of a pair of scissors, or an instrument formed like scissors, on a large scale, viz., about thirteen inches in length, and of proportionate thickness, with the edges rounded, that they may not cut, and with a guard, or projection on each blade, about three inches from the points, to prevent their entering farther than is necessary to the skull of the child. Having pulled the perforator through one of the parietal bones of the head of the child, or through a furrow, if one can be found, (see *Labour, Difficult*) until stopped by the guard, the handles must be opened, and the instrument turned round, by which means the aperture in the skull will be enlarged, in every direction, when the perforator may be withdrawn. See the figure.

**PERFUME**, an agreeable artificial odour, striking the sense, or organ of smelling.

Perfumes are generally made or composed of musk, ambergris, civet, rose, and cedar-woods, orange-flowers, jasmine, jonquils, tuberose, and other odoriferous flowers.

Into these also enter florals, frankincense, benzoin, cloves, mace, and other like drugs, commonly called aromatics. Some perfumes are also composed with aromatic herbs, or leaves, as lavender, marjoram, fage, thyme, hyfip, &c.

Perfumes were anciently much in use, particularly those into which musk, ambergris, and civet enter; but they are not generally diffused since people have become sensible of the harm they do to the head. In Spain and Italy, however, they are still very common.

**Perfumes, Suffusis**, in **Pharmacy**, &c. are topical or external medicines, composed of certain powders and gums, which, being mixed together, and thrown on the boils, produce a vapour or smoke, fulminating in the several diseases. See Suffusis.

Dured mercury is sometimes applied by way of suffusis, called fumes of cinbarum.

There are dry perfumes, made up in trocher, pills, &c. of olibanum, musk, aloes, &c. and most viscous ones mixed with the juices of balsam, &c.

**Perg**, in **Geography**, a town of Aonia; 6 miles S.E. of Aigis. Also a town of Aulalia; 12 miles E. of Styregg.

**Perga**, in **Ancient Geography**, a town of Asia Minor, in the interior of Pamphylia, between the rivers Ccefroa and Cataraetes.

**Perga**, or Parga, in **Geography**, a town of Albania, on the coast of the Adriatic; 25 miles W.N.W. of Arta.

**Pergam** a town of European Turkey, in Romania; the seat of a bishop; 60 miles S.W. of Adrianople.

**Pergamo**, a town of Asiatic Turkey, in Natale, situated at the foot of a mountain, on a river formerly called "Cicus," with a harbour about 15 miles from the sea; inhabited chiefly by Turks, with some Chirilians, who have a church, and are poor; 144 miles S.S.W. of Constantinople. N. lat. 35° 11'. E. long. 27° 0'.

**Pergamus**, in **Ancient Geography**, (now Pergamo.) a town of Mycia, seated on a spacious plain on the banks of the Cicus. The territory of this town was watered by two rivers, one of which traversed the town, and the other ran S.W. of it at a little distance. This territory was pleasant and fertile; and the town was built on the foot of a rock, in the form of a cone, upon which was a fortified castle, where the ancient kings deposited their treasures.

The inhabitants of this city pretended to be descendants of the Arcadians, who arrived in this part of Asia with Telephus, son of Hercules; and they say that Eclesipaus came to Pergamus with a learned colony of Greeks, and practised medicine in this place. The Pergamens paid him great honours, calling him by the title of god the saviour, and the sovereign god. They constructed for him a magnificent temple, in which they offered sacrifices, and they celebrated in honour of him public games. The temple was visited by all the people of Asia Minor, and thus Pergamus became famous: the worship of this god continued in it till the establishment of Christianity. Pergamus was at first governed by its own magistrates, who were independent of any other power. It was afterwards under the dominion of the kings of Lydia, from whom it was transferred to the kings of Persia. After the death of Alexander it was subject to Antipater, and at his death it was transferred to Lydamachus, one of the successors of Alexander, according to Strabo. This prince deposited his treasures in the castle, and entrusted the custody of them to Pheidias of Thos, who fortified the castle and laid the foundation of the kingdom of Pergamus, which lasted 153 years. Eumenes, one of the kings of Pergamus, enlarged and embellished this city. He enriched it with a library containing 200,000 volumes, for the transmission of which parchment was here first invented, and thence called by the Latins Charta Pergamena. In Pergamus were likewise invented those costly hangings, which we call tapestry, and which the Romans named "Alaba." from aula, a hall, because the hall of Attalus, who invented them, was the first room adorned with this furniture. Galen was born in this city. At Pergamus was one of the seven churches mentioned in the Revelation. Attalus III., surnamed Philometer, having no children, bequeathed his estates to the Romans, A. U. C. 621. Artilonicus, the natural son of Eumenes I., contended the kingdom of Pergamus with the Romans, but after different events, he was made a prisoner and conducted to Rome. The kingdom of Pergamus was reduced to a Roman province, and bore the name of "Percamnopor Aisia." In praecursus of this king, it was divided from it. Under the Romans the government of Pergamus was democratic, conducted by a council appointed by the people, under the direction and superintendence of a magistrate, who was president and who was chosen annually. Pallas, Hercules, and Jupiter were divinities held in great respect at Pergamus; but the most celebrated was Eclesipaus; and Apollo, who was regarded as his father, received singular honours at Pergamus. Trojan had divine honours at Pergamus; and the gods and the emperors had temples here, the most considerable of which was that of Eclesipaus. The temple of Augustus in this city was conducted at the expense of the province of Asia; the pagoda had eight columns, and is represented on many medals. This city celebrated, with a magnificence that was very expense, the Olympic, Pythian and Attian games, and also others in honour of Eclesipaus and the emperors. These games were preceded by solemn sacrifices. There were many persons at Pergamus, who conducted the offices of religion, the chief of whom bore the name of pontiff or chief priest. The "Necephori," or wood consecrated to Jupiter, was held in high veneration. This city accumulated...
lated great wealth by industry, by the commerce of parchment, and by the fabric of stuffs and tapestry. It is now an inconsiderable place, thinly inhabited. In the neighbouring fields may still be found the ruins of the palace of the Attic kings, an aqueduct and a theatre.

PERGOLI, in Geography, a town of Aulonia; 8 miles E. of Streyregg.

PERGOLA, a town of the duchy of Urbino; 8 miles E. of Capri.

PERGOLESI, Giovanni Battista, in Biography, a gifted musician, born at Caforia, a little town about ten miles from Naples, in 1704. His friends discovering, very early in his infancy, that he had a disposition for music, placed him in the conservatorio at Naples, called Dei Poveri in Giesu Grillo, which has been since suppressed. Gaetano Greco, of whom the Italians still speak with reverence as a cantupuntif, prefided then over that celebrated school. This judicious master soon perceiving uncommon genius in his young pupil, took particular pleasure in facilitating his studies, and communicating to him all the mysteries of his art. The progress which the young musician made was proportioned to the uncommon advantages of nature and art with which he was favoured; and at a time when others had scarcely learned the gamut, he produced specimens of his abilities which would have done honour to the first mailers in Naples. At the age of fourteen, he began to perceive that taste and melody were sacrificed to the pedantry of learned counterpoint, and after vanquishing the necessary difficulties in the study of harmony, fugue, and scientific texture of the parts, he intreated his friends to take him home, that he might indulge his own fancies, and write such music as was most agreeable to his natural perceptions and feelings.

The infant he quitted the conservatorio, he totally changed his style, and adopted that of Vinci, of whom he received leffons in vocal composition, and of Haffe, who was then in high favour. And though he so late entered the course which they were pursuing with such rapidity, he soon came up with them; and, taking the lead, attained the goal, to which their views were pointed, before them. With equal simplicity and clearness, he seems to have surpased them both in graceful and interesting melody.

His countrysmen, however, were the last to discover or allow his superiority, and his first opera, performed at the second theatre of Naples, called "Dei Fiorentini," met with but little success. The prince of Stigliano, first equerry to the king of Naples, discovering, however, great abilities in the young Pergolesi, took him under his protection; and from the year 1730 to 1734, by his influence, procured employment for him at the Teatro Nuovo. But during this period, the chief of his productions were of the comic kind, and in the Neapolitan dialect, which is unintelligible to the rest of Italy, except the "Serva Padrona," fet for the theatre of San Bartolomeo.

It was not till the year 1735, that an account of his merit penetrated so far as Rome, and inclined the directors of the opera there, to engage him to compose for the Tordinona theatre in that city.

Pergolesi, ambitious of writing for a better theatre, as well as for better performers, than those for which he had hitherto been employed, and happy in having the exquisite poetry of Metastasio's Olimpiade to set, instead of the Neapolitan jargon, went to work with the zeal and enthusiasm of a man of genius, animated by hope, and glowing with an ardent passion for his art.

The Romans, however, by some unaccountable fatality, received his opera with coldness; and the composer being a young man but little known, they seemed to want to be told by others that his music was excellent, and would soon, by the admiration of all Europe, make them ashamed of their injustice and want of taste.

To complete his mortification at the ill reception of this opera, "Nerone," composed by Duni, the next that was brought on the stage, and for which his was laid aside, had a very great success.

Duni, a good musician, and a man of candour, though greatly inferior in genius to Pergolesi, is said to have been ashamed of the treatment which he had received; and with an honest indignation declared, that he was out of all patience with the Roman public, "frenetico contro il pubblico Romano." He even tried during the short life of this opera, to make a party in its favour among the professors and artists who were captivated with the beauty of the music; but all their efforts were vain; the time was not yet come when judgment and feeling were to unite in its favour.

Pergolesi returned to Naples with the small crop of laurels which had been bestowed on him by professors and persons of taste, who in every country compose but a very inconspicuous part of an audience. He was, indeed, extremely mortified at the fate of his opera, and not much disposed to resume the pen, till the duke of Matalon, a Neapolitan nobleman, engaged him to compose a masque and vespers for the festival of a saint at Rome, which was to be celebrated with the utmost magnificence.

Though Pergolesi had but too much cause to be dissatisfied with Roman decrees he could not decline the duke's proposition, and it was on this occasion that he composed the "Mafi, Dixit, et Laudate," which have been since often performed for the public, and transcribed for the curious. They were heard for the first time in the church of San Lorenzo in Lucina, with general rapture; and if any thing could confolve a man of genius for such unworthy treatment as he had lately experienced at Rome, it must have been such hearty and unequivocal approbation as he now received in the same city.

His health, however, daily and visibly declined. His friends had perceived, by his frequent spitting of blood, for four or five years before this period, that he was likely to be cut off in his prime; and his malady was still increased by this last journey to Rome. His first patron, the prince of Stigliano, who had never ceased to love and protect him, amended him to take a small house at Torre del Greco, expanding Naples, or the seaside, almost at the foot of mount Vefu- vius. It is imagined by the Neapolitans, that perfons afflicted with consumptions are either speedily cured, or killed, in this situation.

During his last sickness, Pergolesi composed his celebrated cantata of Orpheus and Eurydice, and his "Stabat Mater," at Torre del Greco, whence he used to go to Naples from time to time to have them tried. The "Salve Regina," which is printed in England, was the last of his productions, and he died very soon after it was finished, in 1737, at the age of 33.

The infant his death was known, all Italy manifested an eager defire to hear and polys his productions, not excepting his first and most trivial farces and intermezzi; and not only lovers of elegant music, and curious collectors elsewhere, but even the Neapolitans themselves, who had heard them with indifference during his lifetime, were now equally solicitous to do justice to the works and memory of their deceased countryman. Rome, sensible now of its former injustice, as an amende honorable, had his opera of Olimpiade revived; an honour which had never been conferred on any composer.
composer of the 18th century. It was now brought on the
stage with the utmost magnificence, and that indifference
with which it had been heard but two years before, was now
converted into rapture.

Pergoleli's first and principal instrument was the violin,
which was urged against him, by envious rivals, as a proof
that he was unable to compose for voices. If this objection
was ever in force with reasonable and candid judges, it must
have been much enfeebled, not only by the success of Per-
goleli in vocal compositions, but by Sacchini, whose princi-
pal study and practice, during youth, were likewise bestowed
on the violin.

It was the opinion of the Hon. Horace Walpole, after-
wards earl of Orford, that Mr. Gray first brought the
compositions of Pergoleli into England. His opera of
Olimpiade was first performed on our stage in 1748, when
Monticelli acquired uncommon applause in the air, "Trem-
ende oculi atroces," and the scene where the "aria par-
I:ante: Se cerca fe dice" occurs; which, though it has often
been said since to more elaborate and artificial music, its ef-
effect has never been so truly dramatic; all other compositions
to those words are languid on the stage, and leave the actor
in too languid a rate for his situation. When we men-
tioned this opinion to Pacchierotti, in a conversation on the
subject, he very well applied our English vulgar phrase to
Pergoleli, by saying, "He had hit the right nail on the head."

The words "Tremende oculi atroces," are not Metafal-
fico's, nor have we ever been able to discover who they are,
or how they happened to be set by Pergoleli; the air, how-
ever, "A due cori," is admirable.

From all the information which we were able to procure
at Rome and Naples, concerning the premature death of Per-
goleli, there does not seem the least foundation for the
story concerning his having been poisoned. The disease of
which he died was a consumption, that preyed upon his
lungs during the last five or six years of his existence, and
the most active and important of his life. As envy was said
to have inflamed his concursors to have recourse to poifon
in order to get rid of so formidable a rival, it has been well
observed, that the success of Pergoleli's productions was
never sufficiently brilliant to render him such an object of
envy to his brethren as to make it necessary to dispatch him
by unfair means. Mem. fur la Vie et les Ouvrages de
Pergoleli, par M. Boyer, Mercure de France pour Juillet, 1772,
p. 197.

The art of music, however, did not die with Per-
goleli, as may be seen by the lift of his succeffors, who, pur-
posing the track which Vinci, Haffc, and Pergoleli first had
traced out, have advanced into new regions of invention,
taste, grace, elegance, and grand effects.

We were allured at Rome, by a musician who had known
Pergoleli personally, that he was a flow workman; "but
the gods fell to mortals," says Epicharmus, "all that is
great and beautiful at the price of immense labour;" 

Salvini tells us that the celebrated composer Carlifiini,
being praised for the grace and ease of his melodies, used to
cry out: "Ah! with what difficulty is this ease required!"
Ab ! quello facile, quanto è difficile !

He had perhaps more energy of genius, and a finer taste,
than any of his predecessors: for though no labour appears
in his productions, even for the church, where the parts are
thin, and frequently in unison, yet greater and more beauti-
ful effects are often produced in performance than are pro-
mised in the score. And, indeed, it frequently happens,
that a score in which the texture of the parts is very ar-
tificial, ingenious, and amusing to the eye, affords nothing
but noise and confusion to the ear. As the Italians in the
sixteenth century were the masters to all Europe in elaborate
composition, even to a pedantic excess, so they have been
the first, in modern times, to abjure its absurdity.

The ease and simplicity of Vinci's and Pergoleli's style,
were soon imitated with fervency by men of no genius, who
always appear more contemptible in light than laboured
strains; and those, putting facility to an infipid excess, soon
rendered opera music proverbially fimply and frivolous. Of
this number were Lampugnani, Pefcetti, Peligrini, Giaco-
melli, Paleazzi, Schiaff, Pampani, and many others.

The church music of Pergoleli has been confurred by his
countryman, Padre Martinii, as well as by some English
musical critics, for too much levity of movement, and a
dramatic call, even in some of his flow airs; while, on the
contrary, Eximeno says, that "he never heard, and perhaps
never shall hear, facred music accompanied with instrumens,
so learned and so divine, as the Stabat Mater."

As the works of this master form an era in modern music,
and as general prairie and censure is seldom just and satis-
factory to discriminating minds, it was our intention to have
inferted here some critical remarks resulting from a late care-
ful examination of his principal productions for the church;
but upon calculating the businesse which we have fill on
our hands before we arrive at the end of the gigantic labour
which we have, perhaps too rashly undertaken; we find
that critical discussion must give way to matters of fact,
or our volumes will be rendered too numerous or too un-
wieldy.

Of the sonatas ascribed to Pergoleli, for two violins and
a bafe, if they are genuine, which is much to be doubted,
they will not bear comparison with the bold, varied, and
elegant compositions of Boccherini, Haydn, Mozart, and
Vanhal. They are composed in a fimply style, which was
worn out when Pergoleli began to write; at which time ano-
other was forming by Tartini, Veracini, and Martini of
Milan, which has been since polished, refined, and enriched
with new melodies, harmonies, modulation, and effects.

No less and accurate judgment can be formed of the merit
of a composer of past times, but by comparing his works
with those of his predecessors and immediate competitors.
The great progress that has been made in instrumental music,
since the decease of Pergoleli, will not diminish his reputa-
tion, which was not built on productions of that kind, but
on vocal compositions, in which the cleverest, simplicity,
truth, and sweetness of expression, justly entitle him to su-
premacy over all his predecessors and contemporary rivals,
and to a niche in the temple of Fame, among the great im-
provers of the art, who, if not the founder was the princi-
pal polishcr of a style of composition both for the church
and stage, which has been constantly cultivated by his suc-
cessors, and which at the distance of 70 years from the
short period in which he flourished, still reigns throughout
Europe.

PERGUBA, in Geography, a town of Ruffia, in the
government of Olomou; 63 miles N. of Petrozavodik.

PERGULARIA, in Botany, so called from pergula, a
balcony, or trellis, in allusion to its twining habit and fra-
grant blossoms, which render this genus very desirable for
bowers. Runnhius first gave the name of Flos pergularius

to the Linnaean Pergularia glabra, which however does not
answer to the generic character, and is eltabliscd by Mr.
Brown as a distinct genus, under the appellation of Vailari
adopted from Bumairan's Fl. Ind. s. 31. The true Linnaean
Pergularia is founded on our first species, hereafter described.
Linn. Mant. 8. Brown Aefcpl. in Tr. of Wern. Soc. v. 5,

Gen. Ch. Cal. Peranthin inferior, of one leaf, in five erect, acute, permanent segments. Cor. of one petal, salver-shaped; tube inflated, various in length; limb in five oblong, horizontal, slightly twisted segments. Crown of the flowers of five compound erect leaves, undivided at the funnelling, with a 'tongue at the back, furnished with the pointed appendage at the point. Neck a row of glands round the base of the germen. Stem Filaments five, oblong, dilated, the leaf of the top and bottom, anthers sessile, membranous, of two cells; mazes of pollen erect, filaked, soon deposited in pairs on the glands of the stigma. Fil. German two, ovate; styles very short; stigma common to the two, concave, obtuse, downy, with five lateral glands receiving the masses of pollen. Peric. Fillicles two, ovate, smooth. Seeds numerous, comose. 

1. P. austratiana. Sweet Green Pergularia, or Chinese Creeper. Sm. 1c. Pl. 1. 16. Andr. Repof. 1. 453. — Leaves heart-shaped, pointed, rather downy. Periclies axillary. Calyx shorter than the tube of the corolla. Sir Joseph Banks is said to have sent this to Kew about the year 1784. It is cultivated in China, as a favourite bow plant, though of what precise country a native is not known. We have been told it is w'd in Sumatra. The late Lady Amelia Hume received a fine plant of this species in 1789, which covered the deck of the ship with its fragrant green blossoms, during a great part of the voyage, and has since been widely propagated in this country. It thrives either in a shade or warm conservatory, flowering throughout the summer and autumn, and exhaling, in an evening, that peculiar, light, lemon-like, but luscious fragrance, of which the Chinefe are so fond, and which belongs to various greenish nifted flowers, as the Chloranthus incisifolius, and some Orchideae. The root is branched, widely spreading. Stem shrubby, round, branched, twining and climbing to a great extent; downy when young; the bark spongy and cracked when old. Leaves opposite, filaked, deflexed, heart-shaped, rather taper pointed, entire, ovate, oblong, veiny, downy at the veins and margin, paler beneath, each two or three inches long. Sepal none, but the foottails, much shorter than the leaves, are glandular at their summit, as well as on each side at the base. Periclies axillary, foliary, drooping, forked, many-flowered, downy. Bracteas lanceolate, at each division of the pericie. Flowers the size of a primrose, pale yellowish-green, bearded within, their segments linear-oblong, oblique, the length of the tube, fringed. 

Linnaeus had in his herbarium a Chinese specimen of this plant, marked tomentosa, with a note at the back signifying that the Catholic clergy at Macao prepare, from its milky juice, a medicine for the dysentery. He cultivated the fame in his house, and described it in his Monograph. 53. The name and specific character however do not apply to this, but to a very different plant, Forskall's Asecus cordata. Flores frangipes, Rumph. Amb. a. etvar. v. 7. 58. t. 26. f. 1. seems to be intended for our present species; though Cyanthochrom odoratissimum, of Loureiro, by the description of the yellow flowers, probably belongs rather to the following. 

2. P. minor. Sweet Yellow Pergularia, or Wejt-Coalt 

Creeper. Andr. Repof. 1. 384. Curt. Mag. t. 755. (Cyanthochrom odoratissimum; Loureiro. Cochinch. 1663) — Leaves heart-shaped, obnude with a point. Pericies axillary. Calyx nearly as long as the tube of the corolla. — Native of the East Indies, where it is cultivated for the same reason as the foregoing. By dried specimens, we could hardly discern any specific difference between these two plants, but when compared alive, they appear to be distinct species. Besides what is noted in the specific character, the plant is rather smaller in all its parts, with fewer flowers in each panicle. The corolla has a broader and blunter segments, of a tawny yellow on their upper surface, though not so round and orange-coloured as Mr. Andrews exhibits them. P. minor was introduced into England by Sir Joseph Banks in 1784, and blooms in a rove all summer long. 

3. P. purpurea. Purple Pergularia. Vahl. Symb. v. 3. 44. Willd. n. 4. (Asecus cordata; Burm. Ind. 72. t. 27. f. 2.) — Leaves heart-shaped, taper-pointed, smooth. Periclies terminal. Calyx much shorter than the tube of the corolla. — Native of Java. We know it but from Burman's work. He says the stem is erect, and flowers purple, in terminal umbels or panicles. Mr. Brown has not examined the fruiting of this or the following, and merely says they "may belong to Pergularia." 

4. P. japonica. Japan Pergularia. Thunb. Jap. 111. Willd. n. 5. — Leaves heart-shaped, smooth. Pericies axillary. Calyx longer than the tube of the corolla. — Gathered by Thunberg near Nagasaki in Japan, flowering in August. Stem twining, simple, smooth. Leaves acute, ribbed, an inch long. Foottails shorter, smooth. Umbels erect. Stigma, according to Thunberg, terminating in a long, erect, white, wavy, tapering thread, the length of the corolla, which is rather contrary to the generic character. Another species may be found in Willdenow, P. edulis, Thunb. Prodr. 38. discovered at the Cape of Good Hope, and said to have a herbaceous stem, with ovate leaves. Of this we know nothing. Mr. Brown excludes it. 

PERHAY, POINT DE, in Geography, a cape on the W. coast of France; 6 miles S.E. of Point St. Matthew. 

PERHO, a town of Sweden, in the government of Vasa; 36 miles E. of Jacobfled. 

PERI, J. Coro, in Biography, a native of Florence, the principal inventor of recreative, and the compiler of "Europe," written by Ruspini, the first opera that was composed to the foottails and to new species of music for the royal nuptials of Mary of Medicis with Henry IV. of France in 1600, was public exhibited at Florence in the most splendid manner, and in which Peri, the composer, performed a vocal part. Peri is said by Battista Doni to have been not only a good composer in the new style, but a famous singer and performer on keyed instruments. 

PERIA, in Geography, a town of Perizia, in the province of Ira; 90 miles W. of Ipsaham. 

PERIAC, a town of France, in the department of the Aude, celebrated for its salt works; 6 miles S.W. of Narbonne. 

PERICLUTUM, a town of Hindoostan; 30 miles S.S.W. of Dindigul. 

PERIADA, in Ancient Geography, a town of Greece, in the island of Euboea. Strabo. 

PERIAGOGE, in Rhetoric, the same with peribola. 

PERIAGRUM, in Geography, a town of Hindostan, in Commerc; three miles W.N.W. of Errood. 

PERIAGUA, in Sea Language, a sort of large canoe, 4 Q.
in the Leeward islands, South America, and the gulf of Mexico.

This is composed of the trunks of two trees hollowed and united together; and thus differs from the canoe, which is formed of one tree. See Boat.

PERIAMMA, a word used by some medical writers to express an amulet.

PERIAMOODY, in Geography, a town of Hindooftan; 30 miles W.S.W. of Dindigul.

PERJAN, a town of Grand Bucharia; 34 miles E.S.E. of Andseb.

PERIANDER, in Biography, a tyrant of Corinth and Coreya, was the son of Cyphius, who before him had obtained an unjust authority over his fellow-citizens. Periander succeeded him about the year B.C. 628, and in order to secure his power put to death the principal persons in Corinth. In almost every other respect he well merited the title of tyrant, which has ever been attached to his name; but he was very inimical to that luxury which involved the inhabitants of the city, and he kept the country in peace by means of his fleet which gave him the control of the sea. He is also applauded for not having imposed taxes upon his people, excepting those which resulted from the export and import of merchandise. His private life was faulted with enormous crimes, with a detail of which we will not fully our pages. He banished his son Lycephon to Coreya, for fleeing an abhorrence of the cruelty inflicted on his mother, but in his old age he sent to recall him, in order to govern Corinth in his dead, while he himself intended to retire to Coreya. The people of that island prevented the exchange by putting the prince to death. Periander took a just and ample revenge on the favage perpetrators of the deed; but not contented with this, he indulged the most cruel resentment on the innocent, by sending three hundred youths of the best families to be made eunuchs by king Alyattes of Sardis. These victims to royal madness, hopping by the way to Samos, were rescued by the people, and it has been asserted that the chagrín occasioned to Periander by the disappointment, caused his death, at the age of 85, in the year B.C. 534. He was a man of great talents, and an inspiration on his tomb at Corinth, preserved by Laertius, proves that his country regarded him as a wise and able ruler. He was traditionally reckoned among the seven wise men of Greece, and some of his maxims, which are rather prudential than moral, seem to justify the title. The maxim most known is, "There is nothing which prudence cannot accomplish."

PERIANTH, Perianthium, in Botany, from τής about, and αῦθες, a flower, is the most usual sort of Calyx, see that article, which is immediately contiguous to, or more properly makes a part of, the flower. Such are the five green leaves, with their urn-shaped base, in the rose; and the tubular cup of a pink, including the scales at its base. In this last instance the perianth may be called double; and is avowedly so in most of the mallow tribe, while in the icabious it is triple. When the term calyx is used without any particular explanation, it means a perianth.

This part is either deciduous, as in the poppy, or permanent, as in the pine. In many instances it becomes enlarged, thickened, or hardened, crowning or enveloping the fruit. Its situation is either inferior, below the germin, or superior, above that part. The petals and stamens are sometimes inserted into it, as in the strawberry. (See Perigynous Insertion.) Its forms are infinitely various, on which the characteristic distinctions of many genera depend. In some instances it is divided, more or less deeply, in others undivided; in some it is of one leaf, in others of several. Its form is either regular or irregular; its divisions equal or unequal. Compound flowers have a common perianth. The hue of the part in question is usually green; but not unfrequently otherwise, in which last case only it is technically said to be coloured. Many flowers have no perianth, as the tulip, which is defluent of any calyx at all; and the narcissus, which has another kind of calyx, the sheath, or perianth. Some, as the umbeliferous tribe and the genus Euphorbia, are effemed by Linnaeus to have an involucrum as well as a perianth; but we would rather use the term bractea for any external covering, or accompaniment, of a floral period, periodizing, as the genus Linnaeus, to form his subdivisions of forms of this principal class.

PERIAPAT, in Geography, a town of Hindooftan; 27 miles N.E. of Comibatore.

PERIAPATAM, a town of Hindooftan, in Myfor; taken in 1791 by the British army under general Abercromby; 24 miles S.W. of Serngapatam. N. lat. 12° 15'. E. long. 76° 31'.

PERIAPPATAM, a town of Hindooftan, in the Carnatic; 20 miles N.W. of Madras.

PERIAPTON, τής πέριαπτος, a kind of medicine, otherwise called perianmus, or amulet; which, being tied about the neck, is supposed to prevent, or cure diseases.

PERIBOACA, in Geography, a river of Canada, which runs into the lake of St. John, N. lat. 48° 32'. W. long. 72° 20'.

PERIBOLE, in Medicine, a word used very frequently by Hippocrates, and in different places, in very different senses. Sometimes it signifies a translation of the humours from one part to another; sometimes only the dregs or garments of a patient. In the first of these senses, the word is frequently used to express a translation of the morbid matter from the centre to the surface, in the termination of a disease, by the breaking out of pustules all over the body.

PERIBOLE, τής πέριβολος, in Rhetoric, is used where many things are accumulated into one period; which might have been divided into several. We have an instance in Cicero's defence of Flaccus: "Quod si effet aliquando futurum, ut aliquid de L. Flacci pernicie cogitaret, nuncum tamen exiliari, judices, Decimum Lelium, optimi viri filium, optimi ipsum ipse prædium, summæ dignitatis, eam fulcepturum accusationem, quæ eclethaturum potius civium odio, & furori, quam ipsum virtut, atque infruit ædulcentius, convenire.

Now this long period might very well have been divided into the three following: 1. Quod si effet aliquando futurum, ut aliquid de L. Flacci pernicie cogitaret; nuncum tamen exiliari, judices, Decimum Lelium, eam fulcepturum accusationem. 2. Eft enim es optimi viri filium, optimi ipse prædium, summæ dignitatis. 3. Accusaturo vero hæc eclethaturum potius odio et furori, quam ipsum virtut
tutisque instinçtus adolescentiae, conveniret." See Punctum cordis.

PERICA, in Geography, three small islands in the bay of Panama, which give shelter to ships, out of the command of the town of Panama.

PERICALAMITES, in the Materia Medica of the Ancients, a name given by Rome to the adarce.

We find the word pericalamitis in a prescription recorded in Galen, and it has generally been understood to mean phlyaxis, that being called calaminus: but the adarce is the thing signified by the name, which expresses its manner of formation, it being always found concreted about the stalks of seeds that grow on the edges of waters.

PERICARDIARY, an epithet given to worms generated in the pericardium, or capulus of the heart.

M. Andry makes these one of the twelve kinds of worms engendered in the human body: they sometimes occasion convulsions, the paroxysms of which last but a little while, but return incessantly.

These worms are accompanied with a frightful paleness of the face, a loose pulse, and violent pains of the stomach and breast.

They sometimes occasion a palpitation of the heart. M. Andry adds, that they have been known to occasion sudden death.

PERICARDITIS, in Medicine, signifies an inflammation of the pericardium, or men branous bag which surrounds the heart.

The symptoms which accompany an inflammation of the pericardium cannot be distinguished in practice from those which attend inflammation of the subjacent part of the heart itself. In fact, the inflammations of both parts are often combined: for whenever the inflammation of the pericardium is violent, it extends to the muscular fibres of the heart, to a considerable depth. The symptoms, which have been observed, are, the general affection of the system called fever; pain in the region of the heart, which is often, but not always, attended with palpitations, and with inflammation of the irregular pulse, cough, difficulty of breathing, and sometimes syncope. But all these occur in inflammation of the heart.

See Carditis.

PERICARDIUM, in Anatomy, (from περικαρπία, about, and καρπος, the heart,) the membrane surrounding the heart. See Heart.

PERICARP, PERICARPIUM, in Botany, from περικαρπία, about, and καρπος, fruit, (or more strictly, seed,) the seed-velvet. This is formed of the enlarged germs, and is extremely various in different plants. It is not necessarily always present, there being many tribes of plants in which the seeds are naked, and guarded only by the integuments of the flower. The latter in such cases not only enfold the feed, but in some instances to entirely assume the nature of a pericarp, as to become juicy and coloured; witness Com melina Zannoni, and the mulberry with its allies. Several genera of grasses are distinguished from others by the firm union of their hardened corolla to the feed, which takes place as the latter advances to maturity.

The use of the pericarp is to protect the seeds till ripe, and then, in some way or other, to promote their dispersion. It is curious to observe how admirably the very same part is contrived, to answer these opposite intentions. This is generally accomplished on hygrometrical principles. While moist or juicy, the valves remain closed; but in drying, they split or fly asunder; thus moreover, by an elastic action, assailing in the dispersion of their contents; and that in a dry state of the atmosphere, which is most favourable to the sowing of seeds in general. An exception to this rule has been observed, in some annual species of Menthastrum, natives of the sandy country of Africa, where they are so dry but enjoy the benefit of rain. The capsules of these expand by means of wet alone, when the elastic valves, of each separate cell, project their seeds to a distance, to take advantage of a favourable moment for vegetation, that might not soon occur if they were sent abroad during the dry season.

Juicy pericarps commonly serve for the food of animals, more especially birds, in whose dung their seeds are deposited, at a distance from the spot where they grew, and in a condition peculiarly favourable for vegetation.

The different kinds of pericarp will be found under the different articles of Capsule, Follicle, Legume, Bacca, Drupa, Pometum, Silqua, Strobilus. Hence genera, and occasionally even natural orders, derive some of their most important marks of distinction.

PERICARPIA, περικαρπία, compounded of περικαρπία, about, and καρπος, the seed, a name sometimes given to medicinal plants that are applied to the seed; otherwise called ephi carpis.

PERICHELÆUM, in Botany, from περικαρπία, about, and καρπος, a hair or bristle, is a scaly sheath, peculiar to molluscs, which owes its name to the situation around the base of their bristly-like fruit-stalk. It belongs also to the male, or barren, flowers of these plants, and indeed constitutes their calyx in both sexes. The perichelæum consists of several imbricated leaves, differing, in a more or less striking manner, from the genuine foliage of the plant, either in structure, dimensions, or colour. In Hypnum it is of great consequence, constituting, by its presence, a part of the generic character, and affording powerfully, by its diversities of shape, proportion, or structure, in the discrimination of species. Its duration is remarkable in some instances, even to the extent of three or four years, long after the feed and its pericarp have disappeared; of which we fearlessly know an example among the generality of other plants. More frequently it is deciduous, after having accomplished its original purpose of protection to the tender organs which it envelopes. See Perigonium.

PERICHAREIA, a word used by the ancients to express a sudden surprize of joy, such as has been frequently known to occasion death.

PERICONDRIUM, (from περικαρπία, and καρπος, cartilage,) the investing membrane of cartilages. See the article Membrane, under the division fibrous membranes; and Cartilage.

PERICHORESIS. See Circumincession.

PERICHORUS, formed from περικαρπία, and καρπος, country, in Antiquity, a name given by the Greeks to their profane games and combats, i.e. to such as were not consecrated to any of the gods. See Games.

Perichorus, in the original, signifies near, or neighbouring; apparently because none of the people of the neighbourhood attended at these obscure exercises. The champions here did not fight in honour of any god, or hero, as in the others; but only for the prize-fake.

PERICHRIXIS, a word used by the ancients for a line, principally of the oleaginous or spurious kinds, and as thin and fluid as oil.

PERICLASIS, from περικαρπία, and καρπος, to break, in Surgery, a fracture attended with a considerate wound of the soft parts, and exposure of the bone.

PERICLES, in Biography, one of the most illustrious statesmen of ancient Greece, was a native of Athens, and son of Xanthippos, a distinguished general, who gained the
PERICLES.

the battle of Mycale against the Persians. He received the liberal education that was common among the Athenians of rank. One of his masters was Damon, who, under the pretext of teaching him music, in reality gave him lessons in politics. Another of his masters was the celebrated philosopher Anaxagoras, from whose instructions he gained an acquaintance with the phenomena of nature, that freed him from the effects of the superstitions of the times. Having an infatuable thirst for knowledge, he attended the lectures of Zeno of Elea, a philosopher and formidable disputant. By means of these, and other advantages which his father gave him, and by the command of his excellency, Pericles acquired an elevation of sentiment, and strength of character, that enabled him long to maintain an almost uncontroll'd authority over a people of all the most difficult to manage. The family connections of Pericles were with the arillocracy; but being sensible of the jealousy with which this party was viewed by the body of the people, in whom real power resided, and, moreover, finding the post of head of the nobility pre-occupied by Cimon, he at first held back from public affairs, and employed his talents in endeavouring to obtain the favour and suffrages of the democracy. The manners which he affected were opposite to those of Cimon; those of the latter were of a learned and seditious kind; but Pericles avoided all entertainments and public amusements: he neither received nor paid any visits of ceremony, and was never seen abroad except in his way to the Prytaneum and assembly, and maintained a cold gravity in his demeanour. Not being himself a member of the court of the areopagus, he endeavoured to lessen its authority. The species of eloquence which he adopted was of the lofty and dignified kind; and such were his powers, that he was said to thunder and lighten in his harangues. He was particularly careful to say nothing that might displease the people, and, probably through caution, left none of his orations in writing, though it was known that he wrote them all down before they were delivered. In early life, when the passions are more easily roused to action, he was celebrated for great patience in bearing any insults offered him, a quality which greatly favoured his rise. As an example of this power over his feelings, it is recorded, that having been treated with great outrage at a public assembly, by a simple citizen, who even followed him, at night, to his house, with the most abusive language, Pericles calmly ordered one of his servants to take a torch and light the man home.

When the popular party had procured the impeachment of Cimon, Pericles was appointed one of the conductors; he however acquitted himself with great moderation, and spoke of this great man with the respect due to his character and talents. The exile of his rival gave full scope to his ambitious purfuits. As Cimon had fed and clothed the people, for which he had received disgrace and banishment in return, Pericles, well knowing their passion for public diversions and shows, caused the poorer citizens to be supplied with money out of the treasury to enable them to obtain admission, and he likewise caused them to be paid for their attendance on the courts of judicature. In the war between the Athenians and Lacedaemonians, which broke out in the year B.C. 458, Pericles exposed himself to great danger at the battle of Tanagra, and afterwards unsuccessfully invaded the Peloponnesus, with a fleet and small body of troops. Finding the people dejected of the return of Cimon, he proposed a decree for that purpose; and it is said, through the medium of Elpinice, Cimon's filler, he made a private agreement with that general, that the latter should have the supreme command abroad, while he himself should direct the public affairs at home. After the death of Cimon, Pericles may undoubtedly be regarded as the master of Athens. He contrived always to occupy the attention of the people, either in sending out new colonies or engaging in expeditions; and by public works, which he set on foot, he both flattered the vanity of the Athenians by the splendour of their city, and provided employment for a number of artists and mechanics of all descriptions. To supply the expences of these grand undertakings, he ventured upon a bold expedient, which was that of removing the public treasures of Greece from Delos to Athens, which was the centre of the empire. He also said that the money having been raised for the purpose of defence against the barbarians, and the Athenians having by their sole efforts effectually answered this purpose, the allies had no longer any right to demand an account of its expenditure. His personal integrity with respect to pecuniary matters was above suspicion, of which a remarkable instance is recorded. While engaged in an expedition against Eubea, the Lacedaemonians made an incursion into Attica. Pericles thought it most expedient to avert this form by money, and accordingly, by means of a large bribe to the tutor of the king of Sparta, procured the return of their troops. When he came to make up his accounts, he charged a sum of ten talents, as "hid out in a fit manner upon a proper occasion." And the Athenians passed the article without further explanation. Perceiving in his invasion of Eubea, he made himself completely master of that important island in the year B.C. 447, and soon after concluded a truce of thirty years with the Lacedaemonians. Upon the occasion of a large present of corn to the Athenians by the king of Egypt, a law, which Pericles had procured to be passed, disfranchising all Athenians of half-blood, was enforced with such rigour, that 5000 p. f. rians, his herto considered as freemen, were sold as slaves. This arbitrary act displayed the great power of Pericles, but probably was not disagreeable to the majority of the citizens, whose confidence was increased by the diminution of the number. A war between the Athenians and Samians took place B.C. 446, which is said in part, to have been produced by the influence of Alcibiades and Pericles. It was on his return from the war that he pronounced the funeral oration which was ascribed to Alcibiades, and which was so grateful to the Athenians, that the women crowded r and him, and placed garlands on his head. After Thucydides had been sentenced to banishment, in the party congress of Athens, the authority of Pericles became still more overbearing, and at length excited the jealousy of the Athenians. Some of his friends were prosecuted: Anaxagoras, his revered preceptor, underwent a charge of irreligion. Alcibiades was publicly accused both of impatience and of favouring the illicit amours of Pericles. He pleased her cause in person, and procured her acquittal, and he prevented any personal attack upon Anaxagoras, by sending him out of Athens, himself accompanying him, as well as to show him a marked personal respect, as to save him from the rude attacks of the people. When the Spartans, taking part with the small states of Greece, sent their demands of reparations of injuries to Athens, denouncing war in case of refusal, Pericles, in a speech which is preferred by Thucydides, persuaded the Athenians to reject the conditions, and was thus the cause of the Peloponnesian war. His conduct was ascribed by some persons to the purpose of finding his countrymen so much employment, that they should not be able to attend to the accusations which his enemies were preparing against him; and a story to this effect is related by Plutarch, that young Alcibiades, seeing Pericles one day very thoughtful, and asking the reason, was told by him, that he had a lot to account for the public money which had passed
through his hands: then, said Alcibiades, " ready to give no account at all."

When the war began B.C. 431, it was the advice of Pericles that the Athenians should neglect the defence of their colonies in the country, and turn all their attention to fortifying the city, and equipping fleets. In pursuance of this policy, when he was appointed to the command, he suffered the inferior army of the Spartans and their allies to advance without opposition, unmoved by the murmurs of the Athenians; but at the same time sent a powerful fleet to the coasts of Peloponnesus, and to Locris and Ægina, which more than retaliated the ravages committed in Attica. At length, however, domestic calamity united with public disaster, completely overbalanced him. His eldest son Xanthippus, who had lived on ill terms with his father, died of the plague, and the dreadful disease carried off the filter of Pericles, and almost all his relations and intimate friends. In short, Paralus, his only remaining son, by his first wife, also died; and at the funeral, as he was placing a wreath of flowers on the head of the corpse, he burst into tears, and withdrew in an agony of grief. The Athenians, to soothe him, repealed his own law for disinheriting children of the half-blood, and he enrolled as a freeman his son by Alcmaia. But his end was now drawing near, and his faculties were well nigh impaired. He fell into a lingering illness, which enfeebled both his body and mind; still however the lamp was not entirely extinguished. Some vigour of intellect remained to the last; for when he lay near expiring, and his friends round his bedside were enumerating the great actions of his life, he suddenly raised himself on his bed, and addressing them, said he wondered they should dwell upon circumstances in which fortune had the chief share, and which were common to him with many others, and forget that which was his peculiar glory, viz. " that no Athenian had ever put on mourning on his account." He died in the year B.C. 429. His character has been thus drawn: " though by no means a man of strict virtue, Pericles had many features of greatness. His philosophical education enlightened his mind, and raised him above the prejudices of the age. Of his happy application of this superiority the following instance is mentioned. As he was going on board his galley to take the command of the fleet, an eclipse of the sun took place, which terrified his pilot to such a degree that he was incapable of his duty. Pericles, perceiving his embarrassment, pulled off his cloak, and wrapping it round the man's head, asked him if there were not any thing ominous in being thus deprived of light? the man replied in the negative: then, said he, what difference can you make between this darkness and the other, except that which shades the sun is bigger than my cloak? The pilot felt the comparison, and was cured of his fear. The administration of Pericles is particularly memorable for the magnificent decorations it conferred on the city of Athens. Vast sums were undoubtedly lavished far above the jubilees, but they did not have the character of refined art upon Athens, which the retained after the had lost all her political distinction. Pericles was left execrable in folleteries that high ambition and spirit of aggrandisement in his countrymen, which was the cause of their greatest disasters, and he too much favoured that corruption of manners of which he himself participated. Univer. Hist. Plutarch.

PERICLEAE, in Ecclesiastical Music, a term in canto fermo. It implies the interpolation of one or more notes in the intonation of certain chants, in order to arrive at the final close, and to inform the choir that they have to pursue and finish the rest. This, in secular music, would be called a cadence.

The species are three. 1. P. lichenoides, Tode, t. 8. f. 61. This is found in summer on the stems of plants, and proceeds from a black crust-like base, so as very nearly to approach the nature of that genus of Lichenes called Calciolum; 2. P. hyfoides; and 3. P. feronosus, both found likewise on the stems and branches of plants.

PERICRANIUM, from περιοσ and κορόνα, the diad., in Anatomy, the peritoneum of the skull.

PERIDIDUM, in Botany, a term introduced by Perfoun, for the round, membranous, dry edge of the seeds, in some of its first section of Fungi, the Antiseptum, which bear their seeds internally, and not throughout the surface of an expanded membrane called Hydnum; see that article. The various kinds of Puff-ball, Lycoperdon and its allies, afford good examples of a Peridium.

PERIDONIUS LAPIS, in Natural History, a name given by some of the writers of the middle ages to the pyrite, which they call alb pyrite.

PERIDROME, PERIDROMUS, in the Ancient Architecture, the space or an ile in a periptere, between the columns and the wall.

Salmanus observes, that the peridromes served for walks among the Greeks.

PERIDROMIDES, Περιδρομίδες, in Antiquity. See Xysti.

PERIDROMOS, a word used by the old Greek writers to express the extreme edge of the hairs of the head, when hanging down in their natural form.

PERIEGETES, Περιεγέτες, a Greek term, signifying a person who leads or conducts another about a thing, to shew it him, &c.

It is applied in antiquity to geographers; especially to those who described the sea-coasts: thus Dionysius is styled periegetes, for publishing a geography in hexameter verses, which Eufathius has commented on, both in Greek.

The name periegetes was also given to those who conducted strangers about in cities, to shew them the antiquities, monuments, curiosities, &c. thereof. These were the same with what they now call the antiquaries in Italy.

PERIERS, BONAVENTURAE DES, in Biography, a French writer, was born at Arras-le-Dieu, in Burgundy. In 1536 he became valet-de-chambre to Margaret of Valois, sister of Francis I. He published several translations and other pieces,
pieces, in verse and prose, but he is chiefly noted for his work, entitled "Cymbalum Mundii," written first in Latin, and translated by himself into French, under a fictitious name, first printed at Paris in 1557 by Morin, who was imprisoned on account of it. This work consists of four dialogues in the Lucianic style, ridiculing the follies and false opinions of mankind. It has been charged with gross impiety, upon the supposition, that under the appearance of laughing at the heathen theology, it meant to mock an attack upon Christian mysteries, and religion in general. It was cenured by the theologians of Paris, and ever after passed as a prohibited, or at least a scandalous work, on which account it became very rare, and much sought after by the curious. It is said the author of it made an unhappy end, by falling on his sword in a fit of despair. Moretti.

PERIES, in Geography, a town of France, in the department of the Channel, and chief place of a canton, in the dioclet of Coutances; 8 miles N. of Coutances. The place contains 2557, and the canton 10,255 inhabitants, on a territory of 140 kilometres, in 16 communes.

PERIESTECOS, in Medicine, an epithet for diseases, signs, and symptoms, which are satirical, and prognosticate the future better health of the patient.

PERIGÉEUM, PERIGEE, formed of περί, about, and γέω, earth, in Astronomy, that point of the sun's or moon's orbit, wherein they are at their least distance from the earth. In which sense perigee lands opposed to apogee.

PERIGEE, in the Ancient Astronomy, denotes a point in a planet's orbit, wherein the centre of its epicycle is at the least distance from the earth.

PERIGNAC, in Geography, a town of France, in the department of the Lower Charente; 10 miles S.E. of Saintes.

PERIGONIUM, in Botany, a more recent term than Perichasma, invented by Linnæus for the same part in Moschis, the scaly leaves enveloping the flowers. It is derived from περί, about, and γόνιον, generation, and being common to the flowers of those plants in general, whether male or female, united or separated, the author judged it more proper than a word which literally applied only to the leaves that surround the fruit-ellips. (See Perichasma.) There is however no end of thus changing terms, when once generally established; and the inconveniences of such a measure, greatly counterbalance any possible advantages. This improved denomination conveys no new idea, nor additional information, but rather lefs; for it is, in its meaning, ambiguous, as applicable to both calyx and corolla; whereas these plants posses a distinct and peculiar corolla in their calyptra, which is equally a perigonium, as encompassing the flower during impregnation, but not a perichasma, because it is removed upwards, as soon as the fruit-ellips, or bristles, is formed. Perichasma therefore, as an appropriate appellation for the calyx, and for the calyx only, is preferable, in our opinion, to Perigonium.

PERIGORD, in Geography, a country of France, so called before the revolution; now the department of the Dordogne.

PERIGRAPHIE, a word usually understood to express a careless or inaccurate delineation of any thing; but in Vellatus it is used to express the white lines or imprefions that appear in the mucous rectus of the abdomen.

PERIGUEUX, in Geography, a town of France, and principal place of a dioclet, in the department of the Dordogne, and the capital of Perigord before the revolution; the see of a bishop, and residence of a governor. This place has some remains of antiquities, has an amphitheatre, a temple of Venus, &c. It is famous for its partridge-pies, which are sent all over Europe. The town contains 5733, and the canton 11,676 inhabitants, on a territory of 140 kilometres, in 10 communes. N. lat. 45° 11'. E. long. 0° 47'.

PERIGYNEOUS INSERTION, in Botany, from περί, about, and γόνιον, a female, expresses the insertion of the stamens neither above nor below the calyx, but into a surrounding part, whether calyx or corolla. Such is the character of the third, sixth, ninth, and fourteenth calyces in Juffieu's system. In the first of these instances the author considers such insertion to be into the calyx; as he arbitrarily fo denominates the covering of the flower, in all his monocotyledonous clavxes, whatever its appearance or structure may be, and whether it be single, as in molt, or double, as in Narcissus, Tulbaghia, &c. In the 6th class he assumes a similar principle. In the 9th he considers the insertion to be sometimes into the calyx, sometimes into the corolla. In the 14th the calyces, as well as the polypetalous corollas, are inserted into the calyx.

Mr. Salisbury, in a paper published by the Linnaean Society, in the 5th volume of its Transactions, contends that there is no such thing in nature as an insertion of stamens into the calyx, but that where they proceed from any real integument of the flower, it must be a corolla. This appears to us well made out, with respect to the liliaceous plants. But the most valuable part of Mr. Salisbury's paper is a demonstration that Juffieu has, in various instances, mistaken the origin of the calyx, and that in such they are inserted into the receptacle, which he pleases to name torus, and not into either calyx or corolla. This is the case with the Atriplices, Junci, and Polygoni; while in the Bicornes, the corolla, whether it bears the stamens or not, is itself inserted into the receptacle, not as Juffieu supposes, into the calyx, and therefore the plants of that order are neither medially nor immediately perigynous.

The chief difficulty in the subject before us, and it is one of the most arduous in theoretical botany, respects Juffieu's 14th class. In the plants which compose this class, Mr. Salisbury considers every thing below the line where the stamens are inserted, whatever its appearance, texture, or substance may be, as either a germ, or a receptacle, alias torus. We should feel little difficulty in according to this decision, as far as concerns Pyrus, Mespilus, Rosa, &c.; but it surely would be forcing analogy too far to name the lower part of the deciduous calyx of Amygdalus a receptacle, and the teeth only a calyx, though both together are forced off entirely, by the swelling germen, nor is there any line of distinction between them. Neither among the Omegae of Juffieu, can we bring ourselves to distinguish between the teeth of the calyx, though deciduous, and its tube, in Epilobium, or Fuchsia. In Ribes, whose affinity to Saxifraga, so ingeniously pointed out by Mr. Salisbury, we cannot but admit, the whole calyx, bearing the faded petals and stamens, falls off entirely. Who can distinguish its lower part from the upper, so as to term one a calyx the other a receptacle? Perhaps these are among the exceptions to which all systematical laws, as applied to nature, are always found liable. We do not point them out for the sake of invalidating an ingenious hypothesis, which we consider as throwing great light upon the subjedt, at least; but rather as matter of caution. The curious reader may find in the Transactions of the Linnaean Society, v. 10. p. 3, &c., and on the subject of calyx and corolla, in Intro. to Botany, more than we think it necessary to introduce here, on a subject chiefly hypothetical.

PERIHELION, formed from περί, about, and ἡλιος, Sun, in Astronomy,
Astronomy, that point of the orbit of a planet, or comet, wherein it is at its least distance from the sun.

Perihelion stands opposed to aphelion. The ancient astronomers, instead of this term, used perigium; because they placed the earth in the centre.

PERIJA, in Geography, a town of South America, in the government of Caracas; 80 miles S.W. of Maracaibo.

PERILEUCOS, in the Natural History of the Ancient, a name given to an agate; but not of a distinct species, but only a particular appearance of the lead-coloured agate, more universally known among them by the name of plattchates.

Gen. Ch. Cal. Perianth inferior, of one leaf, erect, permanent, each half way down into five nearly equal segments, the uppermost very short. Cor. of one petal, irregular, four-leaf; the upper segment emarginate; the lateral ones spreading; the lower longer, obtuse. Stam. Filaments four, simple, dilated, shorter than the corolla; anthers cloven. Fili. Germens superior, four, styles two, thread-shaped. joined together, the length of the filaments; flagma simple. Peri. the unchanged calyx. Seeds four. Eff. Ch. Upper segments of the calyx very short. Stamens separtate. Styles two, joined together.

1. P. osyndi. Balm-leaved Perilla. Linn. Sylv. Veg. ed. 14. 533. Willd. n. 1. (Melissa maxima; Arduini. Spec. fac. 2. 28. t. 13.) —Originally obtained by Arduini from India. It was introduced at Kew in 1770, by M. Richard, where it flowers in July and August.—— Root annual, branched. Stem erect, herbaceous, three feet or more in height, quadrangular, furrowed, purple when old, rough with hairs. Branches opposite, crotchting each other in pairs, short. Leaves opposite, stalked, ovate, rough, veined beneath, acute at each end. Bracteis lanceolate, erect, scarcely hairy. Flowers in spikes at the extremities of the stem and branches, all inclined one way, very hairy, of a white colour. Seeds ovate, rufly-coloured, reticulated.——The whole plant has a strong balsmy fragrance, and may be substituted for the balm of the shops.

PERIM, in Geography, a small island in the straits of Babel-Mande, about four miles from the coast of Africa, having a good port, but no fresh water. N. lat. 12° 36'. E. long. 43. 50'.

PERIMETER, formed from peri, and metron, measure, in Geometry, the ambit or extent that bounds a figure or body.

The perimeters of surfaces, or figures, are lines : those of bodies are surfaces.

In circular figures, &c. instead of perimeter, we say circumference or periphery.

PERINEOCELE, from perineum, and ooele, a rupture, in Surgery, a rupture, or hernia, in the perineum.

PERINALDO, in Geography, a town of France, in the department of the Maritime Alps, and chief place of a canton, in the district of Monaco; 18 miles E.N.E. of Nice. The place contains 1283, and the canton 4858 inhabitants, on a territory of 571 kilometres, in 6 communes.

PERINDA, a town of Hindoostan, in Dowlabad; 23 miles S.E. of Carmulla. N. lat. 18° 33'. E. long. 75° 50'.

Vol. XXVI.
PER

PERIOD, Hipparchus's, is a series of three hundred and four solar years, returning in a constant round, and restoring the new and full moons to the same day of the solar year, according to the sentiment of Hipparchus.

This period arises by multiplying the Calippic period by four. Hipparchus affirmed the quantity of the cycles of the moon, the sun, and indiction, 775, 28, 19, 15; and hence concluded, that in one hundred and four years Calippus's period would err a whole day. He therefore multiplied the period by four, and from the product cast away an entire day. But even this does not restore the new 29 and full moons to the same day throughout the whole period: but they are sometimes anticipated 1 day, 8 hours, $23'\ 29''\ 20''$. See CAILPPIc Period.

Period, Julian, so called as being adapted to the Julian year, a series of seven thousand nine hundred and eighty Julian years; arising by the multiplication of the cycles of the moon, the sun, and indiction, 775, 28, 19, 15, into one another; commencing from the first day of January in the Julian year.

The Julian period is also produced by multiplying the Victorian period by fifteen. Since every year in the Julian period has its particular cycles of the moon, the sun, and indiction; e. gr. only the first has the moon's cycle one, the sun's cycle one, and cycle of indiction one; all the years of this period are accurately distinguished from each other.

This period was invented by Scaliger, as a common receptacle of epochs, to facilitate the reduction of years of a given epoch to those of another epoch likewise given. It agrees with the Constantinopolitan epoch, or period, used by the Greeks, except in this, that the cycles of the sun, moon, and indiction, are reckoned differently; and in that the first year of the Constantinopolitan period differs from that of the Julian period.

To find the year answering to any given year of the Julian period, and especially see EPOCH.

Period, Metonic, or Cycle. See Cycle of the Moon.

Period, Victorian, an interval of five hundred and thirty-two Julian years; which elapses, the new and full moons return on the same day of the Julian year, according to the sentiment of the inventor Victorinus, or Victorius, who lived in the time of pope Hilary.

Some acribe this period to Dionysius Exiguus, and hence call it the Dionysian period; others call it the great paffchal cycle, because it is invented for computing the time of Easter.

The Victorian period is produced by multiplying the lunar cycle nineteen, by the solar cycle eighteen; the product of which is five hundred thirty-two. But neither does this restore the new and full moons to the same day throughout its whole duration, by 1 day, 16 hours, 58' 59'' 49''.

Period, Chaldaic. See SAROS.

Period, in Grammar and Rhetoric, denotes a little compass of discourse, containing a perfect sentence; distinguished at the end by a point or full stop (.); and its members or divisions marked by commas, colons, &c.

De Colonia defines period, a short, but perfect sentence, consisting of certain parts or members, depending one upon another, and connected together by some common vinculum.

The celebrated definition of Aristotle is, a period is a discourse which has a beginning, a middle, and an end, all visible at one view.

Rhetoricians consider period, which treats of the structure of sentences, as one of the four parts of composition.

The periods allowed in oratory are three: a period of two members, called by the Greeks διοιολος, and the Latins bi

members; a period of three members, τριοιος, trimembris; and a period of four, quadrifembris, tetramembrus.

A strict oratorial period does not allow of either more or fewer than these; it is possible indeed to introduce a period of one member, called by Aristotle monoioles, or simple period; but it will be repeated a flaw, and is a thing never practiced by the masters.

The period may be likewise prolonged to five or six members; but then it changes its name, and, instead of period, commences what they call a periodical discourse.

A period of two members the fame Cicero supplies us with: "Ergo & nihii max prifitum vitae confcutudinem, C. Cezar, interculafum aperuisti: & his omnibus ad bene de republica sperandum quafi fignum aliquid fuflufit." A period of three members the fame Cicero gives us in the exordium of his Manilian oration: "Nam cum ante per quarum heus auxilioritate loci contingere non auferem; flatuserque nihil hue nibil perfefium ingenio, elaboratum induftria, afferri operore; omnium tempos amicorum temporibus tranfmittendum putavi." A period of four members he gives us in that admirable description of punishment of paricides: "Ita vivent, ut ducere aumnum de ceelo non quant: ita meriantur, ut eorum offa terram non tangant: ita jactantur fluitibus. ut nuncquam ablautur: ut ipfe rem ejcuntur, ut ne ad fada quidem mortui conquiefcant." The laws and measures of periods are pretty briefly regarded by orators, at least they are so by the ancient ones: in ordinary discourse, and in the modern tongues, authors are much less severe. In oratory, the members of periods are to be equal, or nearly equal; that the pauses or rets of the voice at the close of each member may be nearly equal: but in writing not intended for rehearsal, this is disregarded.

Common discourse allows of periods both longer and shorter than oratory; which admits of none less than two members, nor greater than four. Short mutuated periods break the stream, and check the course of the sublime; and long ones embarrass and keep the mind too long in suspense; and even strain the voice, which is never to stop but at the ends of periods. Philares, Hermogones, Terence, &c. compose the juet period, called by the Latins ambitus and cir- cuitus, to four members; agreeably to the dithich:

"Quattor e membris planum formare videbis
Rhetora circuitum, live ambitus ille vocetur."

Of which sentiment is Cicero, who in his Orator says, "Confaït ille ambitus & plena comprehendere e quattuor fere partibus, quaemem dicatur, ut & aures limilat, & ne brevier fit quam fatis fit neque longior." An instance of a periodical discourse the fame author gives us in the opening of his oration for Archias the poet: "Si quid in me fit ingenii, judicis, quod fentium quam fit eodem, aut fi qua exhoratique dicendi, in qua non meuis illemediacriter effe verum; aut fi hujus rei ratio aliquas ab optimis artium iludibus & disciplina profecta a maxima coeifere nullum etatis ex oppugnare, eum rerum omnium vel in primis hic A. Licinius fruendum me repeta prope fure jure debet."

In the formation of these periods, two things are chiefly to be regarded, their length and cadence. As the length ought to be fured to the breath of the speaker, the ancient rhetoricians shrewdly admit of more than four colons. As to the cadence, what Cicero has observed is found true by experience, that the ears judge what is full, and what is deficient; and direct us to fill up our periods, that nothing be wanting...
wanting of what they expect. When the voice is raised at
the beginning of a sentence, they are in suspense till it be
finished; and are pleased with a full and just cadence, but are
fond of any defect, and are displeased with redundancy.
Care must, therefore, be taken, that periods be neither de-
cicient, and as it were maimed, that is, that they do not
drop before their time, and deform the ears of what seemed
to be promising to them; nor, on the other hand, offend
them by too long and immoderate expositions. This rife
and cadence of the voice in pronunciation depend on the na-
ture and situation of the members. In a period of two
members, the turn of the voice begins with the latter mem-
ber. If a sentence consists of three members, the inflexion
is built made at the end of the second member. But a period
of four members is reckoned the most complete and perfect,
where the inflexion begins at the middle, that is, with the
third member. An equality of the members should likewise
be attended to in the composition of a period, the better to
adapt their rise and cadence. And for this reason in sen-
tences of three members, where the cadence begins with the
third; or in those of four members, where it begins at the
fourth, it promotes the harmony to make the last member
the longest. Ward's Or. vol. i. lect. 23. See Sentence.

Periods are said to be either round, round, or quadrati,
which, according to their different economy and cadences.
Period, Square, is that consisting of three or four equal
members, formally distinguished from each other: as that of
Ciceron on the punishment of patricides.

Period, Round, is that whose members or parts are so
connected, and fitted into each other, as that the junctures
or conjunctions are fearcely seen; but the whole flows equally
round, without any notable stops or inequalities. Such are
the dicous and tricous of Ciceron above mentioned.

Period is also used for the character (.) with which the
periods of discourse are terminated and expressed: this is
popularly called a full stop, or point. See Punctuation.

Father Bulfinch observes two difficulties in the use of the
period, or point; i.e. in distinguishing it from the colon, or
double point; and in determining justly the end of a period,
or perfect sentence.

It is observed, that the supernumerary numbers of a pe-
riod, separated from the rest by colons and semicolons,
usuall commences with a conjunction. Yet it is certain these
fame conjunctions sometimes rather begin new periods, than
supernumerary members of old ones. It is the sense of
things, and the author's own disposition, that must make
the proper distinction of the two in effect it is. No
rules will here be of any service, unless this be admitted as
one, that when what follows the conjunction is of as much
extent as what precedes it, it is usually a new period: oth-
erwise not.

The second difficulty arises hence, that the sense appears
perfect in several short detached phrases, whereas it does not
seem there should be periods: a thing frequent in free dis-
course; as, We are all in suspense; make your proposals im-
mediately; you will be blamed for detaining us longer. Where
it is evident, that simple phrases have perfect senses like
periods, and ought to be marked accordingly; but that the
shortness of the discourse making them easily comprehended,
the pointing is neglected.

Period, Semi. See Semi-Period.

Period, in Numbers, is a distinction made by a point or
comma, after every sixth place, or figure: and is used in
numeration, for the reader distinguishing and naming the
several figures or places, which lie under Numera-
tion.

Period, in Medicine, signifies both the paroxysm and the
interval of those diseases, which occur and cease, and again
return and go through a similar course, at regular periods of
time. See Intermittent.

Period of the Blood, periodus sanguinis, the circle of the
blood, or the tour it makes round the body, for the support
of life. See Circulation.

Period of Perfection, in Greek Music. With respect to
the period of greatest perfection in the music of Greece, it
is a subject which seems to merit some discussion. Plato,
Aristotle, Aristocles, and Plutarch, were for ever com-
plaining of the corruption and degeneracy of music. The
famous Plato, indeed, regarded it as fit only for the gods,
and their celebration in religious ceremonies, or as a vehicle
for religious and moral lectures in the education of youth;
and with a methodical spirit cenured all such as was used
in theatres, social festivity, or domestic amusement; but mo-
dern divines might, with equal propriety, declaim against
the profane use of bread as an aliment, because it is admi-
nistered in the most solemn rite of our religion. A line
should certainly be drawn between the music of the church
and of the theatre; but totally to silence all musical sound,
except upon solemn occasions, seems to border upon down-
right fanaticism.

With respect to perfection and depravity, there is nothing
so common among musical disputants, as for the followers of
one sect to call that degeneracy, which those of another
call refinement. But Plato seems to have been always too
fond of ideal excellence in every thing, to be satisfied with
any other.

PERIODEUTA. Περιοδεούται, a church officer among
the Greeks, established by the council of Laodiæa, in towns,
&c. where there were no bishops.
The periodeute was a kind of rural dean; so called
according to Zonaras, because always on the road, going
from one quarter to another, to keep the people in their
duty.

Hence Gregory of Thessalonica calls them ambulantes,
walkers. Ballamon calls them exercito; by which name they
are known among the Greeks at this day.

PERIODIC, Periodical, something that terminates
and comprehends a period.

Periodic, in Grammar, is applied to a stile, or discourse,
that has numbers, or which consists of just and artful pe-
riods.

PERIODICAL Diseases are such as occur, in regular
paroxysms, at certain intervals of time. In this sense they
are nearly the same as intermittents. See Intermittent.

Periodical Month. See Month.

Periodical Winds. See Winds.

PERIGEUS, περίγευς, formed from περί, about, and 
γεύς, I inhabit, in Geography, such inhabitants of the globe as have
the fame latitudes, but opposite longitudes; or live un-
der the same parallel, and the same meridian, but in dif-
fert semicircles of that meridian, or opposite points of the
parallel.

These have the same common seasons throughout the year,
and the same phenomena of the heavenly bodies; but their
hours, or times of the day, are opposite to each other.
When v. e. with the one it is mid-day, with the other it is
midnight.

PERIPHTHALMIUM, compounded of περί, about,
and φθαλμός, eye, in Natural History, a thin film, which
birds can draw over their eyes to defend them, without shut-
ting their eye-lids; otherwise called the mitigating mem-
brane.

PERJOREE, in Geography, a town of Bengal; 10
miles W. of Currukeergah.
PERIOTSTEUM, from περιοτσ, a bone, in Anatomy, the membrane which covers the bones. See Membrane.

The periosteum is liable to inflammation from a variety of causes, and particularly the venereal disease and the scurvy; this generally terminates in an abscess or gangrene: if not speedily removed, the bones will be injured. The cure is, in general, the same as in other inflammations; but the particular intention is to carry the pcecant matter outwards by fomentations and incisions. Cases of this kind generally terminate in amputation.

PERIPATETIC PHILOSOPHY, the system of philosophy taught and established by Aristotle, and maintained by his followers, the Peripatetics.

A specimen of the Peripatetic philosophy, see under Aristotelian.

PERIPATETICS, ἰππαταιτίς, a sect of philosophers, the followers of Aristotle, or the maintainers of the Peripatetic philosophy: called also Aristotelians.

Cicero tells us, that Plato left two excellent disciples, Xenocrates and Aristotle, who founded two sects, which only differed in name; the former taking the appellation of Academics, who were those that continued to hold their conferences in the academy, as Plato had done before; the others, who followed Aristotle, were called Peripatetics; from περιοτσείκας, because they disputed walking in the Lyceum; which was a grove in the suburbs of Athens, which had previously been used for military exercises. See Lyceum.

Ammonius derives the name Peripatetic from Plato himself, who only taught walking; and adds, that the disciples of Aristotle, and those of Xenocrates, were equally called Peripatetics; the one Peripatetics of the Academy, the other Peripatetics of the Lyceum; but that, at length, the former quitted the title Peripatetic, for that of Academic, on occasion of the place where they assembed; and the latter retained simply that of Peripatetic.

The greatest and best part of Aristotle's philosophy, (for an account of which, see the biographical article of Aristotle;) he borrowed from his master Plato: Serranus affirms confidently, and says he is able to demonstrate it, that there is nothing crotchety in any part of Aristotle's philosophy, dialectics, ethics, politics, physics, or metaphysics, but is found in Plato. And of this opinion are many of the ancient authors, Clemens Alexandrinus, &c.

Gale endeavours to shew, that Aristotle borrowed a good deal of his philosophy, both phyleal, about the first matter, and metaphysical, about the first being, his affections, truth, unity, goodnes, &c. from the sacred books; and adds, from Clearchus, one of his (Aristotle's) scholars, that he made use of a certain Jew, who affihed him therein.

Aristotle, when he withdrew to Chalced (see his article), was succeeded in the school of the Lyceum by one of his favourite pupils, Theophrastus, whom he appointed to this office in the 2d year of the 114th Olympiad, B.C. 323. (See Theophrastus.) Under his conduct the Peripatetic school maintained such high reputation that he had about 2000 scholars. Theophrastus was succeeded by Strato of Lampacus (see Strato), who undertook the charge of it in the 3d year of the 123d Olympiad, B.C. 286. After his death this school was continued, in succession, by Lycon of Troas, who enjoyed the friendship of Attalus and Eumene, and filled the chair till the 135th Olympiad; by Aristo, of the island of Cos, whom Cicero characterizes as more distinguished for the elegance of his language than the depth of his philosophy; by Crisolus, a Lydian, who, with Caracaeus and Diogenes, was deputed by the Athenians on an embassy to Rome, and who is said to have held the doctrine of the eternity of the world; and by Diodorus, with whom the uninterrupted succession of the Peripatetic school terminated. Of this school Demetrius Phalerus was an illustrious ornament, see his article. The Peripatetic philosophy found its way to Rome, in the time of Sylla, with the writings of Aristotle and Theophrastus. However, the obscurity of Aristotle's writings greatly obstructed the progress of this philosophy; and Cicero, who seems to have had some respect for the Peripatetic philosophy, acknowledges that it was understood by very few even of the philosophers themselves. Under the Caesars, it regained its ancient credit; and from the time of Andronicus, the preceptor of Plutarch, who, with Tyrannio, brought it to Rome, to that of Ammonius, that is, till the time of Nero, the peripatetic doctrines were taught with great purity in its schools. But after Ammonius it began to experience the influence of that spirit of confusion, which prevailed among the Eclectic philosophers; and the plan of Antiochus, who had formerly attempted a coalition between Aristotle, Plato, and Zeno, was revived. From this time the Peripatetic sect was divided into two branches: the one consisting of such as attempted to combine the doctrines of other schools with those of Aristotle; the other, including those who wished to follow more closely the steps of the Stagyrites.

Julius Caesar and Augustus patronized the Peripatetic philosophy; the former in the person of Sosogenes, the latter in that of Nicolaus. Under the tyrannical reigns of Tiberius, Caligula, and Claudius, it experienced worse fortune; many excellent men of this sect, as well as others, being either banished from Rome, or obliged, through fear of persecution, to remain silent. In the reign of Nero, the philosophers of this sect, as well as others, the temporary protection of the imperial court; but after a period of five years, they shared the fate of the professors of magical arts, or, as they were then called, mathematicians, and were again banished the city. During the first century of the Roman empire, we find few celebrated names among the Peripatetic philosophers. The principal are Sosigenes, Boethius, Nicolaus, and Jules. About this time Ammonius, the preceptor of Plutarch, attempted to extend the authority of Aristotle beyond the limits of his own sect, by blending the Platonic and Stoic doctrine with the Peripatetic. After his death many Platonists studied the writings of Aristotle, and commented upon them; and thus prepared the way for the formation of the Eclectic sect under Ammonius Socca, who flourished about a century later than Ammonius the Peripatetic. (See Ammonius and Eclectic.) After this time we meet with several genuine followers of Aristotle, of whom the most celebrated was Alexander Aphrodisius. (See his article.) Among the Eclectic commentators upon Aristotle, we may reckon, besides Porphyry, Jamblenchus, Plutarchus, Neleorius, &c., Diopius, Themistius, Olympiodorus, and Sphocles. From this concise detail, we may learn, that under several of the Caesars, the philosophers of this school shared, with their brethren, the common discouragements and infelicities of oppression. The concise and logical method of philosophizing, which prevailed in this school, could obtain few admirers at a period remarkable for a loofe and florid kind of eloquence. Befides, the doctrine, which the Peripatetics of this period had received from their master, suffered much adulteration from the unwearyed endeavours of the Alexandrian philosophers to embellish an Eclectic system. Many bold, but injudicious grammarians and critics, attempted to supply chafms, and to clear up absurdities, in the writings of Aristotle, from their own ingenuous conjectures, which they presumed to incorporate with the
the author's text. Even Alexander Aphrodisius, who pro-
fessed to restore the genuine Aristotelian syllem, not con-
fining himself to the doctrine of his master, contributed to-
wards its adulteration. But nothing proved so injurious to
the Peripatetic philosophy, as the rage for commenting upon
the works of Aristotle, which prevailed among his followers.
Notes, paraphrases, arguments, summaries, and disser-
tations, piled up, century after century, under the general
name of commentaries upon Aristotle, created, as might be
expected, endless disputes concerning the meaning of his
writings; and it may perhaps be inferred with truth, that
their genuine sense, after all the pains which have been
taken to explore it, yet remains, in many particulars, undis-
covered.

Some knowledge of the Aristotelian syllem was intro-
duced among the Jews by Arilobulus, an Alexandrian Jew,
who lived in the reign of Ptolemy Philometer, and was an
admirer of the Greek philosophy. In order to facilitate
the study of Aristotle among the Jews, his writings were, in
a subsequent period, translated from the Arabic into the He-
brew tongue; and towards the close of the 13th century,
the name of Arilobulus was so highly respected among the
Jews, that they not only called him the prince of philo-
osophers, but maintained that his philosophy was the perfection
of human science, and could only be excelled by the doc-
trine of divine revelation; and in order to screen themselves
from censure for submitting to receive wisdom from a heathen
philosopher, they pretended that Arilobulus was himself a
profeyle to Judaism, and was indebted to Solomon for a
great part of his philosophy.

The commencement of the Aristotelian philosophy among
the Arabians may be referred to the time of Al-Mamon,
who, among other writings in various languages, caused the
works of Galen and of Arilobulus to be translated into Arabic.
After his death, which happened in the year 853, philosophy
continued its progress among the Saracens, to which the
eminent schools that were founded in different parts of the
city in no small degree contributed. (See Saracens.)
In order to accommodate the established syllem, which was
guarded by the function of penal laws, to their philosophical
ideas, they blended the abstract speculations of the schools
with the gross and vulgar conceptions of the Koran. They
made use of the subtleties of the Aristotelian philosophy in
the defective and corrupt state in which it had come into
their hands, to affix them in improving upon the literal
reading of their sacred books, and thus gave a new, and for the
most part a metaphysical, turn to the religion and law of
Mohammed. This, it is said, by one of their own writers,
was the origin of their religious sects. Many of the Ara-
bian philosophers, among whom we may reckon Jacobus-
Al-Kendi of Basora, Abu Farabi, or Abu Nair, a native of
Baktr Flarb, who flourished in the 10th century, Al-Rafi,
called also Abubeker and Al-Manfor, a native of Raif, in
Persea, Avicenna, Avanus, a Spaniard Saracen, who flour-
ished about the middle of the 12th century, Avenzoar or
Seville, Thophall of the fame city, and Averroes, acquired
celebrity by their commentaries upon Aristolote, and other
philosophical works. In every branch of science, in which
Aristotle led the way, the Arabian philosophers followed
him as an infallible guide; instan that their tenets, as far
as they are distinct from the peculiar dogmas of the Koran,
are, without variation, those of the Peripatetic school.

In the earlier ages of Christianitv, the Platonic philo-
osophy was more generally preferred to the Peripatetic: the
Christian fathers pointed the severest censure against the
Peripatic and Epicurean sects. The doctrines of the
Peripatickets concerning divine providence, and the eternity
of the world, chiefly excited their averton against this sect; and
besides this, they were much displeased with Ariloltole,
for having furnished heretics and infidels with the weapons
of sophistry. Nevertheless this did not prevent the doctrine
of Aristolote from forcing its way into the Christian church.
Towards the close of the fifth century, it rote into con-
iderable credit: the Platonics, interpreting, in their scholos,
some of the writings of Arilolote, particularly his dialectics,
and recommending them to young persons. This seems to
have been the first step to that universal dominion, which
Aristotle afterwards obtained in the republic of letters;
which was also very much promoted by the controversies
which Origen had occasioned: he was zealously attached to
the Platonic syllem: and, therefore, after his condemnation,
many, to avoid the imputation of his errors, and to prevent
their being counted among the number of his fol-
lowers, openly adopted the philosophy of Arilolote. Nor
was any philosophy so proper for furnishing thes weapons
of subtle distinctions and captious sophisms, which were
used in the Neltorin, Arian, and Eutychian controversies.
About the close of the fifth century, the Aristotelian phil-
osophy, as well as science in general, was almost universally
declared; and it was chiefly owing to Boethius, who had ex-
plained and recommended it, and who united the Platonic
with the Arilololote doctrine, that it obtained a higher
degree of credit among the Latins than it had hitherto
enjoyed. Towards the end of the seventh century, the Greeks,
abandoning Plato to the monks, gave themselves up entirely
to the direction of Arilolote, and in the succeeding century,
the Peripatetic philosophy was taught every where in their
public schools, and propagated in all places with considerable
succes. John Damascenus, who flourished at the begin-
ing of the eighth century, very much contributed to its
credit and influence, by composing a concise, plain, and
comprehensive view of the doctrines of the Stagirite, for the
infruction of the more ignorant, and in a manner adapted
to common capacities. Under the patronage of Phoebus;
and the protection of Barda, the study of philosophy, having
for some time declined, revived again about the end of the
ninth century. About the year 1030, a revolution in phi-
losophy commenced in France; when several eminent logi-
cans, who followed Arilolote as their guide, took neverthe-
less the liberty of illustrating and modelling anew his phi-
losophy, and extending it beyond its limits. In the second
fourth century, three methods of teaching philosophy
were practised by different doctors; the first was the ancient
and plain method, which confined its refurchases to the phi-
losophical notions of Porphyry, and the dialectic syllem,
commonly attributed to St. Augustine, and in which were
laid down these general rules, that philosophical inquiries
were to be limited to a small number of subjects, left, by their
becoming too extensive, religion might suffer by a profane
mixture of human falsity with its divine wisdom. The
second method was called the Arilololotean, because it con-
cluded in explanations of the works of that philosopher, sev-
eral of their books, being translated into Latin, were almost
every where in the hands of the learned. The third was
to be used in the free method, employed by such as were bold
enough to search after truth, in the manner the most adapted
to render their inquiries successful, without rejecting the
succeos of Arilolote and Plato.

About this time, dialectic philosophy was supposed to be
the key of theology, without which it would be impossible
to unlock the mysteries of sacred wisdom. On account of
this supposed alliance between logic and theology, the former
was made the principal object of study in all the schools,
and those who excelled in the dialectic art were regarded
with
with the highest admiration, and attended by crowds of pupils. The Aristotelian philosophy had now for several centuries been studied by the Saracens, and was at this time taught in their schools in Spain. These schools were visited by many of the western Christians, who learned Arabic, that they might be able to read translations of Aristotle, and other philosophical writings, and who afterwards translated many Arabic books into the European tongues. Another cause which served to establish a general taste for the Peripatetic philosophy, and particularly for the Aristotelian logic was, that about this period many Greek copies of the writings of Aristotle were brought from Constantinople into the west. Before this time, though they had been read in the original by a few monks, more learned than the rest, most persons had been contented with the translations of Victorinus and Boethius. But, at the beginning of the 12th century, the original writings of Aristotle were studied in Paris; whence they were introduced among the Germans, by Otho of Freisingen, in the time of Abelard. The guards of the church were alarmed by the innovations of new opinions, which this fondness for logical disputations introduced; and after having sentenced the works of two Paphian teachers of theology to be publicly burned, a general prohibition of the use of the physical and metaphysical writings of Aristotle in the schools, was issued first by the synod of Paris, and afterwards, under pope Innocent III., by the council of Lateran. The evil that had caused the alarm was not suppressed; but the fondness for the subtleties of Aristotelian logic and metaphysics became so general, that the orthodox clergy complained, that scholars spent their whole time in disputations. It was at length found necessary, under certain restrictions, to favour the study of Aristotle. Accordingly his dialectics, physics, and metaphysics, were by express statute received into the university of Paris. It was ordered, however, in 1251, by a bull of pope Gregory IX., that only such books of Aristotle should be used in the schools, as had been examined and purged from errors. In several other countries, the Aristotelian philosophy was received with less opposition. In England, the writings of the Stagirite were read with great avidity; and in Germany and Italy the study of Aristotle was very much encouraged. The name of Aristotle, from the end of the twelfth century, obtained universal dominion; and so far were his writings, after this time, from falling under the censure of councils and popes, that the philosophy of Aristotle, and that of the Saracens, became the main pillars of ecclesiastical hierarchy. In the year 1452, Charles VII. ordered the works of Aristotle to be read and publicly explained in the university of Paris. Thus the union between the Peripatetic philosophy and the Christian religion was confirmed, and Aristotle became not only the interpreter, but even the judge of St. Paul. At the commencement of the reformation, Luther, who was early initiated in the Peripatetic philosophy, rejected both this and the scholastic, as not only irreconcilable with the Christian faith, but the cause of endless controversies in the Christian church. In various parts of his writings he expresses great contempt for Aristotle and his followers. Melancthon so far expounded the doctrine of Aristotle, as to attempt the revival of the pure Peripatetic philosophy in the schools. Although at the beginning of the 16th century, the scholastic philosophy began to fall into general contempt, Aristotle still retained, in a great degree, his authority. This event was owing to so many concurrent circumstances. The partisans of the Platonic system, who, under the patronage of the Medicean family, had long maintained their ground against the Aristotelians, lost their influence as that of their patrons declined; and the advocates of the Peripatetic philosophy proportionally increased, and, after a violent conflict, obtained a victory. This victory was facilitated and completed by those enquirers extending beyond the region of metaphysics and theology, into the subjects of natural history and philosophy, which were not the business of the schools of Rome. The Peripatetic philosophy continued to be zealously maintained, on account of the allegiance which its dialectics afforded them in the defence of the established faith; and because many of the doctrines of this system coincided with those of the school of Aristotle. The deference which had been long paid to the decisions of Aristotle, induced the first reformers of learning to direct their principal attention to his writings; accordingly the number of critics and common tutors became very considerable. The first persons of this description employed themselves in verbal, rather than philosophical criticism, and in correcting the text of their author. But commentators of a different class were chiefly employed, from Pomponatus to the middle of the seventeenth century, in ascertaining and refuting the true Aristotelian philosophy. It would be an endless task to enumerate all the learned men, who, in the fifteenth and sixteenth centuries, attached themselves to the Aristotelian system. Among the Roman Catholics we may mention Nicholas Leonicus Thomaeus, a Venetian, born in 1457, who seems to have been one of the first that attempted to refute the genuine Aristotelian philosophy; Pomponatus of Mantua, born in 1462, who taught the doctrines of Aristotle and Averroes in the schools of Padua and Bologna, and who had many followers of great celebrity; such as Simon Porta, a Neapolitan, Julius Caesar Scaliger, a celebrated philologist, and Lazarus Bonamico, who rivalled Erasmus in elegant Latin:—Majorizius of Milan:—Scapulveda of Cordova:—Peter Victor of Florence:—Zabarella of Padua:—Strozza of Florence:—Cesalpina, an Italian:—and Caesar Cremoneus of Modena. Among the Protestants, especially in Germany, we find in their public schools many learned men, who were followers of Aristotle. At the commencement of the reformation, indeed, both the scholastic philosophy, (which fee,) and the dogmas of Aristotle, were rejected with great indignation, particularly, as we have already observed, by Martin Luther. But afterwards, when men of the foundell judgment and best erudition, perceived the value of philosophy as a guard against fanaticism, much labour was devoted to the promotion of learning, and to the encouragement of a love of science. The first place in this class of reformers is unquestionably due to Philip Melancthon (see his article.) At Leipzig, Simon Simon of Lucca was distinguished; in the academy at Tubingen flourished Jacobus Scheikus, and in that of Altdorf, Philip Scherbus, whose contemporaries, of the same school, was Nicholas Tanurulis. To these we may add Erneitus Sowerus, a native of Nuremberg, and Hermannus Conringus, one of the most illustrious ornaments of the Germanic schools, (see his article;) and also Chirillanus Driesius, a native of Stettin in Pomerania, Melchior Zeidler of the same place, and Jacobus Thomasius of Leipzig, chiefly memorable as the preceptor of the illustrious Leibnitz.

The general prepossession in favour of the Aristotelian system, which from a variety of causes, some of which have been enumerated, prevailed for several centuries after the revival of letters, was attended with much inconvenience and mischief. Opinions were imbued from the Peripatetic philosophy, wholly incommensurable with the principles of true religion; such as, for example, that God, the first mover, wholly intent upon the contemplation of his own intellect, disdainers

PERIPATETICS.
The peripetia is a crucial element in ancient drama, serving as a turning point in the plot that reveals the true nature of the action and the tragic outcome. In the play of Oedipus, for example, the peripetia occurs when Oedipus learns that he has killed his father and married his mother, thereby fulfilling the prophecy of his birth. This revelation is not a result of chance or accident, but rather a consequence of the actions of the characters. The peripetia is thus a moment of truth, a realization of the consequences of past actions, and it often leads to a tragic conclusion.

The peripetia is not merely a plot device, but an essential component of the drama's structure. It is a moment of transition, where the fortunes of the main characters change dramatically, and it provides a critical point for the audience to understand the nature of the action and its implications. The peripetia is thus a fundamental element of the dramatic art, and its role is to create a sense of suspense and tension, and to reveal the true nature of the action to the audience.
Rigma. "Pijf. German or two, ovate, approximated; styles combined above; stigma capitate, feebly pointed, dilated, and notched at the top. Peric. Follicles two, cylindrical, widely spreading, smooth. Seeds numerous, imbricated, crowned with hair. Receptacle longitudinal, thread-shaped.

Obs. From this genus are now separated, by Mr. Brown, P. Secamone of Linnæus, and emiceta of Wildenow; both referred to his genus Secamone, hereafter to be described, as being P. echinata of Linnæus, see Onystelma; P. indica, see Hemidesmus; P. capularis of Forker, see Parsonella; and P. flosulmis of Wildenow, see Gymnema. P. tunicata of the last-mentioned author appears to be like his wife rejected by Mr. Brown; but we neither know the plant, nor where he has placed it. The Linnean P. africana is made by him a Gymnachmus. The following species only therefore remain.

1. P. græca. Common Periplota. Linn. Sp. Pl. 309. Sm. Fl. Græc. Sibth. t. 249, unpubl. Schmidt Arb. v. i. t. 46. (P. folis oblongis; Hort. Angl. t. 15. Duham. Arb. v. 2. 104. t. 21. P. repens angustifolia; Ger. Em. 902.)—Corolla hairy on the upper side. Leaves ovate, acute.—Native of hedges and thickets in the Levant. Dr. Sibthorp gathered it on Mount Athos and near Prusa. Gerarde had the plant in his garden, and it has ever since been cultivated in England, as a hardy climber, flowering plentifully in July and August, and distinguished by the abode name of Virginian silk. Lord Bute gave a description of this Periplota, as a new genus, without any idea of its being a description plant, to Peter Collinson, which the latter forwarded to Linnæus. The stem twines round every thing in its way to the extent of several yards, and is much branched, round, and smooth. Leaves opposite, on short stalks, ovate, sharp-pointed, entire, smooth and shining, very beautiful, two or three inches long, deciduous; the lowermost on each branch short, rounded and obtuse. Flowers corymbose, at the ends of short lateral branches, inodorous, singularly elegant though not ollentans, brown, with a violet loddin, each an inch in diameter. They convey an idea of some brown kinds of Auricula.

2. P. levigata. Smooth-flowered Periplota. Ait. Hort. Kew. ed. i. v. 1. 301. Wild. n. 3. (P. pinacifolia; Cav. Ic. v. 3. 9. t. 217.)—Corolla smooth. Leaves oblong. Native of the Canary islands, whence it was sent by Mr. Maffon to Kew in 1779, and where according to Cavallines it is called Granadilla. The stem is fluter and more upright than the former. Leaves smaller, more obvolute. Flowers yellowish-green, equally terminal, but smaller and smooth. We find their segments frequently emarginate, though sometimes entire, agreeing in those respects with the following.

3. P. angustifolia. Narrow-leaved Periplota. Labillard. Syr. fasc. 2. 13. t. 7. Wild. n. 4.—Corolla smooth. Leaves lanceolate, obtuse.—Gathered by M. Labillardiere, from whom we have a specimen, near Laodicea ad mare, and in the island of Lampedula. It is also found in Barbary. The stem tends still more upright and straight than in the last, and the leaves are more lanceolate, but their flowers exactly agree, notwithstanding a supposed difference in the apex of each segment, pointed out by Wildenow. This is very probably a variety of the levigata.

Mr. Brown mentions a fourth species, brought by Dr. Afzelius from Sierra Leone, which we have not seen, and of which no character or description is given.

Periploïa, in Gardening, comprises plants of the woody climbing kind, of which the species cultivated are the common Virginian silk or periplota (P. græca); the green periplota (P. echinata); the Indian periplota (P. indica); and the African periplota (P. africana).

The first is sometimes called climbing dog's-tongue. The second species has a twining, thrybby, even stem; the leaves are opposite, petioled, even, underneath paler, veined transferably; the panicles axillary, alternate, dichotomous, shorter than the leaves; the flowers are small. It differs obviously from the first sort in its small copious flowers. It is said to be a native of Egypt; but its place of growth is uncertain; flowering in July.

The third has many slender stalks, which twine about each other, and, by a shrub, or other support, will rise near three feet high, putting out several small side-branches; these are hairy, as are also the leaves; which are about three quarters of an inch long, and half an inch broad, standing by pairs upon very short footstalks; the flowers come out in small bunches from the side of the stalks; are small, of a dull purple colour, and have a sweet scent. It flowers in the summer, but does not produce seeds in this climate. It is a native of the Cape.

In the third sort there is a variety with smooth leaves and stalks, which comes from the Cape.

Method of Culture.—These plants may be easily increased by layers made from the young wood in the early spring or summer season. When they are fully rooted, they may be taken off, and planted out, the first or hardy kind, either where they are to remain, or in the nursery, to be afterwards removed; and the two last, or tender sorts, into pots, to be protected during the winter. The first sort likewise often succeeds by cuttings, and also the two last by the use of the hot-bed.

But they may all be increased also, by sowing the seeds procured from abroad in pots of light earth, plunging them in the hot-bed. They should all be placed near support, to prevent their trailing upon the ground and fading among other plants.

Where the two last sorts are kept continually plunged in the tan-bed of the floor, they thrive and flower much better than in any other situation; but they should not be kept too warm in winter, and in the summer they should have a large share of free air admitted to them; for when they are kept too close their leaves will be covered with insects, and the plants become sickly in a short time.

The first sorts only require a little protection in the winter. They all afford variety among potted plants in general.

Periplus, /περιπόλοσ, a voyage, or navigation, round a certain sea or sea-coast. Arrian has described all the coasts of the Black sea, after having inspected them in quality of general of the emperor Adrian; to whom he dedicates the description, under the title "Periplus of the Euxine sea.''

The "Periplus Hannonis" is one of the most curious fragments transmitted to us by antiquity, and it is the only authentic monument of the Cartaginian skill in naval affairs. But some doubts have been entertained concerning its antiquity. (See Africa.) The periplus of the Erythisean sea was published by Dr. Vincent. See also Africa.

Periplysis, a name given by some authors to a diaphyra, in which the fruits are extremely thin and watery, and very frequent, and large in quantity.
PERIPNEUMONY.

PERIPNEUMONY, in Medicine, from περιν, and πνεύμων, the lungs, is an inflammation of the lungs and their investing membrane.

The peripneumony (peripneumonia) has been commonly distinguished by medical writers from the pleurisy (pleuritis); the former appellation being applied exclusively to inflammation seated in the substance of the lungs themselves; and the latter to inflammation affecting the pleura, or investing membrane of the lungs, as well as its doublet, which lines the interior surface of the cavity of the chest. This distinction, however, is of little moment; for, as Dr. Cullen observes, "neither do our diagnostics serve to ascertain exactly the seat of the disease, nor does the difference in the seat of the disease exhibit any considerable variation in the state of the symptoms, nor lead to any difference in the method of cure." We shall, therefore, treat of pulmonary inflammation as one disease, in the symptoms of which there may be some shades of difference in different cases, but to which it is scarcely necessary to appropriate different names.

Few diseases are so distinctly characterized by their symptoms as simple inflammation of the organs of respiration. However various its seat, or its degree of violence, it is accompanied by these four symptoms; namely, fever, difficult breathing, cough, and pain in some part of the thorax. These symptoms may be variously modified, in different instances; but they are all invariably present, where the lungs or their investing membrane are affected with inflammation.

The disease almost always begins with a cold stage, that is, with more or less chills and shivering; and this is speedily followed by increased heat, frequency of pulse, depression of strength, and other symptoms of what is called fever. Sometimes, however, the increase of the fever is very gradual, and the symptoms at first moderate, and the peculiar pectoral symptoms do not immediately appear; but frequently these symptoms accompany the fever from the beginning. For the most part the pulse is frequent, full, strong, hard, and quick; but, in a few instances, especially in the advanced state of the disease, it is weak and soft, and at the same time irregular.

The difficulty of breathing is always present, and the oppression is greatest in the act of inspiration; both because the air-cells of the lungs, being compressed by the turbidity of the blood-veils, do not easily admit of a full dilatation, and because the dilatation and distention of the inflamed membranes aggravate the pain attending the disease. The difficulty of breathing is somewhat varied by the posture of the patient; it is generally greater when he lies upon the side affected; but sometimes the contrary happens; and often he cannot lie easy upon either side, and can breathe only with ease, when lying on his back; and sometimes the oppression becomes so great, that he cannot breathe easily, except when in somewhat of an erect posture. This orthopnea, as it is technically called, implies a dangerous degree of violence, although to a careless observer, the circumstance of the patient sitting up (when, in fact, he is unable to lie down) might lead to an inference, that the disease was moderate. The greater facility of respiration in the erect posture, under such circumstances, is the result of the more easy descent of the diaphragm, when the abdominal viscera no longer press it upwards, and the consequent more free dilatation of the lungs.

A cough is also an invariable attendant on peripneumony; but in different cases, it varies much in its violence and urgency, and in the pain which it occasions. It is sometimes dry, that is, without any expectoration, especially in the beginning of the disease; but it soon becomes moist, from the great effusion from the turgid veils, and more commonly it is moist even from the first. The matter expectorated is various both in consistence and colour, and frequently it is streaked with blood; sometimes, indeed, blood is brought up in considerable quantity, yet without the injurious consequences attending an ordinary hemoptysis.

The pain accompanying this disease, is, in different cases, felt in different parts of the thorax, but most frequently in one side. It has been said to affect the right side more frequently than the left; but this is by no means certain. Sometimes it is felt as if it were under the sternum, or breast bone; sometimes in the back between the shoulders; and sometimes darting from the one to the other. When the pain is in the sides, its seat is very various; but the part of all others most frequently affected, is about the sixth or seventh rib, near the middle of its length, or a little more forward; in which situation it is often severe and pungent; while, in others, it is often more dull and obtuse, with a sense of weight rather than of actual pain. In general it continues fixed in one place; but sometimes it shoots from the side to the shoulder-blade, on one hand, or to the sternum and clavicle on the other.

This varying state of the symptoms has been assumed as the foundation of the different apppellations given to pulmonary inflammation, and especially the different degree of acute and chronic inflammation of the lungs, of hardness or softness is the pulse, and of the oppression of respiration. An acute or fibrillary, fixed in one point of the side, and remarkably increased by the act of inspiration, and still more by that of coughing, together with a hard pulse, and a dry cough, at first, is considered as characterizing an inflammation seated in the pleura, surrounding the lungs, or lining the ribs; and therefore constituting the pleurisy: while on the other hand, an obtuse and deep-seated pain in the breast, not remarkably increased by respiration, which is constantly oppressed, and often requires an erect posture, together with a pulse often soft, and frequently with a taut and livid countenance, is deemed indicative of inflammation in the substance of the lungs, and therefore called more specifically peripneumony. But although an attention to these different forms of the disease is necessary, as they afford important indications in respect to the prognosis, yet there is little foundation for referring the disease to a different seat in these cases. It seems probable, as Dr. Cullen judiciously suggests, that every acute inflammation begins in membranous parts; and in every diffusion of peripneumony pleurisy, both the surrounding membrane and the substance of the lungs appear to have been affected in the inflammation. In short, wherever the disease begins, it appears to be communicated speedily to the other parts of the organ.

Some writers have given a particular apppellation (parapneumony) to an inflammation of the pleura, covering the upper surface of the diaphragm, and have supposed it to be attended with peculiar symptoms of delirium, rigor farinosus, and other convulsive motions; but it is certain, that an inflammation of that portion of the pleura, and affecting also even the muscular substance of the diaphragm, has often taken place without any of these symptoms; nor have any deflections, or authentic records of deflections, afforded any support to the opinion, that an inflammation of the pleura, covering the diaphragm, is attended with delirium, more commonly than other pulmonary inflammation. See PARAPNEUMONY.

The causes of peripneumony are very well known. Perions
PERIPNEUMONY.

of a considerable vigour of constitution are most liable to be attacked with it; whence, although it may affect any age and either sex, it seldom occurs before the age of puberty, and most commonly in the middle age of life, from thirty-five to fifty-five, more frequently in men than in women, and seldom in those who are sedentary, or delicate from any other cause. Previous diseases of the lungs, such as asthma, or the preface of a deformed chest, and particularly the previous occurrence of peripneumony itself, occasion a predisposition to this inflammation.

Among the occasional causes, cold is certainly the most common, especially sudden and great vicissitudes; whence peripneumony is most frequently seen in the winter and spring, and in cold climates. Like all the other organs of the body, the lungs are liable to be inflamed by violence, or by whatever obstructs, irritates, or otherwise injures their structure: whence blows on the chest, falls, &c., sometimes produce peripneumony; great exertions of the voice or breath, such as loud and long-continued speaking, singing, or playing upon wind-instruments, or even violent exercise, occasionally excite the disease; excessive intemperance was also remarked by Hippocrates as one of the causes of pneumonic, as of other inflammations. Sometimes peripneumony occurs as a symptom of other inflammatory fevers, especially of the measles and small-pox; and in many cases, it originates from common catarrh, by an extension of the inflammation from the mucous membrane of the bronchiae to the substance of the lungs. Sometimes again it originates from metaplasia, as it is called, of gout, rheumatism, erysipelas, &c.; or at least, it comes on suddenly at the time when the external symptoms of these diseases disappear. Cold, under certain conditions of the atmosphere, has occasionally given rise to the disease, in great numbers of people at the same time, so as to produce a sort of epidemic peripneumony, and even to excite a fulpicion of its depending upon contagion.

Inflammation of the lungs may terminate either in health, in death, or in some other disease. It terminates in health, by what is called the resolution of the inflammation. This proves, however, seldom takes place without being attended by some evident evacuation. In some rare instances, a spontaneous hemorrhage from the nose, occurring early in the disease, has put a period to its course; or a copious diarrhea has had the same effect: but these are not to be looked for. The evacuation most frequently occurring, and apparently the most effectual in promoting resolution, is an expectoration of a thick white or yellowish matter, often a little streaked with blood, and which is brought up copiously, and without violent coughing. If the violence of the inflammation is not subdued, it goes on to a fatal termination, or to end in some other state of disease. One termination, by which it ends fatally, is peculiar to inflammation in this organ; namely, an effusion or extravasation of blood and coagulable lymph into the interstitial substance of the lungs, which, by compressing at once both the air-cells and the blood-vessels, interrupt both the breathing and the circulation, and produce a fatal suffocation. The most common termination of pneumonic inflammation, when it is fatal in the early part of its course, seems, however, to be in an effusion of the coagulable lymph only into the cellular substance of the lungs, producing a similar compaction. In other cases, the functions of breathing are interrupted by a profuse effusion of viscid mucus into the air-cells and bronchial passages, by which the access of air is prevented.

Where peripneumony goes through its course, it is apt to terminate in other diseases, especially in suppuration and abscesses. This is itself becomes a formidable malady, and, unless the constitution of the patient be vigorous, and the abscess opens into the branches of the trachea by a small aperture, is often fatal. These abscesses, when they take place in the substance of the lungs, are called venoms: they sometimes consist of small cavities containing pus; and at other times the cavities are very large, so that the greater part of the substance of the lungs has been destroyed. Where they open into the cavity of the chest, emptying their contents there, the disease called empyma is produced. Sometimes, however, empyma is formed by an inflamed state of the pleura, exterior to the lungs. In either case, the pus may be accumulated in the whole cavity of the chest, or it may be confined to a part of it by adhesions taking place between the lungs and the pleura, which invells the ribs; but when pus is evacuated into the cavity of the chest, by the burting of an abscess in the lungs, it is almost always confined within certain limits by adhesions. See Baillie, Morbid Anatomy, p. 52.

These adhesions of the lungs to the ribs, or, more properly speaking, of the pleura invelling the lungs to the same membrane lining the chest, are among the common consequences of pneumonic inflammation. Sometimes they extend over the greater part of the chest, and, tying the lungs closely to its paries, produce a permanent difficulty of breathing, with a cough. Sometimes, however, they are only partial, and loosely tied, so as not to impede the free motion of the lungs. Where the adhesions are considerable, and the inflammation has been severe, another formidable disease occasionally arises, namely, dropy of the chest, from the effusion of a large quantity of serum from the inflamed surface into the cavity of the former.

It may be mentioned as a singular circumstance, however, that anatomists seldom examine a body after death, in which some degree of adhesion between the lungs and the ribs is not found. "There would often seem to be slight degrees of inflammation in the pleura," says the able morbid anatomist above quoted, "where the symptoms above stated have not existed at all, or have been so obliquely marked as to be altogether overlooked. In examining the chest of adults after death, it rarely happens that adhesions are not discovered in some part of it, uniting the surface of the lungs to the pleura, which lines the paries of the chest. The marked symptoms of pleurisy, however, are by no means so frequent. It seems, therefore, probable, that slight inflammations may attack the pleura; sufficient, however, to throw out coagulable lymph, which is afterwards changed into adhesions, and yet persons shall not be sensible of any disease in the chest." Morbid Anat. p. 58.

A termination of peripneumony in gangrene is mentioned by authors; but we have never seen or read of any well-authenticated instance of such a termination.

The accuracy of prognosis, in the early stages of peripneumony, is of considerable importance; hence, if the opportunity of employing active remedies he passed by, it is not easy to retrieve the injury. The danger of the disease in the early stage is chiefly to be estimated by the degree of difficulty in the respiration. When the patient can lie on one side only; when he can lie on neither side, but upon his back only; and still more, when he cannot breathe with tolerable ease, except the trunk of his body be erect, the progressive impediment to the breathing will be obvious. And if, even in the erect posture, the breathing is extremely difficult; if there is also a turgescence, and flushing, or purplish hue of the face, together with partial sweats about the head and neck, and an irregular pulse; the danger of the disease is extremely great. It will be yet more alarming, if any degree of delirium or confusion of the ught occur, or if the patient speaks merely of general indisposition, without referring
PERIPNEUMONY.

referring his sufferings to any particular organ. Under such circumstances, even where there is little apprehension on the part of the patient, and when his strength is not materially sunk, death often speedily ensues.

The violence of the fever may always be considered as an indication of a violent disease, as well as an acute pain, very much interrupting inspiration; but these are not more inquisitive of danger, than an obtuse pain, with a weak opressed pulse, and very difficult respiration. When the pains, which at first had affected one side only, have afterwards spread into the other; or when, leaving the side first affected, they entirely pass into the other; there are always marks of an increasing, and therefore of a dangerous disease. As the inflammation is seldom resolved without some expectoration, so a continued dry cough is always an unfavourable symptom: but a sudden cessment of the expectoration, after it had already commenced, is indicative of still more danger; as it implies either a great diminution of the patient's strength, or a renewed augmentation of the inflammation. A copious yellowish expectoration, tinged with blood, is therefore to be deemed favourable.

When peripneumony terminates fatally, this event most commonly happens within the first week, some time between the third and seventh days from the attack. Nevertheless, it is not unusual for the disease to undergo a remission within the same period, which may prove fallacious, and the violence of the disorder may be renewed with greater danger than before. Hence it occasionally happens, that the disease terminates in death in the second, third, or even fourth week, after several remissions and aggravations; a circumstance which should teach us, that we should not measure the activity of our remedies according to the period of the disease, but according to the actual condition of the symptoms.

When, however, a peripneumony has continued steadily for many days, with its symptoms neither very violent nor very slight, and without any marked remissions, suppuration is certainly to be apprehended. This, however, is not to be determined by the number of days; for instances of resolution have occurred as late as the tenth day, and even at a much later period, where great remissions have occurred. But if, during a steady continuance of the symptoms for ten or twelve days, no signs of a resolution have appeared; and if the difficulty of breathing have increased, while the pain and other symptoms have somewhat abated; and, at the same time, the expectoration, which had begun, have again ceased, suppuration must be confidently expected. When suppuration is actually begun, the patient is affected with frequent rigors or shiverings, and with a sense of cold felt in different parts of the body; the pulse a'fo becomes less frequent and weaker, but sometimes fuller than before, and occasionally quicker; and the patient can now lie more easily upon the affected side than upon the other. As the suppuration proceeds, there is a considerable remission of the pain, which had before substan. While at the same time the cough, and more especially the difficulty of breathing, continue, and are rather augmented. The frequency of the pulse is now rather increased, and the feverish state suffers considerable exacerbations every evening, and by degrees a hectic in all its circumstances is formed. When the abscess is fully established, there is sometimes a very evident enlargement of the side where the matter is accumulated. If it assume the form of empyema, the abscess must ultimately break and discharge its contents, either into the cavity of the chest, forming the abscess just named, or into the branches of the trachea (windpipe). In the former case, it may be sometimes dis- charged either by a natural ulceration of the intercostal parts, or by a surgical operation. (See Empyema.) In the latter, and more common termination, the patient may be sudded by the sudden bursting of the contained pus into all the bronchial passages; or a copious purulent spitting may ensue, by which the abscess may be more gradually and safely emptied. Nevertheless, this mode of termination is more frequent in a small number of individuals, of robust habit, this course of purulent expectoration, and the hectic that accompanies it, will be fulfilled until the abscess heals; yet, in the majority of cases, all the symptoms of true pulmonary consumption ensue, and the patient dies, worn out with the perpetual irritation and discharge.

Of the Cure of Peripneumony.—The extreme importance of the lungs in the living body, as the seat of a function the most necessary to life, and the obvious danger, just described, of allowing inflammation to proceed to suppuration, even after the more early fatality of this disease has been avoided, equally prove the necessity of an early and vigorous employment of remedies, when the symptoms of peripneumony or pleurisy occur.

The remedy chiefly to be depended upon is blood-letting, freely and early employed. The quantity of blood drawn must of course be regulated by the violence of the disease, and the vigour of the patient's constitution, and ought generally to be as large as this last circumstance will allow. The remission of the pain and the relief of the respiration, during the flowing of the blood, may limit the quantity to be then drawn; but if these symptoms of relief do not appear, the bleeding should be continued until some degree of stiffness and faintness, the signs of approaching lycopenes, come on. This direction is as old as the writings of Hippocrates. It will often happen, that one bleeding, however copious, will not prove a cure of the disease: for although the pain and difficulty of breathing may be much relieved by the first bleeding, these symptoms very frequently recur after a short interval, and often with as much violence as before. In the event of such recurrence, the bleeding must be repeated, even in the course of the same day, and perhaps to the same quantity as before. Sometimes the second bleeding may be larger than the first. There are persons who are constitutionally liable to faint even upon a small bleeding; and, in such persons, this may prevent the drawing of so much blood at a time, as a purmonic inflammation may require; but as the same persons are frequently found to bear subsequent bleedings better than the first, these may be carried to the extent which the symptoms of the disease seem to demand. For it is according to the state of the symptoms, that the bleedings must be determined to be repeated; and they will be more effectual, when employed in the course of the first three days, than afterwards; but they are not to be omitted although four or five days may have elapsed, before the physician is called in; nay, if there be a recurrence of the urgent symptoms, as described above, the bleeding should be repeated at any period of the disease, especially within the first fortnight, and even afterwards, if a tendency to suppuration be not evident, or if, after an apparent solution, the disease shall have again returned.

There is in peripneumony, as in some other acute inflammations, a state of pulse occasionally recurring, which, to an inexperienced practitioner, appears to contra-indicate the use of the lancet: it is soft, and small, or what has been called an oppressed pulse; but it rises, and becomes fuller and larger after blood-letting. Under such circumstances, the propriety of the blood-letting is to be determined, by
the urgency of the other symptoms, especially of the difficulty of breathing. In a similar manner, a pulse that is irregular, and beats with considerable intermissions, in peripneumony, will become regular after the relief of blood-letting; and such a state of pulse, therefore, when the pneumatic symptoms are urgent, is not to be considered as contra-indicating, but as more strongly demanding the use of the lancet.

With respect to the quantity of blood which ought, or which with safety may be taken away, no general rules can be delivered; as it must be different according to the state of the dis ease and the constitution of the patient. In an adult male of tolerable strength, a pound of blood, avoirdupois, is a full bleeding; any quantity above twenty ounces is a large, and any quantity below twelve, a small bleeding. Sydenham was of opinion, that the average quantity of blood necessary to be drawn for the cure of pleurisy, was forty ounces; but this must differ widely in different cases. If the bleeding be performed on the first or second day, perhaps a single bleeding of fourteen or sixteen ounces may be sufficient to effect a cure; but if it be delayed, several repetitions of the operation may be necessary, and a strong man will bear the loss of even five or six pounds, in the course of two or three days.

When a large quantity of blood has been taken from the arm, and then, from the state of the patient, the safety of a repetition of that evacuation is doubtful, some blood may be still taken locally, by means of leeches, or cupping. From the flowwet of the operation of leeches, the cupping is commonly to be preferred. This local blood-letting will be particularly proper, when the continuance or recurrence of pain, rather than the difficulty of breathing, becomes the urgent symptom; and then the cupping and scarifying should be performed as near to the seat of the pain as possible.

Fomentations and poultices to the part pained have been recommended, and may be useful; but the application of them is often inconvenient, and certainly much less beneficial than that of blisters. Very early, in the disease, a blister should be applied as near to the pained part as possible. But, as when the irritation of a blister is present, in the height of the inflammation, it seems to render bleeding less effectual, so its application should be delayed till blood-letting shall have been employed. If the disease be moderate, the blister may be applied immediately after the first bleeding; but if the disease be violent, and it is presumed that a second bleeding may be necessary soon after the first, it will then be proper to delay the blister till after the second bleeding, when it may be supposed that any further bleeding may be postponed, till the irritation arising from the blister shall have ceased. It may be frequently necessary in this disease to repeat the blistering; and, in that case, the plasters should always be applied somewhere on the thorax; for, when applied to more distant parts, they have little effect. Experience has proved, that keeping blistered parts open, or making what is called a perpetual blister, has much less effect than the repeated counter-irritation of a fresh blister.

Blisters are always safe; they do not weaken the patient; neither do they tend to interrupt the expectoration. Expectoration does sometimes take place early in the disease; but, at that period, if the symptoms continue urgent, the solution of the disease cannot be trusted to the expectoration; neither has the bleeding been found then to diminish it; on the contrary, it is often observed to promote it. It is only in the more advanced stages of the disease, when the patient has been already much debilitated by large evacuations, and by the continuance of the disorder, that bleeding seems to stop expectoration; but under such circumstances, the bleeding is on every account improper.

While these evacuations are referred to, it must be obviously necessary to adopt most rigorously what has been called the "antiphlogistic regimen"; to exclude every thing flatulent or fennilitic, both in quantity and quality, from the food and drink; to supply the patient with light diet and acidulated fluids; to keep him entirely at rest, and to interdict him from unecessary talking; and particularly to prevent the irritation which might arise from any increase of heat. For this purpose, it will be proper to keep the patient out of bed, while he can bear it easily; and, when he cannot, to cover him very lightly while he lies in bed; the temperature of his chamber should be kept uniformly cool.

Some practitioners, apparently upon theoretical grounds, have objected to the use of purgatives, upon the supposition that the evacuation which they occasion may tend to suppress the expectoration; but in the vigour of the patient and of the disease, such an apprehension is absolutely groundless. On the contrary, the free evacuation of the bowels, by costing purgatives, conduces, like the blood-letting, to diminish the local and general inflammatory action. In the turgid and loaded state of the lungs, the framing of vomiting is likely to be productive of mischief, and can answer no useful purpose; the practice of exhibiting emetics, even in nauseating doses, is therefore to be deprecated, and is exploded by all judicious practitioners.

As the occurrence of a free expectoration is generally a favourable symptom, and often appears to put a termination to the disease, to various expeditious medicines, and other means of promoting this excretion, have been proposed. But none of these appear to be possessed of any efficacy; and some of them, being acrid stimulant substances, cannot be administered with safety. It is more than questionable, indeed, whether there is any sub stance in nature, whichpossesses a direct expectorant power. (See Expectorant.) The gums, such as ammoniacum, myrrh, &c. usually employed, are too heating to be given in an inflammatory affection; and quills, &c. though lefs stimulant, have no power, perhaps, independent of the nausea, which they may produce.

This inhalation of the fumes of warm water, after the violence of the inflammation is subdued by blood-letting, has been found to afford considerable relief to the cough in many cases; but, in some, it has appeared to aggravate the distempers.

One of the most pernicious pieces of practice, which is apt to be referred to by the ignorant and inexperienced, is the administration of opiates, with a view to allay the cough, in the beginning of the disease. The effect of such medicines is directly the reverse; for they increase theoppersion, and difficulty of breathing, and all the inflammatory symptoms. In a more advanced stage of the disease, however, when the highly febrile condition and the difficulty of breathing have been in a great measure subdued, and when the urgent symptom is an irritating cough, occasioned by the acrid mucus, and proving the chief source of the continuance of the pain and of want of sleep, a judicious employment of opiates often affords great relief. Although they moderate the cough, they actually promote expectoration, at this period of the disease; for, by occasioning a temporary stagnation of the thin fluid, which was diffused diffusely by frequent coughing, they produce a thickening, or what physicians have called a conceited state
PERIPNEUMONY.

state of the matter, which is more easily discharged. Mucilaginous and oily humours contribute in some measure, though in a much more trifling degree, to the same purpose, by allaying the acrimony of the mucus, which occasions too frequent coughing, and by befocing and defending the fancies from its irritation.

PERIPNEUMONY, Buffard or Spurious, the Peripneumonia notha of medical writers, was not very accurately distinguished till modern times; and the fagacity of Sydenham fuccefs has led him to the first diagnosis of the complaint. Nevertheless, even he left it under considerable obscurity, so that the term has been often employed without a definite acceptance. We shall first describe the symptoms, and then endeavour to point out the pathology of the disease.

The peripneumonia notha most commonly attacks persons that are few, or what advanced in life, and who are of a full phlegmatic habit, but most particularly those who have been frequently subject to catarrhal coughs, attended with much expectoration. It often makes its attack like the habitual catarrh, from which it cannot at first be distinguished. In other cases it comes on with languor, repletion, and thievings, alternating with fits of heat. The patient soon finds himself oppressed in his breathing, and complains of a sense of weight, fomere, and constriction in the chest, which is sometimes accompanied by an obtuse pain. The respiration is more frequent than natural, and is performed with a slight wheezing noise; and if the patient be defired to make a deep inspiration, and to expand the chest to its full capacity, his effort is either interrupted by a fit of coughing, or, if accomplished, his uneafiness is increased, and the pain, if any existent, is aggravated. At the same time with the difficulty of breathing, or soon after, a cough commences, which is often at first unaccompanied by expectoration; but this soon follows, and in many cases a considerable quantity of a white viscid mucus is brought up. The cough, when it becomes frequent and violent, is very generally attended with a peculiar rending head-ache, over the eye-brows, which is intolerably aggravated by every fit of coughing, giving a fentiment, as Sydenham remarks, as if the head were torn in pieces.

The functions of the mind are in general but little disturbed in peripneumonia notha. There is often, however, a considerable degree of vertigo, accompanied with much flushing of the face, and not uncommonly a degree of drowsiness, which the patient is unable to account for. The frame exhibits no invariable deviation from the usual state, although it does not affume the dry coat of acute peripneumony. The digestive powers are at a stand; the patient is not merely indifferent to food, but he commonly latches it as much as in idiopathic fever; he has thirst, but it does not appear to be urgent. The urine is conflantly loaded, turbid, and highly coloured. The pulse in this disease is not fo correctly the measure of its urgency and violence, as in some others: it is always frequent, with some degree of sharpness; but it is at the same time small and feeble. The blood, when drawn, however, shows a bloodyafe, as in other inflammatory affections.

There is often considerable uncertainty with respect to the prognosis of this disease. For although it often goes on like a common catarrh, of greater violence than usual, and, after the employment of some remedies, is entirely relieved by a free and copious expectoration; yet sometimes a violent exacerbation of the symptoms suddenly takes place, and terminates the life of the patient, when the previous indications of danger had not been very evident. Where the expectoration is free, although the excretion be copious, and when the breathing at the same time is little oppressed, a favourable issue may be commonly anticipated. But on the other hand, the disease often proves fatal in consequence of a redundant secretion of the mucus, rapidly clogging up the bronchial passages, and producing suffocation. This occurs especially in those persons who are advanced in years, and where lungs have been left in a relaxed state by previous attacks of the disease: for this complaint in a remarkable manner generates a predisposition to future attacks.

There is another termination of peripneumonia notha, which probably every practitioner has observed, and which has been well described by Dr. Badham. It sometimes becomes," says this author, "the origin of a spurious consumption; and it is no uncommon thing to confume the violence of the symptoms, and yet not to conquer the disease. The patient recovers, perhaps, a little strength, and leaves his bed, but his respiration is uneasy and oppressed. The cough and pitting, though mitigated in violence, continue to harass him: his pulse becomes more feeble and frequent, and a general debility takes place, attended with a decided loss of flesh. He becomes subject to irregular sweats, and in the course of a few months the emaciation often makes rapid advances. A person who sees this complaint after it is formed, and some time established, is ready to conclude, that he has to do with phthisis pulmonalis; but if he be able to trace it from its origin, he will discern that it is an affection essentially different from consumption, however strong the resemblance in external character. There are also materials for diagnosis. The author has known patients in an extreme state of debility and emaciation, consequent to bronchial inflammation, diffuse the chest to its full capacity without feeling much uneainess, and not any pain, because the substance of the lung is not diseased. They lie down in bed much more easily than consumptive patients, have no shuddering pains in the chest, and though they sweat, there is nothing like the profuse discharge from the skin, which produces the solution of the hectic paroxysm. The appearance of the sputa might perhaps be taken into the account; but this cannot be exclusively depended upon." Badham, on the Inflammation of the Mucous Membrane of the Bronchis, P. 45.

The exciting causes of the spurious peripneumony are the same with those which produce the more common varieties of catarrh, namely, vicissitudes of the atmospheric temperature. The disease is, however, more frequent about the commencement of winter, when the cold suddenly sets in. We have had numerous opportunities of observing the effects of sudden change of temperature, in the months of November and December. In producing this disease: and have seen the same individuals attacked, year after year, with a violent chronic catarrh, accompanied with a profuse excretion of mucus, until at last, as the lungs became more and more debilitated, the annual attack put on the character of peripneumonia notha, by which many such patients are carried off. The disease is most prevalent in damp and foggy feasons, and it is common during the occurrence of epidemic catarrh, or influenza.

Some difference of opinion has prevailed, as to the precise nature of the affection of the lungs, which constitutes the spurious peripneumony. Diffusion of persons who have been destroyed by the disease, has always exhibited the bronchial cells and tubes loaded with a thick or puriform mucus, and commonly also bearing obvious marks of inflammation in the lining membrane. When this is considered, as well as the fact, that the disease is certainly often a common catarrhal affection at first, and that a catarrh is a mere inflammation of the mucous membrane of the bronchus, and, in old or relaxed habits, is frequently attended with a large excretion of mucus, little doubt can be entertained that the disease consists in an inflammation of the lining membrane of the
the bronchial passages and cells; in other words, that it is bronchitis, as Dr. Badham has correctly termed it. The disease, then, must be considered as differing from catarrh in the more extensive spreading of the inflammation, and in the more debilitated condition of the habit, and of the lungs in particular, of the patients in whom it commonly occurs. And it differs from pleurisy and peripneumony, inasmuch as the former is confined to the membranes, or covering, membrane of the lungs, the bronchial membrane being but slightly and secondarily affected. In like manner, perhaps, the inflammation of the mucous membrane, in peripneumonia notha, may, in its more acute degree, extend secondarily and partially to the parenchyma of the lungs, and thus produce an aggravated disease, in fact, a complication of the spurious with the true peripneumony.

The treatment of peripneumonia notha will of course be necessarily varied in different cases, in proportion to the age and vigour of the patient, and according as the symptoms approach more or less to those of the true peripneumony. When the inflammatory symptoms are considerable, indeed, the treatment in the two complaints differs only in degree.

In consequence of the great tendency to effusion, however, in all cases of the spurious peripneumony, and of the advanced age and relaxed habit of body in which it commonly appears, blood-letting must be employed with much caution. It is sometimes proper, indeed, to begin with a moderate blood-letting; but after the inflammatory symptoms have to a certain degree yielded, it is advisable to attempt the cure by an attention to diet, proper expectorants, and local evacuations alone. There are few complaints, indeed, in the treatment of which more caution and discrimination are required, the inflammatory symptoms often urging the necessity of one set of remedies, while the tendency to effusion points out another of very opposite effects. All that can be done in such cases, is to study with care the nature of the symptoms and the habit of body, and obviate that tendency which seems more immediately to threaten danger, but at the same time in such a way as shall as little as possible increase the opposite train of symptoms. The tendency to inflammation must be obviated with as little loss of strength as the nature of the case admits of; and that to debility, by means which tend as little as possible to excite irritation and increase the complaint. After all that can be said, therefore, much must depend on the discretion of the practitioner.

As general blood-letting can seldom be resorted to, without the risk of eventually increasing the complaint, we must endeavour to supply its place by the more affusive use of local remedies, especially by local blood-letting and blisters. Where the disease approaches to the nature of peripneumony, leeches or cupping glasses, after scarification, may be applied to the chest. Blisters, however, are safe and useful in all cases, when applied to the thorax, and should not be omitted. The use of moderate purgatives seems to afford a safer mode of evacuation in peripneumonia notha than blood-letting. Dr. Cullen, indeed, is doubtless of their efficacy; but Sydenham assures us that, according to his experience, they are more useful than in the true pneumonia. The refult of general experience, however, seems to be, that mild cathartics only, or styphers, are proper in this disease; for, although it is of great consequence to prevent irritating matter from lodging in the alimentary canal, yet much or frequent evacuation is found hurtful.

The beneficial effects of emetics in this complaint, in which the freedom of the expectoration is a matter of great importance, might be anticipated, and experience confirms the expectation. Nor is their tendency to promote perspiration, which, if general and not profuse, nor brought out by heat-measures, is far the most favourable, to be overlooked. With respect to the other medicines, denominated expectorants, which are often recommended in these bronchial affections, we have already stated how little efficacy they possess, which merits the appellation. (See Expectorants.)

The more mitant articles of this class, such as the salicylic gum-resin, ammoniac, aëris fructa, &c. may be productive of some benefit; but when a copious flow of the complaint continues, they are but too hot to be admissible, where the inflammatory condition is still present in any degree. The ipecacuanha, or the squill, in its preparation with vinegar, are more applicable; but they are, perhaps, chiefly efficacious by the degree of nausis which they excite, and therefore rather belong to the class of emetics.

Where the mucus is extremely thick and viscid, the inhalation of the steam of warm water contributes to facilitate expectoration, by diluting the phlegm. Little, however, is to be expected from ground-ivy, hyssop, and some other popular peptoral medicines. If they produce any actual alleviation of the cough, it is probably merely in consequence of the mucilage which they contain, which, like the various emulsions, liquificates the phlegm, and relieves the irritation of the cough, by blunting the facies, and shielding the passages from the acrimony of the mucus.

Purgatives, which are in fact opiates, are too often resorted to injudiciously in this disease, and it is necessary to enforce much caution with respect to the employment of these medicines in spurious peripneumony. They act by lessening the sensibility of the diseased parts to the irritation of the accumulating excretions of the lungs, and thus interrupt for a time the efforts to expectorate, and at the same time they interfere, as it were, a veil between the actual state of disease and the observer, and deceive him as to the quantity of the excretion. But the great evil is, that, during the interruption to expectoration which opium occasioned, if the fluid be still copiously poured into the bronchial passages, and the strength be much reduced, the lungs become clogged up, beyond the powers of the patient to unload them, and the danger of actual suffocation is aggravated, or absolutely brought on. It is only, therefore, after the inflammatory affection, and the febrile state of the constitution is gone, and nothing but irritability remains, that opiates may be used at the discretion of the practitioner.

Where the strength appears to be much funk, cordials and stimulants can scarcely be ventured upon, so long as any inflammatory symptoms remain; preparations of the bark are generally hurtful, and even wine, diluted with water, though less irritating, can only be admitted in cases, when the patients, as often happens, have been long habituated to the use of stimulating liquors. The only safe mode of supporting the strength, is by the cautious but affusive administration of light, liquid, vegetable food. For so long as a fever remains, the antiphlogistic regimen is indispensably required. See Cullen, First Lines, lec. 379. Wilton, on Febrile Diseases, vol. iv. chap. 11. Badham on Inflamm. Afections of the Bronchius, chap. iii. Alfo, Boerhaave, Aph. 867, with Van Swieten's Commentary; Sydenham, Op. lec. vi. cap. 4. Morgagni, de Sed. et Causis Morbos, epift. xxii, art. 11-15.

PERIPOLIUM. In ancient Geography, a town of Magna Graecia, in the part called Bruttium. It belonged to the Locrian-Epizephyrians, on the banks of the small river Alex or Halas.

PERIPTERE, περιπτέρε, formed of περι, about, and πτερ, wing; q. d. winged on every side, in Ancient Architecture, a building encompassed on the outside with a series of
of inflatile columns, forming a kind of ile, or portico, all around.

Such were the haflicas of Antonine, the epitom of Severus, the portico of Pompey, &c.

Peripteres were properly temples which had columns on all the four sides; by which they were distinguished from prothyta, and amphiprothyta, the one of which had no columns before, and the other none on the sides.

M. Perrault observes, that periptere, in its general sense, includes all the specific of temples which have porticoes of columns all around, whether the columns be diptere, or pseudo-diptere, or simple periptere; which is a species that bears the name of the genus, and which has its columns distant from the wall by the breadth of an inter-columnation. For the difference between periptere and peristylo, see Peristylo.

PERIPYEMA, from περιπυ, and τοα, πα, in Surgery, a collection of matter around any part.

PERIRHANTERION, περιρράντηριον, in Antiquity, a vessel usually of stone or brass, filled with holy water, with which all those who were admitted to the sacrificial were sprinkled, and beyond which it was unlawful for any one that was βίβλος, or profane, to pass. Some say it was placed in the αἴων, or inmost recedes of the temple, into which none entered but the priest; but Cæsareon will have it to be placed at the door of the temple, which opinion seems more probable, because all persons who were εντόλης, or unpolluted, were permitted to pass beyond it.

PERISCEPASTRUM, from περι, and σκεπαστήρων, in Ancient Geography, an islet placed by Pliny on the coast of Ionia, a province of Asia Minor.

PERISABOR, a town of Asia, in an island of the Euphrates, according to Ammianus Marcellinus. Zofimus calls it Berabara, and says that it was well fortified, and that it was not inferior in grandeur to Cteiphon. It was situated S.E. of Sippasea.

PERISA, in Geography, a town of Persia, in the province of Irae; 50 miles S. of Hamadan.

PERISCEPASTRUM, from περι, and σκεπαστήρων, a wild onion, denotes, in Surgery, a particular bandage, which encircles the head in succelfive folds, like the layers of that bulbous root.

PERISCH, περισχ, q. d. circumambitus, of περι, about, and σκεπαστήρων, in Geography, those inhabitants of the earth, whose shadows do, in one and the same day, successively turn to all the points of the horizon.

Such are the inhabitants of the frozen zones, or those who live within the compas of the arctic and antarctic circles; for as the sun never goes down to them after he is once up, but moves always round about, to do their shadows; inasmuch that, in the same day, they have their shadows on all sides.

PERISCYLACISMUS, περισκυλακισμός, a method of purification in frequent use among the Greeks. It was done by drawing a whelp round the person to be purified.

The word comes from περισκυλακία, a whelp.

PERISCHYPHISMUS, from περι, and κυλια, gibbous, in Surgery, an incision made across the forehead, or from one temple to the other, over the coronal furrow, formerly practiced in considerable inflammations of the eyes. The lips of this wound were kept affixed with lint, and when the disordered abated, the denuded bone was rasped, and the wound healed. P. Ægineta, lib. vii. c. 7.

PERISSACHOREGIA, a term found in the Code, about the meaning of which authors are much divided.

Alicat, and some others, will have it to be the name of an office; viz. that of curator of the annona, or provisions, from περίσσακα, abundance, and γραφή, to lead, or bring. Others take it to be the office of a magistrato, who was to look to the augmentation of the annona, and the distribution of the same. Dom. Maecri will have it to signify a donative, or distribution made to the soldiers, over and above their pay, See Donative.

PERISSOLOGY, περισσολογία, in Rhetoric, a quality of style directly opposite to brachylogy, and is otherwise called macrology. See Macrology, Brachylogy, and Diction.

PERISSON, in Botany, a name given by the ancient Greeks, and afterwards by the Romans, in the time of Pliny, to a kind of nightshade, which makes those people who took it internally run mad. It was also called pentadryon, and anhydron, and by S. manicum, astrichnum, or simply manicum.

PERISSOSIS, a word used by Hippocrates to express a redundance of humour.

PERISTALTIC, in Anatomy, from περίσταλτος, to contrag, a term applied to the motions of the alimentary canal, by which its contents are carried forwards or backwards. See Intestine.

PERISTAPHYLIUS, a name given by some writers to two muscles of the soft palate. The peristaphylius externus is the circumflexus palatii; the internus is the levator palati. See Deglutition.

PERISTAPHYLO-PHARYNGEUS, a name given by Winlow to some fibres of the constrictor pharyngis superior. See Deglutition.

PERISTERITES, the Pigeon-flock, in Natural History, a name given by some whimsical people to an odd conformation of a pebble, which they suppose to represent very exactly a pigeon without its wings. It seems to have been a mere flatus nature, in the formation of a common pebble. The variations of figure in the common pebbles are to ininite, that a perdon of a fertile imagination might find refemblances to all the parts of the creation in the fones of a single gravel-pit. The giving names to such accidental things is not only unnecessary, but mischievous, as it causes great confusion in natural history.

PERISTERNA, in Anatomy, is used for the lateral parts of the thorax.

PERISTIARCHUS, περισταρχος, in Antiquity, a name given to the perdon that officiated in a lustration.

The word comes from περισταρχος, another name for χαρακτηρα, a demonstrator.

PERISTOMA, in Anatomy, a word used by authors to express the villous coat of the intellines.

PERISTOMIUM, in Botany, from περις, about, and τοα, the mouth, because it encircles the orifice of the capsule; see Fringe of Mosses.

PERistyle, περίστυλος, formed from περις, about, and τοα, column, in Ancient Architecture, a place or building, encompassed with a row of columns on the inside; by which it is distinguished from the periptere, where the columns are disposed withoutside.

Such was the hypsthre temple of Vitruvius; and such are now some haflicas in Rome, several places in Italy, and most cloisters of religious.

PERistyle is also used by modern writers for a range of columns, either within or without a building.

Thus we say, the Corinthian peristylo of the portal of the Louvre, &c.

PERISTYLN, περίστυλη, among the Athenians, a large square place, though sometimes oblong, in the middle of the gymnasium, designated for walking, and the performance of
PER

of those exercises which were not to be performed in the palestra.

PERSYSTOLE, περσύστολη, in Physiologia, the pause or interval between the two motions of the heart, or pulse; viz. that of the systole, or contraction; and that of the diastole, or dilatation.

PERITAS, in Geography, an island in the Spanish main; to miles W. of Cumana bay.

PERITHE, a name by which some of the writers of the middle ages have called the πυρίτης; they say it has great virtues against the gout; some of them also have called it the λαπίς περινούς.

PERITO, in Geography, a town of Naples, in Abruzzo Ultra; miles W.S.W. of Celano.

PERITONEÆOREXIS, from περιτόνευμα, the peritoneum, and ἐφικτότερος, to stretch round; the serous membrane which lines the abdomen, and covers the viscera contained in that cavity.

The abdomen or lower belly is a large cavity, containing the organs concerned in digestion, in the secretion and excretion of urine, and part of those employed in generation. It occupies the part of the trunk comprehended between the chieft and the lower extremities. We have to consider, in the anatomy of this part, the containing parts, sides, walls, or πυρίτης, as they are technically termed, and the contained organs, or the abdominal viscera.

The figure of the abdomen, viewed altogether, butadmits of any general description; more particularly on account of its connections with the chieft above, and the limbs below, which obscure its outline. We may distinguish, on the external aspect, an anterior and posterior, a superior and inferior, and two lateral regions.

The anterior region, called the belly in common language, is oblong and convex, particularly below. The whole of this diaphragm being formed of muscles and other soft parts, its figure is subject to all those changes, which the motions of the abdominal viscera in respiration, and in the various movements of the trunk, and the numerous alterations in the bulk of the organs, according as they are full or empty, must produce. The convexity of the belly is the least, when we lie horizontally on the back: it is increased in the erect attitude, because the pelvis altogether is bent backwards in relation to the upper part of the trunk; and it is still greater in the kneeling posture, because the spine is then more bent backwards, and the abdominal viscera thrown forwards. The abdominal muscles, particularly the recti, are thrown into an unpleasant state of tension in the latter position. When air is taken into the chest, the abdominal viscera are thrust forwards, so as to make the belly more prominent; and it falls again when air is expelled in expiration.

The middle and upper part of this region presents a superficial depression, called the scrobiculus cordis, or pit of the stomach; and a little below this, on the middle line of the abdomen, is a more or less depressed cicatrix, caerd the navel or umbilicus.

The front of the abdomen is subdivided into three regions; a superior, middle, and inferior, called the epigastric, umbilical, and hypogastric. The first begins at the end of the epiand cartilage, and extends to the level of a line drawn from side to side, between the most prominent points of the inferior boundary of the chest. The middle of this region is properly called the epigastrium, while the lateral divisions, covered by the ribs, are named the right and left hypochondria. The umbilical region reaches from the lower boundary of the epigastric to the level of a line drawn between the two cruriae of the osa innominata: the lateral portions of this division are called the flanks or sides. The remainder of the abdomen, below the line last mentioned, is the hypogastric region: this is sometimes divided into an upper and a lower: the middle of the former is the hypogastricarium, and the sides are the ilia: the middle of the latter is the region of the pubes, and the sides are the groins or inguina.

The arbitrary distinctions first indicated may be clearly shewn, by placing four ribbons on the body: two transversely, of which one crosses at the lower edge of the ribs, and the other at the cruriae of the osa innominata; and two perpendicularly, from the anterior and superior spines of the osa innominata to the edges of the chest. Thus the front of the abdomen will be divided into the nine parts enumerated already.

The pollerd region consists of two parts. The superior, called the loins, presents a middle depression, corresponding to the spinous processes of the lumbar vertebrae, and two lateral elevations, produced by the masses of the spinal muscles. The lumbar region, however, taken altogether, is concave from above downwards: this concavity is least in the recumbent posture, increases when we stand up, and is more considerable in proportion as we bend the chest backwards. The lower comprises two rounded prominences, formed by large masses of muscle, covered by a thick platum of fat, and called the buttocks. They are separated from each other by a longitudinal depression leading to the anus; and each is bounded below by a large fold, which distinguishes it from the rest of the thigh.

The upper region is not perceived externally; it is formed by the diaphragm, and corresponds exactly to the base of the chest. We have only to state here that it is convex, and slightly divided at the middle into two prominences; and that it is much higher in front than behind, rising as high as the eniform cartilage, and even above it in the former aspect, and flaxing from this to the lat ribs and lumbar vertebrae in the latter. For a more particular account of the form and relations of this boundary of the abdomen, which separates it from the chest, see Diaphragm.

The lateral regions are much less extensive than the anterior and posterior, with which they are continuous, and are defined by the lower edges of the ribs and the cruriae of the osa innominata. They are concave from above downwards, and convex from before backwards; and, as the sides of the abdomen are here, as in the front, formed by muscles, they are subject to changes from the same causes. The concavity is greater in the flaxing or upright, than in the recumbent posture. Above the lower edge of the ribs, the cavity of the chest begins; but the surface of the diaphragm lies in contact with that of the ribs, although they are both covered by the pleura, and the convexity of the upper region of the abdomen rises into the chest, and is covered behind and at the sides by the latter cavity. Hence a sharp instrument would pass in the intervals of the lower ribs, and through the diaphragm into the abdomen, without wounding the lung. See Lung and Diaphragm.

The inferior region of the abdomen presents at the two sides the attachments of the lower limbs; and in the middle, the generative organs and anus. The space between the two latter is called the perineum. (See Perineum.) The generative organs and anus are described under Generation and Intestine.

The abdominal parieties present the same regions on the inside: the anterior, covered throughout by the peritoneum, is concave and smooth, and contiguous to the abdominal viscera. The posterior affords attachments to the various viscera;
PERITONEUM.

The peritoneum is a serous membrane, which, heisides lining the cavity of the abdomen, covers the surfaces of most of the contained viscera, and forms, in order to arrive at these viscera, duplicatures or folds which fix them in their situation, and cover them. It forms also a means of conveying a notion of its arrangement with respect to the viscera, it has been compared to a bag without an opening, of which the superior, anterior, and lateral parts are not more extensive than is sufficient for covering the corresponding portions of the parieta; while the back, very large, not only covers the posterior part of the cavity, but is applied over the viscera, furnishing them an external investment. Hence it follows, that if it could be dissected off from all the viscera, we should have a large and entire bag, and see clearly that they are all on the outside of the bag.

We shall proceed, in the next place, to trace the course of the peritoneum, and follow it in the formation of its different folds.

It lines the concavity of the diaphragm, and passes from the posterior and inferior edge of the greater muscle over the appendices, the psoas, the lumbar vertebrae, aorta and vena cava, the spermatic vessels, the renal capsules, kidneys, and ureters. The three viscera left mentioned are behind the bag, and separated by it from those contained within the cavity.

It then lines the great hollows of the offa innominata, covering the iliac interni muscles and spermatic chords, and descends into the pelvis, covering the rectum entirely above, and about one-half of it below. From the sides of the rectum it is produced over the fascia, the offa innominata, the internal iliac vessels and great nerves, the obturatores interni, coccygei, and levatores ani. At about two inches from the anus, it is reflected from the upper surface of the rectum to the lower part of the vagina, and covers its posterior half. It ascends over the back of the uterus, and its appendages, envelopes the fundus uteri, and front of the organ, and is then reflected from the front of the cervix to the posterior and inferior part of the bladder. It mounts over the back of that organ, and descends a little from the fundus, particularly if it be full, to the back of the pubes; if it be empty, the membrane ascends from the bladder to the bone. Between the rectum and the vagina there is conseqently a small process of peritoneum, forming a cul-de-sac, at the mouth of which there are two lateral folds more or less prominent: the end of this cul-de-sac is the most depending part of the peritoneal cavity. A similar but shorter pouch, terminating also in a blind end, is formed between the uterus and bladder, and there are two lateral folds.

VOL. XXVI.
PERITONEUM.

folds connecting these organs. In the male, too, the peritoneum passes over the vasa deferentia. The corresponding cul-de-sac in the male subject is between the bladder and rectum. Where the rectum descends from the fundus of the bladder to the front of the abdomen, a third kind of process is formed. Further descriptions of these parts will be found in the articles Generation and Kidney. As the membrane passes from the bladder to the abdominal parietes, it forms three folds, including the umbilical arteries and uteri. See Kidney.

In the iliac fossa the peritoneum is continued over the large intestine, covering the cæcum on the right, and the sigmoid flexure of the colon on the left side. To the latter it furnishes a loose fold, continuous with that which the rectum has in the pelvis; but it binds the former closely in its situation. (See Intestine.) The membrane is then continued on each side into the lumbar region. From the bladder and pelvis the peritoneum rises to bound the front of the abdominal cavity, and lines the back of the recti, and the internal surface of the transversi, and then reaches the edge of the diaphragm, the point from which we commenced the description.

Thus a large membranous bag is formed, simple and oval above, and ending in a single, double, or triple procelves below; viz. the productions between the rectum and bladder, between the bladder and uterus, and vagina and rectum, and between the bladder and pubes, where it exists.

The folds of the peritoneum have been partly mentioned in this article: they are all particularly described, with the viciae to which they belong, in the various parts of this work. We have only to notice a few of them here shortly.

On the left side of the diaphragm the perineal lining extends, without producing any procelves, backwards to the spine; then it is prolonged over the splenic vessels and the spleen, reaches the great end of the stomach, and is continued with the anterior layer of the great omentum: with the peritoneum of the lumbar region it forms a small fold under the anterior end of the spleen. At the cæophageal opening of the diaphragm, the membrane passes over the front of the stomach.

On the right side of the diaphragm the peritoneum forms folds, connecting the liver to its surface, and called the ligaments of the liver. (See Liver.) From the concave surface of this organ, the peritoneum extends to the small curvature of the stomach, under the name of the little omentum. (See Epiploon.) Under the edge of the latter process is an opening, called the foramen of Winslow, leading into another peritoneal cavity, in front of the vertebral column, behind the stomach, and above the transverse mesocolon, having no other communication with the general cavity. If we suppose the peritoneum to enter at the opening just mentioned, we may trace it forming the back of the little omentum, then over the back of the stomach. Uniting to the front layer on the stomach, it forms the anterior lamina of the great omentum. This, after covering the arch of the colon, and the small intestines, is reflected on itself to form the back layer, which is fixed to the arch of the colon, and is continuous with the transverse mesocolon. The latter fold is composed of two layers; the superior of which goes in front of the duodenum, the pancreas, the vena cava, and the appendices of the diaphragm, to the opening, from which we commenced the description. For a more particular account of all these parts, see Epiploon. The inferior layer of the transverse mesocolon goes over the lower part of the duodenum, and then is continued on the back of the abdomen.

In the lumbar regions the peritoneum is continued over the ascending and descending colon, without forming any thing like a fernenery: it also covers here more or less of the kidneys. Having enveloped the colon, it forms in the middle of the abdomen, extending obliquely from above downwards, and from left to right, the broad fold that covers the small intestine, called the fernenery. See Intestine.

The peritoneum, like all serous membranes, has two surfaces; an external adherent one, and an internal, which is free. The first is applied to the sides of the cavity, and to the different viciae and, where folds are formed of two layers, these are applied to each other. The adhesion of the membrane to any of the parts just mentioned is not uniform. To the liver, spleen, stomach, and intestines, (excepting a part of the duodenum,) it is most closely and almost inseparably connected. The union is much less firm in the cafe of the pancreas, bladder, uteru, and vagina. To the tendons of the tranversi, and of the diaphragm, the connection of the membrane is most intimate: it can hardly be separated entire. The adhesion is much less firm to the diaphragm, and to the muscular fibres of the transversi. But the loofeattachment of all is in the lumbar regions, in front of the vertebral column, and about the pelvis, where a copious and easily lacerable cellular tissue joins it to the neighbouring parts. This structure allows the pus of abscesses to pass from one part to another, as in the plos abices, &c. Above the pubes, and behind the recti, there is much loose cellular tissue, which allows the peritoneum to quit these muscles, and apply itself on the bladder, when that organ, in its dilated state, ascends into the cavity of the abdomen. At the opening for the vena cava, the peritoneum is separated from the pleura only by cellular tissue; the two membranes are also near together at the oesophageal and aortic orifices of the muscle. At the side of the uniform cartilage, and the lower edge of the fibres of the diaphragm, arising from the left rib, the two membranes come in contact.

Wherever there is much cellular tissue on the surface of the peritoneum, it contains more or less fat. This fluid is also copiously deposited in most of the folds of the membrane.

The free surface of the membrane is distinguished by no peculiar character; as in all other serous membranes, it is perfectly smooth, and moistened by an exhalation, which merely gives a lubricity to the parts during life, but is visible in the form of actual fluid after death.

Unnatural adhesions, the consequence of inflammation, are much more rare here than in the pleura. Can we explain this phenomenon, by the more numerous and extensive motions of the abdominal contents? In the violent exertions of the body, in respiration, in the natural execution of the digestive functions, &c. the relations of the different parts to each other, and to the sides of the cavity, are incessantly changing; and they correspond to each other only in small points, on account of their rounded outlines. Where there is less motion, as in the upper part of the cavity, between the liver and spleen and the diaphragm, or in old irreducible herniae, adhesions are much more common.

The peritoneum is thin, like all organs belonging to the serous system. It is thickeft about the loins, and the sides of the abdomen; thinner in the folds attached to the viciae, and very thin on the liver, spleen, stomach, and intestines. In the omenta its tenacity is extreme. It is diaphanous, and consequently allows the colour of the subjacent organs to appear through it.

On its organisation, properties, and uses, we have nothing
thing to add to the general account of these subjects in the article Membrane.

In the fifth kind, the peritoneum, or membrane surrounding the abdomen, is very variously coloured. In some it is of a thinning flivery whitenss, as in the cypress, pearcr, eoces, &c. In others it is of a fine pale flesh-colour, as in the salmon; and in some it is wholly black, or else variegated with very numerous black spots, as in the elapse, gah, cotti, and spari.

**Peritonitis**, in Medicine, an inflammation of the peritoneum, or membrane lining the cavity of the abdomen, and invading all its visera, and also extending itself to form the omentum.

As the peritoneal membrane occurs in three situations, somewhat distinct from each other, though still but a continuation of the same structure, Dr. Cullen divided the disease into three species: 1. The peritonitis propria, when the inflammation is seated in that part of the membrane strictly so called, which lines the parietes of the abdomen; 2. Peritonitis omentalis, when it is seated in the omentum; and 3. Peritonitis mesenterica, when it is seated in the investing membrane of the mesentery. The symptoms and method of treatment requisite for their cure are nearly the same under all these forms, and we shall treat of them under the same head.

It must be premised, however, that the peritoneum is subject to two kinds of inflammation: the one acute, and accompanied by symptoms of violent constitutional disturbance, which is the proper peritonitis of authors; the other of a more chronic form, which we shall describe separately.

§ 1. The acute peritonitis generally commences, like the other visceral inflammations, with chills and shiverings, though these are sometimes slight, and occasionally absent altogether: the pulse becomes quick and frequent; there is considerable thirst; and the general affection, called fever, ensues. These symptoms are attended from the very beginning with a sense of heat and pain in the abdomen, at first generally confined to some one part, though sometimes diffused over the whole of its surface. Pain is much increased by pressure, or, in other words, there is a great tenderness or firmness of the belly; but it is not accompanied by any inclination to go to stool. The pulse is at least one hundred in a minute, and small; yet the tongue is not much altered at first from its natural appearance.

In the course of twenty-four hours, however, the pain and tenderness on pressure increase, so that even the weight of the bed-clothes sometimes becomes intolerable, and the pulse rises to a hundred and twenty or thirty in a minute: at this time the tongue begins to be covered with a cream-coloured mucus, and, though it is moist, there is great thirst. A considerable degree of tension and swelling now takes place over the whole abdomen, and the patient finds moat relief from pain by remaining motionless upon the back, with the knees in a small degree elevated. This position, while it throws the weight of the intestines to the spine, and therefore removes the pressure of them from the inflamed membrane, at the same time relaxes the abdominal muscles, and prevents any irritation over the outer surface of the inflamed part. As these muscles are called into action by any attempt to rise or even to turn, so much a motion necessarily aggravates the acute pain; whence absolute rest, as just flaxed, is most easy to the patient. The tension of the belly continues to increase to the fifth, seventh, or eighth day, on one of which days, uleter proper measures have been taken to remove the disease, the patient most commonly expires. Previous to death, the pain often suddenly ceases, and the most experienced may conceive that this is an indication of amendment in the disease; but if the symptoms be minutely examined, it is found that, at the same time, the pulse is sinking in strength and increasing in rapidity, that the strength of the patient is also feebly diminished, the countenance collapses, cold clammy sweats break out, the extremities lose their vital warmth, and at length a laborious respiration manifests the concluding struggle of life. A favourable prognosis, however, is to be deduced from a gradual effusion of the pain, especially when it is accompanied by a diminution of tension and tenderness, and at the same time the pulse becomes fuller and less frequent, the skin less parched, soft, and moist, the respiration less laborious, and the countenance more open and expressive of ease.

Inflammation of the peritoneum may be distinguished from colic by the permanency of the pain, and the frequency of the pulse, as well as by the tenderness on pressure, even before any tension of the abdomen has taken place; and by the absence of any inclination to go to stool, when the pain is fever, as well as by the undiminished suffering, when an evacuation of the bowels is effected, either spontaneously or by medicine. It is not so easily distinguished from inflammation of the bowels or enteritis. In this latter disease, however, there is obstinate constipation, and the pain is more acute, and not so much aggravated by external pressure; the abdomen is also commonly affected with vomiting. See Colic and Enteritis.

The appearances which present themselves on the diffusion of peritonitis who die of peritonical inflammation, are, a redness of the peritoneum, which is crowded with a number of very small vesicles, carrying a florid blood, and also considerably thickened, more pulpy, and less transparent than natural. When a portion of the inflamed peritoneum is separated from the abdominal muscles, there is commonly no appearance whatever of the inflammation having spread into the muscles; but where the peritoneum covers the intestinal canal, the inflammation is sometimes found to have penetrated not only into the muscular coat of the intestines, but even into the villous membrane. The reason of this difference probably is, that the peritoneum is less connected with the abdominal muscles than with the intestinal canal, so that the inflammation passes more readily from the peritoneum to the former than the latter.

The inflammation of the peritoneum is sometimes found to have been slight and partial; at other times great and universal. When it is slight, and affects that part of the membrane which is connected with the intestinal canal, it often forms broad bands of inflammation, which run along the course of the intestines, and are bounded by the contact of the different portions of the intestines among themselves. In this case, the coats of the intestines are not thicker than usual, the inflammation being slight, and confined to the peritoneum itself. Where the inflammation is great, the intestines are much thicker and more naffy. This evidently arises from the greater accumulation of blood in the small blood-vessels, as well as from the extravasation of fluids into the substance of the intestines, in consequence of the strong inflammatory action of the vessels. The mesentry and mesocolon are much thicker than in their natural state, and there is also a remarkable change in the omentum. It is frequently as thick as a person's hand, and lies as a circumcised mass along the great curvature of the stomach. The principal cause of this change in these parts is the extravasation of the coagulable lymph into the cellular membrane between the laminae of the peritoneum which form them.

Besides these appearances, there is in many places thrown out a layer of a yellowish pulpy matter, gluing different portions;
portance. Nevertheless it is necessary that the bowels should be kept open, and this should be effected with as little irritation as possible. For this purpose castor oil, or small doses of the sulphate of magnesia, may be administered with advantage; and emollient glysters may be injected, which, at the same time that they procure foops, will act as internal fomentations. Fomentations may be also applied externally to the abdomen, when the tenderness is sufficiently removed to admit of the pufhure. It is scarcely necessary to add that the firielt antiphlogiftic fyrern must be adopted, both in refpect to diet and medicine.

It may be right to mention an irregularity in the com- plains, which is apt to mislead the practitioner, and to deter him from retorting the proper meafures, fo effential to counteract the magnitude of the danger. There is now and then, at the very firft attack, a great degree of protra- tion of strength, accompanied likewise by a pufhe fearcely perceptible at the wrif, as might induce us to confider the patient at the point of death, and unequal to undergo the treatment above recommended. The appearances, however, feem to arise wholly from the inflammation extending to the peritoneal coat of the ftomach and intelles. Here, as in different circumstances, the pain or pufhure muft be the cri- terion to determine our practice; and if the pain fhould be found exquisite, no accidental symptom fhould lead us from urging relief chiefly to the lancet. Such a decision will soon be fubfcribed to by a freedom in the action of the arteriel fyrern, the pufhe becoming fuller and ftronger, by an abate- ment of the languor and protraction of strength, and by a diminution of pain. See Pemberton On Diseafes of the Abdom. Vifcera, chap. i.

§ 2. The chronic peritonitis was but curforyiy noticed by medical writers, until the attention of the profes- fhion was called to it by Dr. Pemberton, in the valuable work to which we have juft referred, and from which we fhall select our description of the difeafe, which is by no means of very un- common occurrence.

The attack of the chronic inflammation of the peritoneum is very different from that of the acute fpecies. It advances by degrees, manifesting itself only by occasional superficial pricking pains over the abdomen, without producing any inclination to go to ftood: the pufhe is somewhat accelerated, and the tongue (particularly in the morning) is slightly covered with white fur. There is also confiderable fhrit; yet there is no exacerbation of fever in the evening, nor any hectic fhiftes on the cheeks: on the contrary, the coun- tenance is full of languor, and the face is pale and doughy.

In the early stages of the difeafe, the patient is capable of performing his ordinary avocations, and only complains, after fatigue, of a certain degree of tightnefs and pricking forenefs acrofs the abdomen, from one as ilium to the other. This frate will continue, with little variation, for many months, during which the operations of the bowels will sometimes proceed naturally, though more commonly the patient is colitive. There is no tenion of the fkin of the ab- domen, as in the acute fpecies; on the contrary, the fkin and abdominal muscles are sometimes observed to fit loofely upon the peritoneum, which gives a fension to the touch, as of a tight bandage underneath, over which the fkin and muscles may be laid (as it were) to play. The patient always complains more of the tightnefs than of the pain; and as this tightnefs is much increafed by any congestion in the intelles, the relief which he experiences from evacu- ating their contents, leads him to attribute his fensions to an habitual coftivenefs, for the removal of which fuppofed evil all his endeavours are ufually directed.
In the mean time the disease gains ground, till it assumes, from some accidental circumstance, either the acute form above described, or till coagulable lymph is slowly thrown out from the inflamed surface, which, becoming in part organized, will glue together the convolutions of the intestines. In the former case the danger will be extreme, in consequence of the great debility to which the patient will have been reduced by the duration of the preceding disease; and in the latter case an equal danger will be incurred by the interruption of the peristaltic motion. Sometimes a resolution of the inflammation takes place from the effusion of a fluid, when, dropping in the belly is produced, which renders the situation of the patient still more hopeless.

The disease, indeed, is full of danger, as well from the slow infectious progress which it makes to undermine itself the constitution, as from the accidents to which it exposes the patient during the long course of management required in its treatment. As another cause of danger, also, may be added, the want of resolution, which we have so often to regret in patients during the cure of a chronic disease, where the advantages of the plan, from its gradual operation, are not so obvious to the senses. The symptoms, which indicate recovery, are, an abatement of the prickings of the abdomen, and a diminution of the frequency of the pulse to eighty in a minute: but even under these appearances, however favourable, a relapse is always to be dreaded.

On resolution, all the convolutions of the intestines are sometimes found blended together into one mass, so that it is impossible to separate them from each other, or from the peritoneal coat of the parietes of the abdomen. Sometimes the mesenteric glands are also found enlarged, but without any appearance of suppuration or of eructation, but apparently in consequence of the irritation of the inflamed membrane, by which they are surroundcd.

The treatment of chronic peritonitis consists in forbidding animal food, or broth, and all fermented liquors; in enforcing the absolute necessity of rigidly adhering to a milk and vegetable diet; and, above all, in taking away blood once or twice in the week to the quantity of six ounces each time. This plan is to be pursued till all fatinations of prickings, and all whitening of the tongue, have disappeared. If the constitution should shew signs of considerable derangement, it would be preferable to take the blood from the arm: but if, on the contrary, the local disease has made but little disturbance in the fylum, then the blood may be taken by the application of fix or eight leeches to the abdomen, or by cupping. The bowels are to be kept in an open state, so that one or two evacuations shall take place each day; for which purpose small doses of the sulphate of magnesia, or caflor oil, may be given daily. See Pemberton. On Diet of the Abdom. Viisera, chap. i.

PERITROCHIUM, in Mechanics, a wheel or circle, concentric with the bale of a cylinder, and moveable together with it, about an axis. The axis, with the wheel and levers fixed in it to move it, constitutes that mechanical power, called axis in peritrochio; which see. See also Mechanical Powers.

PERIVALE, in Geography, a town of Hindoostan, in Marwar; fifteen miles N. of Ramanadorum.

PERJURY. Perjurium, in Law, the crime of swearing falsely, absolutely, and falsely, in a lawful oath, administered in some judicial proceeding, by one who has authority, in any matter relating to an issue, or cause in question; whether it be of the person's own accord, or by subornation of another.

The law takes no notice of any perjury but such as is committed in some court of justice, having power to administer an oath, or before some magistrate or proper officer, invested with a similar authority, in some proceedings relative to a civil suit or criminal prosecution; for it exempts all other oaths unnecessarily at least, and therefore will not punish the breach of them. The perjury must also be corrupt, (that is, committed malo animo,) wilful, positive, and absolute; not upon surmise or the like: it must also be in some point material to the question in dispute; for if it be only in some trilling collateral circumstance, to which no regard is paid, it is no more penal than in voluntary extrajudicial oaths.

Subor nation is the offence of procuring another to take such a false oath as constitutes perjury in the principal. If a man calls another perjuror, he may have an action upon the cafe. If he calls him forsworn, no action lies, because the forswearing may be extrajudicial.

At common law, the punishment of perjury, and subornation of perjury, was anciently death; afterwards banishment, or cutting out the tongue; then forfeiture of goods; and now it is line and imprisonment; and the offender is ever afterwards incapable to be a witness. (3 Inst. 163.) By statute 5 Eliz. c. 9, perjured committing wilful and corrupt perjury, in any cause depending concerning lands or goods, &c. in any of the courts of record, leet, ancient demeine court, hundred court, court baron, or court of flannary, shall forfeit 20l. and be imprisoned six months, and their oaths shall not be received in any court of record, so that they are disabled from being jurors or witnesses; and if the offenders have not goods or chattels to the value of 20l. they shall be sent on the pillory in some market-place, and have both their ears nailed to it; and unlawful and corrupt procuring and suborning a witness to give false testimony in any court of record, &c. or corruptly procuring any witness to testify in perpetuum rei memoriam, incurs a forfeiture of 40l. And if the offender be not worth 40l. be shall suffer six months imprisonment, and stand on the pillory one whole hour in some open market near the place where the offence was committed; and he shall incur perpetual infamy. But the prosecution is usually carried on for the offence at common law; especially, as, to the penalties before inflicted, the statute 2 Geo. II. cap. 25. made perpetual by the 9 Geo. II. cap. 18, superadds a power for the court to order the offender to be sent to the house of correction for seven years, or to be transported for the same period; and makes it felony, without benefit of clergy, to return or escape within the time. Our ancient law inflicted the punishment of deliberate murder on wilful perjury, when it was the cause of the death of an innocent person; and by the laws of France it was universally capital.

But corporal and pecuniary punishments, exile and perpetual infamy, are more suited to the genius of the English laws; where the fact is openly discussed between witnesses on both sides, and the evidence for the crown may be contradicted and disproved by those of the prisoner. And with regard to the punishment of deliberate murder above-mentioned, as the mere attempt to destroy life by other means is not capital, there is no reason that an attempt by perjury should; much less that this crime should in all judicial cases be punished with death. For, as judge Blackstone observes, to multiply capital punishments lessens their effect, when applied to crimes of the deepest dye; and, detestable as perjury is, it is not by any means to be compared with some other offences, for which only death can be inflicted, and therefore it seems already (except perhaps in the instance of deliberate murder by perjury) very properly punished by our present law; which has adopted the opinion of Cicero (de Leg. 2. g.), derived from the law of the twelve tables, "perjurii pena divina,exitium; humana, dedecus."
To convict a man of perjury, a probable evidence is not enough; but it must be a strong and clear evidence, and the witness must be more numerous than those on the side of the defendant, for otherwise it is only oath against oath. (10 Mod. 194. Str. 1350.) It seems that the court will not ordinarily at the prayer of the defendant grant a "certiorari" for the removal of an indictment of perjury; for such crime deferves all possible disconveniance, and the "certiorari" might delay, if not wholly discourage, the prosecution.

Quakers making solemn affirmation wilfully and corruptly shall suffer as in cases of perjury. 8 Geo. c. 6.

If perjury be committed in a spiritual cause, the spiritual judge hath authority to inflict canonical punishment and prohibition will not go. But the judge cannot punish pro salute animae; and the party accused by such perjury must recover his damages at the common law. In the statute of the 5 Eliz. c. 23, concerning the writ de excommunicato capiendo, perjury in the ecclesiastical court is specified as an offence, among others, for which a person may be excommunicated; and conviction of perjury, either in the temporal or ecclesiastical courts, is cause of deprivation of benefice.

PERJWINKLE, in Botany. See Pervinca.

Pervinca, in Natural History, the English name of a species of shells, being the turbo littoreus of Linnaeus. It has five spires; the first ventricose; in younger subjets frizzated spirally; in the old, smooth and of a dulky colour. This abounds on mild rocks, far above low-water mark, and is eaten in great plenty by the poor. The Swedish peasants believe, that when these shells creep high up the rocks, they indicate a storm from the south.

Perizonius, James, in Biography, a learned critic, was born in 1631, at Dam, in the province of Groningen, where his father was master of a public school. His family name was Varbrück, which, according to the custom of the times, he changed to Perizonius, having a similar signification in Greek. He, in his youth, studied at Deventer, and afterwards at Utrecht under Gravesius. The invasion of Lewis XIV. interrupted his academical studies in 1672, but he resumed them in 1674 at Leyden, where he attended the lectures of Theod. Rychius. His first public employment was that of rector of the Latin school at Delft. In 1681 he was appointed professor of history and eloquence at Franeker, and in 1693 he removed to the same professorship, with that of the Greek language, at Leyden. He died in his 64th year, in 1715. He was author of a great number of learned works, of which the following are the principal: "Animadversiones Historiae," containing of explanations of many passages in the Greek and Latin writers; "Dissertationes," in several volumes 4to., chiefly relative to Roman history; "Orationes," "Origines Babylonicae et Egi"p"ticae;" an edition of Ælian's Various History, with a Commentary. Perizonius had collected a numerous and well chosen library, and a cabinet of medals, which were sold after his death. He left to the university of Leyden several ancient manuscripts, and scarce editions of the classics. More...

Perkel, a town of Cardita, on lake Van; 18 miles E. of Arghia. Perler, a town of Brandenburg, and capital of the Mark of Pregnitz, situated on the Stoptenitz, and containing about 378 houses, occupied principally by trade men and farmers; 62 miles N.W. of Berlin. N. lat. 53° 8'. E. long. 11° 58'.

Perlican, New, a noted harbour on the E. coast of Newfoundland island, eight leagues W.S.W. of Old Perlican, and five leagues from Random head. It has a wide and safe entrance, and ships may ride in it, locked from all winds, in from 10 to 5 fathoms water.

Perlstein, in Mineralogy. See Perlstone.

Permacon, in Geography, a town of Ruffia, and capital of a government, on the Kama; 808 miles E. of Petersburg. N. lat. 57° 40'. E. long. 56° 14'.

Permacoil, a town of Hindooftan, in the Carnatic; 17 miles N.N.W. of Pondicherry. N. lat. 12° 14'. E. long. 70° 55'.

PERMALFAOOR, a town of Hindooftan, in the Carnatic; 12 miles S.S.W. of Corjeveram.

Permanent Air and Quantity. See the substan
tives.

Permeable denotes a body considered as its pores are capable of letting somewhat pass through them. See Por.

Permelly, in Geography, a town of Hindooftan, in the circear of Aurungabad; 30 miles N.W. of Nander.

Permiuns, a branch of the Finns, called in the Icelandic Reports "Biarmians," and denominated by the Ruffians "Permiaks," situated in the governments of Perm and Viafta, and in the northern districts of the river Oby. In the middle ages the Scandinavians seem to have given the name of Biarmis to the whole people, and in the tenth century to the country between the White sea and the Ural. The Permians on the Dwina were discovered in the ninth century by Othere of Halgoland, a prince at the extremity of Norway, who afterwards entered into the service of Alfred the Great, and drew up an account of this voyage in the Anglo-Saxon language. The Icelandic reports abound with accounts of these people. According to these reports the Permians on the White sea, and the people about the Dwina, were the most wealthy, most powerful, and most remarkable of all the northern Finns. Here the carved image of the god Yummal, who was the universal deity of the Finns, as Perum was of the Slavonians and Lettes, and Odn of the Germans, had its far-famed temple, the description of which borders on the marvellous. According to this description the temple was artfully constructed of costly wood, and so richly ornamented with gold and precious stones, that it threw a radiance round the whole circumjacent country. The image of the god wore a golden crown set with 12 precious stones, a necklace worth 300 marks in gold, and a dres which overweighed the lading of three of the richest ships that navigated the Grecian sea. The figure also bore on its knees a golden chalice of such capacity, that four men might quench their thirst from its contents, and this vessel was filled with the fame valuable metal of which its masts confined. The northern free-booters were tempted by the reports of the wealth of this country to make inroads into it, and to take away some spoil from this temple. Even several Norwegians made predatory excursions into Persia, and usually returned with rich booty. We find also that the Scandinavian mariners visited this country for the purposes of trade, &c. without any piratical views. It is a curious inquiry how these Permian Finns accumulated so much gold, and how their country became the mart of a great and lucrative commerce. In very remote ages the Permians were already famous for their trade with the Persians and Indians. These nations brought their commodities over the Caspian up the Volga, and the Kama, to Ticherdyn, a trading town of ancient date on the river Kolva; and the Persians transported these goods as well as their own products along the Petthara to the Frozen ocean, where they bartered them with the people of those parts against furs.
furs for their oriental trade. The ruins of ancient towns bear witness to the flourishing condition and the civilization of this people. The Permians appear, by historical traces still subsisting, to have been the only race of the Finns, who were a polished and commercial people, and known to other nations, while their indented tribes were in a state of barbarism. The reports likewise speak of kings and a fort of political constitution in Burmeland. With the year 1217, the expeditions of the Norwegians to Permia ceased; but probably at an earlier period in the 11th and 12th centuries, the republic of Novgorod made itself master of this country, leading thither Russian colonies to keep the people in subjection. About the year 1372 the Christian faith was propagated in Permia by bishop Stephen. The Novgorodians having renounced all claim to this country, the Permians for a considerable period maintained the liberty of choosing their rulers from their own body. In 1543 the czar Ivan gave them the first viceroy, to whom the chief of the inhabitants was to act in a subordinate capacity in the affairs of government, and who had his seat at Kolmogor, and afterwards at Archangel. At present the whole of ancient Borma, the borders of which cannot now be accurately defined, is divided into several governments; and the descendants of the Permians, heretofore so famous, numerous, and powerful, are dwindled away into an insignificant remainder, who, amidst thorough Russians, have left almost all their national characteristics, even to their own language. Tooke's Russia, vol. i.

PER MINIMA, in Medicine, denotes a perfect mixture of the smallest particles of several bodies, or ingredients.

PER MINIMA, in Pharmacy, denotes an intimate and perfect mixture of natural bodies: wherein their very minima, i.e. their atoms, or first component particles, are supposed to be accurately blended together.

If silver and lead be melted together, they will thus mingle per minima.

PERMISSION, PERMISIO, in Reristories, a figure which differs in nothing from conception, except that the latter relates only to argument and pleading, but the former to action. E.g. "Quoniam omnibus rebus crepitis, ipsis minimis separatis animus et corpus: haec ipse, quae de multi redundant, nobis et vestra condono potestate. Vos me quod pacifice videtur, utamini, atque abutamini, licet impune. In me quiescet libentatim, &c."

PERMISIO, the right or privilege of doing anything. See WORK.

PERMIT, a certificate granted by excise officers, and signed by them, expressing the quantity of liquor, the name of buyer and seller, and that the duty hath been paid, or that it hath been condemned as forfeited.

PERMITTIT—quae non Permittit. See QuaRE.

PERMSKOE, in Geography, a government of Russia, including the province of Perm and Ekaterinburg: bounded on the N. by the government of Vologda and Tobolsk, on the E. by that of Tobolsk, on the S. by Uplinskoe, and on the W. by Vitiaz, about 360 miles from N. to S., and from E. to W. 240—260. N. lat. 55° 15'—61° 15'. E. long. 52° 63°. The province of Perm extends from N. lat. 55° 20' to 61° 14', and from E. long. 52° to 58°.

PERMUTATION, the trick, or exchange, of one thing for another. See Exchange.

Permutation, in the Canon Laws, a real and actual exchange of two benefices.

Permutation is a means of bringing benefices into commerce without simony.

The conditions required to a canonical permutation are,

1. That there be benefices permitted on either side, though the revenues be unequal; and, in case of inequality, no compensation is to be made in money, but only a pension is to be charged on the greater.

2. That each of the permutes quits their benefices, and make a procreation ad regignandum quiz that the permutation be followed by a collation of the ordinary.

3. That the ordinary be informed of the cause of the permutation.

4. That those to whom the presentation or election to the benefices belongs, give their consent; or, in case of their refusal, that the consent of the diocesan be had.

The chief rules of permutation are, that if one of the permutes cannot enjoy, he re-enters, with full right, into the benefice he has quitted; and that, if he die before he has accomplished the permutation, on his part, by the taking of possession, the permute, who has accomplished, retains both benefices, unless they fall into the regale.

Permutations of quantities, in Algebra, the changes, alternations, or different combinations, of any number of quantities. See these several articles.

Permutatione Archidiaconis, et ecclesiae eadem anna exu cum ecclesia et prebenda, is a writ inflicted to an ordinary, commanding him to admit a clerk to a benefice upon exchange made without Reg. of Writs.

PER MY & for towns, a joint-tenant is said to be feized of the land he holds jointly, per my & for tout, i.e. he is feized by every parcel, and by the whole, tout tenit, et nihil tenet; feu tout conjunctum, et nihil separatum. Bracé.

PERNABACABA, or Paranambacaba, in Geography, a mountain of Brazil, near the city of St. Paul.

PERNALLA, a town of Hindoostan, in Guzerat; 38 miles S. of Surat. N. lat. 20° 35'. E. long. 72° 53'.

PERNAMBUCO. See Fernambuco.

PERNANCHY, from the French prendre, to take, in Law, the taking or receiving any thing.

Trades, in pereancy, are tithes taken, or which may be taken in kind.

PERNES, in Geography, a town of France, in the department of Vaucelles, and chief place of a canton, in the district of Carpentras. The place contains 3621, and the canton 6358 inhabitants, on a territory of 100 kilometres, in six communes.

PERNETTI, James, in Biography, historiographer of the city of Lyons, and a member of the academy of that place, who was a native of Forez. He assumed the title of "Miles Ecclesie Lugdunensis," and was a man of polite manners, and entirely void of pedantry. He died at Paris in 1777. His works are, 1. History of Cyrus, in three vols. 12mo.; 2. Councils of Friendship; 3. Letters on Phygognomy, three vols.; 4. The Abuses of Education; 5. Picture of the City of Lyons. He had a relation who was librarian to the king of Prussia, and who wrote a dictionary of painting, sculpture, and engraving; and a dissertation on America against Paul, in two vols. 8vo.

PERNETY, Antony Joseph, was born in 1716, at Roane, in Forez. He entered into the order of Benedictines, and devoted himself to study, and the composition of numerous works, in which he displayed a sympathetic spirit with a singular mode of thinking. Some of the principal of these are the following:—"Dictionnaire de Peinture, Sculpture, et Gravure," 1757; "Dictionnaire Mytho-hermétique," 1758; "Dictionnaire de la Philosoponie;" 1756. Journal Historique d'un Voyage fait aux Isles Malouines, en 1763 et 1764, two vols. 8vo. 1769; this account of a voyage made by himself, contains many curious particulars; it was translated into English, and read with interest at the time of the dispute with Spain, relative to these islands, which are the same name the Falkland islands; "Dissertation sur l'Amé-
rique et les Américains;" in this work and in his "Examen des Récérences Philosophiques de Pauw sur les Américains," he controverts the opinions of Pauw. He was author of many other works, and communicated several memoirs to the academy of Berlin, of which he was a member, and in which capital he resided a long time. He at length returned to Valence, in the department of La Drôme, where he died about the close of the century.

PERNIA. in Geography, a town of Croatia; 16 miles S.E. of Carlstadt.

PERNIOUS ISLANDS, a cluster of islands in the South Pacific ocean, about 15 miles in circuit, so called by Roggewein, on account of the wreck of one of his vessels on the coast of one of them in 1722. S. lat. 16°. W. long. 140° 45'.

PERNIO, from περνής, the heel, a chilblain, a kind of complaint frequently affecting the heel. See Chilblain.

PERNO, in Geography, a town of Sweden, in the province of Nyland, at the mouth of a river which forms a bay on the N. coast of the gulf of Finland; 12 miles E. of Borgo. N. lat. 62° 26'. E. long. 16° 4'.

PERNOVA or PERNIO. of Profits, he who takes or receives the profits of any thing. From the French pereur, taker.

PERNOV, or PERNNOV, in Geography, a town of Russia, in the government of Riga, on a river near the Baltic, fortified and defended by a castle. After several times changing masters, it was finally, with the rest of Livonia, annexed to Russia; 92 miles N. of Riga. N. lat. 58° 30'. E. long. 42° 10'.

PERNSTAIN, a town of Austria; 12 miles N.N.W. of St. Wolfgang.

PEROE, a town of Hindooistan, in Bahar; 45 miles S.W. of Patna.

PEROJOA, in Botany, Canav. 1c. v. 4. 29. t. 534. f. 2, was so named by Louis Née, who gathered the plant at Port Jackson, New South Wales, in honour of Francis del Perojo, a Spanish apothecary, who had been his botanical companion in a journey over the hills of the north of Spain. Mr. R. Brown however reduces the Perogoia to his genus Leucopus; see that article, fech. 4.

PEREAL. See Momordica.

PERONE, in Anatomy (πόρονεις, Gr.) the fibula.

PERONEAL ARTERY, an artery of the leg, running near the fibula. See Anatomy.

PERONES, in Roman Antiquity, a kind of high shoes formed rudeley of raw hides, and reaching up to the middle of the leg; though in the more ancient times of the commonwealth, the senators used them, yet in later ages they were only used by the ploughmen and labourers. Hence Peronatus Arator. Perius, Sat. 5. ver. 192. and Juvenal, Sat. 14. ver. 186.

PERONEUS, in Anatomy, a name given to three muscles which arise from the fibula.

The peroneus longus, (long peronier latéral, pérono-tar-tien) is a long muscle, situated on the outside of the leg, and extending from the upper end of the fibula to the posterior extremity of the first metatarsal bone; it is thick in its upper half; thin, narrow, and flattened in the lower. It arises from the upper third part of the outer surface of the fibula, from two aponeurotic fepta, of which one separates it from the extensor digitorum longus communis, and the other from the soleus and the flexor longus pollicis pedis, and on the outside and upper part from the internal surface of the fascia of the leg. The upper extremity reaches as high as the outer part of the upper end of the fibula, and the back of the external tuberosity of the tibia. It is covered on the outside by the fascia of the leg. It descends at first obliquely from before backwards, increasing a little in size; then it soon begins to decrease, and forms a tendon first visible on the external and anterior part. This tendon descends, and is confined there by a fibrous sheath, lined with a synovial membrane.

Below the malleolus it separates from the tendon of the peroneus brevis, and passes downwards and forwards in a groove of the os calcis, where it is again confined by a fibrous sheath. It then turns over the external side of the os cuboideum, and runs obliquely inwards and forwards in the channel hollowed out on the under surface of that bone, to which it is confined by a very strong fibrous sheath. It terminates at last by an attachment to the under and external part of the posterior end of the first metatarsal bone. Where it rubs against the surface of the os cuboideum, the tendon has a thick and hard knot of a cartilaginous consistence, and sometimes even bony.

It extends the ankle joint, either by drawing the heel backwards and upwards, or by carrying the leg backwards on the foot. If it acts in the former manner, when we are standing, the elevation of the foot is accompanied by that of the leg and of the rest of the body. It must draw the outer edge of the foot outwards, and thus point the great toe towards the ground. If it acts in company with the tibialis posterior, the foot will be extended in the straight direction.

The peroneus brevis (court péroneier latéral, pérono-fusmetatarfien) is an elongated and flattened muscle, placed at the outer part of the leg, and extending from the lower two-thirds of the fibula to the fifth metatarsal bone. Its origin commences from the beginning of the second third portion of the fibula from above, and it occupies the outer surface of the bone to the lower fourth part, below which it is connected to the bone only by cellular tisue. The front edge corresponds to the extensor communis digitorum longus and peroneus tertius, and the back to the flexor longus pollicis, to which muscles it is connected by aponeurotic fepta.

The upper end of the muscle is narrow and pointed, it increases downwards and upwards, but diminishes again at the bottom of the leg, where it forms a tendon, passing behind the malleolus internus in the same groove with that of the former muscle. Having arrived at the bottom of the fibula, it turns forwards and a little downwards along the outer surface of the os calcis, and is inserted into the posterior extremity of the fifth metatarsal bone. Sometimes a small production is detached from it, to run along the metatarsal bone, and join the extensor tendon of the little toe.

The peroneus brevis is covered externally by the fascia of the leg. Its use is the same with that of the preceding muscle.

The peroneus tertius (nonus Vefali, péroneier antérieur, pérono-fus-metatarfien) does not always exist. It lies on the anterior and inferior part of the leg, and extends from the lower third part of the fibula, to the posterior end of the fifth metatarsal bone. It is elongated, and flattened laterally. Its origin, which is confined with that of the extensor digitorum longus, occupies the lower third part of the front of the fibula; the muscular fibres pass obliquely downwards and inwards, and end in a tendon, which goes under the transverse ligament at the ankle, in company with the tendons of the extensor digitorum longus. It then turns upwards, runs over the extensor brevis digitorum, and is expanded before its insertion into the posterior part of the fifth metatarsal bone. The outer surface of this muscle, which is inclined forwards, is covered by the fascia of the leg; the inner surface corresponds to the extensor longus pollicis.
pollicis. The outer edge is separated by a small aponeurosis from the peroneus brevis. It bends the ankle joint, either by moving the foot on the lower end of the leg, or by carrying the leg forwards on the foot. In bending the foot, it will raise the outer edge particularly; but, if it acts in conjunction with the tibialis anticus, the foot will be bent without any inclination to either side.

PERONNE, in Geography, a town of France, and principal place of a district, in the department of the Somme, surrounded by marshes and strongly fortified. It has been called "Pacelle," because, though often besieged, it has never been taken. It is a very ancient place, and the kings of the Merovingian race had a palace here. The place contains 3706, and the canton 14,215 inhabitants, on a territory of 1624 square miles, in 22 communes. N. lat. 50° 22'. E. long. 2° 1'.

PEROS Juncalus, in Orthoënomes, a name of a small species of the Phytactus or parrot kind, with a long tail. See Phytactus.

There are several kinds of this bird. 1. The common, which is green, red, and yellowish, and was the first species of parrot brought into Europe, and well known among the ancients. 2. The perosquetta, which is green all over, without any variegation. 3. The pale, green, and red kind. 4. The red and green-crested kind. 5. The red kind, with wings variegated with black and green.

Befide thefe, Margrave has described seven other Brazilian kinds, called the quinquepulchra, huirínea, yendaya, tuitera, tuiter, tuiper, ana, and guiebutis; and two others, to which no particular name has been given; one of the fize of a swallow, all over green, with a black beak, and a very long tail; and the other of the fize of a parrot, of a deep green on the back, and paler green on the belly, and with a shorter tail. See Rush.

PERORATION, Peroration, or Conclusion, in Rhetoric, the epilogue, or last part, of an oration; wherein, what the orator had infixed on through his whole discourse, is urged afresh, with greater vehemence and passion.

The peroration consists of two parts: 1. Recapitulation, wherein the substance of what was diffused throughout the whole speech, is collected briefly and curiously, and summed up with new force and weight. 2. The moving of the passions; which is so peculiar to the peroration, that the masters of the art call this part fedit affeditum.

The passions, to be raised in the peroration, are various, according to the various kinds of orations; in a panegyric, love, admiration, emulation, joy, &c. In an invective, hatred, contempt, &c. In a deliberative, hope, confidence, or fear.

The qualities required in the peroration are, that it be vehement and passionate; and that it be short; because, as Cicero observes, tears soon dry up.

The peroration was Cicero's master-piece: here that great orator, not let his judges and auditors on fire, but even seemed to burn himself; especially when he was to raise pity and commiseration towards the accused; where, as he himself tells us, he frequently filled the forum with weeping and lamentation. He adds, that, where there were several orators to speak for the same person, the peroration was always referred to him; and subjoins, that if he excelled herein, it was not owing to genius, but the grief himself moved. This is abundantly evident in his Milonic peroration, where he says, "fed finis fit: neque enim prae lacer- minus jam loqui possum; & hic fc lacermini defendi veta: " and in that for Rabirius Polthumas: " Sed jam, quoniam, ut fpero, idem quam potui, tibi praefici, Polthume, reddam etiam acrynias quas debec— jam indicat tot hominum fletus, quam carus tuus; & me dolor debilitat, includitque vocem." 7.

The peroration, or conclusion of an oration or discourse, must vary according to the strain of the preceding part. Sometimes the whole pathetic part is most properly introduced in the peroration. (See Pathetic.) Sometimes, when the discourse has been entirely argumentative, it is fit to conclude with summing up the arguments, placing them in one view, and leaving the impression of them full and strong on the mind of the audience. For the great rule of a conclusion, and what nature obviously suggests, is to place that last in which we choose that the strength of our cause should rest. Sermons commonly conclude with inferences; when this is the case, they should rise naturally, and so much agree with the strain of sentiment throughout the discourse, as not to break the unity of the sermon. Dr. Blair observes, that, in all discourses, care should be taken to conclude at the proper time, so as to bring our discourse just to a point; neither ending abruptly and unexpectedly; nor disappointing the expectations of the hearers, when they are looking for a close; and having round and round the conclusion, until they become heartily tired of us. We should endeavour to go off with a good grace; not to end with a languishing and drabbling sentence; but to close with dignity and spirit, that we may leave the minds of the hearers warm; and dismiss them with a favourable impression of the subject, and of the speaker. Blair's Lect. vol. ii.

PEROS BANKOS, in Geography, a range of small islands in the East Indian sea. S. lat. 5° 30'. E. long. 72° 10'.

PEROSINA, an island in the Adriatic, about 12 miles in circumference. N. lat. 45° 17'. E. long. 14° 22'.

PEROT, an island of Canada. See Ottawas.

PEROTA, a town of Mexico, in the province of Tlascala: 45 miles E. of Puebla de los Angeles.

Gen. Ch. Cal. Glume of two equal, acute, awned valves, containing a single flower. Cor. of two minute, awnless, membranaceous valves, much shorter than the calyx: Nectary of two minute scales, at the base of the germen. Stam. Filaments three, capillary; anthers oblong. Fil. Germen superior, oblong; style capillary, deeply divided, shorter than the calyx; ligaments feathery, widely spreading. Peric. none, except the closed permanent calyx. Seed one, linear-oblong.

Obf. The characters of this genus of graces were erroneously given by Dr. Solander, who mistook the calyx for a corolla. Willdenow copies this error, superadding another, that the "corolla is encompassed with woolliness," which last is, without any remark, adopted by Mr. Dryander in the second edition of Hort. Kew. The mistake arose from the quotation, in the first edition of Saecularum Ficarinum, Linn. Sp. Pl. 79, as a synonym to Perotis laiticha; for though Willdenow, even without seeing the plants, suspected a specific difference, it appears that he took his generic character from that Saecularum, which is no Perotis at all. Mr. Brown has not thought proper to point out these errors particularly, but he has, for the first time, given a correct definition of Perotis, which we have adopted. 4 U 1, P.
1. P. latifolia. Broad-leaved Perotis. Ait. n. 1. Wild. n. 1. 4 s. (Anthoxanthum indicum; Linn. Sp. Pl. ed. 1. 28. ed. 2. 40. A. n. 25; Linn. Zeycl. 10. Gramen geniculatum brevifolium crispum, fipica purpuro-fuscicata maderafpatanum; Pluk. Phyt. t. 119. f. 1. Alopecuros malabarica, folium undulatis, fipica pretenui; Scheuchz. Agrof. 91. 1. 2. f. 9 g, H. Tsjeria-Kurenpulu; Rheedee Malab. v. 12. 117. t. 62.)—Stems ascending; much branched. Leaves ovate-lanceolate, wavy, with fpirous teeth.—Native of the East Indies, from whence Dr. Solander is said to have procured it for Kew garden; in 1777. It is annual, flowering in the height of August and September. Root of many long, whitish, wavy, downy flires, apparently adapted to a fady soil. Stems numerous, ascending, a foot high, much branched, copiously jointed, leafy, round, smooth. Leaves numerous, hardly an inch long, spreading, ovate, acute, rather pungent, glaucous, ftriated, smooth on both fides, rough at the edges with minute fpirous teeth; sheathes fho. ribbed, about the length of each leaf, except the upper ones, which are five times longer. Spikes foltary, terminal, purplish, three inches long, of very numerous fowers, which are imperfectly fwerched, and fand on short flalks. Calyx min-utely downy, strongly keeled, above half an inch long in-cluding the awns. Scheuchzer's excellent description, and correct figure, leave no doubt as to its fynonym. That of Rheede, not having examined, we take upon Scheuchzer's authority chiefly, for every other writer who has touched upon this grafs has made some efiftake. Wildenow's variety f is the true Saccharum ficatum of Linn. Sp. Pl. ed. 1. 54, where Plukkenet's t. 92. f. 5 3 richly cited for it, and Bur-mann has represented the genuine plant in Fl. Ind. t. q. f. 3. That grafs feems to us really a Saccharum; or at leat an Imperata of Brown. In Linn. Sp. Pl. ed. 2. 79, its fyno-nyms are totally perverted, for every one there mentioned belongs to Perottis latifolia.

2. P. rara Narrow-leaved Perotis. Br. n. 1.—"Stem erect, somewhat branched. Leaves linear, smooth; the lower ones flat; the upper involute."—Gathered by Mr. Brown in the tropical part of New Holland. We have been no fpecimen of this.

The English's P. polypheba, which is Saccharum panicum, Lamarck Illuftr. v. 1. 155. 140. f. 3, and perhaps Andro-ponog crinitum, Thumb. Jap. 40. t. 7, is judged by Mr. Brown to be a plant of a genus by itself, very nearly related to lis Imperata. (Saccharum cylindricum of Lamarck, Wildenow, and Sm. Fl. Grec. Sibth. t. 54. Lagurus cyl-indricus of Linnæus,) but differing in having awns to the calyx, no inner vale to the hermaprodit floret, and only one ftamen, marks which perhaps are not fufficient in this cafe to found a genus upon. See Saccharum and Lagurus.

PEROTTI, Nicolò, in Biography, one of the early Italian literati, was born in 1420. He was educated under Volpe at Bologna, and after finifhing his fudies, became himfelf a professor in that city, firit of polite literature, and then of phyfology. He made himfelf known by various tranflations of Greek authors into the Latin language. As early as 1425, or 1428, he fent to pope Nicholas V. his ver-fion of the three firft books of Polybius, to which he after-wards added two more, all that were then known of that author. He fubfequently tranflated Epictetus's Enchiridion, the Commentary of Simplicius upon Aristotle's Phy-fics, and Tatian's Oration to the Greeks. He was made poet laureat to the emperor Frederic III., and was em-ployed in high official fitions by ferveral of the popes. He was particularly attached to cardinal Befarione, whose conclavift he was after the death of Paul II. On this occa-

fion, it has been faid that some cardinals coming to wait on Beffario with the purpofe of faftening him pope, were re-fused admiflion by Perotti, on the plea that he was engaged in his fudies; and that after the election of cardinal Rario, Beffario coolly faid to him, "By your untimely care, you have loft me the tiara, and youfelf a hat." He was, how-ever, appointed to honourable offices under the court of Rome, being made governor of Umbria in 1465; of Spo-leto in 1471; and of Perugia in 1474. He died in 1482. His writings are numerous, but his most celebrated work was entitled "Cornucopia," being a difflafe and learned Commentary on Martial's book on Spectacles, and the firft book of his epigrams. It was not published till after his death; it contains a treafure of erudition refpeétng the Latin language. Moreri. Bayle.

PEROUR, in Geography, a town of Hindoostan, in the cirear of Gooty; 24 miles S.S.W. of Anantpoul.

PEROUSSA, LA, a town of France, in the department of the Po, on the river Clufion; it gave name to one of the four valies of France, six miles North Pinerolo.

PEROUSE, J. F. G. L. in Biographical, a celebrated but unfortunate navigator, was born at Bouloufle in 1741. He entered into the French navy when he was only in his fifteen year, in which he paflod a life of almost conflant service. By the firmnefs of his character, and his profefional skill, he was regarded as fit for the moft arduous en-terprifes. The triumphs of the French marine were few in his time; yet he commanded in the fecuflfeful attempt to defroy the English fettlement in Hudfon's Bay in the year 1782. On the reftoration of peace, it was refolved by the French miniftry that a voyage of discovery should be un-derfaken to supply what had been left defective in the voy-agés of our illufrious navigator captain James Cook, and his efociates. Lewis XVI., who may well have flyed the unfortunate, drew up the plan of the intended expedition with great judgment and intelligence, and La Peroufe was the perfon fixed upon to conduct it. With two ffrigates, la Boufufe, et l'Altnolabe, the firit under his own com-mand, the fecond under that of M. de Langue, but fubject to fubordina, they failed from Brefl in August 1785; af-focked at Madeira and Teneriffe, and in November an-chorod on the coaft of Brazil. Thenfe they proceeded round Cape Horu into the South fea, and in February 1786 caft anchor in the bay of Conception, on the coaft of Chili. At this time, fo well had the means of preferving health been employed, that they had not a man fick. The ships reached Eaftcr island in the month of April, and thence failed, without touching at any land, to the Sandwich islands. On June 23d they anchored on the American coaft, in lat. 53° 37', and landed on an ifland to explore the country and make obfervations. At this place, M. Pe-roufe had the misfortune of having two boats wreacked, with the losf of all their crew. Thence he ran down to California, and in September anchored in the bay of Mon-terey, where they took their departure across the Pacific ocean, and in January 1787 arrived in the Macao roads. In February they reached Manilla, which they quitted in April, fhiping their cargo for the iflands of Japan. Paffing the coafts of Corea and Japan, they fell in with Chinese Tartary, in lat. 42° 44', and ran to the northward. They anchored in a bay of the ifland of Sagalen, and thence proceeded up the shallow channel between that ifland and the continent as far as 51° 29'. Returning thence they reached the fouthen extremity of Sagalen in Augufl, and paffed a ftrait between it and Jeflo, fince named Peroufe ftrait, into the North Pacific. On the 6th of September they anchored in the harbor of St. Peter and Paul in Kamt-
Kamtschatka. The ships having refitted they set sail, and arrived at the Navigators' islands in December. In the bay of Mazuma they met with a friendly reception from numerous natives, and began to take in refreshments. A party of sixty, under the command of M. de Langlade, went ashore to procure fresh water, when a most unfortunate occurrence took place, in which they were attacked by the natives, and M. de Langlade and eleven of his men lost their lives. Quitting this place without any attempt at vengeance, Peroufe proceeded to New Holland, and arrived at Botany Bay in January 1788, and here terminates all that is known of the voyage of this navigator, from the journal which he transmitted to France. He had many and very important objects of research remaining, but was never more heard of. The vessels were probably wrecked, and all the crews perished, in that ocean which shall hereafter be called to give up its dead. Many efforts were made to obtain information of them, but they were fruitless.

In 1798 was published, at the expense of the French nation, and for the benefit of the widow of Peroufe, "Voyage autour du Monde par J. F. G. de la Peroufe," in three vols. 4to. It was translated into the English. The discoveries of this navigator are chiefly in the seas between Japan and China, and China and Tartary.

Peroufe's "Strait of La. in Geography," a narrow channel of the North Pacific ocean, between the islands of Sagalien and Jefo; about 20 miles in breadth.

Perenagard, a town of Hindostan; 20 miles S of Calicut.

Perpendiculur, in Geometry, a line falling directly on another line, so as to make equal angles on each side; called also a normal line.

Thus the line IG (Plate XI. Geometry, fig. 4.) is perpendicular to the line KH; i.e. makes right and equal angles with it.

From the very notion of a perpendicular, it follows,
1. That the perpendicularity is mutual; i.e. if a line, as IG, be perpendicular to another, KH; that other is also perpendicular to the first.
2. That only one perpendicular can be drawn from one point in the same plane.
3. That if a perpendicular be continued through the line to which it was drawn perpendicular; the continuation will also be perpendicular to the same.
4. That if there be two points of a right line, each of which is at an equal perpendicular distance from two points of another right line; that line is parallel to the other.
5. That two right lines perpendicular to one and the same line, are parallel to each other.
6. That a line, which is perpendicular to another, is also perpendicular to all the parallels of the other.
7. That perpendiculars to one of two parallel lines, terminated by those lines, are equal to each other.
8. That a perpendicular line is the shortest of all those which can be drawn from the same point to the same right line.

Hence the distance of a point from a line, is a right line drawn from the point perpendicular to the line or plane; and hence the altitude of a figure is a perpendicular let fall from the vertex to the base.

To erect a Perpendicular GI on any given point G, in a right line ML; one foot of the compasses being in G, with any interval at pleasure, cut off equal parts on each side GH and GK; from the points K and H, with an interval greater than the half of KH, strike two arcs intersecting in I; the right line GI is perpendicular to ML.

Perpendiculars are both described in practice by means of a square: one of whose legs is applied along that line, to or from which the perpendicular is to be let fall or raised.

To erect a Perpendicular on the end of a given line, suppose at P; open your compasses to any convenient distance, and, setting one foot in C, describe the arc RPS: lay a ruler from S through C, it will find the point R in the arc, whence draw PR, which is perpendicular to PS.

To let fall a Perpendicular on a given line MP, from a given point L (fig. 5.); set one foot of the compasses in L, and with the other cross the given line in the points M and G. Then setting the compasses in G and M, strike two arcs intersecting each other in a; then lay a ruler from L to a, and the line KL, described thereby, is the perpendicular required.

A line is said to be perpendicular to a plane, when it is perpendicular to all right lines, that can be drawn in that plane, from the point on which it inflicts.

A plane is said to be perpendicular to another plane, when all right lines drawn in the one, perpendicular to the common section, are perpendicular to the other.

If a right line be perpendicular to two other right lines, intersecting each other at the common section, it will be perpendicular to the plane passing by those two lines.

Two right lines perpendicular to the same plane are parallel to each other.

If, of two parallel right lines, the one is perpendicular to any plane, the other shall also be perpendicular to the same plane.

If a right line be perpendicular to a plane, any plane passing by that line will be perpendicular to the same plane.

Planes, to which one and the same right line is perpendicular, are parallel to each other: hence all right lines perpendicular to one of two parallel planes, are also perpendicular to the other.

If two planes, cutting each other, be both perpendicular to a third plane, their common section will also be perpendicular to the same plane.

Perpendicular to a curve, is a right line cutting the curve in the point in which any other right line touches it, and is also itself perpendicular to that tangent.

Perpendicular, in Fortification. See Military Construction, according to M. Vauban's Method, and according to Count Pagan's method.

Perpendicular, in Gunnery, is a small instrument used for finding the centre line of a piece in the operation of pointing it to a given object. See Pointing of a Gun.

Perpendicular Roots. See Fibrous Roots.

Perpendicularity of Plants, in Vegetable Physiology, or the tendency which the forms of plants in general have to ascend, while their roots descend, is a curious phenomenon, first particularly noticed by M. Dodart, who laboured without much success to explain it; nor was M. de la Hire more happy in his theory on the subject. Dr. Darwin has, in our opinion, given the best explanation. He supposes that the root is most stimulated by moisture, the ascending part of the plant by air, and that each extends itself in the direction in which it meets with its requisite stimulus. This theory accounts, not only for the general direction of the stem and root, but for the occasional variations observable in both.

Perpensum, in Botany, a name applied by the younger Burmann to the Gunnera of Linnaeus; whether adopted from Pliny, whose Perpensia is synonymous with Baccharis, or Baccharis; or whether in allusion to the con-
federation and trouble it cost him, in trying to understand the structure of the very singular flowers, we are uninformed. See Gunnera.

PERPETUARY. Cape, in Geography, lies on the N.W. coast of North America, N. lat. 44° 6'. E. long. 235° 52'. This is the northern extreme of the projecting land; and the southern extreme was called by Cook Cape Gregory, in N. lat. 43° 30'. E. long. 235° 57'.

PERPETUAL, something that endures always, or that lasts for ever.

PERPETUAL is sometimes also used for a thing that lasts, or holds, during a person's life.

Thus offices, &c. held during vita, are sometimes called perpetual offices. In this sense, M. Fontenelle was said to be perpetual secretary of the Royal Academy of Sciences. Hence the French called him absolutely, M. le Perpétuel.

PERPETUAL Action. See Action.

PERPETUAL Curate. See Curate.

PERPETUAL Glands, in Anatomy, are those which are natural; thus distinguished from the adventitious ones. See GLANDS.

PERPETUAL Lamp. See LAMP.

PERPETUAL Motion, in Mechanics. See MOTION.

PERPETUAL Occupation and Apparition, Circle of. See CIRCLE.

PERPETUAL Pills, Pilula Perpetua, among Physicists, are pills made of regular of antimony; which, being swallowed and voided fifty times, will purge every time with undiminished force. See ANTIMONY.

PERPETUAL, or Endless Screw. See SCREW.

PERPETUAL Virginity. See VIRGIN.

PERPETUATING the Testimonial of Witnesses. See PROVING a Will in Chancery.

PERPETUITY, in Annuities, denotes the number of years' purchase which is to be given for an annuity that is to last for ever, and it is always the quotient of unity divided by the interst at 1% for a year, or 100% divided by the rate of interest. Thus, the perpetuity is 33.33, 28.57, 25, 20, or 16.666, according as interest is reckoned at 3, 3 1/2, 4, 5, or 6 per cent. See Annuities and Assurance.

PERPETUITY, Perpetuities, in the Canon Law, the quality or the benefice that is irrevocable, or whose incumbent cannot be deprived, except in certain cases determined by law. It is asserted with reason, that the perpetuity of benefices is established by the ancient canons; and that priests are inextricably attached to their churches, as by a spiritual marriage. It is true, by the corruption of the times, the secular priests being fallen into great disorder, and even contempt, the bishops anciently called the religious to their assistance, and committed to them the care of souls, and the administration of parishes; still reminding them back again to their cloisters, when they thought fit, and again revoking them ad nutum.

But this vague and uncertain administration only lasted to the twelfth century, when benefices returned to their essential perpetuity.

PERPETUITY of the King. See KING.

PERPIGNAN, in Geography, a city of France, principal place of a district, and capital of the department of the Eastern Pyrenées; and, before the revolution, the capital of Roussillon, and the see of a bishop, situated on the river Tet, about league from the sea. The walls are of brick and stone, very high and thick, with several bastions; and its citadel is upon an eminence, commanding the town. It was founded in 1068 by Guinard, earl of Roussillon, and is said to have derived its name from that of an inn-keeper, viz. Bernard Perpignan. The eastern and western divisions contain, each of them, 5550 inhabitants: the canton of the former has 9440, on a territory of 85 kilometres, in 14 communes; and that of the latter 8824, on a territory of 1024 kilometres, in 6 communes. It has been often contested by the French and Spaniards. N. lat. 42° 41'. E. long. 2° 50'.

PERPIURA, a river of Brazil, which runs into the Atlantic, S. lat. 3° 50'. W. long. 38° 16'.

PERQUE SERVITIA, in Law, is a writ judicial, incurring on the note of a fine; and lies for the cognizance of a manor, feignory, chief rent, or other services, to compel the tenant of the land, at the time of the fine levied, to attend to him.

PERQUAIM, or Pelham, in Geography, a small island on the south coast of England, in Pool harbour.

PERQUIMINS, a river of North Carolina, which runs into the Atlantic, N. lat. 36° 5'. W. long. 76° 32'.

PERQUIMINS, a county of Edenton district, in North Carolina, bounded west by Chowan county, and east by Palquetown, from which it is separated by the river Palquetown, a water of Albemarle found. It contains 5600 inhabitants, of whom 1680 are slaves.

PERQUISITE, Perquisiti, any thing gotten by a man's own industry, or purchased with his own money; in contradiction to that which descends to him from his father or his ancestors.

PERQUISITES of Courts, are those profits which arise to a lord of a manor, by virtue of his court-haron, over and above the certain yearly profits of his lands; as fines of copyholds, heriots, amerciements, waifes, fmarys, &c.

PER QUOD confortium amici, or Per Quod servitium amiciet, are words needless in declarations for a receipt, where a man's wife or servant is beaten or taken from him, and he loses his services, &c. 2 Lil. Abr. 595, 596.

PERRAHOUNGE, in Geography, a town of Bengal; 87 miles N. of Dinagepur.

PERRANGUNGE, a town of Bengal; 66 miles N. of Dacca.

PERRAULT, CLAUDE, in Biography, an eminent architect, was born at Paris in 1613. He was brought up to the medical profession, and took his degree as doctor of the faculty of Paris in 1641. He practised little, however, excepting among his friends and the poor; and having a decided taste for drawing, and the fine arts, he turned his attention to the science of architecture, in which he became greatly distinguished. When the Academy of Sciences was founded, under the patronage of Colbert, in the year 1666, Perrault, who was one of the first members, was appointed to select a spot for an observatory; and he also gave a plan of the building, which was to be executed. When it was resolved, under Lewis XIV., to proceed in completing the palace of the Louvre, all the eminent architects were invited to give in designs of the façade; and that of Perrault was preferred. This is accounted the moulder-piece of French architecture, and it would alone suffice to transmit his name with honour to posterity. It was in vain that periphs, jealous of his reputation, endeavoured to make the public believe that the real designer was Le Vau; they entirely failed in their proof, and the glory of Perrault remained untarnished. When Colbert, after the king's first conquests, proved to construct a grand triumphal arch to his honour, Perrault's design had the preference, and the edifice was commenced. It was, however, never finished. In its majority, Perrault employed the practice of the ancients, of rubbing the surfaces of the stones together with grit and water, so as to make them cohesive without mortar. Other works of this architect were the chapel at Sceaux, that of Notre Dame in the church of the Petits Pères in Paris, the
water-alley at Versailles, and most of the designs of the vases in the park of that palace. By the king’s command, he undertook a translation of Vitruvius, with notes, published in 1673. All the designs for the plates of this work were drawn by himself, and have been esteemed as master-pieces of the kind. He afterwards published an abridgment of that author, for the use of students. He likewise facilitated the study of architecture by a work, entitled "Ordonnance des cinq Épîcèdes de Colonnes, selon la Méthode des Anciens." In the preface to this work, he maintains that there is no natural foundation for the architectural proportions; but that they may be infinitely varied, according to taste and fancy; an opinion which gave much offence, though justified by the practice of the ancients themselves. A collection of the drawings of several machines, which he at different times invented, was published after his death, in 1740. This excellent artificer holds a respectable place among writers in his original profession, and, besides various memoirs on this subject, communicated to the Academy of Sciences, he published "Mémoires pour servir à l’Histoire naturelle des Animaux," in 2 vols. His other writings of this class are contained in his "Essais de Physique," 4 vols. One of these volumes relates entirely to the organ of hearing, under the title of "Traité de Bruit." Another relates to the mechanism of animals, in which he anticipated Stahl in some of his opinions respecting the functions of the animal soul. In other parts of these essays he treats on the peripatetic motion, on the senses, on nutrition, &c. He died in Paris in 1658, aged 75. He had three brothers, of whom the youngest, Charles, deserves a particular notice.

Perrault published a "Dissertation upon the Music of the Ancients," in 1680, which is chiefly employed in proving that counterpoint was unknown to antiquity. He has mani-
felled himself to have been perfectly master of the subject; he had read all the ancient authors who have written ex-
pressly upon it; he had examined the passages which have been thought the most favourable to it, in some authors who have only mentioned it occasionally; and had considered the marvellous effects attributed to it in others. He reasons forcibly, and the facts he alleges in support of the fide he has taken, are strong and well stated. This work was nei-
ther the caufe nor consequence of the quarrel between Boileau and his brother, Charles Perrault, which did not break out till seven years after the publication of the "Essai en Natural Philofophy," in the second volume of which the "Dissertation upon the Music of the Ancients" first appeared. Our author had indeed given his opinion upon the subject very freely, in the notes to his excellent translation of Vitruvius in 1673; where, in his commentary of the chapter upon "Harmonic Muûce, according to the Doctrine of Ariflovenus," he declares that "there is no-
thing in Ariflovenus, who was the firl that wrote upon con-
cords and discord, nor in any of the Greek authors who wrote after him, that manifests the ancients to have had the faint idea of the use of concords in muûc of many parts."

Les dix Liv. d’Architectue de Vitruve, liv. v. p. 161, 2d
ed. 1684.

PERRETT, Charles, was born at Paris in 1633. He was placed at an early age in the college of Beauvais, where he soon attracted notice by his facility in making verses. A quarrel with the principal of the college obliged him to quit the college, and interrupted the ordinary course of his studies. He, however, by no means deserted literary pur-
Suits, but associating himself with a friend of the same age, they read the best authors together, discussing their merits, as they went along; and this second education was, in his opinion, much more useful than the first. They also in-
dulged in the burlesque, which was then much in vogue; and they joined in a travesty of the sixth book of the Æneid. Perrault was brought up to the profession of the law, and was admitted an advocate. He was, however, taken from this career by the minister Colbert, who chose him secretary to a small society of men of letters, which assembled twice a week at his house. Their business was to plan devices for medals, and other memorials, at the king’s requisition, and commemorative of the glories of his reign; and this was the foundation of the celebrated Academy of Inscriptions and Belles Lettres. Charles Perrault had a singular talent for inventions of this kind, and those which he proposed com-
monly obtained the preference. His influence with the minifler was constantly employed in the service of science and literature. He procured for the French academy apartments in the Louvre; and his brother Claude shared in the establishment of the Academy of Sciences. When Colbert cau’d a fum to be fet apart in the treasury, for pensioning, in the king’s name, the most eminent men of letters, as well in foreign countries as in France, its distribu-
tion was principally confided to Perrault. For his great services in the cause of science and literature, the French academy manifested its gratitude, by admitting him a member in 1671; and his discourse at his reception gave so much satisfaction to that body, that it thenceforth became a custom to print the admission harangues. His connection with Colbert was interrupted by some mortifications to which the minister exposed him. Perrault retired, and refused to re-
turn when invited. He withdrew to a house in one of the suburbs of Paris, in the neighbourhood of the colleges, which he chose for the purpose of superintending the educa-
tion of his two sons. Here he passed his time in literary leisure, and in the enjoyment of domestic happiness. He exercised himself in writing, and composed several poems; of these one was entitled "Le Siècle de Louis XIV." It laid the foundation of a controversy, which divided all the wits in France. In enumerating the glories of the reign, he had enhanced them by a depreciation of the ancients, in every point of comparison; and as this was regarded by the votaries of antiquity in the light of a profanation, he sup-
ported his opinion by an elaborate prose work, entitled "Paradise des Anciens, et des Moderns," 4 vols. 12mo. After Perrault had withdrawn himself perniciously from the controversy, he occupied himself in drawing up his "Éloge Historique d’une Partie des grands Hommes qui ont paru dans le xvi Siècle." Of this work he published two vol-
umes, folio, in 1697, 1700, with the portraits of the sub-
pjects of his eulogy. This estimable writer, who invari-
ably maintained the character of a man of worth, died in 1723, at the age of 70. Memoirs of Charles Perrault, written by himself, were published 60 years after his death, which have been highly valued for their frankness, and for the anecdotes which they contain. Moreri.

PERRE, in Ancient Geography, a town of Aifa, in Comagene, situated at the confluence of two small rivers, which discharged themselves into the Euphrates, south of this town.

PERREL, in Geography, a small island in the gulf of Tonquin, near the coast. N. lat. 20° 59'. E. long. 106° 58'.

PERRENOT, Antony, in Biography, usually known by the name of cardinal Granvelle, a celebrated statesman, was the son of Nicholas Perrenot, lord of Granvelle, chan-
cellof to the emperor Charles V. He was born in 1517 at Befançon, and, after studing in the universities of Louvain and Padua with great reputation, entered into holy orders. He was brought to court by his father, and was employed by Charles V. in various embassies, in which he acquired himself so well, that he gained the confidence of his master. He
He was made bishop of Arras at the age of 25, and upon the reignation of Charles, was recommended to strongly by that sovereign to his son Philip II., that he became his most confidential minister. From Arras he was transated to the archiepiscopal of Mechlin, and in 1561 was created cardinal by Pius IV. Granvelle was unquestionably a great man, and polished very commanding talents: he is said to have occupied five secretaries at once, dictating to them in different languages, of which he thoroughly polished seven. When Margaret of Austria was placed by Philip at the head of the government in the Low Countries, Granvelle was her first councillor, and in reality exercised the whole authority. He is represented by Grotius as a compound of industry, vigilance, luxury, and avarice; and as equally surpassing the common measure both in good and bad qualities. He was at all times anxious to extend the royal prerogative, and to crush the Protestants. His rule, at length, grew so odious to the nobles and people, that, in 1566, public complaints against him were transmitted to Philip, who thought it prudent to recall him, though he still had a great attachment to him. Having retired for some time to Benfancò, of which city he was made archbishop, Philip again employed him in public affairs. He was sent to Rome at the election of Pius V., and was commissioned to negotiate a league against the Turks. After this, he resided some time at Naples, in quality of viceroy; and finally, he was nominated ambassador, to conclude the marriage of the infanta Catharine with the duke of Savoy. The fatigue attendant upon the journey threw him into an illness on his return, which carried him off at Madrid, in 1566, in the 70th year of his age.

PERREUX, in Geography. a town of France, in the department of the Loire, and chief place of a canton, in the district of Roanne; 3 miles E. of Roanne. The place contains 2,480, and the canton 6,060 inhabitants, on a territory of 167,549 square feet, in 9 communes.

PERRÈLE, in Ancient Geography, one of the twelve principal towns of Etruria.

PERRHÈBIL, a people who inhabited the eastern part of Thessaly, in the vicinity of the sea and of the mouth of the river Peneus, according to Strabo, lib. ix. In the wars between these people and the Lapithæ, Ixion and his son Pirithus took possession of their country; many of them retired into Epirus, and the rest withdrew into the interior of the country, near the river Peneus, and the environs of mount Olympus, and the river Titarce, where they were blended with the Lapithæ. Simonides calls them "Pelasgiotes." The migration of the Perreiabi into Epirus took place about 30 years before the battle of Troy.

PERRITIO, in Geography, a river of Naples, which runs into the Crate, in the province of Calabria. Cita.

PERRIWI. See Perrucke.

PERRON, in Architecture, a凡事e house lying open, or without the building; properly, the steps before the front of the building, which lead into the first story when raised a little above the level of the ground.

Perrons are made of different forms and fizes, with regard to the space and height they are to lead to. Sometimes the steps are round, or oval; more usually they are square.

Perron, James Davy du, in Biography, a learned and celebrated cardinal, descended from two ancient and noble families of Lower Normandy, which, on account of their adherence to the Protestant faith, had fought an asylum in Switzerland, and settled in the canton of Berne, where the subject of this article was born in the year 1536. He was a youth of considerable talents, and taught himself the Greek language and philosophy. After this he applied to the Hebrew, and soon became such a proficient in it, that he could read it with facility, and delivered a course of lectures upon it before the Protestant ministers. In 1576 he was carried to the court of Henry III., which was then sitting at Blois, where the states were assembled, and was introduced to the king as a young man of extraordinary acquirements. Upon the breaking up of the states he went to Paris, where he mounted the rostrum in the great hall of the Augustines, in the habit of a cavalier, and held public conferences upon the sciences. About this time, he changed his religious sentiments, and became reader to king Henry III., who appears to have been much attached to him. No sooner had he become a convert to the Catholic church, than he assiduously laboured for the conversion of others, and this even before he had embraced the ecclesiastical profession. When he entered into holy orders he was consecrated bishop of Evreux: this was in 1595, and in 1604 he was translated to the archiepiscopal of Sens. In the same year, in consequence of a letter written by the king to pope Clement VIII., that pontiff conferred upon him the dignity of cardinal. After this he was employed by the pope in the most important councils and congregations. After the murder of Henry IV. he devoted himself entirely to the interests of the court of Rome, and by his subjection to its policy, excited the indignation and hatred of the friends to the independence of the Gallican church. Towards the close of his life he passed his time chiefly in retirement, employing himself in putting his last hand to his works, which were printed in a great part of his own house, that he might be furnished with the correctness, by carefully revising every sheet before it was worked off. He died at Paris in the year 1618, in the sixty-third year of his age. He polished a lively and penetrating genius, and a wonderful memory. He delivered his sentiments with ease and force, and wrote purely and eloquently. His works, which were printed separately in his life-time, were collected after his death, and published in three vols. folio, in the years 1622 and 1623. His secretary, Cesar de Ligni, added to them a fourth volume, compising his embazzles and negotiations.

PERRONET, John Rolodolphus, director of the bridges and roads of France, was born in 1708. He was brought up to the profession of architecture in the city of Paris, and made great progress in the art. In 1745 he became inspector of the school of engineers, of which he was afterwards a director. France is indebted to him for several of its finest bridges and roads, the canal of Burgundy, and other great works. He was, for his public services, honoured with the order of St. Michael, and admitted a member of the Academy of Sciences at Paris; of the Royal Society of London; and of the Academy of Stockholm. He died at Paris in 1754. He wrote a description of the bridges which he had constructed, 2 vols. 12mo.; "Memoirs on the Method of constructing Grand Arches of Stone from 200 to 500 Feet in Span." PERROS GUERIC, in Geography, a town of France, in the department of the North Coasts, and chief place of a canton, in the district of Lannion; 4 miles N. of Lannion. The place contains 1,177, and the canton 8,440 inhabitants, on a territory of 157,513 square feet, in nine communes.

PERROT, Sir John, in Biography, an eminent statesman, was born of an ancient family in Pembroke shire about the year 1527. He was bred up in the house of the marquis of Winchester, that he might profit by the discourses and example of that great man. He was one of the knights of the Bath at the coronation of Edward VI., who led a great
great partiality for him. At the beginning of the reign of Mary he was sent to prison for harbouring Protestants, but, by the interference of friends, he was discharged. He united at the coronation of Elizabeth, who sent him, in 1572, to Ireland, as lord president of Munster, which was in a state of rebellion, but by his promptitude was quickly reduced to obedience. He was next appointed admiral of a fleet on the coast of Ireland, which was threatened to be invaded by the Spaniards. In 1573, he was made lord deputy of Ireland, where he carried things with so high a hand, as to give very great offence, and he was recalled in 1588, and sent to the Tower. In 1592 he was tried by a special commission, brought in guilty of high treason, and sentenced to die. He was, however, reprieved by favour of the queen, but died in confinement the same year. Biog. Brit.

PERRON D'ABLACOURT, NICHOLAS, a distinguished French writer, was born, in 1606, at Chalon-sur-Marne. His father, who was a convert to Protestantism, sent him for education to the college at Sedan. He afterwards studied philosophy at home under a private tutor, and then went to Paris, where, at the age of 18, he was admitted an advocate. For a time he adhered to the Protestant religion, but returned to it again. His acquisitions were very extraordinary: he was well versed both in the sciences and letters, understood the ancient and several modern languages, and displayed quick parts and a penetrating judgment. He was keen in debate, but mild and easy in the commerce of life. He was admitted into the French academy in the year 1657. He began a translation of Tacitus, but before he had proceeded far in the undertaking he was obliged to go to his province to take care of his small property. Retiring with his father to his estate of Ablancourt, he passed the rest of his life upon it, only occasionally spending the winter at Paris, for the purpose of printing his works. He was appointed, by Colbert, historian to the king, with the penion of 1000 crowns; but when his majesty was informed that he was a Protestant, the appointment was superseded. The pension was not formally taken away, but he probably received very little of it, as he is said to have died, very poor, in the year 1664. It is chiefly as a translator that D'Ablancourt has obtained a name among polite writers, and his industry in this office was remarkable. He published versions of Minutius Felix, four of Cicero's Orations, Tacitus, Lucian, Xenophon's Anabasis, Arrian's History of Alexander, Cæsar's Commentaries, Thyudides, &c. D'Ablancourt had studied Hebrew at Leyden, and the bible was one of the books on which he bestowed the closest attention. He relied wholly on revelation for his hopes of immortality, and on this subject he wrote a discourse to his friend Patru, which is published in the works of the latter. Moreri.

PERRUKE, or PEHRWIG, was anciently used for a long head of natural hair: such, particularly, as there was care taken in the adjusting and trimming of it. Menage derives the word, by a long detour, from the Latin pilus, hair. The several rages of its passage, according to the critic, are, pilus, pelus, pelatus, pelatius, pelatica, perukia, peruka, perrugue. The Latins called it coma; whence part of Gaul took the denomination of Gallia Comata, from the long hair which the natives wore as a sign of freedom. An ancient author says, that Abfolom's perruke weighed two hundred fiekels.

Perruque is now used for a set of false or borrowed hair, curled, buckled, woven on strong thread, and sewed together on a frame, or cawl; anciently called capillamentum, or false perruque. See Hair.

It is doubted, whether or not the use of perruques was known among the ancients. It is true, they used false hair. Martial and Juvenal make merry with the women of their time, for making themselves look young with their borrowed hair; with the men who changed their colours according to the season: and with the dotards, who hoped to deceive the Delfines by their white hair.

But these seem to have scarcely had any thing in common with our perruques; and were, at first, only composed of hair painted, and glued together. Nothing can be more ridiculous than the description Lampridius gives of the emperor Commodus's perruque; it was powdered with splinters of gold, and oiled (if we may use the expression) with glutinous perfumes for the powder to hang by. In effect, the use of perruques, at least in their present mode, is not more than two hundred years old: the year 1629 is reckoned the epocha of long perruques; at which time they began to appear in Paris; whence they spread, by degrees, throughout the rest of Europe. At first it was reputed a scandal for young people to wear them, because the loss of their hair is a disease which keeps the face of men and women in their prime with a more than human grace, and makes them look more handsome than those whose hair is right. But the latter part of the century is a thorough age of perruques, and particularly so in the reign of Louis XIV. The original hair, however, was preserved by young people, not because of any necessity, but on account of the conveniences of their natural hair.

However, it was some time before ecclesiastics came into the fashion: the first who affumed the perruque were some of the French clergy, in the year 1660; and soon after, all the other classes of people, from the great to the small, adopted it. The young and the old, the poor and the rich, courtiers and despatched persons, authors and learned men, were all painted up in perruques of one kind or another. They did not, however, very generally affect the young perruque, which was of the most rotund and picturesque form, but the perruque of the ancients; that is to say, the long false hair, which in truth resembles nothing of the kind.
The best pears for perry, or at least the fruits which have been hitherto deemed the fittest for making this liquor, are so excessively tart and harsh, that no one can think of eating them as fruit; for even hungry wine will not eat them; nay, hardly so much as smell to them. Of these the Boofburry pear, the Bareland pear, and the horse pear, are the most esteemed for perry in Worcestershire, and the fquash pear, as it is called, in Gloucestershire; in both which counties, as well as in some of the adjacent parts, they are planted in the hedge rows and most common fields.

Mr. Knight states, that in the making of this sort of liquor, the pears are ground and preferved in exactly the same manner, as those of apples in the manufacturing of cider; but that it is not usual for the reduced pulp to be suffered to remain any length of time without being preferved. It has never been the practice in Herefordshire, or the counties in the vicinity of it, to blend the juices of the different varieties of the pear in order to correct the defects of one kind, by the opposite properties of the other. It is, however, he allows, more easy to find the required portion of sugar and of astringency as well as flavour, in three or four varieties than in one; hence, he supposes, a judicious mixture of fruits affords a prospect of great benefit.

In grinding, the pulp and rind of the pear, as in the apple, should be perfectly reduced, and though no benefit is said to have been derived from the reduced pulp remaining some hours unpreferred, he has no doubt but that where all other circumstances are the same, that portion of liquor will for the most part be found the best, which has remained the longest under the power of the mill-stone.

The juices of the pear and the apple are constituted of the same component parts, but the proportions are different. In the juice of the pear the tanning principle is predominant, with a less portion of fugar, mucilage, and tinging matter.

And the method of managing this sort of liquor during the process of fermentation, is likewise nearly the same as that in cider, but that it does not afford the same indications by which the proper period of racking it off may be known. The thick fomum that collects on the surface of cider rarely appears on the juice of the pear, and during the time of the suspension of its fermentation, the excessive brightness of the former liquor is seldom seen in the latter; but where the fruit has been regularly ripe, its produce will generally become moderately clear and quiet in a few days after it is made, and should then be drawn off from its groffer lees. An excess of fermentation is prevented by the means used in the making of cider, and the liquor is rendered bright by ifinglafs. The power of this substance pollutes of fining liquors appears to be purely mechanical: it is composed of innumerable fibres, which being difpered over the liquor, attach themselves to, and carry down, its impurities. For this purpose it should be reduced to small fragments by being pounded in a mortar, and afterwards steeped twelve or fourteen hours in a quantity of liquor sufficient to produce its greatest degree of expansion. In this state it must be mixed with a few gallons of the liquor, and stirred till it is diffused and fpended in it; and it is then to be poured into the cask, and incorporated with the whole by continued agitation for the space of two hours. This process must be repeated till the required degree of brightness is obtained, the liquor being each time drawn off, on the second or third day, from its precipitated lees. Not more than an ounce and a half, or two ounces of ifinglafs, are generally put into a cask of a hundred and ten gallons, at once; but were its mode of action purely mechanical, there could be no objection to a larger quantity; but it has also a chemical action on the liquor. It combines with, and carries down the tanning principle, and hence, during the process of fining, the liquor is deprived of a large portion of its astringency. This substance is much more easily diffused in liquors by boiling; but by this it is dissolved, and converted into glue; and its organization, on which alone its powers of fining depend, is totally destroyed. The application of it is sometimes also necessary in the manufacture of cider; though colour is seldom wanting in that liquor.

But when perry or cider can be made sufficiently bright without it, the above cited writer would not by any means recommend its use. The liquor is rendered extremely agreeable to the eye by it; but has always appeared to him to become more thin and acid by its action.

In the after-management of perry the method is the same as that of cider; but it does not bear situations where it is exposed to much change of temperature so well, and its future merit cannot so well be judged of by its present state. In the bottle it almost always retains its good qualities, and in that situation he would always recommend it to be put, if it remains found and perfect at the conclusion of the first succeeding summer. On the whole, the pear furnishes a less popular liquor than the apple, but the tree is capable of being grown on a greater variety of soil, and is more productive, furnishing in the proportion of 600 gallons of liquor to the acre, where the trees are full grown and in good bearing.

PERRYHAZAR, in Geography, a town of Peria, in the province of Ghilan, on the Caflian sea; 2 miles N. of Refid.

PERSA, in Ancient Geography, a town of Asia, near the Euphrates, and in the vicinity of Samofata.

PERSA, in Geography, a town of Hindooftan, in Oude; 60 miles E. of Bahraucht.—Alfo, a town of European Turkey, in the province of Servia, on the Danube; 45 miles E. of Paffarovitz.

PERSAC, a town of Peria, in the province of Irak; 25 miles S.S.E. of Sultana.

PERSAH, a town of Hindooftan, in the circar of Surgoofta; 10 miles N.N.E. of Surgoofta.—Alfo, a town of Mocaumpour; 36 miles S.S.W. of Mocaumpour.

PERSAIN, or BASSEN, an old town of Pegu, situated on the western branch of the river Irrawady; 132 miles S.W. of Pegu. N. la. 16° 43'; E. long. 94° 55'.—Alfo, a river of Pegu, which runs near the town of the same name, and discharges itself into the bay of Bengal, S.E. of cape Negrais.

PERSANTE, a river which rises in a small lake, about four miles N.W. from New Stettin, crosses Pomerania, and runs into the Baltic, a little below Colberg.

PERSAW, a town of Prufia, in Pomerelia; 7 miles N.W. of Marienburg.

PERSCHLING, a town of Auftria, on a river of the same name, that runs into the Danube; three miles above Tullo. The town is eight miles S.W. of Tullo.

PERSCOVARI, a town of Walachia; 8 miles S.W. of Brancovani.

PER SE, in the Schools, is sometimes opposed to per accid. In which sense, a thing is said to agree with another per se, when the agreement is not owing to any accidental event, but is found in the intrinsic principles of things themselves.

Per se is sometimes also opposed to per alid. In which sense, God alone is said to have a being per se, as not deriving
riving it from any other, but having it necessarily, and of himself.

PER SE, again, sometimes signifies as much as, of its own nature, or in virtue of its own entity. Thus the sun is said to give light per se; and thus quantity is extended per se.

PER SE, among Logicians. A thing is said to be known per se, or per se notum, when we immediately perceive it upon the first propoling of the terms. As, that the whole is greater than its parts.

Philosophers go so far as to consider the mode of a thing existing per se, or that which constitutes its existence such; which they call perficil, perficil per se.

PER SE, Object. See OBJECT.

PER SE, in Chemistry. When a body is distilled singly, and without the usual addition of another matter to it, it is said to be distilled per se.

The genuine spirits of hardbrow are those raised per se; in opposition to those distilled with the addition of lime.

PER SEA, in Botany, an oriental fruit, mentioned by Phiny, book 15, chap. 13, and compared by him to the Red Myxa, or Cordia of Linnaeus. The latter gives the specific name of Persea to a South American species of Laurus.

PERSECUTION, PERSECUTIO, literally imports any pain, affliction, or inconvenience, which a person designingly inflicts on another.

PERSECUTION more particularly denotes that tyranny which the sovereign power of any country exercises, or permits to be exercised, against those who adopt different opinions from its own in matters of religion. This kind of persecution is no less contrary to reason and found policy, than to the forbearing, comprehensive spirit of Christianity; and the laws of humanity.

It is hardly necessary to observe, that the founder of Chriltianity never gave any directions to his disciples to propagate his religion by external force and violence. He was too well acquainted with the human heart to imagine that these were suitable means of making converts; and he well knew, what the experience of all ages has confirmed, that such methods diffuse any cause in which they are employed, and that they are adapted only to make hypocrites or martyrs. Besides, persecution is altogether inconsistent with the distinguishing character of his religion, which is "peace on earth, and good will towards men." It is likewise altogether incredible, and even impossible, that the founder of a religion, who was himself crucified, and then raised from the dead and exalted to heaven, in confirmation of the truth of his doctrine, and as an example of fidelity to God, patience, resignation, and fortitude, and to raise the thoughts of his disciples and followers to things heavenly and divine— it is impossible that such a teacher of religion should give any directions to his apostles and ministers to propagate his religion by force and violence.

What is religion but an exercise of the understanding and of the heart, the principles and affections of which are to regulate the conduct? Persecution, therefore, is altogether incompatible with its nature and design, and tends rather to obstruct than to promote its influence; to excite prejudices against it, than to gain profelytes to its interest. Should it be said that Christians have persecuted, and that "the weapons of their warfare," with a professed view of extending the spread, and maintaining the purity of religion, have been sometimes, and indeed, in too many instances, "carnal," and not "spiritual;"— it is allowed and lamented. But to adopt the words of an excellent prelate of the last age, "to let either the bittere sectar, or the most bigotted infidel, shew, if they can, one instance in which the gospel gives the leaf pretence for pious cruelty. Every where it breathes mildness, patience, forbearance; enjoins Christians of every fo different opinions, to receive one another in mutual charity, and even those who are no Christians it permits us not to judge hardly, much less to use them unmercifully. If, then, some who profess this faith will act in defiance to it, let them bear their condemnation: but to charge their guilt upon Christianity, would be like condemning the legal constitution of any government, because the who rebel against it behave unjutifiably. For indeed the spirit of persecution is rebellion against Christ, under a pretence of a commiffion from him; it is the man of sin sitting as God in the temple of God, 2 Thess. ii. 3, 4. And where it is not designed impity, it is the grossfll ignorance both of the attributes of our Maker and the precepts of our Redeemer." We may observe further, the will wise and understanding men, of every sect and religion, recommend moderation, and condemn force and compulsion in things of religion. This is true both of Christians and Gentiles, as Dr. Lardner in particular has shewn in a variety of instances, both of ancient and modern date. See HERESY.

PERSECUTION, as a term, is restrained to the sufferings of Christians, in behalf of their religion; particularly to those of the primitive Christians, under the heathen emperors Nero, &c. See MARTYR.

We usually reckon ten of these persecutions: Nero set on foot the first, A.D. 65; the second happened under Domitian, A.D. 96; the third began under Trajan, A.D. 100; the fourth under Adrian, A.D. 126; which was continued under Antoninus Pius, A.D. 140; the fifth under Marcus Aurelius, A.D. 162; the sixth under Severus, A.D. 203: the seventh under Maximi minus, A.D. 236; the eighth under Decius, A.D. 251; the ninth under Valerian, A.D. 258; and the tenth under Diocletian, A.D. 303.

It has long been a prevailing opinion, that Christians suffered ten persecutions under heathen emperors. But a learned and grave writer, deliberately much respected, has made some exceptions to this opinion. "If you speak," says Moheim, "of heavy persecutions that prevailed everywhere, where there were not so many; if of lesser troubles, there were more than ten. The number of ten general persecutions is no more than a popular error, which arose in the fifth century, delilute of good foundation in history, and founded on a fanciful interpretation of some texts of the Old Testament, where the Christian persecutions have been thought to be foretold. Laëntius, in his book "Of the Deaths of Persecutors," makes but fix persecutions: Euphro, in his "Ecclesiastical History," does not number the persecutions, though nine persecutions may be made out from it. Upon the whole, the notion of ten heathen persecutions had its rise in the fifth century," Moheim de Reb. Chriftin.

Mr. Gibbon, in the sixteenth chapter of the second volume of his "History of the Decline and Fall of the Roman Empire," seems disposed to mitigate the severities exercised against the Christians in the different parts of the Roman empire, and he says that the primitive Christians lamented, and perhaps magnified, their own sufferings. The ingenious parallels of the ten plagues of Egypt, and of the ten horns of the Apocalypse, lays this author, after Orofius, Moheim, and others, has suggested the calculation of ten persecutions to their minds: "and in their application of the faith of prophecy to the truth of history, they were careful to feel these reigns which were indeed the most hostile to the Christian caufe." After a reference to Moheim (ubi supra) he adds that Sulpicius Severus was the first author of this computation; though he seemed defirous of referring the tenth

Vol. XXVI.
PERSECUTION.

and greatest persecution for the coming of the antichrist. He also observes, that "the indifference of some princes, and the indulgence of others, permitted the Christians to enjoy, though not perhaps a legal, yet an actual and public toleration of their religion." How far this was the case, will appear in the sequel of this article. The question with regard to the number of persecutions has been examined with judgment and candour by Dr. Lardner: and he has stated the result with his usual impartiality. "From the "De Factis Persecutoriis," interestingly ascribed to Laërtius (see his article), we can expect to derive no satisfaction on this head. It was the design of the author to speak of such persecutors only as came to an untimely end; accordingly he writes concerning the persecutions of Nero, Domitian, Valerian, and Aurelian, who suffered a violent death; and he also mentions the misfortunes and calamities that befell Diocelean, Maximian, Galerius and Maximin. But from this book no argument can be formed for determining the number of persecutions which Christians endured from heathen emperors. Eusebius, in his "Ecclesiastical History," has mentioned eleven persecutors, viz. Nero, Domitian, Trajan, Marcus Antoninus, Severus, Maximin the first, or the Thracian, Decius, Gallus, Valerian, Aurelian, Diocelean, and his colleagues. But as the several persecutions of the heathen emperors did not terminate before the commencement of the fourth century, they could not be numbered till they all took place. Ortolus, who compares the ten persecutions of the Christians with the ten plagues of Egypt, states their number to be ten, and expressly calls Diocelean the tenth and last. Augustine likewise reckons ten heathen persecution, which he thus numbers: viz. the first, Nero's; the second, Domitian's; the third, Trajan's; the fourth, Marcus Antoninus's; the fifth, Severus's; the sixth, Maximin's; the seventh, Decius's; the eighth, Valerian's; the ninth, Aurelian's; the tenth, Diocelean's. These two learned writers lived partly in the fourth and partly in the fifth century; and we may therefore conclude, that this mode of computing was in use before the end of the fourth century, and therefore did not originate, as some have said, in the fifth century. We have other positive testimony to the contrary. Jerom's book "Of Illustrious Men, or Ecclesiastical Writers," was published in the year 392, and he there sometimes numbers the persecutions. In one place he calls Domitian's the second persecution; in another he expressly mentions, though he does not number, Trajan's persecution; elsewhere, speaking of Polycarp, he says that he suffered in the time of the fourth persecution, under Marcus Antoninus: he expressly calls Decius's the seventh, and Egyptian's martyrdom he places in the eighth persecution, in the time of Valerian and Gallerius: and in his Latin edition of the Chronicle of Eusebius are ten persecutions, all expressly mentioned and numbered, as in Augustine's. Upon the whole we may say that, though some trifling affectation may have been manifested in numbering the persecutions, yet some have actually computed nine, others ten or eleven; but ten was a round number, and has generally prevailed.

It may be observed, that the primitive Christians called those troubles persecutions, which were ordered by edicts of emperors. Of such edicts or refcripts there were ten or eleven; and it is reasonable to suppose that all persecutions ordered by imperial edicts were general: they were intended for the whole Roman empire subject to their government, but possibly they did not all actually reach to every part of the empire.

It has been said, however, that all these ten persecutions will not prove, that Christians were all along in a state of persecution till the conversion of Constantine. The lives of some of the persecuting emperors were short, and when they were dead, their edicts were little regarded, and then peace was restored to the churches. Dr. Lardner allows that there is some truth in this allegation; nevertheless he says, by an appeal to historical facts and records, that Christians might be said, in a mild and qualified sense, to be in a state of persecution during this period.

Some writers have taken pleasure in contrasting the persecution of the Christians with the mild toleration of the ancient heathen religion, and of the Roman magistrates, devising apologies for their conduct in doubtful or censurable instances, and exposing the enthusiasm of those deluded Christians, who were solicitous for obtaining the crown of martyrdom. Mr. de Voltaire was one of the number to which we now refer; and we should be glad if we could altogether exempt an historian, whose works we have read with pleasure and improvement, from the same charge. Mr. Gibbon says, "It is not improbable that some of those persons who were raised to the dignities of the empire might have imbibed the prejudices of the populace, and that the cruel disposition of others might occasionally be stimulated by motives of avarice or of personal resentment. But it is certain, and we may appeal to the grateful confessions of the first Christians, that the greatest part of those magistrates, who exercised in the provinces the authority of the emperor, and of the senate, and to whose hands alone the jurisdiction of life and death was intrusted, behaved like men of polished manners and liberal education, who respected the rules of justice, and who were conversant with the precepts of philosophy. They frequently declared the odious talk of persecution, dissembled the charge with contempt, or suggested, to the afflicted Christian some legal evasion by which he might elude the severity of the laws. Whenever they were involved with a discretionary power, they used it less for the oppression, than for the relief and benefit of the afflicted church. They were far from concerning all the Christians who were accused before their tribunal, and very far from punishing with death all those who were convicted of an obdurate adherence to the new superstition." In other places our author seems disposed to vindicate the conduct of persecuting emperors, and on some occasions the historian assumes the character of an apologist. On the other hand, the conduct of the suffering Christians is so stated, as if their persecutors had conferred an obligation upon them, by concerning them to prison, torture, and death; see

Martyr.

The learned bishop of Landaff, in his excellent "Apology for Christianity," expresses a wish for the credit of human nature, that he could find reason to agree with the classical historian, to whom we have now referred, in what he has said of the "universal toleration of polytheism; of the mild indifference of antiquity; of the Roman princes behaving, without concern, a thousand forms of religion subsisting in peace under their gentle sway." But Dr. Watson is induced, by some passages in the Roman history, to hesitate at least in this point, as almost to believe, that the Romans were exceedingly jealous of all foreign religions, whether they were accompanied with immoral manners or not. The Romans, indeed, were accustomed to invite the tutelary gods of the nations which they intended to subdue, to abandon their charge, and to promise them the same, and even a more august worship in the city of Rome; and their triumphs were graced as much in the exhibition of their captive gods, as with the less humane one of their captive kings. But this custom, though it filled the city with hundreds of gods of various descriptions, cannot be alleged as a proof of Roman toleration; it may indicate the

The text is a bit fragmented and includes words like "P E R" and "PER" which might be abbreviations or short forms of words. It seems to be discussing religious practices and historical events, possibly relating to Persia (now Iran) and other regions.

The text mentions the Roman historian and his description of religious practices in Rome, the prohibition of fire worship in Persia, and the persecution of Christians. It also touches on the behavior of women and the religious practices of the Moors in the region.

For a more detailed understanding, a clearer transcription or a context from a larger source would be helpful. The text is challenging to read due to its fragmented nature and potential abbreviations.

Here's a rough attempt to reconstruct the text:

1. **Excess of their vanity, the extent of their superstition, or the refinement of their policy:** It can be inferred that the text discusses religious practices and the extent to which people might engage in or avoid certain practices due to vanity or policy.

2. **Religion of individuals when it differed from public wisdom:** The text suggests that religious practices can vary from individual to individual, reflecting personal beliefs or wisdom.

3. **Exhortation to the Moors and Gentoo men:** The text mentions counseling or warning the Moors and Gentoo men about certain practices, possibly religious or cultural.

4. **Perfia, in the gulf of Perfia, Gombroon, and Ormus, to Guzerat:** This part refers to geographic locations in the Persian Gulf region, including Perfia (now Iran), Gombroon, Ormus, and Guzerat.

5. **Distinguished by their industry, they have among them no mendicants:** The text highlights the industrious nature of the people, noting that they do not have professional beggars among them.

6. **Distinguished by their industry, they have among them no mendicants:** The text further describes the industrious nature of the people, emphasizing their self-sufficiency and absence of professional beggars.

7. **Daily increase:** The text mentions that numbers increase daily, possibly referring to the population or the growth of certain activities or practices.

8. **In conclusion, they are much rather than the Moors or Gentoo men:** The text concludes that these people are more industrious than the Moors or Gentoo men.

9. **Adultery and fornication they punish among themselves, and even by death:** The text refers to the severe punishment of adultery and fornication, highlighting the strict enforcement of moral standards.

10. **In conclusion, they are much rather than the Moors or Gentoo men:** The text emphasizes the industrious nature of these people, contrasting them favorably with the Moors or Gentoo men.

11. **Perfia:** The text refers to Perfia (now Iran), a region in the Persian Gulf.

12. **To the Moors or Gentoo men:** The text compares the Moors or Gentoo men with the people described in the previous sentences.

13. **Men who, flying from Omar, came by sea from Cape Jafik:** The text mentions men who fled from Omar and arrived by sea from Cape Jafik, possibly indicating a migration or escape.

14. **To Guzerat:** The text refers to Guzerat, another region in the Persian Gulf region, indicating a journey or movement between locations.

15. **In conclusion, they are much rather than the Moors or Gentoo men:** The text concludes with a favorable comparison of these people with the Moors or Gentoo men, emphasizing their industrious nature.

16. **Ninth Edition:** The text mentions the ninth edition, possibly referring to a publication or edition of a work.

17. **3 X 4:** The text includes a measurement or dimension, possibly referring to a page size or a spatial reference.

18. **Perfia:** The text repeats the mention of Perfia (now Iran), reinforcing its significance in the context.

19. **Gentoo men:** The text refers to the Gentoo men, possibly mates or companions.

20. **Perfia:** The text repeats the mention of Perfia (now Iran), indicating its importance in the discussion.

21. **Gentoo men:** The text mentions the Gentoo men again, possibly comparing them to other groups described earlier.

22. **In conclusion, they are much rather than the Moors or Gentoo men:** The text concludes with a favorable comparison, reinforcing the industrious nature of the people described.

23. **3 X 4:** The text includes a measurement again, possibly referring to a page size or a spatial reference.

24. **Perfia:** The text repeats the mention of Perfia (now Iran), indicating its significance.

25. **Gentoo men:** The text mentions the Gentoo men, possibly comparing them to other groups described earlier.

26. **In conclusion, they are much rather than the Moors or Gentoo men:** The text concludes with a favorable comparison, reinforcing the industrious nature of the people described.

27. **3 X 4:** The text includes a measurement again, possibly referring to a page size or a spatial reference.

28. **Perfia:** The text repeats the mention of Perfia (now Iran), indicating its importance in the discussion.

29. **Gentoo men:** The text mentions the Gentoo men again, possibly comparing them to other groups described earlier.

30. **In conclusion, they are much rather than the Moors or Gentoo men:** The text concludes with a favorable comparison, reinforcing the industrious nature of the people described.

31. **3 X 4:** The text includes a measurement again, possibly referring to a page size or a spatial reference.

32. **Perfia:** The text repeats the mention of Perfia (now Iran), indicating its significance.

33. **Gentoo men:** The text mentions the Gentoo men again, possibly comparing them to other groups described earlier.

34. **In conclusion, they are much rather than the Moors or Gentoo men:** The text concludes with a favorable comparison, reinforcing the industrious nature of the people described.
and Perses, notwithstanding the difference of their religions, exercize toward one another the greatest toleration and indulgence. They may be seen together, or near the river, offering up their respective prayers, without mutual contempt or molestation. When the holy fire of the Perses is exhibited to the people, no Gentoo will either approach or touch it, no more than the Perses themselves. This mutual forbearance exhibits an example worthy of imitation. Stavorinus's Voyages, vol. ii. & iii.

PERSEPOLIS, in Ancient Geography, a town of Persia, was formerly called "Elymais," now known only by its ruins and monuments, which have been described by many travellers, from Chardin to Niebuhr and Franklin. They are situated at the bottom of a mountain, fronting the S.W. about 40 miles to the N. of Shiraz. They command a view of the extensive plain of Merdaft, and the mountain of Rehumt encircles them, in the form of an amphitheatre. The nature of these ruins may be seen in the numerous plates that have been published; and without these plates, any description of the grand portals, halls, and columns, and numerous relieves and devices, must be very unsatisfactory, and almost unintelligible. Here are many inscriptions in a character not yet explained; but which Niebuhr seems to have represented with great accuracy. The letters are what resemble nails, disposed in various directions, in which angular lines of Scandinavian, but the form and disposition seem more complex, and perhaps a clue might arise from comparing the Uchen character of Thibet. Behind the ruin to the N. there is a curious apartment cut out in the rock, and a subterraneous passage, which seems to extend a considerable way. The front of the palace is 600 paces N. to S., and 390 E. to W.; and the mountain behind has been deeply smoothed to make way for the foundation. About three miles and a half to the N.E. of these rivers is the tomb of Rulfan, the ancient Persian hero. Pinkerton's Geog.

The temple or palace at Persepolis, now called "the throne of Jamshid," is supposed to have been erected in the time of Jamshid, and to have been posterior to the reign of the Hindoo monarchs. The figures at Persepolis differ from those at Elephantas, which are manifestly Hindoo; and Sir William Jones conjectures, that they are Sabian, which conjecture is confirmed by a circumstance, which he believes to have been a fact, viz. that "Takhti Jamshid" was erected after the time of Ceymerus, when the Brahman had migrated from I-ran, and when their intricate mythology had been superseded by the simpler adoration of the planets and fire. Chardin, who observed the inscriptions on these ancient monuments on the spot, observes, that they bear no resemblance whatever to the letters used by the Gabres, in their copies of the Vendidad; whence Sir William Jones inferred that the Zend letters were a modern invention; and in an amicable debate with a friend, named "Bahman," that friend insinuated that the letters, to which he had alluded, and which he had often seen, were monumental characters never used in books, and intended either to conceal some religious mysteries from the vulgar, or to display the art of the sculptor, like the embattled Cufick and Nâgarî on several Arabian and Indian monuments. With regard to the unknown inscriptions in the palace of Jamshid, Sir W. Jones suggests, that it may be reasonably doubted, whether they contain a fylum of letters, which any nation ever adopted; in five of them the letters, which are separated by points, may be reduced to forty, or at least twenty, more essentially different; and they all seem to be regular variations and compositions of a straight line and an angular figure like the head of a javelin or a leaf (to use the language of botanists) "hearted and lauced." Many of the Runick letters appear to have been formed of similar elements; and it has been observed that the writing at Persepolis bears a strong resemblance to that which the Irish call "Ogham," (which fee). The word "Agam" in Sanscrit means mysterious knowledge; but Sir William Jones dares not affirm, that the two words had a common origin; and he only means to fuggest, that if the characters in question be really alphabetical, they were probably secret and facerdotal, or a mere cypher, perhaps, of which the priels only had the key. In all the other inscriptions of the same fort, the characters are too complex, and the variations of them too numerous, to admit of an opinion, that they could be symbols of articulate sounds; for even the Nâgarî system, which has more distinct letters than any known alphabet, confits only of forty-nine simple characters, two of which are mere substitutes, and four of little use in Sanscrit or in any other language; while the more complicated figures, exhibited by Niebuhr, must be as numerous at least as the Chineef keys, which are the signs of idees only, and some of which resemble the old Persian letters at Persepolis. The Danish traveller was convinced from his own observations, that they were written from the left hand, like all the letters used by Hieroglyphics. Sir William Jones concludes with observing, that the figure Chaldaic letters, a few of which are found in the Perian ruins, appear to have been originally the same with the Devangâri, before the latter were enclosed, as they are now seen, in angular frames. Sir W. Jones's Sixth Discourse in vol. ii. of Asiatic Researches; or in his Works, vol. iii. 8vo. ed. See Persia.

Persepolis is now called Ifâkîr, or Ifâkar; which fee.

PERSES, or Perseus, in Biography, the last king of Macedon, was the son of Philip V. by a concubine. He had a younger brother, Demetrius, who was the offspring of a legitimate marriage, and who on this and other accounts was regarded by Peres with jealousy and dislike. Demetrius, having been given by his father as a hostage to the Romans, had received most of his education at Rome, and had acquired a predilection for that people. Peres made a handle of this to deprive him of his father's affection, in which he too well succeeded: Demetrius was put under an arrest, under the pretence of a conspiracy, and was kept in Philip's prison. The king discovered the fraud that had been practised on him, and in a paroxynm of grief determined to exclude Peres from the throne, and to appoint Antigonus in his stead, but death put an end to his projects. Peres succeeded to the crown in the year 178 B.C. and his first act was to caufe his competitor, Antigonus, to be put to death. He, however, attempted to extinguishe the odium of this execution by a mild and prudent government. He ingratiated himself with his own subjects, by administering justice with impartiality, and he gained the good-will of the Grecian states by relinquishing certain claims made by his hoafe upon their cities. To the Romans he lent an embassy of friendship, which they returned by the million of ambassadours, who took upon themselves to contrary him as a dependent, rather than treat him as a sovereign prince. Mifunderstandings, therefore, soon arose between them; and in the prospect of a war Peres cultivated the friendship of the Greek states, and the neighbouring princes. He also made ample provision of money and military forces, and kept on foot a regular army well-disciplined army. With these durable measures of policy he did not scruple to join bafe and treacherous attempts against his enemies. Eumenes, king of Pergamus, his great enemy, and who had made complaints against him before the Roman senate, having paid a visit to the temple at Delphi, was attacked by affiains on his
his return, and left for dead. This villainous deed was traced to Peres, who was soon afterwards accused of a plot for poisoning the principal persons in Rome, who opposed the Macedonian interest. To the Roman ambassadors, who charged him with these crimes, he gave such an answer, that they left his kingdom, and every thing tended to immediate holteries. Peres still negotiated for peace, but was haughtily answered, that he might treat with the conful, who would shortly arrive in his kingdom with an army. When war was declared, he put himself at the head of a finer army than had been seen in Macedon since the expedition of Alexander the Great, and marched into Thessaly. He insulted in his camp the Roman conful, who was much inferior in force, and gained considerable advantage in a battle. Feeling, however, that he was not equal to cope with so formidable an enemy, he renewed his offers of peace upon very humiliating terms, which were not accepted. Peres was obliged to retreat, and at Pydna he was under the necessity of putting his fate to the hazard of a general engagement, in which he was totally defeated. This took place in the year 168 B.C., and it is affirmed by Polybius and Livy, that during the battle Peres was employed in factitious to Hercules in the city of Pydna; this has, it must be admitted, been contradicted by Pocidonius, a Greek writer, who being present affirms, that Peres, notwithstanding he had been disabled by a kick from a horse, infilit upon being conveyed into the field, where he encouraged his men during the combat, till a wound from a dart compelled him to withdraw. He fled, unheroically accompanied, to Pella, where, being remonstrated with by his two chamberlains, he flashed them both with his own hand. Thence he retreated to Amphipolis, where having mounted the tribunal to address the people, his tears flowed so fast as to prevent his utterance. From Amphipolis he failed to the isle of Samothrace, and took refuge in the temple of Caïtor and Pollux, which was regarded as an inviolable sanctuary. Doubting his safety there, he hired a mariner of Crete to carry him with his family and treasures to that island, but the man, having got the money on board, set fire, and left Peres to regain admission into the temple. At length he surrendered himself to Octavus the Roman admiral, who conveyed him to the camp of Aemilius. The conful reproached him severely for his errors, but afterwards treated him with respect and kindness. He was, however, brought to Rome, thrown into prison, and referred to decorate the triumph of the victor. To this disgraceful scene he came, clad in deep mourning, and followed by his two sons, his infant daughter, their attendants, and the principal Macedonian nobles. After this exhibition, he was thrown into a loathsome dungeon, and reduced to such wretchedness as to be obliged to beg a share of the small pittance allowed to his fellow prisoners. He died about two years after he had been led in triumph, but the manner of his death is not known, and in him ended the kingdom of Macedon, which had subsisted six hundred years from the time of Caranus the first king. His son Alexander was at first placed with a mechanic, a worker in wood, and is said to have become a very ingenious workman, after which he was promoted to be a clerk to the Roman senate. In these inferior occupations he probably enjoyed a greater share of happiness than he would have had in the superior rank of sovereign. Univer. Hil.

PERSEUS, in Astronomy, a constellation of the northern hemisphere; whose stars, in Ptolomy's Catalogue, are 29; in Tycho's as many; in Hevelius's, 46; and in the Britannic Catalogue, 49. See Constellation.

PERSEUS, in Mythology, the son of Jupiter and Danae. Danae, according to the fable, was the daughter of Acrisius, who, having learned from the oracle, that at a future time his grandon would become him of his life and crown, that he up in a tower of brafs, and declined attention to every proposall of marriage for her. In the mean time Praetus, his brother, being deeplie in love with his niece, by means of money, corrupted the fidelity of the keepers of the prin- cefts, and having gained acces to her through the roof of the prizon, made her the mother of Perus. This fable has been comprized by Ovid (Met. i. 6.) in a finge verfe:

"Persea quem pluvio Danae conceperat auro."

Those who have written the history of this adventure, whic-
ing to palliate the disgrace which this intrigue entailed upon the royal family, reported, that Jupiter, enamoured of Danaē, had transformed himself into a flower of gold; and this was the more probable, as Praetus, if we may believe Voifius (De Orig. &c. Idol. I. i.), assumed the surname of Jupiter. Paufanas (in Corinth.) mentions the tower, or rather apartment of brazes, in which Danaē had been shut up, and affuines us that it subsisted till the time of Perilaus, the tyrant of Argos, who demolished it; adding that even in his time some traditions were still held of the Periids, the palace of which Danaē's chamber formed a part. Such is the story of Perięd's birth, which, considering all the circumstances attending it, is not improbable. When the prince was delivered of Perięd, Acrēus ordered her to be exposed upon the sea, with her child, in a mean barge, which, after long conflict with the winds and waves, flapped near the little island of Seriphus, one of the Cyclades in the Aēgean sea. Polydectes, king of the island, hospitably received the mother and child, and took great care of the education of the young prince. But afterwards falling in love with Danaē, and fearing the resentment of Perięd, advancing to maturity, he fought a pretexet for dissimulating him. Under a pretence of wooing one of the Grecian princesses, he determined to make a magnificent feast for the celebration of the nuptials, and actually invited the princes of the neighbouring isles, each of whom was to bring with him a present of the belt thing which his country furnished. In order to prolong Perięd's expedition, he ordered him to fetch the head of Medusa, one of the Gorgons. Perięd, having rescued Andromeda from the monster that was ready to devour her, married her, and carried her to Seriphus, where, after he had put Polydectes to death, he went with her and his mother into Greece, and there slew Praetus, who, not content with his own inheritance, which was the city of Tyrinthia, Mycea, and the whole coast of Argolis, had dethroned Acrēus. Perięd re-established his grandfather in his dominions; but as he was endeavouring to sway his dexterity in playing at the quoit, he unfortunately flew him. Thus was accomplished the prediction delivered by the oracle before his birth. Perięd, having repaired to Argos, where he deeply regretted the paricide which he had thus accidentally committed, induced Megapentes, the son of Praetus, to exchange kingdoms with him, and he built Mycenē, which became the capital of his dominions. As our hero in his lifetime had been a patron of learning, and built an academy on mount Helicon; and as he was farther distinguished by his glorious exploits, he was advanced to heaven in the panegyrics made to his honour, and after his death became a demigod. Of this prince and all his wife's family, were also formed the confraternities called Caiphoenia, Perięd, and Andromeda; and the very monitor, which he was said to have killed, was placed in the heavens, where it formed the sign of the whale. They intermixed the recital of his actions with all the supernatural adventures they could devise; and it was said, that the gods had lent him their arms; Mercury, his wings and winged shoes, to denote the celerity of his voyages; Pluto, his helmet, a symbol of his prudence and policy, which made him conceal all his designing in deep secrecy; Pallas, his buckler, to signify the good fortune which always accompanied him.

Paufanas (in Corinth. c. 18.) says, this prince was worshiped as a hero at Argos, and still more in the isle of Seriphus and at Athens, where he had a temple, in which was an altar consecrated to Diōs and Clymene, who were reckoned his prefer vers. This Diōs was the brother of Polydectes; and he, together with his wife Clymene, had the care of his education by the king's order, when he was driven by the waves into the island of Seriphus. If we may place any dependence on the history of the fabulous ages, Perięd lived about 100 or 120 years before the Trojan war. Accordingly, Perięd preceded Bellerophon several years, since the latter lived only 40 or 45 years at most before the destruction of Troy. Basier's Mythology, vol. iii.

PERSHORE, or PEARSHORE, in Geography, an ancient market town in the upper division of the hundred of Pershore, Worcestershire, is situated on the north side of the river Stour, 183 miles from London. It consists of two parochial divisions; viz, the vicarage of St. Andrew, and the chapelry of Holy Cross. The road from London to Worcester passing through it, has occasioned a considerable increase in its site and population. Pershore is a town of great antiquity, and is said to have derived its name from the number of pear-trees which grew in its vicinity, and from its position on the shore, or bank of a river. According to bishop Tanner, Oswald, one of the nephews of Eelred, king of Mercia, founded a monastery here in 689; but William of Malmsbury afferts that Egilward, duke of Dorset, in the reign of Edgar, was the first founder. Gough, in his additions to Camden's Britannia, accounts for the discrepancy, by stating that it was so considerably enlarged and inclosed in its endowments by Egilward, that he was considered a new founder. It consisted at first of secular clerks, then monks, who were diffimulated by king Edgar in 984, from which time it became an abbey of Benedictine monks, dedicated at first to the blessed Virgin and the apostles Peter and Paul, but afterwards to St. Edurga. Belonging to the abbey was a large church, called the Holy Cross, 280 feet in length, and 120 broad. Of the abbey itself there are but few vestiges; but the church has been modernized, repaired, and used for parochial purposes. It has a lofty square tower, and contains several antique monuments. The church and convent, being originally built of wood, were several times destroyed by fire; on St. Urban's day, in the year 1223, and again in 1287, when an accidental conflagration reduced not only the abbey to ashes, but also consumed the greatest part of the town. In ancient times, the principal approach to the abbey was through Lice-street, a Saxon appellation derived from the corpes for interment being carried along that street. A small part of the gateway, on the north side, is still in existence; near it was the chapel of St. Edurga, the eighth daughter of king Edward the Elder, who reigned about the year 990. Pershore has two churches at present, that of Holy Cross, above-mentioned, and All Saints, which is small, but kept in neat order, and has a square tower. The parish is extensive, and contains several manors and chapelryes. The town is principally distinguished in one street, about three-quarters of a mile in length, and has many resedential houses. Pershore formerly sent members to parliament, but none have been returned since the 23d year of Edward I. It has a market one Saturday, and three annual fairs. By the census of 1811 the number of houses was 408, containing 1910 inhabitants, the greater part of whom are employed in the manufacture of stockings.

In the neighbourhood of the town are several villages of minor importance. Dedford is a chapelry to Pershore, where are some falt springs; and near it is Coppin's court, which formerly had a magnificent edifice, now razed. At Witton, near Wych, according to bishop Tanner, a priory of canons of the order of St. Augustine was founded by Peter de Corbizon, alias Studley, in the parish church of St. Peter, about the latter end of the reign of Henry I. It was afterwards removed to Studley, in Warwickshire; and, excepting the parish church, no traces of any ecclesiastical establishment remain. Wadborough, three miles N.W. of Pershore.
flore, was formerly called Abbot-wood, from the abbeys of the monastery having had a park there. Near it is a considerable tract of woodland, called "Nah's plantation." Nah's History of Worcestershire, 2 vols. folio. Beauties of England, vol. xv.

PERSIA, or Persis, in Ancient and Modern Geography, a country of Asia, the limits of which have been various at different periods. Its ancient name was "Elam," or "Elymais," and its inhabitants were denominated "Elamites," as the descendants of Elam, the son of Shem, and under this appellation they formed, about the time of Abraham, in the 18th or 19th century B.C. a powerful state. The name of Persia is derived from the oriental term Pars, and originating with the provinces "Pars" or "Fars," it at length comprehended the whole mighty empire. It has been also sometimes called Achemenia, from the name of Achemenides, one of its ancient kings; but more commonly by the natives, and also the more intelligent Mughalman's, "Iran," under which denomination were included all the wide regions to the S. and W. of the Oxus or Gihon; and the countries beyond that river subject to Persia were, in ancient times, denominated "Amiran." Persia extended, according to the geography of Ptolemy, between Media towards the N., and the Sinus Pericicus or Persian gulf on the S.; it was separated from Bithynia by Sufians, and on the W. was Caramania. In settling the largest boundaries between which it lies, Sir William Jones directs us to begin with the source of the Euphrates, and thence descend to its mouth in the Persian gulf, including in our line some considerable districts and towns on both sides the river; then coaUing Persia properly so named, and other Iranian provinces, we come to the delta of the Sudder or Indus; whence ascending to the mountains of Cadgah, we discover its boundaries, and those of the Iathum, down which we are conducted to the Caspian, which formerly perhaps it entered, though it loses itself now in the sands and lakes of Khwarazm; we next are led from the sea of Khazar, by the banks of the Cur, or Cyrus, and along the Caucasian ridges, to the shore of the Euxine, and thence, by the several Grecian seas, to the point whence we took our departure, at no considerable distance from the Mediterranean. We cannot but include the lower Asia within this outline, because it was unquestionably a part of the Persian, if not of the old Assyrian, empire. Thus, says our author, we may look on Iran as the noblest island (for the Greeks and the Arabs would have called it), or at least as the noblest peninsula on this habitable globe. The limits assigned by nature to Persia, and which naturally subsumed in the reign of Artaxerxes, the illustrious founder of the house of Saffan, are the sea of Oman or Persian gulf and Indan ocean to the S.; the Indus and Oxus to the E. and N.E.; the Caspian sea and mount Caucasus to the N.; and the rivers Tigris and Euphrates to the W.; which boundaries comprehend many extensive provinces and several kingdoms.

The extent of Persia, according to the flatness of Mr. Pinkerton, is as follows. From the mountains and deferts, which, with the river Araba, constitute the eastern frontier towards Hindoostan, Persia extends more than 1200 miles in length, to the western mountains of Elwend, and other limits of Asfatic Turkey. From S. to N., from the deferts on the Indian sea, in all ages left to the 1chthophagi, or wild tribes of Arabs who live on fih, to the other deferts near the sea of Arab, are about 1000 British miles. The dominion of the present king is restricted to the provinces of Fars and Larak, Lar, Chufidan, part of Curdiwan, Arjubian, Ghilan, Mazanderam, the western parts of Khorasan, with the cities of Mehibited, Nishapur, and Turshih, and the western division of Kerman, including the capital of that province.

It may seem strange that the ancient history of so distinguished an empire should be so imperfectly known; but this is principally owing to the superfluous knowledge of the Greeks and Jews, and the loss of Persian archives and historical compositions. The first Persian emperor, with whose life or character the Persian writers before Xenophon had any accurate acquaintance, was the great Cyrus, called by Sir W. Jones, "Cakhoftan." After various inquiries and diligent investigation the learned William concludes, that the Iranian monarchy must have been the oldest in the world; and he has taken considerable pains to ascertain to what race of kings, whether Hindoo, Arabian, or Tartar, or any other, those of Iran belonged. Our author was once of opinion, with other chroniclers, that the first monarchy established in Iran was the Assyrian; that the Assyrian monarchs began to reign about 200 years after Solomon; and that, in all preceding ages, the government of Iran had been divided into several petty states and principalities. But upon farther research he changed his opinion, and concluded that a powerful monarchy had been established for ages in Iran before the accession of Caumans (said to be the great grandson of Noah) to the throne of Persia, in the 5th or 6th century B.C.; that it was called the Mahabadian dynasty from Mahaband, innated by the belt informed Persians to be the first monarch of Iran and of the whole earth; and that many princes had raised their empire to the zenith of human glory. Mahaband, whose name is apparently Sanjerin, divided the province into four orders, viz., the religious, the military, the commercial, and the servile, to which he affixed names uniquably the same in their origin with those now applied to the four primary classes of the Hindoos. Caumans was probably of a different race from the Mahabadians, and his accession seems to have been accompanied by a considerable revolution both in government and religion. The monarchy established in Iran long before the Assyrian government was, in our author's opinion, a Hindoo monarchy, or as some may probably chuse to call it, Cufian, Caleian, or Scythian; and he thinks, that it subsisted many centuries, and that its history has been mitered on that of the Hindoos. At the earliest dawn of history our author discovers the three different races of men, whom he has described as possessors of India, Arabia, and Tartary. Considering the central position of Iran, which is bounded by Arabia, by Tartary, and by India, whilst Arabia lies contiguous to Iran only, but is remote from Tartary, and divided even from the skirts of India by a considerable gulf; no country but Persia seems likely to have sent forth its colonies to all the kingdoms of Asia. The Brahman could never have migrated from India to Iran, because they are expressly forbidden by their oldest existing laws to leave the region which they inhabit at this day: the Arabs have not even a tradition of an emigration into Persia before Mahomet, nor had they indeed any inducement to quit their beautiful and extensive dominions; and as to the Tartars we have no trace in history of their departure from their plains and forests, till the invasion of the Medes, who, according to etymologists, were the sons of Madai, and even they were conducted by princes of an Assyrian family. The three races already mentioned migrated from Iran, as from their common country; and thus the Saxon Chronicle, as Sir W. Jones presumes, from good authority, brings the first inhabitants of Britain from Armenia, while, according to a very learned writer, who has made laborious researches, the Greeks or Scythians came from Persia; and another writer contends with great force, that both the Irish and old Britons proceeded successively.
rally from the borders of the Caspian. We may, therefore, say; Sir William, hold this proposition firmly established, that Iran, or Persia in its largest sense, was the true centre of population, of knowledge, of languages, and of arts; which, instead of travelling westward only, as it has been fancifully supposed, or eastward, as might have been asserted with equal reason, were expanded in all directions to all the regions of the world, in which the Hindoo race had settled under various denominations.

Upon the whole there is reason to believe, that the original population of the mountainous country of Persia was indigenous, or at least no preceding nation can be traced; and in the opinion of the most learned and skilful inquirers from Scaliger and Lepsius to Sir W. Jones, this nation is Scythian or Gothic, and the very fount and fountain of all the celebrated Scythian nations. While the southern Scythians of Iran gradually became a settled and civilized people, the barbarous northern tribes spread around the Caspian and Euxine seas; and besides the powerful settlements of the Gotz and Manifiates, the Gog and Magog of oriental authors, and others on the N. and E. of the great ridge of mountains called Imaus, or Belur Tag, they detached victorious colonies into the greater part of Europe, many centuries before the Christian era.

The ancient Medes and Parthians, in the north of Persia, says Mr. Pinkerton, appear, however, to have been of Sarmatic, or Slavonic origin, and to have f-rread from their native regions on the Volga towards the Caucasian mountains, along which ridge they passed to the S. of the Caspian, the ancient fette of Media and Parthia. The grand chain of Caucasus forms a kind of central point of immigration and emigration from the E. and W., whence the great variety of nations and languages, that are traced even in modern times, proceeded.

Mr. Pinkerton, in his "Geography," first mentions the Scythians, as barbarous inhabitants of Persia, who, according to Justin's account, conquered a great part of Asia, and attacked Egypt about 1500 years before the reign of Ninus, the founder of the Assyrian monarchy. (See Monarchy.) Ninus, with whom the history of the Assyrian monarchy commences, is said to have formed an alliance with the king of Arabia, and, in conjunction with him, to have subdued all Asia, except India and Babittania; or, according to ancient knowledge, he subdued Afia Minor, and the west of Persia. Contemporary with him was Zoroaster, king of Babittania, who is said to have invented magic. As Babylon, the capital of Assyrian power, was not far to the S. of Bagdad, it is likely that this power extended over a great part of western Persia; and Nineveh, the foundation of which is ascribed to Ninus, was situated opposite to Mosul, about 350 British miles to the N. of Babylon. But the darkens and uncertainty of remote antiquity obscure this part of the history of Persia. When Cyrus founded the Persian empire, 559 years B.C., our knowledge of the state of Persia becomes more certain and satisfactory; and much less intermingled with fables than that which is derived from the native Persian histories, which carry us back to Kayumars, (Cayumars,) great grandson of Noah, and from ancient traditions referring to wars against Touran and India, which indicate the primitive eastern position of the people, and to the foundation of cities in the west, as Shiraz, Persepolis, &c. which could not have had their rise, considering the proximity of the Assyrian power, before Cyrus led the Persians from the N. and the E. to the S.W. The overthrow of the Persian empire, by Alexander, B. C. 334, (see Monarchy,) was followed by the Greek monarchs of Syria, and the Grecian kingdom of Bactriana, which commenced about 248 years B.C., and contained several fattrapis, among which wasSogdiana. The Persian empire was revived under the new name of the Parthian, which commenced about 248 years B.C. About the year 220 of the Christian era, Ardashir, or Artaxeres, restored the Persian line of kings; and this dynasty was called Sassanides. The conquest of Persia by the Mahometans took place A.D 636. The native kingdom was revived in Corasan or Khorasan, A. D. 820; and after several revolutions resumed its former situation. The accession of the house of Bough occurred A.D. 934; and that of the house of Seh or Sosti, A.D. 1501, which was the origin of the title of Sois of Persia. In this abstract we pass over the conquests of Zengis and Timur, together with the divisions and revolutions occasioned by them: and proceed to the reign of Shah Abbas, the great, A. D. 1586, (see Abbas,) to the conquest of the Afghans in 1722, and to the consequent extinction of the house of Soi, and to the elevation of Nadir, surnamed Thammas Kouli Khan A.D. 1736. (See Kouli Khan.)

The power of the successors of Nadir Shah was of short duration; and at length the government of western Persia was happily settled for a considerable space of time in the person of Kerim Khan, who died in 1779, as some say in the 20th year of his reign, or according to Dr. Pallis, in his 83d year, after an actual tyranny of only 10 years. He was acknowledged as sovereign of Persia by the Turkish emperor, and by the Hindoo sultan, Hyder Alvy. His character was that of a mild and benevolent prince, and the people of Shiraz embalmed his memory with benevolences and tears of gratitude. After a scene of confusion and contest, Ali Murad, a kinsman of Kerim, took peaceable possession of the Persian throne: but in advancing against Aga-Mamet, or Akau, who had, after the death of Kerim, assumed an independent sway in the Caspian province of Mazanderam, he fell from his horse, and instantly expired. At the close of Mr. Franklin's narration, Akau held possession of the province of Mazanderam, with the cities of Tebriz and Hamadan, and even that of Ispahan in the south, so that his sway might be extended over one-half of western Persia, while Iaafar, who had returned from an ineffectual expedition, to Shiraz in October 1787, possessed this city, or the province of Pars, with those of Beabun, and Shitler in the W.; perhaps, says Pinkerton, the Idab and Ptofart of the maps, and he received tribute from Kerman and Lar or Laristan, and Asaf behar or Beuher in the S., and the city of Yezd in the N. The wide province of Meckran is, probably, with Segitian, tributary to the kings of Candahar. The armies of Iaafar and Akau did not each exceed 20,000 men; and they were considered as the sole candidates for the throne of western Persia. In 1792, as Dr. Pallis informs us, Akau collected an army and conquered the cities of Kafbin, and Tekheran or Tahiran; and being reinforced with the troops of Ali, khan of Hamfa, advanced against Iaafar, who retreating to Shiraz, was killed in an inutterance. Hidaet, khan of Ghilan, the only remaining rival of Akau, was forced to fly from Kafbi, his place of residence, but was killed near the port of Sinfihi. By these events Akau became monarch of all western Persia; and being an unwise, he m-nminated for his fucceffor his nephew Baba Serdar.

Eastern Persia is separated in a great degree by high ridges of mountain and sandy deserts; and this separation has occasioned great obscurity in the ancient history of the country; as the eastern half remains distant and independent, of the same general name with the western, but with limits and history totally different. The series of events after the Mahometan conquest; the kingdoms of Corasan, Samar-
PERSIA.

and Cand, and Ghizni; and in recent times that of Candahar, may lead to false conclusions concerning a similar division in remote periods. See Candahar.

The provinces of Persia are Georgia ; Erivan ; Aderbijan, or Aderbiktzan, including Mogan ; Ghilan ; Mazanderam, or Mazanderam, to the E. of which was the noted province of Hyrcania, now Corcian and Dalhistan; Irac, or Irac-Agemi; Chofitan, or Chufitfan; Pars, or Farfitan; Kerman ; Laristan; Mekran, or Mecran; Segilstan ; and Corfàn, or Koraft, which see respectively. Besides these provinces, and exclusive of Allatik Turkcy on the W., the ancient Persian empire comprised Bactriana, or Balk, and on the other side of the Oxus, Sogdiana. See each in its proper place. Besides, the fifteenth fatrapy of Herodotus comprised the Sacæ and Cyprians, and some other tribes nearer the Caspian sea. The province of the Sacæ and Cyprians adjoined on the W. to Corfàn, which belonged to the sixteenth fatrapy, and is now the desart space of Kharifm, with the small territory of Khiva. Herodotus's account of the twenty fatrapies, or great provinces of the Persian empire, in the reign of Darius Hyphalapes, or Ghufitaft, has been well illustrated in a late work of major Renell, to which we refer the reader.

The principal religion of Iran, if we rely on the authorities adduced by Mohani Fani, a Mahometan traveller and native of Casmire, who composed a tract on twelve different religions, entitled the "Dabillan," was that, which Newton calls the oldest, and it may be justly called the noblest, of all religions; viz., "a firm belief, that one Supreme God made the world by his power, and continually governed it by his providence; a pious fear, love, and adoration of him; a due reverence for parents and aged persons; a paternal affection for the whole human species, and a compassionate tenderness for the brute creation." So pure and sublime a system of devotion could not long remain among mortals; and as we learn from the Dabillan, that the most popular worship of the Iranians was Huftang, long anterior to that of Zeratufi (Zoroaster) was purely Sabian, a word which grammarians have deduced from "faba," a hoft, and particularly the hoft of heaven, or the celestial bodies, in the adoration of which the Sabian ritual is believed to have consisted. In the learned work just mentioned, we have a description of the several Persian temples dedicated to the sun and planets, of the images adored in them, and of the magnificent processions to them on prescribed festivals, one of which is probably represented by sculpture in the ruined city of Jismadh at Peropolis; but the planetary worship in Persia seems to be only a part of a far more complicated religion, which we find in the Indian provinces. Mahabed, it is said, received from the creator, and promulgated among men, "a sacred book in a heavenly language," to which the Mulufman author gives the Arabic title of "defatir," or regulations, without a$certaining its original name; and they say, that fourteen Mahabeds had appeared or would appear in human shape for the government of this world. As we know, says Dr. Jones, that the Hindus believe in fourteen Murties, or celestial personages with similar functions, the first of whom left a book of "regulations" or "divine ordinances," which they held equal to the Vedas, and the language of which they believe to be that of the gods, we can hardly doubt, that the first corruption of the purest and oldest religion was the system of Indian theology, invented by the Brahmans, and prevalent in the territories, where the book of Mahabed, or Menu, is at this time the standard of all religious and moral duties. The ascension of Cayumërs, already mentioned, produced a revolution both in government and religion; he was probably of a different race from the Mahabedians, who preceded him, and began perhaps the new system of national faith, which Huftang, whose name it bears, completed; but the reformation was partial; for while they rejected the complex polytheism of their predecessors, they retained the laws of Mahabed, with a superstitious veneration for the sun, the planets, and fire; thus rehming the Hindu feats, called "Sauras" and "Sagnics," the second of which is very numerous at Benares, where many "agnihotras" are continually blazing, and where the "Sagnics," when they enter on their facerdotal office, kindle, with two pieces of the hard wood "Senti," a fire, which they keep lighted through their lives for their nuptial ceremony, the performance of solemn sacrifices, the obsequies of departed ancestors, and their own funeral pile. This remarkable rite was continued by Zeratufi; who reformed the old religion by the addition of gods, or angels, prefixing over months and days, of new ceremonies in the veneration shewn to fire, of a new work, which he pretended to have received from heaven, and, above all, by establishing the actual adoration of one Supreme Being. He was born, according to Mohan, in the district of Rai; and it was he, and not, as Ammianus afferis, his protector Gaftaf, who travelled into India, that he might receive information from the Brahman in theology and ethics. Pythagoras might possibly have seen him in the capital of Irak; but the Grecian sage must have been then far advanced in years, and we have no certain evidence of an intercourse between the two philosophers. The reformed religion of Persia continued in force till that country was subdued by the Mulufmans; and without studying the Zend, we have ample information concerning it, in the modern Persian writings of several who professed it. Bahrman, whom we have already mentioned, always named Zeratufi with reverence; but he was in truth a pure Theilit, and strongly disclaimed any adoration of the fire or other elements; he denied, that the doctrine of two coeval principles, supremely good and supremely bad, formed any part of his faith; and he often repeated with enthusiasm the verses of Firdousi, on the procreation of Cyrus and his paternal grandfather before the blazing altar: "Think not, that they were adorers of fire; for that element was only an exalted object, on the image of which they fixed their eyes; they humbled themselves a week before God; and, if they understanding be ever so little exerted, thou must acknowledge thy dependence on the being supremely pure." Sir William Jones cloes this detail with avowing as firm a conviction, that the doctrines of the Zend were distinct from those of the Veda, as that the religion of the Brahman with whom (he says) we converse every day, prevails in Persia before the accession of Cayumërs, whom the Parfis, refpect to his memory, consider as the first of men, although they believe in an universal deluge before his reign.

With the religion of the old Persians, their philosophy was intimately connected; for they were attentive observers of the luminaries, which they adored, and established, according to Mohan, who confirms in some degree the fragments of Beroes, a number of artificial cycles with distinct names, which seem to indicate a knowledge of the phenomena of the equinoxes revolve; they are said also to have known the most wonderful powers of nature, and thence to have acquired the fame of magicians and enchanters. Our author proceeds to make some remarks on that metaphysical theology, which has been professed immemorially by a numerous sect of Persians and Hindus, was carried in part into Greece, and prevails even now among the learned Muftulmans, who sometimes allow it without refiove. The modern philosophers of this persuasion are called "Suts," either from the

Vol. XXVI.
Persia.

Greek word for a Sage, or from the woollen mantle, which they used to wear in some provinces of Persia. Their fundamental tenets are, that nothing exists absolutely but God; that the human soul is an emanation from his essence; and though divided for a time from its heavenly source, will be finally reunited with it; that the highest possible happiness will arise from its reunion, and that the chief good of mankind, in this transitory world, consists in as perfect an union with the eternal spirit, as the incumbrance of a mortal frame will allow: with other particulars, for which we refer to Sir William Jones's Sixth Dicéouvre. See Parsees and Magi.

The religion of Persia at this time is the Mahometan, which, as it was introduced by the sword, has been followed by its usual effects, the destruction and depopulation of the country. Nevertheless the Persians are said to adopt a milder system of this creed, than that which is followed by the Turks and Arabs. As they reject several absurdities, they are regarded by the other Mahometans as heretics, and are denominated "Chias," or Schites, while the pretended true believers assume the name of "Sunnis." Chardin has particularly described the Persian system of Mahometanism. The priests of this religion, or Mullahs, are in Persia often styled "Akonda," signifying leaders; and they not only preach in the mosques, but are often schoolmasters. The Pachnamas are superior Mullahs, or vicars of the Imams. The Fakirs or Calendars are wandering monks, or rather sturdy beggars; who, under the pretext of religion, compel the people to maintain them in idleness. See FAKIR.

The language of the first Persian empire was the mother of the Sanferit, and consequently of the Zend and Parsi, as well as of Greek, Latin, and Gothic. When Amurahavan sat on the throne of Persia, two languages seem to have been generally prevalent in the great empire of Iran; that of the court, thence named "Deri," which was only a refined and elegant dialect of the "Parsi," so called from the province Pars or Fars, of which Shiraz is the capital, and that of the learned, in which most books were composed, and which had the name of "Pahlavi" or "Pahlavi," either from the heroes, who spoke it in former times, or from Pahlun, a tract of land, which is said to have included some considerable cities of Irak. The ruder dialects of both these languages were, and still are, spoken by the ruffians in several provinces; and in many of them, as Herat, Zabal, Sisilan, and others, distinct idioms were vernacular, as it happens in every kingdom of great extent. Besides the Parfi and Pahlavi, a very ancient and abstruse tongue was known to the priests and philosophers, called "the language of the Zend," because a book on religious and moral duties, which they hekli faceted, and which bore that name, had been written in it; while the "Pazendi," or commentary on that work, was composed in Pahlavi, as a more popular idiom; but Bahman, a learned follower of Zarathush, and Persian reader to Sir W. Jones, affirmed him, that the letters of his prophet's book were properly called "Zend," and the language "Avetha," as the words of the Vedas are Sanferit, and the characters "Nagari." The Zend, appropriating the name to the sacred language of Persia, and the old Pahlavi, are almost extinct in Iran; for among 6 or 7,000 Gabres, who reside chiefly at Zend, and in Kerman, there are very few who can read Pahlavi, and scarcely any who even boast of knowing the Zend; while the Parfi, which remains almost pure in the "Shahnamah," has now become, by the intermixture of numberless Arabian words, and many imperceptible changes, a new language, exquisitely polished by a series of fine writers in prose and verse, and analogous to the different idioms gradually formed in Europe, after the subversion of the Roman empire. Sir W. Jones affirms us, that hundreds of Parfi nouns are pure Sanferit, with no other change than such as may be observed in the numerous vernacular dialects of India; that very many Persian imperatives are the roots of Sanferit verbs; and that even the moods and tenses of the Persian verb subtitative, which is the model of all the rest, are deductible from the Sanferit by an easy and clear analogy. Hence he concludes, that the Parfi was derived, like the various Indian dialects, from the language of the Brahman; and he adds, that in the pure Parfi he finds no trace of any Arabic tongue, except what proceeded from the known intercourse between the Persians and Arabs, especially in the time of Bahram, who was educated in Arabia, and whose Arabic verbs are still extinct, together with his heroic line in Deri, which many suppose to be the first attempt at Persian versification in Arabic metre. But besides, "the composition of words," in which the genius of the Persian delights, and which that of the Arabic abhors, is a decisive proof that the Parfi sprang from an Indian, and not from an Arabian, stock. After full consideration, both Sir William Jones and his reader Bahman were convinced, that the Zend bore a strong resemblance to Sanferit, and the Pahlavi to Arabic. The Pahlavi our author conceives to be a dialect of the Chaldaic. By the nature of the Chaldaean tongue most words ended in the first long vowel, like "Shamm," heaven; and that very word, unaltered in a single letter, is found in the Zend; together with a multitude of others, all Arabic or Hebrew with a Chaldaean termination. In Pahlavi the verbal terminations of the Persian are added to the Chaldaic root. All the words cited by the learned judge are integral parts of the language, not adventitious to it, like the Arabic nouns and verbs engraven on modern Persian; and this distinction convinces him, that the dialect of the Gabres, which they pretend to be that of Zarathush, is a late invention of their priests, or subsequent dialects. Our author has further shewn, that the language of the Zend (which was at least a dialect of the Sanferit, approaching perhaps as nearly to it as the Pracrit, or other popular idioms, which are known to have been spoken in India two thousand years ago. Upon the whole Sir William Jones concludes, that the oldest discoverable languages of Persia were Chaldaic and Sanferit; and that, when they had ceased to be vernacular, the Pahlavi and Zend were deduced from them respectively, and the Parfi, either from the Zend, or immediately from the dialect of the Brahman; but all had perhaps a mixture of Tartarian; for all the beil lexigraphers assert, that numberless words in ancient Persian are taken from the language of the Cimmerian, or the Tartars of Kipshak. See PERSIAN TONGUE.

The more ancient monuments of Persian literature unapparently perished when the Mahomedan fanatics conquered the country in the 7th century. One of the oldest remains is the famous "Shahnamah," or history of kings, a long heroic poem of Ferdusi. Sadi, an excellent and entertaining moralist, writes in prose mingled with verse, like several of the Icelandic fages; and a translation of his works is very desirable. The Amaceon of the Earl of Half, whose tomb is venerated in the vicinity of Shiraz, and a splendid copy of whole works is chained to his monument. But the arts and sciences in general are little cultivated by the Persians, who are said to be lost in abject superfluation, and fond believers in astrology, a proud sophistry, as Pukerken justly expresses it, which connects the little brief destiny of man with the vast rotation of innumerable fuses and worlds. The education of the modern Persians is chiefly military; and their gross slanteries and obliquity of expression, evince, that they have
Persia.

have totally forgotten the noble fylem of their ancestors, who, in the first place, taught their children to speak the truth. The low state of the arts and sciences in Persia is the more surprising, as education is exceedingly cheap. Children are taught at the schools, and afterwards at the "Madrasah," or colleges, to read and write their native tongue. Arabic, moral philosophy, metaphysics, and the principles of their religion. Some of these colleges are magnificent and richly endowed: they are built in a quadrangular form, with an open court in the centre, divided into a number of cells, which are appropriated to the use of the masters and their scholars. These colleges are principally inhabited for their origins to kings and other great men, who look upon it as meritorious in the eyes of God and the prophet, to employ their wealth in pious and charitable foundations.

The poetry of the Persians abounds with the most sublime and varied images, as well as the most pathetic descriptions. There is no country, as it is said, where so considerable a knowledge of their bell writers in poetry descends even to the lowest classes of the people as our country. The majority of the Persians, we have said, Sadi, Hafiz, and Ferdousi. The writings of Sadi incalculate the doctrines of morality. Hafiz sings of love and wine; but many of his odes are received by his countrymen in a mystical sense, and are supposed to allude to the fulness of the earthly happiness, and the duties which mortals owe to their creator. In the Shahnamah, the great production of Ferdousi, the oriental scholar will discover passages, which would not, perhaps, disgrace the most eminent classical authors.

In historical composition, the Persians claim little consideration. All their works of this kind are written since the time of Mahomet, and are written, with few exceptions, in an inflated style, full of exaggeration and embellishment. Some of the Persian romances are very beautiful; but the most entertaining stories have never, for the most part, been committed to paper, and are only known from oral tradition. Story-tellers are common in this country, and the king always keeps one to amuse his leisure hours.

With regard to science, their knowledge is very limited; they possess some knowledge of algebra and geometry, and their most learned are other really acquainted with the writings of Euclid, Aristotle, and Plato, which have been translated into Arabic. Astronomy they regard as the most sublime of all studies, probably from its connection with astrology, to which they adhere, as we have said, much addicted. In physic and surgery they are grossly ignorant. In sculpture and painting the Persians have at no time attained to any degree of perfection. In architecture, as well as sculpture, the ancient Persians would appear to have surpassed their descendants, in proof of which we may refer to the ruins of Persepolis, Shusher, and Ctesiphon.

The general outlines of all cities in Persia are the same. They are surrounded by a mud, and sometimes a brick wall, flanked at regular distances with round or square towers. The streets are narrow and dirty, having a gutter through the centre; and the houses, which are low, flat-roofed, and built of brick or mud, have each a small court surrounded by a high wall. They have seldom any windows to the street. The palaces of the nobility, though mean in their exterior appearance, are convenient and elegant within: they are divided into several courts, in the most retired of which is the "haram," or apartments of the women. The central court is usually square, divided into parterres of flowers, with a jet d'eau continually playing before the window of the "dewan kana," or public hall. The walls and ceilings of this hall are ornamented with a profusion of paintings, and inlaid with looking-glasses; the floor is covered with carpets and sumuds; and one entire side of the room is occupied by large faliows of painted glass. The apartments of the haram are often fitted up with great taste and magnificence; but the sleeping rooms and apartments of strangers are generally small. The bazaars, or market places, in some cities, particularly those of Lar and Shiraz, may be accounted handsome buildings; but the mosques, mausoleums, and colleges, are the chief ornaments of the Persian cities.

For an account of the manners and customs of the Persians in the 17th century, we refer to Chardin, Thévenot, Sanfón, and other travellers; and an idea of modern manners may be derived from the travels of Gmelin in China. The Persians still pride themselves in universal politeness and hospitality. With a conceit of their superior wisdom and sagacity, they blend a passionate temper; and their recent commotions have tainted their national character with cruelty. Their temperament is fanguine; and both rich and poor are generally gay, and indulge immediate mirth after the most violent quarrels.

A late writer describes the Persians as "a remarkably handsome race of men brave, hospitable, patient in adversity, affable to strangers, and highly polished in their manners. They are gentle and inimitating in their deportment, as companions, agreeable and entertaining; but, in return, they are totally devoid of many estimable qualities, and profoundly vered in all the arts of deceit and hypocrisy. They are haughty to their inferiors, obsequious to their superiors, cruel, vindictive, treacherous, and avaricious, without faith, friendship, gratitude, or honour." "Frugal in his diet, built in his constitution, capable of enduring astonishing fatigue, and inured, from his infancy, to the extremes of heat and cold, hunger and thirst, nature seems to have formed the Persian for a soldier."

They are much attached to the fair sex, and not averse from wine. Their general complexion is fair, with a tint of olive; but those south about Shiraz, in Candahar, and in the provinces towards India, are of a dark brown. They are commonly fat, with black hair, high forehead, aquiline nose, full cheeks, and a large chin; and the form of the country is frequently oval. A Persian beauty is most esteemed when of middle stature, with long black hair, black eyes and eyebrows, long eye-lashes, a clear complexion, with very little red, small nose, mouth, and chin; white teeth, long neck, breast not full, small feet and hands, slender figure, and extremely smooth skin. In the purchase of Georgian and Circassian slaves, it is probable that these marks are as familiar as those of a beautiful horse among jockeys. Those females that are Georgian slaves are extremely beautiful and highly animated, but they excel more in the grace and elegance of their persons than in the regularity of their features. They are sometimes brought from their native country, as an article of trade; but most of them are carried away by the Persian armies in their predatory incursions into Georgia. Their price varies according to the supply of the market. In 1810 a young and beautiful Georgian girl might be purchased for about 80£. sterling. In this country courtesans are not only common, but encouraged by the government; they are regularly licensed, and pay a duty to the flat.

The men are generally strong and robust, and inclined to martial exercises; but they are particularly subject to disorders of the eyes. They commonly shave the head; but the beard is sacred, and an object of careful attention. To talk disrespectfully of his beard, is the greatest insult that can be offered to a native of this country; and an attempt to touch it would probably be followed by the instant death.
of the offender. The drefs of the Persians consists of a long robe, reaching nearly to the feet, and a high cap, which, when covered with a shawl, has some resemblance to the ancient tiara. A sash is bound round the waist, in which a small dagger is flung; and no perfon conceives himself drest without a sword. They often wear three or four light drests over one another, fastened with a belt or sash; and they are fond of large cloaks of thick cloth. The drests of the women are extremely simple: it is composed, in the summer, of a silk or mullin shift, a loose pair of velvet trowsers, and an "ul-khalîq," or veil. The head is covered with a large black turban, over which a Câshmirian shawl is gracefully thrown, so as to answer the purpose of a veil. In the cold weather, a cloath-bodied robe, reaching to the knees, and fastened in front by large gold buttons, is worn over the veil. This is made of velvet, or "Kimcobi," and sometimes ornamented with jewels.

The natives of Persia do not recline on cushions, in the luxurious manner of the Turks, but sit in an erect posture on a thick felt, called a "numud." They seldom or ever have fire in their apartments, or the smallest feaon; but in order to be warm, fold themselves in a fur pellicle, or a "kerounee," which is a handsome robe of crimson cloth, lined with thaws, or velvet. They rise with the fun, and having drested and paid their prayers, take a cup of coffee, or some fruit. They then enter on the business of the day, if they have any; or else smoke and converse until about 11 o'clock, at which time they usually have their breakfaft, and then retire into the harem. Here they remain until about 3 o'clock, when they return to the hall, fee company, and finish their busines. Between 9 and 10, the dinner, or principal meal, is served up. Boiled rice variously prepared, currie or pillaws, and mutton and fowl differently drested, constitute their mosl usual diin; of which they eat moderately, but in a manner diluting to European delicacy. Their meat is boiled to excess, and the meal is enlaried with pot-herbs, roots and fruits, cakes, hard eggs, and above all sweet-meats, of which they are very fond. Wine they never take before company; although in private they are notorious drunkards, and invariably drink before they eat. They are passionately fond of tobacco, which they smoke almost incessantly through the whole day; and this confitutes the principal amufeement of a man of fortune. Hunting and hawking, as well as various gymnami, exercises, are their favourite amusemens. By these means their bodies become hardened and active; and as they are taught to ride from their youth, they manage their horses with great boldnes and address. They frequently use the warm bath, but seldom change their linen. They are remarkable for cleanliness both in their persons and habitation. Circumcision is performed by a surgeon, sometimes within ten days after the birth, and at others ten years; but that of girls is unknown, and confined to the Arabs. Marriages are conducted by female mediation, and the ceremonies somewhat resembling the Russian. Polygamy is allowed, but the first married is the chief wife. Burials are conducted with little splendour, and the day of death is commonly that of expulfure. They believe that a particular angel is the foe authority of death, by the special command of God: hence suicide is very rare, and duels absolutely unknown. The wives of the peafantry are employed in the management of the house; they never go abroad without covering the lower part of the face with a veil. In the higher circles, they are almost always confined to their cell in the harem, and chiefly pass their time in drinking coffee, and smoking the "calcัน," but agreeably to the practice of the Mahometans, little attention is paid to the improvement of their minds.

The government of Persia appears to have been always despotic. That of eastern Persia, or the kingdom of Candahar, is represented as mild; and it is to be hoped, that of western Persia, when firmly established, will assume the fame character. The present monarch rules with an absolute sway, and he is under no restraint in the exercise of his power; and has an uncontrolled dominion over the lives and property of his subjects. Here is no senate or national assembly of any kind. The functions of government are exercised by the sovereign and his two principal ministers, the "vizier azem," or grand vizier, and the "ameen doulah," or lord high treasurer. The former superintends every thing connected with foreign relations, and even commands the armies, in the abience of the king or the prince. The latter, who is subordinate to the other, principally attends to internal arrangements, such as the collection of the revenue, and the cultivation of the lands. Subordinate to the ministry is a regular gradation of officers, who occupy posts in the household, army, and revenue departments. The governors of the provinces assume the title of "beglers-begs," those of the districts that of "hajji," or "zâki;" and between them is the management of a "khâna." The jurisprudence of this empire is founded, as in other Mahometan states, on the doctrines of the Koran. The "fichki-oel iflam" is the nominal judge of civil and criminal law; but the governors of the different towns and provinces, are, in reality, the persons who decide in cafes of importance. In the capital the king himself daily sits in judgment, and the award is not always consonant to justice. The most common punishments to men of exalted rank are death and deprivation of right; and to those of the lower orders, mutilation and the bastinado on the soles of the feet. Theft is a crime always punished with the most unrelenting severity. The body of the culprit is sometimes torn asunder, by being bound to the branches of trees afterwards sepa- rated. Trifling disputes are, in general, settled by the "cazi" and "daroga" of the bazaars.

The flanding army of the empire, as it may be called, consists of the king's body guard, amounting to about 10,000 men, and the "giolaulas," or royal slaves, who are about 3000. But the military force of the Persian empire is constituted by the number and bravery of the wandering tribes. When the sovereign wishes to assemble an army, the chiefs of the different tribes are commanded to send to the royal camp a number of men, proportioned to the power and strength of each tribe. The army, thus assembled, consists chiefly of cavalry; and as they seldom receive either clothing or pay, they are only kept together by the hope of plunder. The present king, by an extraordinary effort, might probably, in this way, be able to collect together a force of 150,000 or perhaps 200,000 men. The rulers of Persia have entrusted the defence of their dominions to the cavalry, which is excellent. Their arms are a feymetar, a brace of pittols, a carabin, and sometimes a lance, or a bow and arrow, all of which they use alternately, at full speed, with the utmost dexterity. The pittols are either fluck in the girdle, or in the holsters of the saddle; the carabin or the bow is slung across the shoulder; and the lance, which is light and shafted with bamboo, is wielded in the right hand. As the Persian armies receive no regular pay, but are kept together merely by the hope of plunder, it is considered as incumbent on the king to take the field once a year, against the Ruffians, Afghans, or Turcomans, his im- mediate neighbours. But they know nothing of war as a science; and they are entirely ignorant of the principles of fortification, and of the arts of attack and defence. The chief artillery is composed of "zumbarooks," or small swivels,
The army of western Persia united, and somewhat re-inflated in prosperity, might amount to about 100,000 effective men, and this probably may be the amount of that of Candahar. The chief merchants in Persia are the Armenian Christians and the Hindoos, so that the commerce of the country has been always in the hands of strangers. The name of a warlike navy has been altogether unknown. The revenue of Persia cannot be accurately ascertained; but it is thought probable that the monarch of Candahar may clear from his various provinces about three millions sterling, while western Persia scarcely supplies two millions. The whole revenue has been by some estimated at 700,000 tomans, the toman being computed at about 53, or about 32 millions of French livres. The revenue, as stated by the writer above named, does not exceed three millions, and it is derived from two sources; the tax on land, and the duties and imposts on all kinds of merchandise. This writer urges, that the tax on land belonging to the crown or to individuals, may probably amount to two-thirds of the whole.

The capital city of Persia is Isphahan, which fee: and the second city is Shiraz, which also fee. The other cities are Teffils, Derbent, Erivan, Tебriz or Tauriz, Rafael, Sari, Bistam, Khavar, Tahiran, Casbon, Sultania, Hamadan or Amadan, Kom, and Cahan, which fee respectively. On the banks of the Ahwaz, or ancient Choafpes, Kiah and Ahwaz are of small account: nor is Toftar, or Shukurabad, though the capital of a province, of much account. In the proximity of the Persian gulf, Karadjan, Firuzabad, and Zaran or Yardan, hardly deserve the mention. Lar (which fee) is the capital of a province. For the towns on the Persian gulf, see Persian Gulf. Tiz and Gaudal are two ports on the coast of Mechran, of no great importance. The capital of Kerman is Yezd, which fee. North of Yezd is Isfair, which fee. The other cities of western Persia scarcely deserve commemoration. In passing to the eastern division, or the kingdom of Candahar, we find Cabul, the metropolis, and Candahar, a city of small size, chiefly worthy of notice as the grand passageway between these extensive empires. Zarang is supposed to equal any city in Segitlan; and the other chief towns on the Himmed are Dargalp, Bolf, and Rokhage or Arokhage. The dominion of Zemaun Shah comprises a considerable portion of Korafan. Here we find Herat, Mefchid, &c. The southern province of Meckran naturally coincides in allegiance with Segitlan and Sind to the empire of Candahar; but its northern limits have not been defined, though major Renell informed us that they include Gaur, a considerable city and province. Balian belongs to the same portion of Bucharia. After this cursory mention of some of the principal places in eastern and western Persia, we refer for a more particular description of them to the articles that occur under their respective names.

The manufacturers and commerce of Persia may be said to be annihilated, though a few carpets still reach Europe at extravagant prices. The trade with Russia and the Caffian is of small account, consisting of salt and naphtha from Baku, and some silk from Shirvan and Ghilan. The Persian merchants also bring goods to Balfursh, the largest town in Mazanderam, where they trade with those of Russia. On this subject the reader will derive satisfactory information from the Travels of Mr. Hanway; the second edition of which was published in 2 vols. 4to. 1754. From Charin we learn what was the state of the manufactures and commerce of this country in the 17th century. Embroidery on silk, cloth, and leather, had attained high perfection: earthen-ware was made throughout Persia; but the bell was that of Shiraz, Mefchid, Yezd, and Zarang, where it was singularly beautiful, equaling the Chinese porcelain.
PERsIA.

porcelain in fineness and transparency: some forts refilited fire, and the fabric was so hard as to produce lafting mortars for gridding various substances. (See MURAHINE.) The manufactures of leather and bagreen were also excellent; and they were distinguihed for their brazier, using the tin of Sumatra for lining their vessels. The bows of Persia, its finely damasked fafbes, its razors, and other works in steel, were in high estimation; and the Perians excelled in cutting precious stones, and dyeing bright and lasting colours. Their cotton and woollen cloths, and those made of goats' and camels' hair, with their silks, brocades, and velvets, were superior manufactures. The carpets, chiefly from the province of Segilian, were brought to Europe through Turkey, and in Chardin's time called Turkey carpets: they were valued by the number of threads in the inch, being sometimes 14 or 15. The stuffs made of camels' hair were supplied chiefly from Kerman, and those of goats' hair from Mazanderam; but the cotton cloths were obtained principally from Hindooftan; but the fabric of broad cloth was unknown, and supplied by a kind of felt. The standard native merchandise was silk. To Hindooftan were sent tobacco, preferred fruits, especially dates, wines, horses, porcelain, and leather of different colours: to Turkey, tobacco and kitchen utensils: and to Russia, manufactured silks. The little commerce which the country now enjoys is principally carried on by the Armenians, whose habits, migrations, and industry, bear some resemblance to those of the Jews. They are scattered over the kingdom, and held in greater respect by the Persians than is usual in a country of their intolerant precepts of the Koran. They seldom intermarry with any other sect, and preferve inviolate the religion and customs of their ancestors. As they are not allowed to interfere either in political or military concerns, their cowardice is proverbial. The principal colony of Armenians was that brought from Julfa, on the banks of Araxes, and established by Shah Abbas the Great at Ifpahan. This colony, in the time of Chardin, amounted to 14,000 families: but the tyranny of the Afghans, and subsequent civil wars, have reduced the extensive and beautiful suburb of Julfa to a heap of ruins, and its inhabitants to about 400 families. The Armenians, however, are not confined to Ifpahan, but are to be found in all the commercial towns of the empire. The chief imports from India are sugar, indigo, spice, cloths, piece goods, chintz from Mafulpitam, woollen cloths, cutlery, and other European articles. From Afghan, cutlery, woollen cloths, watches, jewellery, arms, and fine glafs are imported. The returns for these articles are bullion, raw silk, pearl, shawls, carpets, wine, and horses.

The climate of Perfia is various in different parts; depending less on difference of latitude, than on the nature and elevation of the country; so that it is said to be the country of three climates. The northern provinces on the Caspian are comparatively cold and moist: in the centre of the kingdom, as Chardin observes, the winter begins in November, and continues till March, commonly severe, with ice and snow, the latter falling chiefly on the mountains, and remaining on those three days' journey W. of Ifpahan for eight months in the year. From March to May high winds are frequent; but from May to September the air is serene, refrefhed by breezes in the night. The heat, however, is during this period excessive in the low countries, bordering on the Indian ocean and Persian gulf, in Chu-fultan, the defarts of Kerman, and also in some parts of the interior, particularly at Tehraun, the capital. From September to November, the winds again prevail. In the centre and south the air is generally dry; thunder and lightning are uncommon; and a rainbow is seldom seen. Earthquakes are almost unknown; but heat is often destructive in the spring. Near the Persian gulf the hot wind, called "Samiel," sometimes suffocates the unwary traveller. The summers are, in general, very mild, after ascending the mountains. To the N. of Shiraz the winters are severe, infomuch, that in the vicinity of Tehraun and Ta-breer, all communication is cut off, for several successive weeks, between these cities and the adjoining villages. The climate, notwithstanding this sudden transition from heat to cold, is singularly healthy, with the exception of the provinces of Ghilan and Mazanderam. The air is dry; the dews not infalubrious. The atmosphere is always clear, and at night the planets shine with a degree of lustre unknown in Europe; and as it seldom rains, here are none of those damp or pelliferous exhalations so common in the woody parts of Hindooftan.

The distinguihed features of this country are a deficiency of rivers and a multitude of mountains: its plains, where they occur, are generally defart. So that Persia may be divided into two parts by deserts and mountains, and this division, it is said, has generally influenced its history and destiny in all ages. The soil may be regarded as unfertile, and, according to Chardin, not more than one-tenth part was cultivated in his time. The mountains of this country, which are for the most part rocky, without wood or plants, are interfered with vallies, some of which are flowy and sandy, and some consisting of a hard dry clay, which requires much watering; and hence the Persian farmer is much employed in irrigation. What has now been said relates to the central and southern provinces; those in the north being sufficiently rich and fertile. The most common grain of Persia is wheat, and this is excellent. Rice is a more universal aliment, and regarded by the Persians as delicious: this is generally produced in the northern provinces, those being the belt watered: barley and millet are grown but oats are little cultivated. In Armenia there is some rye. The plough is small, and drawn by lean cattle, so that it merely scratches the ground. After the plough and harrow, the spade is used for forming the ground into furrows, with ledges or little banks to retain the water. The dung is chiefly human, and that of pigeons mingled with earth, and preferred for two years to diminish its heat. In the N.W. countries the vines are interred during the winter; and when inefals attack the tree, they lay fresh earth to the roots. The nature of the soil in this country varies almost as much as the climate; in the southern and eastern provinces it is light and sandy: in the western and interior parts, hard and gravelly; and in the northern division, which borders on the Caspian sea, rich and loamy. The silk worm is cultivated in most parts of the country, but particularly in the province of Ghilan; and the vicinity of Kahan; cotton, indigo, and tobacco, are also raised; and no country can exceed this in the variety or qualities of its fruits. The present depressed state of agriculture is owing, in a great measure, to the unsettled nature and disposition of the government, which affords no protection to private property, and offers no encouragement to industry. The rivers of Persia, not taking into account the Euphrates, Tigris, and Indus or Sinde, which are not properly Persian, are the Ahwaz (supposed by some to be the Gyndes of Herodotus), the Zeinedeh of d'Anville, and called by the Turks Kara Sou (ice Karasa), or the black river; which is reckoned one of the most considerable in Persia, and pursues a course of about 400 British miles, from the mountains of Elwend to the efluary of the Tigris and Euphrates:—the Rup, or Divrud; the principal of those rivers
rivers that flow from the range of mountains in the N.E. and fall into the Persian gulf:—the Krek and Mekhíd, rivers of Mekran, which join and form the river of Mend, so called from a town by which it passes:—the Haur and the Araba, the latter of which serves as a boundary towards Hindoo-Ran:—the large river of Gihon, or Amu, in the N.E.:—the river Tedjên, or Tedýen, to the W., being the ancient Ochus, and flowing into the Caspian:—the Kizíl Ozen, or Sehíd Rud, rising, according to d'Anville, in the mountain of Elwend, not far N. of Hamadan, and by a winding course running into the Caspian; which river is the Mardus of antiquity,—and the Sivudra of Gmelín, rising on the confines of Turkey, and falling into the sea below Langorod; abounding in pike, carp, and other kinds of fish, esteemed by the Persians; and, as Gmelín says, in sturgeons:—farther to the N., the large river Aras, the ancient Araaxes, which falls into the Kur or Cyrus (see Kur):—the mountain rivers of Peria, soon left in sandy defects, are the Zenderud, rising in the western chain of Elwend, passing by Ipahan, and soon after losing itself in the sea:—the Kho Afp of d'Anville, the Correng of Chardin, which passes by Shitler:—the Bundamir (which see):—the Kuren, a considerable stream from the N.E. that flows into the lake Baktegan:—and the Humend, or Hindmund, which see.

The lakes of Peria are the Aria Pulsus of antiquity (see Aria):—the salt lake of Baktegan (which see):—the large lake of Urmia (see Urmia):—the lake Van:—and the lake of Erivan, about 120 British miles to the N. of Urmia, about 25 leagues in circumference, with a small isle in the middle: this lake abounds with carp and trout, and is the Lynchnites of Toltémen.

In presenting to our readers a brief view of the mountains of Peria, the first object that merits attention is the direction of its chief chains. To these we may refer the Caucasian ridge (see Caucasus):—the Hindoo-Kho, which is an extension of the Belur-Tag (see both these articles):—the Elwend, so called from a particular mountain in the vicinity of Hamadan, and reckoned the greatest chain of mountains in Peria, of very great height, extending to the south of the lake of Urmia, where it is connected with the Caucasian ridge:—a parallel ridge on the W., called by the Turks Atragha Tag, supposed to be the Zagros of the ancients, which separates Assyria from Media, and extending to the lake of Van:—and Hettzardara, (which see). Chardin considers the noted Damavend of the Persians, as a ridge dividing Hyrcania from Parthia; that is, in other words the mountains of Mazanderam; and he adds that of the mountains between Fars and Kerman, the most remarkable is called Jaron; but the mountains of Kurdislan alone present forests. The great western range of mountains is called in some parts the mountains of Loorislan; and more to the S. the Adveran and Dinar, with Ajuduk, N. of Lar. It detaches some remarkable branches to the S.E., as that on the W. of Kom, Calhau, Nathan, &c., which from a particular mountain may be called the range of Elburz. Another branch spreads to the S. of Ipahan, which d'Anville considers as the same with what the Persians call the thousand mountains, or Hadrâ. Still more to the S. a large and extensive branch extends between the rivers Kuren and Bundamir; and presents on the western side of its further extremity the noted ruins of Persepolis. The pafs of Khavar is near the southernmost extent of the Caucasian heights of the Mazanderam; and Mr. Pinkerton thinks there is no reason for believing that any ridge extends into the great Saline desert. We learn from Mr. Forster that there are no ranges from Caspadar to Korsan. Herat stands on a plain; but to the N. of Dochabad and Turhiz, there is a range of mountains covered with snow. About three miles E. of Khana hoody, a chain of mountains of some height extends N. and S.

Some have represented the province of Fars as separated from Kerman by a range of mountains; but the real barrier is a defert of sand, extending from the S. of the lake Baktegan to the proximity of Zarang, and connected with the great defert which divides Peria into two parts. There are no mountains of consequence on the E. of Fars. A low range, called Meder by d'Anville, passes N.E. through the heart of Kerman; while that country is divided from Mekran by a range in the same direction, called by d'Anville Kofez. Some other nameless ranges traverse Mekran in the same direction; that nearest Hindooftan being called by the ancients the Lakheé mountains. On the N. of Mekran, a considerable range runs E. and W. which has not been named by d'Anville; but it is, says Pinkerton, to be the Be-adius of Potolomy. Further to the N., the mountains of Wulli extend from the neighbourhood of Shatran across to the lake of Vaihind, and may be considered as forming one range with that on the N. of Mekran, called by La Rolette Gebelabad. This range however terminates in the great defert to the S. of Zarang. In the E. of Segitfan there is a ridge N. and S. called Solaran Koh, or the mountains of Solman. It is probable also, that there are considerable height on the N. and W. of the sea of Zurr; one called Berhek, and another Ouk, the former being noted for a fire-temple, the refort of the Guebres or Gabres.

The deferts of Peria are the following:—on the E. of the Tigris, N. lat. 33°, a considerable defert commences, pervaded by the river Alwaz, and extending to the N. of Shitler, which is about 140 British miles in length from E. to W., and about 80 in breadth, and is now inhabited by the wandering tribes called Karezam. The great Saline defert extends from the vicinity of Kom, or Koom and Kathian, to that of the sea of Zurr, in a line from E. to W. of about 400 British miles, and from N. to S. in breadth about 250; but joining in the latter quarter with the great defert of Kerman by the Nauben Dejian, which extends about 350 miles. These two extensive deferts may thus be considered as stretching N.W. and S.E. for a space of about 700 miles, by a mediual breadth of about 200 (not including in the length the other 200 miles of the defert of Mekran); thus interfingering the wide empire into two nearly equal portions. This immense extent is impregnated with nitre and other faults, which taint the neighbouring lakes and rivers. In the bay of Mekran, and towards the Indus, are other deferts of great extent.

A third great defert, that of Karakum, or the black sand, forms the northern boundary of Korasan and modern Peria. The defert of Margiana is placed by Potolomy on the N.W. of Aria; and if, with d'Anville, we suppose Margiana to have derived its name from the river Margus, or Margbab, this defert may be in the vicinity of Backia. The Persan deferts are restricted to a few spots in Korasan, the mountains of Mazanderam and Ghilan, and thence towards Kurdislan. But timber is chiefly supplied by Mazanderam, which from this circumstance receives a name signifying the land of oxen.

The indigenous vegetables of Peria are very much unknown. The saline deferts are for the most part defillete of trees, and support hardly any plants except thofe that are also found on the sea-shore. On the high mountains they are much the same as those observed on the Alps of Switzerland and Italy. The plants on the hills and plains adjoining the Caspian are better known. On the mountainous ridges are found...
found the cypress, the cedar, and several kinds of pines, while the lower hills and scarp of rock are shaded and adorned with limes-trees, oaks, acacias and chestnuts: the fumac is also abundant, and the fraxinus ornus, or manna ash-tree, is less common. The most esteemed of the cultivated fruits of Europe are indigenous in Persia, and have probably been diffused from hence over the whole west. These are the fig, the pomegranate, the mulberry, the almond, peach and apricot. Orange-trees of an enormous size are found in the sheltered recesses of the mountains, and the deep warm land on the shore of the Caspian is peculiarly favourable to the culture of the citron and the lemonia. Apples, pears, cherries, walnuts, melons, besides the fruits already mentioned, are everywhere to be procured at very low prices; the quinces of Ifpahan are the finest in the East; and no grape is more delicious than that of Shiraz. In the provinces bordering on the Caspian sea, and mount Caucasus, the air is perfumed with roses and other sweet-scented flowers. Among the vegetable productions we may enumerate cabbages, cucumbers, turnips, carrots, peas, and beans; and the potatoe, which has been lately introduced, thrives remarkably well. Poppies, from which an excellent opium is extracted, fenna, rhubarb, faffron, and affafoetida, are produced in many parts of the kingdom. The vine grows here luxuriantly, and further to the S. cotton and sugar are articles of common cultivation. Poppies, large and beautiful, and the weeping willow, border the course of the streams, and the marshy tracts abound with the kind of ruth that serves for the fine Persian matting. Ornamental shrubs or herbaceous plants are little known; but the jasminia, the blue and scarlet anemone in the thicket, and the tulip, and ranunculus in the pastures, are abundant and beautiful, and give an air of elegance to the country.

According to Chardin, the Persian horses are the most beautiful in the East; but they yield in speed, and, as some say, in beauty also, to the Arabian. However, they are larger, more powerful, and all things considered, better calculated for cavalry than those of Arabia. There are several breeds of horses, but the most valuable is that called the Turkoman, which are so hardy, that they have been known to travel 1000 miles in eleven successive days. The Arabian blood has also been introduced into this country. Their usual food is chopped straw and barley; their bed is made of dung, dried and pulverized, and every morning regularly exposed to the sun. They are clothed with the greatest attention, according to the climate and season of the year; and during the warm weather kept in the stable during the day, and taken out at night.

Mules are also here in considerable request; and the afs resemble the European: but a breed of this animal has been brought from Arabia, of an excellent kind, the hair being smooth, the head high, and the motion spirited and agile. Although the mules are small, they are fairly proportioned, carry a great weight, and those that are intended for the saddle are taught a fine amble, which carries the rider at the rate of five or six miles an hour. The camel is also common; and these animals are exported from Persia to Turkey, which have, as Chardin says, only one hunch, while those of India and Arabia have two. The Persian cattle in general resemble the European: swine are scarce, except in the N.W. provinces. The flocks of sheep, among which are those with large tails, are most numerous in the northern province of Erivan, or the Persian part of Armenia, and Baku. The few forests abound with deer and antelopes; and the mountains supply wild goats, and probably the ibex, or rock goat. Hares are common. The ferocious animals are chiefly concealed in the forests, such as the bear and boar, the lion in the western parts, the leopard, and as some say, the small or common tiger. Seals occur on the rocks of the Caspian. The hyena and chackal belong to the southern provinces. The seas abound with fish of various descriptions; the Caspian affordsurgeon, and delicious carp. The most common river-fish is the barbel. The tame fowls of wild and tame fowl are common in Persia and in Europe, with the exception of the turkey, whose nature does not seem to be congenial to this climate. Pigeons are numerous, and partridges are large and excellent. The boobul, or oriental nightingale, enlivens the spring with his varied song.

The Persians have been long accustomed to tame beasts of prey, and even to hunt with lions, tigers, leopards, panthers, and owls.

As to the mineralogy of this country, it affords neither number nor variety of treasures. Chardin affirms us, that it has no mines of gold or silver. The lead mines of Kerman and Yazd produce the usual mixture of silver. In the northern provinces there are many mines of iron, but the metal is hard and brittle. Mines of filed ore, or carbonated iron, are also wrought in the same districts, and these are impregnated with sulfur, that the filings, when thrown in the fire, flash like gunpowder. Copper is chiefly found on the mountains of Mazanderan, and near Cabzin, but it is brittle. There are two mines of the turquoise, one at Nisfapour in Korasan, and another in a mountain called Feruzkoh, S. of the Caspian. The pearls of the Persian gulf have been long famous. (See PEARL.) Otter, an intelligent traveller in Persia, says, that among the articles sold in the bazars of Ifpahan are diamonds of Golconda; rubies, topazes, and sapphires of Pegu; emeralds of Sial or the Thebais; and baly rubies from Bedakhan, a country between the rivers Gihon and Murtag, which also produces lapsis lazuli, amiantus, and rock crystal. Sulphur and nitre are found in the mountains of Demavend: whole deferts are, in some instances, covered with sulphur, and others with salt, that near Cabzin being remarkably pure. Rock-fault is found near Ifpahan, and in the dry climate of Kerman, if we may credit Chardin, it is even employed in building. Free-stone, marble, and slate, are chiefly obtained from Hamadan; and near Tauriz is a marble, as Chardin calls it, which is transparent, like rock-crytal, through tables an inch in thickness, of a white colour, blended with green, probably a kind of jade. Towards the Tigris are pools of bitumen, or rock-tar, and naphtha abundance near Baku. In Erivan and Fars are mines of tale, and of a pure white nard used like soap. For an account of the mummy of Korasan, see MUMMY. Although mineral waters abound in this mountainous country, they are generally disregarded both by the physicians and the people.

Barbarous princes seem to have entertained the idea, that bad roads contribute to the security of their dominions. The Turks and Persians are, without doubt, of this opinion; for the public highways, and particularly those that lie towards the frontier, are very much neglected. The only mode of travelling is by riding either a mule or an ass. For women of high rank, and for sick persons, there is, indeed, a vehicle, called a "tukte rowan," which is transported by two mules, one before and the other behind; but the women and children of the poor are carried in baskets, flung across the back of a mule or camel. The length of the stage (which sometimes exceeds forty miles), and badness of the accommodation, render travelling very unpleasant. Here are no regular establishments for the transmiffion of intelligence, and therefore it is necessary for the dispatch of letters from one part of the kingdom to another.
another, to send a "chupper," or express horseman, or a messenger on foot, who is called "caffid." Although the distance be ever so great, the chupper seldom changes his horse; for in Persia, there are no post-houses and relays of horses as in Turkey. They travel at the rate of four or five miles an hour, and have been known to go from Tehrann to Bushire, a distance of 700 miles, in the space of ten days. The caffids will also travel for many days successively at the rate of sixty or seventy miles a day.

Among the chief natural curiosities of this country, we might mention the fountains of naphtha, in the vicinity of Baku, and in the adjoining province of Absheron; and the blue flame issuing from the ground, and particularly from an horizontal gap, about sixty feet long by three broad, in a neighboring rock. The naphtha is much used by the Persians, and particularly by the poorer sort, as we use oil in lamps, or to boil their victuals, though it communicates a disagreeable taint. That which is white, and of a thinner consistency, and which is found only in small quantities, is drank by the Ruffians both as a cordial and a medicine; taken internally, it is said to be good for the stone, for disorders of the brain, and for any disease caused by the cold. Externally applied, it is said (see Hanway's Travels, vol. i.) to be of great use in scrobutic pains, gout, cramps, &c. It has also the property of spirits of wine to take out greasy spots in silk or woollens, but it leaves after the use of it an abominable odour. They say it is carried to India as a great rarity, and being prepared as a Japan, is the most beautiful and lasting of any that has been yet found. Near the spot where this naphtha is procured are springs of hot water, which boil up in the same manner as the naphtha. Bathing in this warm water is found to strengthen and procure a good appetite, especially if a small quantity of it is drunk. These remarkable springs have been described by Kämpfer at the end of the 17th century, by Gmelin in 1775, and more fully by Hanway ubi supra. In an adjoining peninsula there are many other wells; and the revenue arising from this uncommon product to the Khan of Baku is computed at 40,000 rubles. See Everlasting Fire.

The progressive geography of this celebrated country may be traced through Strabo, Pliny, the historians of Alexander, and other classical authors, and afterwards through the Arabian authors, Ebn Hankel, Edrisi, Abulfeda, &c. &c. to the modern labours of Chardin, Hanway, Franklin, Gmelin, Pallas, &c. &c. We have been principally indebted for the materials of this article to the composition of Mr. Pinkerton, in the 2d volume of his Geography; to the 6th Dicouree of Sir William Jones; to Hanway's Travels; and Kennew's Geographical Memoir on the Persian Empire, 1813.

PERSIAN, a town of Hindooistan, in Baglana; 18 miles E.S.E. of Baffeen.

PERSIAN Empire, and Monarchy. See Monarchy.

Persian Gulf, called also the Sea of Omar, and the Green Sea, a sea or inland lake, bounded on the north by Persia, and elsewhere by Arabia, except at the eastern extremity, where it communicates with the Arabian sea; about 500 miles from E. to W., and from 120 to 250 in breadth, from N. to S. The principal river which runs into it is the Euphrates. The southern coast in particular has been celebrated for its pearl-fishery. (See Pearl.) The coasts both on the N. and S. belong chiefly to colonies of Abians. This celebrated gulf has been always more remarkable for the factories of foreigners, than for its native establishments. Bender-Abassi was a port opposite to the island of Ormus, or rather on the coast between Ormus and Kifhim. Kifhma, and is now more commonly known Vol. XXVI.

by the name of Gombroon. The trade, once considerable, is now greatly declined, and even the Dutch left it, and settled in the isle of Kark or Garek. The French Indian commerce has failed; and the English staple is Baflora. But Bushire, and Rik, or Bundark, are also sometimes frequented. See these several places under their appropriate denominations.

The Arabian shore of this gulf has never been surveyed; and as it has many sand-banks and shoals, the navigation is difficult and dangerous. The Persian shore is more elevated than that of Arabia; and the islands with which the gulf abounds are chiefly on that side. This is a safe coast, on which, generally speaking, there are regular soundings, and ships may almost everywhere procure shelter from violent gales of winds, either in bays or under the lee of the islands.

The promontory of Cape Musfledom (called by the natives Ras-ul-Gibel), at the entrance of the gulf, and on the Arabian shore, is said to be the termination of a mountainous tract, inhabited by a tribe of perfons defended from a mixture of Arabs and Portuguese, who have hitherto repulsed the encroachments of the Wahabees. The small islands, or rather islets, called for four miles are kept in ten miles to the N. of the Cape, and the channel between them is reported to be free from danger. At Rams, a pratical town, N. lat. 25° 53', the mountains retire, and the water begins to shoal. From this place, to the town of Shorga, a distance of seventeen leagues, it is hazardous for ships to approach the coast, owing to the prevalence of the N.W. winds. From Shorga to Grane, a large town in N. lat. 29° 12', the coast is denominated by the Arabs "The Coast of Danger." It is unknown to Europeans, and supposed to abound in coral and pearl banks. The greater part of the Arabian shore is in the possession of the Joshmi Arabs, a licentious band of pirates, who, by their depredations, obstruct the commerce of the gulf. Their principal rendezvous is Ras-ul-Khyma, a town about seven miles S.W. of Rams. At the mouth of the gulf is the celebrated island of Ormus or Hermus. (See Ormus.) Larrek is a small island, ten miles S.S.W. of Ormus, about fifteen miles in circumference. The largest island in the gulf is Kifhim, or Jezira Derauz, i. e. Long Island. (See Kishma.) On the opposite side of the sea is a more elevated island of Angar. This is completely encompassed by the two islands, which are not above three miles distant from each other, so that a ship can anchor close to either shore at all seasons, there being a sufficient depth of water for a line of battle ship lying within half a mile, and small craft within one hundred yards of the shore. No pilot is necessary. The island of Angar is somewhat longer than Ormus, now uninhabited, though formerly well peopled. The Great Tomb is a low island, about three miles in length, and two and a half broad; distant twelve leagues from the S. point of Angar, N. lat. 26° 30'. The Little Tomb is rather left, and distant from the former four miles, a barren and rocky island. Baftman lies eleven leagues N.N.W. 3/4 from Shorga, N. lat. 25° 54', above five miles long, remarkable for a high round hill in its centre, and uninhabited. Polior, the Pulora of the Greeks, is about five miles long, and four broad, uninhabited, encompassed with deep water, and having a long reef of dangerous rocks running from the W. to the N., the northern end being in N. lat. 26° 20' 19". Such lies in the meridian of Polior, and the parallel of Baftman, and is much such an island as the latter. Nabeful is a small uninhabited island, without vegetation, ten miles S.S.W. of Polior. Ken, the ancient Kataia, is flat, and better planted than most of the islands in the gulf. Formerly it had a
flourishing commerce, and now it can supply ships with refreshments. The S. end is in N. lat. 26° 27', about 10 leagues N.E.N. ½ N from Polior. Anderavia, or Inderabia, seven leagues from Ken, is a low, level, and narrow island, about three miles in length, N. lat. 26° 40'. Buhheah, inhabited and covered with date trees, is about sixteen miles in length, and five or six in breadth. The island of Bahrein is one of the finest in the gulf. (See Bahrein.) Tarent, close to the shore, and opposite to Kalif, although not so large, is a finer island than Bahrein, about seven miles long, and as much in breadth, well supplied with good fresh water, and embellished with many delightful gardens, which produce abundance of fruits of various kinds. The island of Karrack, the Icarus of Arrian, contains about twelve or thirteen square miles; affords a good anchorage at all seasons, mostly rocky, supplied with abundance of water, and now peopleed with about three or four hundred inhabitants, who subsist by gardening and fishing. The island of Corojo, lying about one and a half or two miles N. of Karrack, contains about two square miles, and is of a light sandy foil; it has plenty of water, though not so good as that of Karrack, uninhabited, but not incapable of cultivation. It will produce both wheat and barley during the rainy seasons. Kinner's Geoq. Mem. of the Persian Empire.

Persian Language, one of the living oriental languages; spoken in the empire of Russia.

The Persian language is rich, melodious, and elegant; it has been spoken for many ages by the greatest princes in the politeest courts of Asia; and a number of admirable works have been written in it by historians, philosophers, and poets, who found it capable of expressing with equal advantage the most beautiful and the most elevated sentiments. Accordingly sir William Jones very much laments the neglect of this language that has generally prevailed among the learned; and he recommends the acquisition of it by a variety of considerations; but particularly from its utility to those who transact the concerns of Europe in India. In order to facilitate the attainment of it, he has published an excellent compendious grammar, and prefixed to it some instructions relating to the bell method of learning this language. We shall avail ourselves of his work in giving an abridged history of the Persian language, and then some account of the language itself. The history of the Persian tongue may be divided into four periods, like that of the empire; and under each dynasty there was an apparent change in the dialect of the kingdom, especially under the two last, viz. the "Saffian" and "Mohammedan" dynasties; and these are the only periods, of which any certain records remain.

In the infancy of the Persian empire, under Cyrus and his descendants, it cannot be supposed that any great pains were taken to perfect the language, which, if it were sufficiently clear and inelligible, would not be thought to want elegance. Herodotus affirms us, that even after the reign of Cyrus, the whole education of the Persian youth, from the age of five years to twenty, confined in only three points, riding, throwing the javelin, and the practice of moral virtue; which account is also confirmed by Xenophon. Nevertheles it ought not to be imagined, that the ancient Persians, especially those of the second period, were entire strangers to the art of composition either in verse or prose; but what their language was, what were their rules of verification, or what was the course of their studies, no mortal can pretend to know with any shadow of exactness. The Greeks can give us no assistance, nor are we much enlightened by the writers after Alexander; it is necessary therefore to consult the Persians themselves. From the great traveller Chardin, we learn, that the old Persian is a language entirely loll, in which no books are extant; and of which there are no rudiments remaining. (See Persia.) We have therefore no account of the Persian language till the time of the "Saffian" kings, who flourished from the opening of the third century to the middle of the seventh, during which period an academy of phylaic was founded at Gandharpur, a city of Korafan, and as it gradually declined from its original institution, it became a school of poetry, rhetoric, dialectics, and the abstract sciences. In this excellent seminary the Persian tongue must have been much refined, and the ruficitia of the old idiom was succeeded by a pure and elegant dialect, which being constantly spoken at the court of Behram Gür in the year 351, acquired the name of "Deri," or courtly, to distinguish it from the "Pehlavi" or "Pahlavi," or language of the country. (See Persia.) This published idiom did not, however, supercede the ancient dialect; for several compositions in Pahlavi were extant even after Mahomet, which appear to have been written by order of the Saffian princes. Anahîvan, furname "the juft," who reigned at the close of the 6th century, when Mahomet was born, obtained from India a collection of fables, translated by his chief phyfician from the Sanscript language, which he acquired for this purpose; this collection he translated into the Pehlavian dialect; about 140 years after, it was turned from Pehlavi into Arabic, by order of Almanfou, second caliph of the Abbasides; and this is the volume now found in every language of Eternal, under the name of "Calîla va Demna," or the "fables of Pulpay." A fine copy of the Arabic version is deposited in the public library at Oxford; and if the work of Barziquek, the above-mentioned phyfician, could be found, we might thus recover a considerable part of the old Persian language; the fame, perhaps, which was spoken in the "second period" by Themistocles and Xenophon. In the reign of Anahîvan, Mahomet polished the language of his country; and when the battle of Cadefia gave the falt blow to the Persian monarchy, the whole empire of Iran was foon reduced under the power of the firit Mahometan dynasty; and the ancient literature of Perfa, which had been promoted by the family of Saffan, was immediately discouraged by the succifors of Mahomet; because fome Persian romances, brought into Arabia, were extolled to the difparagement of the Koran, the people to whom they were read alleging, that "the fories of griffons and giants were more amufing to them than the moral lefions of Mahomet." Accordingly a chapter of the Koran was immediately written to flop the progress of these opinions, and other meafures were taken to check their fubversion. This is suppofed to have been the moving caufe of that enthusiasm of the Mahometans, which induced them to burn the famous library of Alexandria, and the records of the Persian empire. It was a long time before the native Perfians could recover from the shock of this violent revolution; and their language seems to have been little cultivated under the caliphs, who gave greater encouragement to the literature of the Arabians: but when the power of the Abbasides began to decline, and a number of independent princes arose in the different provinces of their empire, the arts of elegance, and chiefly poetry, revived in Perfa; and there was hardly a prince, or governor of a city, who had not feveral poets and men of letters in his train. The Persian tongue was confequently refored in the 10th century; but it was very different from the Deri or Pehlavi of the ancients; it was mixed with the words of the Koran, and with expressions from the Arabian poets, whom the Persians considered as their masters, and affected to imitate in their poetical meafures, and the turn of their verses. The oldest Persian
Persian Language.

Persian poems, of which Sir W. Jones obtained any knowledge, are those of Ferdousi, and which, in his account of them, are represented to be a glorious monument of oriental genius and learning; and of which he further says, that if it should be generally understood in its original language, will contaminate the merit of invention with Homer himself, whatever be thought of its subject, or the arrangement of its incidents. He has furnished an extract from this poem, and adds, that it will exhibit a specimen of the Persian tongue, very little adulterated by a mixture with the Arabic, and in all probability, approaching nearly to the dialect used in Persia in the time of Mahomet, who admired it for its extreme softness, and was heard to say, “that it would be spoken on that account in the gardens of Paradise.” Of these two languages was formed the modern dialect of Peris, which, being spoken in its greatest purity by the natives of Pars or Farifian, acquired the name of “Parpar;” though it is even called “Deri” by Hafiz. Nearly in the same age, viz. at the close of the 10th and beginning of the 11th centuries, the great Akeul Ola, surnamed Alami from his blindness, published his excellent ode in Arabic, in which he professedly imitated the poets before Mahomet. At this time, and soon after, the Persian language became altogether mixed with Arabic. At Shiraz, called “the Athens of Persia,” flourished in the 11th century Sadi, a native of this city; who wrote several pieces, both in prose and verse; and by means of an extract from his “Gulistan,” or bed of roses, Sir W. Jones has shewn us how the Persian and Arabic languages were mixed together in his age. The fame city had the honour of producing, in the 14th century, the most elegant lyric poet of Asia, Shemsheddin, surnamed “Hafiz,” of whose productions Sir W. Jones has transcribed two Gazals or anacoretic odes, with a translation. There is nothing, says our much respected author, which affords a stronger proof of the excellence of the Persian tongue than that it remained uncorrupted after the irruption of the Tartars, who, at different times, and under various leaders, made themselves masters of Persia; for the Tartar princes, and chiefly Tamerlane, who was a patron of Hafiz, were so far from discouraging polite literature, like the Goths and Huns, that they adopted even the language and religion of the conquered country, and promoted the fine arts with a bondless munificence; and one of them, who founded the Mogul empire in Hindoostan, introduced the Persian literature into his dominions, where it flourished to this day; and all the letters from the Indian governors are written in the language of Sadi. The Turks themselves improved their Harh dialect by mixing it with the Persian; and Mahomet II., who took Conflantinople in the middle of the 15th century, was a protector of the Persian poets, among whom was Nourreddin Jami, whose poem “On the Loves of Joseph and Zelikha” is very highly extolled by our author, who has given a specimen of his elegant style. In the 16th and 17th centuries, under the family of Seh, the Persian language began to lose its ancient purity, and even to borrow some of its terms from the Turkish, which was commonly spoken at court.

The Persian characters are written from the right hand to the left, and the language consists of 32 letters, which vary in their form as they are initials and medias, or finals, both connected and unconnected. For the pronunciation both of the confonants and vowels, we refer to Sir William Jones’s Grammar, from which we make the following extracts.

The short vowels are seldom written in the Persian books, and the omission of them occasions a perplexity to the learner of the language.

He will soon perceive with pleasure a great resemblance between the Persian and English languages, in the facility and simplicity of their form and construction. The former, as well as the latter, has no difference of termination to mark the gender, either in substantives or adjectives; all inanimate things are neuter, and animals of different sexes either have different names, or are distinguished by certain words, denoting male and female.

The Persian substantives, like ours, have but one variation of case, which is formed by adding a certain syllable to the nominative in both numbers; and answer often to the dative, but generally to the accusative case in other languages. When the accusative is used indefinitely, this syllable is omitted; but when the noun is definite or limited, that syllable is added to it. In Persian there is no genitive case; but when two substantives of different meanings come together, a hebra, or short e, is added in reading to the former of them, and the latter remains unaltered. The same rule must be observed before a pronoun possessive, and before an adjective. The other cases are expressed, for the most part, as in our language, by particles placed before the nominative.

Our article a is supplied in Persian by adding the letter ya, or as it is founded er, to a noun, which refrains it to the singular number.

The Persian plural is formed by adding certain characters for syllables to the singular: but these terminations are not, as in many languages, wholly arbitrary; on the contrary, they are regulated with the utmost precision. It must not be omitted, that the Arabic substantives frequently have two forts of plurals: one formed according to the analogy of the Persian nouns, and another after the irregular manner of the Arabian; and this circumstance, besides several others, proves the impossibility of learning the Persian language accurately, without a moderate knowledge of the Arabic: and for the learner to peruse with attention the Arabic grammar of Peroius, of which there are two fine editions, one by Golius, and another by Albert Schultens, before he attempts to translate a Persian manuscript.

The Persian adjectives admit of no variation, but in the degrees of comparison. The positive is made comparative by adding to it one character for a syllable, and superlative by means of another. An adjective is sometimes used substantively, and forms its plural like a noun: if it be a compounded adjective, the syllables denoting the plural number and the oblique case are placed at the end of it.

The personal pronouns are, 1, men, I; thus, fing. men, 1; plur. ma, we; obl. meri, me, mira, us. 2. To, thou; thus, fing. to, thou; plur. young, you or ye; obl. tara, thee; founa, founai, you. 3. 0, he, thus, fing. 0, he, she, or it; plur. yl, they; obl. bera, him, her, or it; ylara, them. The possessives are the same with the personals, and are distinguished by being added to their substantives. Our reciprocal pronouns, even and elf, are expressed in Persian by certain words, which are applicable to all persons and sexes. For the demonstrative pronouns, this, thes, that, these, in the several cases singular, plural, and oblique, there are appropriate characters or expressions. Certain syllables prefixed to pronouns personal change them into possessives, and are read with a short vowel. The relatives and interrogatives are supplied by the invariable pronouns ke and che; of which the former usually relates to persons, and the latter to things.

The Persians have active and neuter verbs, like other nations; but many of their verbs have both an active and neuter fene, which can be determined only by the construction. These verbs have properly but one conjugation, and but
three changes of tense, the imperative, the aorist, and the preterite; all the other tenses being formed by the help of certain particles, or of the auxiliary verbs signifying to be, and to be willing. The passive voice is formed by adding the tenses of the verb subjunctive to the participle preterite of the active.

Our author has exhibited the inflections of the auxiliary verbs, and an analysis of all the tenses of a Persian verb, shewing in what manner they are deduced from the infinitive, which is properly considered by the oriental grammarians as the spring and fountain of all the moods and tenses, and which, therefore, in Arabic is called the "mudar," or the source. The Persians are very fond of the participle preterite, and it is very often used by their elegant writers to connect the members of a sentence, and to suspend the sense till the close of a long period. In poetry it sometimes is used like the third person preterite of a verb. Our author has subjoined a table of the moods and tenses, as they answer to those of European languages.

In the ancient language of Persia, there were very few or no irregularities: the imperative, which is often irregular in the modern Persian, was anciently formed from the infinitive, by rejecting the termination 
imperative; for originally all infinitives ended in 
the Arabs introduced their harsh consonants before that syllable, which obliged the Persians, who always affected a sweetness of pronunciation, to change the old termination of some verbs into 
and by degrees the original infinitives grew quite obsolete; yet they still retain the ancient imperatives, and the aorists which are formed from them. This little irregularity is the only anomalous part of the Persian language, which, nevertheless, far surpasses in simplicity all other languages, as Sir William Jones says, ancient or modern, of which he has any knowledge.

One of the chief beauties of the Persian language is the frequent use of compound substantives, in the variety and elegance of which it surpasses not only the German and English, but even the Greek. These compounds may be multiplied without end, according to the pleasure and taste of the writer: they are formed either by a noun and the contracted participle, as in the word signifying "heart-allowing:" or by prefixing an adjective to a noun, as in that for "sweet-smelling:" or by placing one subjunctive before another, as in the word denoting "rose-checked." If we consider the vast number of epithets that may be compounded after these three forms, and that these epithets are often used for substantives, without a noun being expressed, we must allow that the Persian language is the richest in the world. These compounds are thought so beautiful by the Persian poets, that they sometimes fill a distich with them.

The construction of the Persian tongue is very easy, and may be reduced to a few rules, most of which has in common with other languages. The nominative is usually placed before the verb, with which it agrees in number and person. It is remarked, however, that many Arabic plurals are considered in Persian as nouns of the singular number, and agree as such with verbs and adjectives. Another irregularity in the Persian syntax is, that the cardinal numbers are usually joined to nouns and verbs in the singular. The adjective is placed after its substantive, and the governing noun is prefixed to that which it governs. Conjunctions which express conjunction, condition, will, motive, &c. require the conjunctive or potential mood. Prepositions and interjections are fixed to nouns in the nominative case.

The modern Persians borrowed their poetical measures from the Arabs, and they are very various and complicated. There are nineteen sorts of metre, which are used by the Persians; but the most common of them are the iambic

measure, or the trochaic measure, and a metre that consists chiefly of those compounded feet, which the ancients called 
measures, and which are composed of iambic feet and spondees alternately, as 
lyric poetry, these verses are generally of twelve or sixteen syllables; but they sometimes consist of fourteen syllables. Other lyric verses contain thirteen syllables. The Persians sometimes use a measure consisting of trochees and spondees alternately; but the most common Persian verse consists of eleven syllables, in which measure are written all the great Persian poems, whether upon heroic or moral subjects, as the works of 
and of Jami, the Bolton of Sadi, and the Mefnavi of the excellent Gorki. The Persian syllable is pronounced to our common heroic rhyme. The profody of the Persian is extremely easy and simple: their vowels called 
and 
are long by nature: the points, which they commonly suppress, are naturally short; and every short syllable that ends with a consonant is long by position. But the Persians, like other poets, have many licences; they often add a short vowel, which does not properly belong to the word; they also shorten some long syllables at pleasure, by omitting the vowels 
and 
We shall here add, the verses of eleven syllables, which are used in the great Persian poems, always rhyme together in couplets.

The Persian elegy differs only in its length from the ode, except that the "caffedeh" often turns upon lofty subjects, and the "gazal" comprises for the most part the praises of love and meritment, like the lighter odes of Horace and Anacreon. The most elegant composers of these odes are Jamé and Hafiz, each of whom has left an ample collection of his lyric poems. Sir William Jones, among other numerous translations, has given us a translation in verse of a beautiful Persian song by Hafiz. If this article had not already been so extended, we should have felt disposed to gratify our readers with a transcript of it; but we must content ourselves with referring to the close of Sir William Jones's Persian Grammar, or to his Works, vol. v.

Persian Lily, in Gardening, the common name of a plant of the flower kind. See Eritillaria.

Persian Wheel, in Agriculture, is a machine for raising a quantity of water sufficient to overflow lands bordering on the banks of rivers, &c. where the stream is too low to do it alone.

Such a wheel is represented in Plate XIV. Hydrostatics and 
with which water may be raised by means of a stream A B turning a wheel C D E, according to the order of the letters, with buckets, a, a, a, a, &c. hung upon the wheel by strong pins b, b, b, &c. fixed in the side of the rim; but the wheel must be made as high as the water is intended to be raised above the level of that part of the stream in which the wheel is placed. As the wheel turns, the buckets on the right hand go down into the water, and are therefore filled by Hafiz. If this article had not already been so extended, we should have felt disposed to gratify our readers with a transcript of it; but we must content ourselves with referring to the close of Sir William Jones's Persian Grammar, or to his Works, vol. v.

The wheel must be made as high as the water is intended to be raised above the level of that part of the stream in which the wheel is placed. PER

within; these hollows opening into the holes C, D, E, F, in the outside of the wheel, and also into those at O in the box N upon the axis. So that, as the holes C, D, &c. dip into the water, it runs into them; and as the wheel turns, the water rises in the hollow spokes c, d, &c. and runs out in a stream, P, from the holes at O, and falls into the trough O, from whence it is conveyed by pipes. And this is a very easy way of raising water, because the engine requires neither men nor horses to turn it. See Overflowing of Land.

Persian, or Pecfic, in Architecture, a name common to all flutes of men, serving instead of columns, to support entablatures. See ORDER.

They only differ from caryatides, in that those represent flutes of women.

The Persian is a kind of order of columns, first practiced among the Athenians, on occasion of a victory their general Paunianias obtained over the Persians. As a trophy of this victory, the figures of men dressed in the Persian mode, with their hands bound before them, and other characters of flattery, were charged with the weight of Doric entablatures, and made to do the office of Doric columns.

Persian columns, M. le Clerc observes, are not always made with the marks of flattery; but are frequently used as symbols of virtues, vices, joy, strength, valour, &c. as when made in the figures of Hercules, to represent strength; and of Mars, Mercury, fauns, satyrs, &c. on other occasions.

Persian Eros, and Year. See EPOCA and Year.

Persian Bible, and Coins. See the subintimates.

PERSICA, in Botany, the Malus Persica, or Persian Apple, of the ancients, our Peach. See Amygdalus.

PERSICA Concha, in Natural History, a name given to a very remarkable and beautiful sea-shell, which authors have long been at a loss to reduce to any genus. Aldrovand has thrown it to the end of his work, and says, it would be of the turbinated kind, if it did not want the turba. It is truly of the genus of the concha globofa, or dolium.

PERSICA Terra, an earth of the ochre kind, known in the colour hoffs of London by the name of Indian red.

It is a very fine purple ochre, of a considerably compact texture, and great weight; while in the earth it is of a pure blood-colour, and is not to be cut with the ipade, but is dug with iron crovs, and falls in irregular maffes. It is of a rough daffy surface, and full of considerably large, bright, glittering particles; these are white and of a fine lufire. It adheres firmly to the tongue, is rough and harsh to the touch, stains the hands very deeply, and is of a rough altrigenous taffe, and makes a very violent effervescence with acid menstrums.

It is dug in the island of Ormus, in the Persion gulf, and in some parts of the East Indies.

PERSICARIA, in Botany, so called by the old writers, from the likeness of its leaves to those of the peach-tree. (See POLYGONUM.) The word is now become the popular English appellation of a very fine species. Polygonum orientale, whose leaves however bear no resemblance to the peach, nor to those of the original Pervaria.

PERSIUS, AULUS PERSIUS FLACCUS, in Biography, a celebrated R. man, poet, is said to have been born at Verc, in Tuscany, in the year 34 of the Christian era. He was educated according to his rank, being of an equestrian family. He studied at Rome, and as he grew up he lived in intimacy with several of the most eminent personages of his time, and was generally beloved for the modesty of his disposition, and the fluavity of his manners. He died at the early age of 38, and bequeathed to his preceptor his library of 700 volumes, with a confiderable sum of money, but the philopher accepted only the library, and divided the money among Pervius's sisters. As a poet, Pervius is only known by his Satires, which were in high reputation among his countrymen. They are of a grave fententious kind, chiefly turning upon topics of general morals. The philosophy of his preceptor Cornutus, to whom one of them is dedicated, has given them an elevation and purity of sentiment, which in some parts places them in the first rank of moral poetry; but their extreme obferility almofts destroys the pleasure of a perusal. The subtitles of Pervius are generally printed with those of Juvenal. The best editions are those of Hacq Caffon, in 1605, Paris, and in 1647, London.

PERSO, in Geography, a town of Italy, in the country of Friuli; 10 miles N.W. of Udina.

PERSOLATA, in Botany, a word used by Pliny, as the name of a kind of burdock, different from the perfonata. He has, in the beginning of the chapter, spoken of the arctium of the Greeks, which he says the Latins sometimes called perfonata, and afterwards adds this persolata; which, he says, was a plant vulgarly known, and called by the Greeks archtium.

He seems to allow, that the Greeks called both these plants by the same name; but he distinguishes the persolata from perfonata, by saying that the former has leaves like those of the great gourd, but larger and more hairy. It is probable, therefore, that he distinguished, under these two names, the two different species of the great burdock common with us, the one with simple, the other with woolly heads.

PERSON, PERSONA, an individual substance of a rational or intelligent nature.

The father and fon are reputed in law as the same person; an ambassador represents the person of his prince.

The word person, peron, is said to be borrowed a personando, from perforating or counterfeiting; and is applied to have first signified a mask; by reason, says Boethus, in larva concussa fons volutus; and hence the actors who appeared masked on the stage, were sometimes called larvati, and sometimes perfonati.

The fame author adds, that as the several actors represented each their single individual person, vis. Cephus, or Chremes, or Hecuba, or Medea; for this reason, other people, who were also distinguished by something in their form, character, &c. whereby they might be known, came also to be called, by the Latins, peronas; and, by the Greeks, περσονα.

Again, as these actors rarely represented any but great and illustrious characters, the word came, at length, to import the mind; as being a thing of the greatest regard and dignity among human matters. And thus men, angels, and even God himself, were called perons. Things merely corporeal, as a stone, a plant, or a horse, were called by them, hypopoera, or hypopota, but never perons.

Hence also the learned imagine, the fame name peron came to be used to signify some dignity, whereby a person is distinguished from another; as a father, husband, judge, magistrate, &c.

In which sense we are to understand that of Cicero: Cesar never speaks of Pompey but in terms of honour and respect; but he does many hard and injurious things against his person.

His for the name peron. As for the thing, we have already defined peron, an individual substance of a reasonable nature; which is the fame as Boethius's definition.

Now a thing may be individual two ways. 1. Logically,
as it cannot be predicated of any other; as Cicero, Plato, &c. 2. Physically; in which sense a drop of water, separated from the ocean, may be called an individual. Peron is an individual nature in each of these senses; logically, says Boethius, since person is not spoken of universals, but only of singulars and individuals; we do not say the person of an animal, or a man, but of Cicero and Plato; and physically, since Socrates's hand or foot are never considered as persons.

This last kind of individual is denominated two ways; positively, as when the person is said to be the whole principle of acting; for whatever thing action is attributed to, that do the philosophers call a person: and negatively, as when we say, with the Thoinists, &c. that a person consists in this, that it does not exist in another as a more perfect being.

Thus, a man, though consisting of two very different things, viz. body and spirit, is not two persons; since neither part alone is a whole principle of action, but one person, since the manner of his consisting of body and spirit is such as constitutes one whole principle of action; nor does he exist in any other as a more perfect being; as, e.g. Socrates's foot does in Socrates, or a drop of water in the ocean.

Person, in Grammar, is a term applied to verbs and pronouns, which being conjugated, are applicable to three different persons.

I love, is a verb used in the first person; thou livest, designs the second person; he loveth, makes the third: and thus in the plural number.

I, thou, he, are pronouns of the first, second, and third persons.

Verbs agree with their nouns, in number and person.

Person, Persona, in Dramatic Poetry, the name and part of an actor; or of him pretended by the comedian.

At the head of dramatic pieces come the dramatic persons, the lift of actors, and characters that are to appear on the stage.

The ancient tragedy was only a simple chorus: Theopis was the first who introduced a person to relieve the chorus; and Aeschylus added a second.

F. Boiffé observes, that, in the epic and dramatic poem, the name of the poet sustains the chief part throughout the whole piece, and the characters of all the other persons must be subordinate to him.

Person, Persona, in Law. See PARSON.

Person, in Geography, a county of America, in Hillborough district, North Carolina; containing 6402 inhabitants, of whom 2082 are slaves.

PERSONA, see preced. Quad, &c. See QUOD.

PERSONABLE, PERSONABILIS, in Law, implies the being able to hold or maintain a plea in court.

That is, as the civilians would express it, habere personam fidandi in judicio.

Thus they say the defendant was judged personable to maintain this action. Old Nat. Brev. 142.

The tenant pleaded, that the demandant was an alien, born in Portugal, without the ligeance of the king; and judgment was asked, Whether he should be anwered? The plaintiff said, he was made personable by parliament.

Kitch. fol. 124.

PERSONABLE is also used to signify a capacity to take any thing granted or given.

PERSONAL, something that concerns, or is restrained to, the person.

In disputes among the learned, there is ever something personal intervened; in ethics, it is a maxim, that all faults are personal; i.e. they do not pass to our descendants.

PERSONAL Action, in Law. See ACTION.

PERSONAL Goods, or Effects, is that confitting of money, moveables, &c. which every person has in his own disposal (see CHATTELS), in opposition to lands and tenements, which are called real estate.

PERSONAL chattels, covenant, differs, history, liberty, possession, privilege, service, and titles. See the substantives.

PERSONAL, Pronoun, or verb Personal, in Grammar, a verb or pronoun conjugated in all the three persons.

They are thus called, in opposition to impersonals, which have only the third person.

PERSONALITY, PERSONALITAS, in the schools, the quality of a person; or that which constitutes an individual in the quality of a person.

The philosophers being used to consider matter and form in every other thing, do the same in person. The matter of person, according to them, is a singular substance, endowed with reason; for substance may, at the pleasure of God, either be, or not be, a person; inasmuch as, they say, the human nature in Christ is not a person. The form of person, which they call substractivity, supposibility, and personality, is that by which the aforesaid substance becomes individual.

The school divines are divided about what it is that distinguishes the several personabilities in the Trinity. Some will have it to be only the different relations: others, as Floraventius, contend for some incommunicable substance: St. Bonaventure, and St. Thomas, take it to be different origins that distinguish the personabilities; which opinion is the most followed. See TRINITY.

PERSONALITY, or Personality, in Law. An action is said to be in personality, when it is brought against the right person.

PERSONATA COROLLA, in Botany, is a monopetalous irregular corolla, whose mouth is cloied by a kind of palate, as in Amurinum. The term is derived from perona, a mark, and its application in the present instance, whether intended or not by Linnaeus, is peculiarly happy; the plants furnished with such a corolla being, as it were, of the regular pentandrous tribe, under a mark, which they occasionally lay aside. See PELOREA and PERSONATE.

PERSONATE, the fourth natural order among the fragments of Linnaeus, nearly analogous to the Scrophularia and the Vicles of Jussieu, embracing moreover some that are subjoined to his Salanae. This order is characterized by a monopetalous unequal corolla: the anthers are usually four, two of them longest, or sometimes only two in all: the style solitary; and a fruit, generally superior, of two cells, with numerous seeds. Many of the plants are fiddel and poisonous, few of them aromatic, though the flowers of some are fragrant. They are all more or less naturally allied to the first order of the Linnean class Penandria, but they arrange themselves either in the Dianthus Monogyne, or rather, principally, in the Dipsaniana Angiospermae, according to the laws of the artificial system. Some are thorny in habit, but the greater part are herbaceous. The leaves are mostly simple; the inflorescence either axillary, corymbos, spiked or panicked. It is by an unaccountable error that Linneus has marked Melandrea as belonging to this natural order, in his Mantilla, p. 14, that genus being evidently referrible to his meteeth order, the Hesperides. Gieke, who points out this mistake, well observes, that there is no order in which so many genera bear the name of batoids as in this of the Peronate.
PERSONIFYING, or Personalizing, the feigning a person; or attributing a person to an inanimate being; or giving it the figure, sentiments, and language of a person. See Phosphoporia.

The poets have personified all the passions; and even made divinities of them, which were worshipped by the heathens; as the goddess Periaphis, the god Sleep, the Furies, Envy, and Discord, and Fame, Fortune, Victory, &c.

Personifying is essential to poetry, especially to the epicour.

PERSONONIA, in Botany, was so named by the writer of the present article, in honour of his highly deserving friend and correspondent, Christian Henry Perfoon, author of many valuable works on Fungi, in which department of Botany this author decidedly takes the lead. He has also edited a Synopsia of the vegetable kingdom, on the plan of the Linnaean Systema Vegetabilium, but in a very small type, printed at Paris, where he now resides. Mr. Perfoon was, if we mistake not, born of Dutch parents, at the Cape of Good Hope. Two other genera have been inderited to him, one by Willdenow in his Sp. Pl. v. 2. 331, which is the Carapa of Aublet, t. 357, and Lamarck t. 301; and another by Michaux, Fl. Boreal-Amer. v. 2. 104, of the class Symnorosia. These are both of a posterior date to the genus of which we are to treat, and which is now generally adopted. Sm. Tr. of Linn. Soc. v. 4. 215. Mart. Mill. Dict. v. 3. Brown Tr. of Linn. Soc. v. 10. 159. Prod. Nov. Holl. v. 1. 371. Ait. Hort. Kew. v. 203. Gegen v. 3. t. 220. (Pentadaftylon ; ibid. t. 220. Br. Linkia ; Cavan. Ic. v. 4. 61.)—Clasf and order, Tetrandria Monogynia. Nat. Ord. Protoc. Juss. Brown.

Eff. Ch. Petals four, recurved, bearing the flamenos about their middle. Nectary of four glands. Gemen superior, flaked. Stigma obtuse. Drupa with a nut of one or two cells.

Obf. Mr. Brown remarks, that the flake of the germin is jointed in some species, and that the cotyledons are, for the most part, more than two. The habit is shrubby or arborescent; the bark sometimes flaky. Leaves scattered, entire, mottly flat. Flower-flakes axillary, foliate, without bracteas, or racemose, with a foliary bractea. Flowers yellow. We follow Mr. Brown in the order and names of the twenty-two known species.

4. P. juniperina. Labill. Nov. Holl. v. t. 32. t. 45.—Leaves awl-shaped, straight, pungent. Flowers axillary, solitary. Gemen smooth, with two kernels. Found on dry heaths and about the sides of hills, in Van Diemen's land, as well as on the fourth coast of New Holland. The stem, according to Labillardiere, is a yard or more in height, determinately branched, round, and leafy. Leaves rigid, above an inch long, rather hairy, as are the short axillary flower-flakes. Petals clothed externally with rigid hairs, yellowish. Fruit red, estable, its nut usually with two kernels.

6. P. mollii.— "Leaves lanceolate, elongated, villous, very soft beneath. Corolla bearded. Gemen smooth, with two kernels."—Gathered by Mr. Brown, near Port Jackson, about the sandy banks of rivers.

7. P. linearis. Linear-leaved Perfoon. Ait. n. 1. Andr. Repof. t. 77. Curt. Mag. v. 760. Venten. Malmaif. t. 32.—Leaves linear, elongated, smooth. Flower-flakes straight. Corolla downy. Stalk of the germin without a joint. Stem arborescent. Bark smooth. On hills and in open fields about Port Jackson, from whence specimens and seeds were first sent by Dr. White in 1792. The plant was raised by the late Mr. Robinson of Stockwell, in 1794. It proved a hardy greenhouse shrub, flowering copiously in the latter part of summer. The young branch, as well as the flower-flakes, and backs of the petals, are downy. Leaves copious, spreading, two inches or more in length, and not a line wide. Fruit globose, smooth.

9. P. virgata. — "Leaves linear, or somewhat oblong, scattered, vertical, very smooth in every part. Flower-flakes smooth, straight. Corolla smooth. Stem arborescent. Bark even."—Gathered by Mr. Brown, on the sea shore, near Sandy Cape, on the east coast of New Holland.

10. P. flexifolia.— "Leaves nearly linear, pointed, crowded, twirled at the base, smooth on both sides, besprinkled with shining dots; their edges rough. Corolla smooth. Stem shrubby."—Native of the florny sides of hills, on the south coast of New Holland.

11. P. scabra.— "Leaves linear-lanceolate, pointed, rough on both sides, besprinkled with shining as well as minute opaque dots. Corolla downy."—In the same country and situations as the last.

12. P. satulata.— "Leaves lanceolate-lateulata, pointed, rather concave, very rough on both sides with crysalline points."—Gathered by Mr. Brown in the same places as the two last.

13. P. nutans. — "Leaves linear, smooth. Flower-flakes axillary, recurved, smooth as well as the corolla."—Found by Mr. Brown near Port Jackson, in woods on a sandy foil, at the foot of the mountains.

Gathered by Sir Joseph Banks, near Endeavour river, on the east coast of New Holland; and by Mr. Brown, at Carpentaria, on the north coast, near the sea shore.

15. P. lanceolata. Lance-leaved Perfoona. Ait. n. 2. Andr. Repof. t. 74.—Leaves eliitie-lanceolate, pointed, smooth and even. Stalks axillary, single-flowered. Corolla silky, with close-prefed hairs. Stalk of the germen without a joint. Native of fields and hedges towards the sea coast at Port Jackson, from whence seeds were early sent to this country. Plants are said to have been first raised in 1791, by J. Wollaston, Esq., at Flatford. The young leaves are about two inches long. Flowers yellow, as in all the red. Fruit globose, the size of a black currant.

16. P. falscina. Perf. Syn. v. i. 118. (Linkia levis; Cavan. f. 221. t. 389.)—Leaves lanceolate-oblong, unequal, refeved. Stalks axillary or racemose. Corolla nearly smooth. Stem arborescent. Bark falky. Native of fields, hills, and woods, in the neighbourhood of Port Jackson. The leaves are three inches long, their sides more or lefs unequal, giving them a falcate fpect. Flowers—flalks and young branches falky. Corolla nearly smooth. Fruit elliptical; its nut with two kernels. Mr. Brown fupfected that Cavanilles's plant may rather be a variety of this, but it was not fouf to three feet with the prefent fpecies, though his plate does not exprefs any inequality in the shape of the leaves. We have a fpecies with obovate leaves, that fems a variety of falscina.

17. P. ferralsina. Sm. Exot. Bot. v. 2. 47. t. 83. (P. laurina; Perf. Syn. v. i. 118. Br.)—Leaves elliptical, acute, veiny. Stalks axillary, many-flowered, clothed, as well as the backs of the petals, with rusky falky hairs.—Native of fields near Port Jackson, from whence it was originally fent dried by Dr. White. We have not heard of this beautiful fpecies in any garden. The ftem is fhrubby, three or four feet fhort, with smooth branches. Leaves for the most part nearly oppofite, two or three inches long, and about one broad, smooth, fhiriny, veiny. Flowers in fhort, denfe, axillary cluf ters, accompanied by small bracteae, which, as fwell as flalks, and the backs as well as marfs of the petals, are denfely cloathed with fhiriny rusky hairs of a deep rufky orange-colour. The germen is covered with fimilar hairs, but the flyle is fmoth. This fhrub flowers in its native country in November.

18. P. profrata.—" Leaves oval, obtufe, downy at the margin. Stalks axillary, with one or more flowers. Stem procumbent."—Gathered by Mr. Brown in fruit, the flowers being all pale, near S. dy Cape, on the east coast of New Holland, growing in fand near the sea fhor.e.

20. P. articulata.—Leaves lanceolate, elongated, equal, smooth. Stalks axillary, with one or more flowers. Corolla nearly smooth. Lower joint of the flalk of the germen as long as the glands."—Gathered by Mr. Brown in Lewin's Land, with the foregoing.

21. P. longifolia.—" Leaves linear, elongated, falcate. Stalks axillary, with one or more flowers. Corolla downy, with close-prefed hairs. Lower joint of the flalk of the germen longer than the glands."—From the fame country.

PERSPECTIVE is the art of repreffenting objects on a definite furface, fo as to affect the eye when seen from a certain point, in the fame manner as the object itself would, were it exi lactly fixed in the point in view.

We shall introduce this article with a brief history of the rise and progress of perspective, and close it with an enumeration of the principal writers on the theory and practice of the art.

The art of perspective owes its birth to painting, and particularly to that branch of it which was employed in the decorations of the theatre, where landscapes were principally introduced, and which would have looked unnatural and horrid, if the fame of the objects had not been pretty nearly proportioned to their distance from the eye. The ancients muft, therefore, have had considerable knowledge of this art; though the only ancient author from whom we can obtain any information relative to its antiquity, is Vitruvius; who, in the proem to his feventh book, informs us, that Agatharcus, at Athens, was the first who wrote on this fubject, on occasion of a play exhibited by Euchylus, for which he prepared a tragic scene; and that afterwards the principles of the art were more diffimly taught in the writings of Democritus and Anaxagoras, the disciples of Agatharcus, which are no longer extant.

The perspective of Euclid and of Heliodorus Lariffenus contains only fome general elements of optics, that are by no means adapted to any particular practice; though they furnish fome materials that might be of fervice even in the linear perspective of painters.

Geminus of Rhodes, who was a celebrated mathematician in the time of Cicero, hath likewise written on this fubject.

We may also infer, that the Roman artists were acquainted with the rules of perspective, from the account which Pliny, (Nat. Hift lib. xxxv. cap. 4.) gives of the representations on the fceene of those plays given by Claudius Pulcher; by whose appearance, he fays, the crowds were fo deceived, that they endeavoured to fettle on the fictitious roofs. However, of the theory of this art among the ancients we know nothing; as none of their writings have escaped the general wreck of ancient literature in the dark ages of Europe.

Perspective muft, without doubt, have been fent, when painting and sculpture no longer excelled. Nevertheless, we have reaon to believe, that it was practifed much later in the eflern empire.

John Tzetzes, who lived in the twelfth century, speaks of it as if he was well acquainted with its importance in painting and statuary; and the Greek painters, who were employed by the Venetians and Florentines, in the thirteenth century, seem to have brought fome optical knowledge with them into Italy: for the disciples of Giotto are commended for observing perspective more regularly than any of their predecessors in the art had done; and they lived in the beginning of the fourteenth century.

The Arabian were not ignorant of this art; as we may presume from the optical writings of Alhazen, who lived about the year 1000, cited by Roger Bacon, when treating on this fubject.

Vitellius, a Polander, about the year 1270, wrote largely and learnedly on optics.

Our
Perspective.

Our own friar Bacon, as well as John Peckham, archbishop of Canterbury, treated this subject with surprising accuracy, confiding the times in which they lived.

The most ancient authors, who professedly laid down rules of perspective, were Bartolomeo Bramantino, of Milan, whose books, entitled "Regole di Perpétiva, e Misure delle Antichita di Lombardia," is dated 1440; and Pietro del Borgo, likewise an Italian, who was the most ancient author met with by Ignatius Danti, and who is supposed to have died in 1445. The last writer supposed objects to be placed beyond a transparent tablet, and endeavoured to trace the images, which rays of light, emitted from them, would make upon it. But his work is not now extant. However, Albert Durer constructed a machine upon the principles of Borgo, by which he could trace the perspective appearance of objects.

Leon Battista Alberti, in 1450, wrote his treatise "De Pictura," in which he treats principally of perspective.

Balthasar Peruzzi, of Sienna, who died in 1536, had diligently studied the writings of Borgo; and his method of perspective was published by Serlio in 1540. To him, it is said, we owe the discovery of points of distance, to which all lines that make an angle of 45° with the ground line are drawn.

Guido Ubaldi, another Italian, soon after discovered, that all the lines that are parallel to one another, if they are inclined to the ground line, converge to some point in the horizontal line; and that through this point, also, a line, drawn from the eye, parallel to them, will pass.

His perspective was printed at Pefaro in 1600, and contained the first principles of the method afterwards discovered by Dr. B. Taylor.

In 1583, there was published a book, written by Giacomo Barrezi, of Vignola, commonly called Vignola, intitled "The Two Rules of Perspective, with a Learned Comment," by Ignatius Danti. In 1615, the work of Marolois was printed, in Latin, at the Hague, and engraved and published by Hondius. And in 1625, Sirigatti published a treatise of perspective, which is little more than an abstract of Vignola's.

The art of perspective has been gradually improved by subsequent geometers, particularly by professors Gravefande, and, in a much greater degree, by Dr. Brook Taylor, whose principles are in a considerable measure new, and far more general than those of any of his predecessors. He did not confine his rules, as his predecessors had done, to the horizontal plane only, but made them general, so as to affect every species of planes and lines, whether they were parallel to the horizon or not; and thus the principles were made universal. Further, from the simplicity of his rules, the whole tedious progress of drawing out plans and elevations for any object is rendered entirely useless, and therefore avoided: for by this method, not only the fewest lines imaginable are required to produce any perspective representation, but every figure, thus drawn, will bear the nicest mathematical examination. Moreover, his system is the only one calculated for answering every end of those who are practitioners in the art of design; because from hence they may be enabled to produce the whole, or only so much of an object as is wanted, and by fixing it in its proper place, may determine its apparent magnitude in an instant. It explains also the perspective of shadows, the reflections of objects from polished planes, and the inverse practice of perspective.

His "Linear Perspective," was first published in 1715; and his "New Principles of Linear Perspective," in 1719, which he intended as an explanation of his first treatise. In 1738, Mr. Hamilton published his Stereography, in 2 vols. folio, the same, and the most complete system of perspective, both as to theory and practice, on the same principles, is that of Mr. Malton, the second edition of which was published in 1779, 4°. We have also treatises on this subject, by the Defart, originally written in French, at Paris, translated by Mr. Chambers, and printed at London, in 1726, Highmore, Ware, Cowley, Kirby, Priestly, Ferguson, &c.

The instruments necessary for drawing according to the rules of perspective, are a tee square, a parallel ruler, a drawing board (which is only a frame board made exactly square), a fecto, a protractor; to which may be added a drawing pen, and a black-lead pencil.

Proposition.—It is a well-known fact, founded on experience, that objects reflect their lights, shades, and colours in straight lines, and describe an image in the eye which produces that sensation of the object called vision, which see.

Corol. 1.—If a straight line be opposed to the eye, and not directed to it, the rays or straight lines which issue from all points of it to the eye, form a plane.

Corol. 2.—If any plane or solid be opposed to the eye, the straight lines or rays which issue from all points of the surface to the eye form a pyramid, provided that with respect to the plane of the eye it is out of its surface. The following are definitions of the terms employed.

1. The straight line reflected from any point of a line or surface, is called a visual ray.

2. A plane composed of visual rays is called an optic plane.

3. A pyramid composed of visual rays is called an optic pyramid.

4. An optic plane or pyramid is called a system of rays.

5. If a system of rays be intercepted by a plane, the common section is called the cenographic or perspective representation of the body.

Corol.—Hence the representation of any right line, or rectilinear figure, or solid, is also rectilinear.

6. The plane on which the section is made is called the picture.

7. The point, line, surface, or body, from which the rays proceed to the eye, is called the original object.

Corol. 1.—Hence, if the original object be a plane, and the picture parallel to it, the representation will be a figure similar to the original.

Corol. 2.—If any part of an original object touch the picture, the part which is thus in contact will be the cenographic representation of that part.

8. The vertex or point of the pyramid where the eye is placed, is called the point of sight, or point of view.

9. If the original object be situated on a plane, this plane is called the original or primitive plane.

10. If a plane be supposed to pass through the eye parallel to the picture, this plane is called the directing plane.

11. The intersection of the picture and the original plane is called the intersection or intersecting line of that plane.

12. The intersection of any original line with the picture, is called the intersecting point of that original line.

Corol.—Hence the intersecting points of all lines in any original plane, are in the intersecting line of that plane.

13. If a straight line be supposed to be drawn through the
the eye parallel to any original line, the line so drawn is
called the parallel of that original plane.

Corol. — Hence, if any number of original lines be parallel
among themselves, one line can only pass through the eye
parallel to them all.

14. If a plane be supposed to pass through the eye pa-
rallel to any original plane, or the plane of an original object,
the plane thus passing through the eye is called the parallel of
that original plane.

Corol. — Hence, if any number of original planes be parallel
among themselves, one plane only can pass through the eye,
which will be parallel to them all.

15. The intersection of the parallel of any original
plane and the picture, is called the vanishing line of that
plane.

Corol. 1. — Hence the intersecting and vanishing lines are
parallel to each other.

Corol. 2. — Hence all original parallel lines have the fame
vanishing line.

Corol. 3. — Hence the parallels of every two original planes
have the same inclinations as the originals.

Corol. 4. — The vanishing point of the common intersec-
tion of any two planes, is the intersection of the vanishing lines
of these planes.

16. The intersection of the parallel of any original line is
called the vanishing point of the original line.

Corol. 1. — The vanishing points of all lines in the fame
original plane, are in the vanishing line of that plane.

Corol. 2. — Hence any number of original parallel lines can
have only one vanishing point.

Corol. 3. — Hence original lines which are parallel to the
picture have no vanishing point, because their parallels can
never cut it.

Corol. 4. — The lines which generate the vanishing points of
two original lines, make the same angle with the eye as the
originals do with each other.

17. The intersection of the original plane and the direct-
ing plane, is called the directing line of that plane.

18. The intersection of any original line with the
directing plane is called the directing point of that origi-
nal line.

Corol. — Hence the directing points of all lines in the
fame original plane are in the directing line of that plane.

19. A straight line drawn from the directing point of any
original line to the eye is called the director of that original
line.

20. The intersection of the vanishing plane and the di-
recting plane is called the parallel director, or parallel of
the eye.

Corol. — Hence the intersecting line, the vanishing line, the
parallel director, and directing line, are all parallel to each
other.

21. If a straight line be drawn from the point of sight
perpendicular to the picture, the point where it meets the
picture is called the centre of the picture; and the part of
the line intercepted between the point of sight and the centre
of the picture is called the distance of the picture, or principal
distance.

22. If a straight line be drawn from the point of sight
perpendicular to a vanishing line, the point where it meets
the vanishing line is called the centre of that vanishing line;
and the part intercepted between the point of sight and the
centre of the vanishing line, is called the distance of that van-
ishing line.

Corol. 1. — Hence a line drawn from the centre of the pic-
ture to the centre of a vanishing line, is perpendicular to
that vanishing line.

Corol. 2. — The distance of a vanishing line is the hypoten-
use of a right-angled triangle, the base of which is the
distance of the picture, and the perpendicular the distance
between the centre of the picture and the centre of its
vanishing line.

23. If the distance on a vanishing line from the vanishing
point to another point, be equal to the distance of that van-
ishing point from the eye, the other extremity of this dis-
tance, which is not the vanishing point, is called the point of
distance.

24. The point where a perpendicular drawn from the
centre of the vanishing line cuts the intersecting line, is called
the centre of the intersecting line.

25. If the original plane be the level of the earth's sur-
face or horizon, it is called the ground plane.

26. If the original plane be the horizon, the vanishing
plane is called the horizontal plane.

27. If the picture be perpendicular to the horizon, it is
called a vertical picture.

28. When the original plane is the ground plane, the
intersecting line is called the ground line.

29. When the original plane is the ground plane, a plane
drawn through the eye perpendicular to the ground plane
and to the picture, is called the vertical plane.

30. The intersection of a vertical plane with the vertical
picture, is called the vertical line.

31. The intersection of the vertical plane with the di-
recting plane, is called the prime director, and by some the
eye director.

32. The intersection of the vertical line with the ground
plane, is called the foot of the vertical line.

33. The intersection of the vertical director with the
ground plane, is called the elevation point, or prime directing
point.

34. The distance between the elevation point and the foot
of a vertical line, is called the elevation line, or line of
elevation.

35. A straight line drawn between the intersecting and
vanishing points, is called the indefinite representation, or
projection of that line.

Axiom 1. — The common intersection of two planes is a
straight line.

2. The common intersection of two straight lines is a
point.

3. If two straight lines meet in a point, or are parallel to
each other, a plane may be made to pass through both of
them.

4. If a straight line meet two parallel straight lines, or
two straight lines meeting in a point, all the three straight
lines are in the same plane.

5. Every point in any straight line, is in any plane which
the line is in.

6. Two planes which are parallel cannot intersect.

7. One part of a straight line cannot be in a plane while
another part is out of it.

Several of these axioms are propositions in the eleventh
book of Euclid's Elements, where they are demonstrated;
but if the notion of a plane is understood, their evidence
will be admitted upon the fullest reflection, so that it
would be but of little use to attempt to prove them.

In Plate 1. fig. 1. W X Z Y is the original plane; A B N I
the picture; T S W X the directing plane parallel to the pic-
ture; and S V L T the vanishing plane, or parallel of the
original plane; V L, the intersection of the parallel of the
original plane and the picture, is the vanishing line; I N, the
intersection of the picture and the original plane, is the in-
tersecting line; S T, the intersection of the parallel of the
original
original plane and the directing plane, is the parallel of the eye; and WX, the intersection of the directing plane and the original plane, is the directing line.

In all the figs. 1, 4, 5, and 6, E is the place of the eye. In figs. 2 and 3, the parallel of the original plane is not represented. In each of the figs. 1, 4, 5, and 6, the intersecting line is denoted by IN, the vanishing line by VL, if necessary in the figure, the directing line by WX, and the parallel of the eye by ST.

Theorem 1.—The indefinite projection of a straight line not parallel to the picture, passes through its intersecting and vanishing points.

This is evident, since the original line and its radial are parallel to each other. The eye, the intersecting point, and the vanishing point, are all in the same plane with the original line and its radial; and, therefore, if a line be drawn in the picture between the intersecting and vanishing points, all the three straight lines will be in the same plane; and, consequently, the indefinite representation will be in the same plane with the original straight line and the eye.

Since the whole practice of perspective depends upon this theorem, our readers will take the following illustration.

In Plate 1, fig. 1, QR is an original straight line, R its intersecting point, W its vanishing point, and W a line in the picture joining the intersecting and vanishing points.

Now since E W' and R Q are two parallel lines, let a plane be supposed to be drawn through both, it will pass through the eye at the extremity of the radial E W'; and because the straight line R W joins the two straight lines Q R and E W', the lines R Q and W W' are in the same plane with the eye, and consequently R W' is the intersection of the plane of rays on the picture from the straight line Q R.

Further, let E F, G H, I K, and L M be parallel original lines, they will have W' for their common vanishing point, therefore the several indefinite representations from the intersecting points F, H, K, and M, will all terminate in W'.

If an original straight line and its radial are in the same straight line, the whole indefinite representation of that line will be in its vanishing point.

Theorem 2.—The projection of a line parallel to the picture is also parallel to its original.

Let A B, (fig. 2) be an original line parallel to the picture, a b its representation, and E A B the optic plane, E being the place of the eye. Now a b is the intersection of the optic plane, that is, of the triangle E A B with the picture; and because A B is parallel to the plane of the picture, and A B, a b in the plane of the triangle E A B, a b is parallel to A B; for if otherwise, A B would meet the picture in the intersection a b, or a b produced, and consequently could not be parallel.

Corol.—The projections of several lines parallel to one another and to the picture, are also parallel to one another. Thus, if A D and B C be parallel to one another, and to the picture M N K, a d and b c will be respectively parallel to A D and B C, their originals.

Theorem 3.—The representation of a line parallel to the picture is to its original, as the distance of the picture is to the distance between the eye and the picture passing through the original line parallel to the picture; for let the plane Q R Z Y (fig. 2) be parallel to the plane M N K of the picture; and let E F be drawn perpendicular to the original plane and to the picture, to meet the original plane in F, and the picture in f; join A F and a f, then A E F will be a plane, A F the intersection of the plane of the triangle and the original plane, and a f the intersection of the plane of the triangle and the picture.

Now in the similar triangles E a b and E A B,}
and E A B,

Also in the similar triangles E a f and E A F,

Therefore, by comparing these equal ratios,

Consequently, the representation of a line parallel to the picture, is to its original as the distance of the picture is to the distance of the eye, and a plane passing through the original line parallel to the picture.

Corol. 1.—The angle which the representations of any two original lines parallel to the picture make with each other, is equal to the angle made by the original lines; because each representation is parallel to its original.

Corol. 2. The projection of any plane figure parallel to the picture is similar to its original, for let A B and A D be two contiguous original lines, and a b and a d their representations. Now in the similar Triangles E a b and E A B,

Also in the similar triangles E a d and E A D,

Therefore, by comparison, a b : a d :: A B : A D

Consequently, the sides about the equal angles are proportional.

Theorem 4.—The projection of a line is parallel to its director. Because E Q, E D, and W' R, (fig. 1) are all in the same plane; and since the directing plane is parallel to the plane of the picture, the director E D is parallel to the indefinite representation W' R; because "if two planes be cut by another plane, their common sections with it are parallel." B. 11. prop. 16. Euclid.

Corol. 1.—The projections of lines that have the same director are parallel to each other.

Corol. 2. When the original line is parallel to the picture, it is also parallel to its director, and therefore in the parallel of any given plane passing through the original line, and consequently the vanishing line of that plane, and the projection of the line, are parallel to each other.

Theorem 5.—The distance between the projection of any point of a straight line, and the vanishing point of the line, is to the distance between the intersecting point and the vanishing point, as the distance of the vanishing point is to the distance between the direct point and the original point.

That is, in fig. 1. q W' : R W' :: E W' : D Q.

Now because of the parallel planes which form the diagram, W' E D R is a parallelogram, therefore R W' is equal to D E'; now the triangles q E W' and E' D' Q are similar, because their sides q E and E' D' are parallel; therefore q W' : D' E' or R W' :: E W' : D Q.

Corol.—Hence the distance between the representation of any point in a straight line, and the vanishing point of the line, is to the distance between the intersecting point and the vanishing point, as the distance of the picture is to the distance between the original point and the directing plane.

The foregoing theorems, with the following corollaries arising from the definitions, contain all the principles which we conceive necessary in the perspective representation of any rectilinear object. But if the reader is desirous of knowing the best methods for the representation of circular objects, he must be prepared with the knowledge of conic sections, and the harmonic division of lines.

Corol. 1. Prop. 1.—If there be a straight line opposed to the eye, and not directed to it, the straight lines which issue from all points of it to the eye form a plane.

Corol. def. 5.—Hence the representation of any straight line, rectilinear figure, or solid, is also rectilinear.

Corol. 1. def. 7.—Hence, if the original object be a plane, 5 A 2 and
and the picture parallel thereto, the representation will be a
figure similar to the original.

Corol. 2.—If any part of an original object touch the
picture, the part which is thus in contact will be the repres-
entation of that part.

Corol. def. 12.—Hence the intersecting points of all lines
in any original plane, are in the intersecting line of that
plane.

Corol. def. 13.—Hence if any number of original lines
be parallel to each other, one line can only pass through the
eye parallel to them all.

Corol. def. 14.—Hence if any number of original planes
be parallel to each other, one plane can only pass through the
eye, which will be parallel to them all.

Corol. 1. def. 15.—Hence the intersecting and vanishing
lines are parallel to each other.

Corol. 2.—Hence all original parallel lines have the same
vanishing point.

Corol. 3.—Hence the parallels of every two original
planes have the same inclination as the originals.

Corol. 4.—The vanishing point of the common intersect-
on of any two original planes, is the common intersection
of the vanishing lines of these planes.

Corol. 1. def. 16.—The vanishing points of all original
lines in the same plane, are in the vanishing line of that
plane.

Corol. 2.—Hence any number of original parallel lines
can have only one vanishing point.

Corol. 3.—Hence original lines which are parallel to the
picture have no vanishing point.

Corol. 4.—The radials which generate the vanishing points
of two originals make the same angle with the eye as the
originals with each other.

Corol. def. 18.—Hence the intersecting line, the vanis-
ing line, the parallel director, and the directing line, are all
parallel to each other.

Corol. def. 19.—Hence the directing points of all lines
in the same original plane, are in the directing line of that
plane.

Corol. 1. def. 32.—Hence a line drawn from the centre of
the picture to the centre of a vanishing line, is perpendicular
to that vanishing line.

Corol. 2.—The distance of a vanishing line is the hypo-
thenuse of a right-angled triangle, the base of which is
the distance of the picture, and the perpendicular the dis-
tance between the centre of the picture and the centre of the
vanishing line.

Description of the Diagrams for Illustrating the Principles
of Perspective.—In fig. 1. is shown the method of finding the
representation of a point, first by the intersecting and va-
nishing points. Let Q be any point in the original plane.
Through Q draw any line, Q R, meeting the intersecting
plane I N at R, and through E' draw E' v' parallel to Q R,
meeting the picture in v'; join v' R, and the visual ray
Q E' cutting the indefinite representation v' R at q;
the representation of the point Q; because from theorem 1,
the indefinite representation of a line falls through its
intersecting and vanishing point, and because the visual ray
E Q is in the same plane with the parallelogram R D E' v',
Q will therefore cut R' v' at q.

Secondly, by the intersecting and directing points. Draw
any line, Q D', through the original point, cutting the in-
tersecting line I N at R, and the directing line W X at D'; join
D' E', which will be the director of the original line by
definition 10; draw R' v' parallel to D' E', and draw the
visual ray Q E', cutting R' v' at q, then q is the repre-
sentation of Q, as before. For since R D E' v' is a plane, and
the point's E' and Q, and the indefinite representation R v'
in that plane; the visual ray joining E' and Q must cut R v'
at q.

This diagram also shows, that if L M and Q R be two
original lines, having the same directing point D', and if M
and R be the intersecting points, the indefinite representa-
tions M v' and R v' will be parallel. This appears from
corol. 1. theorem 3.

In this diagram it is also shown, that if E F, G H, K
L M, be several parallel lines intersecting the picture at
F, H, K, M, and if the radial E' v' be drawn parallel to any
one of them cutting the picture in v', their indefinite rep-
resentations will terminate in v'. This appears evident,
since any one of the lines E F, G H, &c. is in the same
plane with E v', from the fourth axiom, and because the
eye at V is in E' v', each of the indefinite representations
will be cut by any visual ray from its original to the eye at E'.

Fig. 2. shows the representation of a plane figure par-
allel to the picture. Let the original figure be A B C D,
in the plane Q R Z Y parallel to the picture I N M K,
and let E be the place of the eye in the directing plane
G H X W. Draw any director E' D' through each angular
point A, B, C, D, of the figure; draw A P, B S, C T,
D Q, parallel to E' D', cutting the original plane in P, S,
T, Q; draw D' P, D' Q, D' S, D' T, cutting the intersect-
ing line in p, q, r, s, t; draw p a, s b, t c, q d, parallel to
E' D'; from the angular points A, B, C, D, of the original
figure, draw the visual rays E' A, E' B, E' C, E' D, cutting
the plane of the picture I N M K respectively at the points
a, b, c, d, in the lines p a, s b, t c, q d. Because A P, a p,
and E' D' are parallel to each other, they are therefore in
the same plane; therefore the straight line A E' will cut p a
at a, consequently, a is the representation of A. In the same
manner it may be proved that b is the representation of B,
and so on of the rest.

Fig. 3. shows the representation of a plane figure by means of the directing plane in a plane inclined at any angle,
or perpendicular to the picture. Let A B C D be the origi-
nal figure. Take any point D' in the directing line W X
as a directing point; draw the director D' E'; from the angular points A, B, C, D, draw A D', B D', C D', D D',
cutting the intersecting line at p, q, r, s, t; draw p a, q b, r c, t d,
parallel to the director D' E'; draw the visual rays A E',
B E', C E', D E', cutting the lines p a, q b, r c, t d, at the points
a, b, c, d, and a b c d is the representation of the figure
A B C D; for p a is parallel to D' E', and the straight
line A D' joins these parallels; therefore p a, D' E', and
A D', are in the same plane; and because the angular point
A, and E' the place of the eye, are in that plane, the
visual ray A E' is also in that plane, and therefore will cut
p a at a. In the same manner each of the other points
b, c, d, may be proved to be the representation of each of
the points B, C, D.

Fig. 4. shows the representation of a plane figure in a
plane inclined to the picture at any angle, or perpendicular
to it, by means of a directing point and the vanishing
points of the sides.

In the quadrilateral A B C D be the original figure.
Take any directing point D', and draw D' E' the director;
draw the radial E' v' parallel to A D and B C, cutting
V L, the vanishing line, at v'; also draw the radial E' v'
parallel to A B and D C, cutting V L at v'. Then if the figure
be a parallelogram, draw lines to the directing line
D' from each of the nearest angular points, B, A, D',
to cut the intersecting line I N at p, q, s, t; draw p h, q g,
in s d, parallel to E' D'; produce the side B A of the
original
original figure to meet the intersection I N' at i; join i v', cutting q a at a, and p b at b, then a is the representation of the point a; join a v', cutting s d in d, and draw b v' and d v', cutting each other at c, then a b c d is the representation of A B C D, as required. For i v' is the indefinite representation of B A by theorem 1, and q a is the representation of the line q a, theorem 3; and since the original lines B A and q A meet or cut each other at A, their indefinite representations will also meet each other at a, and because the vanishing point of a line is a point in the indefinite representation; and if two points in the indefinite representation are found the whole indefinite representation may be drawn. Now since a is the representation of the point A, and a v' the representations of another point in the side A D, a v' will be the indefinite representation of A B.

In the same manner it may be shown, that a v' is the indefinite representation of A D; then since s d is the representation of s D, and the point D is both in s D and A D, therefore its representation d is at d, the intersection of s d, and a v', the indefinite representation of these lines: for the same reason b is the representation of B, and by reasoning as above, it may be shown that c is the representation of C. Therefore the whole figure a b c d is the representation of A B C D. It is upon this principle that all architectural drawings are put in perspective, by only using the original plane, first supposing the picture, the vanishing plane, and the directing plane, removed: they then draw the plan, A B C D, of the building or edifice, and fix upon D' as a flat point, and then draw the intersection I N', then draw lines from the several points to cut I N'; and supposing the picture to stand perpendicular to the original plane, as is generally the case, the directing plane S T X W will also be perpendicular to the original plane; then as D' in this case is the flat point, the director D'E becomes perpendicular also to the original plane, and hence the directorial indefinite representations s d, q a, p b, will be perpendicular to the intersection I N'. Then taking another separate piece of paper for the picture, draw two parallel lines I N' and V'L at a distance from each other, equal to the height of the eye, I N' being the intersecting line, and V'L the vanishing line; then transferring all the intersections to I N'on the picture, draw lines from each point perpendicular to I N', and they will give the directorial indefinite representations; then the vanishing points being found upon the original plane, the whole object may be represented with more advantage in this manner than in any other, as the indefinite representations of all lines on the original plane fall in the same straight lines with the representations of original lines perpendicular to the original plane from the figure original points.

Fig. 5. shows the representation of a plane figure by means of vanishing points only; viz., by finding the vanishing points of the sides, and producing the sides of the figure to their intersecting points, then the intersections of the indefinite representations will form the figure a b c d, which is the representation of the original figure A B C D, depending entirely upon theorem 1.

This method is, however, not so convenient as the flat point: or prime directing point, as it requires much more space to produce all the original lines, than to draw them from each of the points of the object to the directing point, and more particularly when the plan of the object is very remote from the intersecting line, or when large in proportion to the distance, and on this account, though elegant in theory, it is not eligible for practice.

Fig. 6. is here given, in order to shew that it will be the same thing, whether the plan of the object is laid on the vanishing plane, extended beyond the picture, or upon the original plane, the point E' for the eye and the vanishing line being situated in the same manner with respect to the figure a b c d, that the point D' and the intersection 1 N' are in respect to the similar and equal figure A B C D. For let the figures a b c d, and A B C D, be placed so that the corresponding sides a b, A B, c d, C D, &c. shall be parallel; then supply the lines a A, b B, &c. to be joined, then these lines will also be parallel to each other; and because the points D' and E' are alike situated to each of these figures, if D' E' be joined, D' E' will be parallel to a A, b B, &c. and parallel to the plane I N' L' V'. Let D' be drawn parallel to A B, meeting I N', or I N' produced, and draw D' C perpendicular to I N', cutting it in C, also draw E' parallel to a b, meeting V'L', or V'L, produced at a', and draw E' C perpendicular to V'L', meeting it in C', then the intersecting points G, M, N, will have the same distances in respect of each other, and with respect to w and C', that g, m, n, have in respect to each other and to the points v' and C; it will therefore be the same thing whether we use the vanishing plane, or the original plane, in order to ascertain the intersections, the centre and distance of the picture, and the vanishing points, so as to draw the object unconnected with the original plane, as explained in fig. 4, as each of the lines drawn in the one plane has the same extension as its correspondent line in the other, and the angle made by any two adjoining lines in the one plane, is equal to the angle formed by the corresponding lines of the other.

The foregoing diagrams, with the explanations which accompany them, shew the nature of forming the representation from the original object, supposing all the planes to exist in their real position; but this is not the case in practical perspective; the picture, the original plane, and the vanishing plane form one, and must be reduced to one plane surface in the following manner: for the intersecting line, the vanishing line, the parallel of the eye, and the directing line, to be as hinges to the four planes, viz., the plane of the picture, the directing plane, the part of the original plane between the intersecting and directing lines, and the vanishing plane; now as these planes are all parallelograms, and the opposite planes being equal, they will, therefore, continue parallel in all positions when moved round the four fingers, and consequently may be all made to coincide in one plane: now let it be supposed that the picture, the directing plane, and the vanishing plane, are moveable upon the original plane, which remains stationary, and let these planes be made to coincide with the original plane, so that the picture may cover that part of the original plane between the intersecting line and the directing line; either entirely, or in part; then by this means the part of the original plane beyond the intersecting line will be wholly uncovered. Suppose all the radicals to have been previously drawn on the vanishing plane, in order to produce the vanishing points, it is evident that these radicals will be still parallel in the coincident plane of the planes. The practice, with regard to the use of vanishing points, may therefore be as follows: upon any convenient plane, draw two parallel lines for the intersecting and vanishing lines, then the area or space comprehended between these lines is the picture, the space adjacent to the intersecting line is the original plane, and the space adjacent to the vanishing line is the vanishing plane, so that the picture lies between the vanishing and original planes: draw the original figure in the original plane in the intended position to the intersecting line, and fix upon the eye with regard to its distance from the vanishing line, and its position in regard of the flat line: draw lines through the eye parallel to the sides of the original figure as radials, in order to produce the vanishing points; continue the sides of the original figure to the intersecting
PERSPECTIVE.

facing line, and join the corresponding intersecting and vanishing points, then the space included by the indefinite representation will be the representation of the original figure. For if the whole scheme were supposed to be raised into its original position, the eye would be brought into its true place, the radials would be parallel to the original side of the object, and the indefinite representations would be in the same plane with the radials and sides of the original object. Though the space between the intersecting and vanishing is called the picture, the picture is by no means limited to this space, but extends upwards, and does not reach the vanishing lines plane, so that, in most cases, what is commonly called the picture is the least part of it, except in bird's-eye views, or where the horizon is taken very high in consequence of the spectator being placed upon an elevated situation.

In the practice of perspective, where the plan of the object is given, the principal directing point used in conjunction with the vanishing points of the sides is the most convenient, as it has already been observed; the vanishing plane is here supposed to be removed, as all the planes in the practice of perspective delineation are supposed to coincide. The intersecting and vanishing lines may be drawn as before; then the principal directing point or station point may be fixed in the same position to the intersecting line, that the eye is in regard of the vanishing line; then the eye and the station point will be at a distance from each other, equal to the height of the picture, and in a straight line perpendicular to the intersecting line; or the distance of the eye from the vanishing line will be equal to the distance of the station point from the intersecting line; also the position and distance of the eye from the object will be the same as when all the planes are brought into their real position.

It must be here observed, that in the motion of these planes round the principal lines, as before observed, the parallel of the eye and the vanishing line always keep the same parallel distance in all positions; but these lines vary in respect of the object in the original plane, because these lines are not in the same plane with the original plane; and the intersecting and directing lines, also the original figure, are in the same plane, viz. in the original plane. Therefore the station point, or any other directing point, may be fixed in position to the original object and intersecting line. This is the foundation of the practice of perspective with regard to the use of the directing line, and, therefore, the directing point has the same relation to the intersecting line that the eye has to the vanishing line.

In order to prevent repetition in the enumeration of the following problems, the eye, the vanishing line, and intersecting line, are always given in position; the eye is denoted by E'; the vanishing line by V, L, and the intersecting line by I N, but as the original object may be of an indefinite number of forms, it is only enunciated in each problem.

**Problem I. Plate II.** Fig. 1 and 2.

Given any original straight line A B, oblique to the intersection I N, to find its indefinite representation. 

**Solution.**

Produce A B to its intersecting point B', through B' draw the radial E' V', and join B B' V; then B B' V is the indefinite representation of the line A B. **Theorem 1.**

If there be any number of original parallel lines A B, A B, &c. and if B, B, &c. be their intersecting points, and V' the vanishing point of any one, it will be the vanishing point of the whole system. **Corol. 2, def. 16.**

**Problem II.** Fig. 3 and 4.

Given any original point A, to find its representation. 

Draw any two lines through the point A, find each of their indefinite representations C V', B V', problem 1, and the intersection a of C V', B V', will be the representation of the original point A.

For since the original point, A, is in each of the original lines A B and A C, the representation, a of the point, A, is in each of the indefinite representations, and is therefore at a, their intersection.

**Prob. III.** Fig. 5.

Given any original line A B, oblique to the intersection, to find its indefinite representation.

Find the indefinite representation C V of A B by problem 1; draw A E and B E, cutting C V at a and b, then a b is the representation of A B.

For let A E' intersect I N at D, and V L at G, then D is the intersecting point, and G the vanishing point of the original line A D; therefore G D is the indefinite representation of A D; and since w V C is the indefinite representation of the original line A B, and since each of the original lines is drawn from the point A, the intersection, a, of the two indefinite representations C V and D G will be the representation of the point A by problem 2. In like manner it may be shewn that b is the representation of the point B, therefore a b is the representation of A B.

**Problem IV.** Fig. 6.

To find the representation of any original line A B parallel to the picture.

Find a, the indefinite representation of the point A, problem 2; draw a b parallel to the original line A B; join B E', cutting a b at b, then a b is the representation of A B.

For since a is the representation of A, problem 2, and since any original line parallel to the intersection must have its representation also parallel to the intersection; and, lastly, because b is the representation of B, a b is the representation of A B. For it may easily be shewn, that if two planes cut one another, and if these be cut by a third plane, so that its intersection with one of them shall be parallel to the intersection of the two first, the other intersection will also be parallel to the two first.

**Problem V.** Fig. 7.

An original oblique line A B, being divided into several parts, to find the representation of the parts.

Find the representation, a b, of the original line A B, problem 3; and through the several divisions of the parts in A B draw lines to the eye at E', cutting a b at e and f; then b e, e f, f a, are the parts corresponding to those of the original line A B.

This is evident from problem 2.

**Problem VI.** Fig. 8.

Given the point, A, of an original line parallel to the picture, and perpendicular to the original plane, to find the representation of the said line.

Through A draw any line A B, cutting I N at B, and find its indefinite representation B V, problem 1, and find the representation, a, of the point A in the indefinite representation B V; draw B C and a d perpendicular to I N; make B C equal to the original line; draw C V, cutting a d at d, then a d is the representation of the original line inflected upon the given point A.

**Demonstration to Problem VI.**—For, suppose the plane INL V of the picture to be raised perpendicular to the original plane, and the objective line to be raised in position; also imagine a straight line drawn through the other extremity of the objective line, out of the original plane, parallel to
PERSPECTIVE.

To find the representation of parts A D, D E, E B, into which an original line A B, oblique to the intersection, is divided.

Find the indefinite representation, \( e v \), of the line A B, by problem 1; then by the directing point D, and director D E, find the representations \( a d, d e, e b \), of the original points A, D, E, B, as in problem 7.

Then \( a d, de, eb \), are the representations of A D, D E, E B.

This is evident from the demonstration, problem 7.

To find the representation of a line parallel to the picture perpendicular to the original plane.

Find the indefinite representations, \( b v \) and \( e v \), of any straight line A B, and that of another parallel to it, passing through the other extremity of the objective line out of the original plane, as in problem 6; draw \( A D' \), cutting \( I N \) at \( f \); and draw \( f d \) parallel to \( D'E' \), cutting \( b v \) at \( a \), and \( e v \) at \( d \); then \( a d \) is the representation required.

This is evident from the demonstration of problem 6, and because the direct, \( D'E' \), is perpendicular to the intersecting line \( I N \), the indefinite representation \( af \), of \( A f \), as well as the representation, \( a d \), of the original of the objective line, are perpendicular to \( I N \); and because the point, \( a \), is common to the two straight lines \( af \) and \( a d \), \( af \), is in the same straight line with \( a d \), and, consequently, they make only one straight line, \( f d \), perpendicular to \( I N \).

The following problem shows the method of finding the representation of plane figures by means of the vanishing points.

To find the representation of any plane rectilinear figure in the original plane.

Find the indefinite representation of every side of the original figure by problem 1, and the intersections of all the indefinite representations will form the representation of the figure required.

If the vanishing points of any original line exceed the limits of the picture, the extremities of that line may be found by problem 3, or by problem 7.

Parallellograms will have two vanishing points.

The foregoing problems are requisite in finding the representation of an object in the original plane. The following is to obviate the necessity of drawing the original object, or having it given but to perform the operation from a knowledge of the construction of the figure.

To find the representation of an original line A B, parallel to the intersecting line.

Through either extremity A, draw any line \( A e \), meeting the intersection in \( e \); find the indefinite representation \( e v \) of \( A e \), problem 1; draw \( D A \) and \( D B \), cutting \( I N \) at \( e \) and \( d \); draw \( e a \) parallel to \( D'E' \), cutting \( v e \) at \( a \); draw \( a b \) parallel to \( A B \); and draw \( a b \) parallel to \( D'E' \), cutting \( a b \) at \( b \); then \( a b \) is the representation of A B.

For the representation of the point A is in the indefinite representation \( a v \) of \( A e \), problem 1; it also is in the indefinite representation \( e a \) of \( A e \); therefore the representation of A is at the point \( a \), the intersection of these two indefinite representations; and because the original line, A B, is parallel to the intersecting, \( a b \) will also be parallel to the intersection; therefore the representation of the point, B, will be in the line \( a b \); but the representation of B is also in the indefinite representation, \( b v \), of the line \( B D \); therefore the representation of the point, B, being both in \( a b \) and \( b v \), must be at \( b \), their intersection; therefore \( a b \) is the representation of the line A B.
original point from the interfacing point, is transferred upon the interfacing line from the interfacing point, in order to save room; thus, if $V' L'$ be the vanishing line, $1' N'$ the interfacing line, $E'$ the place of the eye, $a$ an original point, drawing any line $a d$, and its radial $E' a$, and joining the vanishing point, $v'$, to the interfacing point $d$ and making $w' 1$, on the vanishing line, equal to $v' E'$, the distance of the eye, and $d e$ on the interfacing line equal to $d a$, the point, $m$, will be found, whether $a E'$, $b f$, or $c i$, be joined, as is evident, because the indefinite representation, $d v'$, is divided into two portions in the constant ratio of $a d$ to $v' E$.

**PROB. XIII. Fig. 2.**

Given the vanishing and interfacing lines of a plane, the vanishing and interfacing points, $v'$ and $d$, of an indefinite line in that plane, the distance of the eye, and the distance of a point in the original line, to find the representation of the point.

Join $v' d$, the interfacing and vanishing points; make $v' 1$ equal to the distance of the eye, and $d e$ equal to the distance of the point in the original line; join $e 1$, cutting $d v'$ at $m$, and $m$ will be the representation of the original point.

This appears evident from problem 12.

**PROB. XIV. Fig. 3.**

The vanishing and interfacing lines of a plane, the vanishing and interfacing points, $v'$ and $d$, of a finite line on that plane, the distance of the vanishing point from the eye, and the distance of the nearest extremity of the line to its interfacing point being given, to find the representation of the line.

Join $v' d$, the indefinite representation; make $v' 1$ equal to the distance of the eye on the vanishing line, also $d a$ equal to the distance of the nearest extremity, and $a b$ equal to the original line on the interfacing line $1 N'$; join $a 1$, cutting $v' d$ at $f$, and $b 1$ cutting $v' d$ at $g$, then $f g$ is the representation of the original line.

This appears evident from problem 12, as the points $f$ and $g$ are each the representation of a point in the original line.

**PROB. XV. Fig. 4.**

The definite representation $a e$, and the vanishing point, $v'$, of a line being given, to divide $a e$, representing the original line, confidirg of parts of a given ratio.

Through either extremity, $a$, of the definite representation, draw $1 N'$ at any angle with $a w'$, and through $v'$ draw $v' 1$ parallel to $a E'$, on the contrary side of $a v'$; make $a b$, $b C$, $C D$, $D E$, equal to the parts of the original line, or in the same ratio; join $E C$, which produce to $i$; also join $B i$, $C i$, $D i$, cutting $a e$ at $b$, $c$, $d$, then $a e$ is divided as required.

For in the similar triangles,

- $b a B$ and $b a v'$, $b a : a B :: b v' : v' 1$
- $c a C$ and $c a v'$, $c a : a C :: c v' : v' 1$
- $d a D$ and $d a v'$, $d a : a D :: d v' : v' 1$
- $e a E$ and $e a v'$, $e a : a E :: e v' : v' 1$

Therefore alternately,

- $b a : b v' :: a B : v' 1$
- $c a : c v' :: a C : v' 1$
- $d a : d v' :: a D : v' 1$
- $e a : e v' :: a E : v' 1$

And because the parts $a B$, $a C$, $a D$, $a E$, continue in the same ratio with $v' 1$, the points, $a$, $b$, $c$, $d$, $e$, will be inviable, whatever angle the lines $a' E$ and $v' 1$ form with $v' a'$ and whatever be the lengths of $a B$, $a C$, $a D$, $a E$; and because the lines $a 1$, $B i$, $C i$, $D i$, $E i$, represent a series of parallels, cutting the original of $a e$, the points $a$, $B$, $C$, $D$, $E$, will represent the interferences, and $v' 1$ the distance of the eye.

**PROB. XVI. Fig. 5.**

The centre $C$, and distance of the picture, the vanishing and interfacing lines of a plane, the vanishing point of a finite line in that plane, the feet $x'$ and distance of the nearest extremity of that line from its feet being given, to find the representation of the line.

Make $C D$ on the vanishing line equal to the distance of the picture, and $x y$ on the interfacing line equal to the distance of the feet of the nearest extremity of the given line; join $C x'$ and $y D$, cutting each other in $g$; join $g y'$; find the point $i$, such that the distance $v' i$ may be equal to the hypothenuse of a right-angled triangle, whose base is $v' C'$, and perpendicular $C D$ the distance of the picture; draw $x g a$, cutting $1 N'$ at $a$; make $a b$ equal to the original line; join $b 1$, cutting $g v'$ in $b$, and $g b$ is the representation required.

**PROB. XVII. Fig. 6. No. 1.**

The centre and distance of the picture, the vanishing and interfacing line of a plane perpendicular to the picture, the feet of the nearest extremity of a line in that plane, the length of the line, and its inclination to the interfacing line being given, to find the representation of the line.

In $N'$, let $x$ be the feet of the nearest extremity of the line; make $x y$ equal to its distance, and make $C D$ equal to the distance of the picture; join $C x'$ and $D y'$, cutting each other at $g$. In $N''$, make any angle $a e$, on the line $a e$; make $e a$ to $e b$ as radius to the conic of inclination of the given side; make $e c$ equal to its length; find $e d$ a fourth proportional to $e a$, $e b$, $e c$; transferred to $1 N'$, $N''$, from $x$ to $f$, and draw $f e$ cutting $g v'$ at $b$, then $g b$ is the line required.

This is evident, as if we consider the points, $a$ and $b$, in the original lines perpendicular to the picture; then the space intercepted upon the interfacing line by the two perpendiculars, will be in the same proportion to the original line as radius to the conic of inclination.

**PROB. XVIII. Figs. 7 and 8.**

Given the indefinite representation of two lines in the same plane, interfacing each other at $b$; a finite portion, $b a$, of the indefinite representation $b v'$, and the distance of the eye, $v'$ and $v''$, from each vanishing point, $v'$, $v''$; to find a portion of the indefinite representation $b v''$, the original of which shall be equal to that represented by $a b$, or in any given ratio with the original of $A B$.

Through the point $b$, draw $d e$ parallel to the vanishing line $V' L'$; join $a 1$, which produces to $d$, in fig. 7, but to cut $e d$ in $d$, fig. 8; make $e b$ to $b d$ in the ratio required, and join $e 2$, cutting $b v''$ at $c$; then the original of $b a$ will be to the original $b c$ as $b d$ to $b e$, as required.

This is evident by considering $b a$ as the representation of a line inclined to, and $b d$ the representation of another coinciding with, the picture, and $i$ the vanishing point of a line forming the base of an isofaces triangle with each of these lines; therefore, $a b d$ will be the representation of an isofaces triangle, of which $a d$ will represent the base, and $a b$ and $b d$ the two equal sides; in like manner, $e b$ will represent an isofaces triangle, of which $e e$ will represent the base, and $e b$, $b e$, the two sides.

In
In this and the following examples, where the representations of lines are required to be delineated without the use of the geometrical plane, the vanishing points are always marked $v$, with an index over the right-hand side of it, in order to distinguish the number of vanishing points: thus, $v_1, v_2, v_3$, &c. denote the first, second, and third vanishing points. The distances of these vanishing points are simply denoted by their indexes: thus, $v_1$ placed upon the vanishing line, denotes the distance of the vanishing point $v_1$ from the eye, 2 of $v_2$, and so on of others.

**PERSPECTIVE.**

**Pror. XIX.** Fig. 9.

The indefinite representations, $e$ and $a$ $v_1$, of two lines in the same plane; the distances, $v_1$ and $v_2$, of their vanishing points, $v_2$ and $v_3$, on the vanishing line, $V_1$, of their plane; also, a finite portion, $c d$, of the indefinite representation $e', v_1'$, being given: through a given point, $a$, in the indefinite representation $a v_1$, to represent the length of an original line, which shall be equal to, or in a given ratio to, the original line represented by $a v_1'$. Through $e'$ parallel to $V_1$, and through $a$ draw $a b$ parallel also to $V_1$, join $a d$, and produce it to $g$; also produce the indefinite representation $a v_1'$ to meet $g$ in $e$; make $e f$ to $e g$, in the ratio of the original to be represented from the point $a$, on the indefinite representation $a v_1'$, to the original represented by $e d$; join $f e$ cutting $a b$ at $b$, and join $b c$ cutting $a v_1'$ at $b$; then $a b$ is the representation required.

For $a b c d$ represents a parallelogram, with two sides parallel to the picture; and because $e f$ and $a b$ represent opposite sides, the original of $e f$ is equal to the original of $a b$: and because $a b b$ represents an isosceles triangle, of which $b b$ is the base, the original of $a b$ is equal to the original of $a b$, therefore the original of $a b$ is equal to the original of $e f$; and because $e g$ represents an isosceles triangle, the original of $e g$ is equal to the original of $e d$: and because $e g$ and $e f$ are in a line parallel to the vanishing line, the original of $e g$ and $e f$ are parallel in the same indefinite line to the interfacing line of their plane, and have the same ratio as the representations $e g$ and $e f$; therefore the original of $e d$ has to the original of $a b$ the ratio of $e g$ to $e f$, as required.

**Pror. XX.** Fig. 10.

Given the eye, the vanishing and interfacing lines, and the place of the eye in position; to find the representation of a parallelogram, whose angles and dimensions, also the fest, $x$, of the nearest angular point, and its distance from the interfacing line, are known.

Draw $E C'$ perpendicular to $V_1 L$, the vanishing line, cutting it in $C$, the centre of the picture; make $C D'$ equal to $C E'$, and $x y$ equal to the distance of the nearest angular point of the parallellogram, from the interfacing line; join $x C'$ and $y D'$, cutting each other in $e$, the representation of the nearest angle, as in problem 16. Through $E'$ draw $M N$ parallel to $V_1 L$; make the angle $M E' v_1'$ equal to the angle which the side of the original parallellogram adjoins the nearest angular point, as the angle of the interfacing, or makes with a line drawn from the nearest angular parallel to the interfacing; make the angle $v' E' v_1'$ equal to the nearest angle of the parallellogram: join $v' v_1'$ and $v_1 v'$; from the indefinite representation $e v_1'$, cut off the portion $e f$, to represent a line equal to the original side, of which $e v_1'$ is the indefinite representation, by problem 16; that is, make $e f'$ equal to $v' E'$; join $e f$ and produce it to meet the interfacing line in $f$; make $a b$ equal to the original side; join $a b$, cutting $e v_1'$ at $f$; in like manner, make $v_1' v_2$ equal to $V_1$. XXVI.

$V_1 v_2$ and join $z e$, cutting the interfacing line in $e$; make $c d$ equal to the other adjoining side of the nearest angle, and join $d z$, cutting $v_1'$ at $h$; join $b v_1'$ and $f e'$, and $e f b$ is the parallellogram required.

The original figure, though here shown, is of no other use than to assist the imagination in the construction.

**Pror. XXI.** Fig. 11.

Given the interfacing and vanishing lines, and the place of the eye in position, the fest $x$, the distance of the centre of a circle, and its radius, to find the representation of the circle.

**Method 1.**

Make $x f$, on the interfacing line, equal to the distance of the centre of the original circle from its fest $x$, and $C'D'$ on the vanishing line equal to $C'E'$, the distance of the eye; join $x C'$ and $y D'$, cutting each other in $e$, the representation of the centre of the circle; through $e$ draw $e d$ parallel to $I' N'$, the interfacing; make $x a$ and $x b$ each equal to the radius of the circle; join $C'a$, cutting $e d$ in $c$, and $C'b$, cutting $e d$ in $d$, and $c d$ is the representation of a diameter parallel to the picture; then to find the representation of $e f g$ of any diameter drawn through $e$ at pleasure; produce $f g$ to its vanishing point $v_1'$; make $v_2' v_3'$ on the vanishing line, equal to $v' E'$, the distance of the eye from the vanishing point; join $z e$, cutting $f g$ in $g$, also $z d$, and produce it to $f$; then $f g$ is the representation of a diameter of the original circle inclined to the interfacing line. In like manner may the representations $b b', b b$, be found; etc. by transferring the distance of each of their vanishing points from the eye on the vanishing line, and drawing two lines from each point of distance to $e$, and $d$, the one cutting, and the other produced till it cut the indefinite representation belonging to the distance so transferred, then a curve being drawn through all the extremities of the representational diameters, will be the representation of the circle required.

The original circle, $A$, is placed in its position for the same reason as before given, prob. 21. This is an application of problem 18, from which its evidence appears.

The following are several easy methods of drawing the representation of a circle, and are exceedingly useful where accuracy is required, particularly in the representation of large circles.

The interfacing and vanishing lines, the centre and distance of the picture, the fest and distance of the centre, and the radius of the circle, are supposed to be given till it is otherwise announced; $C'$ denotes the centre, and $C'D'$ the distance of the picture, and $x$ the fest of the centre of the circle, and $y$ its distance, as in prob. 20, 21.

**Method 2.** Fig. 12.

Draw $x A$ perpendicular to $I' N'$; make $x E$ and $x D$ each equal to $x A$; describe the arc $x B$; join $A E$ and $A D$, cutting the arc $x B$ at $C$ and $B$; draw $C F$ and $B G$ parallel to $I' N'$, cutting $I' N'$ at $F$ and $G$; join $E C'$, $F C'$, $x C'$, $G C'$ and $D C'$; also join $y D$, cutting $E C'$, $F C'$, $x C'$, $G C'$, and $D C'$, at $b, m, n, c$, and $d$; draw $b a$ parallel to $I' N'$, cutting $x C'$ in $e$, and $D C'$ at $a$; draw $d e$ parallel to $I' N'$, cutting $x C'$ in $g$, and $E C'$ at $e$; through $n$ draw $f h$, also parallel to $I' N'$, cutting $E C'$ at $f$, and $D C'$ at $m$, also join $e$, cutting $G C'$ at $h$, and $F C'$ at $k$, and $e$ will also cut $f b$ or $y D'$ at $m$; through the points $e, b, k, g, b, f, m, e$, draw a curve, which will be the representation of the circle required.

This will easily appear, when it is considered that the tangent to
gent of 45 degrees is equal to the radius, or by infepting $f g. 14$, where the part $M F G$ is equal and similar to $A E D$.

**Method 3. Fig. 13.**

Make $x b$ and $x a$ each equal to the radius of the circle; join $b C$, $a C$, and $a C'$; make $x y$ equal to the distance of the centre $G$ from the feet $x$, and join $y D'$, and complete the representation $d e f$ of the circumcribing square, as in fig. 12; divide the representation $h g$, of the parallel diameter, into seven equal parts, letting one-seventh from $h$, and the other seventh from $g$, each towards the centre; draw $k l$, and $m n$, tending to $C'$, cutting the diagonals in the points $l$, $l$, $m$, $n$, then through the points $l$, $b$, $k$, $p$, $n$, $g$, $q$, draw a curve, which will be the representation required.

This will readily appear by observing in fig. 12, that the representation of the parallel diameter $f b$ is divided in the same proportion as $E D$, or as $E A$, fig. 14; now $E L$, $K A$, $F H$, or $I G$, fig. 14, is very nearly equal to one-seventh of the diameter $E A$; draw $M C$ perpendicular to $E A$, cutting the semi-circumference at $C$; through $C$ draw $F G$ parallel to $E A$, and through $E$ and $A$ draw $E F$ and $A C$ parallel to $M C$, and join $F M$ and $G M$, cutting the circle in $D$ and $B$; through $D$ and $B$ draw $L H$ and $K I$ parallel to $M C$, cutting $E A$ at $L$ and $K$, and $F G$ at $H$ and $I$.

Now suppose the diameter $E A$ to consist of seven equal parts, the radius $M E$ or $M A$ will be $3 s$; that is, $M D$, or $M B$, will be $3 s$.

By Euclid, b. i, prop. 47, the square of $M D$, or $M B$, is equal to the squares of $M L$ and $L D$; but $M L$ is equal to $L D$, therefore the square of $D M$ is double the square of $M L$; that is, the square of $M E$ is double of the square of $M L$; hence $M L$ will be obtained arithmetically thus: $L M = \left(\frac{M E^2}{2}\right)$; therefore $E L = E M - L M = E M - \left(\frac{M E^2}{2}\right) = 3 s - \left(\frac{3 s^2}{2}\right) = 1.026, &c.$ which is exceedingly near to unity, the error being in excess.

Fig. 15. is an application of method 3, fig. 13, to planes at different altitudes, to obtain the representation of a circle, when the feet of its centre is given on the original plane, and the feet of the centre of the circle on the original plane, given on the intersecting line, and the distance of the feet of the centre of the circle on the original plane, from its feet on the intersection also given. The ellipsis below is the representation of a circle below the eye.

To represent a circle above the level of the eye, let $x$ be the feet of the centre of the circle on the original plane, given on the intersecting line; let $x y$ be the distance of the two feet. Draw $y o$ perpendicular to $I N$, and make $x y$ equal to the distance of the centre of the circle from its foot on the original plane; draw $o D'$; then, having found the representation of the circle below the eye on the original plane, as in method 3, fig. 13, let $e c$ be the representation of the diameter parallel to the picture, and $a$ the representation of the centre; draw $a p$ parallel to $y o$, cutting $o D'$ in $p$; draw $a w$ parallel to $V L'$, the vanishing line; draw $c w$ parallel to $y o$; make $p w$ equal to $p w$; through $a w$ draw $s t$, tending to the centre $C$ of the picture, cutting $o D'$ in $t$; and through $z$ draw $q r$, tending also to $C$; cutting $o D'$ at $r$; draw $r s$ and $q t$ parallel to $V L'$, and $s q$ will be the representation of the circumscribing square; then complete the circle as in method 3.

**Method 4. Plate IV. Fig. 1.**

Let $A B C D$ be the representation of the circumscribing square, with two sides of the original parallel to the intersecting line, consequently the other two perpendicular thereto; and let $G H$ be the representation of a diameter parallel to the intersecting line, and $I$ that of the centre; $E F$ the diameter perpendicular to the intersecting line. Divide $I H$ into any number of equal parts (as three), and through the points of division ($1, 2,$) draw the lines $F m, F n$; draw $H K$ parallel to $E F$, cutting $A B$ at $K$; divide $K H$ into the same number of equal parts as $I H$, and through the points of division draw the lines $E m, E n$, then the points $m$ and $n$ are in the curve as well as the points $E$ and $H$. In the same manner, the curve $E q p G$, for the representation of the other quarter, will be found; also in describing the representation $G F H$ of the remote semi-circle, proceed for the representation of each quarter in the same way, only changing the points $F$ and $E$ for each other, and the whole curve will be obtained.

**Method 5. Fig. 2.**

Let $G H E$ be the representation of the remote semi-circle in the same position as before. Divide $I H$ into any number of equal parts (as three), also divide the line $B H$ perpendicularly to represent the original of $B H$, divided into three equal parts; that is, since $B C$ is the indefinite representation of a line $C$ its vanishing point, $B k$ is a line drawn through $B$, and $C d'$ another drawn parallel thereto, and on the contrary side of $B C$. On $B k$ let off the distances $B 1$, $1 2$, $2 3$, equal to each other; join $k H$, and produce it; meet $C d'$ in $t$, and draw each of the lines $t 1$, $t 2$, $t 3$, tending to the point $t$, cutting $B H$ at $l$ and $m$, the same as in problem 15; then having drawn the lines $E l$, $E m$, as in method 4, draw $E p, E q, m q$, and $e$, in the points of intersection $p$ and $q$ will be in the curve. In the same manner may be the part $F r s G$ be obtained, and also the representation of the remote half, if necessary.

Fig. 3. is the representation of a segment less than a semi-circle, the chord of the original segment being parallel to the intersecting line; the operation is the same as in method 4. It is hardly possible to conceive any method more convenient and more easy than this, as the perspective representation is found geometrically, without any other vanishing points than the centre of the picture.

**Method 6. Fig. 4.**

Having completed the representation, $A B C D$, of a circumscribing square, the sides of the original being parallel and perpendicular to the picture; find the perspective centre $I$, which may be done by drawing the two diagonals; find the representation $G H$ of the diameter parallel, and that of $F E$ of the diameter perpendicular to the picture; produce $G H$ both ways to $K$ and $L$, making $G K$, and $H L$, each equal to $I H$ or $I G$; join $E F$ and $K L$, and $E F$; also join $E D$, $F A$, $E C$, and $F B$, cutting the lines drawn from $K$ and $L$ to the points $E$ and $F$, at $a$, $b$, $c$, $d$, which are points in the representation of the circle; therefore through all the points $a$, $E$, $b$, $H$, $c$, $F$, $d$, $G$, draw a curve which will represent the circle required.

Fig. 5. shews the same thing for the representation of a semi-circle with its diameter parallel to the picture.

The methods shown by figs. 1, 2, 3, 4, and 5, are derived from the following consideration.

Let $A B$ (fig. 6) be any straight line cutting another $C D$ at $E$, and dividing it into the equal parts $E C$ and $E D$; and if $C F$ and $D G$ be drawn parallel to $B A$, and if $F G$ be drawn through $A$, parallel to $C D$; and if $C E$ and
and C F be divided into any equal number of parts in the same ratio from C, and lines be drawn from the points of division in C F, to the point A, and lines through the several divisions in C E from the point B to cut the former drawn to the point a, the respective intersections of every two lines will be in the curve of an ellipsis, of which C E is an ordinate, and A E an abscissa. In the same manner the opposite part of the curve may be described, and also the other portion on the opposite side of the double ordinate D C.

Now to shew the truth of this: let A B (fig. 7.) be a diameter, and g f an ordinate; draw f e parallel to B A, and A e parallel to g f; divide f e and g f in h, and the latter in k, and draw h A and B k, and produce B k to meet h A at C, then C is a point in the curve.

Because the triangles

\[
\begin{align*}
&BD:BG :: DC:Gk, \\
&AD:Ah :: DC:ib or gf,
\end{align*}
\]

familiar, and because the triangles

\[
\begin{align*}
&BD:Bg :: DC:Gk, \\
&AD:Ah :: DC:ib or gf,
\end{align*}
\]

familiar, and by construction,

\[
\text{Therefore by multiplication:} \quad BD \times AD:BG \times AG :: DC^2:gf^2.
\]

A well-known property of the ellipsis.

Now in fig. 1, E F is a diameter, and I G, I H, ordinates at the same point I; and as the perspective representation of a circle is the section of an oblique cone, it is an ellipsis, and as the method is the same as that now demonstrated, it is therefore founded in truth. In fig. 3, the same data are given. In fig. 4, E A divides I G into two equal parts, which have their origins also equal; and F B divides I H into two equal parts, which have their origins also equal. Again, E K divides A G into two parts, the origins of which are equal; and E L divides B H into two parts, the origins of which are equal; and since a circle can be drawn through as many points found in the same manner, this method for finding eight points in the curve is correct. The same might have been observed of fig. 2; for the parts in the double ordinates I G and I H are divided equally, and the parts in A G and B H perpendicularly into parts, the origins of which are equal.

Nothing can be more expeditious, nor more convenient for practice, than the method which this principle furnishes, when it is considered that no point can be found geometrically, but by the interferences of two straight lines. Its great advantage lies in the regularity of the operation; in not distorting the eye with irregular crossings. As many points may be found as required, without the least confusion, within the compass of the circumscribing parallelogram, which is not the case with many other methods derived entirely from the principles of perspective. It may be always well applied when the curve is the representation of a circle inscribing a square, the sides of which are parallel and perpendicular to the picture.

Method 7. Fig. 9.

Let W X Y Z be the representation of a square circumscribing the representation of the circle required; and let A B be the representation of a diameter of the original circle perpendicular to the picture, and D C the representation of the radius parallel thereto. Bicef A B in I; through I draw b i parallel to D C; draw B e perpendicular to b i, cutting it in e; draw D a parallel to B e; with the distance B e, from the point C, describe an arc cutting b i at f; join C f, which produce to a; through a and I draw m n; then if the straight line a C be moved, so that the point a may slide along the line m n, and the point f along b i, the extremity C will trace the representation of the circle required.

For draw f t parallel to D a, cutting D C in t.

Then because of the similar triangles

\[
\begin{align*}
&\{Cf:ft :: Ca:aD, \\
&Bf:dt :: Bc:dc.
\end{align*}
\]

But because C f = B e,

\[
\{ft = D t
\]

it will be B e: D c :: I t = a D and C a = I f.

Again, by the similar triangles

\[
\{Bt:Dc :: Bf:Bf,
\]

Therefore by equality,

\[
\{Bt:Id :: I f = aD.
\]

But by duplication,

\[
\{Bt:'Id' :: I f' :: ad'.
\]

And by division,

\[
\{Bt' = ID' = (B f + I D') \times (B f - I D') = A D \times B D, \text{and} a D' = a C' = D C' = I f' = DC',
\]

therefore by substitution B f: A D \times B D :: I f' = DC', which is a known property of the ellipsis; and as the perspective representation of a circle is an ellipsis, being the section of an oblique cone, the curve described is the true representation of the original circle, for the rays which proceed to the eye form the surface of a cone, and being cut by the picture produce an ellipsis.

In this manner an ellipsis (fig. 8.) may be described by a continued motion, having any two conjugate diameters b i and a B given, or a diameter and ordinate, without previously finding the two axes.

But as it is not very easy to make an ellipsograph move freely in every position of two conjugate diameters, from the obliquity of the interferences, it may be done upon the same principle, by finding points in the curve upon the straight edge of a thick piece of paper, marking the points a f and C (fig. 9.) upon the edge; then supposing a f is first placed upon any point in the line m n, carry the other end of the slip until the point marked f fall upon b i, then mark the extremity C upon the plane of description or paper, and the point so marked will be in the representation of the circle required. In the same manner as many points will be found as will be sufficient to complete the curve with sufficient accuracy.

But as the method of describing an ellipsis by continued motion from the two axes is by much the most accurate, we shall here shew the method of finding a conjugate diameter, to a diameter or ordinate given, before we can proceed with the next method.

Lemma.—Let ABCD (fig. 10.) be the representation of a square circumscribing the original circle, and let E F be the representation of the diameter perpendicular to the picture, k f the representation of the radius parallel to the picture, and k the representation of the centre. Bicef E F at a; through a draw m n parallel to A B or D C; draw F g perpendicular to m n, cutting m n at g; from the point i, with the distance F g, describe an arc cutting m n at h; draw k i parallel to F g, and produce i h to i; make o m and a n each equal to i f; then m n is the diameter conjugate to F E. This method is evident from the construction given in method 7, fig. 9.

Method 8. Fig. 11.

The representation A B C D of a square circumscribing a circle, having its sides parallel and perpendicular to the picture, being given, to find there representation of the circle by means of the two axes.

Find G the representation of the centre, E F the representation of the diameter perpendicular, and G H the representation of the radius parallel to the picture. Then by the preceding lemma, find the semi-conjugate diameter r v; draw E k perpendicular to A B; make E k equal to r v; 5 B 2; join
join \( r, k \), and bisect it by a perpendicular \( a, o \), meeting \( A, B \) at \( a \); from \( a \) as a centre, with the distance \( a, o \) or \( o, k \), describe the semi-circle \( p, q \), cutting \( A, B \) at \( p, q \); join \( k, p \) and \( k, q \); from \( k, \) with the distance \( k, e \), describe the arc \( m, n \), cutting \( k, q \) at \( m \), and \( k, p \) at \( l \); join \( p, q \) and \( r, q \); produce \( r, q \) to \( t \), and draw \( m, q \) parallel to \( k, r \), cutting \( q, t \) at \( u \); then \( r, s \) and \( r, u \) are the semi-axes, as shown by the writers on conic sections; make \( r, s \) equal to \( r, u \), and \( r, t \) equal to \( r, s \), and \( u, w \) and \( t, v \) will be the axes by which the curve may be described by means of an instrument at one continued movement, and the curve thus described will be the representation of the circle required.

**Method 9.** Fig. 12.

Supposing every thing given as in the last method, \( F \) being the representation of a diameter perpendicular to the picture, \( E \) that of the centre, \( A, B, D \) and \( C \) that of the sides of the square parallel to the picture, and \( A, D, B, C \) the other two sides perpendicular to the picture; draw \( F, X \) perpendicular to \( A, B \); make \( F, X \) equal to \( A, F \) or \( F, B \); from \( X, \) with the radius \( X, F \), describe an arc; draw \( X, N \), \( X, B \), \( O \). &c.; meeting \( A, B, N, B, O, \) &c.; join \( N, E, B, E, \) \( Q, F, E \); make angles on the other side of \( F, X \) equal \( F, X, M, X, L \), &c.; produce the legs to meet \( A, B \); from the points in \( A, B \) draw lines to \( E, \) and produce these lines on the other side of \( E \); from the points \( M, L \) draw \( M, E, \) \( L, K, \) &c.; meeting \( A, B, C, \) &c.; the curves drawn lines to \( E, \) and produce these lines the other side of \( E \); from the points in \( A, B, \) &c.; the curves drawn lines to \( E, \) and produce these lines the other side of \( E \); from the points \( M, L \) draw \( M, E, \) \( L, K, \) &c.; meeting \( A, B, C, \) &c.; of the lines with the former are in the curve, for each two lines are drawn from the same common point in the circle \( K, L, M, F \), which may be looked upon as the original; thus the point \( M \) is represented by \( f, l \) by \( e, k \), and by \( d, \) the extremity of the diameter parallel to \( A, B \) by \( G \).

In cases of this kind, where lines radiate from a centre in approaching the parallel diameter they frequently run out to a distance beyond the bounds of the drawing. The following remedy is very convenient; let \( X, m \) be a line, which if produced would not meet \( A, B \) within a convenient distance; from any point \( s \) in \( A, B \), draw \( S, Q \) parallel to a straight line, supposed to join the points \( X, E \); make \( S, Q \) equal to the part of the line intercepted between the line \( A, B \) and the point \( X, \) and the point \( X, \) and make \( S, Q \) equal to the other part, and join \( R, Q \); now let \( X, m \) meet \( S, Q \) in \( m \); draw \( m, n \) parallel to \( Q, R \), and \( S, R \) at \( n \); make \( S, Q \) equal to \( S, R \), and draw \( e, o \), which will be the line corresponding or representing \( m, X \), and thus of any other.

**Method 10.** Fig. 13.

Let \( E \) be the representation of the centre, \( D, Q \) a diameter parallel, and \( F, G \) a diameter perpendicular to the picture; bisect \( F, G \) in \( m \), through \( m \) draw \( g, p \) parallel to \( D, Q \); find the extremities \( g, p \) and \( p, d \), by the preceding lemma, fig. 10; join \( D, m \), and produce it to \( n, \) make \( m, n \) equal to \( m, D \); join \( Q, m \), and produce \( Q, m \) to \( o, q \); make \( m, o \) equal to \( m, q \); draw \( F, l \) parallel to \( A, H \), cutting \( D, n \) at \( y \); and make \( y, t \) equal to \( y, l \); draw \( F, s \) parallel to \( B, l \), cutting \( Q, o \) at \( v \), and make \( v, t \) equal to \( v, s \); draw \( G, u \) parallel to \( H, A \), cutting \( D, n \) at \( x \), and make \( x, u \) equal to \( x, G \); draw \( G, p \) parallel to \( I, B \), cutting \( o, Q \) at \( w \); make \( w, r \) equal to \( w, G \); then will the points \( a, u, r, n, t, s \), be in the representations of the circle. For since \( w \) is the centre of the ellipsis, and \( D \) is a point of contact, \( D, n \) will be a diameter, it will therefore be bisected by the centre \( m \), therefore the point \( n \) is in the curve. Again, because \( Q \) is a point of contact, \( Q, o \) is a diameter, therefore \( o, q \) is equal to \( w, Q \), and therefore the point \( o \) is in the curve. Again, because \( D \) and \( G \) are points of contact, and \( D, n \) is a diameter; and because that \( G, n \) is parallel to \( H, A \), a tangent at \( D \), \( G, n \) is a double ordinate; it is therefore bisected by \( D, n \) at \( x \), therefore the point \( u \) is in the curve. By the same method of reasoning as in the case of \( u \), it will be proved, that the points \( r, f, \) and \( s, \) are in the curve of an ellipsis, wherever all the points \( g, q, o, w, r, n, t, s \), as well as the four points of contact \( D, F, Q, G \), are in the curve of an ellipsis; here are fixed additional points besides those which the circumfcribing square furnishes, from the considerations only, that the centre bisects all the diameters; that if there be two tangents, and the points of contact given, and if a line passes through one of the points of contact and the centre, it will be a diameter; and if another passes from the other point of contact parallel to the tangent, at the extremity of the diameter, it will be a double ordinate; and, lastly, that all the double ordinates are bisected by the diameter.

**Method 11.** Fig. 14.

Let \( V, V \) be the vanishing line, and \( I, N \) the intersecting line, and let \( b \) be the point where the original circle touches the intersecting line; let \( D, R \) be the directing line, \( D, R \) the point of inflexion, or prime directing point.

Through \( D \) draw \( E, D, C \) perpendicular to \( R, D, \) and make \( V, V \) equal to the height of the picture; and make \( D, R \) equal to \( D, E \); draw \( b, c \) perpendicular to \( I, N \), and make \( b, c \) equal to the radius of the circle; from \( e, \) with the distance \( e, b \), describe an arc \( d, b, a \); draw \( a, e, c, \) and \( d, f \), tending to the point \( D, \) to cut \( I, N \) at \( e, \) and \( f \); draw \( e, n, \) and \( e, m \); parallel to \( D, E, \) draw \( d, k, d, q \), and \( a, j \), tending to \( R, \) to cut \( I, N \) at \( b, q, \) and \( i, j \); transfer \( f, k \) to \( f, i \), from \( f, i, q, \) to \( t, u \) to \( t, u, \) and \( e, r \) to \( e, n, \) and then \( i, b \); make \( a, e, n, \) and \( o, u \); then will \( b \) be the centre, \( i, b \) and \( u, n \) conjugate diameters of the ellipsis, which will be the representation of the circle.

For since \( D \) is the directing point of the lines \( d, f, e, \) and \( a, c \), the lines will have parallel representations; join \( R, E, \) and \( k, i \), or suppose them to be joined, then \( k, i \) will be parallel to \( R, E, \) therefore \( k, i \) will be the representation of the line \( d, k \), and because \( f, l \) is the representation of \( d, f \), their intersection \( i \) will represent the point \( d, f \); in like manner it may be shown that the point \( u \) represents \( t, \) and the point \( b \) represents \( a, \) and if the lines \( d, f \), and \( e, a \) are tangents to the circle at the points \( d, \) and \( b, \) therefore these representations \( f, l \) and \( e, a \) are tangents to the ellipsis at \( i, f, \) and \( b, a \); and therefore \( i, b \) is a diameter; and because \( u, n \) is parallel to \( f, l \) and \( e, a, n, u \) is a diameter conjugate to \( i, b \).

**Method 12.** Fig. 15.

This process is almost similar to the last, except that the point \( D, \) is taken in a line perpendicular to the intersection; this causes the conjugate diameter \( i, b \) to be parallel to the intersection, and the other, \( q, n, \) to tend to the centre of the picture.
PERSPECTIVE.

This method, by means of directors, furnishes conjugate diameters at once; whereas if vanishing points are only used, we have only a diameter and ordinate, or double ordinate, and consequently the other diameter, which would be conjugate to the one given, must be determined by a geometrical process. The use of the directing point is therefore much more convenient, and much more accurate in the representation of curves. The directing line is always at hand when the perspective delineation is raised from a geometrical plan instead of a perspective one.

Method 13. Plate V. Fig. 1.

Let L M J K be a square circumscribing the original circle B C D E F G H I; draw the diagonals J L and K M, cutting the circle at C, E, G, I; through the centre A draw F B parallel to M J or L K; join G I and E C; produce M I, G I, F B, E C, and L K, to their intersecting points n, m, &c.; find the vanishing point v of the perpendiculaires of F B, and draw the indefinite representations n v, m v, &c.; also produce the diagonal M K to meet I N at t, and find the vanishing point o of the diagonal M K; draw the indefinite representation o v of the diagonal, which will cut the indefinite representations drawn to o v of the parallels; find the vanishing point p of the sides J K and M L; draw lines to p v from the intersections in o v, p v, and produce these lines to cut the respective indefinite representations drawn to v in the points which represent those of the circle; then a curve being drawn through the corresponding points b, c, d, e, f, g, h, i, will form the representation of the circle.

This evidently appears from the property of the circle, and the method of finding the perspective representation of a point in the original plane.

Method 14. Fig. 2.

Let A be the centre of the original circle, and let B, C, D, E, F, G, H, i, be points in the circumference; let E' be the place of the eye in respect of the vanishing line V L'; draw E' C' perpendicular to V L', cutting it in C'; make E' D' equal to the height of the picture; draw the two lines D' H' and D' B' to the circle; draw A B perpendicular to D' H', and A B perpendicular to D' B'; let the lines H D' and B D' cut I N in t, s, from the points C, D, E, F, G, draw the lines C t, D t, E t, &c. tending to D', cutting the intersecting line in the points t, s, &c.; from all the points t, s, &c. draw lines parallel to the directer E' E'; from the same points B, C, D, E, F, G, H, draw the parallels B p, C p, D p, &c. cutting I N in p, q, r, &c.; find the vanishing point v of the lines B p, C p, D p, &c. and join the intersecting points p, q, &c. to v, cutting t, e, s, d, &c. at b, c, d, e, f, g, h, which will be the corresponding points to B, C, D, E, F, G, H, of the original circle; draw b h, which will be a diameter. The points of the other half will therefore be found by continuing the parallel from t, s, &c. on the upper sides of the diameter b h, and repeating the ordnates upwards to the points t, s, k, l, m, n, then a curve being drawn through all the points will give the representation required; as is evident from the directing and vanishing points.

Method 15. Fig. 3.

To draw the representation of a rectangle inclined to the picture, and having two of the edges perpendicular to the original plane, and consequently the other two parallel thereto, the original plane being perpendicular to the picture; the feet A B of the rectangle being given.

Produce A B to its intersecting point s; find the vanishing point v of A B, and thence the representation a b of A B; draw n s perpendicular to I N'; make n e equal to the height of the rectangle, and join e v; now suppose the lower side to rest on the original plane, and a b will be the representation of the lower side of the rectangle; draw a d and b c parallel to n e, cutting e v at e and d, and a b c d is the representation of the rectangle required.

For n e is the intersection of the plane of the rectangle with the picture; and because the rectangle is perpendicular to the original plane, and the original plane perpendicular to the picture, the vertical sides of the rectangle will be parallel to the intersection n e, and consequently the representations b c and a d will be also parallel to n e; therefore a b c d is the representation of the rectangle.

PROB. XXIII. Fig. 4.

To find the representation of a circle in a plane perpendicular to the original plane, the plane of the circle being inclined to the picture and the original plane perpendicular thereto; the feet A B of the plane of the circle being given on the original plane.

Find the representation a b c d of the circumscribing square by the preceding problem, making the sides of the square parallel and perpendicular to the original plane; then find the representation of the circle by any of the preceding methods, or bifect the intersection a f at l; draw l e perpendicular to f a; make l e equal to f o for l n; join e n and e f; from e, with the radius e f, describe the arc g h; join e f and e n, cutting the arc at g and h; draw g k and h l parallel to e f, cutting g n and h m at k and l; then v being the vanishing point of A B, join k v, l v, i v; draw the diagonals e a and b d, cutting the former lines at u, w, g, and z. Then through all the points u, v, w, x, g, r, z, and t, draw a curve, which will be the representation of the circle required.

This is plain by inspecting the square circumscribing the representation of the original circle in the present figure, where the correspondence of the quarter of the square, as also that of the circle with the circumscribing triangle n e f, and the quadrant b g of the arc of a circle, are shown.

The principle here used is the same as that employed in problem 21, method 3, figure 12, for finding the representation of a circle.

PROB. XXIV.

To find the representation of any rectangular prism, given its situation on the original plane.

Find the representation of the nearest angle of the base; from the point thus found draw a perpendicular; find the height of that perpendicular to as to represent the corresponding line formed by the two vertical planes of the object; from the bottom draw a line to each vanishing point; also from the top of the perpendicular draw a line again to each vanishing point; find the representations of the two remote angles of the base; from each of the points thus found draw a line parallel to the line representing the nearest vertical edge of the solid, cutting the upper line drawn to the vanishing point, and this construction will finish the representation of the prism, provided that both the base and the top are in planes on different sides of the vanishing line. If the base and top are both below the vanishing line, proceed as before, and complete the representation of the two adjoining vertical planes which form the nearest angle; then from the upper extremity of each perpendicular which forms the remote vertical arms of the object, draw a line to the vanishing point of the opposite side, which
PERSPECTIVE.

which will complete the representation of the parallelogram, by which the top of the prism is formed.

Or in short thus; find the representation of each vertical plane which forms the front angle of the object according to problem 24, figure 3, and these planes will form the representation of the rectangular prism, provided that the planes of the base and top are on different sides of the vanishing plane; but if on the same side of the vanishing plane as the two lines nearest the vanishing line, and which run to the vanishing point, represent the nearest angle of the side next the vanishing plane, whether above or below the eye; draw a line from the remote extremity of each line to the vanishing point of the other adjoining line, which also represents the opposite side, and the quadrilateral formed by each pair of lines drawn to each vanishing point will form the representation of the plane parallel with and next to the vanishing plane.

In representing any solid situated in the original plane, it will only be necessary to produce one line of the base of the solid; by which means the height of the plane which represents the side infilling on the line produced will be ascertained by letting the height of the object on a line perpendicular to the intersecting line from the intersecting point of the side of the base, and drawing a line to the vanishing point of that line from the upper extremity, thence determining the representation of the plane infilling on the side produced; then drawing a line from each end of the line representing the arcs of the two adjoining planes, will give the height of the figure representing the other adjoining plane.

In fig. 5. a b e g f s is the representation of a right prism standing upon the rectangle A B C D; the side A B is produced to b, and the height is set on the perpendicular from b to i; the lines b v' and i v' being drawn, give the height of the trapezoid a b f s, which is the representation of the side standing upon A B; a line being drawn from b and another from i to v', gives the height of the trapezoid b c g f, which represents the adjoining side standing upon B C; and the two trapezoids f b a e, and f b e g, form the whole representation a b c e f s of the prism, which has A B C D for its base; the lines A a, B b, C c, drawn from the two remote angles to the point of sight E, give the points a, b, c, upon the indefinite representations b v' and b v'; a b is first determined, which is the representation of the line produced; then draw the indefinite representations of the points a and b is determined; drawing the perpendiculars a e and b f, the points e and f are determined; drawing the indefinite representation f v', and drawing e g parallel to b f or a e, f g is also determined, which finishes the representation of the solid.

The prismatic solid T above, of the same description, is delineated by setting the height of the lowest side parallel to the vanishing plane upon b l from b to k, and the height of the solid itself from k to l; drawing the lines k v' and l v'; then the lines a c and b f, continued upwards to cut these lines, give the representation of the face of the solid in the plane of the solid in the plane with A B; drawing lines from the point where b f cuts the lines k v' and l v' to v', determines the adjoining face.

Any side of a solid may be produced in order to get the height, as appears by the representation O, which is that of a solid, the base of which is N; one of the remote sides being produced instead of one of the hither sides to the intersecting. It is only finding the height of the line representing the corresponding arcs, then completing the front parallelogram of which that arc is a side, and the other adjoining a front side, as above.

R and S represent right parallelepipeds with two faces parallel to the picture, and consequently the vanishing point of the horizontal lines is the centre of the picture; the side of the solid comes in contact with the picture, and has therefore its representation equal and similar to the original; the principle is the same as those already described.

PROB. XXV.

To represent a pyramid, with its axis perpendicular to the original plane.

Find the representation of the base, or the front part of it, then the representation of the axis; join the apex to each point, representing the two remote angular points of the object; and that representing the nearest angle, and the two triangles thus formed, will constitute the representation of the pyramid.

In fig. 6. b i k r is the representation of a pyramid standing on H I K L. The height of the axis is found by drawing M I parallel to one side; setting the height of the pyramid on the perpendicular I p; drawing p v' and i v'; drawing a line from the centre, M, of the base to E', cutting i v' at r, gives the base of the perpendicular, which being drawn to meet the indefinite representation p v', gives the vertex.

Then the representation of the indefinite plane, which is the plane of the base of the pyramid, will be determined by drawing a line parallel to A B or D C from the centre of the base, to meet the intersecting line in k, and setting the height of the vertex from the original plane from c to f'; drawing f v'; producing A B to d, and representing the sides A B and B C, as if the base were in the original plane; setting the height of the base, which is the uppermost side, on the perpendicular d g; drawing g v', and the perpendiculars a a', b b', cutting g v' at a' and b'; drawing b v' and c c' parallel to b b', gives the two sides b a' and b c', which represent the two nearest sides of the base.

The representation of the feet of the centre of the base will be found by joining ev', and by intersecting this line by another line from the centre of the feet of the base to the point of sight E; drawing a perpendicular from the intersection meeting f v', gives the representation, g, of the meeting of the sides.

The following practical examples are derived from the preceding problems, founded on the theory of the directing plane, which theory, where a plane of the object is given, furnishes the most expeditious and practical, and the most easily comprehended. The prime director and flatting point are employed. The eye is only used for drawing the parallels of lines in the original object. The lines on the plane representing original vertical planes are produced to their intersecting points, and perpendiculars are raised from each such point on the intersecting line, and the height of each respective plane of the original object set thereon; these perpendiculars will be the intersections of the vertical planes of the object, and the two extremities of each perpendicular will be the intersections of lines parallel to the original plane in each vertical plane. Lines being drawn from the intersecting points of the intersecting lines of the vertical planes, to their vanishing points, gives the indefinite representation of the lines which have the said vanishing point. The prime directing point, D', is used in cutting off portions from the indefinite representations, to represent original difficulties, which are the feet of lines parallel to the original plane given in the plan. This mode of cutting off finite portions to represent original lines is very expeditious; for by using this principle directing points, the indefinite representations of all the lines drawn on the original from all points of the plan, are perpendicular to the intersecting and vanishing lines, by the theory of the directing plane.
plane; and as the vertical lines of the object are represented by vertical lines in the picture, the indefinite representations of the lines drawn to the prime directing point, forms one straight line with the representation of the perpendicular, which represents the vertical arraies of the object. Another conveinency of this method of employing the prime director and prime directing point is, that the plan of the object may be drawn on one piece of paper, the vanishing points of the sides, and the intersecting points of the lines which radiate to the flaton point found, and the whole may be transferred to another piece of paper, for the purpose of forming the delineation of the object. It must also be observed, that the sides of all the vertical planes which form the plan must be produced to their intersecting lines then proceed with the remaining part as directed above.

Curves are found by drawing two lines from each original point, and finding their indefinite representations, one by means of a vanishing point, and the other by the director and directing point, only using one directing point and vanishing point for the whole of the points so found.

**Example 1. Plate VI.**

Fig. 1. No. 1. shews the representation of a house with wings by the preceding method; No. 2 is the plan; No. 3 the principal elevation. CD is the intersecting line of the vertical plane, infiniling upon the line AB on the plan; GH is the intersecting line of the plane of the receding part of the front, infiniling upon EF of the plan; LM is the intersecting line of a vertical plane, paffing along the ridge of the roof, infiniling upon AL in the plan; CD is the height of the summit of the pediments, GH the height of the receding part of the elevation, and LM is the height of the original plane or base; MN is the indefinite representation of the line which forms the ridge of the roof; H' is the intersecting line of the top of the wall of the receding plane; D'W' the indefinite representation of a line joining the top of the pediments; and QW' the indefinite representation of a line through the lower points of the pediment. The points n, n, which represnt the summit, and r, s, t, u, which represent the bottom of the pediment, a and p, which give the representation, a, p, of the top of the receding plane of the front, and the points r and q, which give the representation, p, q, of the ridge of the roof, represented by IA on the plan, are all found from the prime director D'E', and the prime directing point D'. The bottom part is found by drawing lines from the intersecting points, L, G, C, of the base lines of the vertical planes, which give the indefinite representations of the lines forming the base of the original object to the vanishing plane: these indefinite representations to the vanishing plane are cut by the parallels of the director, which limits the portions represnting the lines that include the base of the object. The roof is formed by joining r, s, o, u, w, p.

In the plan there are four syellons of parallel lines, one parallel to each front, making two; the other two are the lines representing the hip lines of the roof. In finding the intersections of the vertical planes, only the seryes of parallels to AB are produced.

**Example 2.**

Fig. 2. No. 1 is the representation of a house, with a bow in the middle of the front. Every thing with regard to the straight lines is found as in the preceding example; only one thing must be observed, that in the representation of the bow, or any of its intermediate horizontal fections, the intersection of each plane is found, and the intersecting points found on the intersecting line of the base plane transferred to each intersecting line. Thus IN is the intersecting line of the base plane; and therefore the intersecting line for the representation of the arc CD of the circle, which represents the plan of the bow; m, n, o, p, are the intersecting points of a series of lines, drawn parallel to IS, the plan of the front plane; m' n' o' p' is the intersecting line of a plane a fection of the bow, parallel to the base of the object; m" n" o" p" the intersecting plane of the top of the bow; m'" n'" o"" p'" is the intersecting line of a plane parallel to the base of the object above the level of the top of the bow, in order to shew more clearly how a fection of the cylindric bow may be represnted at different heights. The points are thus transferred to each of these intersections: through the intersecting point m of IS, in the intersecting line IN, draw the perpendicular m'm'm'm'; make m'm' equal to the height of the intersection of the bow, m'm' equal to the height of the top of the wall; draw the lines m'm' o' p', and m" n" o" p"; then draw the lines m'n', n'o', o' p'; and m, n, o, p, in each intersecting line, draw lines to the vanishing point o', then the indefinite representations found by the director and directing point, will give the points in the curve, which being joined gives the representation of each curve of the bow.

No. 3. shews the elevation of the front of the house, which therefore gives the length of the house and breadth of the bow; No. 4 shews the elevation of the flank or end, which therefore gives the breadth of the house and the projection of the bow. Each of these elevations gives also the height of the object. By this means any arc of a circle may be represnted: this is only the application of problem 21, method 14, which shews the representation of a whole circle.

**Example 3. Plate VII.**

Fig. 1. No. 1 is the representation of a flight of steps with two kirbs, which are about a step higher than the top of the landing, and terminate in a plane parallel to the horizon; No. 2 is the plan.

Find the intersection, CD, of the vertical plane paffing through AB on the plan; let the height of the steps from C to D; from the extremities and several divisions of CD, draw lines to the vanishing point o', which will give the indefinite representations of the horizontal lines, forming the top of each step in a fection of the plane of the infide of the kibr. The vertical lines, forming the face of the kirbs, are represnted by the intersected part of the paralles of the director D'E'. The vanishing line of the arraies, and internal quoins of the steps, is supposet to be out of the picture upon the vanishing line (fig. 2.) at o': lines are then drawn through all the points, representing the fection made by the infide of the kibr to the vanishing point o', which gives the planes of the kirbs and treads. The height of the kibr might have been obtained upon CD, but is found by setting it on FG, which is the intersecting plane of the plane of the face of the kibr, through E B upon the plan. The remaining parts of the representation to be finished is sufficiently plain by the bare inspection of the figure, and from what has been said in the preceding problems and examples.

Another very excellent method of finding the ends of the steps upon the infide of the kibr, is by finding the vanishing point of their inclination, when the vanishing point is accessible; make o', on the vanishing line, equal to the distance, o', E, of the vanishing point, o', from the eye E': draw o' o' perpendicular to the vanishing line V L; make the angle o' 1 o' equal to P Q R, No. 3; when having obtained the point k, the representation of B on the plan, which
which is the lower edge of the rifer in the plane of the kirb, draw \( b, v' \), which will be the indefinite representation of a line, touching the lines of concourse of the internal angles in the plane of the inside of the kirb; then indefinite representations being drawn to \( v' \), from all the points in \( C D \), will cut the line \( b, v' \); draw a perpendicular from each intersection between every two lines, from \( C D \) to the vanishing point \( v' \), and these perpendiculars will represent the rifer on the inside of the kirb.

**Example 4.**

Fig. 2. \( N^2.1 \) represents a flight of returning steps, as shown by the plan \( N^2.2 \). The diagonal plane passing through the nearest angle of the steps, is produced in order to obtain the intersection \( A B \) for a line of heights. The representation of the section passing through the diagonal being found, draw lines from every point found in the said representation to each vanishing point of the sides, and the lines thus drawn are the indefinite representations of the arrales and internal quions; the rest is completed as in the preceding examples.

Fig. 3. is the representation of a flight of steps, without a plan, with the top of the kirb parallel to a plane touching the nosings. Given the intersection of the plane of the rifer at \( A \); supposing the vanishing points \( v, v' \), to be found from the known inclination of the sides to the picture, and the vanishing point \( v' \), as in the third example.

Make \( A G \) equal to the distance of the intersecting point \( A \) from the nearest angle, \( G H \) equal to the thickness of the kirb, \( H I \) equal to the length of the steps, and \( I C \) equal to the thickness of the farther kirb. Then the point \( z \) is the distance of the vanishing point \( v' \) from the eye, draw lines from the points \( G, H, I, C \), to \( z \), meeting \( A v' \) in \( K, M, N \); draw \( K, O, M, N \) and \( u, v \), perpendicular to \( I^3 N^3 \). Set the height of the front part of the kirb upon the perpendicular \( A B \); draw \( B v' \), cutting the perpendiculars in \( o, p, q, r \); draw \( A v' \); make \( A E \) equal to the horizontal distance of the inclined part on the top, from the nearest point of concourse of the lower edge of the rifer, and the lower edge of the outside of the kirb; then the point \( u \) being the distance of the vanishing point \( v' \) from the eye, draw \( E u \) to \( v' \); meeting \( A v' \) at \( i \), draw \( k, v' \) and \( r, v' \), meeting \( k, v' \); make \( E F \) equal to the whole height of the kirb; draw \( i, v' \) parallel to \( E F \), or perpendicular to \( I^3 N^3 \); draw \( F u \) to \( v' \); meeting \( u, v' \) in \( o \); draw \( u, v' \); make \( A K \) equal to the horizontal breadth of the kirb; draw \( K, w \) to \( u, v' \); meeting \( A v' \) at \( o \); draw \( w, v' \); meeting \( k, v' \); drawing \( k, w \); cutting \( k, v' \); cutting \( k, v' \); drawing \( x, y \); perpendicular to \( I^3 N^3 \); cutting \( o, v' \); and \( k, v' \); will form the hinder end of the nearest kirb. The section of the hither side of the remote kirb is completed as in the third example; having the tops \( o, p, q, r \), of the vertical faces of the front of the kirb, the inclined surfaces may be formed by the vanishing point \( v' \); and terminated by drawing the perpendiculars \( v' \) to meet \( o, u, v' \), then drawing \( v, v' \). The horizontal parts at the top are found by drawing lines to \( v, v' \), and another line to \( v' \).

**Example 5.**

Fig. 4. \( N^2.1 \) shows the representation of a stair with three circular steps. The principle of the method is in finding the representations of several vertical sections, all passing through the axis of a cone surface, which would touch the nosings of the steps, then drawing a curve through all the corresponding points of each respective nosing, will form the representation of the whole series. The sections may very easily be obtained without the use of the vanishing points, by representing the heights of each step upon the cone, and setting the heights upon each intersecting line of the plane of each section, then joining the lines from all the points in each intersecting line of heights to the respective point in the axis; then the line \( D C \), on the section \( N^2.2 \), being drawn to touch the nosings; then \( A E \) and \( B A \) being produced to meet \( D C \) in \( D \) and \( C \); with the radius \( A C \), \( N^2.2 \), describe an arc of a circle \( A B C D E \), \( N^1.1 \), so as to meet the two half planes which terminate the sides; find the representations \( a, b, c, d, e \), then the axis of the cone being found, draw the lines \( a f, b f, c f, d f, e f \); these lines will represent the sides of the cone in each section, and consequently will represent the lines touching the nosings; then the points where these lines are cut by the lines drawn from the several points in each line of heights, to the corresponding points in the axis, gives the points in the nosings of each section; the points of concourse for the internal angles will be found, by drawing a perpendicular from each point of representation of the nosings, to the next line, which represents a line in the plane of the vertical section, and in the plane of the tread; the distance between the foot of the perpendicular and the next lower point representing the nosings, represents the breadth of the step in the section. This is, if the plane of the section \( F A \) be produced to \( E \) as to meet the picture in \( G H \); set the heights of the steps on \( G H \), draw lines from the points \( G \) and \( H \), and also from the intermediate divisions to the corresponding points in \( a, f \); gives the points \( a, i, k, l \) in the line \( a f \), representing the plant side of the cone in that section; then drawing the perpendiculars, \( i, m, k, l, o \), represent the sections of the rifer, and \( i, n, o \), represent the heads. The points \( a, i, k, l \), \( d, e \), of the curve representing the corresponding points \( A, B, C, D, E \), of the intersection of lines in the curved surface of the cone with the horizontal plane, will be found by the directing point \( D \).

**Example 6.**

Fig. 6. shows the method of representing several lines, drawn to a common point of concourse, without finding the vanishing points of these lines. The method is as follows: find the representation of the point of concourse \( C \); continue all the lines which terminate in \( C \) to the intersecting line \( A B \); join all the points in \( A B \) to the point \( r \), and their radiations will be the indefinite representations of the other original lines which radiate from \( C \); but if any of these lines should prove to be inacceptrable, draw \( F H \) parallel to \( C \), cutting \( A B \) in \( F \); let \( C E \) cut \( A B \) in \( D \); make \( F L \) equal to \( D C \); if \( E \) equal to \( D \); join \( L F \); let the inaccessible lines meet \( A F \) in \( G \) and \( H \); draw \( G I \) and \( H K \) parallel to \( L \), to meet \( A B \) in \( I \) and \( K \); make \( F \) and \( H \) equal to \( F \) and \( K \); draw \( b e \) and \( g \), then \( b e \) and \( g \) will represent \( H C \) and \( G \).
indefinite representations of lines in each diagonal plane parallel to the original plane, being found, draw lines to the station point $S$, each to cut its respective line, will give the representations of the points in each plane, and, joining the corresponding points, will give the representations of the lines of concourse, or those which form the arraies and internal quoins. The representation of the points in one of the mitres on the front part being found, the other will easily be determined, by drawing parallels to the intersecting line from the points ascertainment, and setting these parallels by lines drawn to the directing point from the respective points of the mitre, to be ascertainment on the plan $N$. 2. draw indefinite representations from the points representing the middle mitre towards the centre of the picture; also draw lines from $F$, the intersection of the diagonal plane, through the mitres which terminate the apparent magnitude, to the vanishing point on the vanishing line of the original plane, cutting the former lines drawn to $C$, and the intersections will give the points to represent the third mitre, which forms the outer extreme boundary of the cornice.

The indefinite representations of the heights of the mouldings in the plane of each diagonal, are necessary in order to draw the curves correctly. The vanishing point of the lines in the plane of the diagonal, through the extreme mitre of the cornice being out of reach, the line $RT$ perpendicular to the vanishing line is taken at half the distance of the intersecting point $F$, from a line drawn perpendicular from the vanishing point of the lines in the plane of this diagonal. Bifect $TR$ at $K$; set half the height of the members downwards from $K$ to $L$; then join the corresponding points in $KL$ to those of $FG$, will give the lines representing the heights of the mouldings in the diagonal plane.

**Example 8.**

Fig. 2, shews the representation of a cornice inclined to the picture. The method of finding the representation of the mitres is the same as in the last example; the vanishing point of the representations of the lines of concourse of the mouldings which appear in one of the faces is suppos'd to be out of reach, therefore one-third of the distance of the point $M$ from the vanishing point is taken, and set from $M$ to $m$; then drawing $m$ perpendicular to the vanishing line, so as to be intersected at $n$ by the faid line, make $m$ one-third of $mn$. Produce the line $A$, and the other lines which are parallel thereto, to their intersecting points $M$, $I$, $F$, $D$, and describe the section of the cornice $MIFDEGHKN$. The line $WO$, parallel to the vanishing line, being suppos'd to correspond to $MD$, draw a figure $WTOPOPSVX$, so that all its divisions may be one-third of those of the section $MIFDEGHKN$, then lines being drawn from the corresponding points of each fimal figure, will give the indefinite representation of the lines of concourse of the several mouldings. The remaining parts are completed by the directing point and the other vanishing point.

This method of describing a section of the cornice with the picture is much preferable in point of accuracy to that of finding the representation of the mitre of the angle of the object, which pretends itself to the eye; because when the eye is in the plane of the diagonal, the points which form the divisions of the mouldings in the mitre cannot be ascertainment; or if the eye is nearly in the plane of the diagonal, the interflection will be so very oblique, as to render the perspective heights very uncertain, though the lengths of the lines representing the arraies and internal quoins may be obtained with sufficient accuracy.

### PROB. XXVI.

Given the centre $C$, and the distance of the picture, the feat $F$, and distance of the centre of a sphere from the picture, and the radius of the sphere, to find the representation of the sphere.

**Method 1.** Fig. 3.

Join $FC$; draw $C'E'$ and $FD$ perpendicular to $FC$; and upon contrary sides of the face; make $C'E'$ equal to the distance of the picture, and $FD$ equal to the distance of the centre of the sphere from its feat. On $D$, with the radius of the sphere, describe the circle $ABC$; draw $AE'$ and $C'E'$, tangents to the circle at $A$ and $C$, cutting $FC'$ at $a$ and $k$; also draw $DE'$, cutting $ok$ in $d$; bisect $ok$ in $r$; and through $r$ draw $ml$ perpendicular to $DE'$, cutting $CE'$ and $AE'$ at $w$ and $l$, and $DE'$ at $t$; from $t$, with the distance $tm$ or $tr$, describe the semicircle $ml$; draw $sn$ perpendicular to $ml$, cutting the semicircle in $n$; through $s$ draw $pq$, perpendicular to $ok$; make $sp$ and $sq$ each equal to $sn$, then $ok$ is the greater, and $pq$ the smaller axis of an ellipse, which will give the representation of the sphere.

For if $C'E$ and $FD$ be turned perpendicular to the plane of the picture, but on contrary sides thereof, and the circle $ABC$ in the same plane with $FD$ and $FC$, the point $E'$, the line $ok$, the tangents $C'E'$ and $AE'$, and the circle $ABC$, will be all in one plane perpendicular to the picture; then considering $ABC$ as a section of the sphere, $E'$ the eye, $C'E'$ and $AE'$ will be visual rays cutting the picture in $a$ and $k$; therefore the points $o$ and $k$ are the representations of $A$ and $C$ respectively; considering all the tangent rays around the sphere to the eye at $E'$ as forming a cone, and the picture a cutting plane, and because the plane $CEA$ is perpendicular to the picture, the line $ok$ will be the axis of the axis of the cone, and therefore $ok$ will be the tranverse axis of the ellipse. Turning the plane of the semicircle $ml$ perpendicular to $DE'$, $ml$ will be a semi-section of the cone parallel to its base, and $sn$ will be at right angles to $ok$, and $sn$ will coincide with $sp$; and since it has been demonstrated that the section of a cone cut by a plane is an ellipse, and the perspective representation is the section of a cone of rays made by the plane of the picture, $ok$ and $pq$ are the axes of an ellipse, which will represent the sphere according to the conditions given.

**Method 2.** Fig. 4.

Join $FC'$; make $FD$ equal to the distance of the centre of the sphere from its feat, and $CG$ on the vanishing line equal to the distance of the eye; join $DG$, cutting $CF$ at $d'$, draw $dg$ parallel to $IN$; make $FX$ on the intersecting line equal to the radius of the sphere, and join $XC'$, cutting $dg$ in $g$; then $d'$ is the centre, and $dg$ the radius of a sphere, from which a cone of rays will proceed to the eye under the same superficies, or under the same angle as one of a radius $DA$ or $DG$, fig. 3; placed at the distance $FD$, from its feat $F$, beyond the picture. Therefore, with the radius $dg$ describe the circumference $ena$ of a circle; draw $E'a$ and $E'c'$ tangents to the circle at $a$ and $c$; produce $E'a$ to meet $FC'$ at $a$, and let $E'c'$ cut $FC'$ in $k$, then $ok$ is the tranverse axis; bisect $ok$ in $r$, draw $ln$ perpendicular to $d'E'$, cutting $E'a$ and $E'c'$ at $l$ and $m$, then proceed with the remaining part of the construction, as in fig. 3.

**PROB. XXVII.** Fig. 5.

To make a right-angled object appear under a given angle.

$5\theta$ Let
Let AF, FB, be two sides of a rectangular object, or rectangular prism; it is required to be viewed under a given angle. There are two ways in which this may be considered, whether one side can be seen or two sides; in either way the object appears to be viewed under a straight line. The general appearance of the object is when two sides are seen, and then the apparent angle under which it is viewed is subtended by the diagonal of the plan, or section of the object, parallel to the original plane. Therefore, upon the diagonal AB describe the segment of a circle A E D C B, to contain the angle required; then the object may be viewed under the required angle, anywhere within the angle contained, by producing the two sides of the object. The object may be viewed so as to see one side under the same angle, and the angle subtended by the same right line, so long as the base of the eye continues on that side; consequently, when the base of the eye is not upon any of the vertical planes of the object, two sides of the object will be seen at the same time.

**Prob. XXVIII.** Fig. 6.

Given the centre and distance of the picture, and the angle under which a right prismic object is to be viewed, and the position of the object to the picture, to determine either side of the object, and the situation of the nearest angle, the proportions of the lineal dimensions being supposed to be known.

Let F be the centre of the picture, IK the vanishing line, FE perpendicular to IK, the distance of the picture. Draw EA parallel to IK; draw the plan E B C D E, similar to that of the original object, in the same position to AE as the sides of the object has to the vanishing line IK. Let SU, N'2, be the angle under which the object is to be seen; bisect SU by the straight line VT; make the angles FE'C and FE'H equal to VTS or VTU, and let the points G and H meet IK; join EB; draw LM parallel to E'B, meeting G E' and H E' in I and M; draw LN parallel to E'E, and MN parallel to BE; join E'N, and produce it to meet IK in e, then is the point where the angle of the object will rest on the vanishing line. Produce FE and EB to I and K; draw ea parallel to FE, cutting E'K in a; draw ab parallel to IEK; draw H parallel to FE', cutting E'K in e; join Fe, and produce it to meet ab in b; draw bd parallel to FE', cutting E'K in d, then ad is the side of the object.

**Prob. XXIX.** Fig. 7.

Given two parallel planes perpendicular to the original plane, the place of the eye, and the inclination of a vertical picture to the parallel planes, to find the situation of another vertical plane contained by the two parallel planes at right angles thereto, and also to the original plane, so that the distance of the lines in the picture representing the vertical terminations of the contained plane shall be the greatest possible.

Let I be the point of sight, QE and PF the intersections of the vertical planes, which are parallel to each other; draw IQ, making an equal angle with QE or PF to the inclination of the picture, and either of the parallel planes, then QI will be the directing plane. Let FF meet QI in P; draw IB perpendicular to EQ, cutting it in B, and FP in A. Find BE a mean proportional between BQ and AP; draw EF perpendicular to BQ; join EI and FI; then taking f N parallel to IQ, as the intersection of the picture, the distance fe on the intersection, intercepted by two lines from E and F to the slant point I, will be greater than any other distance, ed, on the same intersection, terminated by two lines drawn to the slant point I, from the extremities of any other line DC, parallel to and on either side of EF, contained by EQ and FP.

Since by a known proportion in perspective,

\[
\begin{align*}
ec : EC &= QN \times QI : QC \times QE, \text{ or in this case } QE' \\
fd : FD &= PM \times PI : PD \times PF \\
\text{but } EC &= FD \quad \text{and } PM = QN \\
\text{and } PM &= QN \\
fe : fd &= QI \times PF' : PI \times QE' \\
&= BQ \times PF' : AP \times QE' \\
&= BO^2 (EB + AP)' : EB'(EB + PQ)', \text{ which is a ratio of equality.}
\end{align*}
\]

The demonstration to this problem was furnished by H. Warburton, esq., F.R.S. It is useful in the representation of windows in a straight front, supposing to be continued at pleasure, in order to ascertain the proper gradation of the reveals, and the place on the picture of that which will be representated of the greatest breadth. It is evident that when the eye is in the plane of one of the reveals, those succeeding will continually increase to a certain apparent breadth; after which, they will decrease again ad infinitum, and thus terminate in a mere line, or infinitely narrow surface.

It may be applied to any row of parallel, similar, and equal plane figures, where the corresponding sides are in one and the same plane.

**Prob. XXX. Method. 1. Plate IX.** Fig. 1.

Given a point in the representation of a line, the position of the line to the intersection, the vanishing line of its plane, and the centre and distance of the vanishing line, to find the indefinite representation of the line, without finding the vanishing point, or placing the eye in its position, supposing there is a want of space to extend it to its full distance.

Let A be the given point in the indefinite representation, VL the vanishing line, and C the centre of the picture; draw C B perpendicular to VL, and make CB any part of the whole distance, as one-third; join CA, and make CD the same proportional part of CA that C B is of the whole distance, that is, because C B is one-third of the whole distance, make CD one-third of CA; draw BH, making the angle C B H equal to the angle which the original line is supposed to make with the intersection, and let BH meet V L in H; join HA, cutting DG in F; make DG equal to three times DF, and join AG; then AG will tend to the vanishing point, as required. The credit of this invention is due to Noble.

For it is evident that if CB be produced to E', and EA be drawn parallel to BH, to cut VL at v'; and if AG be produced, it will meet v'; because the straight line BH is drawn
drawn parallel to the side, E\textsubscript{1}E\textsubscript{2}, of the triangle C'E'E\textsubscript{2}, the other two sides, C'E\textsubscript{2} and C'E\textsubscript{}1, will be cut proportionally; therefore C'H will be a third part of C'\textsubscript{2}.

Now in the similar triangles \{ AD : AC' :: DF : C'H \}

Also in the similar triangles \{ ADG and AC'E' \}

Therefore by equality of ratios

\{ DF : CH :: DG : C'E' \}

Therefore AG produced will meet the vanishing line VL, at the point v.

**PROB. XXXI. Fig. 2.**

Given two straight lines, AB and CD, inclining to each other: to draw any number of lines through each of the given points E, F, G, &c. to tend to the same point with AB and CD.

This problem has two cases.

**Case 1.** fig. 2.—When all the points are in the same straight line.

Produce the straight line EFG to cut AB in B, and CD in D; draw AC parallel to BD, cutting AB in A, and CD in C; draw AL, making any angle with AC, and make AB, AL, AL, Al, respectively equal to BE, BF, BG, BD; divide AC in the same proportion as AL, that is, join IC, and draw k\textsubscript{1} in, bm, parallel to IC, cutting AC at o, n, m; draw oG, nF, mE; then E\textsubscript{m} F\textsubscript{n} G\textsubscript{o}, would meet the point of concourse of BA and DC, as is evident from the construction.

**Case 2.** fig. 3.—When the points E, F, G, are not in the same straight line.

Through each of the points E, F, G, draw the straight lines PQ, RS, BD, cutting the lines AB and CD in F, Q, R, S, D, B, draw AB at any angle with AC, and make AB equal to the greatest, BD of the parallel lines, and join BC; from A cut off AM equal to BD; draw \( \text{mg} \) parallel to BC, cutting AC at g; join gG. Again, from the point A, with the radius SR, describe an arc, cutting BC at i; join iA; from Ai cut off AM equal to SF; draw mF parallel to BC, cutting AC in f; and join fE; find eE in like manner; then E\textsubscript{b}, G\textsubscript{g}, F\textsubscript{f}, eE, will have the same point of concourse, if produced.

**Method 2. Cafe 1. Fig. 4.**

Draw \( b m \) parallel to BD, and produce BA to b; make b\textsubscript{m} equal to BD, and on b\textsubscript{m} set \( b l', b k, b i \), respectively equal to BG, BF, BE; join mC, and produce E to meet AB in S; then join fs, k\textsubscript{2}, i\textsubscript{2}, cutting AC in g, f, e, respectively equal to EF, Ff, Gg; then E\textsubscript{e}, F\textsubscript{f}, G\textsubscript{g}, will have the same point of concourse with BA and DC.

**Case 2.** fig. 5.

Draw T\textsubscript{b} parallel to BD, and produce BA to T; make T\textsubscript{b} equal to BD; join kC, and produce BC to meet BA in S; draw ml, nk, si, to meet Ch in l, k, i; through the points l, k, i, join lI, k\textsubscript{1}, i\textsubscript{2}, cutting AT at e, u, v; make or equal to YG, uq equal to Xc, and t\textsubscript{p} equal to WE; draw ps, qS, rS, cutting CA at e, g, f; join gG, jF, eE, then will E\textsubscript{e}, F\textsubscript{f}, G\textsubscript{g}, have the same point of concourse with B A and DC.

**Method 3. For both cases.** Fig. 6.

When two lines, D E and D F, meeting in D, have each an inescapable point of concourse with a third line, VL, draw DC, making any angle with VL, cutting VL in C. In DE take any point E, and draw EA parallel to DC, cutting VL in A; also in DF take any point F, and draw FB parallel to DC, cutting VL in B; divide each of the lines DC, EA, and FB, into an equal number of equal parts; then if DE and DF represent any two lines in a vertical plane, any point being given in perspective in the same plane, a line being drawn through the given point, so as to divide the corresponding part of each adjacent scale in the same proportion, will tend to the vanishing point on the one side: thus, if through the point p, laying a straight edge upon p, we find that it does not cut the corresponding points of section in the lines DC and FB, by moving it till it divide each corresponding part, on which it falls in the same proportion at g and b, then gb will tend to the vanishing point of DF.

In like manner, gi may be drawn to the corresponding point at i in AE, and by this means a number of lines may be drawn in the same way to represent lines in the plane of the vertical planes, and each two which meet in DC to represet lines in a plane parallel to the original plane.

The credit of this practical invention, as well as the following one, is due to Edward Noble.

**PROB. XXXII. Fig. 7.**

Given the vanishing line VL with its centre, and supposing the distance of the eye to be known in extension only, admitting there is a want of room to extend it to its position, to determine the vanishing points of two or more lines inclined at given angles with the intersection.

Let VL be the vanishing line, F its centre; draw FE perpendicular to VL; make FE equal to \( \frac{1}{2}, \frac{1}{3}, \frac{1}{4} \) of the distance of the picture, as the space may admit; through E draw GH parallel to EL; draw two lines, EA and ED, meeting VL in A and D, making an equal angle with GH to those of the original lines and the intersection; on the vanishing line make F\textsubscript{w} the same style of F A that the whole distance of FE of the eye is of FE; in like manner, make F\textsubscript{w} the same style of FD that FE is of FE; and \( \text{w} \) and \( \text{w} \) will be the vanishing points. In the present instance, FE is one-third of the true distance of the eye. Figure 8 is found upon similar principles to figure 7 and shews the situation of the vanishing points, by taking one-fourth of the distance of the eye; in this the angle AED is acute, the other AED, in figure 7, being a right angle. The truth of this is very easily shewn; for produce FE to E', and join E'F; then, because the fides F\textsubscript{w} and F\textsubscript{w} of the triangle FE'E'F are divided in the same ratio at F and E, the straight line \( \text{E'A} \) is parallel to \( \text{E'E} \), but the straight line \( \text{E'A} \) is parallel to the original; therefore E'E'F is also parallel to the original; consequently, F\textsubscript{w} is found in the same place as if the parallel of the original had been drawn through the eye at E, and is therefore the vanishing point of the original line parallel to EA; F\textsubscript{w} may also be proved in a similar manner to be the vanishing point of original lines parallel to E D.

**PROB. XXXIII. Fig. 9.**

To find the representation of a line parallel to the original plane, in a plane perpendicular to the said plane, given the fact of the line, and its distance from its feet, without having recourse to the vanishing point, which is here supposed to be inaccessible.

Let the fact of the line be AB; at any convenient distance draw dE' perpendicular to IN, cutting IN at E; draw the line E'\textsubscript{w} through the eye at E, to meet the vanishing line in \( \text{w} \); draw A\textsubscript{d} and B\textsubscript{e} parallel to the interception, cutting dE'\textsubscript{w} at d and e; draw db and eg parallel to E'\textsubscript{w}, cutting the interception in g and b;
PERSPECTIVE.

Draw $gq$ and $bm$ perpendicular to $IN$; make $gn$ and $bi$ equal to the height of the original line; draw lines from $n$ and $l$, tending to the point $v$, cutting $EE'$ at 1 and 2; draw $Ae$ and $Bf$ parallel to $E'e'$, cutting the intersection in $e$ and $f$; draw the lines $fr$ and $eg$, tending to the vanishing point $v'$; draw $GH$ and $ve$ perpendicular to $IN$; draw $rs$ and $a ve$ parallel to $VL$, cutting $rv$ at $r$, and $GH$ at $wv$; join $rav$, which will tend to its proper vanishing point, as required. In the same manner, the representations $RG$, $txuy$, $ohI$, &c. of any series of parallel lines to the original plane in a vertical plane infiting upon $AB$, may be found.

PROB. XXXIV. Fig. 10.

To find the representation of a line parallel to the original plane, and in a vertical plane, the vanishing points being inaccessible as before, given the sects of the extremities of the ichnography of the line, the distance of each extremity from its feat, and the centre and distance of the picture.

Let $A$ and $G$ be the sects of the extremities of the ichnography. We shall here suppose the distance of the picture to exceed the limit of the vanishing line: in such cases, take one-half, one-third, or one-fourth, &c. of the distance of the picture, and take the like part of the distance of each extremity of the ichnography. In this case, let $C'$ be the centre of the picture, and $C'D$ one-fourth of the true distance; make $AI$ and $GK$ one-fourth of the distance of the respective extremity of the ichnography of the line from the sects $A$ and $G$; draw $IC$ and $GK$, cutting $AC$ at $E$; and $KD$, cutting $C'G$ at $G'$; join $EG'$, which is the representation of the ichnography of the line; draw $AB$ and $EF$, $CH$ and $GD$, perpendicular to $IN$; make $AB$ and $GD$ equal to the height of the original line; join $BC$, cutting $EF$ at $F$; and $DC$, cutting $GH$ at $H$; draw $HF$, which will be the representation of the line required. In this manner, a sects of lines in a vertical plane may be found, by applying the height upon $AB$ and $GD$, and joining their upper extremities to the centre $C'$; then joining the corresponding points of section will give the sects of lines required.

PROB. XXXV.

To find the representation of a right prismatic object, so that the original may appear under a given angle, and the extremes equally distant from the centre of the picture, given in position the right sects of the object, and the vanishing line of the original plane, in which it is situated in the vanishing plane.

Let $ABCD$ (fig. 11) $N^2$, 2, be a sect of the object; draw $AB$, $N^2$, 1, parallel to the vanishing line $N^2$, 2; bisect $AB$ in $D$; draw $CD$ perpendicular to $AB$: make the angles $BAC$ and $ABC$, $N^2$, 1, each equal to half the supplement of the given angle; through $A$, $N^2$, 2, draw $AE$ parallel to $AC$, $N^2$, 1; and through $C$, $N^2$, 2, draw $CE$ parallel to $BC$; then it is evident that the angle $AE'C$, $N^2$, 2, is equal to the angle $ACB$, $N^2$, 1; therefore, the object, or its right sect $ABCD$, will appear to an eye at $E$ under the angle required. Now, suppose the object to be represented to be a house, and $ABCD$ the plan, or horizontal sect, made by the vanishing plane; and let the dimensions of the plan, for the sake of convenience in laying room, be half of those of the real object. Let $N^2$, 3 be an elevation of the front to the full size. In $N^2$, 2, draw $E's$ and $E'^s$, cutting $VL$ in $w$ and $w'$; in $VL$ make $w's$ equal to $w'v''$, and $w''2$ equal $v'v''$; produce the side $AB$ to meet $VL$ in $s$; draw $Bf$, tending to the point $E'$, cutting $VL$ at $f$; draw $E'C'$ perpendicular to $VL$, cutting it in $C'$; and this will be a preparation for drawing the representation of the object as follows.

Take any convenient line $VL$, $N^2$, 4, for the vanishing line, and place thereon double the distances $C''w''', C''''w'$, $C''''w''$, $C''w'$, $N^2$, 2, as shown by smaller characters at the corresponding points; then, in $N^2$, 4, $w'$ is the vanishing point for the horizontal lines of the one side of the object, and $v''$ that for those of the other side of the object; 1 is the dividing point for the lines tending to $v''$, and 2 for the lines tending to $v'$, and $f$ the point through which the representation of the angle of the building pale; through $f$ draw $yn$ perpendicular to $VL$, meeting $IN$ in $y$; make $ya$ double of $fr$, $N^2$, 2; draw $A'w'$, $N^2$, 4, cutting $yn$ at $a$; draw $A'b$ parallel to $yn$; make $A'b$ equal to the height of the elevation $N^2$, 3; join $B', C'$, cutting $yn$ at $n$; then $an$ is the representation of the angular line of the object. Join $an$, and produce it to meet $IN$ at $g$; make $gb$ equal to the length of the front, $N^2$, 3; place on $gb$ the intermediate divisions of the doors and windows; from the point $b$, from the intermediate divisions, draw lines tending to 1, cutting $ow'$; from the points of section draw perpendiculars, which will terminate the breadths of the windows and door; from the point $a$ draw $oe$, tending to the dividing point 2; make $ex$ equal to the breadth of the building; join $ow'$, and draw $xg$, tending to 2, cutting $ow'$ at $q$; draw $gp$ parallel to $on$; also draw $nos'$, cutting $gp$ at $p$; then $onqp$ is the representation of the flank of the building; let the heights of the apertures on $AB$, and draw lines to $v''$, which will complete the representation of the openings of the windows and door; and, that of the entire object.

If, by setting the measures upon the base line, they should give the intersecions very oblique, produce $A'B'$ to $C'$, and draw $CD$ parallel to $VL$, apply the measures to $CD$, divide $CE$, and drop the perpendiculars.

This is the first time that a rule has been shown for representing a right prismatic object, so that the original will appear under a given angle, and to fix the object at a given distance, with the plane of the picture at the same time. This gives also a rule for making the length of the picture, and the distance of the eye from its centre in a given ratio; for $AB$, $N^1$, being made equal to any distance, the perpendicular $DC$ may be made in any proportion to $AB$. This method finds the position of the object, so as to give the most perfect representation possible, for the picture in the position here found will be the nearest to a spheric surface; the plane of the picture being considered as tanging the spherical surface at the middle of its length.

In the method hitherto used for finding the position of an object, the plan was first drawn; the point of view was moved on the paper until it came into what was thought an agreeable position for the view; then two lines were drawn to the eye from those two points of the object which would form the greatest angle; the angle of view was bisected, and the bisector was drawn through such a point of the bisecting line as would make the picture, as might be thought, of sufficient dimensions. But in taking the position of the picture in this way, the proportion of the length of the picture to its distance was only guided at, nor could the object be viewed under a given angle.

It must also be noticed here, that the method of finding the representation, as is to be found in all previous writers on perspective, without the geometrical plane of the object, does not give its position.

PROB. XXXVI. Plate X. Fig. 1.

To find the representation of a rectangular fold, by making
To put a right rectangular prismatic object in perspective by one dividing point only, and by using the same measures for both sides of the object.

Let A'B'C'D' be the plan of the object, E' the point of view; V'L' the vanishing line, as before; draw the parallels E' E, and E' G of the sides of the object; bisect the angle E'E'G by the straight line E'd, cutting E'G in d, then d will be the dividing point in the vanishing line V L.

Let the object be drawn as a house, as at fig. 1, N° 1 and 2; and the plan, fig. 2, N° 1, being only one-third of the size, is used only for the purpose of ascertaining the vanishing points, the dividing point, or other particulars respecting the inaccessible vanishing point.

Draw an angle A B B', fig. 2, N° 2; make a A to b B in the ratio of G E' to G d; apply the several measures i, j, k, l, m, n, and so. fig. 1, N° 2, to h A, fig. 2, N° 2, from b to i, from i to j, from j to k, and so. Also at fig. 2, N° 3, draw another angle A B B', making a B to b B in the ratio of G E' to G d, as before, in N° 2; upon the line a B make b p, b q, b r, equal to b p, b q, b r, fig. 2, N° 2; join A B; draw r', q', p', parallel to A B, cutting b B at r', q', p'. Also in fig. 2, N° 2, join A B, and draw i j', i k', j k', parallel to A B, cutting b B at the points i, j', k'.

Transfer the triple multiples of the several distances of V L, fig. 2, N° 1, to V L, fig. 2, N° 4, as shown by the corresponding letters, except C E and C G.

Now because the surface of paper in fig. 2, N° 2, is not sufficient to contain the vanishing points, prepare fig. 2, N° 1, thus; draw E I and G H perpendicular to V L; make E I and G H equal to three-thirds of C E', the distance of the picture; join I E' and H E'.

In N° 4, fig. 2, draw C E' perpendicular to V L', and make C E', N° 4, equal to C E, N° 1; upon the vanishing line V L, make C E' equal to C E', N° 1; and C G equal to C G, N° 1; draw E I and G H perpendicular to V L', making E I and G H equal to E I and G H, N° 1; join E I and E' H, which will tend to the vanishing points.

Let the dimensions in fig. 1, N° 1, be applied in No. 4, fig. 2, to C E, C d, &c. in altitude upon the corner from C upwards and downwards; then draw lines tending to the vanishing points, as shown in the preceding problems; draw any convenient line, P Q, parallel to V L'; continue the corner line of the building to meet P Q in b; make b i, b j, b k, &c. also b p, b q, b r, &c. equal to b i, b j, b k, &c. fig. 2, N° 2, and b p, b q, b r, N° 3; then C d being the triple multiple of C d, N° 1, the point d will be the dividing point; draw b R and b S tending to the vanishing points; from the several points i j, k, l, and p, q, r, draw lines tending to d, to cut b R and b S; from the point of fiction draw lines perpendicular to V L', which will give the corners of the building and the sides of the windows. Let us now suppose the walls completed with their apertures.

Now C g being the height of the roof upon the corner of the building from the vanishing line, and the height of the left-hand corner being at w, draw g w and w y, tending to the vanishing point e; through g draw n t parallel to V L; make g e equal to b o; make g t and e u equal to the half of b r', N° 2; draw x y and t n, tending to the dividing point d, gives the points y and e for the extremities of the ridge, the points y and e being joined to the wall heads completes the roof.

This method is entirely new, and perhaps is the safest method of practice that has ever been devised.

To find the representation of a hipped truncated roof, supposing,
posing the dimensions of the walls to be the same as in fig. 2, N° 4.

Let $\psi$ and $\varphi$ be the vanishing points, of which $\psi'$ is inacceqible, and let $P$ be the dividing point, found as that of fig. 2, N° 4, the positions of the other points being taken from fig. 2, N° 1. Draw $I^I N^I$ the intersecting line of the truncated part of the roof, that is, draw $I^I N^I$ parallel to $V^I L^I$, equal to the height of the top of the roof from the level of the eye; make $g k$ the proportional measure of the breadth of the inclined part of the roof; that is, the real measure being applied to the scale $b A$, fig. 2, N° 2, or fig. 2, N° 3, and reduced to the scale $b B$, gives the proportional measure. The other measures upon $I^I N^I$ are all supposed to be reduced in the fame manner, and are consequently in the same ratio as the real measures; $g b$ is the proportional measure of the sides of the truncated part parallel to the front, and $g i$ the proportional measure of the end of the paid part; draw $k i$, tending to the dividing point $P$, cutting $l n$ at $m$; draw $m o$, tending to the vanishing point $\psi'$; draw $i o$, tending to the dividing point $P$, cutting $m o$ at $o$; also draw $h n$, tending to the dividing point $P$, cutting $l n$ at $n$; then the lines $m n$ and $o r$ represent the two visible parts of the truncated plane of the roof; join $n j$, $m f$, and $o r$ will complete the representation of the roof. This is evident, since the line $l n$ represents the front line of the truncated part; and because that $P$ is the vanishing point of the diagonal, the line $g m$ is in the plane of the diagonal, and therefore the point $m$ is properly acertained.

Or a truncated hip roof may be thus represented: let $g$, fig. 4, be the height of the roof at the middle corner, as before; draw $g r$, tending to the vanishing point $\psi'$, upon the left, and $g v$, tending to the vanishing point, upon the right; make $g b$ and $g l$ equal to the breadth of the inclined part; make $b i$ equal to the side of the truncated plane parallel, and next to the front, and make $l m$ equal to the breadth of the truncated plane; draw $i t$, $m u$, tending to the dividing point $P$, cutting $g i$ at $i$ and $u$, and drawing $e i$ at $i$; vanishing point on the left; draw $h o$ at $o$ and $r p$, tending to the dividing point $P$, cutting $g o$ at $o$ and $g p$; draw $s x$ and $s t$, tending to the vanishing point on the right, cutting $e t$ at $e$, and $s x$ at $r$ and $x$; then $r s$ and $r x$ will be the two sides of the truncated flat; then joining $e y$, $r f$, and $e x w$, will complete the whole representation of the roof.

It is somewhat strange that the base line, or intersectation of the plane on which the objects are placed, is the only intersectation that is to be found in treatises of perspective; but if the intersectation of each plane above the eye were used, instead of describing every parallel plane upon the base, much less confusion would ensue, and much greater accuracy would be acquired. As the angles become less obtuse, that is to say, they approach the right angle by becoming more acute, all the indefinite representations would be cut more at right angles, and, therefore, the intersectations would be less oblique. In order to comprehend clearly the perspective representation of polygons, it will be necessary to attend to their geometrical construction. An equilateral polygon may be constructed according to several methods, but the most eligible for the purpose of perspective is the following.

PROB. XXXIX. Figs. 1, 2, 3, 4, 5, 6.

The angle made by the two sides of a regular polygon being given, to construct the polygon according to a given side.

From the angular point cut off the two sides to their determine length: then to obtain each successive side, proceed each time as in the following operation.

From the extremity of one side, which is not the angular point, draw a line parallel to the other side; from the extremity of the other side draw a line, making a given angle with that side equal to the angle of the sides of the polygon, and let the line last drawn meet the line parallel to the middle line; and three sides of the polygon will be thus determined. Proceed in the same manner with the two sides forming the last angle, and a fourth side will be obtained, and thus successively till the whole figure is included.

From this geometrical description it appears, that if the vanishing points of the sides of a polygon are found, the whole may be constructed perspectively.

PROB. XL.

To find the perspective representation of a polygon, given a similar figure to the polygon to be constructed, and the lengths of the sides.

Find the vanishing point of each of the sides, and the representation of the two sides nearest to the intersecting line.

Then repeat the following operations in finding each successive side. From the extremity of one of the representations of the two sides, which is not the angular point, draw a line to the vanishing point of the other side; then draw a line from the extremity of the other side, which is not the angular point, to the vanishing point of the next succeeding side, and the point of intersectie of the two lines thus drawn will terminate the third side.

Then if the polygon be a trignon the thing is done, but if it conflict of more sides the same operation must be repeated for each.

If one of the vanishing points of one of the sides be inaccessible, repeat the operations round in the same order, until one end of the inaccessible side is found; then repeat the operations in the contrary order, until the other end of the inaccessible line is found; then join the two points, which will complete the perspective representation of the polygon.

With regard to finding the vanishing points. If the polygon has an even number of sides, there will be only vanishing points for half the number of sides; but if the number of sides be odd, every side will have a vanishing point; shoul the number of sides be even, each radial may be marked with the digits 1, 2, 3, &c. then marked again with the same digits added to half the number of sides of the polygon. Thus, if the figure be a hexagon, as $A B C D E F A$, fig. 2, N° 1; the figure, N° 2, having all its radials parallel, has its radials numbered 1, 2, 3, and again 4, 5, 6, because the three lines continue the succeeding numbers. This is also manifested in figs. 4, N° 1 and 2. In N° 2, the radials are numbered 1, 2, 3, 4, then 5, 6, 7, 8, repeated upon the same lines, and thus every radial gives the vanishing points of two sides, as is indicated by the numbers. But if the number of sides of the polygon be odd, the numbers are repeated upon each second radial, then again upon the intermediate radials, beginning with that which lies between the first and second, as figs. 1, 3, and 5, plainly shew.

Fig. 6 shows the representation of a hexagon upon the foregoing principles; the sides $e f$ and $e k$ are first found by the vanishing points $e^{++}$ and $w^{+-}$, which are the first and last sides of the polygon, then drawing $k g$ to the vanishing point $w^{++}$ of the side $e f$, and from $f$ drawing $f g$ to the next vanishing point $w^{++}$ in succession, gives the next side $g z$; $g b$ is found in the same manner.

Fig. 7, is another example of the principle; where the number of sides are even, the figure represented is an octagon. It will be observed in this as well as in fig. 6, that every vanishing point serves for two opposite sides, so that
in every half number of sides in going round from any side, the half will have the fame vanishing point again as that side; or in any number of adjoining sides which consist or more than half the number of sides in the whole polygon, the first and half of these sides will have the fame vanishing point; and thus in the hexagon the vanishing points $v, v', v''$ are respectively the vanishing points of the opposite sides, which in order would be $v', v'', v$. The same is to be understood of fig. 7.

**Prob. XLII. Fig. 9.**

Given the centre and distance of the picture, the interfeting and vanishing lines of a plane perpendicular to the picture, and the infilling line $A B$ of a plane perpendicular to the original plane inclined to the interfeting, to find the interfeting and vanishing lines of the infilling plane.

If $A B$ do not meet the interfeting $I'N'$, produce it till it meet in $B$; draw $E'C$ parallel to $A B$, cutting the vanishing line $V L$ in $C$; through $C$ draw $V''L''$ perpendicular to $V'L'$, and $V''L''$ will be the vanishing line; also through $B$ draw $I'N''$, and $I'N''$ will be the interfeting line of the plane.

For the angle $C' C E$ is equal to the angle $I B A$; then when these angles are raifed perpendicular to the plane of the picture, and on contrary sides of it, the planes whose interfetions are $I'N'$ and $V''L''$ will be parallel to each other, and therefore their interfetions $I''N''$ and $V''L''$ are also parallel to each other.

**Prob. XLIII. Fig. 10.**

Given the interfeting and vanishing lines of an original plane, the feas of a line at a given angle with the interfeting, the inclination of the incumbent line and the position of the eye in respect of the vanishing line, to find the vanishing point of the line whose feas is given.

Let $A B$ be the feas of the line given; through $E'$, the place of the eye, draw $E D$ parallel to $A B$, cutting $V''L''$ in $D'$; through $D$ draw $V''L''$ perpendicular to $V'L'$; make $D E$ equal to $D E'$; and make the angle $D E F$ equal to the inclination of the line to the original plane, the leg $E F$ cutting $V''L''$ at $F$; then $F$ is the vanishing point required.

Or take any point $H$ in $E D$, and draw $H K$ parallel to $V''L'$; make $E H$ to $H K$ as the tangent of inclination of the line to the original plane; join $E K$, and produce it to meet $V''L''$ in $T$. For draw $D G$ and $H I$ perpendicular to $A B$, and make $H I$ equal to $H K$; join $E I$, and proceed to $G$; then $E H = E D = H I = D G$, also $E H = E D = H K = H I = D F$; therefore $D F$ is equal to $D G$, consequently $F$ is the point required.

**Prob. XLIV. Fig. 11.**

Given the centre and distance of the picture, and the feas and distances of two points of an original line on the picture, to find the indefinite representation of the line.

Let $C'$ be the centre of the picture, $C$ and $D$ the feas of the two points; join $C D$; draw $C A$ and $B D$ perpendicular to $C D$; make $C A$ equal to the distance of the point, whose feas is $C$, and $D B$ equal to the distance of the point, whose feas is $D$; join $A B$; produce $A B$ and $C D$ to meet each other at $E$; draw $C E$ parallel to $C F$; and $C E'$ parallel to $C'O$; make $C E'$ equal to the distance of the picture; draw $E' F$ parallel to $A F$, and join $F$, and $F$ is the indefinite representation required.

**Prob. XLV. Fig. 12.**

Given the interfeting and vanishing lines of an original plane perpendicular to the picture, the position of the eye in respect of the vanishing line, and the feas of two points of a line, and their distances, to find the indefinite representation of the line.

Let $A$ and $B$ be the feas of the two points, $V'L'$ the vanishing line, and $I'N'$ the interfeting line of the original plane, and $E'$ the place of the eye; join $A B$, and produce it to meet the interfeting $I''N''$ at $e$; draw $B D$ and $A C$ perpendicular to $I''N''$; make $B D$ equal to the height of the point, whose feas is $B$, and $A C$ equal to the height of the point, whose feas is $A$; draw $e f$ perpendicular to $I''N''$; make $e h$ equal to $e f$; through $E$ draw $E' h$ parallel to $A B$, cutting $V''L'$ at $h$; from $V''L'$ cut off $h i$ equal to $e f$; make the angle $h i j$ equal to the angle which the line $A B$ makes with $C D$; and through $h j$ draw $V''L''$ perpendicular to $I''N''$, cutting $v''j$ at $v''$; join $w', v''$; and $w' i j$ is the indefinite representation required.

**Prob. XLVI. Fig. 13.**

Given the centre and distance of the picture, the interfeting line of an original plane, and its inclination to the picture, to find the vanishing line, its centre, and distance of the original plane.

Let $A B$ be the interfeting line of the original plane, $C$ the centre of the picture. Through $C$ draw $C E$ perpendicular to $A B$; draw $C D$ perpendicular to $C E$; make $C D$ equal to the distance of the picture; and make the angle $C D E$ equal to the supplement of the inclination of the original plane to the picture; through $E$ draw $V'L'$ parallel to $A B$; then $V''L'$ will be the vanishing line, its centre, and its distance, as required.

**Prob. XLVII. Fig. 14.**

Given the centre and distance of the picture, and the vanishing
vanishing line of a plane, to find the vanishing point of lines perpendicular to that plane.

Let C' be the centre of the picture, V'L' the vanishing line of the plane. Through C' draw C''L'' perpendicular to V'L', cutting V'L' at C''; draw C.E perpendicular to C''L'', and make C'E equal to the distance of the picture; join C''E and make the angle C'E = right angle, and let E meet C''L'' in \( v \); then \( v \) is the vanishing point required.

**PROB. XLVIII. Fig. 14.**

Given the centre and distance of the picture, the vanishing line of a plane, and the vanishing point of the common intersection of the plane, whose vanishing line is given, and another plane at right angles, to find the vanishing point of the other plane. Let \( v \) be the vanishing point of the common intersection.

Find \( v' \), the vanishing point of lines, perpendicular to the plane, whose vanishing line is V'L', and join \( v'v \), which is the vanishing line required.

This is easily conceived, by supposing the triangle C'E'v perpendicular to the plane of the picture upon the line C''v'.

**PROB. XLIX. Fig. 14.**

Given the centre and distance of the picture, and the vanishing point of parallel lines, to find the vanishing point of planes perpendicular to the lines, whose vanishing point is given.

Let C' be the centre of the picture, \( v' \) the vanishing point of the parallel lines; join \( v'v \) and produce \( v'c' \) to \( C' \); draw C'E perpendicular to \( v'c' \); make C'E equal to the distance of the picture; join \( v'E \); draw E'C perpendicular to \( v'c' \); through C draw V'L' perpendicular to \( v'c' \), and V'L is the vanishing line required.

**PROB. L. Fig. 15.**

Given the centre and distance of the picture, the vanishing line of one of the planes of a rectangular prism, and the vanishing point of the common intersection of that plane and the plane of the adjoining side, to find the vanishing lines of the other two sides, their centres, and distance.

Let C be the centre of the picture, V'L' the vanishing line of the plane of one side, \( v \) the vanishing point of the common intersection of that side with the next adjoining side.

Find the vanishing line V''L'', of parallel lines perpendicular to parallel lines, whose vanishing point is \( v' \) by the last problem. Produce \( v'c' \) to \( E' \), cutting V''L'' at \( C'' \); make \( C''E' \) equal to \( C''E '' \); draw C'E' perpendicular to V''L'' and V'L', and consequently the vanishing point of the intersection of two adjoining sides; from \( v'' \), with the radius \( v''E'' \) describe an arc, cutting C'E' at \( E'' \); join \( v''E'' \); E'E'' \( v'' \); make the angle \( v''E''v'' \) at right angles, and let \( v'' \)

cut V'L' at \( v'' \); join \( v''v'' \) for the vanishing line V''L''; draw C'E'' perpendicular to V''L'', cutting V''L'' at \( C'' \); from \( v'' \), with the radius \( v''E'' \), describe an arc, cutting C'E' at \( E'' \); join \( E''v'' \) and \( E''v'' \); then V'L', V''L'', V''L'\( v'' \), are the vanishing lines, C', C', C', their respective centres, and C', C', C', and C'E', C'E', their respective distances, which might have been otherwise found by drawing right-angled triangles, making the distances of the centre of the picture, and the centre of the vanishing line, the bases, and the perpendicular at the centre of the picture equal to the distance, as shown by the dotted triangles.

**PROB. LI. Figs. 16 and 17.**

Given the common intersection of two planes, the feet of a line in one of them, and the inclination of the line to the same plane, to find the feet of the line in the other plane, and its inclination to the same.

Let I'N' be the common intersection of the two planes, A B the feet of the line; let \( A \) be the intersection I'N' at \( A \); make the angle B A C equal to the inclination of the line; draw B C perpendicular to A B, cutting A C in C. This problem may be divided into two cases; one when the two planes are at right angles to each other, and the other when they stand oblique. In the former case, (see fig 16), draw Bf perpendicular to I'N', cutting it in \( d \); make \( dE \) equal to \( B, C \), and join \( A \); draw \( e \) perpendicular to \( A \); make \( eF \) equal to \( dB \), and join \( fA \); then \( A \) is the feet of the line, and \( eA \) gives its angle of elevation on the other plane. In the latter case, draw \( Bf \) perpendicular to \( B \); make \( F \) equal to \( B \); and make \( \angle B \) equal to \( \angle C \); through \( N \) draw parallel to \( A \); and make \( \angle A \) equal to \( \angle F \), and join \( N \); then \( \angle A \) is the feet of the line on the other plane, and \( \angle A \) the corresponding angle of elevation.

By means of this problem, whatever lines are given in position to the plane, the position of the fame lines may be found to the picture, and the representation may be found as in problem 16.

**PROB. LII. Fig. 1.**

Given the centre and distance of the picture, the vanishing line of a plane, and the vanishing point of the intersection of that plane, and another plane, and the inclination of the plane, to find the vanishing line of the other plane, and its centre and distance.

Let C' be the centre of the picture, V'L' the vanishing line of a plane, \( v' \) the vanishing point of the intersection of that plane with another plane; join \( v'c' \); draw \( C'E ' \) perpendicular to \( C'v ' \); make \( C'E ' \) equal to the distance of the picture, and join \( E'v ' \); draw \( C'D \) perpendicular to \( v'v ' \), cutting \( v'E ' \) at \( D \); from \( C'v ' \) take \( C'B \) equal to \( C'D \), and let \( C'E ' \) cut \( V'L' \) at \( A \); produce \( A'C \) to \( F \); make the angle \( A \) to \( B \) equal to the inclination of the planes; join \( v'F \), which gives the vanishing line V'L', as required; draw \( C'E ' \) perpendicular to V'L', cutting it at \( C \); make \( v'E ' \) equal to \( v'E ' \), and join \( v'E ' \); also draw \( C'E ' \) perpendicular to V'L', cutting V'L at \( C \); make \( v'E ' \) equal to \( v'E ' \), and join \( v'E ' \).

**PROB. LIII. Figs. 2 and 3.**

Given the centre and distance of the picture, the representation of a line, with its vanishing point, and the indefinite representation of another, from a given point in the latter, to cut off a portion, so that the originals of the two representations shall have a given ratio.

Let C' be the centre of the picture, \( v ' \) the vanishing points of one of the lines, and \( w ' \) the vanishing point of the other; join \( w ' \) and \( v ' \) by the straight line V'L', which will be the vanishing line of their plane; draw \( C'E ' \) perpendicular to V'L', cutting V'L at \( C \); draw \( C'E ' \) perpendicular to \( C ' \); make \( C'E ' \) equal to the distance of the picture, and join \( C ' \); make \( C'E ' \) equal to \( C ' \); join \( v'E ' \) and \( v'E ' \); from \( v'E ' \) take \( v ' \), equal to \( v'E ' \); also \( v ' \) equal to \( v'E ' \).

This problem may be resolved into two cases; first, when the two lines meet in a point, figure 2.

Let \( ae \) be the given representation, and \( a \) the indefinite representation, having respectively the vanishing points \( v ' \) and \( v ' \).
\[ \nu' \text{ and } \omega' ; \text{through a draw } c \text{, parallel to } V'1L' \text{; join } i, e, \text{ which produce to } e; \text{ make } a e \text{ to } a d \text{ in the original ratio required; draw } d', \text{ cutting } a\nu' \text{ at } i, \text{ and } e, \text{ cutting } a\sigma' \text{ at } e; \text{ then } a e \text{ and } a d \text{ are the representations of two original lines in the ratio of } a c \text{ to } a b. \]

But if the two lines do not meet at the same point as in figure 3; let \( c d \) be the representation given, \( \omega' \) its vanishing point, and \( a \sigma' \) the indefinite representation of the other; through the extremity \( a \), draw \( \nu'1N' \); join \( i e \) and \( 1 d \), which produce to meet \( 1\nu'1N' \) at \( f \) and \( g \); from \( a \) take \( a c \) to \( g\sigma' \), in the ratio required; join \( e 2 \), cutting \( a\sigma' \) at \( o \); then the original of \( a b \) will have to the original of \( c d \) the ratio required.

### PROB. LV.

**Fig. 5.**

Given the centre and distance of the picture, the intersecting

and vanishing lines of a plane perpendicular to the picture, the fide of a rectangle in the original plane, and the inclination of the plane of the rectangle to the original plane, and the distance of the nearest point to the intersecting line, to find the representation of the rectangle.

Let \( V'L' \) be the vanishing line, \( 1\nu'1N' \) the intersecting line of a plane perpendicular to the picture, \( C' \) the centre, and \( C'E \) the distance put in position as usual; and let \( A \) be the point of the \( \nu'1N' \) side of the rectangle on the original plane, \( e \) the point of the nearest point \( A \) and \( A \) is its distance; find the representation \( a \) of the point \( A \), and then of the straight line \( A D \); and let \( E' \omega' \) be the parallel of \( A D \); draw \( E' \nu' \) perpendicular to \( E' \omega' \), and let \( E' \omega' \) meet the vanishing line \( V'L' \) in \( \nu' \); through \( \nu' \) draw \( V'L' \) perpendicular to \( V'L' \); find the point \( 1 \) in \( \nu' \), by making \( \nu'1 \) equal to \( E' \omega' \); make the angle \( \nu'1 \) \( \omega'1 \) equal to the inclination of the plane to the original plane; join \( \nu' \omega' \), that is, \( V'L' \), which will be the vanishing line of the plane incumbent on the original plane; draw \( C'E' \nu'1V'L' \) perpendicular to \( V'L' \), cutting \( \omega'1 \) at \( C' \); from \( \nu' \), with the radius \( E' \nu' \), describe an arc, cutting \( C'E' \) at \( E' \); or upon \( V'L' \), as a diameter, describe a semicircle, cutting \( C'E' \) at \( E' \); then \( C'\) is the centre, and \( C'E' \) the distance of the vanishing line \( V'L' \), and \( \nu' \omega' \) the vanishing points of the sides; make the rectangle \( E'MN'O \) similar to the original figure, and alike situated; draw the diagonal \( E' \nu' \), and produce it to meet the vanishing line \( \nu'1 \) at \( \nu' \); join \( \nu' \) and \( \omega' \), which give the indefinite diagonal; draw \( d' \omega' \), cutting \( a\nu' \) at \( e \); draw \( e\nu' \); produce \( \nu' \) \( c \) to \( \nu' \); and join \( a \nu' \), cutting \( \nu' \) \( e \) at \( b \), then \( a b c d \) is the representation required.

### PROB. LVI.

**Fig. 6.**

Given the centre and distance of the picture, to find the representation of a rectangle in a secondary plane, with an angle resting on the primitive or original plane; given also the intersection of the secondary and original planes, and their inclination, together with the fide and distance of the resting point.

Find \( m \), the representation of the resting point, by means of its cast and distance, and the centre \( C \) and distance \( C'E' \) of the picture; draw \( E' \omega' \) the parallel of the intersection, cutting \( V'L' \) in \( \nu' \); draw \( E' \nu' \) perpendicular to \( \nu'E' \), cutting \( V'L' \) at \( C' \); on \( V'L' \) make \( C'E' \) equal to \( C'E' \); through \( C'E' \) draw \( V'L' \) perpendicular to \( V'L' \); make the angle \( C'E' \) \( \nu'1 \) equal to the inclination of the secondary plane to the primitive or original plane; let \( \nu'1 \) meet \( V'L' \) in \( \nu' \); through \( \nu' \) and \( \nu' \) draw \( V'L' \), which is the vanishing line of the inclined plane required to be represented; find its centre \( C' \) and distance \( C'E' \); join \( E' \omega' \); make the angle \( E' \omega' \) \( E' \) equal to the angle which one of the fides of the object makes with the intersection of its plane and the primitive; let \( E' \omega' \) meet the vanishing line \( V'L' \) in \( \nu' \); also make the angle \( \nu'E' \) \( \nu'1 \) equal to the angle of the original figure next to the intersection of its plane with the original plane; let \( E' \nu' \) meet \( V'L' \) at \( \nu' \); then the representation \( m \) may be completed as in the last problem, fig. 5. Or proceed thus; bring the distance of the eye upon the vanishing line \( V'L' \) from each of the vanishing points; then 2 and 4 are the dividing points; join

**Vol. XXVI.**
join $\psi$, and the representation $m$ of the nearest corner; produce $\psi m$ to $i$; through $i$ draw $I'N'$ parallel to $V'L'$, and $I'N'$ will be the intersection of the inclined plane and the picture; through the points $z$ and $m$ draw $m d$, cutting the intersection in $d$; make $d c$ equal to the original of the side $m p$; draw $e 2$, cutting $m \psi'$ at $p$; also draw $4 m$, and produce it to meet $I'N'$ at $b$; make $b c$ equal to the original of the side $m n$; draw $e 2$, cutting $m \psi'$ at $n$; draw $n \psi'$ and $p \psi'$, cutting each other at $o$; then $m n o p$ is the representation, as before.

**PROB. LVII. Fig. 7.**

To find the representation of the portion of a rectangular prism, cut by a plane so that two of the parallel faces will be equal trapezoids, the other two parallel faces being equal rectangles, the solid being formed like a pent-house; given the centre and distance of the picture as usual, the base of the prism on the original plane, the picture and the arrafes of the object being perpendicular to the original plane.

Let $A B C D$ be the base of the solid; find its representation $m n o a$ as usual, as also the vertical planes of the solids $n o b a$ and $m n a d$; on the vanishing line $V'L'$ make $\psi' 2$ equal $\psi E'$; through $\psi'$ draw $V'L'$ perpendicular to $V'L'$; make the angle $\psi' 2$ $\psi'$ equal to the inclination of the terminating plane, and let $2 \psi'$ meet $V'L'$ in $\psi'$, which will be the vanishing point of the two inclined sides, and $\psi'$ will be the vanishing point of the two level sides; the plane $a b c d$, being drawn according to the respective vanishing points, will complete the representation of the solid. The representation of the top might have been obtained without raising the vertical sides from the base; thus, draw $A S$ perpendicular to $V'L'$, cutting $I'N'$ in $E$; make $E S$ equal to the height of the arrafes or quoin upon $A$; draw $S A$ parallel to $V'L'$; make $S A$ equal $E A$; then $S$ is the foot of the top of the arrafes on the picture, and $S A$ its distance from the picture; find $a$ the representation of the apex of the solid angle, having the centre and distance of the picture, and the feet $S$ and distance $S A$ of the original of the point $A$; then the vanishing line $V'L'$ being found as before, produce $B A$ to meet $I'N'$ at $F$; draw $F G$ perpendicular to $I'N'$; make $F G$ equal to the height of the front plane, and the point $G$ will be a point in the intersection of the inclined plane with the picture; therefore draw the line $I'N'$ parallel to $V'L'$, and $I'N'$ will be the intersection of the inclined plane; find the centre $C'$, and distance $C'E'$ of the vanishing line $V'L'$; join $E' \psi'$ and $E' \psi$; on the vanishing line $V'L'$ make $\psi' 5$ equal to $\psi E'$, and $\psi' 4$ equal to $\psi E'$; then $D Q$ being perpendicular to $A D$, and the angle $D A Q$ equal to the inclination of the plane, $A B$ will be the length of the side parallel to the base, and $A Q$ that of the side inclined thereto; through $5$ and the point $a$, draw $5 a$, which produce to meet $I'N'$ at $e$; in $I'N'$ take $e f$ equal to $A Q$; join $f s$, cutting $a \psi'$ at $d$. In like manner join $4 a$, which produce to meet $I'N'$ at $g$; make $g b$ equal to $A B$, and join $b 4$, cutting $a \psi'$ at $d$.

Draw $A' D'$, $B' D'$, and $C' D'$, cutting $a G'$ at $E'$, $F'$, $G'$; then apply $E' F'$ and $E' G'$ from $a$, upon the line passing through $a$, parallel to $V'L'$; then cut off $a \delta$ and $a d$ by means of the points $4$ and $5$, as before.

**PROB. LVIII. Fig. 8.**

To find the representation of a rectangular prism, situated with its faces inclined to the original plane, and to the picture laying upon one of its arrafes on the original plane; given the extent and distance of the nearest point of concourse of a solid angle, the inclination of the arrafes of the solid in the original plane to the picture, and the inclination of one of the arrafes to the horizon, and the centre and distance of the picture.

Draw the horizontal line $V'C'$ and $C'E'$ perpendicular thereto; draw $E'A$ parallel to $V'C'$; make the angle $A E' C'$ equal to the inclination of the arrafes to the picture.

Find the point $a$, the representation of the nearest angle, by means of the centre and distance of the picture, and the extent and distance of the nearest point of concourse of the arrafes.

Through $C$ draw $V'L'$ perpendicular to $V'E'$; now as the solid lays upon one of its arrafes, two of its planes will be perpendicular to the horizon, and consequently will have their vanishing line perpendicular to the vanishing line of the horizon; therefore $V'L'$ will be the vanishing line of the arrafes in these perpendicular planes.

Draw $C'E'$ perpendicular to $V'L'$, and make $C'E'$ equal to $C'E'$. Through $E'$ draw $G H$ parallel to $V'L'$; make the angles $G E' v'$ and $H E' v'$ equal to the inclination of the planes to the horizon, then $v'$ and $v'$ will be the vanishing point of the arrafes, which terminate the ends that are perpendicular to the horizon.

Find $v'$ the vanishing point of original lines, perpendicular to original planes, whose vanishing line is $V'L'$.

Cut off $a b, a d$, and $a f$, as in problem 54, fig. 4; then lines being drawn to the respective vanishing points will complete the solid.

N. 1. shows the method of reducing the proportions according to what was shown in the last problem, by applying the meafures at once to the nearest angle.

**PROB. LIX. Fig. 9.**

To find the representation of a rectangular solid; given the centre and distance of the picture, the inclination of one of the faces of the solid to the picture; which have the nearest point of concourse, and the extent and distance of the nearest point of concourse.

Find $V'L'$ the vanishing line of the plane of the two planes of the solid, whose inclination is given; also the centre $C'$; and the distance $C'E'$ of the vanishing line.

Draw $G H$ parallel to $V'L'$; make the angles $G E' \psi'$ and $H E' \psi'$ equal to the angles which the arrafes make, with a line parallel to the picture at their point of concourse in the same plane, and $\psi' \psi'$ in $V'L'$ will be the vanishing points of the arrafes of the two sides, whose inclinations are given.

Find the vanishing point $v'$ of original lines perpendicular to planes which have $V'L'$ for their vanishing line.

Find $f$ the representation of the nearest point of concourse of three arrafes.

From each of the indefinite representations cut off the different sides, and the solid will be completed, as in the last example.

**PROB. LX. Fig. 10.**

The centre and distance of the picture, and the inclination of an original plane, making a given angle with the picture, being given, to find the representation of a wedge, with
with the point of concourse of three of the arrases in the picture, the base of the object being in the plane whose interfection is given, three of the sides of the solid perpendicular to the original plane.

Let $1^N$ be the interfection of the original plane, the point of concourse of the nearest angle in the interfection $1^N$.

Find the vanishing line, $V^1L^1$, of the original plane, whose interfection is $1^N$; as also its centre $C^1$, and distance $C^1E^1$.

Find the vanishing point, $\psi^1$, of the interfection of the inclined side of the wedge, with the original plane, and draw the line of interfection $\psi^1\epsilon$.

Find the vanishing point, $\psi^2$, of the other side; the vanishing points, $\psi^1, \psi^2$, being in the vanishing line $V^1L^1$.

Find the vanishing point, $\psi^3$, of original lines, perpendicular to original planes, which have $V^1L^1$ for their vanishing line.

Join the vanishing points $\psi^1$ and $\psi^2$, and produce $\psi^1\psi^3$ to $\psi^4$.

Find the centre $C^1$, and distance $C^1E^1$, of the vanishing line $\psi^1\psi^4$, that is of $V^1L^1$; join $\psi^2\epsilon$.

On the radials $E^1\psi^1$ and $E^1\psi^2$, make $E^1G$ and $E^1F$ in the ratio of the sides, which have $V^1L^1$ for their vanishing line; join $GF$; draw $E^1\psi^1$ parallel to $GF$, and $\psi^4$ will be the vanishing point of the two inclined arrases.

Find the representations, $ab$ and $ac$, of the hither sides of the base. Join $\psi^1a$ and $\psi^2b$; join $\psi^3c$, which produce to meet the indefinite representation $a\psi^4$ in $d$; join $d\psi^4$, cutting $\psi^1\psi^4$ at $e$, which completes the entire fold.

By joining $\psi^1\psi^2$, $V^1L^1$ will be the vanishing line of the inclined plane $abed$; and by finding the centre $C^1$, and distance $C^1E^1$, and joining $E^1\psi^1$ and $E^1\psi^2$, the original portion of the inclined plane may be found, by drawing the diagonal $ae$, and producing it to meet the vanishing line $V^1L^1$ at $\psi^1$, and joining $\psi^4E^1$, then the rectangle $KLME^1$, whose other sides meet the radial $\psi^1E^1$ in $L$, is the original of the inclined plane; and thus any figure may be drawn in the original plane, whose vanishing line is $V^1L^1$.

The principles of light and shade will be treated under the article Shadows.

The writers on perspective are very numerous. The following, (some of whom have been already mentioned in the brief history of the science at the commencement of this article,) are the principal, with the dates of their performances, as near as can be ascertained.

Guido Ubaldus, 1600, Latin, folio; Bernard Lamy, 1701, 8vo.; F. Gravendafe, 1711, 8vo.; translated into English by Stone, 1724; Mar loos, Vredeman Friece, the Jefuit, 1719; 4to.; Pozzo, folio. The Jefuit was translated into English by E. Chambers, 1726.

Ozanam's Mathematics contain also a treatise on Perspective. There are all foreign works. The following list contains all, or nearly all, the English authors, or their works, that have written on perspective.

Humphry Dittun, 1712, 8vo.; Moxon, folio; Brook Taylor, two treatises, one in 1715, and the other in 1719; both 8vo.; Langley, 1730, 4to.; Oakley's Magazine of Architecture, Perspective, and Sculpture, 1730, folio; Halfpenny, 1731; Hamilton, 1738, folio; Dr. Brook Taylor's Method of Perspective, by Kirby, 1754, letter-prent, 4to., and plates, folio; Sirigati by Ware, 1754, folio; Kirby's Parallel suppressed; Kirby's Perspective of Architecture, 1760, large folio; Highmore, 1763, 4to.; Fournier, 1764, 4to.; Cowley's Moveable Schemes for illustrating the Principles of Perspective, 1765, 4to.; Ferguson, 1765, 8vo.; Ware's Complete Body of Architecture contains a treatise on Perspective, 1768, folio; Priestley, 1770, 8vo.; Edward Noble, 1771, 8vo.; Thomas Malton, 1775, folio; Bradberry; Shiraton in his Cabinet and Upholsterer's Drawing-Book, 4to.; Wood of Edinburgh, 1797, 8vo.; the Painter's Mauiflack by James Malton, 1800, 4to.; Dillons, 1805, letter-prent, 8vo., and plates, folio; Edwards, 1806, 4to.; Thomas Noble, second edition, 1809, 4to.; Wood's Lectures, London, second edition, 1809, 4to.; W. Daniel, 1810, small 8vo. for children; a thin quarto without the name of the author, the title being "A New Treatise on Perspective, founded on the simplest Principles, containing universal Rules for drawing the Representation of any Object on a vertical Plane," 1810, thin 4to.; Dr. Creffwell, A.M., 1811, 8vo; Malte in his Elements of Architecture, 1812, 4to.; and Mr. S. Taylor, 1813, small 8vo. Before the above authors and treatises are Muller, Mansi, and Emerson, who have written octavo treatises in their mathematical courses. A thin quarto was written by Dowdell, a painter. The Arrifs's Repository, published by C. Taylor, Hatton Garden, contains also an article on perspective.

But of all the above works, or authors' works, Dr. Brook Taylor's is the most celebrated, on account of the universality of his principles in their application to planes and objects. For though vanishing points in every position were known to Guido Ubaldus, and s'Gravendafe not only understood the use of vanishing points, but the use of directors also in the representation of a point, anterior to the appearance of any thing published by Brook Taylor; but Brook Taylor has extended his theory not only to vanishing points, but to the vanishing lines of planes in every situation, which, when once ascertained, the representation of an object is found by the fame means in each plane, and consequently with the same facility. Hamilton seems to be the first writer who introduced the practice of setting the radial, or parallel of the original line from the vanishing point, upon the vanishing line, and the original line from the intersecting point upon the intersecting line, in order to ascertain the representation of any point, or any part or parts of the original line, and to find the originals from the representations given. (See problems 8 and 9, book ii. sect. 2, of his Stereography, and the following corollaries from problem 8.) This author is the first who has applied the harmonical division of lines to perspective. Noble's Perspective contains several inventions: his methods of drawing indefinite representations to inaccessible vanishing points, both by scales and other means, are new. Thomas Malton's treatise on this subject is an able performance. His theory is well arranged, and demonstrated with true geometrical spirit. The choice of his examples in the component parts of architecture, before uniting the whole into a complete edifice, are excellent.

The works on perspective of the following gentlemen, among the authors already enumerated, are performed shortly upon the principles of Dr. Brook Taylor: Hamilton, Kirby, Highmore, Fournier, Priestley, Noble, Thomas Malton, J. Wood, Edwards, J. G. Wood, Creffwell, A.M.

Though Mr. James Malton pretends to unite the principles of Dr. Brook Taylor with those of Vignola and Sirigatti, he might have referred them with more propriety to s'Gravendafe's invention of directors, as the use of the fitting point, which is only a directing point, can be more easily explained upon the principles of the directing line, director, and directing point, than by any mechanical notion; so that the methods which he uses may be referred entirely to the principles of Dr. Brook Taylor. In the method used in James Malton's Perspective, every point of an object in the original plane is found in the picture, by a line drawn between the intersecting and vanishing point, or drawn from some point already found, and the vanishing point, and an-
other line drawn by the directing point and the director; for when the director of an original line coincides with the intersection of the vertical plane, the representations directed will be perpendicular to the intersection, or to the vanishing line; therefore, lines thus drawn in the picture will fall in the same straight lines with original lines parallel to the picture, and to the vertical plane, infiring upon the remote extremes of the lines drawn to the directing point. This, therefore, admits of the plan of the object either being connected with the picture, or separated from it, as convenience may require. This circumstance has even been overlooked in the more excellent treatise of the father of the gentleman, upon whose work the remarks are now made.

It is something remarkable, that in Broek Taylor's Perspective, he no where directs the radial to be placed upon the vanishing line. except in problem 10. Inverse perspective, notwithstanding the very near affinity thrown in problems 3 and 4, which one would have thought might have led to that application; particularly, considering the great use which Kirby, Highmore, Fournier, Priestley, E. Noble, Thomas Malton, J. Wood, Edwards, and others of inferior note, have made of it, in representing original measures without the use of the plan. It is to be observed, that in Broek Taylor's Perspective, when he finds the representation of an original figure without the plan, he first finds the representation of a side of the figure; then the representation of a line, whose original will make an angle of the figure with the original side of the projection given; then determines the proportion of the last line, found by supposing the two sides to be joined by a third line, making a triangle; then finds the vanishing point of the third side. He then proceeds with another side, if more than three, in the same manner; so that he supposes the original figure divided into triangles, by drawing diagonals, and constructs angles at the eye, equal to those which he supposes the originals to have; then finds the vanishing points of the sides, and of the diagonals; and, by drawing the successive lines to the respective vanishing points, completes the whole representation. When, he finds the projection of each triangle, if more than one, in the succession which they adjoin each other, until the whole representation is completed. Now, by placing the length of the radials upon the vanishing line, the originals may be represented, without supposing the figure to be resolved into triangles. But what is still more to be wondered at, in respect to Broek Taylor, in problem 10, of the edition 1719, the intersection of a plane, its vanishing line, with the centre and distance of the vanishing line, are given, to find only the length of the original of a projection given, which is a problem in inverse perspective; he absolutely lets the length of the radial on the vanishing line; and had he done so, in finding the representations of original figures, he would have been the sole inventor of the practice, without the use of the ground plan, or the figure to be represented being placed in its true situation.

Perspective is also used for a kind of picture or painting, frequently seen in gardens; and at the ends of galleries; designed expressly to deceive the sight by representing the continuation of an alley, a building, landscape, or the like.

Perspective, Aerial, is sometimes used as a general denomination for that which more restrictively is called aerial perspective, or the art of giving a due diminution or degradation to the strength of light, shade, and colours of objects; according to their different distances, the quantity of light which falls upon them, and the medium through which they are seen; the chiaro-furo, or clair-obfure, which consists in expressing the different degrees of light, shade, and colour of bodies, arising from their own shape, and the position of their parts with respect to the eye and neighbouring objects, whereby their light or colours are affected; and keeping, which is the observance of a due proportion in the general light and colouring of the whole picture; so that no light or colour in one part may be too bright or strong for another. A painter who would succeed in aerial perspective, ought carefully to study the effects which distance, or different degrees or colours of light have on each particular original colour, to know how its hue or strength is changed in the several circumstances that occur, and to represent it accordingly. As all objects in a picture take their measures in proportion to those placed in the front, so in aerial perspective, the strength of light, and the brightness of the colours close to the picture, must serve as a measure, with respect to which all the same colours at several distances will have a proportional degradation in like circumstances.

Perspective, Alley in. See Alley.

Perspective, Architecture in. See Architecture.

Perspective, Bird's eye view in, is that which supposes the eye to be placed above any building, &c. as in the air, at a considerable distance from it: this is applied in drawing the representations of fortification, when it is necessary not only to exhibit one view as seen from the ground, but so much of the several buildings as the eye can possibly take in at one time from any situation. In order to this, we must suppose the eye to be removed a considerable height above the ground, and to be placed as it were in the air, so as to look down into the building like a bird that is flying. In representations of this kind, the higher the horizontal line is placed, the more of the fortification will be seen, and vice versa.

Perspective, Diagonal. See Opera Glas.

Perspective, Graphical. See Graphical.

Perspective, Machines, is a machine by which any person may delineate the true perspective figure of objects, without the help of the rules of this art. Mr. Ferguson has described a machine of this kind, the invention of which he ascribes to Dr. Bevis. The plane of this instrument, Plate XXIV. Miscellaneous, exhibited in fig. 1, and fig. 2, is a representation of it when made use of in drawing distant objects in perspective. \( abef \) (fig. 1) is an oblong square board, reprented by \( ABEL \) (fig. 2); \( x \) and \( y \) (X and Y) are two hinges on which the part \( c \) \( d \) \( f \) (C L D) is moveable. This part consists of two arches or portions of circles \( clm \) (C L M) and \( dnf \) (D N L), joined together at the top \( f \) (L), and at bottom to the cross bar \( dc \) (D C), to which one part of each hinge is fixed, and the other part to a flat board, half the length of the board \( abef \) (A B E F), and glued to its uppermost side. The centre of the arch \( cm \) is at \( d \), and the centre of the arch \( dl \) is at \( c \).

On the outer side of the arch \( dn \) is a sliding-piece \( e \), (much like the nut of the quadrant of altitude belonging to a common globe,) which may be moved to any part of the arch between \( d \) and \( i \); and there is such another slider, \( a \), on the arch \( cm \), which may be set to any part between \( c \) and \( l \). A thread \( ep \) (C P N) is stretched tight from the centre \( c \) (C) to the slider \( e \) (N), and such another thread is stretched from the centre \( d \) (D) to the slider \( a \) (O); the ends of the threads being fastened to these centres and sliders.

Now it is plain, that by moving these sliders on their respective arches, the intersection \( p \) (P) of the threads may be brought to any point of the open space within the arches. In the grove \( k \) (K) is a straight sliding bar \( i \) (I), which
which may be drawn farther out, or pulled farther in, at pleasure.

To the outer end of this bar $I$ (fig. 2.) is fixed the upper right piece $HZ$, in which is a groove for receiving the sliding piece $Q$. In this slider is a small hole $r$ for the eye to look through in using the machine; and there is a long slit in $HZ$, to let the hole $r$ be seen through when the eye is placed behind it at any height of the hole above the level of the bar $I$.

In delineating a perspective representation, $e.g.$ of the house, $q,s,p$, a great way off, place the machine on a steady table, with the end $F$ of the horizontal board, $A B E F$, toward the house. Draw the Gothic-like arch $D L C$ let upright, the middle part of the open space (about $P$) within it may be even with the house when you place your eye on $Z$, and look at the house through the small hole $r$. Then fix the corners of a square piece of paper with four wafers on the surface of that half of the horizontal board which is nearest the house; and all is ready for drawing.

Set the arch upright, as in the figure; which it will be when it comes to the perpendicular side $r$ of the upright piece $s$, fixed to the horizontal board behind $D$. Then place your eye at $Z$, and look through the hole $r$ at any point of the house, as $q$, and move the sliders $N$ and $O$ till you bring the interection of the threads at $P$ directly between your eye and the point $q$; then put down the arch flat upon the paper on the board, as at $S T$, and the interection of the threads will be at $W$. Mark the point $W$ on the paper with the dot of a black lead pencil, and let the arch upright again, as before; then look through the hole $r$, and move the sliders $N$ and $O$ till the interection of the threads comes between your eye and any other point of the house, as $p$; then put down the arch again to the paper, and make a pencil mark thereon at the interection of the threads, and draw a line from that mark to the former one at $W$; which line will be a true perspective representation of the corner $p q$ of the house.

Proceed in the same manner, by bringing the interection of the threads successively between your eye and the other points of the outlines of the house, as $r i$, $s$, &c. and put down the arch to mark the like points on the paper at the interection of the threads: then connect these points by straight lines, which will be the perspective outlines of the house. In like manner find the points of the corners of the door and windows, top of the house, chimneys, &c. and draw the finishing lines from point to point: then shade the whole, making the lights and shades as you fee them on the house itself, and you will have a true perspective figure of it. Great care must be taken, during the whole time, that the position of the machine be not shifted on the table; and to prevent such an inconvenience, the table should be very strong and steady, and the machine fixed to it, either by ferews or clamps.

In the same way, a landscape, or any number of objects within the field of a view through the arch, may be delineated, by finding a sufficient number of perspective points on the paper, and connecting them by strait or curved lines as they appear to the eye.

The arch ought to be at least a foot wide at bottom, that the eye at $Z$ may have a large field of view through it; and the eye should then be, at least, $15$ inches from the interection of the threads at $P$ when the arch is set upright. For if it be nearer, the boundaries of view at the sides near the foot of the arch will subtend an angle at $Z$ of more than sixty degrees, which will not only strain the eye, but will also cause the outermost parts of the drawing to have a disagreeable appearance. To avoid this, it will be proper to draw back the sliding bar $I$, till $Z$ is $14\frac{1}{2}$ inches distant from $P$; and then the whole field of view, through the foot-wide arch, will not subtend an angle to the eye at $Z$ of more than forty-five degrees; which will give a more easy and pleasant view, not only of all the objects themselves, but also of their representations on the paper whereon they are delineated. So that, whatever the width of the arch be, the distance of the eye from it should be in this proportion: as $12$ is to the width of the arch, so is $14\frac{1}{2}$ to the distance of the eye (at $Z$) from it.

If a pane of glass, laid over with gum water, be fixed into the arch, and the eye put upright when they are perfectly level; through the hole $r$ may delineate the objects upon the glass which he sees at a distance through and beyond it, and then transfer the delineation to a paper put upon the glass. Ferguson's Perspective, chap. iii.

Mr. Kirby has also contrived and described an instrument that will be useful in taking extensive views, &c. The ruler $A B$ (fig. 3.) is $19$ inches long, and is graduated into $19$ equal parts; it has a dove-tail groove on its upper edge to receive the perpendicular ruler $G$, which has one end fitted to it, so as to slide very easily; this ruler is $14$ inches long, and is divided into $14$ equal parts, and upon the back side of it $F$ is a line drawn exactly in the middle, to which is fixed a sliden line with a small plummet at the end. The ruler $A B$ is fixed by two ferews $a, c$, to two pieces of thin brafs; and these pieces of brafs are fixed at the other ends by two ferews $d, e$, to a stroner piece of brafs $b f$, which goes close to the ruler $A B$, and has a joint at $X$ turning upon a ferew: below this joint is a piece of round brafs about six inches long, which goes into a hole through the head of the ruler, and serves to stiffen it at a proper height, or lower, by means of a screw $C$. $C D E$ represents part of this staff, the whole length of which is about three feet, and at the bottom is a rank ferew made of iron and fixed to the staff. $H I$ is a wire $22$ inches long, with a ferew at $b$ to go into the hole $b$; the piece of brafs wire bent into the form $i k$, is fixed to the wire $H I$ by the ferew $k$; and the part $i$ goes into the hole $f$ in the brafs-piece $b f$. The small wire $K L$ is about $12$ inches long, and flattened at $K$, at which place is a little hole above one-eighth of an inch in diameter; this wire $K L$ is fitted to the holes $l, m, n, o$, which are made in the larger wire $H I$, and it may be placed higher or lower by means of a small screw. This instrument is used in the following manner: fix a paper upon a drawing board, as in fig. 4, and divide the paper lengthways into $19$ equal parts, and perpendicularly into $14$ equal parts; making these divisions greater or smaller according to your design. Then take the staff, and fix it strongly in the ground by means of a ferew at bottom, and at a convenient distance from the prospect which you intend to take. After this, put the instrument together as in fig. 5, and fix the ruler $A B$ exactly horizontal by means of the plummet on the perpendicular ruler and the brafs joint $X$; then fix the wire $K L$, so as to have the eye-hole exactly level with the horizon or equal to the height of the eye, and take care to have the greatest distance of the eye-hole from the ruler equal to the whole length of the longest ruler $A B$, and never less than the distance $b l$. Having thus fixed the instrument, proceed to make the drawing; look through the eye-hole, and then move the perpendicular ruler in the groove, till you get one edge exactly against some principal object; then will the parts upon the ruler shew how high the object is from the bottom of the ruler, $i. e.$ from the bottom of the picture, and you will
will also know its apparent height; therefore transfer this to the paper in those figures which correspond with the divisions upon the rulers. For the breadth of objects, move the perpendicular ruler so as to be even with the sides of an object, and the divisions upon the lower ruler will shew their apparent breadths. After the same manner, get the places and apparent sizes of as many principal objects as are necessary for affording you, in completing the whole drawing, which may be done by this method with great exactness. When the drawing is finished, the instrument may be taken to pieces and put into a box, which may serve as a drawing board; the top may be screwed into the staff, which will serve as a walking-stick, and the too to fit on may be made very portable: so that every part of this apparatus may be carried by one person without any inconvenience.

Kirby, ubi supra, b. ii. p. 65, &c.

**Perspective, Military,** is that wherein the eye is supposed to be very remote from the table or plane. See Bird's Eye View, in Perspective.

**Perspective, Scenographic.** See Scenography.

**Perspective of Shadows.** See Shadow.

**Perspective, Specular,** is that which represents the objects, in conical, spherical, or other mirrors, erect and clear, whereas on other planes they appear confused and irregular. See Mirror and Anamorphosis.

**Perspicuity,** Perspicuitas, in Rhetoric, is a principal excellence of style, to which all the ornaments and beauties of speech ought to give way: as it is necessary to render a discourse intelligible, and forms one of the constituent parts of elegance. "Prima el eloquentiae virtus perspicuitas," says Quintilian, lib. viii. cap. 2. There are three different ways in which perspicuity in a composition may be violated; viz. by obscurity, ambiguity, and unintelligible expression. The common sources of obscurity are some defect in the expression, arising from ellipses in language, the affectation of conciseness, or rapidity of thought in writers, or a bad choice of words; a bad arrangement of the words, so that the construction is not sufficiently clear; the use of the same word in different senses in the same sentence, an uncertain reference in pronouns and relatives: too complicated or artificial a structure of the sentence, so that the sense is too long suspended by parentheses; the injudicious introduction of technical words and phrases; and, lastly, very long sentences. Ambiguity may be occasioned either by using some expression which is equivocal, or by ranging the words in such an order that the construction is rendered equivocal. The fall fault proceeds either from great confusion of thought, which is commonly accompanied with intricacy of expression, or from affectation of excellence in the diction, evidenced by the injudicious use of figures, or from a total want of meaning. In these several ways, a speaker may express himself obliquely, and so convey his meaning imperfectly to the mind of the hearer; or express himself ambiguously, and so, along with his own, convey a meaning entirely different; or express himself unintelligibly, and so convey no meaning at all. Dr. Campbell in his "Philosophy of Rhetoric," vol. ii. book 2, chap. 6, has well exemplified and exposed these offences against perspicuity. It is partly observed by Quintilian, ubi supra, that by perspicuity, care is taken, not that the hearer may understand, if he will; but that he must understand, whether he will or not. See Style.

**Perspiration,** in Physiology, the office of the skin, by which it forms and discharges various matters, principally fluids, from the blood; or the matters themselves so discharged. It is distinguished as sensible and insensible, according as it consists of fluids recognizable by the senses, or of such as escape our observation. See Integuments.

**Perspiration of Plants,** in Vegetable Physiology, takes place chiefly from the surface of their leaves. In order to collect the liquor perspired, it is only necessary to introduce a branch of the plant into any sufficiently capacious glass vessel; when the fluid which exudes will trickle down the sides of the glafs, in great abundance, especially if the experiment be made in fun-flime. The liquor thus obtained is of a clear watery nature, scarcely distinguishable to our senses, or to our chemical enquiries, from the sap of the same plant, whatever it may be, procured by wounding its branches before the foliage expands. This, which may be termed the insensible perspiration of plants, becomes in some cases sensible; as when it runs down, like a flight flower, from Willow or Poplar trees, in hot sultry weather; or when it collects in drops on the leaves of Plantain trees in a snow. Hales and others have made experiments to ascertain the quantity of insensible perspiration in various plants. The great annual Sun-flower was found to perspire about seventeen times as much as the ordinary insensible perspiration of the human skin. The Cornelian Cherry, Cornus mas, is said to discharge, in twenty-four hours, as much fluid as is equal to twice the weight of the whole shrub. Succulent leaves perspire much flower than others, though they absorb in a far more rapid proportion.

This watery perspiration is the only excremenitious discharge of the vegetable body. The sap being carried up into the leaves, where it is acted upon by air and light, for the most important purpofes, yields those various and highly curious secretions, which, being carried down into the bark, afford matter for the increase of the tree, as well as for the manifestation of its various qualities. The great bulk of the sap which remains, as it does not return to the root, like the blood of animals to their heart, can be disipopofed of no otherwise than by a copious evaporative process of the leaves. Darwin is of opinion that this watery perspiration rendered a further service to the plant, by being acted on by light, so as to give out oxygen, which was immediately absorbed by the air-vessels. But this hypothesis is inadmissable on many accounts, nor need we here repeat that which is adopted under the article Leaf.

The sensible perspiration of many plants is of a very different nature from the above watery evaporation, and is to be considered as an actual secretion. Such are the mucilaginous exudation found on the leaves of the Lime-tree, Tilia europae; the faccharine matter perceptible on Orange trees, hops, beech, and other plants, which is one kind of honey-dew, and either owing to some injury to their roots, or to the sudden influence of a cold, or otherwise noxious, atmosphere. The Ciflus genus, and many other shrubs of warm countries, afford a resinous exudation from their leaves and young twigs. The Fraxinella, Dictamus albus, is very remarkable for a highly inflammable vapour, which in hot still weather issues from, and hovers around, the plant, exploring on the approach of a lighted taper. Manu is said to have been scarped from the leaves of Fraxinus Ormus, though usually procured only from the sap of that tree. A kind of wax may in like manner be obtained, as some report, from the leaves of Rosemary. A copious glutinous perspiration is observable on young leaves of many kinds, as the Cherry, Plum, various Poplars, and abundance of aromatic herbs. Pelargonium inguinale is singular for its exudation of a soft oily matter, that stains the fingers with a red or vermilion-like tinge.

PERTELS, a town of Austria; six miles N. of Bohminf Weidlofen.

PERTH, a royal borough, and the county town of Perthshire, Scotland, is situated in the middle of a verdant plain, on the western bank of the river Tay, at the distance of forty miles and a half N. by W. from Edinburgh. This plain is divided by the town into two parts, called the north and South inches, or islands, each of which measures about a mile and a half in circumference, and both are appropriated for the benefit and amusement of the inhabitants of the place.

Perth is a town of very high antiquity, and is generally allowed to have owed its origin to the celebrated Roman general Agricola, who penetrated into this part of the country about the year 70. He is said to have fixed on this spot the site of the city, originally of a winter camp, and afterwards of a colonial town, from the resemblance its scenery bears to that in the vicinity of ancient Rome. So striking is the similitude, indeed, that the Roman soldiers when they first saw the river Tay, and the adjacent plain, are recorded to have exclaimed with one consent, "Ecce Tiber! Ecce Campus Martius! Behold the Tiber! Behold the field of Mars." Hence the Tay was called New Tiber, by the Italians for many centuries; and Foroum, a Scottish historian, gives the name of Tyber-Mere, to an extensive moor which lies west of the town. An aqueduct, said to have been constructed here by Agricola, is still in existence, and supplies the mills and wells with water. In ancient times when the town was fortified, it also supplied the ditches, by which the latter was surrounded.

Of the history of Perth during its Roman occupation, and for several centuries after the retreat of that people from Britain, nothing certain is known. Neither is it recorded at what period it became a chartered town. Alexander Nechan, an English writer, who read lectures on history at Paris in 1180, described Perth as a place of great opulence. In 1210, according to the Scottish historians, it was strongly fortified by king William, who also renewed its former charters, and granted it many additional privileges. At that time Perth was reckoned the capital city of Scotland, and even at the present day it ranks inferior only to Edinburg and Glasgow. Between the years 1201 and 1459, no fewer than fourteen great national councils were held here. During the fame period, Perth was also the usual residence of the Scottish monarch, and consequently of the nobility, many of whose ancient mansions still adorn its streets. It was then likewise, as it is still, an extensive commercial town. Fordun informs us, that the merchants of Perth visited, in their own ships, the Hanse towns; and it is a part of the eulogium conferred on Alexander III., who died in 1286, that he devised successful measures for securing the trading ships of that nation against pirates, and against being detained on flight pretences in any foreign port. "In consequence of the care which he exercised about the trade of the kingdom, which, for some years during his minority had been on the decline, multitudes of ships soon came from divers regions loaded with goods of various kinds to be exchanged for the commodities of this country."

The German merchants, or Flemings, also early frequented the port of Perth with mercantile views; and many individuals of that nation conversant in the linen and woollen manufactures, and in staining of cloth, appear to have fixed their abode in the town, and to have been received as burghers. King William, however, following the example of his grandfather king David, put the foreign merchants of Perth under great restrictions; and to prevent the settlement of foreign manufacturers there, granted, in his charter already mentioned, that the burghers might have a separate guild of their own, "fullers and weavers excepted."

Edward I., of England, added greatly to the importance of Perth, by increasing the strength of its fortifications, and making it the residence of his deputies. King Robert Bruce conceiving its occupation to be of signal importance to his cause, attacked this town in 1306, but was repulsed by the earl of Pembroke, who fell out, and defeated the king at Methven. In 1311, however, Bruce renewed the attack, and after an obstinate siege of six weeks, succeeded in storming the fortifications, which he levelled with the ground. After the battle of Duplin, these were re-edified by Edward Baliol, but were soon again razed by the patriotic Scots. In 1335 king Edward III. took possession of Perth, and refided in it for a considerable period. According to the English historians, John, earl of Cornwall, brother to that monarch, died here in Oct. 1336; but they omit a singular circumstance mentioned by Fordun, which is, that he received his mortal wound from the king's own hand. In 1339 Perth flood a long siege against the regent Robert, but was taken by draining the ditch. In 1437 James I. of Scotland was murdered at the Black Friars monastery, by Robert Graham, who wounded him in twenty-eight different places, and the queen twice, during the scuffle between them. At this period the town walls seem to have been in a state of demolition; as we find them repaired, at a very considerable expense, by king James II., from whose reign nothing of a political nature worthy of notice occurs on record, till the year 1600, when the earl of Gowrie's house here was the scene of one of the most problematical events in Scottish history. We allude to the execution of what is commonly designated the "Gowrie conspiracy," by John Ruthven, the then earl, and his brother Alexander. These two young men, according to the story published by the court, having prevailed upon king James I. to visit Perth, (on the pretence of shewing him a suspicious person whom they had apprehended,) attempted to murder him, but were foiled in the attempt, and both slain by his majesty's attendants. Upon this, the inhabitants of the town assembled round the house, threatening revenge upon the royal party, and it was with considerable difficulty they were prevailed on to disperse.

After the battle of Tithermoir, in 1644, Perth was feized by the marquis of Montrose; and in 1651 it was taken by Cromwell, and fortified with a citadel on the South inch, capable of containing a garrison of five hundred men. In 1715 the earl of Marr, at the head of a detachment of the rebels, obtained possession of it, and occupied it as a place of arms, till after the battle of Dunblane, on Sheriffmuir, when they were dilogged by the duke of Argyle, and compelled to retreat further to the north, with the Pretender. The fame party likewise held this town in 1745, when prince Charles was proclaimed king, and new magistrates were appointed. The modern prosperity of Perth may be dated from this period; for being the centre of the rebellion,
rebellion, it was the resort of all the disaffected from the north, during a considerable length of time. Thus its ancient activity was in some degree revived. The march and refidence of the contending armies produced a market here for all sorts of goods; capital was gained by inducious pedlars; and advantage taken of its favourable situation to render it a place of trade. Hence it has been remarked that Perth is a singular instance of a town that owes its prosperity in a great measure to the calamities attendant on rebellion and civil war. Since that turbulent period it has increased nearly one half in extent and population.

Perth, in its municipal capacity, is a royal borough, and joins with Dundee, Forfar, Cupar of Fife, and St. Andrew's, in sending one member to parliament. It is governed by a provost, three bailies, a dean of guild, a treasurier, and nineteen councillors, most of whom are elected from the incorporated trades. The funds of the corporation are very considerable, and of late years have been expended with great judgment in various improvements. Perth being the county town, the sheriff's-court meets here; and the lords of justice hold a court here every six months, when they go on their circuits. The provosts have been sheriffs within the town since the time of king Robert III. They bear also the office of coroner, which office however is never exercised in Scotland.

This town, considered in reference to its buildings, is one of the handsomest in Scotland. It occupies a site which might, indeed without impropriety, be selected as the seat of government, and the emporium of commerce. The Tay, which is navigable up to the quays at common tides for floops and small craft, and in spring tides for vessels of large burden, admits of great extension of trade. This river flows here in a direction nearly north and south; but at a short distance below Perth it turns to the westward, and is lost behind the hill of Kinoull. Over it is a handsome bridge of ten arches, which cost about 25,000l. and is 906 feet in length, and 22 in breadth, with the parapets. The piers are founded ten feet beneath the bed of the river, upon oaken and beechen piles. The architect of this magnificent structure was Mr. Smeston. It connects Perth with Kinoull, which is a borough of barony under the superiority of the nobleman who holds that title.

The two chief streets in Perth are called the High street and South street, both of which run from east to west, and are nearly parallel to each other. Along the side of the river runs another considerable street. The new town, which was begun in 1798, contains a circus and a terrace of very handsome appearance. This portion of Perth is situated on a plot of ground, where formerly stood the monastery of Black friars, in which James I. of Scotland was murdered, as has been already mentioned.

Among the public buildings are several worthy of attention. The town-house, which forms the eastern termination of High street, is a large well built structure, as is likewise the guildhall, which stands about the middle of the same street. Several of the incorporated trades have halls, of which that of the Glover's is the most elegant. The parish church, which was formerly the property of the abbey of Dumfermline, and is a large and ancient edifice, is now separated into three divisions, called the ealt, middle, and west kirk; besides there is another parish church, dedicated to St. Paul, a chapel of ease, and a variety of chapels and meeting-houses appropriated to the public worship of dissenters. St. John's church is remarkable from the circumstance of the reformation in Scotland having first publicly broke out here, on the 11th of May 1550, when John Knox preached a sermon against idolatry, after which the priest being imprudent enough to display his images and relics, he was attacked by the audience, who broke the images in pieces, tore the pictures, overthrew the altars, and entirely defaced every implement of Catholic superstition in the church. This done, they proceeded to the different monasteries in the town and its neighbourhood, and pillaged or demolished the whole of them.

The chief institutions in Perth of a public nature are a grammar-school, an academy, and a literary and antiquarian society. The grammar-school has long been regarded as one of the belt in Scotland. Many celebrated statesmen and scholars have received the early part of their education here; and, among others, the admirable Crichton, and the late celebrated and excellent William, earl of Mansfield. The academy is of much more recent establishment than the school, having been commenced about the year 1761. It is, however, in a very flourishing condition, and is usually attended by from eighty to a hundred students, who are instructed in various branches of learning. The literary and antiquarian society was founded 16th December, 1784. Belonging to this institution is a general library, besides a large collection of rare books, original essays, ancient manuscripts, coins, medals, and other subjects of antiquity, suitable to the definition of the establishment.

Perth at present is a place of very considerable trade. There is a constant intercourse by water between Perth and London. Every four days, during the fishing season, a smack fails, and usually makes the passage within a week. A number of merchant vessels likewise frequent this port; and those of heavier burden are loaded or discharged in the river, by means of hoys. The staple manufacture of the town is linen; but the cotton trade is rapidly on the increase. The number of looms employed in the town and suburbs is estimated at about two thousand. Cotton-mills, bleach-fields, and print-fields, have been established in different schools, and leather is also one of the manufactured products of Perth; and great quantities of that article are made into boots, shoes, and gloves, for foreign consumption. From the vicinity of the Highlands, the manufacture of doe-skins and buck-skins has long been established in this town. Here is a respectable banking establishment, under the firm of the Perth Bank; besides a branch of the bank of Scotland.

Perth, according to the parliamentary returns of 1811, is divided into four parishes, and contains in the aggregate 4715 houses, and 16,948 inhabitants. The markets are well supplied with all kinds of provisions and luxuries. The annual fairs are eight in number, and are usually well attended.

Of the ancient importance of Perth, while it was a royal residence, few traces remain; with the exception of the parliament-house, and some modernized mansions of the old nobility; such as the houses of the bishop of Dunkeld, earl of Errol, and earl of Athol. The original fortrefs belonging to the town is now a ruin, and not even the seats of its monastic institutions are discoverable to the eye. Gowrie-castle, already mentioned as the residence of the earls of Gowrie, is situated on the four-east side of the town. It was built, or, perhaps, more properly speaking, rebuilt, in 1520, by the countess of Huntly. After the forfeiture of the Gowrie estates, it became the property of the corporation, and was presented in 1746, by the magistrates, together with the freedom of the burgh, to William, duke of Cumberland, who afterwards sold it to the board of ordnance for the sum of 5000l.; and it has ever since been appropriated as barracks for a company of the royal artillery. In the pleasure-grounds attached to this house is a curious structure, called the Monk's-Tower, the origin and former
The Great and Strong Spey Tower,
And Monk's-Tower builded round a wall of power.

The Spey Tower is gone; it was a stately fortres, and had a strong prison. The Rockis of Craigie were governors of the fortresses. At the reformation, Robert Rofs of Craigie delivered up the keys under a protestation. There remains nothing of it but a pitiful ruin, where the toll-house is. Monk's-Tower yet stands, as described in the poem, in the south-east corner of the garden, on the highest line of the train of artillery. The wall between this and the Spey Tower is the wall of the garden, and the fosse without dull remains.

In digging the foundation of the house here, belonging to colonel Mercer of Aldie, the remains of an ancient British temple were discovered. This edifice is mentioned by Holinshed, and by Jeffrey of Monmouth; the latter of whom says, it was erected by a British king, son to Regan, the second daughter of king Lear. It was dedicated to Mars, and, as we presume, must have been of later date than the Roman invasion, as the architecture of its ruins exhibited considerabled advancement in the building art.

The parishes of Perth, without the town, extends about four miles in length, and three miles in breadth. The soil varies, but is extremely fertile, and well cultivated. The adjacent scenery is highly beautiful, but, owing to most of the estates here being entailed, gentlemen's seats are few, and numbers of other tenants may have been the castle of Ballⲟu, an ancient seat of the earls of Kinnoull, the Castle of Pit-thevils, an ancient seat of the lords Oliphant; and Few-house, a seat belonging to Mr. Marshall of Hall-Cairney. The barracks, in the immediate vicinity of the town, likewise deserve to be mentioned among its ornaments. See Beauties of Scotland, Svo. vol. iv. 1801; also, A Topographical Dictionary of Scotland, by N. Carlile, F.S.A. 2 vols. 4to. 1813.

The five articles of Perth, so called because they were carried by the influence of the court and bishops at a convention or assembly summoned to meet at Perth Aug. 25th, 1618, are as follow: 1. That the holy sacrament should be received kneeling. 2. That ministers should be obliged to administer the sacrament in private houses to the sick, if they desired it. 3. That ministers might baptise children privately at home, in cases of necessity, only certifying it to the congregation the next Lord's day. 4. That ministers should bring such children of their parishes as could say their catechism, and repeat the Lord's prayer, creed, and ten commandments, to the bishops, that they might confirm them and give them their blessing. 5. That the festivals of Christmas, Easter, Whitsuntide, and the Ascension of our Saviour, should for the future be commemorated in the church of Scotland. The king ordered these articles to be published at the market-croffes of the several boroughs, and the ministers to read them in their pulpits; but most of the ministers refused, as they were founded upon no penalty except the king's displeasure. The king, however, determined to obtain the ratification of parliament, issued a proclamation, commanding all ministers who opposed them, and who were preparing a supplication against them, to leave the city of Edinburgh within 20 hours. The ministers obeyed, leaving behind them a protestation against the articles, and an admonition to the members of parliament not to ratify them, as they would answer it in the day of judgment. The court interest prevailed, and the articles were ratified, contrary to the sense of the Kirk and nation. This measure occasioned a persecution through the kingdom, and many of the Presbyterian ministers were fined, imprisoned, and banished by the high commiss. Thus far, King James proceeded towards the restitution of episcopacy in Scotland; but there was still wanting for the completion of the work a public liturgy, or book of common prayer. An inscription through the whole kingdom being apprehended, he defiled from enforcing this unwise measure, and left it to be finished by his son, whose impulsion of it upon the Kirk, without consent of parliament or general assembly, let fire to the discontent of the people, which had been gathering for many years, to demand a new form of church government.

PERTH-AMBOY, a city of America, in New Jersey, pleasantly situated in Middlesex county, at the head of Raritan bay, on a neck of land included between Raritan river and Arthur Kull Sound. Its site is elevated and faubrious. It lies open to Sandy-hook, and has one of the best harbours on the continent, into which vessels may enter in one tide, in almost any weather. It is a port of entry and port-town; but although it is admirably situated for trade, and the legislature has given every encouragement to merchants to settle here, it is far from being in a flourishing state. It contains about 60 houses, and carries on a small trade to the West Indies; 35 miles S.W. of New York. N. lat. 40° 35'. W. long. 74° 30'.

PERTHSHIRE, one of the most extensive and important counties in the northern division of Scotland, is bounded on the S. by the Frith of Forth, and the counties of Stirling and Clackmannan; on the S.W. by the county of Dunbarton; on the W. and N. by Argyle and Invernesshire; on the N. by the latter county and Aberdeen; on the E. by Forfarshire; and on the S.E. by the counties of Kinros and Fife. Its greatest length from E. to W. is, from Blairgowrie to Benloi, measures 77 miles; and its greatest breadth from the Forth at Culros on the S., to the northern extremity of Athol, is not less than 68 miles. According to the best surveys, its superficial contents are estimated at 5000 square miles; that is, 3,200,000 Scotch acres, or 4,068,640 English acres. The whole of this tract was anciently divided into the districts of Athol, Breadalbane, Rannoch, Strathearn, Balquidder, Monzie, Gowrie, Perth and Stornmont, which were called steuaries, and were placed under the hereditary jurisdiction of the great proprietors of lands. These distinctions, however, are now abolished in effect, but are nevertheles still recognized in the common language of the inhabitants.

General Character of the County.—The surface of this county presents, as might be expected from its great extent, much diversity of appearance. It is naturally divided into two portions, called the Highland and the Lowland districts. The former is of bold, mountainous character, and exhibits
fens of the most rugged and romantic magnificence, while
the other is finely intergraded with hill and vale, and dis-
plays all the beauties which the highest cultivation is capable
of manifesting. At the foot of the Grampian hills is the
fertile valley of Strathmore, which is succeeded by the no-
less luxurious and extensive vale of Strathearn. The Carle
of Gowrie has long been considered as the pride of Scot-
land in point of natural prodigies, and is certainly in-
ferior to no portion of Great Britain in the excellence of its
agricultural system. The territory along the Forth is like-
wise in many parts fertile and beautiful, and even the gles
and declivities of the towering Grampians, and their rival
Ochils, offer features of superior exuberance and of partial
cultivation.

Mountains.—Perthshire is intergraded by three very lofty
chains of mountains; called the Grampian, the Ochil, and
the Sidley or Sidlaw hills. The first are celebrated, and
generally well known. They extend in a north-eastern di-
rection, almost across the whole of Scotland, and constitute
what may be termed the Highland district of this county.
(See GRAMPIAN HILLS.) The Ochils bound the vale of
Strathearn on the S., and stretch themselves through the
county of Clackmannan into that of Fife. (See OCHIL
HILLS.) The Sidley hills lie more to the N.E., and extend
from the vicinity of Perth in a direction parallel to the
Grampians. In all these ranges of hills, but particularly in
the Grampian chain, are many summits of very great eleva-
tion. These following are among the most conspicuous for
size, and perpendicular altitude above the level of the
ocean.

Mineralogy, and Mineral Products.—Considering the great
extent of Perthshire, and the character of its surface, we
might readily suppose it to afford abundant materials of in-
terest to the mineralogist. This is accordingly the fact, in so
far as regards scientific investigation; but in a political, or
economic point of view, the minerals of this county are
not of very high importance. The rock of which the Grampi-
ans chiefly consists is granite. On the southern ridges, or
skirts of these mountains, however, both slate and fine-flake
are found in abundance; but here the great sandstone fra-
tum of Scotland terminates, in like manner as the coal field
does to the southward of the Ochils. Hence it may be re-
marked, that Perthshire contains within itself the boundary
between the sandstone and the granite, for the former is only
discovered in small patches to the north, and the latter se-
doms itself to the south, except in the mountains of
Galloway. What is curious, the secondary minerals on the
ridges of the Grampians, such as flate, limestone, and even
sandstone, are affected in their properties by the proximity,
or intermixture of the primary rocks. Thus in the parish of
Little Dunkeld, below Murphy, is an inexhaustible body
of a very fine grained free-flone, which is of a light livid ahi-
colour, and so hard as to resist the action of the atmosphere
for many centuries. The cathedral of Dunkeld was built
of stones from this district, and fully corroborates the above
assertion. In the hills of Birnam the flate is of a very deep
blue colour, bordering on violet; and the same is nearly the
character of the limestone found at Rannoch, Glenlyon,
Breadalbane, and the head of Strathearn. In Montearth is
also a quarry of the same mineral, resembing marble, of
a blue ground, with streaks of white.

Iron-flone appears in some parts of this county, but no
mines of that metal have ever been opened, except on the
southern side of the Ochils, about Culrofs, which, we may
here observe, is the only coal district in Perthshire. A lead
mine was wrought for many years near Tyndrum, in Bread-
albane, as was likewise one in Glenlyon, but these are now
both abandoned. Some lead ore was also discovered about
twenty years back in the mountain of Ben-Ledi. One vein
on the north-east side of the mountain was found to be ex-
trmely rich in silver, but its dimensions were too small to
admit of its being wrought to advantage. In the hill of
Birnam also, several pieces of lead ore have been dug up.
This ore was encrusted with a white sparry, or rather quartz-
ose fibulance. One piece, about six pounds in weight,
confined of unmixed compact ore, of a very small grain,
which produced a considerable portion of pure lead, by mere
reasting in a blacksmith's forge. It was found at the base
of the hill, but the figures on its summit are frequently
filled with similar masses.

Siltes are abundant in different portions of the county.
The principal stratum commences on the borders of loch
Lomond, in Dunbartonshire, and seems to terminate in the
vicinity of Dunkeld. These strates are of two kinds, and
called, from their colour, the blue, and the grey strates. The
former, which are by far the most valuable, are plentiful in
Montearth, and along the north side of the Ochils. Grey
strates also are found in vast quantities in the same districts,
as well as in Strathallan and Strathearn. They consist of
sand-flone, which may be split into thin layers, frequently
six feet square, and are, since the introduction of blue strates
in roofing, chiefly used for malt-kilns, floors, and pavement.
In the parishes of Weiler Foulis is a blue slate quarry of great
value, but it is not wrought to any very considerable extent,
on account of its distance from water carriage.

The best quarries for free-flone in Perthshire, are those in
the parish of Tulliallan on the Forth, and on the estate of
Milnfield, in the south-eastern corner of the county. The
former have long been held in high estimation; and were for many
years wrought by a Dutch company. The latter, however, are
still superior to them, and indeed may be justly reckoned the
best in Scotland, if not in Great Britain. The flone from
these quarries, on account of its fine quality, is commonly
called Kingoode flone. It is of a greyish colour, difficult to
work, and uncommonly hard and durable; so much so, in-
deed, that in several structures built of it four or five cen-
turies ago, scarcely a flone flake has yielded to the influence
of the weather. The Milnfield quarries produce flones of
all sizes, and for every purpose of building. Many of the
blocks raised exceed fifty feet in height, and sixteen in
breadth, and three so thin as to be adapted for pavement,
or for covering flat roofs.

In the vicinity of Drummond castle, and more especially
close to Callender, that peculiar species of rock called brec-
cia, or plum-pudding flone, is very common. It is com-
pofed of a vast variety of small rounded flones, cemented to-
gether
gather by a foot of brown lava. The rounded flones are of
different colours, and are so firmly united, as to form one
solid mass of rock, capable, when used as a building ma-
terial, of withstanding the action of the atmosphere for ages.
It is not, however, susceptible of being smoothed by the
chisel, but admits of being dressed with the hammer. The
vein of it above Callender runs in the direction of south-
west and north-east, for a distance of various miles through
lakes and rivers, mountains and valleys, in a line parallel with
the slates and lime flone strata, and at the distance of about
a mile from each. The hill of Kinnoul, the most westerly
of the Sidlaw chain of mountains, is indeed a perfect min-
erological curiosity, on account both of its peculiar structure
and composition. The southern side presents a stupendous
precipice of the most ragged rock, consisting of lava, in
which different layers or currents are very evident. Some
parts of this rock are perfectly compact; but the greater
proportion of it is full of small cells, resembling thole in
the flag of an iron foundery. Its colour is generally of a
greyish tinge, approaching to lilac. When melted, it forms
a vitreous substance of a dark purple hue, so tenacious that
it could easily be blown into bottles. Among the flones at
the base of this hill, are frequently found very fine agates,
which have fallen from the precipices above, where, by the
affiliation of a pocket telescope, great numbers may be seen
flicking. Sulphate of barytes, rock crysufal, and calerody,
also enter into the composition of this rock. Rhomboidal
calcareous flsp is likewise occasionally discovered here, togeth-
er with a greenish coloured flavie, or soap-flone. A
ridge of the last mentioned rock, about four miles in length,
is found in the district of Montach; and in the neighbour-
hood of Culrofe are extensive beds of fire clay.
From the intimate connection between the mineral springs
of any county, and the solid mineral substances contained
in its bowels, we may here mention that the most remarkable
impregnated flnings in Perthshire, are those of Pitkethly,
which are famed for their efficacy in curing or alleviating
the scrofula, febrity, and gravel; while at the same time
they give tone and vigour to the constitution. When these
springs were discovered is unknown, as even tradition is
silent upon the subject. They have, however, been much
frequented for many years by patients from all parts of the
country. See Pitkethly.

Rivers.—Perthshire is most abundantly supplied with
rivers, as various in their extent as they are diversified in
scenery, and interlacing from alliance with the events of
history, or the strains of poets. The principal among them
are the Forth and the Tay, the former of which receives the
Teath, the Allan, and the Devon, and the latter, the Earn,
The Almond, the Lyon, and the Tummel, (which last is
joined by the Garry, the Braur, and the Tilt;) also the
Bran, and the united streams of the Illa, the Ericht, the
Shee, the Eardle, and the Dean, all of which are juilly
deferring of separate notice, even in article so limited as the
present. See Forth.
The Teath has its source at Benarrow, near Glenfalloch.
Shortly after its rise, it falls into loch Katharine, but issuf
from it again at its easter extremity, it forms Loch Achnak
and Loch Venachar. At Callender it is joined by the Bal-
vay water, and meandering along by Lannick and Downe
calles, Blair Drummond and Ochtertyre, enters the Forth
near Drip. On this river is a valuable pearl fihery. See
Teath.
The Allan rives at Gleneagles, on the northern side of the
Ochil. Its course is at once circuitous and winding, and
its banks, especially from Dumblane to Lecropt, where it
leaves Perthshire, exhibits some of the most beautiful scenery
of which Scotland can boast. Bows has made this river the
theme of one of his finest songs.
The Devon, or Down, has its spring in the parish of Alva,
whence it flows easterly to the Crook of Devon, where it
turns suddenly to the westward, and palling by Dollar, Tilly-
courty, and Alva, pours its waters into the Forth, nearly
opposite to its source, and only five miles from it, though it
runs a course of about forty miles. This river is remark-
able for several natural curiosities, called the Devil's mill, the
Rumbling bridge, and the Cauldron Linn. The Devil's
mill is formed by the water falling by a rapid dellent into
a basin excavated in the rock, and thence into a cavity under
ground, in palling through which it is so strongly agitated
by the peculiar construction of the enclosing rocks, that it
emits a found remoulding that made by the movement of a
large mill. The Rumbling bridge is situated about 350 yards
below the mill. Here the precipitous banks of the river
approach so close to each other, that an arch twenty feet span
is sufficient to form the communication between them; yet
the depth from the bridge to the water is upwards of eighty-
six feet. It is called the Rumbling bridge, from the rum-
bling noise occasioned by the water falling from rock to rock
in its passage through this almost hidden dingle. The Ca-
dron Linn is situated about a mile lower, and consists of two
falls, not more than twenty-eight feet afounder. The first
is thirty-four feet in height, and not more than twelve feet
broad. The second fall is still higher, and between them are
three round cavities, having the appearance of immense caul-
drons, in the highest of which the water is in confluent agita-
tion, as if boiling, while the second is always covered with
foam, and the third is uniformly calm and placid. These
cauldrons are of different dimensions, the smallest being
about sixteen feet, and the largst twenty-two feet in di-
ater. When the river is low, they are seen to communica-
tate by apertures formed by the force of the water, through
the rocks which separate them at perhaps the middle depth of
the cauldron. Hence the great cauldron which commu-
nicates with the lower fall is perforated with a large opening,
refembling a window, out of which the entire body of water
precipitates itself over the rocks with much violence, and
with a very flaking and picturesque effect, particularly if
viewed from below, when the sun shines on the rising va-
pour, and tinges it with the varied colours of the rainbow.
The Tay, the largest river in Scotland, has its source in
the western extremity of Perthshire, in the district of
Breadalbane. In its current to the German ocean, it forms
two large lakes, Loch Dochart and Loch Tay, and terminates
in an eutafy equally important as the Forth. (See Tay
River.) The Earn, which joins the Tay, takes its rise from
a lake which bears its name near the mountain of Benvoir-
lach. It flows through a luxuriant tract of country, which
is desigated by the general appellation of Strathearn, and is
bom in one side by the Grampian, and on the others by
the Ochil hills. The Almond springs from a glen in the
Grampians, called the Narrow glen, and proceeding by
Logic-Allmond, Methven, and Rodgerton, discharges its
waters into the Tay above Perth. The Lyon descends from
the glen Lyon, and runs a course almost as long as the Tay it-
self, before it losses its name by its junction with that river.
The Tummel, which enters it at Logierat, eight miles above
Dunkeld, is still a longer stream, and is distingulished by a
lake named Loch Rannoch, and by some of the finel falls to
be met with in Great Britain. In its course it is joined by
the Garry, which unites the streams of the Braur and the
Tilt. All these rivers run with the usual rapidity of moun-
tain torrents, and display, at different parts of their currents,
several fine cascades, and much picturesque scenery. One
of the falls of the Bruar is upwards of two hundred feet in perpendicular height, but is broken by projecting rocks into three divisions, which rather heighten, however, than diminish the grandeur of the scene. On the Garry, below its junction with the rivers above-mentioned, is the celebrated pass of Killiecrankie, near which victorius Dundee, one of the most intrepid generals of James VII. defeated the forces of king William, under general Mackay, with the loss of two thousand men, but fell himself in the action.

The next river to the north-east, that falls into the Tay, is the Braan, on the banks of which, at the distance of about a mile from the village of Inver, is one of the most enchanting scenes in nature. The path leading from the village is finely ornamented, and terminates in a building resembling a small temple. This structure is called Ollihan’s hall, or the Hermitage, but the ideas connected with either of these names are by no means applicable to it. In front is a vestibule, adorned with a picture of the aged Ollian, which being removed by sliding into the wainscot, the visitor enters an interior apartment, from the windows of which the most sublime and enchanting view imagination can conceive bursts upon the sight. The two rocky sides of the river almost uniting, comprehend the stream into a narrow compass, and the channel being oblique in its descent, the water is forced with unusual violence over a mass of rocks, undermined, disjointed, and fractured into a thousand different forms. At the bottom of the fall is a deep abyss, in which the wheeling waters suffer an agitation, of another kind, but fearlessly less violent. The whole scene is finely shaded with trees; and to those who admire the efforts of art more than the simplicity of nature, is greatly heightened by the reflection of embossed mirrors, which almost completely cover the sides and ceiling of the hall. A natural cave higher up this river, is called Ollian’s cave, from a tradition that it was the occasional retreat of the Celtic bard.

The other rivers which remain to be noticed, viz. the Isla, the Erich, the Shee, the Earldie, and the Dean, with the exception of the laf, also present scenes of the most picturesque description, and fearlessly inferior to those we have already mentioned. On the Erich, indeed, about two miles north from the village of Blairgowrie, is a scene of a peculiarly romantic character. Here, for an extent of 700 feet, both banks are 220 feet in perpendicular height, and are formed of rock, as smooth as if it had been chiselled by the hand of art, but shaded with a profusion of trees, and a great variety of curious plants.

Lakes.—Perthshire is no less fruitful in lakes than in rivers. These are spread throughout every district of the county, but are most numerous in its western division. Some of them are formed by the expanded waters of the rivers, in their course through glens, hemmed in on all sides by lofty hills; and others are formed simply by the occasional currents which pour down the mountain declivities. The principal among them, for extent and beauty of scenery, are loch Rannoch, loch Tummel, loch Dochart, loch Tay, loch Earn, loch Lubnaig, loch Doine, loch Voil, loch Conar, loch Ard, loch Monteath, loch Van-a-choir, loch Achray, and loch Katharine.

Loch Rannoch is formed by the streams of the Grawer and the Erich, and is about twelve miles long, and from one to two in breadth.

Loch Tummel is situated below loch Rannoch, on the river which bears its name.

Loch Dochart is formed by the river Fillan, the principal branch of the Tay. It is upwards of three miles in length, and is distinguished by very fine and romantic scenery, its banks being precipitous, and covered with a profusion of trees. In this lake is one of those natural curiosities, called a floating island, also a stationery island, overhung by a huge promontory, and adorned with the ruins of an ancient castle. The stream which flows out from the lower extremity of this loch is called the Dochart. It discharges its waters into loch Tay, one of the finest lakes in Scotland, extending about fifteen miles in length, and from one to two in breadth. Its banks are beautifully winding, and diversified with wood and lawn, bold and sloping mountains. This lake has at different times, like loch Lomond, suffered violent and unaccountable agitations.

Loch Earn is the source of the river of that name, which falls into the Tay. It is eight miles and a half in length, and one and a half in breadth. For about five miles on each side its banks display a great profusion of natural oak-wood, and as great a variety of beautiful scenery as any district of similar extent in North Britain. Near each end is a small island, evidently artificial, on one of which are still seen the ruins of a castle. The mountain of Benvoirich, at the head of this lake, is distinctly visible from the castle of Edin-burgh, and from the vicinity of Loudon castle, in Air-shire.

Loch Lubnaig is the lowest lake on the river Balvaig. It is above four miles in length; but is extremely narrow, “presenting the same picture with most of our Highland lakes, of a sheet of water arrested in a deep ravine, and thrown back by obstacles from the lower extremity.” Such is likewise the character of loch Doine and loch Voil, which are placed higher up the same river. In the middle of loch Lub- naig is a tremendous rock, called Craig-na-Coileig, the “Rock of the Joint Hunting,” from having been the boundary between the estates of two ancient chieftains, who were wont to meet here on sporting days, and to hunt round the rock in common, after which they separated, each turning towards his own property, to denote that he was at the utmost boundary of his possession.

Loch Conar, or Chon, is situated near the confines of this county with Stirlingshire, and between the stupendous summits of Ben Lomond and Ben Venue. It is nearly three miles in length, and one in breadth. In its bosom are several illets, which as well as the banks are clothed with trees and herbage.

Loch Ard lies to the east of loch Conar, and partakes of the same character of scenery, but is larger, and more irregular in its figure.

Loch Monteath, or Monteth, situated in the district of that name, is admired as one of the finest lakes in Scotland. It is nearly of a circular form, and measures about five miles in circumference. Its banks, which are only gently elevated, are well furnished with trees. On the north side, close to the water, stand the manse and church of Monteath, together with an elegant mausoleum, lately erected for the Garthmore family. But the most distinguishing ornaments of this lake are its two islands, both of which are decorated with the ruins of ancient buildings. On the larger one are the remains of a priory, founded and endowed by king David I., which displays some fine specimens of “Gothic” sculpture. The ruins on the smaller island are those of the ancient residence of the Graams, earls of Monteath.

Loch Van-a-choir, loch Achray, and loch Katharine, are all expansions of the river Teath. The first is about four miles in length, and the second somewhat more than one; they abound with salmon, trout, and pike, and exhibit at different points some fine and delightful views. The last, however, far exceeds the others in every respect, and is indeed at once
PERTHSHIRE.

once among the most interesting lakes any country can boast of; whether we consider the alternate beauty and grandeur of its scenery, or the classic charm it has derived from the creative imagination, and descriptive talents of the author of the Lady of the Lake."

Soil, Climate, and Agriculture.—Perthshire, with respect to these subjects, is naturally divided into three districts, which differ from each other very materially. These districts are termed the Highland district, the Lowland district, and the district of the Carse of Gowrie.

The Highland district, which comprehends by far the larger portion of the county, is included within, or rather formed by, the Grampian mountains. In relation to the whole extent of the Scottish Highlands, it constitutes what are usually denominated the Central or Southern Highlands, in contradistinction to those of Argyllshire, or the Western Highlands, and those of Inverness-shire, or the Northern Highlands. It may also be regarded as the central district of the whole kingdom of Scotland, and is subdivided into small portions, marked by glens or vallies, called Kennoch, Glenlyon, Glenlochy, Glendochart, Glencoe, the environs of loch Tay, and Strath-Tay. Throughout this vail tract of country, contrary to what might be supposed from its northern latitude, the elevation of its vallies, and the contained lands, it is rather of its towering mountains, the climate is not less mild than in the moor lands of Yorkshire. Indeed, the mountains of Perthshire may even claim an equality in temperature with those of Cornwall and Devonshire, and certainly surpass them in dryness of climate, excepting on the western margin of the district, where the quantity of rain which falls is immense. The soil in the vallies here consists in general of a brown loam, of uncommon fertility, lying on a found, dry gravelly, or sandy bottom. A similar soil prevails on the sides of the hills to a considerable height, and is not unfrequently found under the black moosy earth of the heaths. What is remarkable, the slopes of the mountains facing the north are much more productive than those which poifs the southern exposure. This phenomenon is accounted for, by the supposition that the soiluffers more exhaustion on the south than on the north, because of the greater alternation of rain and snow, and of heat and cold, to which the surface of the former is liable, from the action of the sun-beams, and the greater frequency of southern rains. In this district few of the vallies contain lands too fertile for the purpose of its towering mountains.

The climate of this district is mild enough to be pleasant, as is the case with the Lowland district, though it is not very cold in the winter, and is more temperate in the summer than in the Highlands. The sandstone mountains that bound the district on the west render it less exposed to the north-east winds than are the mountains of the Highlands, which lie parallel to the coast of the northern sea. The black mounasty evergreens of the colder parts of the Highlands are replaced by a species of birch, the leaves of which are small, and the branches are gracefully arched, and form a beautiful foliage. In these regions, the soil is less fertile, and the vallies and fields are larger and more scattered than in the Highlands. The climate of Perthshire is such as to enable the people to live comfortably in these districts, as well as in the Highlands.

The Lowland district includes all that portion of Perthshire which lies to the south of the Grampians, with the exception of the Carse of Gowrie, to be afterwards noticed; viz. part of Strathearn (see Strathmore); and those districts of the county, the vales of which flow into the Forth, or the Earn. Along the Forth, for an extent of eighteen miles from Garthmore to the bridge of Allan, the soil of the level lands is a deep, rich clay, of various degrees of fertility. This soil, however, is still covered, for about four miles, by a tract of moors from fix to fifteen feet deep, called the Moats of Kincardine, because situated chiefly in the parish of that name. This moor is supposed to have once covered the whole valley, and was well worthy the investigation of the naturalist. By the exertions of the late lord Kaimies, however, and by the judicious liberality of its proprietor, the moor has been drained, and will doubtless be entirely cleared in a few years. It is wholly let out on leases of thirty-eight years, in proportions of eight acres, to different tenants, who pay no rent for the first seven years, and only one or two marks Scots for the succeeding thirteen years, and twelve shillings for each cleared acre during the last nineteen years. The number of men settled on this moor, in 1801, was 115, of women 115, boys 119, and girls 103.

In the low grounds of Strathearn, wheat is the great object of husbandry, generally after summer fallow, but frequently also after clover ley. In the upper parts of the district, barley and oats are the principal crops. The culture of flax is universal over the whole district, but is not carried to a great extent in any one place. Potatoes are raised in vast quantities on the light soils, as are likewise turnips, especially within the last ten years. Farms here vary in size, from 30 to 400 acres, and are for the most part managed upon the most approved system. The greater part of this district, however, is yet unclofaced. The mansions chiefly in use here are lime and marble, of which last article there is great abundance found in the small lakes, and in the landlocked bogs and moles.

The
The third agricultural district of Perthshire, or the Carse of Gowrie, is situated along the northern shore of the frith of Tay. It is a long, narrow plain, and extends sixteen miles in length; it contains about 18,000 acres of extremely rich and fertile soil. This district, indeed, may be justly styled the border of Great Britain for natural productive force, and yields to no portion of the globe in the intelligence and skill of its farmers. Like the Delta land of Egypt, and those fertile tracts adjacent to the mouths of the Ganges, the Tav., and the Mithi, the Carse of Gowrie has been formed in a long course of ages, and has grown rich by the spoils of the Highlands. The heavy rains which fall near the sources of the Earn, the Tay, the Tummel, the Garry, the Iflas, and their tributary streams, have washed down great portions of soil, and have laid bare the rocks of the highest mountains to give exuberance to the banks of the Tay. The Carse, in fact, is evidently nothing more than what is called in other quarters sea-mud, or sleeche, consolidated by time and gradual deposition. The subjacent here are various, and might form a subject of curious and interesting investigation. The soils also differ. On the banks or bruses of the Carse, which slope gently with a southern aspect, the soil is a hazle-coloured loam, except in the higher part of the ascent, where it is a sharp gravelly kind. In the "low Carse," clay is the prevailing soil. Here the farms are clothed into fix divisions, as nearly equal as the nature of the ground will admit, and the following rotation is that most generally approved of: 1st year, summer fallow;—2nd, the land dugged; 3d, wheat; 4th, pea-s, or pea and beans; 5th, barley, with clover and rye-gras; 6th, oats. Sometimes, however, fallow is excluded, and some green crop substituted. This happens almost universally on the banks or bruses of the Carse; and on the higher grounds, the rating of wheat is only very partial, and the third, fourth, fifth, and sixth years are generally appropriated to hay or pasturage, the seventh to oats, and the eighth to barley. The climate of this district is mild, and favourable to vegetation, beyond perhaps any other in Scotland, as it is completely sheltered, on all sides, by lofty mountains, and by plantations of various kinds of trees. Farms are generally from 100 to 300 acres in extent, and are let on leases of nineteen years, at as high a rent as any field-land in Great Britain. The only artificial manure used is lime; for which nearly 2000l. is paid annually to the lime-works in Fife, or in England.

The live flock of this county consists of horses, cattle, sheep, fowls, bees, and swine, except in the Highland district, where the fow, till lately, was still a more rare phenomenon than a well-cultivated farm. The horses of this district, on the other hand, are too numerous, and almost wholly of the common Highland breed, as well as the cattle. The sheep, however, have of late undergone a considerable change, by intermixture, and are certainly in proved. In the Lowland district, and in the Carse, the horses are an active, middling-sized breed; and in the latter district are many of a heavier kind, for the use of the plough in the lower grounds, where the soil is deep and heavy. Few black cattle are reared in either district, but a certain number of cows are kept by every farmer. On the Ochil hills, and in almost all the mountainous districts, sheep are reared in great abundance. They are mostly of the black-faced breed.

Antiquities and Historical Events.—Perthshire displays a field of great interest to the antiquary, as well as to the historian. Lying north of the Roman wall it was the scene of many conflicts, fought in support of the last glimmer of Caledonian independence in the Lowlands. From a pottage in Cudian, we learn, that the Earn was frequently dyed with blood.

Scotorum cumulos flebit glacialis Juris.

And Tacitus informs us, that at the foot of mount Grampius, Agricola encountered and overthrew the heroic Galgacus. The precise spot on which this battle took place is not certain, but a variety of conjectures have been hazarded upon the subject, of which the most probable is that which fixes it in Stormont, where a large Roman encampment is still visible, together with a numerous collection of cairns, the indubitable memorials of Caledonian strife. At Ardoch is another encampment, probably the most perfect example of ancient caravanserai in Great Britain, and near it are two smaller ones, less perfect in their construction. There is likewise a Roman encampment at Ochil, which communicates with Ardoch by a raised road, or caufeway. Vestiges of a strong military earthen work are also to be traced about two miles from Monzie; and on the hill of Dunmore is another
Loch Tay priory, likewise Augistine, founded by Alexander I., A.D. 1222.

Suggeden hospital on Tay, founded ante 1296.

Tullibardine college church, founded 1446. See TULLIBARDINE.

Tullilium Carmelitte convent, founded A.D. 1262.

Callyx, Palaces, &c.—Perth, Scone, and Abernethy, having been early royal residences, were each adorned with Rately palaces, which are now entirely demolished. Those of the two first mentioned towns fell a prey to the fanatical fury of the reformists. Many calcinated mansions, however, yet exist in different districts of the county, and would be well worthy of description, were our limits allow. The most remarkable among them are castle Campbell, Finlarig castle, castle Comrie, Doune castle, Ballumbri castle, Garn castle, Elcho castle, Kilnaird castle, Gowrie house, Murthly house, Kinfauns's castle, Macbeth's castle of Dunfinnan, Hunting tower, or Ruthven castle, Balloch castle, the residence of lord Breadalbane, Blair castle or Athol house, and Drummond castle. Some of these are in ruins, and some have been so much modernised as to alter in a great measure their original appearance. Beauties of Scotland, vol iv. Sketches of Perthshire by the Rev. P. Graham, D.D. Edin. 1812, 2d edit. 1820.

PERTI, Gio. ANTONIO, in Biography, a solid, grave composer of church music, alla Palestrina, was born in 1566. With his theatrical style we are unacquainted; but as long continued to be employed, not only for the operas of Bologna, but Venice and other cities of Italy, we may reasonably imagine that it was excellent. Paolucci has printed a good duct by this master, in the church style; and Padre Martini has given several admirable specimens of his science in his "Saggio di Contrappunto." This great harmonist, however, does him still more honour, by calling himself his disciple. Perti, before his decease, must nearly have attained the age of 100; for his name appears as the composer of Atide in 1679, and, according to Quadrio, he was living in 1744.

PERTICA, in Astronomy, a sort of comet, being the same with veru.

PERTICA, among the Romans, a long rod for beating the fruit from trees. It was likewise used for a long measure. See PERCH.

PERTICATA, or Particata Terra, in our Old Law Books, is the fourth part of an acre, or a piece of ground containing one perch in breadth, and forty in length. See ROOD, and PERCH.

"Continet in integra superficie 40 perticae."

PERTICI, in Biography, a comic finger and admirable actor, came hither in 1748 with Larchi, another excellent comic finger and actor, and Guadagni for the first time, when he was very young, as serious man in a troop of burletta fingers, brought over upon speculation by fig. Crozza, whose calculations were so erroneous, that he became a bankrupt and a fugitive in a year's time.

PERTICULAS, poor scholars of the isle of Man. The king granted to "L. Macguin de infula de Man, scholari, quandam eleemosynam vocata Perticulas, ad fullmentationcm cujusdam pauperis scholarii, de infula predicta ad exercend. scholias, per projacentes ro'tos quondam reges Anglie datam et concediam." Pat. Hen. IV.

PERTIGI, in Geography, a town of the island of Sardinia; 19 miles S.E. of Castello Aragonese.

PERTINAX, PUBLIIUS HELVIIUS, in Biography, a Roman emperor, was born in the reign of Adrian, A.D. 126. His
His father was a freedman, by occupation a maker of charcoal; but notwithstanding his humble condition, he took care to give his son a literary education. The young man first employed himself in teaching at a grammar-school, but dissatisfied with a sphere that gave no hope of advancement, he entered into the army, and served as a common soldier in Syria. He soon obtained considerable rank, and at length the government of the two Messias was committed to him, and afterwards that of Syria, which he held till the accession of Commodus, in the year 180. Upon this event he returned to Rome, where he passed three years in retirement. During this period he employed himself in embellishing his native place with several elegant buildings; but he permitted his father's house and shop to remain unaltered, as a memorial of his humble origin. He was now sent by the emperor into Britain, where the legions were in a state of great dissatisfaction and indiscipline. The soldiers would very willingly have transferred their allegiance to Pertinax, but he preferred his fidelity inviolate, and incurred much personal danger in quelling the mutinous spirit of the troops. At length he was recalled, and appointed to the important trust of superintending the supply of Rome with provisions. After this he was made proconsul of Rome, twice a consul and governor of Rome. Pertinax was in possession of this last office, when the tyranny of Commodus brought his detestable reign to an end; and he succeeded to the imperial purple, by an apparently free election. All the measures of his short reign were directed to the public good. He found the treasury empty, which he replenished by a public sale of all the articles of prodigal luxury which he found in the palace. He himself adopted a frugal and simple mode of living, and by it, which has been condemned as the meanest parsimony, he was enabled to abolish many oppressive taxes, and he shewed a great disinterestedness and disregard to the accumulation of wealth, by declaring that he would accept of no legacies from persons who left children or other lawful heirs. He discouraged all informations for treason, and administered justice with equal mildness and impartiality. Such a course of conduct was not likely to please those who had profited from the vices of Commodus; and plots were formed to subvert the new government. While Pertinax was absent at Olbia, an attempt was made to raise to the throne the consul Falco. He hastened back and complained of the fact before the senate, but when that body proposed to condemn Falco as a traitor, he declared that no senator should suffer death in his reign, and dismissed him in safety. A spirit of mutiny was by false representations excited among the guards, and three hundred of them proceeded with drawn swords to the palace. The emperor's officers and friends fought for safety by flight, but Pertinax disdained even to conceal himself. He appeared before them with a firm and intrepid air, and expostulated with them upon their conduct, which made such an impression on the minds of the conspirators, that they began to sheath their swords. At this critical moment a Thracian soldier threw his javelin at the emperor's breast, and the feeling of respect being thus dissipated, the rest rushed in, and dispatched him with many wounds. When he saw that his fate was inevitable, he wrapt his head in his toga, and fell without a struggle. This event took place on the 28th of March 193, after a reign of only three months. Electus, and some of his attendants, who attempted to defend him, were slain; his son and daughter only escaped, who happened at the time to be out of the palace. From the number of his adventures, he was called the tennis-ball of fortune, and no man experienced so many changes in his life, with so blameless a character. His character is highly spoken of by contemporary historians, and his memory was highly revered by the Roman people.

PERTISTEGNO, in Geography, a tow. of Italy, in Friuli; seven miles N.W. of Friuli.

PERTUIS, a town of France, in the department of the Vauches, and chief place of a canton, in the district of Apt; 12 miles S.S.E. of Apt. The place contains 4000, and the canton 12,601 inhabitants, on a territory of 337½ kilometres, in 14 communes.

PERTUIS d'Antich, a frait, or narrow part of the sea, between the isle of Oleron and the isle of É.

PERTUIS Breton, a narrow frait of the sea, between the isle of Ré and the coast of France.

PERTUIS de Maumusson, a straight bower the isle of Oleron, and the coast of France, S. of tifland, about one mile wide.

PERTURBATION of the Planets, &c., in Astronomy. See PLANETS, MOON, SATELITE, and SOLAR SYSTEM.

END OF VOL. XXVI.
