PLANTAGINELLA, in Botany, is Vaillant's name for the Linumella; see that article.

PLANTAGINES, the second order of Jullieu's feventh class, for the characters of which class see NECTAGINES. The Plantagines, or Plantagines, as Jullieu now terms them, in which he is followed by Mr. Brown. Prod. Nov. Holl. v. 1. 428, are thus defined.

Calyx mostly in four deep segments. Tube petal-like, con- tracted at the summit, and generally four-cleft, refembling a corolla, but withering and not deciduous, inferior. (This "tube" is the Linnaean corolla.) Stamens four; their filaments long, prominent, inferted into the bottom of the tube." German solitary; style one; stigma simple. Capsule divided circularly, of one or two cells, with one or more seeds in each cell. Pericarp (or albumen) none. Plants herbaceous. Sexes sometimes in distinct individuals.

Jullieu's genera of this order are Pijflium, Plantago, and Littorella. The two first are combined by Linnaeus, as well as by Decandolle and Brown. The latter author describes an albumen of the shape of the seed, and of a densely fibby texture. He remarks that the analogy between the fuppofed corolla of the Plantagine and the membranous tube, which connects the flamen, in the neighbouring order of Amaranthaceae, or Amaranthi, is weakened by the presence of the tube part in the female flower of Littorella, a monocious genus. We would observe however, though by no means inclined to invalidate the opinion of the part in question being a real corolla, that barren filaments are often found in female flowers, and therefore any other organ relating to the flamen, may likewise be present in fuch, while the flaments themselves are absent. See Littorella and Plantago.

Gen. Ch. Cal. Perianth inferior, of one leaf, in four deep erect segments, short, permanent. Cor. of one petal, membranous, permanent, withering; tube swelling in the middle; limb deprefled, in four deep, ovate, acute segments. Stam. Filaments four, capillary, ereft, extremely long, inferted into the tube, alternate with the segments of the limb; Brown; anthers rather oblong, moftly beaked or crefted, incumbent. Pijfl. Germe superior, ovate; style thread-shaped, half the length of the flamen, stigma simple, acute. Peric. Capsule ovate, somewhat membranous, of two or four cells, burfting by a tranverse circular furture, the partition at length becoming unconnected. Seeds several, oblong, convex on one side, concave on the other.

Ofb. In fome species the calyx is equal, in others unequal.

Mr. Brown remarks that P. Coronopus has four cells to the capsule, with one feed in each cell. Gartner, without mentioning the number of cells, says there are four feeds in each cell, in that species. Tournefort made Coronopus a diftinct genus, merely on account of the deep segments of the foliage. It is rather to be wished that Pijflium of authors could have been retained, as there are feveral species of that fuppofed genus, and their branched leafe habit is very different from what is usual in Plantago. Jullieu thought to diftinguifh Pijflium by having folitary feeds, but the fame is the cafe with many indubitable species of Plantago, as P. Bellardi, erecta, media, and others. For the difficulties attending the true nature of the corolla, see PLANTAGINES.

The fourteenth edition of Linn. Syift. Veg. enumerates twenty-four fpecies of Plantago; Willdenow has thirty-three, to which one is to be added from the Prodr. Fl. Grec., four from Mr. Brown's Prodr. Nov. Holl., and five from Mr. Purfi's American Flora. The genus is divided into two very unequal fectiofs, of each of which we fhall give fome examples, particularly mentioning the five Britifh species. The new ones all belong to the firit fective.

verage.
merous. — Common every where throughout Europe, as well
as in North America, flowering at almost allasons, in mild
weather. Root perennial, of many long fibres. Leaves ra-
diant, few, upright or spreading, on channelled ribbed
footstalks, ovate, broad, toothed or waved, nearly smooth,
with seven or nine longitudinal ribs. Stalks several, erect,
longer than the leaves, each bearing a dense cylindrical
spike, of innumerable crowded, small, whitish flowers, with
purple anthers. Stigma downy. Capsule ellipsoidal, small,
each cell containing several seeds, which are the food of
small birds, and are often given to those kept in cages. This
species is subject to many varieties, one of which we suspect
to be P. croffo, Wildid. n. 2.

P. aflatunica, Linn. Sp. Pl. 163, has the appearance of
major, but is more slender, with scattered flowers and an-
th. 26, is intermediate between the foregoing and the follow-
ing.

Valgr. v. 1. 436. P. steppica; Ger. Em. 419.) — Leaves
ovate, downy, deflexed, with very short footstalks. Stalk
round. Spike cylindrical. Seeds solitary. — Common on
open hills and pastures, where the soil is chalky or gravelly,
flowering throughout summer. The broad deflexed leaves
are very conspicuous, and considered as a great blemish by
those who are curious about their gras-plats. A single drop
of oil of vitriul on the crown of each root is said to prove
the best and most certain mode of destroying these in-
truders. The spike is much thicker and shorter than those
of major. The white corolla, pink stamens, and yellow an-
thers, make a far from inelegant appearance.

Rufit. t. 67. (P. longifolia; Matth. Var. v. 1. 437. P. quin-
quevittata; Ger. Em. 422.) — Leaves lanceolate, entire,
acute at each end. Spike ovate. Stalk angular. — Ex-
tremely frequent throughout Europe, in pastures and waste
ground, flowering in summer. The more elongated, erect,
nerower, greener leaves, with three or five ribs, and the
short spike, the calyx of whose flowers is black, corolla
brownish, and anthers white, mark the plant sufficiently.
The entire leaves afford a less ambiguous specific distinction
than the naked spike, by which Linnaeus meant to differenti-
ate between this and P. Lagopus; for the lanceolata has a
bracteate, though not a hairy spike, while Lagopus has a
hair one without bracteas.

Willid. n. 10. Alt. n. 10. Sm. Fl. Grcc. Sibth. t. 144.
— Leaves lanceolate, five-ribbed, distantly toothed. Spike
ovate, hairy. Stalk round, clothed with upright hairs.
Native of the south of Europe, in dry open places; very
common in Greece and the Archipelago. Root perennial.
Habit and size like the last, but the leaves are distinguished
by their neat, prominent, more or less distant teeth. The
spike is shorter, rounder, hairy and pale. Anthers more
obtuse.

(Holofteum falanaticum; Ger. Em. 423.) — Leaves lan-
celolate, oblique, waved, villous. Spike cylindrical, rather
less. Stalk round, longer than the leaves. Native of Spain,
the south of France, the Peloponnedus, and some of the
Greek islands, but not common. It is perennial, flowering
in summer. The divided leafy crown of the root sometimes
affumes the appearance of short stems. The leaves are long
and narrow, spreading in an arched manner, not deflexed;
their surface glaucous, besprinkled with fine soft hairs.
Stalks very hairy, especially when they first spring forth.
Spikes long and slender, the flowers rather distant. Bracteas
and calyx green, edged with white, hairy at the back. Corolla
brown. Stamens red. Anthers yellow, with a small sharp
beak. Style hairy.

Leaves linear, flat. Stalk round, hairy. Spike oblong,
cylindrical. — Native of the Alps of Switzerland and Austria.
Dr. Sibthorp found it about the summit of the Bithynian
Olympus. The root is perennial. Leaves long and nar-
row, with taper points; the edges often fringed. Stalks
hairy. Spike rather cylindrical than ovate. Anthers yellow,
with a blunt beak. Style hairy. The Plantain noitrare of
Reynier, an alpine plant, with a short ovate dark spike,
often mistaken for this, leems rather, as professor Schrader
has hinted to us, a variety of lanceolata.

Sibth. t. 146. (Holofleum, five Leontopodium cicutum
alterum; Ger. Em. 424.) — Leaves linear-lanceolate, hairy,
flat. Stalk round, villous. Spike cylindrical. Bracteas
pointed. — Found in Spain, Italy, Barbary, and on the sum-
mits of the Bithynian Olympus, as soon as it is clear of snow.
The root is annual, erroneously marked perennial in Prodr.
Fl. Grcc. Leaves numerous, spreading, either quite entire,
or toothed near the point. Stalks rigid, erect or ascending,
two or three inches long, numerous, clothed with hori-
zional hairs. Spike thick, hairy, with prominent pointed bracteas.
Corolla tawny, taper-pointed. Anthers yellow, with a pale
two-lobed crest as large as their cells.

n. 17. Alt. n. 16. Sm. Fl. Grcc. Sibth. t. 147. (Ho-
lofleum, five Leontopodium cicutum; Ger. Em. 443.)
— Leaves linear, flat, hairy. Stalk woolly, very short.
Head of flowers roundish, drooping. — Native of Crete and
Cyprus. A small annual species, remarkable for its nu-
meros, short, deflexed, very hairy footstalks. The flowers
form a head, not a spike. The corolla is yellow with a purple
calyx, its segments broader and shorter than in the last.
Anthers yellow, with a little more or less fringed, except that their crest
appears to consist of one tube only.

Em. 425. C. salicifolius; Matth. Valgr. v. 1. t. 449. P. ma-
rina; Ger. Em. 423.) — Leaves linear, channelled, nearly
entire. Spike cylindrical, close. Stalk round, longer than
the leaves. — Native of muddy sea-shores in Europe and
North America, as well as of mountain rocks. — Root long,
perennial. Herb extremely various in size and luxuriance.
Leaves copious, spreading, linear, channelled, dark green,
rather fleshy, occasionally hairy; their margins either quite
entire, or sometimes beset with a few irregular teeth. On
mountains they are generally narrowest and most entire.
Flowers few, ascending, about twice as long as the
foliage, rather hairy. Spike slender, of numerous crowded
or immaculate flowers. Corolla white. Anthers with
a small sharp beak. Style downy. The structure of the
flowers more agrees with P. albiacus. The ripe fruit we
have never examined. This species being, like the Thrift, Sta-
tice varna, found on the lozited mountains, as well as on
the sea-shore, its small alpine varieties have been taken for
alpins.
**PLANTAGO.**

*alpina*, or confounded with *fublata*, neither of which are really known to be natives of Britain.

P. *fuscula.*—Awl-leaved Plantain. Linn. Sp. Pl. 166. Wild. n. 20. Ait. n. 18. (Serpenita omnium minus; Lob. Ic. 439. f. 2. Coronopus five Serpenita minus; Ger. Em. 426.)—Leaves awl-shaped, triangular, liriated, rough-edged. Stalk round. Native of the SWift Alps and the Bithynian Olympos, as well as of the coasts of the Mediterranean. Gerarde might have it in his garden, but we have never seen a garden specimen of this species. Its root is perennial, running down in one great cylindrical body to the depth of a foot, or more, and divided at the crown into many short leafy tufts. The leaves are very copious, from one to three inches long, readily known by their narrow, linear, acute, triangular form, and rough edges. Flowerstalks rather flath, flatty, not numerous. Spikes cylindrical, not always perfectly close, various in length, and number of flowers, which seem to resemble those of *P. maritima*, but we have not been able to investigate their anthers. The bracteas are hairy, as long, or longer, than the calyx.

P. *gentianoides.* Gentian-leaved Plantain. Prodr. Fl. Græc. n. 355.—Very smooth. Leaves ovate, three-ribbed, somewhat waved. Stalk round. Bracteas ovate, naked, shorter than the calyx.—Gathered by Dr. Sibthorp on mount Olympus, with the preceding. Root perennial, thick. Leaves very like Gentiana acaulis. Stalks three or four inches high, quite smooth and naked. Spike cylindrical, flatty, flarcely an inch long, perfectly smooth in every part. Bracteas, as well as the calys, obtuse and pointlets.

P. *varia.* Variable New-Holland Plantain. Brown n. 1.—Hairy. Leaves lanceolate, three-ribbed, toothed; woolly; as well as the flacks, at the bottom. Sphæs many-flowered.—Native of various parts of New Holland without the tropic. Brown. It was sent us from Port Jackson, in 1793, by Dr. White. The leaves are three or four inches long, from half an inch to an inch wide, most tapering towards the base, or flowerstalk, which is half in variable in length; both sides are clothed with dense short pubefcence, and marked with three, occasionally five, longitudinal ribs; margin often beft with ditant, very large and dilated, altho' ovate, teeth, sometimes with obtuse ones, or none at all. Flower-flacks taller than the leaves, at least when fully grown, hairy, round, woolly at the base. Spike cylindrical, hairy, of rather numerous, but sometimes ditant, flowers. Bracteas ovate, concave, rather smaller than the calys. Segments of the corolla rounded, or broad-ovate. Style nearly smooth. This species seems in many points akin to *albicans*, and to *Serraria* and its allies, but very ditinct, as a species, from all of them.

P. *debils.* Weak New-Holland Plantain. Br. n. 2.—Leaves lanceolate, toothed or entire, three-ribbed, flavcid; beaftles, as well as the thread-shaped flower-stalk, at the base. Lower flowers of the spike scattered.—Found by Mr. Brown at Port Jackson, New South Wales. Nearly skin to the foregoing.

P. *hispid.* Hifpid New-Holland Plantain. Br. n. 3.—"Hairy and hoary. Leaves lanceolate, toothed; beaftles, as well as the flower-stalk, at their base. Spike of many imbricated flowers."—Native of the south coast of New Holland. Br.

P. *cornuta.* Fleafy New-Holland Plantain. Br. n. 4.—"Very smooth. Leaves lanceolate, deeply toothed, somewhat flatty; naked, as well as the flower-stalk, at their base. Flowers from one to three."—Native of the island of Van Diemen. Br.

P. *Serraria.* Saw-leaved Plantain. Linn. Sp. Pl. 166. Wild. n. 23.—Ait. n. 20. (P. apula lacinata bulboza; Column. Ecphr. v. 1. 258. t. 259. P. angustifolia ferra hifpanica; Barrel. Lc. t. 749.)—Leaves ditant, flarily, with awl-shaped tooth-like farratures. Stalk round. Spike elongated, flender, cylindrical, imbricated. Bracteas taper-pointed.—Native of Italy, Barbary, Zante, and various parts of the Mediterranean and Archipelago. Root perennial, thick, so as to flume a bulbo us affect. Leaves numerous, acute, hairy, distingufhified by their long, parallel, almost peccinate, teeth, in which they essentially differ from the broad rounded imbricated teeth of *P. macrorrhiza* of Vahl, Wild. n. 22. The flakes also are very much longer and more flender than those of this species, composed of innumerable crowded flowers, and longitudinal taper-pointed bracteas.

P. *Cternus.* Jacq. Mie. v. 2. 351. Ic. Rar. t. 27. Wild. n. 19, appears to us but a levariunt variety of the last; its flumes indeed are shorter, and flaky rather longer; but there is hardly a distinct specific character to be discerned. It is pity that Jacquin did not examine the cells of the capsule. He merely says " fructus congenerum," which conveys nothing, in this case, that we want to know. If he had specificated that the part in question agreed with all the rest of the genus, except *Coronopus*, it would have been decisive.

P. *Loch tingii.* Narrow Annual Plantain. Linn. Sp. Pl. 166. Wild. n. 25. Ait. n. 22. Jacq. Hort. Viên. 2. t. 126.—Leaves linear, with a short stem. Spike ovate. Bracteas obtate, with an orbicular membraneous border.—Native of hills, and the borders of fields, in Spain and the south of France. No species is more distinct, or has been more mistaken, owing to Hadfon and Limnes having referred to this the toothed variety of *P. maritima*, figured in Pettiuer’s English Herbs, t. 1. f. 9, and Ger. Em. 423. The root of *P. Loch tingii* is small, tapering and annual. Plant extremely variable in luxuriance. Leaves upright or spreading, linear, acute, very narrow, befit with fine, ditant, taper teeth. Stalls spreading, thread-shaped, hairy, usually shorter than the foliage. Spike of few flowers, ovate, or almof capitate. Bracteas orbicular, concave, pointlets, formed of a broad membrane, with a thick green keel. The anthers seem to have a membraneous tip, but we have not seen them free, and Jacquin’s figure has no dissected or magnified parts. He describes the capsule very accurately, of two cells, with one seed in each.

Sect. 2. *With a leafy stem.* Seven reputed species. P. *amplocarpa.* The first of these, Cavan. Ic. t. 125, appears a very doubtful species, perhaps allied to *albicans*, and certainly not more truly caulecent than some appearances of that plant. It is perhaps *P. angustifolia languiroa*.
cana, Barcel. t. 759; a specimen of which, from the south of France, we have referred to albinaca.

P. Cygnus. Shrubby Plantain. Linn. Sp. Pl. 167. Wild. n. 32. Ait. n. 29. (P. Pfyllum majus fupinum; Bauh. Htt. v. 3. 513. Pl. fempervirens; Ger. Em. 587. Pf. alterum; Matth. Valgr. v. 2. 414.) — Stem branched, shrubby. Leaves entire, thread-shaped, straight. Bracteas orbicular, with much linear points, much longer than the flowers. — Native of Provence, Italy, Switzerland and Bithynia. The stem is shrubby, and certainly perennial in our gardens, or rather greenhouses. Branches and beads purplish; the latter distinguished by their rounded membranous-edged bracteas, with linear rough points.

The cuts of old authors, given for the true Pfyllum, as Ger. Em. 587, f. 1. Matth. Valgr. v. 2. 413, and the modern plate of Bulliard, t. 363, having large bracteas under the heads of flowers, bear some resemblance to P. Cygnus, but better agree with the <i>indices</i>, Linn. Sp. Pl. 167, and are possibly, like that, but varieties of Pfyllum. The <i>astrufs</i>, Linn. Sp. Pl. 168, appears to us much more nearly luxuriant, bristly, and somewhat shrubby, variety of Pfyllum, with which it precisely agrees in every thing, but the more short and shrubby habit of the stem.

P. Fjauroys. Leafy-spiked Plantain. Wild. n. 29. Ait. n. 26. (P. Fjauroys; Jacq. t. 321. t. 28.) — Stem herbaceous, branched, diffuse. Leaves linear, entire. Heads oblong. Bracteas leafy, elongated, rough.—Native of Egypt. This is a very distinct annual species, whose long recurved bracteas are rough to the edge, scarcely at all membranous. The <i>flakes</i> is rough, much longer and thicker, and perhaps more perfect, in some flowers than in others. Plantago Lanceolata, ribwort plantain or ribegrass, in Agriculture, has a perennial root, which, when old, appears as if bitten off at the end. The leaves are all from the root, truly lanceolate, dilated, distinguished by five (sometimes three or seven) prominent ribs, pointed, entire, or sometimes having a few teeth near the base. According to Withering, in maritime situations they are toothed all along the edges. They are of a dark green, molyly hairy beneath, taper at the base into a long flat footstalk, ribbed like the leaf itself, and at their insertion are inviolate long white woolly hair springing from the crown of the root. The scapes or flowering-flalks upright, longer than the leaves, from among which they spring; they are clothed at the base with the same kind of hair, and upwards are smoothish, round, with five deep furrows, slightly twisted, and terminated by a short ovate spike, imbriated with black scales, and enlivened with the prominent cream-coloured anthers, in its more advanced stage. A spike will sometimes contain one hundred and thirty small flowers crowded close together, with an ovate pointed spike or bractea at the base of each. The capsule contains two oblong shining seeds, of an amber colour, in each cell. The flalks continue to grow after the flowering is over, and sometimes shoot out to the length of two feet more. When it grows in meadows, the leaves are erect and drawn up: but in a dry barren soil they are shorter, broader, and more spread on the ground. It grows spontaneously in dry pastures and other places, where it is often left untouched by cattle, to feed small birds with the copious produce of its seeds. It has often been considered as a weed, occupying the room of grasses, and other useful herbs; but has lately been introduced into culture as a good food for sheep, or to be made into hay for cattle in general. Halle has attributed the richness of the milk in the alpine dauries, in some measure, to this plant. And it has been remarked by Linnaeus, that it has been eaten by horses, sheep, and goats, but that cows refuse it. Sheep, however, will eat it either green or dried, provided it be well gotten; but it does not answer for pasture, without a mixture of clover or grasses, according to some cultivators. Withering suggests that the total absence of this plant, in marshy lands, is a certain criterion of their wretched quality. In proportion as such foils are improved by draining, it will flourish and abound. But others have suggested, that in this climate the produce of this plant is not a criterion of excellence in soil, but merely of its drynesses. But though botanists do not speak favourably of this plant as a paffure or meadow herb, practical farmers hold it in a degree of esteem. And it has been affected by Mr. Zappa of Milan, that it grows spontaneously in every meadow of Lombardy, especially in those which are irrigated; that it vegetates early, flowers at the beginning of May, ripens in five weeks, and is cut with the <i>pca trivalis</i>; that the height of the leaves is about one foot, and of the flake a foot and a half; that it multiplies itself much by the seed and a little by the roots, which it continues to do time to time to reproduce; that it is eaten heartily by every sort of cattle, and in particular by the cows in grapes, and the cows like it most in May, having great influence on the milk; that the hay is eaten more voraciously by cows, and has on them great influence in the fields; in short, that it is one of the best plants either for the milk or the flesh. Where kept well fed down by flock, there can be no doubt of its being a good and nourishing plant for both cattle and sheep flock.

And Mr. Young states, that he had long before recommended this plant for laying land to grass, and sowed it on his own farm. At the same time he thinks it extravagant to propose dandelion and forrel as plants proper for a cow pasture; and conjectures that those plants being found among good ones, have qualities given them which do not properly belong to them; he is likewise inclined to make the same conjecture in respect to narrow-leaved plantain, ribwort, or rib-grass, and holds even have preferred dandelion and forrel to it: but he is cautious of opposing theory to practice. But Dr. Anderson contends that narrow-leaved plantain or rib-grass is well liked by horses and cattle, and yields a very good crop upon rich ground tending to dampness, if it is at the same time soft and fongy; but that upon any soil which has a tendency to bind, or upon dry ground
PLA

ground, it furnishes a very scanty crop. And it has been made use of in some parts of Yorkshire as a summer grases. As an article of pasturage for cattle and sheep, it is there in high esteem; it is not, however, well eaten by horses; and as an article of hay it is held to be detrimental to the crop; retaining its sap an unusual length of time; and when fully dry falls into a small compes, or is broken into fragments, and left behind in the field. One advantage of this plant is, that its seeds may be easily procured genuine. A large proportion of it may be eligible; it has now passed the telt of twenty years established practice, and seems to be full in good estimation even among farmers that are the most attentive in grases husbandry. It has been flated by Mr. Marshall that he made a trial of it in Norfolk, as a substitute for clover, but gained no credit from the experiment: on which it has been observed that the fact is, horses do not affect it, and they are the principal consumers of the clover crop in that county. It is a plant that varies much in size as well as in the breadth of the leaves, &c. The narrow leaves have only three ribs. The spike is sometimes surrounded by large leaves, instead of the usual small bracteas: it sometimes becomes an abortive panicle: and it is found with two or three heads. Its qualities seem to be nearly the same with those of the following; and it is more used than that by the common people in some places.

It is probable that the fort which has been termed grass-leaved plantain (tenuifolia) by Dr. Anderon, is only a variety of this. See Rib Grass.

Plantago Major, the great plantain. This affords more seeds than the former, and is perennial. The root when old is the thickness of the thumb, premorse or stumped, laying strong hold of the earth by its fibres, which strike deeply, and are whitish. The leaves petioled, seven-ribbed, or sometimes nine-ribbed, smooth, but somewhat hairy when young, about a hand in length, often remotely toothed about the edge. The petioles long, convex on the under side, concave above, each forming a kind of sheath at its base. The fapes upright, pubefcent, longer than the leaves. The spikes cylindrical, very long, linear, composed of many closely imbricate flowers, under each of which is a lanceolate conca bractea. This is likewise a plant, according to Mr. Zappa, that may be useful as a cattle food. It grows not only along the roads, near dung-hills, in damp and fat places, but in irrigated meadows also of every district in Lombardy, though more near the borders than in the centre of them; it vegetates later than the above, flowering towards the end of May; the leaf is six inches long, and the flalk almost a foot high; notwithstanding it is not tender, every fort of cattle like it, and cows are as fond of it as of the above fort. It has also been noticed by Mr. Curtis that cattle in general appear very ready to eat the leaves. Sheep, goats, and swine, also eat it well. But it is not in so much elceen among the farmers as the narrow-leaved fort. See Rib Grass.

Plantago, in the Materia Medicâ. The leaves of the plantago major, common great plantain, or weybread, have a weak herbaceous smell, and an aultere bitter fulfafine taft, and their qualities are laid to be refrigerant, attenuating, subtlephious, and diuretic. Plantago was formerly reckoned among the most efficacious of vulnerary herbs; and by the peafants-the leaves are now commonly applied to fresh wounds, and cutaneous fores. Inwardly they have been used in phthisical complaints, spitting of blood, and in various fluxes, both alvine and hemorrhagic. The seeds, however, seem to be better adapted to relive pulmonary diffakes than the leaves, as they are extremely mucilaginous. The roots have also been recommended for the cure of certain intermittents, and from the experience of Bergius, not underpervy. An ounce or two of the expressd juice, or the like quantity of a strong infusion of plantain, may be given for a dose; in agues the dose should be double this quantity, and taken at the commencement of the fit. Plantain has been alleged to be a cure for the bite of the rattle-snake; but for this there is probably little found in the official plants. It is one of the principal ingredients in the remedy of the Negro Cudor, for the discovery of which he received a considerable reward from the assembly of South Carolina. Woodv. Med. Bot.

PLANTAIN, or PLANTANE, in Botany, &c. See Plantago.

Plantain, Water. See ALISMA.

Plantain, Leaff Water. See LIMOSELLA.

Plantain Shoot. See CANNA.

Plantain, Star-headed Water, Damaifonium, is a species of the Alisma; which see.

Plantain-Tree. See MUSA.

Plantain Island, in Geography, a small island in the Atlantic, near the coast of Africa N. lat. 7° 54'. W. long. 12° 18'.

PLANTALANTHUS, in Botany. See CEPHALANTHUS.

Plantaris, in Anatomy, a small mulficle situated in the calf of the leg. See GASTROCNEMIUS.

Plantation, in the Islands and Continent of America, a spot of ground which some planter, or person arrived in a new colony, cultivates and tills for his own use.

Plantations, or colonies in distant countries, are either such where the lands are claimed by right of occupancy only, by finding them defart and uncultivated, and populating them from the mother country; or where, when already cultivated, they have been either gained by conquest, or ceded to us by treaties. See Colony.

But there is a difference between these two species of colonies, with respect to the laws by which they are bound. For it hath been held (Salk. 411. 666.) that if the uninhabited country be discovered and planted by English subjects, all the English laws then in being, which are the birthright of every subject, are immediately there in force. But this must be understood with very many and very great restrictions. Such colonists carry with them only so much of the English law as is applicable to their own situation, and the condition of an infant colony; such, for instance, as the general rules of inheritance, and of protection from personal injuries. But in conquered or ceded countries, that have already laws of their own, the king may indeed alter and change those laws; but, till he actually does change them, the ancient laws of the country remain, unless such as are against the law of God, as in the case of an infidel country. 7 Rep. 17. Calvin's cafe. Show. Parl. cap. 31. See Charter-Governments.

Plantations and Trade, Board of. See Board.

Plantation, in Gardening, a certain collection of different kinds of trees or shrubs, which are cultivated either in nursery grounds or other places, in order to be raised and protected to proper and suitable states of growth for being afterwards planted out in particular situations; or which are planted out for ornamental or other purposes, generally in the way of beautifying portions of ground or particular spots surrounding or lying about country residences, &c. The former are commonly denominated nursery plantations.

As most plantations of the latter fort, besides the ornamental
PLANTATION.

In the forming of every sort of plantation where any kind of ornament is intended, as great a variety as possible of different sorts of hardy trees and shrubs should constantly be had recourse to, such as those of the middling and more tall growths of both the kinds, which in the former or those of the tree sorts are usually the oak, elm, ash, beech, chestnut, hornbeam, birch, alder, maple, fycamore, plane, poplar, lime, walnut, wild cherry, mountain-ash, larch, willow, hazel, &c.; and in the latter, or shrubby sort, the pine, firs, cedar of Lebanon, holly, bay, laurel, yew, ever-green oak, box-tree, and some others. See DECIDUOUS, EVER-GREEN, and FOREST TREES.

In regard to the general disposition of the plants, the deciduous and ever-green kinds may be planted in separate compartments, or in mixture, and sometimes the tree kinds by themselves, some in running varying plantations, towards the boundaries of lawns, parks, paddocks, &c., others in avenues, groves, thickets, and clumps, variously disposed in different sorts; and sometimes the trees and shrubs together, forming shrubberies, wildernesses, shady walks, and wood-works; placing those of taller growth backward, and the lower in front; bordering the whole with the most beautiful flowering shrubs and showy ever-greens, especially the principal walks and lawns, varying the form of all the several compartments, sometimes by moderate sweeps and curves outward and inward, of different dimensions, other parts in long easy bends, varied projections and breaks, so as to diversify the scene in imitation of natural plantations. The proper distances, in planting, may be from five or ten to fifteen or twenty feet: for example, the tall trees designed for continued plantations may be from ten to fifteen or twenty feet, varying the distance in different sorts, according to light and shade, &c.; and those in groves, where open, may be fifteen or twenty feet distance, and where closer ten or twelve; for thickets, five or six feet, or closer in particular places where a very dark shade or thick coverment of wood is required; and in clumps of trees, from five or ten to twenty feet between the trees in each, clump, varying the distance occasionally, according to growth, as also the sorts and numbers of trees in each, from two or three, to five, ten, or more. The form of the clumps may sometimes be triangular, at other times quadrangular, pentangular, &c., and in some curves, others in straight lines, to cause the greater variety. And in shrubbery clumps, and wilderness compartments, where the trees and shrubs are employed promiscuously, they may be planted from five to ten feet distance; the taller growths being placed backward eight or ten feet aunder, placing the lower plants gradually forward according to their gradations, to the lowest in front, as above, at four or five feet distance: and if the trees and shrubs of the plantations in general are disposed somewhat in the quincunx way, they appear to the greater advantage, and produce a better effect in some instances.

Before the making of any of these sorts of plantations, the grounds should, in all cases, be well included in some manner or other, and the plants be afterwards kept properly cleaned, pruned, and thinned out, so as to take their full growths.

Mr. Loudon, in his Treatise on Country Residences, after noticing the great variety which exists in trees, shrubs, and all sorts of wood, both in respect to beauty and utility, remarks, that all ornamental plantations may be divided into two kinds; namely, those whose grandeur is the effect to be produced, and those whose utility is the principal object. And it isasserted, that as grandeur depends more upon the whole than upon the parts, it may be produced where only one kind of tree is employed or made use of; but
but that as variety depends upon the parts alone, many different kinds are necessary. This, it is contended, has given rise to a most erroneous opinion and very pernicious practice among landscape gardeners and planters. Imagining that variety is produced by mixture, their rule is to mix as many kinds together as they possibly can, and never to let two trees of the same species be seen at once. This is said to be their recipe for variety in plantations; which they follow, as far as possible, in every arrangement of vegetables, from the parterre to the forest. But instead of affording variety, it is maintained that it, on the contrary, produces the most distressing incongruity. The eye, in examining the parts, finds no connection—no harmony—no relief—no repose of effect—no difference of composition, or change of character; or, if the surface of such a plantation be looked upon from a distance, it is on account of the indiscriminate mixture of forms, more dull and monotonous than if only one species of tree had been used. Its outline against the sky is a mere unvaried zig-zag line; which, except in artificial plantations, is not to be found in the whole range of nature.

It is further supposed, that this mixture is evidently produced by their ignorance of that which constitutes variety; for it does not, as they imagine, consist in the diversity of separate parts, but in the diversity of their effects when combined together; in a difference of composition and character: this very different from the other is the effect of such a variety; it relieves the eye and interets the mind, without fatiguing either.

Therefore, in forming a plantation with a view to variety, instead of selecting such trees and shrubs as are of opposite character, those differing in the slightest degree are in general much better adapted to the purpose. The upright fiery form of the larch, mixes very ill with the round head of the oak. But by choosing trees of intermediate forms, and placing them in the interval between these extremes, a natural connection and gradation will be produced. By this means, with the bire of trees and shrubs which we please, an endless source of variety in woody scenery may be had from the forms of trees and their modes of growth, independently of any other material of landscape.

But there is another source of variety which arises from grouping, in the manner in which trees are diffused, more than from the number of distinct species. This is chiefly applicable to extensive plantations where the general character is grandeur, as woods, groves, and forests. It is produced by mixing together tall and low growths; planting irregularly, sometimes very close, at other times very wide; by pruning so as to expose trunks, stems, or branches, in some places, and to conceal them in others, &c. Much of the effect also depends on the diversity of age in the low growths, as well as the difference of magnitude and accidental form of the trees. This kind of variety, it is supposed, exists in the greatest perfection in natural forests; and the true way to study its principles is, to observe in them the effects of time, accident, the growing of cattle, the felling of timber, and other circumstances. By this means we shall, it is imagined, be enabled to transfer the same effects, sometimes by different and sometimes by similar methods, to artificial plantations. Natural forests cannot be too strongly recommended to the examination of the ornamental planter. Almost every other operation of planting is mechanical; it is in this mode of grouping, and following the principles of nature, that the man of taste will be distinguished from the mere gardener. The effect of putting in practice the principles to be derived from such a study may be seen, it is said, in Mr. Price's woods at Foxley, which no man of taste ever, it is supposed, saw without being filled with wonder and delight.

A still further source of variety, which is independent of the modes of growth or the manner of disposition, is in the colour. Therefore, in order to assist in the arrangement of a numerous collection of trees and shrubs, a knowledge of the harmony of tints is essentially necessary to the planter, and of very considerable importance to his success in the business.

It may be thought, that the different tints of green in trees are distinctions too minute to be attended to for this purpose; but reflection and experience shew that they are of material consequence in this fort of scenery. Imagine, says the writer, two woods of equal and considerable extent,—the one composed of the yellow green of the weeping willow, the other of the dark green of the oak: how different must be the impression received from each, though the general form and composition of both, at a distance, would appear in some measure the same! It is evident, that the effect of the different greens must be much more conspicuous in scenes intended to be more minutely examined by the eye: how different even the green of the gooseberry-bush and currant-tree when opposed to each other!

It is remarked, that the tints of trees may be considered in respect to their harmony with one another—with external scenery—their gradation—and their particular effects. The harmony of tints is suppos’d, in general, to be derived from the respective agreement, disagreement, and destruction of particular kinds when mixed together; and that these harmonies, discord, and privations, will remain true, although the colours should not be bright. The slightest tinge will have the effect. When weak colours that agree are placed near each other, they support and give spirit to one another. A hawthorn hedge, among the green of pature fields, has, it is asserted, the same dull green appearance: but when opposed to the brown of a ploughed field, it appears with pecurial spirit and force. And again, the ploughed field, were it not contrasted with the hedge or some object of a similar colour, would appear dark and colourless; but opposed to the hedge, it appears of a rich brown. A Huntingdon willow, observed alone, it is maintained, appears green like any other tree; but, contrasted with a chestnut, it approaches to white; and the oak again, by the contrail, appears much darker than before. If plantations were arranged agreeably to these principles, the colours would, it is believed, at all times appear striking and forcible; but from the opposite contrail, that of mixing all colours together, they are annihilated, and their separate effects destroyed. In consequence of this, it is frequently said that trees have no colour but green, except in autumn, and that attention to these principles in their arrangement is frivolous. But nothing can shew greater ignorance of nature. Green is indeed the predominant colour of trees; but it is only in one or two of the summer months that it nearly absorbs every other colour. All trees have their peculiar autumn and spring tints, which in midsummer are only weakened, not destroyed; and, whether it be not of greater importance to attend to the harmony of these tints, than to neglect it altogether, because the effect would be in some cases possible during a month or six weeks in summer, every man of taste or sense is left to judge. It is evident, that the harmony of wood with landscape must depend upon the general principles that have been already mentioned. One principle of harmony is, that the general appearance of the wood planted about a mansion should correspond with the general appearance of the wood in the surrounding country:
The sufficient the lake, as off and tew becomes to To and distance scene, is may- build, pasture, produce place ufeful Thus, follows, is the oak not it place dry may that is "ten- fhewn by maffes fcene, fomeobjcCt, by the the the be praftice belt, thefe And, of other-grounds, or ornament the trees planted, lead to the arrangement of trees and shrubs.

It is remarked, that if we operate with the permanent dark and light greens, as with light and shade in landscape painting, we may produce many of the effects of aerial perspective. The imaginary height of a hill may be increased, by placing dark coloured trees at the base, and lighter kinds towards the summit; so may the apparent breadth of a lake, by planting trees of a dark green on the side nearest the eye, and others of a lighter tinge on the opposite side; in the same manner, bays or receffes may be apparently deepened by placing the light coloured greens on the same arrangement. This mode of operating with the colours of trees will only be deemed unimportant, it is supposèd, by the ignorant or inexperienced.

But though the harmony of tints only produces a pleasing scene, their disfigurement, on the other hand, may produce a striking effect. An outline, which cannot be varied in form, may be broken by the opposition of its tints, or by masses of dark and light green. Two or three trees together, that form a striking contral with all around, may attract the eye, and fix it to, as either to induce it to admire some object, as a building; or prevent it from viewing something disagreeable, or lefs noble, in the scene. Trees of a reddish tint, or ever-greens, have the power of attracting the eye in an affonishing degree; and in many places, where the former have been planted at random among other trees, they detract the whole scenary in the autumnal months.

In regard to the arrangement of the materials of plantations, the great buiñess is that of uniting beauty with utility in the most natural manner, which is best accomplished by the confideration of forests or woody waffles, which combine the species of scenery that approach as near as possible to nature than any other in this country; by this means may be discovered the indications of every valuable or useful practice in beneficial or picturesque planting. But in respect to arrangement where utility alone is the main object, it may be observed, that as every tree has a certain foil and situation, or thofe in which it will prosper better than in any other, that is, produce timber in the greatest quantity and beat quality, and as this tree will in general pay better than more valuable kinds which would not thrive, or would grow too quick in such places; it follows, that in the formation of useful plantations, one great object should be, to accommodate the trees to these circumstances, as already seen. And, as the properties of soils and situations are various, these naturally lead to a correponding variation of the farts of trees also; and this variation, it is supposèd, at once produces ornament and utility. Thus, in natural forests such an arrangement actually takes place. Hence, in one part, the oak is found as the principal tree; the hazel the principal undergrowth; and other particular plants, grasses, and mollæs, chiefly to prevail. While a little further on, a few beeches mingle with the oaks; still more onward the beech becomes the principal tree; the undergrowth changing in the same way, the thorn, with other plants, grasses, and mollæs being found. Ultimately the land becomes moift, when the birch gradually fhews itself, and this moifture increasing as the birch retires, it is proceeded by the alder; each with their appropriate undergrowths, or ever-varying closes of pasture, as fhewn by Gilpin in his "Foreft Scenery," and "Walks in a Foreft," &c. In this manner the arrangement proceeds throughout the whole foreft; and if the foil were minutely examined, it would be found to vary correspondently with the trees. Where the oak abounds, it will generally be deep and good; dry where the beech succeeds belt; and moift in different degrees where the birch and alder prevail.

Planters, it is supposèd, have seldom a sufficient idea of the effects and advantages that might be produced, by having recourse to this mode of arranging vegetables in artificial scenery, whether the rife expectance of planting, the future beauty, or the ultimate utility of it be regarded. Only thofe who combine a knowledge of botany with painting, it is imagined, can conceive the variety and perpetual intereft that may be thus created in a place even of the smallest extent, and with the least natural advantages. In the prefent mode, all improved places have a fañseness in their general appearance; as they are composed of the fame kind of mixture. The shrubbery, or a part of it, in one place, is precisely the fame with another at a diftance from it, and affords a pattern of all others; but were nature followed in this refpeft, the variety would be endless. Nothing, it is believed, could then be more interefting, than to walk or ride through a place thus laid out; to view the trees, shrubs, plants, and even the grasses and ferns; the infinite diversity of shapes, colouring, and composition of the trees and shrubs; and the ever-varying openings and intricate receffes between them; again, varied with groups and turfs of flowering plants and ferns, spreading among the grafs, in every direction; and all this independently of every other object, fuch as buildings, rocks, water, animals, dilant prospect, and even variety in the grounds. So that by this mode of planting, a situation naturally the moift dull and infipid, may be made infinitely varied and interefting. And it is afferted, that this mode of arrangement is not more beautiful in shrubberies, flower-gardens, and green-houses, than it is profitable in countrie residences.

In the disposition of the wood in plantations about countrie residences, the forms of the surfaces the moift defirable to be planted in the grounds, are chiefly to be determined by the character which they are to assume. Where they are of an even or level surface, there can be nothing to interfere with this rule; but when the surface is varied with swells, hollows, and abruptness, the great art is, to combine the natural character of the place with the character to be created; and when these are understood by the designer, the best effect will be produced. However, independently of artificial characters, nature always points out rising grounds for plantations. Wood placed on knolls or swells, it is contended, heightens their effects, and gives spirit, force, and intricacy to a scene, otherwise tame and monotonous. On the contrary, wood placed in the hollows only, or in the hollows and eminences indifferently, destroys all the expression or natural features of the surface, and often produces deformities. Nothing is more noble than a steep hill clothed with wood; but, imagine this hill perfectly bare, while the surrounding country is wooded, and it becomes a deformity in the general view. To plant the hollows, and leave bare the eminences, is, in almost every situation, counteracting nature. Even in pleasure grounds or parks, a group
group of shrubs, or a few trees, placed upon a rise, however gentle, yet off the scene, as it were, at once; but, plant them only in the low places, and they will remain until full grown before they have much effect; and at that time, though the residence may have the appearance of wood at a distance; yet, when it is examined particularly, the features of the grounds are totally destroyed. There are many places in the country which have a sufficient quantity of old wood, which, if it had been planted with a proper regard to the natural variety of the grounds, would have made them as superior to their present state, as that is now to such as are totally destitute of trees. It is not, however, meant that no low situation should be planted, or that trees should be placed formally on the summit of every eminence; on the contrary, dills, dingles, and such romantic places should be shaded with wood; and not a group, nor a single tree should exist, but what appears connected with other trees, as well as with the grounds. Taking the country in a general point of view, the hills should be wooded; the rising grounds between the hills and valleys diversified with handsome residences, pasture lands, and some corn fields; and the lowest parts kept in a state of almost perpetual arable. These valleys in general, in order to promote a more free circulation of air, and favour the particular mode of farming to which they are suited, should be free from plantations, and sometimes even from hedges. Viewed from rising grounds in the autumnal season, they should present broad flat shades of rich yellows, interpersed with farm houses, and relieved by roads, canals, or rivers. An example in illustration of which is suppos'd to be met with in the valley called the Carle of Gowrie in Scotland.

In fact, it is contended, that there is nothing of so great importance as the situation of wood, whether the general appearance of the country and the improvement of its climate, or the beauty and value of individual properties, are had in contemplation. All other operations that can be effected about residencies, are thought comparatively of little consequence. It is the wood, it is suppos'd, like the flowers in a picture, that gives the effect; and as it is by the situation and relative connection of these flowers, that an expressive or unmeaning picture is produced by the painter; so by the site and connection of plantations, a place is either deformed or beautified by the planter. Even small groups and detached trees are of the utmost consequence in this respect, when skillfully performed or put in their places, but where the contrary is the case the whole is spoiled. It is said to be lamentable to see the plantations that are daily making at a considerable expense, without any regard to this principle. In this level country it may, however, be thought of less consequence, than where the grounds are strikingly varied by nature, as in Wales and Scotland, where it is of the first importance. It is conceived, that in less than half a century, wood may completely change the appearance of the residencies of gentlemen, and of the whole country; and there who understand the subject will allow, that there is some danger of the change producing a bad effect, as is illustrated by the example of some parts of Scotland.

In respect to the quantity and disposition of the wood which is to surround residencies, it should either, it is said, be arranged in groups, so close together, as, at a small distance, to appear a connected mass; or one or more large irregular masses must be planted, to which all the groups and single trees should seem to belong. The former method, it is suggested, will have a good effect when the surface is unvaried; but can only be adopted with propriety, when the situation of the residence is elevated or on a de-
made of double their present value, have a much better effect, and afford better shelter. Most plantations, especially in the northern parts of the country, though they generally go under the title of woods, are, in reality, of the grove kind. None of the trees are found kept under the roof in a decided manner, cut over, and allowed to spring up again, while a certain number, from fifteen to thirty feet distance, are preferred until their timber be full grown; but the trees being once planted, are allowed to grow up together, only a few being thinned out where they are too much crowded, and even this is very little attended to. Those removed are either cut over, or grubbed out by the roots, as is found most convenient, without any regard to propriety. In consequence of this management, a few bushes of undergrowth are found in some places, and the rest of the ground, if not shaded too much by the crowded trees, is covered with pasture; and neither the pasture, nor the undergrowth, from being intermixed, can be turned to the advantage of the proprietor. There are other plantations where undergrowth exists among timber trees in a more general way, but of kinds which are of little or no use, except for fuel; and this is by no means a profitable article, especially in a cold district. But, on the other hand, there are woods in some places where both timber and undergrowth are cultivated; and it is from observing the great profits derived by the proprietors of these, that the advantages of raising oak undergrowth in woods is so strongly recommended. The very high price which is given for oak-bark is generally known; and the sum given for an acre of oaks, from twelve to twenty-five years old, valuable for the bark alone, is very considerable. Instances of these kinds are added from the woods of Dunkeld in Scotland, where there are lands of very little value for any other purpose, that contain oak woods, chiefly of the natural kind, the undergrowth of which is sold every twenty-five years, at the rate of from 25l. to 60l. the acre, clear of all expenses; or from 25l. to 48l. the acre annually; independent of the value of the timber trees left, fifty of which commonly remain to each acre. And in more low and sheltered situations, it is contended, that double the advantage would be derived, in consequence of the more quick growth, as in such cases the undergrowth would become equal in fire in the course of twelve or thirteen years, and therefore afford two cuttings instead of one in the same length of time; besides more uniform crops be produced, from the greater regularity in planting, which would be adopted. But left oak undergrowth should be thought to be made more profitable than it really is, it is further remarked, that, in the most cold, hilly situations of Scotland and Wales, it will afford upwards of 2l., and in more favourable situations about 3l., the flat acre annually; and if properly attended to in its early growth, still more. The easy and cheap method of raising it by means of the acorn, is also a great recommendation of it, as well as that of its growing better and more expeditiously in this way. Where an undergrowth alone of oak is wanted, other sorts of timber trees may be planted with the acorns. These statements strongly display the superiority and advantages of woods over other kinds of plantations; but the recommendation of the formation of them, exclusive of groves or coppices, is not by any means intended, as, on the contrary, there are thin kinds of land, with bad under itrata, where the fir formed into groves, is more profitable than any other kind of plantations: and there are steep and rocky banks, where no tree can be so advantageously cultivated as the common ash; and rich moist places, where no plantation will turn out so profitable as offers. But, gene-

nerally speaking, it may be safely ascertained, that woods are the kind of plantation that ought to be most commonly formed; and that though the kind of timber grown in these woods will vary according to the consumption of different places, yet that oak will be found the best and most profitable undergrowth of any. See Woon.

In respect to the third sort, or coppice-wood, it is alone seldom desirable in point of character, though, in many places, it is the most profitable kind of plantation. Its formation is very simple; when of a proper size it is cut down; after which, the fells spring up again; and this operation is had recourse to in a periodical manner. These kinds of woods are, however, in general, under a very wretched fort of management in many parts of this country. See COPPICE.

With regard to the fourth, or group, whether made in the ground, or in the hedges which divide the fields, it should be well and ornamentally formed. And in the fifth, or avenue, whether the rows of the trees be leading to a residence or in other parts of grounds, they should be well suited to the nature of their situations and other circumstances. See AVENUE.

In all cafes where plantations are to be made, it is of great consequence to fix upon the most proper kinds. In ascertaining this, the kinds of woods and species of trees met with in the surrounding country, the market, the present or probable expense of carriage by land or water, and a variety of other circumstances, are to be considered; and that kind fixed upon which will in the end turn out the most profitable. And the plantations being once made, the particular kinds should be held strictly in view in their management afterwards. A collection of oaks designed for a grove, if not gradually thinned out as they grow up, will never, it is supposed, succeed; but if the same collection were intended for a wood, thinning them out, in place of cutting over, would lessen the crop of undergrowth. There is no method of management that will make a collection of siris a wood; nor can a collection of hazels, or other low growths erroneously planted to reace a grove, ever be made to assume that character. The idea of forming and preserving a distinct character in plantations, it is thought, is never sufficiently attended to by planters in general,—a certain space is to be planted, and it is filled up with trees at random. It is supposed to be from this neglect alone, independent of all others, as those of previously preparing the soil to planting, cultivating, and keeping it in order afterwards, training and thinning, with other operations, that few plantations yield one-third of the profit, which they might. It is, however, supposed, that, if the particular kind of plantation to be formed, were previously determined upon, thebusiness might proceed with a degree of certainty unknown and unpractised at the present period, as well as other great advantages be derived from it.

In relation to the outlines or boundaries of plantations, they should, it is imagined, be determined by the character which they are to assume. The tree being a picturesque object, all wood is congequently so; and as the addition of wood to ground is always an addition of picturesque nature, although frequently blended with grandeur or beauty, hence the propriety of irregular or picturesque outlines in all kinds of plantations. Where the character to be produced is that of grandeur, the bounding line, it is affected, should consist of bold angular prominences, succeeded by deep inclinations, forming large bays and promontories; and to give these full greater effect, and vary their outline against the sky, they should be adapted to the variations of the ground, the bays being in the hollows, and the pro-

montories
PLANTATION.

In this mixture of curves and straight lines, the former should generally be obtuse and convex, and the latter of considerable length. All should appear "irregularly great." Such plantations as are made on hills ought always to assume the character of grandeur. Those introduced among cultivated fields, and bounded by straight lines, may also have a very grand effect, if due regard be had to vary their outline, by attending to the angular indentations of hedgerows, or belts of planting; though, in this case, it is impossible to avoid a degree of formality, which is always connected with cultivation, and which, being essential to it, cannot be considered as a deformity. But where a plantation is to be made of a fize which does not assume the character of grandeur, the outline should be composed of such a mixture of straight and curved lines as will relieve each other, produce variety and intricacy, and correspond with the surface of the ground. Nothing can be more unnatural or inipid than a serpentine line, or one wholly composed of curves, as the boundary of a plantation: it is totally void of variety and intricacy, and deficient of force and spirit, which are some of the great objects gained by planting, and which it is the peculiar property of irregular or picturesque forms to confer. The outline, whose ornament is a principal consideration, should be broken by single trees and groups, so as to increase its irregularity, and take away from that formality andsameness which lines of every kind have, when viewed alone. Those who attempt this, without understanding the effect, clog up the bays and recesses, in place of making them appear deeper and more intricate; and thus they do much more harm than good. The outline is also greatly varied, and much improved, by mixing low growths with timber trees along the boundary of the plantation; and afterwards by taking away the fence, and making partial inroads or recesses of different forms and degrees of depth. In open groves, where the trees stand single, and have no fence, the outline is easily varied, and with great effect. The different forms, colours, and shades of green, when no other mode is applicable, may often have a surprising effect in apparently varying the boundary of a plantation; a fine example of which is seen at Kedgeltone. Groups and thicketst, when planted in a place of a circular fence, like a clump, should always have the most irregular outline. This irregularity is apparently increased, by mixing low with tall growths at planting; by removing the fence, when these are grown to a certain height; and by judicious thinning. The great beauty of small groups and single trees arises from their connection, and the bends and inclinations of their limbs. This may be produced, by planting two or more trees or shrubs in one hole, of different kinds, or the same kinds of different sizes, &c.; and connecting these by others intrograding round them. And the most beautiful examples for this sort of work are, if suppos’d, to be found in natural forests, or woody banks and commons, where trees have sprung up in an accidental manner. Examples representing the manner in which small mazes and groups of trees may be grown, without giving a clump-like appearance to the inclosures, are given from the working plans of planting at Barnbrow, and other places. The general forms of the mazes may, it is asserted, be infinitely varied on a level surface; and on an irregular one, they should correspond with it. And, as it is believed that this principle is universally applicable, there can never be the smallest necessity or apology for any thing of the clump kind in such cases.

Plantation, in Rural Economy, a portion of land planted with timber, or other trees. It is plain that plantations, when judiciously made, not only afford great improvement to elates, but are highly ornamental to the country. They should, therefore, be more particularly attended to, where there are large tracts of poor barren lands, that cannot be converted to the more profitable purposes of tillage or grafts. They have also a fine effect in the vicinity of habitations. And in many cases, the proprietors of elates, whether of large or moderate sizes, may reap great pleasure and advantage in allotting a part of them to this use, as they give an air of cultivation and fertility; and after eight or ten years, in many cases, bring in great profit by the gradual thinning of the underwood, besides leaving a sufficiency of standards to attain full growth. The expense attending the making of plantations, and the knowing that they must wait several years before the trees have made any considerable progress, or can afford any advantage, often, however, prove an obstacle in attempting the prosecution of the business. But the expense of planting, where the plants are raised on the grounds, will not be so great as may be imagined, especially as a small plot of nursery-ground will raise plants sufficient, in three or four years, to plant a great many acres of land; and the expense of raising and planting, with the loss of time in waiting till the plants attain some growth, will be compensated by the first full or thinning, in eight or ten years after planting; and the shoots which remain shoot up again, in many of the deciduous kind, and afford a lopping every eight or ten years, exclusively of the due portion of standards, left at proper distances to attain full growth for timber, or other purposes.

It may be noticed, that, in former ages, this island abounded in natural plantations or forests, which spread themselves over the surface of it to a very considerable extent, and which were composed of various sorts of tall or lofty trees of great magnitude, all blended together in a promiscuous manner, and of spontaneous growth. Those vall forests were never planted by any human hands; such only have been employed for ages in cutting them down; for in many places there were such profusions of ileefs wood, that large tracts were obliged to be cleared by degrees, in order to cultivate the ground for other purposes; which, together with the necessary demands for the wood, from time to time, for building, and other uses, as well as that of the owners of such lands reaping considerable advantage from the sale of their timber, continued gradually, one generation after another, the practice of grubbing up and destroying their timber woods and plantations without measure; and but few ever planted any in the place of that which they cut down; so that, in many parts, there is at this time almost a general demolition of woodland, and many considerable elates have fearfully any timber of consequence or value left standing upon them. There is, in short, a want, in most places, of nearly a complete renovation of the timber; which should take place as soon as possible, otherwise the nation, in many parts, may sustain considerable injury, from the increasing fearity of so important an article of internal produce and general consumption. Every portion of land in the kingdom, which is capable and proper for the purpose, ought, therefore, without delay, to be covered with plantations of this sort. All the different deep, waiite, unproductive tracts of land, in different situations, are in general fit for being converted to this use, often with considerable advantage, as from two or three to eight or ten times that which they could be made to afford under any other system of cultivation. It is indeed remarked, that of such barren waiites, there are few spots which would not admit of being improved in this manner, under particular circumstances;
PLANTATION.

circumstances; and that there is a very great number of tracts, of vast extent, on which it would be far more pro-
fitable to the owner than that of attempting any other forts of improvement; as in all those cases where the soil is dry, but of an infertile nature, of a heathy, stiff, hard, clayey quality, with little surface produce, or where it is much covered or filled with rocks and stones; that, in fact, there is hardly any land to poor, barren, rocky, or unproductive, as not to admit of it, when properly managed.

In making plantations, it is necessary to choose such trees as are adapted to the nature of the particular soil and situation. As to the proper sorts of trees, most of the deciduous and evergreen kinds may be employed with propriety; and young plants of from two or three to five or ten feet in height always prove more successful than such as are older, as those of a younger growth always take root sooner, and establish themselves more firmly, so as to form considerably the finest plantations at last, and are of longest duration: for though large trees of from fifteen to twenty feet in height, especially of the deciduous kind, may with care be transplanted, so as to grow, and probably thrive tolerably well for some years; yet, by not rooting firmly, like young plants, they often fail, and, after some years standing, have hardly any shoots, and at last gradually dwindle and perish altogether.

In cases where large plantations are to be formed of forest and timber trees, particular sorts must be chosen, confining of deciduous and evergreen trees. Of the first kinds, the oak, elm, ash, beech, chestnut, hornbeam, birch, alder, maple, linden, plane, poplar, lime, walnut, mountain ash, larch, willow, &c.

There are two methods practised in forming plantations: one is by raising the trees from seed at once, on the ground where the plantation is intended to be, especially the deciduous kinds, and which is effected by sowing the seed in drills, a yard asunder, the plants remaining where raised, thinning them gradually; the other method is by previously raising the plants in a nursery, till two or three feet high, then planting them out into the places allotted them. The former, or that of raising the plants where they are to remain, though it may be more expedient, and at once gets quit of the trouble of transplanting, requires greater attention for a few years, till the plants have shot up out of the way of weeds; but the trees, from their always remaining where raised, without being disturbed by removal, may probably make a greater progress. The latter method, or that of raising the trees first in the nursery, is probably the most commonly practised, as being thought the least troublesome and expensive, with regard to the attendance at first to the young growth. In respect to the preparation of the ground for the final reception of the feed or plants, it is mostly performed by deep ploughing and harrowing upon such ground as the plough can be employed on; but where this or other tillage is not practicable, only young plants from the nursery can be used, digging holes, &c. at proper distances, one for the reception of each plant. Where, however, the ground can be tilled, it will prove very advantageous, by performing it a year before; sowing it with a crop of turnips, or other plants of a similar kind; and when these come off, ploughing and harrowing the ground again, for the reception of either the feed or plants the ensuing season. The most proper season for making this sort of plantation, either by feed or plants, is any time in dry mild weather, in the autumn, as from October till February, or later in moist soils. Where large tracts are to be planted, both the feed and plant methods must be pursued all winter, at every favourable opportunity. The ground, where the plantations are made, should be previously fenced in all round with a deep ditch, to guard against the encroachments of cattle, or other animals. In respect to after-manage-
ment, while the plantations are young, they must have some attendance to destroy weeds, which may be expeditiously executed by hoeing between the rows in dry weather, or occasionally by horse-hoeing: and this care will be needful for two or three years, especially to the feeding plantations, until the trees are advanced out of the reach of weeds; after which no farther trouble will be required, until the trees are ready for the firrt fall or thinning for poles, faggots, &c.

After eight or ten years growth, they are mostly of a proper size to begin the firrt fall by a moderate thinning, which will serve for poles and faggot-wood, to repay some of the expense of planting, &c. But only a part of the plantation should be lopped the firrt year; thinning out the weakest and most unprofitable growth first, leaving a suffi-
ciency of the most vigorous plants pretty close, to grow up for larger purporses; the year following thinning another part, and to continue an annual thinning fall, till the whole plantation has been gone over; cutting each fall down near the ground, leaving the stumps to shoot out again, especially in the deciduous kinds; and by the time the last fall has been made, the firrt will have shot up, and be ready to be cut again. So the returns of the falling may be contrived to be every five, seven, eight, or ten years, or more, ac-
cording to the ufe the poles or wood are wanted for: and if large poles, &c. are wanted, the fall may be only once in fourteen, eighteen, or twenty years. If at every falling be careful to leave enough of the now thriving plants for standards; being left pretty close at firrt, that they may mutually draw each other up in height, but thinned out in every succeeding fall as they increase in bulk, and so as to leave a sufficient quantity of the principal trees at proper distances, to grow up to timber; which in their turn, as they become fit for the purporses intended, may also be felled, according as there may be a demand for them, to the most advantage; having young ones from the stumps coming up in proper succession, as substitutives, so as the ground may always be occupied as completely as possible in all parts.

In regard to the advantages that may be derived from the use of different sorts of trees in plantations, they have been stated as very considerable by different writers. In Mr. Mellish's experience, on a forest sandy soil of 32. an acre value, as stated by Mr. Young in his Eastern Tour, in 1771, and made in different ways; as by cleaning the land in the manner as for grain, ploughing once and then setting the trees, by trench-ploughing and setting, and by not ploughing at all, but letting in holes, with the ground only cleared for them: the results were found nearly equal; but what superiority there was, was in favour of the ploughing method. The sorts of trees were Scotch and spruce firrs, larch, oak, ash, chestnut, beech, birch, &c.; the whole being mixed. The Scotch and spruce firs have grown much the fastest, and generally succeeded with scarcely any failures. The number set on the acre mostly 5000; the expense of inclosing, raising the trees, and planting, 3. the acre. In five years they require thinning, when the wood taken out about pays for the labour; the number thinned out being about a thousand. And in five years more they are thinned again, when another thousand trees are taken out, which make good hedge wood and hedge staves; the value about five pounds more than pays the expense of the labour. When these thinnings have been performed, three thousand are left, which have been found from experience
### PLANTATION.

To be then worth 6d. each on an average, as stands, and clear of all expences, if old. At this time another thousand should be taken out. Two thousand are therefore left, which, at 30 years growth, will be worth, as they stand, 12. each; and at 40 years, they will be worth 22. each. This is the produce of such poor forest lands; but this experienced planter has, Mr. Young says, many Scotch firs planted 35 years ago in good land, which are worth 401. each, and a great many from 25. to 35. On these data, Mr. Young calculates the profit of the plantations, at different periods, in this manner:

<table>

| Or per acre per annum | 5 6 1

It is further stated, that this account of the expenses, produce, and profit, of planting forest land at 3s. an acre, shews the amazing profit of such undertakings. Plantations have, in general, been raised with a view merely to beauty, or else through a very noble patriotic motive of being serviceable to the country; but it is evident, that they may be undertaken with very different views—with those of profit: so that a man may cut down the trees he planted himself, and expect to reap, in so doing, very considerable profit. If he cuts all down at the end of 20 years, and leaves not a single tree, he gains a profit clear of near 70s. an acre, which is 3l. 3s. per acre per annum, from the first planting. Let me ask the most skilful farmers of this country, how they will exceed such a profit, by any fyllem of common husbandry, on such poor land? It before appeared, that common good husbandry, after some improvements, would yield but 1l. 1s. 1d. per acre profit; so that the planting to cut in 20 years, is more than thrice as beneficial, and certainly much less exposed to accidental losses. But supposing the trees left 30 years, in that case the thinnings pay, for
for the first 20 years, 1l. per acre per annum; and at the end of the 30th, the account from the first planting is 5l. 17s. 1d. per acre; and in 40 years, 5l. 6s. 1d. After which time, they may be supposed to decline in quickness of growth, and consequently had better be cut down, in point of profit. It is noticed, that if beauty of situation is not, in some respects, commanded, we seldom see plantations of quick-growing trees; but it is evident, that poor soils should be planted upon in the rare view of profit. A crop of fires, instead of a crop of wheat, barley, or oats, at 20 years growth, so many men may expect to see arriving at perfection, turns out far superior. One of the most profitable farms would be a 30 years leaf of such land, with liberty to plant and cut down. One of 20 years, which is a shorter period than the generality of long leaves, would, thus applied, exceed common husbandry on such soils.

It is added, that Mr. Mellish has a waite, inclosed with a ring fence of 700 acres, which he would let at 3s. an acre, tythe free. Suppose a person hired it under a lease of 30 years:

<table>
<thead>
<tr>
<th>Total expense</th>
<th>£7800</th>
</tr>
</thead>
</table>

*Produce.—Thinning in 10 years, at 5l. an acre* 3500

*Cut down at 30 years, 2000 per acre, at 1s., or 100l. per acre* 70000

*Total produce* 91000

*Total expenses* 7800

*Clear profit* 83200

This account is flatted in the style of a common farm; the first expenditure called stock, and compound interest, not calculated. It is very evident that no man, poffessed of such soils, who can hire them for 20 or 30 years, under a planting lease, need ever be diftrefled at the idea of younger children's fortunes, or raising large sums of money in future. A moderate expenditure will, by planting, secure the certain poffeification of any sum that may in future be wanted.

And in Mr. Bever's experiments, as flatted by the fame writer, Scotch firs, in 18 years, are found to be worth 2s. 6d. And a whole plantation of 50 years growth, worth 50l. on an average: they fland 20 feet square, which is 108 to an acre. In another plantation on a moift sandy loam, larches of 18 years growth, are worth 5s. 6d.: spruce firs among them not half fo good, which Mr. Bever attributes to their being trimmed up; others on fame foil and growth, not ferved to, are almoat double the fize.

Mr. Berney, at Bracan Ash, has also made great improvements by planting land of 20s. an acre. Oaks, of 50 years growth, are worthy 15l. each: they fland 15 feet square; this is 180 on an acre. Larch, in 18 years (20 from the seed), are worth 6s. each: they grow out of underwoods that pay 20s. an acre. Some few of 20 years, worth 15l. each. Silver firs in the fame wood not quite fo large, but they beat both the spruce and Scotch. They all fland 15 feet square in the underwood. And in another plantation without underwood, Scotch firs, of 18 years, are worth 2s. 6d. each: they fland 8 feet square; which is 680 on an acre. or 85l.; that is, 52s. 14d. per acre per annum, exclusive of thinnings. No husbandry, Mr. Young contends, will equal this. A man who would plant for profit must not regret land of 20s. an acre.

The Weymouth pines, in 18 years, much larger than Scotch firs of 22 years.

But in Mr. Fellowes' of Shottefham experiments, who has, according to Mr. Young, tried various trees, some years ago, so that he is now able clearly to judge which is the most profitable; the following are the results.

**Experiment 1.**—A plantation of Scotch firs of 45 years growth, 20 feet square, on land of 15s. an acre, are now worth 20s. each on an average. At that distance there are 108 trees on an acre, or 108l.; which is 2s. 9d. per acre per annum, from the first planting, exclusive of thinnings, which would more than double it. But the grafts under the trees would have let for many years past at 7s. an acre.

**Experiment 2.**—Another plantation of Scotch firs, 38 years growth, standing in rows 14 feet wide and 15 in the rows, are now worth 12s. on an average. This distance gives 500 on an acre; and at 12s. they come to 180d., or 4l. 14s. per acre per annum. The rent of the land 15l.; poor rates, 1s. 3d. per annum; and tythe, till 20 years old, 5s. an acre; the grafts under them now 5s. an acre. It is sufficiently evident, Mr. Young thinks, that no husbandry can equal this.

**Experiment 3.**—Chiefsuts in 38 years, on the same land, standing 14 feet by 10, are worth 15s. each. This is 225l. per acre; or 5l. 16s. per acre per annum, besides thinnings.

**Experiment 4.**—Scotch firs in 38 years, on the same land, measure 17 feet of timber on an average, for which Mr. Fellowes has been offered 11d. a foot; that is, 15l. 7d. a tree. They fland 14 feet by 10. An acre would therefore be 133l. 15s.; or 6l. 3s. per acre per annum, besides thinnings. These trees are 60 feet high.

**Experiment 5.**—On the same land larch trees, of only 31 years growth, are as large as the firs of experiment No. 4, which liews that the larch is a much quicker grower. Spruce by them not fole large as either. The pinner of 38 years, larger than the Scotch. The cedar of Lebanon, of the fame age, would now cut into planks 12 inches wide.

**Experiment 6.**—A very striking comparifon between the larch and the spruce fir, was tried by planting an old gravel pit levelled, furruned by a plantation of Scotch fir, with thofe two farts in alternate rows. The larch is from 6 to 12 feet high; whereas the spruce is but 2 feet on an average.

**Experiment 7.**—A large plantation of many acres of a poor gravelly land at 8s. an acre, containing Scotch and spruce firs and larches, is now 16 years old; they are in fquares of ten feet, and are worthy:

- The Scotch, 25. 6d. each.
- The spruce, 25. 6d.
- The larches, 4s. 6d.

At ten feet, there are 455 trees on an acre. The Scotch, at 2s. 6d. come to 5l. 7s. 6d.; or per acre per annum, 5l. 7s.

The spruce, at 3s. 6d. to 7s. 2d. 6d.; or per acre per annum, 4l. 15s.

The larch, at 4s. 6d. to 9s. 17s. 6d.; or per acre per annum, 6s. 2s.

All three exclusive of thinnings. Suppose, says Mr. Young, we calculate there at no more than paying the rent, tythe, and town charges; and that the larch, in 20 years, come only to 100l., which is however, under the truth; let any
any one calculate the profit of hiring land on a 21 (or more) years lease, and immediately planting. In what other application of the lands can such great profit be made, as gaining $1f, an acre without any risk, and almost without any expense? It is true such a conduct cannot, like the culture of corn and grass, be general, for reasons obvious to every one; but as far as the whole demand of any neighbourhood extends, it is profitable to execute it.

And supposing, says he, 5 acres of larch planted every year; at the end of 16 or 17 years, 5 acres will every year be cut down, of the value of 500l.; from that day a regular product of 500l. a-year is gained from the application of 100 acres of land. Let to a tenant, these 100 acres produce 40l. a-year; but planted, they produce 500l. a-year. What an amazing difference! Or supposing a single acre planted every year, after the expiration of 18 or 20, to cut annually 100l. a-year from only 20 acres, which let, would yield but 8l. a-year. How beneficial a conduct!

Mr. Fellowes has also planted plane-trees, and finds them to thrive amazingly in low moist situations. They will, in fuch, grow much faster than the poplar. One has 30 years growth that will cut into planks 20 inches broad; but to vaunt a size he attributes in some measure to its standing on the edge of a ditch through which the drainings of a farmer’s pigsties run. Poplars, in some parts of the kingdom, are planted in low situations, to the exclusion of every thing else: it is of consequence, therefore, to know that the plane will do better. But Mr. Fellowes, in general, recommends the larch as preferable to every other tree he has tried; and which will pay a planter much greater profit than any of the rest. These statements shew the great profits formerly derived from planting, and they have not been lost since.

Mr. Davis,eward to the marquis of Bath, after observing that oaks and beeches planted on the best spots of ground, and nurfed by Scotch firs, will not be so valuable at sixty years old, as the Scotch firs are on the very worst land at thirty, further states, that four firs will grow where one oak or beech will grow; for firs are the better, and deciduous trees the worfe, for being crowded. And that a great deal of poor heathy hallow land, which will produce Scotch firs in the greatest perfection (and a great deal of the land planted by lord Bath is of that description), will not grow oak or beech at all, nor in fact any thing but Scotch fir.

Even larch has failed universally on all those spots where the upper stratum is peat. Having lately had occasion to cut some rides through some extensive plantations of Scotch firs which were planted just thirty years ago, Mr. Fellowes measured the land, and the trees which were cut off it, very exactly, and the following result shews that the profit of planting Scotch firs has been full 7% compound interest; whereas no plantation of deciduous trees, within my knowledge, has paid five % compound interest. Indeed we usually reckon, in valuing eaffles for sale, that the common growth, even of elm timber, on its most favourite soils, is seldom equal to more than three or three and a half % simple interest.

336 Scotch firs, of 30 years old, cut upon a statute acre, average measure three feet per tree, valued at only 10l. per foot, viz. 2s. 6d. per tree, amount to, per acre, - - - - 42 0 0

At the time of planting, this land, then newly inclosed from a common, was not worth above 2s. per acre per annum, which, at twenty-five years purchase for the fee simple, amounts to - 2 10 0

And the cost of the trees and planting was not above - - - 3 0 0

Total expence per acre, even supposing the land to be annihilated - - - 5 10 0

5l. 10s. principal will increase, in thirty years, as follows:

\[
\begin{array}{c|c|c}
\text{Per cent.} & \text{Simple Interest} & \text{Compound Interest} \\
\hline
\text{5} & 13 15 \ 0 & 23 15 \ 5 \\
\text{7} & 41 17 \ 4 & 77 10 \ 3 \\
\end{array}
\]

So that the Scotch firs, which have increased 5l. 10s. principal to 42l. in thirty years, have paid upwards of 7% compound interest. Transactions of the Society of Arts. &c. vol. xvi.

The statements which are given below, as drawn up by Mr. Mason, shew the great advantage of making plantations with ash, on the grounds of his grace the duke of Newcastle, together with a valuation of the lands previous to their being planted with the trees.

The bishop of Landaff has made the following calculation of the probable profit of converting the wide rocky lands in
Welmorelund into plantations with larch. A thousand
acres of this sort of land might, he supposes, be inclosed
with a circular wall fix feet in height, (where the fones can
be easily gotten, as they may in mold parts,) after the rate of
six shillings an acre, or 300. for the whole; five hundred
larches two feet in height, (as to enable them to refit the
long grafts,) might be planted on each acre for fourteen shillings; hence a plantation of 300,000 larches might be made
for 1000. Now 1000. improved at compound interest, at the
rate of 4l. per cent., would, in 63 years, amount to the
sum of 10,510. This is the accumulated los from attending the
inclosing and planting 1000 acres of rocky land in sixty
years. The rent of 1000 acres, at one penny per acre, is
4l. 3s. 4d. a-year; in eight years the larches would be out
of all danger from sheep, so that the los of rent ought only
to be estimated for eight years; but 4l. 3s. 4d. a-year, though
improved after the same rate of compound interest, would
not amount to 40l. in eight years; fay, however, that it would
amount to 81l. which is allowing more than two-pence an
acre for the annual rent of the land, then would the whole
expence attending the plantation in 60 years be 15,600l. If
the amount of 81l. for 52 years be taken into consideration,
the expence of the plantation in 60 years will be 11,222l.
He has here supposed sheep to be flut out of the plantation
for eight years; if it should be found that sheep will not crop
the larch, (and from more than one observation he has reason
to believe that they will not,) they need not be flut out at all;
nor, on districts where nothing but sheep are depauperized,
need any fence be made. He knows the advocates for
clofe planting, instead of 500, would require 5000 larches
for each acre; he is not convinced of the utility of fuch clofe
planting, except when it is intended to nurfe up oaks, or
other kinds of wood; but if that mode should be adopted,
the thinnings, after twenty years growth, would pay the ex-
 pense of it. At the expiration of 60 years, suppose that
only 250 larches remained on each acre, or that one-half had
perifhed, the probable value of them may be thus estimated.
From a great many experiments made by himself and col-
lected from others, he finds the annual increase in circum-
ference of the larch at fix feet from the ground, to be an
inch and a half on an average of several years; and this
inference has been drawn from the actual admeaurement of
larches in different parts of England and Scotland, and of
different ages, from ten years old to fifty. On this suppo-
sition, the larches would make, one with another, ninety
inches in circumference, at fix feet from the ground. A
larch which makes ninety inches at fix feet from the
ground, would make more than seventy at twenty feet
from the ground; but supposing seventy inches to be the
circumference at twenty feet, and the length of the tree to
be forty feet, neglecting the remaining top; then will its
solid content be eighty-five cubic feet, and the value of the

The larch
PLANTATION.

The trees at nine-pence a foot, above three guineas. But as the trees are supposed to be planted in an high, bleak, barren situation, their annual increase may not be so great as is here supposed; instead of being worth, at sixty years after planting, three guineas a-piece, admit that they are worth only ten shillings each, then would the whole plantation be worth 125,000l., and deducting the whole expense, 10,000l. as before estimated, there would remain a profit of 114,400l. The present value of 114,400l., to be received sixty years hence, is above 10,000l. (interest of money at 4l. per cent.) Ten thousand pounds at 4l. per cent., purchases an income of 400l. a-year; by planting then, a barren estate of a thousand acres, is improved from 4l. 3s. 4d. to 400l. a-year, reckoning the value of a reversion as a present certainty. Sixty years is a great part of the life of a man: but it ought to be considered as nothing in the existence of a nation, or even of a family, which is a little nation.

The waifs lands in this and other countries are a public treasure in the hands of private persons; all of them ought to be converted into arable, meadow, or pasture land, which are capable of admitting, with profit, that kind of improvement; and such of them as will not pay for that mode of improvement, ought to be covered with wood; the high parts, and especially the sheltered dells in the high parts, with larch, birch, willow, and oak, &c.

And in making plantations of this sort, it has been advised by Mr. Harries, esq. of Hanwood, to attend to two circumstances, namely, situation and distance. The strong westerly winds are very apt to bend the upper part of the trees, especially if they stand single, or upon sloping grounds. To guard against this, a shelter of Scotch pines should be planted to the westward, some years before the larch. In respect to giving the plants sufficient room: in eight years they may be twenty feet high, and their lateral shoots extend two yards every way from the trunk; and they should not then be suffered to continue nearer than five or six yards; and what is left may continue to be useful building timber. At first planting, a distance of about seven feet should be allowed; they will then be furnished with sufficient lower branches, which give the tree a steady and tapering trunk. The knife should never be applied to them. There is no tree of quicker growth. He has larches that are twenty feet high in seven years growth, and sixteen or eighteen inches round. At thirty years growth, they measure from four to five feet round, at five feet from the earth. As the larch and fir are so much in use in forming plantations, it may be proper to take some further notice of their properties. In speaking of the larch, the wood, Dr. Anderson observes, is polished of so many valuable qualities, that to enumerate the whole would appear extravagant hyperbole. It is known to refill water, without rotting, almost for ever. The piles of this timber, on which the houses of Venice were built many hundred years ago, are still found as fresh as when first put in. Stakes of it have been tried in the decoys of Lincolnshire, which, between wind and water, have already worn out two or three fets of oak fikes, and do not yet discover any symptoms of decay. It is also known to possess the valuable quality of neither shrinking nor warping when put into work, nor is it liable to be pierced by worms in our climate. Besides, it is known to be one of the quickest growing trees, remarkably hardy, and extremely beautiful. It is much more easily reared than the oak, and could be spread over a great extent of mountains, if sufficiently attended to, at little or no expense, by the natural shedding of its seeds. It would be valuable not only for ship-planks; but even crooked timbers might be obtained by using a little art to bend it when young. For

flood-gates in navigable canals and wet docks, it would exceed every thing that can be obtained in this climate; for barrel-staves it would be inimitable; and in building it would answer all the purposes to which it is now applied, being much flatter and more durable than that wood. When it is also adverted to, that it is next to incombustible, it deserves to be strongly recommended to plant in this country, particularly in the most rugged and barren districts; where, at a very trifling charge, sills might be brought to a hundred times their present value. And that it is so much more valuable than the Scotch fir that is now universally preferred to it, for plantations of large extent, in almost every situation. That as it has only been of late introduced into Britain, the qualities of the wood are not sufficiently understood; for before the last thirty years it was cultivated rather as an ornamental tree than with a view to profit. But wherever it has been introduced, it grows so freely; is so beautiful when in leaf; so highly ornamented when covered with its abundant pink blossoms in the spring; and it is so elegant in its form, that it is sure to become a favourite with the planter. However, in the opinion of Mr. Harte, it grows slowly the first four years; but in twenty years will exceed a fir tree, both in height and circumference, that is double its age.

In making a plantation of larch, the thinnings may be applied to a variety of useful purposes, whilst they are yet of a small size. In fix, eight, or ten years, according to soil and circumstances, the trees will have attained a size sufficient to be made into bay-rakes. They grow so straight, and the wood is so light, strong, and durable, as to be peculiarly calculated for this purpose; and from its shrinking less than any other wood, these rakes will remain longer firm than those made from any other. About two feet cut off from the root end will form the rake head; and five feet above that, with a very little taken off from the thickness of the under part, form the handle. No wood is more proper for the teeth of the rake, than some of the red wood of an alder tree, because it is not only tough, but little liable either to split or shrink. The bow may be made of ah, or of the laurel-leaved sweet-leafed willow (Fila sensidentra), which is still better. Nothing is so fit for shafts to hoes; for it is nearly as strong; and much more durable than ah. Handles for brushes, brooms, fitches, &c. would occasion a vast consumption of these small spars. And light, neat, and strong chairs, for round bottoms, might be made of larch wood at this age. It is likewise observed, that nothing will answer better for hop-poles; for one set of these would outlive two or three sets of ah. Hurdles, spars, and gates, may be made of it both lighter and more durable than of any other wood; and when the trees are of a sufficient size, they may be split down for cart-shafts; and in mining countries they might be employed as polets for supporting the roofs of the mines. And the small tops cut off in making these various works, would furnish a neat, elegant, cheap, and durable kind of railing, to be put upon the top of low walls, especially for preventing light sheep from overleaping them. One end might be let into the coping, whether of sod, clay, or lime; and the other end received into a flipp of fawn larch wood, with holes bored through it to receive their points. From the straightness of the wood, this kind of rail would be very neat without much expense. In the same manner hen-coops, cranes for packing glases, &c. might be made of these materials. But one of the most extensive and beneficial uses of this kind of small wood, is for the purpose of inclining. These spars, when the root is thick enough, may be set up the middle by a few, and cut into lengths of five or six feet; or if smaller, they may be employed whole. As
they are always straight, and nearly of an uniform thickness, if driven into the ground for a few inches in a row, at the distance of a few inches from each other, with the split fides all one way, they would make one of the neatest and most complete fences that can be feen. The tops of these up-rights may be received into a piece of faved plank, with holes bored in it for that purpose; and supported at due distances by feping pieces reaching from the ground to the tops.

It may, however, be noticed, that it muft fand to be of a fufficient age before the timber acquires its belt qualities of strength and durability. The largest of the larch trees on the duke of Atholl’s lawn at Dunkeld, was meafured in the month of March, 1796, and the following are the dimenfions of it.

The whole height was eighty-five feet. There are feveral larches upwards of one hundred feet in height, which are five or fix years younger, but none of fo great a girth. The largest of Mr. Drummond’s was ninety-seven feet high, but left in circumference.

For a trial, the duke of Atholl has applied larch to a variety of purpofes, fuch as mill-axles, flooring in houses, window frames and doors, poles and rails, and boat-building: for all of which it appeared to anfwer fo well, that it is the greatest acquisition of wood ever introduced into Great Britain, efppecially as it attains a confiderable fize on high grounds and bleak expofures, where even Scotch firs either die or become fntined. Fiffing boats, made of larch under forty years growth, laft nearly three times as long as thofe built of Norway fir. The late violent winds blew down a larch in the duke’s lawn of fifty years of age, eighty-fix feet six inches in height, containing eighty-two feet of folid wood; for which four pounds flering was offered as it lay on the ground. And as it is not aftened whatever larch wood is capable of refifting the ftea-worm; Dr. Anderfon has propofed to prove it by finking a piece of the found, well ripened wood, with another piece of found oak wood in the river Medway at Rochester bridge, where it is well known that every other kind of wood is very foon perforated by the ftea-worm.

It is therefore concluded, that on account of the valuable qualities of the wood the larch deferves to be cultivated in this country. And another recommendation of it is, its quicknees of growth. Eight trees being meafured in the spring and autunm of the year 1794, the average of their increafe in height was nearly three feet nine inches and a quarter; and one of them increafed three inches in circumference at two feet above the ground. In another plantation, the trees at eight years growth meafured above twenty feet in height on an average; the trees were from fix to nine inches high when planted. At twelve years old they meafured, on an average, from thirty-four to thirty-fix feet in height. This plantation was on a good soil and in a favourable situation. Nor is it only while the tree is young that it makes fuch vigorous fhoots; for it appears by the meafurement of the trees in Dunkeld, that this in a great meafure continues even till a period of age, beyond that which they have as yet attained; for one hundred and twenty feet in fifty years, gives an average of nearly two feet and a half in height for each year of their growth.

Very great improvements have been made in the northern parts of Scotland, by means of plantations of Scotch pine, upon the bareft moors, and in the bleakest and moft inhospitable situations; the returns of fuch plantations having been fuch as fully to fatisfy the owners. And when the collateral advantages are adverted to, the improvements, Dr. Anderfon thinks, are very great indeed; for in the neighbourhood of fuch plantations, houfes can be reared at fo little expenfe, and the roofs are fo much better than ordmary, as to induce fettlers to make their dwellings much nearer and more commodious than in other places; rails and other dead fences can be fo easily obtained, that poor people are firft enabled to have good well fenced gardens, and then commodious inclofures of larger extent; the branches afford fuel to the fettlers; cutting and manufacturing the wood furnifhes employment to many; population is thereby augmented; hence a defire for land to produce the neceffaries of life, and a confequent increafe of rent to the proprietor. In this way Mr. George Dempifer fells fields rapidly converting into cultivated grounds on his eflate, and yielding to him ten or twelve fhillings an acre rent, not only without any expence to him, but after having derived a confiderable profit from the sale of woods of his own plantiong, which grew upon land that five and twenty years before was not worth, to him, above two-pence an acre, and which might have remained in that state for ages to come had it not been planted. A plantation of Scotch pine can be made as much fels expence than any other tree in the northern parts of Scotland, because the young plants can be afforded at a smaller price. In Aberdeenfhire, plants of two years old (and above that age no experienced planter will ever buy them) sometimes fell at four-pence a thousand, containing of 1200; and they seldom exceed eight-pence; and there are men that will undertake to complete the whole inclofure, and planting at the diftance of a yard from each other, and supply the deficiencies for five years, at the rate of from ten to thirty fhillings the Scotch acre, according to the size of the inclofure, and the nature of the fence.

It is found by experience, that there is scarcely a foil fo bad or any expofures fo bleak, where thia tree will not live, if the plantation be of fufficient extent, and not upon the very summit of high peaked hills. They do not indeed bear the foa air very well; nor is the wood ever of a good quality, or the tree long lived, upon clayey soils. Several persons in the fouth of England have found, that the pinutlar bears the foa blift much better than any other pines. The spruce fir will bear a still more expofed situation than the Scotch pine, and after a few years it fhofts up with fift greater luxurance. But the cones not being to be had in an equal abundance, and the plants being more difficult to rear, they are feld at a much higher price. Silver fir in a good foil fojfiers well, and is a beautiful tree, but the price of the plants is too great to admit of large plantations of them being made.

Where the situation is bleak and much expofed to ftrong blasts of wind, the plantation muft not only be of considerable extent, but the trees being planted very close, fo as to be not more from two to three feet asunder; the more expofed the situation the closer they muft be; for it is obferved, that until the branches intermingle, and thus ferve to give a mutual fupport to each other, the trees never begin to advance with vigour. Where the plantations are thus thick, there is a neceffity for beginning to thin them out from the tenth to the fifteenth year after planting. Where the plantations are extensive, thefe thinnings fell at a small
a small price, but there are few situations in which they will not do more than pay for the expense of cutting them out. Pruning is likewise occasionally necessary in many sorts of plantations. See Pruning, Thinning, and Sheltering Woods and Plantations.

The leaves and branches of the Scotch pine afford a very wholesome nourishment to cattle and sheep. In mountainous countries, where snow sometimes lies upon the ground for many weeks together, the benefit that may occasionally be derived from such plantations will be very great; and the larger branches that are left make excellent firewood in such cafes.

In some districts where the soil is of the loamy and better kinds, there are often large plantations of the fruit-tree, as the apple, pear, and other fruits, in the fields, hedge-rows, &c. See Orchard.

Plantation Suckles, are such tracts or plots of planting as are made round plantations or other woods, for the purposes of screening, protecting, and promoting the growth of their timber trees or underwood.

They are particularly beneficial in these ways, in many exposed situations, as well as for defending the animals from the cold and cutting blasts which sweep over them, as they render the climates of such regions more mild and warm, giving a softness to the air in such exposures.

PLANTE-VER, in Natural History, the name of a herb sent over from China, where it is called kiasfatontchou; that is to say, a plant which at a certain time of the year changes into a worm. The Chineses say, that this is a plant during the summer seasion; but that in winter its flalk dies, and the root becomes a worm. M. Reaumur has well observed, that in the present improved state of natural knowledge, we can give no credit to such marvellous accounts; and of the roots sent over to the Academy at Paris, it appeared, that only a certain part of each was to undergo this change; this, however, if true, was no less a marvel than that the whole should.

Father Parein, who sent it to France, observes, in his account of it, that it was a very scarce plant even in China; being found only at the palace of Pekin there, where also it was not native, but brought from the mountains of Tibet, and formed one of the Chineses divinations. This father had never seen the leaves or flowers of the plant, but only its roots, which were in high esteem there, not only because of their miraculous changes, but from their possessing the virtues of the famous ginseng; but with this advantage, the use of them was not subject to be attended with those hemorrhages which frequently affected the persons who take large quantities of that famous root. The roots of this plante-ver are usually about a quarter of an inch thick, and from an inch to three inches in length; but there are much larger in the places where they grow.

These roots had nothing particular in their figure or appearance; but with these the father sent some of the same which were supposed to be changed into worms, concerning which he observed, that nothing could more exactly express a worm or caterpillar; the head, the eyes, the feet, and the mouth, being all plainly distinguishable, as well as the several folds and cuttings-in of the body. This account was found to be perfectly true; but the mistake was the want of proper accuracy in the observation; for this body, which was supposed to be the root transformed, had in reality never been any part of the plant, but was found to be really and truly a caterpillar.

This was one of the underground kind, or at least of those which go into the ground to pass their transformation: of these we have a great many different species in all parts of Europe, and some of them, when they are entering into their nymph state, have a custom of fastening themselves to the roots of plants. Of this kind was the Chineses insect, which, when the time of its change approached, always selected the roots of this plant as of a proper size and dimension for its purposes; and, gnawing off the end, hollowed away the lump, so as to introduce its tail into the cavity; where it remains covered with the bark of the root, which so nicely joins to it, that people who observe it in a flight way cannot but mistake it to be a part of the root, or the remainder of the root a continuation of its body. The more accurate naturalists will, however, easily distinguish the vegetable fibres, which make up the root from the animal ones of the caterpillar; and to an eye accustomed to such reseaches, the nice joining of the tail to the remainder of the root will easily discover itself. Mem. Acad. Par. 1720.

PLANTED Coat, in the Mange. See Hair.

PLANTIN, CHRISTOPHER, in Biography, an eminent printer, born at Mont-Louis, near Tours, in 1514, learned his art under Robert Mace, printer at Caen in Normandy. He settled at Antwerp, where he formed a considerable establishment; and at length he became one of the most eminent printers of the age. He published a number of important works, to the prefaces of which he has subscibed his name, yet it is asserted, that he had no pretensions to learning, and could not even read Latin. If, however, he was defective himself, he employed able and accurate correctors of the presses, who brought his editions of literary works to great repute. The most celebrated performance that came from his press was a Polyglott bible, printed after that of Alcala. In the course of his trade he acquired large property, which he freely employed for the service of learning and its votaries. He died at Antwerp in 1589, with the title of arch printer to the king of Spain. He possessed a fine library, which he bequeathed to his grandson Balthazar Moret. It was the custom of this period for every printer of reputation to adopt a motto, which he inserted in the title-pages of his works. The devise of Plantin was a pair of compasses, with the motto "Labore et Conflantia." Moreri.

PLANTING, in Gardening, the operation of infenting plants of the fruit-tree and other kinds, seeds, and roots, into the earth, for the purpose of vegetation and future growth.

There are various methods of performing this business in practice for different sorts of plants, seeds, and roots; as hole planting, trench planting, trenching-in planting, slit or crevice planting, holing-in planting, drill planting, bedding-in planting, furrow planting, dibble planting, trowel planting, planting with balls of earth about the roots, planting in pots, &c., all of which are occasionally used by different practitioners in the several branches of gardening, according to the methods are most proper for different particular sorts of plants.

In the first, or Hole Planting, which is the principal method practised with most sorts of trees and shrubs in the full ground, and which is performed by opening with a spade round holes in the earth, at proper distances, for the reception of the plants, each hole should be dug large enough to admit all the roots of the tree or shrub freely every way to their full spread, without touching the fibres of the hole, and about one spade deep, or a little more or less, according to the size of the roots and nature of the soil, so as, when planted, the uppermost ones may be only about three or four inches below the common surface, or as low as they were before in the ground; though in very humid soils, where the water is apt to stand, the holes should be shallower, so as the uppermost roots may stand full
full as high as the general level, or higher if necessary, raising the ground about them, especially when performed in winter. When the soil has been thus dug out, the bottoms should be well loosened; the mould in digging out being laid in a heap close to the edge, in order to be ready to fill in again. The holes being thus prepared, and having lightly trimmed the roots, &c. of the trees, one tree or plant must be placed in the middle of the hole, making all its roots spread equally around; a person holding the plant erect by its stem, while another, with the spade caulis in the earth about the roots, taking particular care to break all large clods, and trim in some of the finest mould first all round the roots in general, flashing the tree occasionally, to cause the fine soil to fall in close among all the small root fibres; and where the tree stands too deep, shake it up gently to the proper height, and having filled in the earth to the top of the hole, it should be trodden gently all round, first round the outside to settle the earth close to the extreme roots, continuing the treading gradually towards the stem, to which the mould should be pressed moderately firm, but no where too hard, only just to settle the earth, and ready the plant in an upright position: then all the remaining earth should be pared in even round the tree, to the width of the hole, raising it somewhat above the general level of the ground, to allow for setting, giving it also a gentle treading; and finishing it off a little hollow at top, the better to receive and retain the moisture from rains, and giving occasional waterings in spring and summer, especially for the choicer kinds of trees and shrubs.

After this, in winter, or early in spring, it may be of advantage to the choicer kinds of trees and shrubs, to lay some long mulch at top of all the earth, both to keep out the winter’s frost, and prevent the drying winds and drought of spring and summer from penetrating to the roots before the trees are well rooted in their new situations. But none, instead of mulch, use grafts turfs turned upside down, especially when planting upon grafts ground, or any out-plantations, where turfs of grafts can be obtained; or in orchards, where the ground is in grafts; in which case it may be proper to bank some turfs round the fides and top of each hole, particularly for large trees; which will ready them more effectually, as well as preserve the moisture, if much dry weather should happen the succeeding summer.

In the second, or Trench Planting, which is a method sometimes practised in the nursery, in putting out feeding and other small trees and shrubs in rows; and also used for box edges, as well as sometimes for small hedge-frets, &c. and always in setting out asparagus; it is performed by opening a long narrow trench with a spade, making one side upright, then placing the plants against the upright side, and turning the earth in upon their roots. When used for young seedlings, or other small trees, shrubs, &c. the ground is previously trenched or dug over: a line is then set, and with a spade held with its back towards the line, a narrow trench six or eight inches deep is cut out, turning the earth from the line, making the line side nearly perpendicular: the plants are then inferted in the trench at small distances, close to the upright side, covering in the earth about the roots in planting them; and having planted one row, the earth should be evenly trodden in all the way along, to settle it close; and fix the plants steady, proceeding from row to row in the same manner.

But in planting larger trees, in the nursery way, by this method, a larger trench will be requisite; sometimes a trench one or two spades wide, with proportionable depth, according as the roots of the trees require, is made; and having opened it all the way along the intended row, the trees are placed along the middle of the trench, filling in some earth to each tree, as placed, one person holding it erect, whilst another throws in the earth; and having placed one row, trim in all the remaining earth evenly; then treading it closely all the way to fix the plants steady, and in a perfectly upright manner.

In the third, or Trenching-in Planting, which is also sometimes practised in light pliable working ground, for young trees in the nursery way, and sometimes with edge-frets, &c. being performed by digging along by a line, about one spade in width, and planting at the same time; a line is set; and then having the plants ready, with a spade begin at one end, and standing sideways to the line, throw out a spit or two of earth; which forming a small aperture, another person being ready with the plants, he directly deposits one in the opening, while the digger proceeds with the diggin the digging one spade wide, covering the roots of the plants with the earth of the next spit; and another aperture being thus formed, another plant is placed in: the digger, still proceeding, covers its roots, as before, with the next spit of earth; and so on to the end of the row, placing them at about a foot, or fifteen or eighteen inches afar, according to the size of the plants. When larger trees with more spreading roots are used, instead of digging the trench only one spade wide; two may probably be requisite for the proper reception of the roots; likewise, in forming the openings for the plants, they should be made large enough to receive the roots freely, digging the earth over them as above. After having planted one row of plants, the earth should be trodden evenly along to settle it to the roots, and ready the plants in an upright position.

There is another method of this sort of planting, sometimes used for some sorts of roots, such as horse radish fets, potatoes, &c., which is performed by common trenching, placing a row of fets in each trench. The horse radish should be planted in the bottom of the open trench, twelve inches in depth, turning the earth of the next over them; and the potato fets be placed about from four to five or fix inches deep, covering them also with the earth of the next trench.

In the fourth mode, or that of Split Planting, which is performed by making flets or crevices with a spade in the ground, at particular distances, for the reception of small trees and shrub plants, a slit is made for each plant, which is inferted as the work proceeds; and is practised sometimes in the nursery way, &c., in putting out rows of small plants, suckers, &c. at about a foot to eighteen inches or two feet high, and which have but small roots: it is also sometimes practised in out grounds, where large tracts of forest trees are planted, and which are planted out at the above sizes, and in the most expeditious and cheapest method.

It is performed in this manner: a line is set, or a mark made; and then having a quantity of plants ready, they are planted, as the work proceeds in making the flets. A man, having a good clean spade, strikes it into the ground with its back close to the line or mark, forming a crevice, taking it out again directly, so as to leave the slit open, giving another stroke at right angles with the first; then the person with the plants inferted one immediately into the second-made crevice, bringing it up close to the flet; and directly presses the earth close to the plant with the foot; proceeding in the same manner to infect another plant; and so on till all is finished; which is a very expeditious way of putting out small plants, for large plantations, but should never be employed, where other better methods can be used.

A man and a boy in this method will plant out ten or fifteen hundred plants, or more, in a day.

In
PLANTING.

In the fifth, or Holing-in Planting, which is sometimes used in the nursery, in light loamy ground: also, sometimes with potatoes, &c., in phable foils; the ground being previously dug or trenched, and a line placed; it is thus performed; a person with a spade takes a small spadeful of earth, to form a little aperture, in which another person directly deposits a plant, &c., the digger at the same time taking another spadeful at a little distance, turns the earth from the bottom hole over the roots: placing directly another plant in the second opening, the digger covers it with the earth of a third spadeful, and so on to the end of the row.

In the sixth, or Drill Planting, which is by drawing drills with a hoe from two to four or five inches deep, for the reception of seeds and roots, and is a convenient method for many sorts of large seeds, such as walnuts, chestnuts, and the like; sometimes also for broad beans, and always for kidney beans, and peas; likewise for many sorts of bulbous roots, when deposited in beds by themselves; the drills for these should be drawn with a common hoe, two or three inches deep; and for large kinds of bulbous roots, four or five inches in depth, covering in the seeds and roots with the earth, always to the depth of the drills.

In the seventh, or Bedding-in Planting, which is frequently practiced for the choicer kinds of flowering bulbs, such as hyacinths, &c., also for the larger kinds of trees, as acorns, large nuts, and other large kinds of seeds, flowers, and kernels: it is performed by drawing the earth from the tops of beds for four inches in depth, then planting the seeds or roots, and covering them over with the earth, drawn off for that purpose; for which the ground should be previously dug or trenched over, raked, and formed into beds three or four feet wide, with alleys between; then with a rake or spade trimming the earth evenly from off the top of the bed into the alleys, from two or three to four inches deep for bulbous roots, and for seeds, one or two, according to what they are, and their size; afterwards, for bulbous roots, drawing lines along the surface of the bed, nine inches distance, placing the roots bottom downward, along the lines, six or eight inches apart, thrusting the bottom into the earth: but when for seeds, they may be scattered promiscuously; and having thus planted one bed, then with the spade let the earth, that was drawn off into the alley, be spread evenly upon the bed again over the roots or seed, &c., being careful that they are covered all equally the above depth, raking the surface smooth and fine.

This method is in occasional practice, in planting several kinds of the larger prime sorts of bulbous-rooted flowers in beds; and nurseriesmen also practice it in planting many of their larger seeds, nuts, &c.

And another method of this kind is occasionally practiced in some parts, particularly for planting potatoes in low wet grounds, which is by dividing the ground into beds, four feet wide, with alleys two or three feet in width; then digging the beds, and placing the potatoe-fets in three rows along each bed, a foot asunder in the rows: this done, the alleys are dug one spadeful depth, calling the soil upon the beds over the fets, so as to cover them four or five inches deep; in this way, where the ground is very wet, the alleys drain the moisture from the beds, so as sometimes to afford great crops. Sometimes, in low moist grounds, that are in graves or fward, the beds are marked out as above, and without digging the ground; placing the potatoe fets immediately upon the fward, then digging the alleys, first turning up the fward, and placing it topily-turvy upon the bed, so as to be fward to fward over the fets; then smithing by applying more earth from the alleys, to cover in the fets, the proper depth of four or five inches. This, in some counties, is called the lazy-bed method, because the ground is not dug over.

In the eighth, or Furrow Planting, which is by drawing furrows with a plough, and depositing fets or plants in them, covering in also with the plough: it is sometimes practiced for planting potatoe-fets in beds, and has been adopted in planting young trees for large tracts of forest-plantations, where the cheapest and most expeditious method is required; but this method can be practiced only in a light pliable ground, and is performed with the furrow being drawn, one or two persons are employed in placing the fets or plants in the furrow, whilst the plough following immediately with another furrow, turns the earth upon the roots of the plants. This is not a mode to be much advised.

In the ninth, or Dibble Planting, which is the most commodious method for most sorts of fibrous-rooted seedling plants, particularly all the herbaceous tribe; also for slips, offsets, and cuttings both of the herbaceous and shrubbery kinds; likewise for some sorts of seeds and roots, such as broad beans, potatoe fets, Jerusalem artichokes, and horseradish fets, with numerous sorts of bulbous roots, &c.; it is expeditiously performed with a dibble or setting-flick, by making a narrow hole in the earth for each plant, inflicting one in each hole always as the work proceeds.

Having a dibble or setting-flick, it is used by thrufing it into the earth in a perpendicular defcent, in depth as the particular plant, &c. may require; directly inferting the plant, seed, or fet, as each hole is made, closing it immediately by a stroke of the dibble. In setting any kind of plants, slips, cuttings, &c., having long hashs or stems, it is proper to make holes a proportionable depth, to admit them in a commodious way in the ground: for example, cabbage-plants, forsyss, &c. should be planted down to their leaves; slips and cuttings should be inferted two parts of three, at leaft, in the ground; being particularly careful in dibbling-in all sorts of plants, to clofe the holes well in every part about the roots; by ifticking the dibble plantings into the ground, &o as to iftike the mould firftly up to the root and fibres, at the fame time bringing it clofe to the stem. See Dibble.

In the tenth mode, or Trowel Planting, it is performed with a garden trowel, made hollow like a scoop, and is useful in transplanting many sorts of young fibrous-rooted plants with balls of earth about their roots, so as not to feel their removal.

The trowel is employed both in taking up the plants and planting them.

In the eleventh, or Planting with Balls of Earth about the Roots, which is the removing of the plant with a large ball of earth about its roots, &o as by having its roots firmly attached to the surrounding earth; it still, during the operation, continues its growing state, without receiving any, or but very little check from its removal: this is often practiced more particularly for the more delicate and choicer kinds of exotics, trees, shrubs, and herbaceous plants; and occasionally for many of the fibrous-rooted, flowery plants, annuals, perennials, and biennials, even in their advanced growth and flowering state, when particularly wanted to supply any deficient compartments; though it is not so eligible for bulbous-rooted plants: likewise when intended to remove any sort of trees or plant out of the proper planting season, as very late in spring, or in summer, it is proper to transplant it with a good ball of earth, to preserve it more certainly in a state of growth. Some trees and shrubs are more difficult to remove with a ball than most kinds of the herbaceous fibrous-rooted plants, though
PLANTING.

though many of the tree and shrub kinds having very fibrous roots, also readily ripe with good balls.

In transplanting any of the tree and shrub kinds by this method, if they grow in the full ground, the operator must be careful to begin to open a trench with a spade at some distance from and round the tree, perhaps a foot, or two or three, according to the size of the tree and expansion of the roots; digging a fort of trench all round, a spade or two wide, or more if large trees, and in depth below all the roots; all the time having great care not to disturb the ball or mafs of earth between the stem and trench, but preserve it as entire as possible. When the whole has been detached, the plant should be removed into the situation for which it is intended, with the whole of its ball about its roots.

When trees or shrubs, with balls to their roots, are intended to be sent to considerable distances, they should be placed finely in offer baskets, in order to preserve the ball, having a basket for each tree; the baskets to be of an upright make, in width and depth in proportion to the ball, with two handles at top, especially if large, and generally worked rather open at the sides, as sometimes the basket and all is placed in the ground, when the plant cannot be readily removed without danger of breaking the ball of earth about it.

In respect to the method of planting in pots in general, having the pots and mould ready for the reception of the plants, previous to planting them place some pieces of tile, pot-herbs, or oyster-shell, &c. over each hole at the bottom of the pots, to prevent the holes being clogged and flapped with the earth, and the earth from being washed out with occasional waterings; also to prevent the roots of the plants getting out: then having secured the holes, put some earth in the bottom of each pot, from two or three to five or six inches or more in depth, according to the size of the pot, and that of the roots of the plant; then infert the plant in the middle of the pot upon the earth, in an upright position, making its roots, if without a ball of earth, spread equally every way; directly adding a quantity of fibre mould about all the roots and fibres, shaking the pot to cause the earth to settle close thereto; at the same time, if the root stand too low, shake it gently up; and, having filled the pot with earth, press it gently all round with the hand, to settle it moderately firm in every part, and to steady the upright posture of the plant, raising the earth however within about half an inch, or lefs, of the top of the pot, as it will settle lower; for some void space at top is necessary to receive waterings occasionally: as soon as the plant is thus potted, give it directly a moderate watering to settle the earth more effectually close about all the roots, and promote their rooting more expeditiously in the new earth; repeating the waterings both before and after they have taken root, as occasion may require.

In transplanting plants in pots from one pot to another, they may in general be shifted with the whole ball of earth contained in the pot about their roots entire, if so as to preserve the plant all along in its growing state, as carefully to shrink or retard its growth by the operation; for plants growing finely in pots, and of some standing, whose roots and fibres have established themselves firmly in the earth, will readily remove out of the pots with the entire ball in one compact lump, surrounding all the roots and fibres, retaining their growing state by still drawing nourishment from the surrounding ball of earth.

The removing of plants from one pot to another with balls, is in some cases to be avoided: as where a plant appears diseased or in a bad state of growth, as it is most probable the fault is in the root of the earth; therefore, it is eligible to shake the whole entirely out of the earth, in order to examine its roots; and trim off all decayed and other bad parts; then, having a fresh pot, and some entire new compost, replant the tree, &c. therein.

In potting plants from the full ground, or beds of earth, &c., if they have been previously pricked out at certain distances, and have stood long enough to fix their roots firmly, many sorts may be potted with balls, particularly most of the herbaceous, fibrous-rooted kinds, and many of the shrubby tribe, by taking them up carefully with the garden trowel, or with a spade, as may be convenient, according to the size of the plants; and, if necessary, pare the balls round to fit the pot.

Seeding plants, or those raised from seed beds, by their growing together, rarely admit of potting with balls to their roots; so that when it is intended to pot such, they must be drawn out of the earth with the root as entire as possible, and be potted separately in small pots, shifting them occasionally into larger.

Sometimes in pot-planting, to save room, and for other purposes, several small plants are planted in each pot, especially when designed as nursery-pots, to receive either small seedlings, offsets, slips, cuttings, &c., just to strike them, and forward them a little at first, either in hot-beds, or for removing them to different situations, such as occasional shade, shelter, &c., and in which some sorts of small slips and cuttings are sometimes planted many together, in one or more wide pots, especially where large supplies of some particular sorts are required, such as myrtle cuttings and pipings of pinks, &c., sometimes to the amount of a hundred or two of these small sets in one capacious pot or wide flower pan. The small seedlings, slips, cuttings, offsets, &c., when they are a little forwarded, or properly rooted, and shoot a little at top, should be all potted off, in proper time, each in a separate pot, especially if plants of any duration; giving them small pots at first, and as they increase in size shifting them into larger ones.

When any large growing plants, such as orange and lemon trees, or any other kinds, are become too large for pots, they should be shifted into tubs; these tubs should be made of full-inch thick plates, and adapted to the size of the respective plants; each tub to be well hooped with iron, and furnished with two hooked or bow iron handles at top, by which to move them, either by hand, or, when very large tubs, to receive poles between two men for moving the plants where wanted; having holes at the bottom of the tubs to discharge the superfluous moisture; placing some stones, &c., to prevent the holes being clogged with the earth; the method of planting and transplanting being the same as in pot-planting.

The twelfth Method, or Planting in Pots, is practised to all tender exotics, in order for moving them to shelter occasionally, such as all kinds of green-house and hot-house plants; and likewise for many sorts of hardy flowering plants, for the convenience of moving them occasionally to adorn particular compartments; and for the convenience of moving some curious sorts when in flower to occasional shelter from the sun's rays and excessive rains, in order to preserve their beauty and prolong the time of their bloom; such as the auriculas, carnations, &c.

In planting in this way, it is highly requisite carefully to adapt the sizes to the size and nature of the different plants intended to be potted: if small plants, begin first with small pots, one plant only to each pot, especially if to remain; but according as the different plants advance in growth shift them into pots one or two sizes larger, which may be requisite to many sorts once a year, to others once in two or three years, according to circumstances.
Garden pots for this use are of several regular sizes, from two to sixty in a caff, distinguished at the pot-houses accordingly; as twos, sixes, twelves, sixteen, twenty-fours, thirty-twos, forty-eights, sixties, or sixty-fours, &c., each pot having one or more apertures at bottom to discharge the superfluous moisture. They are sold by the potters at so much per caff; large and small, all of a price; those of only two in a caff the fame as those of sixty; and from two shillings to half a crown or three shillings per caff is the general price. See Pot, Garden.

Sometimes, instead of buffets, small young trees and other plants with balls, intended to be sent to any distance, are put separately in pots, and when they are to be placed in the full ground, each should be turned out of the pot with the ball entire.

Trees and other plants that have generally grown in pots, where they have been of some standing, have the whole earth by means of the numerous fibres formed into one compact lump, so that it will readily come out entire and firm; or to such as do not so easily quit the pot, a long blade of a knife, or some other thin instrument, may be thrust down between the outside of the ball and pot all round, and it will then readily come out, either in drawing by the stem of the plant, or by 'splitting' the edge of the pot with something; or, if small plants, you may turn the pot mouth downward, and 'split' the edge gently against any firm turbance. In replanting those potted plants, if the fides of the ball of earth are much matted with the fibres of the root, it is proper to pare off the groffest part, together with a little of the old earth, especially if to be planted in pots again; then put it in a pot a fize larger than before, filling up all round with fresh mould, finishing with a moderate watering.

With respect to the proper plate and preparation of trees for planting, it may be observed that young trees, both of the fruit and foreif kinds, are the most fuitable, and succeded best, as from three or four to fix or eight feet in height, and from three or four to five or six years old. See Forest, Dwarf, and Standard Trees.

In foreif-trees, the straigbfeet, most vigorous, and thriving plants of the respective kinds should alwayes be chozen.

In preparing for planting, in taking up the trees out of the nursery, the greatest care is neceffary in raifing them with as great a spread of root as poifible, which is often ill attended to, espefially when large orders of plants are to be drawn in a hurry. The ground about the trees should alwayes be opened with the fpade widely round the roots, and deep enough to get to their bottoms without hacking and cutting them with the fpade, but fo as to raife each plant with all its roots as entire as poifible. After having taken up the trees out of the nursery, &c., it is alfo of great moment to have them replanted as soon as poifible in the places allotted for them; for although by properly covering the roots with lither, or, if fent to any confiderable distance, by tying them in bundles, and packing them up with plenty of straw about the roots, and afterwards clofely matted round, they may be ferved in tolerable good condition a fortnight or longer, yet, where it is poifible to plant them the fame day, or in a day or two after, before the small fibres are fhrunk or dried, it will be of much advantage in the firft growth of the trees; but when this cannot be done, they should be immediately laid in the ground in a trench.

In preparing for planting, the roots muft have occifional trimming, not however to retrench or reduce any but the mained and decayed parts; therefore previous to planting examine the root, and cut out all fuch parts as have been broken or damaged in taking up, and any casual decayed parts or other blemifhes, being careful to leave all the found roots every where entire; leaving alfo all the small fibres that are fresh and vigorous, only trimming off fuch as are become dry and moody; fuffering all the main roots to remain, moitly at full length, except just to tip off their ends a little on the under fide, floping outward; and reduce any very long fragglers, and shorten long perpendicular tap-roots, more particularly of fruit-trees, to prevent their running down into a bad foid, and to promote their throwing out others horizontally.

With regard to the preparation of the heads of the trees, the principal care is to trim off the fragglers shoots and branches from the ftems, leaving the heads for the generality entire, only jut retrenching very irregular branches, and shortening any very long fragglers; always fuffering the main or leading top shoot to remain at length, particularly in foreif-trees, and all others that are to grow to a lofty fature. Fruit-trees, however, fometimes require a more accurate regulation of the head preparatory to planting, particularly dwarfs for efpeffers and walls. If the fruit-tree is taken from the nursery at one year old from the budding and grafting, and with its firft shoot from budding and grafting entire, this firft shoot muft neceffarily be shortened or headed down to force out lateral wood below, to furnifh the bottom properly; but this heading down is not neceffary at the time of planting, but should remain till spring, until the tree has taken fresh root and begins to shoot; for the head remaining greatly promotes the rooting; when in March or the beginning of April, head it down within half a foot, or five or fix eyes of the infection of the bud or graft, and the shoot fo headed will throw out, from its remaining lower eyes, feveral lateral branches the enlufing summer.

If it is two, three, or more years old from the budding and grafting, and the firft shoots were headed down in the nursery at the proper time, it is proper to plant it with its whole head entire, only retrenching any irregular branches or any very luxuriant shoot; or thin out the worf of fuch as are evidently too clofe or crowded, leaving however all the regular branches at full length, except juft to reduce any very long rambler.

For new planting trees it is very improper to retrench the branches too severely, and cut all that remains short, as it is very often prahtised, on a supposition of strengthening their roots, which however has often the contrary effect; for the branches and leaves imbibe the refrefhing influence of the air, &c., which, being conveyed to the roots, proves nutriental, and contributes exceedingly towards vegetation, and consequently promotes the rooting afresh more expeditiously and effectually. Besides, by a ferious retrenching, and a general shortening, of fruit-trees in particular, in moft forts the very parts where fruit would have been foon firft produced are cut off, and it will probably coft the tree two or three years growth to furnifh new branches equal to those cut away, as well as retard its bearing in proportion. And it often happens by fuch a general amputation of the branches of all new planted trees at the time of planting, that they, for want of branches to collect vegetative nourishment, either make very little progrefs in fhootting for two or three years after, or fometimes, when they do fhoot, throw out a profusion of unneceffary wood from the remaining eyes or buds. Therefore if young fruit-trees at planting, whether dwarfs or standards, are furnifhed with five or fix or more good regular principal branches, of one, two, or more years growth, it is improper to retrench any part of them, and diffigure the tree, particularly apples, pears, plums, and cherries, which should at all times be but sparingly fhortened; and since feveral good branches being already obtained in the proper parts to give the head its firft regular form, they in

412

their
PLANTING.

their turn readily furnish more; and if there is a vacancy in any part, it will be better to endeavour to fill it by stop-
piping some of the young shoots produced the summer after planting, by either pinching or pruning them in May or June the same year to three or four eyes, or cutting them down to that length in the winter or spring following. Some fruit-trees, however, such as peaches, nectarines, &c., against walls, require most of their young shoots to be shortened annually.

Forested trees, &c., in their preparation previous to planting, after being drawn out of the nursery, should only have the blanched roots trimmed, and all branches from the lower part of the stem pruned off, cutting the lower ones close, the others to two, three, or four inches, particularly the deciduous kinds, leaving the head always tolerably branchy, and mostly entire; not to trim away all the branches to one leading shoot only, as is often practiced, but leave a propor-
tional share of the upper more erect branches, to form some tolerable head, and only just retrenching the lower fragglers, very long rambling luxuriant, and very irreg-
ular growths, to preserve a little regularity; being parti-
cularly careful to leave always the top or leading shoot per-
cfectly entire, unless it is decayed, or is very crooked, bend-
ing much downwards, &c, in which cases, if any straight shoot is conveniently situated, the crooked part may be re-
trenched down to the straight shoot, which leave entire to
run up in height, as without a leader a tree can never aspire to any considerable stature; for the leader, by its annual erect shoot, gradually increases the length of the stem, and, as it advances, sends out a supply of laterals to furnish the head, branching and spreading.

In planting large tall trees, where it is designed to form shade, shelter, or blind as soon as possible, very little re-
duction of the branches of the head should be suffered, only
to reduce any very irregular growers.

In removing pretty large trees of any sort with consider-
able heads, especially when very spreading or crowded, it may be proper to reduce the whole regularly in some propor-
tion to the root, that the winds may not have too much power to incommode it after planting; in which cases it may be necessary to retrench or reduce some of the most ex-
tensive lower branches, and thin out some where much crowded, reducing others down to some convenient lateral branch they may support, so as each reduced branch may, notwithstanding its reduction, terminate in a leader, having its top entire, not to exhibit naked ends of branches, stand-
ing up like stumps.

In respect to the preparation for planting of all the shrub kind, only just trim the fragglers under branches and shoots from the lower part of the stem, retrenching any luxuriant of the heads that seem to shoot away very irregularly and vigorously at the expense of the neighbouring branches, and reducing long ramblers, &c., just to preserve a little reg-
ularity.

All new planted tall trees should be staked as soon as planted, in order to support them readily every where till they are well rooted and have somewhat established their root, that winds may not overact, or otherwise incommode them; particularly all trees of 6, 8, 10 feet high, and upwards; one tall frail stake being placed to each tree, or more, if the trees are of large size, sharpening the lower ends, and driving them firmly into the ground near the stem; or if larger trees, place it flatways, at a little distance, so as its top reach the upper part of the stem, on the opposite side to that most exposed to the winds, in which it will have the greatest effect; but large trees with full heads, should generally have very tall strong stakes, three
to each tree, placed triangularways, in an oblique or slant-
ing direction, afterwards binding the stems of the trees firmly to the stakes, previously wrapping some soft sub-
stance, such as hay-bands, &c., round them, at the part where it is to be fastened to the stakes, in order to face the bark from being rubbed off against the stakes by the motion of the winds, which is more particularly necessary to tall plants that are much exposed. Large trees of considerable stature, with full heads, are often supported with ropes suspended from the top of the stem three different ways, slanting them tight, and the end of each rope flanked se-

Such new planted trees as are exposed to cattle should each be well fortified all round the stem with thorn bushes, brars, furze, &c.

The general season of planting, for all sorts of trees, is
autumn and spring, as from the beginning of the decay of the leaf, in October, until December, for the former; though evergreens may be begun to be transplanted towards the middle or latter end of September, and continued till December. And for the spring planting, February and March are the principal time, but may be continued occasion-
ally until April; and several sorts of tender young ever-
greens succeed best when planted the beginning of that month, or later. Much, however, in this busines, must depend on the soil and climate of the weather.

In preparing to plant herbaceous fibrous-rooted plants, care is to be had to remove them with good roots; young
seedlings, &c., especially require particular care in drawing them with proper roots. When they are to be taken all clean up, they may be readily loosed and raised out of the earth with some instrunent with all their fibres entire; but when they are only to be thinned, they do not admit of this, as it would disturb the remaining plants, so must be drawn out by hand carefully, with as much root as possible.

Many sorts of fibrous-rooted plants, however, are so hardy, and apt to grow, that if taken up almost any how, with a little root, they will strike; it is nevertheless ad-
viceable to use care in drawing all sorts for planting with tolerable roots, as they will, in proportion, make more pro-
gress in their future growth. And as to any trimming pre-
paratory to planting, very little is wanted, only in some
sorts, cut shortening very long naked spindly roots, and trimming any fragmenting fibres; though in numbers of plants of this tribe hardly any trimming at all is required, either
in root or top.

PLANTING Timber Trees, in Rural Economy, the act of
making plantations with these forts of trees, which is a prac-
tice that has lately been more attended to than formerly;
probably from the advantages of it being more fully under-
ground, and more correctly ascertained. The particular forts
of land that may be converted to this purpose with the great
eft chance of profit, have been already pointed out.

In the accomplishing the busines, the principal difficulty con-
flicts in properly adapting the trees to the nature of the soil, as,
unless that be the case, the success is far from so great as it would otherwise be. The land should also be in a proper state of preparation for the reception and growth of the trees, and the work be executed at a proper season in a
proper manner, and at suitable distances, according to the nature and quality of the soil, and that of the trees; the
whole being well fenced from the attacks of cattle.

Soil.—The particular kinds of soil best adapted to the cul-
tivation of the different sorts of timber trees, and in which
some or other of them will be found to grow in the most
perfect manner, are gravelly or light sandy soils, with free porous subsoils; gravelly or sandy loams on porous subsoils; loamy,
loamy, sandy, or gravelly soils on retentive subsoils; gravelly, chalk or chalky loams on porous subsoils; loamy clays or clayey loams on porous subsoils; and strong clayey or loamy soils on retentive subsoils. Likewise, thin moorish heathy soils on gravelly or porous subsoils, also on clay or retentive subsoils; and besides these kinds of land, there are, as has been seen above, many other thin poor sorts of waffle, in different parts of the kingdom, which are not fit for raising any other descriptions of plants, that might be converted with great advantage to this purpose, as the diminution in the quantities of timber and other wood every where now almost begins to be seriously felt.

Mr. Smith, in the "Survey of Argyleshire," states, that the grounds there which ought to be marked out for this improvement, are such as are mentioned below. The belt land would no doubt bear timber belt; and if arable land could be spared for the purpose, the return might be expected to be in proportion to the value of the soil. But in this county little or no arable land, meadow, or good pasturage, ought to be laid under planting.

It should have only those waste grounds which are capable of this improvement, and of no other. And of these we may reckon, first, those extensive dry moors and moorlands, in the hollows and on the declivities of hills, especially in the inland parts of the county. These lands are generally covered with short heath, mixed with fo little grefs, that they are not worth 6d. the acre. The trunks of trees generally found in them give, however, a sufficient proof of their aptitude to grow timber, and they can never be turned to better account than by planting them; and that with the same kind of timber that is found in them. This is generally fir, and sometimes oak. Whatever it be, follow nature, and you cannot err. It may be said that some of these situations are far from water-carriage. But the whole county is so indented with seas, and so well accommodated with roads, that almost every mountain is accessible by the one or the other. Or, if any of them be not, still it may be profitable to plant it, were it only with a view of converting a great part of the wood to the purposes of extracting from it turpentine, tar, pitch, rosin, and of making pot-ashes. And another kind of ground which ought to be planted, and of which we have large tracts, is that which is covered with brush-wood, such as hazel, birch, &c. seldom allowed by the cattle to rise above two or three feet high. Here nature, which could not be maitaken in the soil, has planted wood, though it has not been allowed to grow, and has marked out the ground as fit for planting. This brush-wood will prove an excellent nurser to young plants, by giving them shelter till they raise their heads above it; after which they will destroy the brush-wood by excluding the sun and air from it, and reduce it to a manure which will help their growth. Among this brush-wood, however, there may sometimes be found some sprouts of oak and ash, which ought to be cut over a few inches above the ground; after which they will shoot up, and thrive exceedingly, from the abundance of roots which they have to nourish them. Patches of dwarfish oak, which the cattle never allow to rise one foot from the ground, are also common in many parts of the county. If these spots were brought within the encolsure of a plantation, and the bushes cut over a little above the surface of the ground, they would soon be valuable. In England, even oak plants are often cut in this manner after one or two years, when they have taken to the ground, and the second fprout is trusted to for the tree; as it is found to grow with greater luxuriance than the first, which was checked by transplanting.

Stools of natural wood, whenever they are, furnish much room for planting; and at a trifling expense, when they are already enclosed. Every vacancy in them ought to be filled up with oak, ash, elm, and other valuable kinds of timber. The ground is fit for planting; the natural wood will thrive in it; and thus it will thrive well, and improve the cop-rice. The proper time for improving a natural wood with planting, is immediately after it is cut, when the fences are in belt repair, and when the sun and air will get at the plants which may be set among bushes of less value. These bushes should afterwards be cut down, so that they are found to hinder the growth of the planting. The dikes of Ar- gyle has done much in this way, and Lord Stonefield, Sir James Campbell, and several other proprietors, have thus improved their natural woods very considerably. In one year, Captain Campbell, of Kin tarbet, with a spirit yet uncommon amongst the most of the proprietors of this county, planted among his natural woods no less than 20,000 trees of valuable timber. At this rate, he will, in a few years, lay the foundation of a sure and large fortune.

And a fourth kind of ground, that should be devoted to planting in this situation, is, that on which a number of venerable native firs are still growing. These memorials of our former forests are not unfrequent in some of the upper parts of the county, particularly in Glenety and Glenur- chay; and they deserve more attention than they have hitherto met with. From the feed which they yield in winter, and which is driven to a distance by the snow, a beautiful plantation rises up in the spring; but when the cattle are driven up to the mountains in summer, this precious crop, the hope of future foresters, is for ever destroyed. This is the more to be regretted, as the quality of this fir is of excellent, as not to be surpassed by any in the world. The feel of this fir is precious, and a single cone of it, if possible, should not be lost. But then, in order to preserve its valuable quality, it should be fown where it is meant it should grow, without passing through the medium of a seed-bed or nursey. And it appears necessary, in order to preserve the quality of the timber, that we should follow nature, and fow the feed directly where we intend the tree should grow. The feed too will thrive where plants would fail.

After some hesitation about parting with any thing we call arable ground, he mentions one other kind of land, which it may sometimes be proper to devote to planting. He means some high fields, which, under the old system of cultivation, were subject to the plough, but never to much ad- vantage. To these poor gravelly fields were manured by folding cattle on them at night. But now, when this syltem is given up, they lie neglected, and many of them are already covered with heaths. With little expense, and much advantage, they might be converted to plantations. The earthen dikes which surround them might be faced with stones, of which the dikes themselves would furnish a great proportion. The tops of the dikes might be planted with firs, if not with quicksets, for more fence and shelter. The fields should then be ploughed, and, if at all convenient, dressed with some lime or other manure, and sown with the feed of the native Scotch fir, and with acorns. By this preparation of the ground, the trees would thrive amazingly, and the wood retain its native quality. There are many thousand acres of waste land in this country as well as Scot- land, that might be converted to plantations with great ad- vantage, and which are fit for nothing else.

A tabular view, taken, with some alteration, from the Agricultural Survey of the County of Kent, shewing the nature of the soil in which different sorts of timber trees are found to succeed in the most certain and perfect manner, with the uses to which they may be applied in different cafes, is given in the following table.

PLANTING.

Mr. Nicol states, that in planting, where it is performed on the more elevated or mountainous tracts, warmth and shelter are to be considered, as without these the trees seldom thrive in a perfect manner. In such situations there is, in general, the most difficulty and the least progress made in the raising of timber trees; the success of the planter depending greatly upon fixing or such sorts of timber trees as may in future become the most highly valuable, on planting thickly with plants of not too large a size, and on a considerable plate, or extent of ground both in length and width being planted. In these unfriendly situations to the growth of trees, small plants must consequently be chosen and planted thick on the ground; as the winds are very prejudicial to trees of a large stature, by lodging the roots, and frequently breaking the fibres; but though this is the most disadvantageous situation for planting, it is possible, with proper care in the above respects, to rear young timber in it. Where it is intended to cover a mountain from its base, it will be most conveniently done by planting round the bafe in the siril instanc, rising gradually; by which means an artificial shelter will be forming, from the progress that will be made by the trees that were first planted, especially if the extent is such as to require several fæcions to complete the planting. The portion first planted should be pretty extensive, in all such cases especially where shelter is principally intended.

The kinds of trees to be chosen for such situations must be regulated, in a great measure, by the soil. The pine would perhaps be found to flourish most, but the larch is preferable as a nurfe. The mountain-ash, the beech, the ash, the fycamore, the birch, the fir, &c. may all be planted with reasonable hope of succés; and where the soil is deep, rich, and the oak. But in low sheltered situations, where the inconvenience of exposure to the winds is obviated, timber-trees may be planted with greater certainty of success; the chief care necessary in this cafe being to fix on trees of a proper kind, and placing them at proper distances, according to their forts and sizes. As these situations admit of most kinds, on the more sheltered parts, the oak, larch, elm, beech, horse-chestnut, walnut, lime, fpruce, and firr fir may be suitable; and on the less sheltered portions, the ash, birch, fycamore, hornbeam, mountain-ash, and firr, with a mixture of larch. It may likewise be noticed that the banks of rivers and canals are mostly favourable for the planter's purpofe, and most sorts of timber and other woods may be raised in fuch situations; the oak, elm, poplar, willow and ozier, according as they are more or less dry; but the preference must depend on the local circumstances of the different cafes.

But in situations near the sea-coast, as they are in general imitable to the growth of timber, the beech and fycamore will be most found the most proper, as bearing the sea air better than other forts. At least they are of great use in nurfing the other sorts of trees till they acquire sufficient strength. It is advised in fuch places, as the belt mode of performing the buifins, to plant, where the banks rife high, in the face of them much within the level of the tops, in order to afford a screen for the trees within till they have attained a sufficient height; but when they are flat, to have recourse to planting in belts, commencing the work as close to the edge of the water as possible, putting the plants in, in a very thick manner in the first rows, as at the distances of not more than about thirty inches, and using fuch plants as are ftrout, well rooted, and not more than eighteen inches growth.

Raising the Plants.—The different methods of providing the plants have been already noticed under the head of Plantation; but the most useful are either by raising them in nurseries near the spot to be planted till of proper sizes, or by purchasing them from nurferymen in the neighbourhood. For extensive tracts of ground the fir is the most advantageous mode, but when only small tracts are to be covered, the latter may often be the most advisable. In forming the nursery grounds, great attention should be paid to having them properly situated in respect to warmth, and the foil well broken down and enriched by proper manures. In Nottinghamshire, in the dukes of Portland's extensive plantations, a well situated and sheltered valley, as contiguous as possible, is fixed upon for the purpose, and a space of ground sufficient for the purpose is well fenced in; large boarded gates being placed at each end, with a road down the middle proper for admitting carriages to convey away the young trees. When after the fence is completed the ground on each side the road is trenched about twenty inches deep, which may be done for about 3l. 12s. or 4l. per acre, according as the land is more or less gravelly. It is best done in the spring, when the plantings fall is over. If, after the trenching, two or three curls of lime be laid on an acre, the land will produce an excellent crop either of cabbages or turnips, which being eaten off by sheep in the autumn, will make the land in fine order for all sorts of tree seeds: but as the oak is the most tree cultivated in general, this is the method pursued in raising and managing that most valuable species. In the autumn, after the cabbages or turnips are eaten off, the ground requires nothing more than common digging. As soon as the acorns fall, after being provided with a good quantity, sow them in the following manner; draw drills with a hoe in the same manner as is practised for peas, and sow the acorns therein so thick as nearly to touch each other, and leave the space of one foot between row and row, and between every fifth row the space of two feet for the alleys. While the acorns are in the ground, great care must be taken to keep them from vermin, which would very often make great havoc amongst the beds, if not timely prevented. Let this caution serve for most other sorts of tree seeds.

As soon as the acorns are come up, the beds require only to be kept clean from weeds till they want thinning; and as the plants frequently grow more in one wet season, where the foil is tolerably good, than in two dry ones, where the foil is indifferent, the time for doing this is best ascertained by observing when the tops of the rows meet, which is done when that is the case by taking away one row on each side the middlemult, which leaves the remaining three rows the same distance apart as the breadth of the alleys. In taking up these rows, the workman ought to be careful neither to injure the plants removed, nor those left on each side. The rest of the young oaks being now left in rows at two feet apart, let them again stand till their tops meet, and then take up every other row, and leave the rest in rows four feet aunder, till they arrive to the height of about five feet; which is full as large a size as is ever wished to be planted. In taking up the two last sizes, the method is to dig a trench at the end of each row, full two feet deep, then undermine the plants, and let them fall into the trench with their roots entire; as very much of their future succeds depends on this point of their being well taken up. And a similar mode is necessary with other sorts of trees in providing them for the purpose of planting.

But in the place of this method, the acorns as well as other seeds of trees are sometimes sown at siril where they are to grow and remain. This method, the author of the Argyleshire Report lays, makes the best timber; the plants suffer no checks, nor feel the inconvenience of a change of foil,
PLANTING.

foil, and the expense of raising an extensive plantation in this manner is very trifling. Besides, it is found that these seeds of trees will grow in situations in which the plants have failed. The most expeditious way of sowing the seed in this manner, is, by a party of three men working together. The first with a paring spade takes up a turf, the second flits the earth with a spade, and the third distributes the feed and covers it. If any of the seedlings fail, they may be replaced by young plants raised on a similar foil, which will soon be reconciled, when very young, to their change of situation. Indeed the oak, when planted from the seed, or at most from the feed-bed, adapts itself wonderfully to almost any foil or situation; though it delights most in that which is very dry and gravelly.

In many cases, after the plants have been kept in the seminary or feed-bed for about two years, they are removed to a nursery of this kind, and planted in rows or lines twelve or more inches apart according to their fort, and from three to five in the rows, where they remain for two years longer, and are then finally planted out.

Preparation.—As soon as the plants have been raised in some of these methods, so as to be in a state for planting out, the next point to be attended to, where the ground has been properly drained, is that of preparing it for their reception. In this business great care is necessary, as much depends upon its being in a good condition for the reception of the plants. It is performed by the plough or the spade according to the different circumstances of the land. When coarse plants prevail, such as heath, furze, broom, &c. they must be fully destroyed by flutting them up, burning, or otherwise clearing them away. When burning is practised, the ashes should be blended with the foil, as they are found of great service in promoting the growth of the plants; in the opinion of Mr. Nicoll. But the mode of preparing by the plough on tillable feites, where the foil is thin, is the cheapest and most effectual of any; as where the land has been in tillage, it wants nothing more than two furrows and an equal number of harrowings, to render it fit for the reception of the trees. But where it is in lay, a crop of oats, &c. should be taken the season before planting; or if it is stubborn, a second crop, perhaps of beans, turnips or potatoes, will be necessary; previously ploughing and harrowing well, and laying the land up in a perfect method. A trench plough is frequently used for this purpose, which tills the ground to twelve or thirteen inches. In this method it is essential to plough to the full depth each time, in order that the roots of the plants may strike down more freely into the soil.

Where the spade is employed, which must be the cafe in deep situations where the plough cannot come, and where there are rock, stones, or other obstructions; the bold planters advise, that the holes or pits should be made to the full depth of the foil, and sufficiently large according to the size of the trees. For those of eighteen or twenty inches in height, whose roots occupy about nine inches when spread out, holes of fifteen inches in diameter may be sufficient. This must, however, be regulated by the judgment of the planter. And as it is of great advantage to the trees that the turfy matter should be well broken down and reduced before the time of planting, it may be useful to have the holes made a proper length of time before the trees are put in, to admit of this being fully effected, especially on the drier and more light foils, where there is a smaller proportion of this material.

Mr. Nicoll states, that from the desire of early appearance it has been too much the cafe to plant forell-trees of too great growth. It is, however, found, that there is not only much faving of expense, but a much greater certainty of success, in planting small young trees than such as are large and of greater age. Such as have been in the nursery two, three, or four years according to their kind, may in common be the most advantageous as timber trees. He also thinks that deciduous trees of all kinds, except the larch, of from three to five feet in height, being carefully raised with good roots, will generally succeed. He has, however, shewn, that a one year's seedling larch, nurtured one or at most two years, will outdo all others of its kind in any soil or situation, and therefore advises planting trees of this age only. First of any kind will succeed better if under than above thirty inches, even in the most favourable soil and situation. Most generally those of fifteen or eighteen inches in height are to be preferred. From this view of the subject, it may occur to some, that to plant seedlings only would be the most advisable and least expensive method. That it would be the least expensive method is obvious; but, that it is most advisable, except for the Scotch and spruce firs, may, he thinks, be disputed.

As the chief property of any young tree intended for transplntation, consists in a multiplicity of healthy fibres; hence the necessity of nurting, in kindly foil, for a year or two, all tap-rooted plants, for the attainment of this object, and that we may commit them to the less genial soil and more untoward situation with greater probability of success. For, whether shall we suppose the plant which has both root and branch to make, or that which has the latter only, in the first season after so important a change of habit, is more likely to succeed?—the latter, certainly. From which alone may be demonstrated the cause why plants of this description surpafs those of greater size, as stated above. These are raised with unbroken, tufty, and fibby roots; those with maimed, lank, fibreless ones; nor do they, with the utmost skill and attention, bear such proportion to the top. Consequendy the fibrels cannot afterwards, by the utmost efforts of human art, be induced to immediately to fetch pafurage for the fulleness of the trunk. For though lopping may in a great measure obviate this, injury is thereby done to the tree. In all soils and situations it is the safest and least expensive method to plant young healthy well rooted plants, where they can be procured.

Distance, Manner, and Time of Planting.—Mr. Nicoll's directions are, that for the most expos'd, bleak feites, and barren foil, from thirty to forty inches may be considered as a good medium; varying according to circumstances. For in an extensive field, it is hardly possible that there is not a variety of soils. Some parts may be deeper and more limy; others more gravelly and rocky. In the former, the greater distance may be advisable; in the latter the latter. But for less exposed feites, and where soil is found above six inches in depth, from four to five feet will be a good medium; varying the distances according to circumstances as above. And far belts, ilripes, or clumps, whose breadth or diameter does not exceed a hundred feet, lying in a bleak situation, and thin soil, the margin, on all sides, should be planted at not more than two feet apart; the interior at three. Thosc lying on a more sheltered situation, and of deeper soil, may be allowed distance according to circumstances. But narrow ilripes, or small clumps, even if the soil may be termed good, should generally be planted thicker than a more extended-maps, that the plants may afford each other shelter.

For the more sheltered feites, where the soil is deep, good, and where apparently every plant will grow, fix feet will be a good medium distance. Wider than this he cannot approve in any case whatever; because at this distance, the plants
PLANTING.

plants have room to grow till their thinnings become useful. But even where this is not an object, there is a greater; namely, that the plants may not grow too fast in their infancy, and that the pruning hook be not much wanted in the formation of flatly timber. It is suppos'd that he who plants too thin, with the idea of faving trouble in thinning, deviates as widely from the right path, as he who thins none at all. It is, therefore, contended that, rather than thin planting, is the safer side to err on. By which mode also, there is a more equal crop on the ground, bording or filling up vacancies being much less necessary. And in opposition to the common practice, it is suppos'd that thick planting is most necessary where the plants are large, as the greatest number die in these cases. The Nottinghamshire Report states, that in the duke of Portland's plantations, where trees of various sizes are planted in an irregular manner, the number upon an acre is usually about two thousand; but in other cases the number is frequently much larger.

With respect to the manner of planting the trees in the plantations, it is probably the bolt method, except where vegetable crops are to be cultivated between, to plant without any regular order, though the line or row manner is frequently practis'd, as being the least troublesome and inexpensive of any that can be adopted. With respect to the most advantageous manner of blending or intermixing the trees, it is observ'd that few have adviz'd the planting in groups, to prevent the suppos'd injury of trees of different growing together; others, however, prefer the mixed method, not only as affording a better means of ascertaining what sorts of timber trees succeed bett', but as enabling the planter to protect them more effectually. It has, however, been fugges'ted by Mr. Nicol, that it matters little whether we plant in distinct groups or in indiscriminate mixture; provided, in the latter case, we ultimately retain the most profitable and flourishing kinds only: for, with the proviso that most of the kinds evidently adapted to the soil and situation be planted according to the mode of thick planting, a sufficiency of them will remain, after all others are thinned away, for a full and final crop. For instance: if it should be suppos'd that the soil is best adapted to the oak; that it is desirable to raise the most valuable kinds rather than the decorative; and that, exclusive of the larch for nurseries, and a few firs to enliven the borders, fuch kinds are to compose the mixture; plant two oaks for one elm, two elms for one beech, two beeches for one ash, two ashes for one birch, and two birches for one fycamore. And thus will the plantation at once be formed, in uniform graduation, of kinds most likely to succeed each other, in the cafe of either dis-agreeing with the soil or climate; and which also succeed each other in respect of value as timber; doing justice, at least, to the patriotick intention of the planter, should the firth and more valuable kinds fail.

It is conceiv'd that in all situations, and on all soils, except those termed humid, and which are adapted to the aquatic kinds only, the larch is, without doubt, the most proper nurse, and therefore should take preference of all others for this purpose. But on sub-humid, or loamy soils, the Lombardy poplar and Huntingdon willow are good subfittates; and, when variety is the object, ought to be mixed with the larch, for the purpose of nurfing the other more valuable kinds. And that on elevated, poor fites, the mountain-ash, for the firth ten or fifteen years, is out-done by the larch only in the office of nurfing, and is juftly admitted for the fake of variety. In all situations, this plant grows quickly in youth. In maritime situations, the fycamore is likewise evidently useful for this purpofe. Few trees, except the above, grow fatter in youth; and none are more patient of the sea-breeze. Consequently, when the site is much exposed thereto, this tree should be freely planted in mixture with the larch for nurfing the oak, beech, elm, &c. if the intention be the culture of ship-timber. It is likewise fugges'ted, that the common pine may sometimes be useful in this view, and afford greater variety. The proportion in which these forts should be employed, must necessarily depend on the peculiaritie of the situation, and other circumftances. Some recommend in thin foils, and bleak situations, tree for tree; and in lefs exposed situations, and better foils, one nurfe for two principal trees; and in most sheltered situations, with good foil, one nurfe for three, four or five principal trees may be a fufficient allowance. On the moist exposed and bleak situations, where the foil is evidently sterile, the safest way is to plant too many rather than too few, as, unless well sheltered, the timber trees never succeed well in exposed situations.

The time of planting these forts of trees with the moft advantage, and the greatest chance of success, differs according to the nature of the foils and the plants, as well as in the ilate of the weather. It has been fated, that in the more porous dry foils, with the harder sorts of trees, the autumn, as from the middle of October to the latter end of November, may be the moft fuitable; as they will be better established against the fummer heats, which are often lefs difficult to new planted trees. But in the moft heavy foils, efpicially thofe of the clayey and loamy kinds, and with lefs hardy forts of trees, the early fpring feaon, as from the middle or latter end of February to the beginning of April, may be the moft proper. The condition of the land should be particularly attended to in this fort of work, as it is equally improper to plant when either in too dry or too moisf a situation. At a time when the foil is neither wet nor dry, the operation of planting is moft eafily, and also moft fucceffuflly performed. The mould adheres not to the fpade, nor does it run in; it divides well, and with little trouble intermingles with the fibres; nor, in the operation of treading and fettinq the plant upright, is it wrought into a mortar, to the evident prejudice of the plant, whatever weather may enufe. Confequently, on a retentive foil, it cannot be proper to plant in time of rain, nor in many cafes for a day or two afterwards; nor after a fall of snow, until for severall days it has entirely disappeared. Whereas on a dry absorbent foil, it may be very proper to plant in time of gentle rains or immediately after heavy showers.

Another circumstance which ought to be regarded in this busines, is the difference in the forwards of the vegetation of different forts of trees, as it should regulate in some degree the time of planting, where those of the fame forts are only made ufe of. In this view, it is adviz'd that the larch, elm, fycamore, lime, horfe-chenut, mountain-afh, birch, alder, poplar, willow, and some others, fhould be put in by the beginning of March; and that the oak, birch, ah, chenut, hornbeam, &c. be finifh'd planting by the beginning of April at the latest. The beft feaon for planting of many trees of the evergreen kind, fuch as the Wey-mouth pine, fpruce, Scotch, filver, and other firs, is fpuppof'd to be in the latter end of July, or in the beginning of the following month, when the weather is inclin'd to be moif or cloudy.

Planting out.—It is adviz'd, that as soon as the trees have been take'n up with care, fo as to injure the fibres of the roots as little as poifible, and a few of the bruifed extremities cut off, they fhould, when intended to be planted in mixture, be put together in proper proportions, and conveyed in this
way to the place where they are to be planted. They must then be distributed on the ground, at the pits or other places, in order to be ready for the planters, as by this means much time is saved, which would otherwise be lost in fortifying. But to prevent the roots from getting too dry, it is necessary not to take up or bring on to the land more than can be planted in a short space of time. But where only one or two fronts of trees are to be planted, the usual practice of carrying the plants along as the planting proceeds, may be the most convenient method for performing the work. And the operation is the best and most readily performed by two persons; a man to do the work, and a boy to hold the plants. In executing the work, the labourer first fills the mould well in the holes or pits that have been previously prepared, rendering it level, and fit for the reception of the plant: or forms new holes according to the mode of planting that is adopted. The boy then places the plant in the hole, with all the fibres of its roots regularly spread out and uncovered, to the depth of about an inch more than it had stood in the nursery, holding it perfectly upright; while the man gently fills in the loose mould, moving the tree a little up and down to let it mix with the roots: the remainder of the earth is afterwards put in; and the labourer proceeds to the preparation of the next hole, leaving the boy to set the plant erect and close the mould about it, which in soils of the fliffer sorts should be only performed in a light manner, but in those of the drier kinds, as the sandy and gravelly, as closely as possible. In this way the work is to proceed till the whole is finished. There are other methods of planting sometimes made use of, as by forming slits, nicks, or openings of other kinds, for as just to press in the roots of the plant; but these, from the roots being confined, and having no loose fresh mould to shoot into, seldom answer in any perfect manner. It is well remarked that much of the success of the planter depends upon this part of the work being well executed; but that great care should be taken, particularly where the land is inclined to moisture, or of a retentive quality, not to plant at too great a depth. In planting on hills, it is directed that the trees should be placed towards the declivity, being put in at the lowest part of the opening: which should, in completing the work, be left the highest, by which the moisture may be better preserved for the support of the plant.

It seems not improbable, the author of Practical Agriculture says, but that in many cases and situations, the planting of small trees of the timber kind might be performed with great convenience and expedition by the affixture of a plough suitable for the purpose, as has been sometimes practised in setting hedge-plants. Where trees of considerable growth are planted, great attention is necessary to have them well secured against the wind, as, when they become loose, the fibres are broken and destroyed that they soon die. This has been commonly effected by means of stakes; but as in this way the trees are often in danger of being injured by rubbing, a practice of ramming the earth closely about the roots has been attempted, which in some soils, and upon small scales of planting, has, it is said, been found to succeed; but in extensive concerns it is wholly inadmissible, from the trouble that must attend it.

When the plants have been all put in, it is a practice in some cases to bow or let the plantations with acorns, as is found that young oaks as well as other trees exceed in growth those that are planted. This work is done either by paring off the surface with a mattock, and letting the acorns with a dibble, or by putting them in flite drills by the hoe, at the distance of about six inches. The best season for performing this business is in April, and it may be performed the first, second, or third year after planting the ground, but the first or second is probably to be preferred. It is advised that great care should be taken to preserve the acorns well, by exposure to the air and frequent turning, as they are very apt to sprout soon after being gathered. The proportions of these and other sorts of seeds that are necessary are thus stated in the Nottingham Agricultural Report.

Quantities per Acre.

Of acorns from four to six fires.
— ahf keys, four fires.
— Spanish chestnuts, one ditto.
— hawthorn berries, one ditto.

It is necessary to bury the ahf keys and hawthorn berries one year in beds or pots of sand before they are sown in these situations.

When the trees have been thus planted out, it is advised as necessary not to lose sight of them, as the young plants should be kept clean and free from the annoyance and choking of coarse weeds of all kinds, for at least three or four years. This may be done by the hoe in many cases; but some have recourse to the culture of different sorts of crops in this view. In this method, however, much care is requisite not only to avoid injuring the plants, but to guard against the soil being too much impoverished, and their growth thereby retarded in too great a degree. And where coarse plants abound, such as hroon, furze, brars, and other similar productions, in all the exposed situations, they should be wholly cut up and destroyed; but in bleak exposures it may be a better practice to only clear them to a distance round the trees, so that they cannot do any injury by rubbing or striking against them, the others being left for the purpose of sheltering and protecting the young trees during their young growth. There is another circumstance likewise to be attended to in this business, which is that of filling up the vacancies that are caused by the dead plants. Where the ground is kept perfectly clean, this may be done at any proper season; but in other cases, when the dead plants cannot be so easily detected, it may be better to delay the buifinses to the third or fourth year, when the deficiencies can be more perfectly ascertained. If this sort of business be done too early, many plants are frequently removed that would have thrown out from the bottom, on account of their not being dead in that part, though wholly gone in the top. It is advised that the plants employed in filling up these vacancies should never be too large, as where that is the case they are liable to die or be destroyed.

There is still another kind of planting which is frequently practiced, but the propriety of which is not yet well ascertained. It is that of setting hedge-rows with trees of the timber kinds. The utility of the practice is maintained by fume on the ground of the degree of shelter and ornament that it affords, and its being a means of raising useful timber at little or no expense; while others condemn it as highly improper, and disadvantageous, on the principle that much injury is not only done to the crops, especially when of the grain kind, by the dropping and the spreading of the roots, but also to the hedge in the places where they stand, by their producing gaps and openings. The author of a late practical work, however, suggests, that though some inconvenience and injury may be sustained where this sort of planting is much in use in arable districts; yet from these being, in a great measure, capable of being obviated by proper training and pruning, and from the naked appearance which is exhibited without them in a country, but more particularly from the vast benefit that may be derived
derived in the way of timber; it would seem that some extent of planting in this method should be attempted in most situations. Mr. Middleton hints, that it would not be an easy matter to make an accurate estimate of the advantages to be derived from such a measure; but in order to gain a slight idea as to the quantity of hedge-row timber, let it be considered that, in well-enclosed, hedged, and cultivated districts, the hedge-rows occupy from a twentieth to a tenth of the whole surface. Even including the common fields, and cultivated slopes and borders of sheep-downs, the average quantity of land occupied by hedge-rows, at this time, amounts to a twentieth, or two millions of acres; all of which might probably be made to produce timber: more than half of it, however, would not do so, by only trimming the lowest side branches off to the height of fifteen feet from the ground. This would permit the air to circulate freely, give every advantage to the occupier's crops; and would leave sufficient tops upon the trees for the purposes of growth and rural ornament.

Under management like this, the hedges would every where present healthy, vigorously-growing, and handsome timber; and would add very much to the profit of the land owner, to the security of the country, and to the pleasures of the traveller. But in performing the work of planting in such cafes, the nature of the land, the fort of husbandry that it is principally conducted under, and the kind of exposure in which it is placed, should be well considered, and the fort of trees properly adapted to it. In dry soils, most sorts of timber trees, as has been seen, may be planted; but in those more rich and heavy kinds, the oak and the elm may be the most proper. The ash should, perhaps, never be had recourse to where the land is at all wholly under the plough; but on lands under the grazing or grazingsystem, it may be planted with advantage. In bleak and exposed situations, the beech is probably the best for this use; and near the sea the fycamore. The trees where the ground is moister in an arable state should be planted at much greater distances than under the contrary circumstances, and such trees as run most to tall clear items be preferred. It is recommended that the young trees in this fort of planting should be larger than in other cafes, being kept in the nursery two years longer than has been here advised, and shifted so as to produce more fibrous roots. When about five or six feet in height they are probably in the most suitable condition for being planted out in these places.

In these cafes the most proper time of planting in hedge-rows is, when the fields are first broken up from the state of lay, as at that time, from their being continued in the state of tillage for some years, there will be less trouble and expense in protecting them from cattle by palings, &c. as well as less danger of their being injured by the browsing of live stock, as they will be advanced beyond their reach by the time the land is restored to grass.

Where the planting is performed in the hedge-rows of grass lands, the trees must always be perfectly secured from the encroachments of cattle, as well as the rubbing of sheep, or other animals, as where this is not the case, they are soon much injured, and frequently wholly deforested. The work of planting in these cafes should be carefully performed in the manner described; and where the trees do not stand perfectly firm against the wind, be well secured by itakes, or other proper means, as they never thrive well when not kept perfectly firm and ready in the soil.

The practice frequently employed of converting the hedge-row timber trees into pollards by lopping off their top branches, should constantly be guarded against as much as possible, as it is the destruction of timber. Where pollards abound, they are mostly cropped once in from about nine to fifteen years, the profits of which, in general, belong to the tenant. This work should be constantly limited by the end of February, when it is in use, at the latest.

As soon as the trees have acquired a tolerable growth, it is necessary, in all cafes, to attend to the proper pruning and thinning of them occasionally as they advance, in order to prevent their growing in an improper manner, and their injury each other by rubbing or being drawn up weak. In the first intention, they are therefore to be occasionally looked over after the third season from planting, and such headed down, or otherwise cut, as may appear necessary for their more regular or perfect growth. When this has been done, the only thing further will be to encourage a leader, by shortening all the other branches that appear to contend with it to nearly one-third of their length, in order to strengthen their main item. The whole is afterwards necessary, is that of properly thinning the strong top branches, and thos on the sides, which may be done by a light bill. This is, however, only applicable to trees of the forest kind; those of the fir and evergreen forest require nothing more than the regulation of their leaders, as that of keeping them angle where they throw out double. The left the side branches are touched the better in all thefe forts of trees, as they are very much hurt by cutting.

On the whole, planting is without doubt the most productive improvement that can be attempted on poor barren lands, and ought to be promoted in every way as much as possible; but more especially by the application of some fort of stimulus which could have the effect of inducing the proprietors of lands, in situations proper for it, not to neglect such undertakings, as being the best means of rendering their properties fully and completely valuable, as well as of benefiting the country.

Planting, Inversely or Reserved, is a method of planting, in which the ordinary position of the plant, or shoot, is inverted; the branches being let in the earth, and the roots reared into the air.

Agricola mentions this monstrosus way of planting, which, he affirms, succeeds very well in moss, or all sorts of fruit-trees, timber-trees, &c. both foreign and domestic. Bradley affirms his having seen a lime-tree in Holland, growing with its first roots in the air, which had shot out branches in great plenty, at the same time that its first branches were turned into roots, and fed the tree.

The indomitable Mr. Fairchild has practiced the fame with us, and gives us the following directions for the performance of it.

Choose a young tree of one shoot, of alder, elm, willow, or any other tree that takes root readily by laying; bend the shoot gently down, till the extreme part be in the earth, and so let it remain till it has taken good root. This done, dig about the first root, and gently take it up out of the ground, and raise it till the item be nearly upright; in which state flake it up.

Then prune the roots, now erected in the air, from the bruises and wounds they received in being dug up; and anoint the pruned parts with a composition of four parts of bees'-wax, four of tallow, two of renin, and two of turpentine, melted together, and applied pretty warm. Then prune off all the buds or shoots upon the item, and crown the wounds with the same composition, to prevent any collateral shootings; and leave the root to nature.

Planting, in Architecture, denotes the laying the first course
PLA

courses of stone on the foundation, according to the measures, with all the exactness possible.

PLANTS, in Botany and Vegetable Physiology, compose the second of the three kingdoms of nature. To define the limits of these, the animal, the vegetable, and the fossil kingdoms, has exercised the ingenuity of philosophers. When fossils were believed to possess a vegetative power, which even Tournefort maintained, the chief difficulty lay in distinguishing them from plants; but since the mineral kingdom has been ascertained to depend on the laws of chemistry alone, all ambiguity on that side of the question is removed. On the other hand, in proportion as the physiology of plants has been studied, their anatomy, nutrition, development, and propagation, have been found so nearly allied to similar functions in animal bodies, that increase of knowledge has but augmented our perplexity. The following are among the most approved definitions, intended to discriminate between animals, vegetables, and fossils.

Jungius, in his Flagge, p. 1, says "a plant is a living body destitute of sensation; or it is a body attached to some certain place or seat, whence it derives powers of nourishment, increasement, and propagation." Linnaeus cites this passage inaccurately in Phil. Bot. 1. He observes, in a manuscript note, that the floating sea-weeds, and Conferes, form an exception.

Boerhaave considers a plant as "an organic body, attached by some part of itself to some other body, whence it derives nourishment." Ludwig affirms that "natural bodies constantly endowed with the same form, and with locomotion, are animals; those which have the same form, without locomotion, are vegetables; and those which have a diversity of form, are minerals." To this Linnaeus well objects, the perfect regularity of form in crystals of the same species, and the want of locomotion in several animals.

Tournefort, in his Flagge, p. 54, says "a plant is an organic body, always furnished with roots, perhaps always with seeds, and almost always with leaves, flowers, and fruits."

Allison has defined vegetables as nourished by pores situated in their external surface, animals by vessels in their internal one.

Linnaeus, in Phil. Bot. 1, has given the most neat, and generally approved, definition. "Stones grow. Vegetables grow and live. Animals grow, live, and feel."—To which he has subjoined, in manuscript, "et se mouvet, mutu possiblit;" i.e. and are endowed with a certain degree of spontaneous motion.

Difficulties attend all these positions. The want of sensation in vegetables cannot be demonstrated, nor are appearances to the contrary wanting; so that it can never serve for a practical mode of discrimination, nor as a basis for any philosophical argument.

Mirbel, in his Traité d'Anatomie et de Physiologie Végétale, has remarked "that plants alone have a power of deriving nourishment, though not indeed exclusively, from inorganic matter, mere earths, salts or airs, substances certainly incapable of serving as food for any animals, the latter only feeding on what is or has been organized matter, either of a vegetable or animal nature. So that it should seem to be the office of vegetable life alone to transform dead matter into organized living bodies."

To this we can find no exception. However inconvenient, and indeed impossible to be used, as a practical test, it appears to be a found philosophical distinction, between the animal and vegetable kingdoms. The fossil or mineral kingdom is essentially distinguished from both, by the want of an organized structure, developed and increased by abstraction; and of a vital principle, essential to the performance of all the functions on which their health, growth and propagation depend.

Plants come under consideration, in various points of view, in a work like the present. For what concerns their anatomy and physiology, see Anatomy, Bark, Cortex, Circulation of Sap, Foundation of Plants, Leaf, Flower, Germiné, Pericarp, &c.: for their scientific arrangement and discrimination, see Botany, Classification, Flora, Figures of Plants, Genus, Species, Natural Orders, System, &c. See also Linchenes and Mucil. The reader is requested to correct two typographical errors in the latter article, column eighth, line 18 from the top, for sorts read sorts; and line eight from the bottom, for sexual read sexual.

Plants of Britain, the natural spontaneous production of our soil and climate, have formed the subject of many separate botanical works. More or less perfect catalogues of British plants have been published by How, Ray, Petiver, Wilton, Hill, Jenkinson, and others, besides a number of local Floras. Ray's Synopsis Methodica Stirpium Britannicarum first set the example of a systematic arrangement, and scientific discrimination, of our native vegetable productions, and has been the foundation of all that has been done since. This excellent work was accommodated to the Linnaean system and principles, with augmentations, by Hudson, and has led the way to the labours of Withers, Lightfoot, Robson, Broughton, Wade, Hull, Curtis, Relhan, Abbott, and the writer of the present article, whose Flora Britannica, extended as yet no farther than the end of the Muecif, was written on a comparison of all that had before been done, with the specimens of the Linnaean herbarium. This Latin work has been followed up and illustrated by the figures, and English descriptions, of the same author's English Botany, drawn, engraved, and published by Mr. Sowerby, which is just now come to a conclusion, in thirty-six volumes octavo, with 2592 coloured plates. In the progress of this latter work, since the Flora Britannica, or the Compendium Fl. Britannicae, appeared, about 150 species have been added to the British list; even in the first twenty-three, or phanogamic, classes of the Linnaean system. We propose, therefore, in the present article, to exhibit a complete catalogue of the Phanogamic plants of Britain, as far as the present state of our knowledge extends, with a reference throughout to the English Botany, in which, with two or three exceptions only, they are now all separately delineated. These amount to 1450. So full an enumeration of British plants has no where, hitherto, appeared; and we shall take the opportunity of correcting mistake of the Flora Britannica, respecting certain species erroneously there admitted. This catalogue is arranged according to the Linnaean system, with these slight alterations only, which are adopted in the Fl. Brit. and accounted for in the author's Introduction to Botany. Each plant is mentioned by its generic and specific names, in Latin and English; then follows a reference to the volume and plate of Engl. Bot.—The particular situation, duration, and flowering month, of every species are subjoined. Whatever the reader may wish to further to know, is to be sought under the name of each genus, at its proper place in the alphabet. New species, not there mentioned, are particularly described or defined, and various necessary corrections are given respecting preceding articles, as in the classes Tetradyama and Gynandra. New matter, regarding ge-
Clafs 1. Monandria.

Ord. 1. Menyanthia.

SALICORNIA. Glaffwort.

HIPPURIS. Mare's-tail.

1. H. vulgaris, common. 11. 763. Pools and ditches. Per. 5.

CHARA. Chara.

This is the larger plant of Vaillant, fig. 8, mentioned as a variety of flexilis in our article Chara, n. 4.

"Smooth, transparent, without prickles. Leaves cylindrical, elongated, all simple. Anther often stalked."

More slender and branched than the last, but more stout and firm in habit than C. flexilis.

"Smooth, transparent, shining, without prickles. Lateral branches repeatedly forked; their segments awl-shaped, acute. Leaves awl-shaped, often branched."

Much smaller and more tufted than the last. When dry almost colourless, shining like glafs.

ZOSTERA. Grafs-wrack.

Ord. 2. Digynia.

CALLITRICE. Water Star-leaf.

PLANTS.

Lycopus. Water-horehound.

Salvia. Clary.

Ord. 2. Digynia.
Anthoxanthum. Vernal-grafs.

Class 3. Triandria.

Valeriana. Valerian.
1. V. rubra, red. 22. 1531. Walls, and chalk cliffs. Per. 6—9.
3. V. officinalis, great wild. 10. 698. Marshes and hills. Per. 6.

Crocus. Saffron.
*1. C. sativus, cultivated. 5. 343. Fields. Per. 9.
2. C. vernus, spring. 5. 344. Meadows and pastures. Per. 3.

Inia. Inia.

Iris. Iris.
1. I. Psued-acorus, yellow. 9. 528. Waters. Per. 7.

Schoenus. Bog-rush.

Stamens but two. Seeds with many bristles at the base.

Stamens three. Seeds with only three bristles at the base.

Cyperus. English Galangale.

Scirpus. Club-rush.
1. S. palustris, marsh creeping. 2. 131. Bogs and ditches. Per. 6, 7.

Eriophorum. Cotton-grafs.
5. E. gracile, fnder mountain. 34. 2402. Highland mountains. Per. 7.

Nardus. Mat-grafs.
1. N. bria, common. 5. 290. Sandy moi1f heaths. Per. 7.

Ord. 2. Digynia.

Panicum. Panick-grafs.

Phleum. Cat’s-tail-grafs.
PLANTS.

5. P. Micheli, Michelian. 32. 2265. Highland rocks. Per. 7.

Aloepecurus. Fox-tail-grafs.
1. A. pratensis, meadow. 11. 759. Pastures and meadows. Per. 5.

Alopecurus. Fox-tail-grafs.
1. A. pratensis, meadow. 11. 759. Pastures and meadows. Per. 5.

Alopecurus. Fox-tail-grafs.
1. A. pratensis, meadow. 11. 759. Pastures and meadows. Per. 5.

Alopecurus. Fox-tail-grafs.
1. A. pratensis, meadow. 11. 759. Pastures and meadows. Per. 5.

Alopecurus. Fox-tail-grafs.
1. A. pratensis, meadow. 11. 759. Pastures and meadows. Per. 5.

Melinis. Melic-grafs.

Sesleria. Moor-grafs.
1. S. caralis, blue. 23. 1613. Limestone rocks. Per. 4.
PLANTS.

FESTUCA. Fescue-grafs.

"Panicle spreading. Spikelets three-flowered, with long awns." —Like the following, but less drooping, and with fewer florets.

"Panicle pointing one way, erect, much branched. Florets two or three, oblong, angular, beardless; the upper ones deciduous. Leaves linear, striated." —Lower and much more slender than the last. The lowermost floret only ripens seed.
15. F. clitter, tall. 23. 1593. Moi't meadows. Per. 6. 7.

BROMUS. Brome-grafs.

"Panicle spreading, compound. Spikelets ovate, turgid, eight or ten-flowered. Florets elliptical, broad, imbricated, smooth-shi'd, with three equidistant ribs at each side." —Two feet high. Panicle smaller and more erect than in the last, but the spikelets are larger, more tumid, and greener. The true arenarius has only two close ribs on each side the keel of the glume.
10. B. fletus, barren. 15. 1030. Waite ground, and fields. Ann. 6. 7.

STIPA. Feather-grafs.

AVENA. Oat-grafs.

This is now admitted as a native species, in consequence of its having been found in Scotland, Wales, Yorkshire, and Cornwall, notwithstanding the contrary opinion expressed in Fl. Brit. 140. See AVENA, n. 22.

"Panicle erect. Calyx containing about five florets. Receptacles bearded upwards. Leaves naked, finely ferrated, with rough sheaths. Stem compressed." —Like A. prae-
beccens in general aspect, but larger in every part, and the leaves are naked, not downy; their edges finely ferrated, as in pratensis. Flowers much larger than in either of these.

LAGurus. Hare's-tail-grafs.

ARundo. Reed.

"Calyx fingle-flowered, full as long as the corolla. Panicle erect, clove. Flowers scattered, erect, with a dorfl awn. Down shorter than the corolla." —Half the size of the last. Calyx acute, but without elongated points. S itu-
pus very short. The panicle is of a purplish bronze hue, not unlike Melica cornuta.

LOLium. Darnel.
1. L. perenne, perennial. 5. 315. Meadows and pastures. Per. 6.

ROTBOLLIA. Hard-grafs.

ELYMUS. Lyme-grafs.
1. E. arenarius, upright sea. 24. 1672. Sandy sea-
coast. Per. 7.

Bupleurum. Hare’s-ear.

ECHINOPHORA. Prickly-Sampire.

†1. E. spinosa, great. 34. 2413. Sandy sea-cliff. Per. 7.

TORDYLLUM. Hart-wort.

†1. T. officinalis, smaller. 34. 2440. Fields, rare. Ann. 6, 7.

2. T. max/min, great. 17. 1173. Chalky ground, rare. Ann. 6, 7.

CAULIS. Bur-parfley.

DAUCUS. Carrot.

“Fruit armed with compressed teeth. Leaflets dilated, succulent, hairy, with rounded segments. Umbels convex when in seed.”—About 18 inches high, woolly rather than hairy, of a more flabby habit than the foregoing. The umbels want the remarkable dark-red central abortive flower, which is characteristic of D. Carota. The compressed teeth which clothe the clefts approach to the nature of D. matricina and muricatus.

BUXUS. Earth-nut.

The B. Buxus, and fennel of Withering, and of Sm. Fl. Brit. 321, prove, on mature examination, to be, as Linnaeus considered them, one and the same species. The root of the former, being near the surface, its flow has no elongated tapering base, and if the herb happens to be luxuriant, the leaves of the general involucre are more numerous than otherwise.

CONIUM. Hemlock.

SELINEUM. Milky-parfley.

1. S. palustris, marsh. 4. 229. Watery meadows. Per. 7.

ATHAMANTA. Stone-parfley.

PEUCEDANUM. Sulphur-wort.

CRITHMUM. Sampire.

HERACLEUM. Cow-parfley.

H. angustifolium, Fl. Brit. 327, proves, on a careful examination, to be only a narrow-leaved variety of this, distinct from the true angustifolium of Linnaeus.

Silene. Catchfly.
2. S. quinquefolia, variegated. 2. 86. Sandy fields. Ann. 6, 7.

S. paradoxus, mentioned in the Fl. Brit. 1267, is to be excluded, as not really of British growth. The Dover Catchfly, Lycobius major alpina, Dubravin persoon, R. 554, has not been found since the time of Ray; and the old specimens, preferred in the British Museum, appear to be something unknown to modern botanists, though not sufficiently perfect to afford specific characters. They are more like the Limnanthus Cuculus villosus, for which Ray's plant was originally taken by Linnaeus and Hudston.

*Brown in Ait. Hort. Kew. v. 4. 82.*

1. H. petrae, rock. 2. 111. (Lepidium petraeum). Lime-
stone. Benn. 3, 4.

Leaves pinnatifid, entire. Petals shorter than the calyx.

Stigma fertile.

Named, by Mr. R. Brown, in honour of Mrs. Hutchins,
of Bantry, in Ireland; a lady whose discoveries in the most
difficult parts of practical botany, well entitle her to com-
memoration. The genus is distinguished from Draba and
*Subularia,* in having but two, instead of many, seeds in
each cell; and moreover from the former in having tumid,
not nearly flat valves; from the latter in not having linear
cotyledons. *Lepidium* has properly an emarginate pouch,
with keeled valves, and solitary feeds. Other species of
*Hutchinsia* are *Iberis rotundifolia* and *Lepidium alpinum*
of Linnaeus.

**Teesdalia. Teesdalia.**

Eff. Ch. Pouch emarginate, inerely heart-shaped. Seeds
two in each cell. Filaments each bearing a scale, at the in-
side, near the base.

1. T. nudicaulis, naked-stalked. 5. 327. (Iberis nu-

Petals equal.

This genus is dedicated, by Mr. Brown, to the memory
of the late Mr. Robert Teesdale, F.L.S. Another species is
the exotic *Lepidium nudicaule* of Linnaeus, differing in
having equal petals, and but four stamens. See *Teesdalia*
hereafter in its proper place.

PLANTS.

Medicago. Medick.
1. M. sativa, purple, or lucerne. 25. 1749. Meadows and pastures. Per. 6, 7.

Class 18. Polyadelphia.

Ord. 1. Polyandra.

Hypericum. St. John’s-wort.

Class 19. Syngenesia.

Ord. 1. Polygamia equilis.

Tragocephon. Goat’s-beard.

Picris. Ox-tongue.

2. P. hieracoides, hawkweed. 3. 196. Gravel or chalk. Bienn. 7, 8.

Sonchus. Sow-thistle.
1. S. oleraceus, blue. 34. 2425. Highland pastures, rare. Per. 7, 8.

Lactuca. Lettuce.

Prenanthes. Wall-Lettuce.
1. P. muralis, ivy-leaved. 7. 457. Walls, or chalky groves. Per. 7.

Leontodon. Dandelion.
2. L. palustria, marsh. 8. 553. Moift meadows. Per. 6, 7.

Apargia. Hawkbit.

Stalks radial, single-flowered. Leaves toothed, rough. Flores hairy at the orifice, glandular at the extremity.
Stalks radical, mostly single-flowered. Leaves with re-vered teeth, smooth. Calyx hairy.

Hieracium. Hawkweed.

4 N 2
5. H.
PLANTS.

CREPIS. Hawk's-beard.
4. C. biennis, rough. 3. 149. Chalky pastures. Bienn. 6, 7.

HYPOCHERIS. Cat's-ear.

LAPSANA. Nipple-wort.
Stem none. Stalks divided; swelling and hollow at the summit. Leaves obvate. The seeds have an elevated border, which is unlike the true Lapsana, but this plant is perhaps better placed here than elsewhere. See Lapsana.

CICHORIUM. Succory.
1. C. Intybus, wild. 8. 539. Gravel or chalk. Per. 7, 8.

ARCTIUM. Bur-dock.

SERRATULA. Saw-wort.

CARDUUS. Thistle.
6. C. heterophyllus, moorland. 10. 675 (Card. nect. roph.) Mountain pastures. Per. 7, 8.

2. C. integrifolium, mountain. 3. 152. Chalky hills. Per. 5—7.

DORONICUM. Leopard’s-bane.

BELTIS. Daisy.

CHRYSANTHEMUM. Ox-eye.

PYRETHRUM. Feverfew.
1. P. Farfana, common. 18. 1231. Rubbish. Per. 6, 7.

MATRICARIA. May-weed.

ANTHEMIS. Chamomile.

3. A.

ACHILLEA. Yellow.

Ord. 3. Polygandria-fragrance.

CENTAUREA. Knapweed.
2. C. nigra, black leffer. 4. 278. Pastures, every where. Per. 6—8.
5. C. Ipaedis, Jerfey. 32. 2256. Pastures, Jerfey. Per. 7, 8.

Clafs 20. 'GYMNANDRIA.

Ord. 1. Monandria.

The natural family of the Orchideae, of which this order entirely consists, has lately received some fresh corrections from the able pen of Mr. R. Brown, given by Mr. Aiton in his new edition of the Hortus Kewensis, v. 5, clafs Gymnandria. By these we have profited in the following arrangement, where we have adopted several of Mr. Brown's new genera; only deriving their distinctions from characters somewhat different from his. It is a strong proof of the validity of such genera, that they will stand this test. We exclude the marks taken from the absence, presence, or number, of the minute pouches whence the manes of pollen originate; not so much on account of the difficulty of having recourse to those parts in practice, but because the distinctions founded thereon do not appear to lead to the knowledge of natural genera. On the contrary, they rather shew the danger of taking any technical character as an infallible guide throughout. We have therefore not adopted the Gymnadenia, nor the Habenaria of this ingenious writer, because they seem to us naturally to belong to Orchis. Nevertheless, we readily submit our opinion to the correction of those who, on mature enquiry, may think otherwise. What is to become of Willdenow's Habenaria, see that article, must be decided by the future study of exotic Orchideae, fearfully known sufficiently at present, to any European botanist, to enable him to form an opinion. See

ORCHIDEA, Orchis, Ophrys, Neottia, Epipactis and Malaxis.

The Orchideae are disposed in three very natural sections, which give the leading distinctions of the genera. 18. Another united to, or rather a continuation of, the column; terminal, in a manner, though sometimes surmounted by a point. 2d. Another parallel to the stigma, and opposite to that part. 3d. Another a terminal vertical moveable lid, either permanent or deciduous. Mr. Brown subdivides this third section, according to the anther being permanent or not, which seems to us unnecessary.

Section 1.

ORCHIS. Orchis.

Eff. Ch. Nectary with a posterior spur.

Bulbs undivided. Lip of the nectary lanceolate, entire; spur very long. Lateral calyx-leaves spreading, deflexed. This is referred to Habinaria by Mr. Brown, because the manes of pollen originate from two distant glands, which are naked, or delititute of a pouch at the base. The flowers are snow-white, with some touches of green, and smell powerfully, in an evening only, like a very sweet honey-fuckle.

2. O. pyramidalis, pyramidal. 2. 110. Chalky pastures. Per. 7.

Bulbs undivided. Lip of the nectary in three equal entire segments, with two prominences above; spur elongated, thread-shaped. This and the fiv fix following, having the gland, or glands, of their manes of pollen enclofed in a single pouch, belong to the true genus of Orchis. Br.

The flowers of O. pyramidalis are crimson, fragrant, combling a short, dense, pyramidal spike.

Bulbs undivided. Lip of the nectary four-cleft, crenate; spur obtuse, ascending. Calyx many-ribbed. Leaves without spots. Flowers purple or crimson. The three calyx-leaves cohere together, in the form of a hood, and are ribbed with green.

Bulbs undivided. Lip of the nectary four-cleft, crenate; spur obtuse. Lateral calyx-leaves reflexed upward. The leaves are spotted with black. Flowers purple, scented. Calyx-leaves with only three ribs, of their own colour. The flanks, bracteas, and germen are purple.

Bulbs undivided. Lip of the nectary four-cleft, rough, with prominent points; spur obtuse, one-third the length of the germen.

Three inches high. Calyx almost black. Lip purple, with entire lobes. Flowers small.

6. O. militaris, narrow-lipped military. 27. 1873. Chalk hills. Per. 5.

Bulbs undivided. Lip of the nectary five-cleft, rough; segments linear. Calyx and petals taper-pointed, confluent.

A foot high. Leaves light green, unspotted. Flowers rofe-coloured, their calyx paler, or whitish. This whole plant, like the following, while drying, exhales a powerful scent of mignonet, woodruff, or new hay.

PLANTS.

Larger. Calyx dark brown externally. Petals and nectary pink or purple.

8. O. hircina, bear. 1. 34. (Satyrium hircinum). Thickets on chalk hills, very rare. Per. 7.

Bulbs undivided. Lip of the nectary three-cleft, downy; middle segment extremely long, linear, twisted, emarginate.

Large andearceft. British plant of this tribe, often a yard high, with from twenty to sixty flowers, whose smell is fetid, and goat-like. Spur hollow, green, like the calyx and anther. Lip two inches long, pubifh-lead-coloured, with a white speckled downy disk.

Hills. Per. 6.

Bulbs clustered, in three pairs. Lip of the nectary in three deep acute segments; spur one-third the length of the germ.

A foot high, slender. Flowers small, numerous, in a dense spike, white, with a green lip, nearly nodorous. — This and the next are made Habenaria by Mr. Brown.

10. O. viridis, green frog. 2. 94. (Satyr. viride).

Meadows. Per. 6, 7.

Bulbs clustered. Lip of the nectary linear, with three terminal teeth; the middle one smallest; spur very short, emarginate.

Five inches high. Flowers green, shorter than their bractea. Lip brownish.

11. O. laifolius, marl. 33. 2308. Wet meadows.

Per. 5, 6.

Bulbs clustered. Lip of the nectary crenate, obflutely three-cleft; spur conical. Bracteas longer than the flowers.

Stem hollow. Leaves unfotted. Flowers crimson, more or less deeply coloured.

Bulbs palmate, spreading. Lip of the nectary crenate, three-lobed; spur cylindrical, shorter than the germ.

Bulbs palmate. Lip of the nectary in three entire segments; spur bristles-shaped, twice as long as the germ.

Leaves narrow, unfotted. Flowers rather small, crimson, with a rich fiphy odour.

This species alone constitutes Mr. Brown’s genus of Gymnadenia, so called from γυμνός, naked, and άδέν, a gland, because the glands supporting the masses of pollen are naked, or deficite of a pouch, and flab close together. In this last character alone the genus is made to differ from Habenaria, whose naked glands are more or less deficent from each other. It seems to us that Habenaria nigra, this Gymnadenia, and Orchis pyramidalis, are so nearly akin, that no affirmed character ought to separate them, and that they all truly belong to the genus Orchis.

ACERAS. Man-Orchis.

Eff. Ch. Calyx spreading. Nectary plane, without a spur. — This genus of Mr. Brown’s, whose name expresses the want of a spur, is well distinguished by that character from Orchis, with which it agrees in having one common pouch for the glands of the pollen. By this last mark Mr. Brown distinguishes it, on the other hand, from the true Ophrys, of which we shall presently speak. We readily admit the genus, as a most natural one, only preferring the more easy characters taken from the shape of the lip, and pollute of the calyx.

Lip of the nectary longer than the germ. Br.

The bulbs are globose. Leaves unpotted. Spike rather long, of numerous fentla flowers, whose closed calyx is green, mostly bordered with brown. Lip long, dependent, yellow, without spots; its segefments four, shaped like those of the Orchis militaris, but generally without the small intermediate tooth.

HERMINIUM. Mult-Orohis.

Eff. Ch. Calyx spreading. Petals three-lobed, shaped like the nectary, which has no spur.

This genus, and its name, are revived from the early works of Linnaeus. The application of the latter, derived, as it seems, from iepος or iepος, a base, or foundation, is not evident to us. The glands of the pollen are naked and distinct, so that it differs from Habenaria of Mr. Brown, as his Aceras does from Orbis, in the want of a spur. We most readily adopt the genus, only preferring, instead of a character derived from the glands, the striking one of the three-lobed pedas, and their uniformity with the lip, the very same uniformity which characterises the Wet Indian orchis. gens of Stellis.

1. H. monorchis, small. 1. 71. (Ophrys monorchis).

Chalk hills. Per. 6.

Leaves radical, two, lanceolate. Br.

Three inches high. Bulbs round, one of them remote. Leave light green. Flowers small, pale yellow, musky.

Orophys. Infert-Orchis.

See the article Ophrys, where we have given Mr. Brown’s characters of this most natural genus. We wish to strengthen, not to invalidate them, by those which, in conformity to our plan, we have taken from the position of the calyx, and shape of the lip. See Aceras just mentioned.

1. O. mycifera, fly. 1. 64. Chalky fatures, sparingly.

Per. 6.

Lip of the nectary four-lobed, elongated, somewhat downy; its disk polished. Column obtuse.

Bulbs ovate. Stem 5 foot high. Leaves unsotted. Spike lax. Calyx green. Petals linear, of a dull deep purple. Lip of the fame colour, with a blueflih, shining, broad, tranferve stripe in the middle. The column has no terminal point.

Lip of the nectary five-cleft, inflated; its small terminal segment awl-shaped, recurved. Column with a hooked point.

Rather larger, with broader leaves. Flowers much larger. Calyx pale purple, with green ribs. Petals oblong, green, fringed with white. Lip remfembling the body of a bee, very prominent and convex, hairy, elegantly variegated with brown and yellow; its margin bent backward, the little terminal point only being recurved forward.

Lip
Lip of the nectary villous, three-lobed, emarginate, point- 
lefs, deflexed. Column acute.

Of more humble growth than the last, with a green calyx, and yellow-green petals. The lip is like the body of a spider, brown, with two principal longitudinal paler stripes, the margin pale, and bent backward, deficient of the pointed appendage seen in the *genus*. 

The *O. arachnoidea*, Andr. Repof. t. 470, a native of Italy and Switzerland, not yet observed in Britain, is a very distinct species from all the *genus*. Haller has figured it in his *Historia*, t. 24, by the name of *Orchis fucifera*; but his account and synonyms are much confused. Andrews confounds it with our *aranae*, which is Curtis's *fucifera*, not *fucifera*. Its character consists in the smallness of the red- 
dish petals, which are not one-third the size of the white calyx-leaves; and especially in the margin of the very broad lip being dilated, and, as well as the pointed appendage, reflexed. This species is omitted in *Hort. Kew*. We have received it long ago from the garden of John Walker, eq. of Arno's grove, Southend.

Section 2.

**Neottia.** Lady's Trances.

Eff. Ch. Calyx spreading, embracing with its base the nectary, which has no spur. Petals spreading. Column without a border. See **Neottia**.

2. *N. repens*, creeping. 5. 289. (Satyrum repens.) Alpine woods. Per. 7.

This leaf is made a distinct genus by Mr. Brown, on ac- 
count of a pouch under the lip; and named *Goodyera*, after the venerable and accurate contributor to the second edition of Gerard's herbal. We lament that we are not sufficiently 
furnished of its difference from *Neottia*; to which it is in habit too finely allied, in our opinion, to be separated by the character above-mentioned.

Our *N. pubescens*, n. 17, is another species of Mr. Brown's *Goodyera*.

**Listera.** Tway-blade.

Eff. Ch. Calyx spreading. Nectary without a spur, not embraced by the calyx. Petals spreading. Column with- 
out a border.

A very distinct genus, separated from the *Ophrys* of Lin- 
neas, and from the *Epipactis* of Swartz and his followers. (See *Epipactis*, n. 10 and 11.) This genus is named in memory of Dr. Martin Lith, the celebrated conchologist, 

whom papers in the Philosophical Transactions, relating to the 
vascular sytem of plants, and the seeds of mushrooms, 
entitle him to botanical commemoration.

Section 3.

**Epipactis.** Helleborine.

1. *E. latifolia*, broad-leaved. 4. 269. (Serapias lati- 
folia.) Mountainous woods. Per. 7, 8.

2. *E. palustris*, marsh. 4. 270. (Scrap. palustris.) Boggy meadows. Per. 7, 8.

5. *E. rubra*, purple. 7. 437. (Scrap. rubra.) Moun- 
tain woods, rare. Per. 5.

**Malaxis.** Tender Tway-blade.

It seems hell not to make the reverted position of the 
flower, an essential part of the generic character.

**Coralorrhiza.** Coral-root.

1. *C. innata*, spur-less. 22. 1547. (Ophrys coral.)(Boggy woods. Per. 7.

Spur of the nectary short, combined with the germen.

Root very much branched.

This interesting and rare little plant has hitherto been 
found in Scotland only, of the British dominions. Roots 
sent in moss from Edinburgh, by Mr. E. J. Maughan, 
bloomed in our garden. These are of a flethy substance, 
much branched and ddivaricated, spreading horizontally; 
they exhale, after having been seven years dried, a very 
sweet smell, like Vanilla. The slender *fles*, a spn high, 
is inveted with a few *flutes*, but defiute of *leaves*, and 
bears a loose spike of a few small yellowish *flowers*. 
Mr. Brown, who has finally established this genus, detected 
the minute and concealed spur. We have a number of exotic 
Species, especially from the East Indies, which seem to 
belong to *Coralorrhiza*. Their flethy tuberous roots, and 
leaves and flowers are peculiar; and, like other Species 
from North America, some of these plants have an evident 
spur, others an obfolute or concealed one.

Ord. 2. *Dianthrea*.

**Cypripedium.** Ladies'-flipper.

Stem leafy. Appendage of the column elliptical, ob-
tufe, channelled. Petals flat.

The figure in Eng. Bot. unfortunately represents the 
appendage as if angular and acute; insomuch that it has 
been supposed to have been drawn from an American 
Species, known by that character; but this supposition 
is refuted by a comparison of the plants. (See *Cypripedi-
um*.) The *calyx*, as we deem it, of this genus is con- 
sidered by authors as composed of three leaves, like all the 
rest of the *Orchidæ*; though the two lowest are, for the 
mof part, nearly united into one.

Ord. 3. **Hexandria**.

**Aristolochia.** Birthwort.

1. *A. Clematis*, common. 6. 398. Thickets and rubi-

Vol. XXVIII.

Sheaths not half the length of the flower-flake. Female spikes three, diffusent, erect, lax and flender. Fruit ovate, triangular, bluntly cloven, twice the length of the obtuse scale.

Wilckes, in Sp. Pl. v. 4. 276, gives a citation of Schkuhr's Carices, fig. 198, and adds that this is Hoppe's C. alpina. It has however nothing to do with alpina of Wahlenberg; see Carec, n. 97.

Sheaths extremely short. Female spikes nearly linear, pendulous; their scales loosely imbricated. Fruit ovobate, with three blunt angles and depressed sides. Root creeping.

Wahlenberg makes this a variety of limosa, n. 30, with which it agrees in the creeping roots, short spikes, and drooping female spikes; but differs in its ovobate, triangular, (not broad and compressed), fruit; much smaller size; and lax blacker scales.

Eff. Ch. Capsules without a ring, globose, even, sessile on a compound flattened flake.

Front pinnate, flowering from its base; leaflets crescent-shaped, crenate.

A spah high, smooth, pale green, simply pinnate, with about six pair of leaflets, and one branched spike.

Osmunda. Osmund-royal.

1. O. regalis, common. 3. 209. Shady bogs. Per. 6. 7.

Lycopodium. Club-moss.

Six species. Healthy mountainous places. Per. 6—8.

Polyodium. Polygamy.

Four species. Walls or dry hills. Per. 5—10.

Aspidium. Shield-fern.

Twelve species. Rocks, heaths, bogs, or shady places. Per. 5—7.

This genus differs from Polypodium, only in having a membranous involucrem to the dots of fructification. See Polypodium.

Asplenium. Spleenwort.

Eight species. Rocks or walls. Per. 3—10.

Scolopendrium. Hart's-tongue.

Blechnum. Blechnum.

Pteris. Brake.

Adiantum. Maiden-hair.

Cysthe. Cup-fern.

Three species. Rocks or walls. Per. 6. 7.

Woodavia. Brittle-fern.

Brown Tr. of Linn. Soc. v. II. 170. t. 11.

Trichomanes. Hair-fern.

1. T. brevifolium, short-britted. 20. 1417. (Hymenophyllum alatum.) Wet rocks in Yorkshire and Ireland, rare. Per. 5. 6.

Hymenophyllum. Filmy-fern.

1. H. Tunbridgeae, Tunbridge. 3. 162. Moill rocks-Per. 5. 6.

Pilularia. Pillwort.

ISOETES.

Ord. 2. Musci.

Buxbaumia. Buxbaumia.

Phasum. Earth-mosses.

Gymnostomum. Beardlefs mosses.

Twenty species. Banks, rocks, and mountains. Ann. or per. 3—8.

Splechnum. Gland-mosses.

Thirteen species. Mountains or bogs, on dung. Ann. 5, 6.

Andrea. Andrea.

Fl. Brit. 1178. Hooker Tr. of Linn. Soc. v. 10. 381.

See Andrea, John.

Eff. Ch. Capule oblong, of four valves, whose points adhere to the lid. Fringe none.

Leaves lanceolate, keeled, fickle-shaped, leaning one way, without a rib.

2. A. Rothi, black mountain. 31. 2162. Dry rocks. Per. 6.

Leaves lanceolate, keeled, fickle-shaped, with a mid-rib, leaning one way. Sheath-scales without a rib.

Leaves ovate-oblong, concave, ribleafs, imbricated every way.

Leaves loosely imbricated, lanceolate, curved towards one side, single-ribbed, as well as the sheath-scales.

This last is three inches, or more, in height, being much taller, and more branched, than any of the rest. The character of the genus was totally mistaken by Hedwig and others, the valves of the capule being supposed the fringe, till Mr. W. J. Hooker corrected the character, as above. See Fringe of Mosses.

Tetraphis. Four-toothed-mosses.

Capule cylindrical. Leaves ovate, acute, single-ribbed.

2. T. ovata, dully. 22. 1422. (Grimmia Browniana.) Sand rocks. Ann. 3.

Capule ovate. Radical leaves flat-shaped, obtuse, ribleafs.

Great diversity of opinion has existed respecting the genus of this moss, referred to Orthotrichum in Fl. Brit. 1269, and incorrectly drawn, as to the fringe, in Engl. Bot. A German botanist, named Funk, has shewn that part to con-
PLANTS.

Fontinalis. Water-moss.
Three species. Running waters. Per. 7, 8.

Funaria. Cord-moss.

Bartramia. Bartramia.
The original Bartramia being referred to Triumphus, this genus of mosses has been dedicated to the memory of Mr. John Bartram, the venerable correspondent of Linneus, Collins, Fothergill and other naturalists, who during his travels in North America, contributed greatly to enrich the gardens and museums of Europe. See the end of the article Bryum. We here subjoin a more ample list of British species.

Fruit-flalks erect, taller than the fronds. Leaves lanceolate, finely ferrated, imbricated in five rows. Branches clumped, slender, upright.

Mnium. Spring-mosses.

Bryum. Thread-mosses.
A full account of the thirty-three species of Fl. Brit. is given by our excellent predecessor, the Rev. Mr. Wood; see Bryum. From these we have only to remove the indicana, n. 23, which Mr. F. Eagle has discovered to be no other than Dierama virium, E. B. 21. 1462. — B. cylin- dricam, n. 6, is longicollum, Swartz Mufc. Suec. 49. t. 6. f. 13. Weberia longicolla of Hedwig. — B. margina- tum, n. 25, is ferratum, Schrad. Spicil. 71. Two species are to be added.
B. triquetrum, long flalked. 34. 2394. Bogs, Ireland. Per. 7.

Stem subdivided. Branches simple, erect. Leaves spreading in three rows, ovato-lanceolate, sharp-pointed, finely ferrated. Capuffe slender, pear-shaped, oblique and incurved. Lid conical. The fruit-flalks exceed all other British mosses in length, extending to three or four inches.

"Stem nearly simple. Leaves ovate, obtuse, concave, converging. Capuffe obovate, oblique. Lid boided." This is one of the very few mosses of which speciments have not yet been procured for delineation in Engl. Bot.

Polytrichium. Hair-mosses.
Sixteen species. Heaths and mountains. Per. or ann. 5—8. See Polytrichium hereafter.

Ord. 3. Hepaticae.
Jungermannia. Jungermannia.
Above seventy species, now illustrating by Mr. W. J. Hooker, in an elegant and learned monograph. Sixty-eight are figured in Engl. Bot.

Blasia. Blasia.

Targionia. Targionia.

Spicilogenus. Bladder-grain.

Marchantia. Marchantia.
Five species. Shady places, or rocks. Per. Various seactions.

Riccia. Riccia.
Four species. Sandy heaths, or in ponds. Ann. 8—12. R. fruticulosa is a Jungermannia, probably not distinct from furcata. See E. B. 35. 2514.

Anthoceros. Horn Liverwort.
2. A.
Thus at the end of the Vegetable, like the Animal, Kingdom, our knowledge vanishes amongst undistinguishable, almost imperceptible, tribes, whose confines blend with each other. The imperfection which we proudly attribute to such as we cannot understand, rather belongs to our own limited powers, or to our superficial enquiries. The accuracy and minuteness of investigation, amongst naturalists of the present day, so far transcends what was usual thirty years ago, that the cryptogamic clubs, like the insect tribes, has displayed a new world, as it were, to the curious enquirer, and has smoothed the way for succeeding observers; who in their turn need apprehend no deficiency of occupation or entertainment.

Plants, in Agriculture, vegetable productions, of which there are numerous kinds, such as herbs of various sorts, comprehending all the different grasses, leguminous vegetables, and cefules of other descriptions; trees, including those of the large or timber kind, and those of a more low or shrubby growth, whether under the name of shrubs, or under-shrubs. But properly, in an agricultural point of view, they chiefly comprehend such grasses or plants of that nature as are employed as the food of animals, and such trees or other plants as are capable of being applied to the purposes of timber, or made use of in the busy arts of husbandry. And it may be further observed with respect to plants, that most of them are hermaphrodite, containing the male and female parts in the same flower; others have flowers on the same stem, some of which are male, and others female. Some likewise produce flowers over the whole without being followed by any fruit, while others of the same sort bear fruit with flowers, in consequence of which they are distinguished into male and female plants. There are many of this sort, as the hop, hemp, and the poplar tree. The female flowers are only followed by fruit, the hermaphrodites, in respect to this, being considered among the female. Plants are capable of being succedanted from very considerable distances, which is a circumstance that the farmer should carefully keep in mind in laying the seeds of particular sorts of plants, as all the cabbage tribe, and many others.

They require nourishment and air, and can employ many animals to assist them, and keep them in a proper state of health. It is interesting, therefore, that the means of support are provided in two different ways, by the radical or root fibres of the plant taking up one part and the leaves drinking up another, the latter from the earth, and the other from the air that surrounds them. See Food of Plants, and Manure.

Moll of the plants which are the principal objects of agriculture, are either raised and increased from the seeds, or the cuttings or other sorts of root, in the fields where they are to grow, as in all the grain and grains kinds, as well as in the potato; but there are a few in which the young plants, or offsets, are made use of, being set out in somewhat the garden method, and in which great care should constantly be taken that they are good in their kinds, and perfect in their nature and difference. These are chiefly of the cabbage, madder, and other similar kinds.

Wheat plants are likewise sometimes transplanted, but the practice is by no means in any degree of a general nature.

In regard to the plants of the tree kind, which are frequently a good deal employed, they are sometimes raised and provided from the seeds in the places where they are to grow;
PLANTS.

grow; and at others reared and procured from the nursery grounds in the proper state for use in the forming of woods, plantations, and other sorts of wooded lands.

In the practice of planting, experience for a long time has sufficiently shown, that where there is any degree of natural shelter or protection in the situation, and particularly where the ground has been properly prepared for the purpose, that such plants as have been transplanted in the nursery, and which are from a foot and a half to two or three feet in height, are the most suitable to be made use of in this intention. And it is directed by Mr. Loudon and others, that in performing the busines, they should be placed from four to six feet distant from each other, being put into the foil in an irregular manner. But that in exposed situations and spots, where shelter and protection are only to be gained by putting them in in a thick or close method, or by that of planting nurseries, transplanted plants which are under a foot and a half in height should alone be had recourse to, being planted out from two feet and a half to four feet apart in such plantations. The space or distance between the plants in both these instances, must of necessity vary greatly, according to the nature of the kind, and other circumstances. Alto the borders and margins of large plantations, as well as narrow strips and patches, ought to be thicker, or more closely planted with those sorts of plants, than the insides of great extents, though in the same exposures; but on the contrary, where the ground is of a deep loamy quality, they may be put at wider distances, than where it is more thin and gravelly in its nature. Likewise in making very extensive plantations, it frequently becomes a matter of importance in setting out the plants, to place them in rows, as in this way they may be cultivated with much greater facility when they approach towards the growth of trees. For in many instances, the necessary cultivation, by such means, can be readily given with advantage by the plough and the horse-hoe; and not unfrequently different kinds of vegetables and roots may be introduced between the rows with great propriety and benefit, as those of the turnip, cabbage, onion, potato, carrot, and various other sorts.

It is contended that in all common plantations, the plants of these descriptions should be put into the ground with some degree of irregularity; but that wherever ornament is the least had in view, it should always be done in a manner, irregularly irregular; they should be grouped, or, in the more plain language of those engaged in the busines, planted out just as if they had grown up by accident from the seed; or in such a manner as is seen in natural forests, where, in some parts, perhaps two or three trees appear to spring from one root, and in others quite thin and more detached. As by this means an endless variety of composition is produced, and at the same time an equal quantity of timber afforded, as the same would have yielded, if planted out in the most regular manner in respect to the distances. In proof of the truth of which, the above writer has adduced the common mode of thinning fields of young turnip plants, that have not sprung sufficiently thick. Some of the plants of which, it is allowed, may stand at two feet, others not above two inches separate from each other; but that wherever two are close together, by being uncumbered all round, they grow more vigorously than the others; and as the bulk swells, pull each other aside; so that in a short time the whole surface of the field is covered. The same thing, it is contended, takes place in natural woods. Suppose two spaces, containing twenty square yards each, and in each space two trees; but in the one the trees to be planted three feet asunder, and the other three yards; when ten years growth has taken place, the bulk and height produced upon each of the spaces would be exactly alike in every respect.

In regard to the methods of introducing or inferring the plants, in making plantations with them, they are in some measure different. The modes either by pitting them in or flat-planting are probably the best, as being the most generally practised; they may, however, be put in by the dibble, though in a practice which can seldom be had recourse to with propriety or much success. With the pine and fir tribe of plants, the mode of planting is mostly considered as more cheap and expeditious, than that of fowing the seeds; but in raising large and extensive woods and forests, or other sorts of plantations, where most kinds of deciduous trees are required, and especially the oak and the ash, which should be the most generally grown, they ought to be produced from the seeds by fowing them in the situations where the plants are finally to remain and become trees. The feed of the oak put into the earth at the same time with a plant of the same kind five or six years old, will, it is suppos'd, over-top it in the course of seven years, and frequently sooner; besides, they are believed by some to last much longer, and ultimately to produce much better and more valuable timber. In all places where the ground is fully and properly prepared, and in which it is desirable to raise oak plants, for becoming trees, it will be found the best method to sow the seeds, as this can be done at less than a fifth of the expense of planting out the young plants, and besides, the trees will turn to advantage, either as timber or undergrowth much more expeditiously. And farther, as the oak is a particularly valuable sort of tree for its bark equally as well as for the timber, it ought to be universally raised; and were the above mode more generally attended to, there would be found a saving, even in the first place, of from three to four pounds the acre, which, to those who plant largely, would be of great consequence.

Plants, in Gardening, young living vegetables of any kind, which are raised or produced from a seed or in any other manner. Plants are of many different sorts and descriptions, as well as employed for a variety of different ues, and in a great diversity of intentions. They may, however, in the view of their garden culture, be principally considered as of the herbaceous, shrubby, and tree kinds, and as being annual, biennial, and perennial in their nature, and the time of their continuance. Every plant may be said to consist of a root, that drives down into the ground, or into some other body in some way or other, and which sends off numerous ramifications, which serve the purpose of fixing it in the earth or other situation, and at the same time to supply it with food or nourishment, or its growth, increase, and continuance. There is likewise a stalk, stem, or trunk, which rises upwards into the atmosphere, and which is composed of a bark in the outer parts, a substance which is called alburnum, more internally a woody material, and a medullary matter, that is termed sap, in the inside of the whole. From this stem or trunk are formed and sent off the different branches and twigs, which contain the leaves and flowers, and which are very different in different sorts of plants. Besides which, all plants are furnished and provided with different sorts of vessels for conveying their sap, juices, and other kinds of fluids, and endued with several different powers, motions, and properties, which serve their different habits of growth, and the ues and intentions which they are to fulfill. See Vegetable, and Vegetation.

The mode of growth and increase in plants, after they have been evolved and sprung up from seeds, or in any other
other manner, is described somewhat in this way by a late writer upon the structure and economy of plants; the root part of a plant at first advances more rapidly than the stem; as it has been found that an oak plant a foot and a half high has a root four feet in length, and that, if the principal root be in any way mutilated, the plant emits radicles in every direction; which always grow faster than if the root had remained perfect. Such radicles at first do not receive any considerable increase; but soon afterwards augment into a body almost equal to the principal root, and then protrude new radical shoots in a lateral direction. Also, that the roots are prolonged at the extreme apex or point, as will be perfectly evident, if any root be coloured with varnish or any other substance of a similar kind in different places; and it is, likewise, well known, that the radicles always shoot out in that part where the earth is the most humid, so that walls are not unfrequently thrown down or overturned by their power of penetrating towards moist places, or situations where the foil is the moistest in its nature.

But the trunk of a plant is expanded throughout its whole length, and not at the apex only, as in the case of the root; for if the tender stem of a plant, at the beginning of spring, was covered over with any other matter of the same kind, and marked in different places, the marks will, after a few months, be found to have receded in the several different parts when formed. It is found that, in the growth, in an annual plant, the expansion of the stem in length continues until the expiration of the flowers has fully taken place; at which time the fibres that constitute the flaky, begin to grow hard, and to be indurated, and ultimately in a gradual manner to become dry and firm.

But in a perennial plant the increas of the stem continues until the leaves fall, or are destroyed in the autumnal season; during which time a german or bud arises in the apex, in which the rudiment of the new stem, during winter, increases slowly until the following spring; when calling out its winter involucra, it continues the increas of the stem in the same way as the inferior part increased during the former year; for in that place where a bud is seated, a tumour extends, which is so continued with the new stem as scarcely to leave any vestige behind it.

It is remarked, that the increas of the stem in breadth does not arise from the dilatation of the ligneous or woody layers, but from the generation of new layers, which are annually deposited by the velluts of the bark. This is said to be fully explained and illustrated by the following experiments. If the ring of the bark be torn from the trunk of a tree, and the ligneous cylinder of the naked part be perfectly surronded with a leaf of tin, and the whole (after having replaced the cut-out ring of the bark) be covered with the tree platter; then, upon cutting the tree some years after, it will appear that the ligneous cylinder, covered with tin, has received no increas, and that the tin, inserted between the ligneous cylinder and the new ligneous irrata, is complete. These ligneous irrata appear to be generated from the cortex; for if metallic threads be inserted obliquely into the cortex, they are after some years found in the wood itself, and not in the cortex or bark of the tree or plant. 11

It is shewn by attentive observation, that the trunk of a tree receives two ligneous or woody layers in the course of the year, and that the thickness of these layers is not the same every year; for it is the greatest when the tree is of a middle age, and the warmer the summer the more slender is the bark.

It would seem, that the bark is protruded by the vital forces, or living power of the velluts, which are placed in the wood of the tree or plant.

And the generation of the branches is supposed to be from the corona, or plexus of velluts, which is situated between the wood and medulla, or pith, from whence they proceed. Each germ or bud produces a new branch, so that it may be said to give birth to a new plant, which was hitherto laid concealed in that particular bud by whose agency the branch contains every part which is essentially necessary to form a new plant, as is evident from cutting off a branch, and planting it in the ground, by which means a perfect tree or plant is produced, and soon grows up. The velluts, it is believed, principally protrude where there is the least refissent in the bark, as in the axilla of the leaves, the nodes, and the joints; the same is noticed in respect to the branches of the root, and explains the reason, why the propagation of plants does not succeed by the slip or branch, unless a node, joint, or germ remain in them. Also why, if a branch of a tree or plant, that is yet adhering to it, be plaited or covered round with earth or moil dung, there proceeds from it a root into these substances. And why the ancients falsely attributed the generation or production of boughs to the medulla or pith of the tree; as in trees which are delitute of this substance, it is seen that no branches are produced or brought forth.

Further, the generation or production of leaves in plants originates from the velluts of the bark only; for, the bark being separated from the wood, no connection of the leaves with the wood can be observed; and the bark alone, if put into water, produces leaves.

Lastly, in the generation or production of the flowers of plants, the exterior bark, or epidermis, would seem to proceed into the cups, the alburnum into the corolla, and the series of velluts into the other parts of them.

Plants are likewise found to be of very different kinds and qualities, in respect to their powers of bearing fruit, or of becoming prolific, as well as that of their differing in many other particulars, as in their natures, modes of growth, and various other points of conferuence.

Many of them have the male and female parts in the same individual flower, whence they are commonly denominated hermaphrodite plants; and there are others, which have the male and female flowers in a state of inermination on the same stem or branch, as is the case with the cucumber and melon, as well as some other kinds of plants. Some have also the flowers all over them without any fruit being produced, while others of the same kind, at the same time, have flowers, and produce fruit, which afford the distinction of male and female plants. But as those of the female fort only produce fruit, those of the first mentioned kind are constantly confidered to be of this nature.

A perfect knowledge of these circumstances is of great advantage in the business of practical gardening, as it can be applied to many useful purposes in providing fruit, as well as good feeds of different kinds.

Much of the labour and attention of the horticulturist is likewise employed in the raising and providing plants of the herbaceous kind, which are extremely numerous, and not a few of them of considerable importance, in the view of food, requiring to be cultivated and produced in a regular and conpliant manner. They differ greatly, however, in their natures and qualities, as well as in their management and means of production. There are some, which have but little stem, being chiefly of a leafy description; others, in which the same part is far more considerable, but of a flithy, tender nature; and still others in which the stalks are tough, hard, and of rather a ligneous quality,
PLA

Whenever herbaceous plants of any of these kinds are to be raised, it is almost constantly done from the young plants, after they have had some little growth from the seeds, and are in a perfect condition in every respect. This method is pursued in all the different kinds of cabbages, cauliflowers, broccolis, and lettuces, as well as with endive, celery, and many others. But there are some which are raised from seeds without being transplanted in the above manner, and a few from offsets or slips, and by dividing the roots of other plants.

In the shrubby and tree kinds, the plants are most frequently increased from seeds, cuttings, layers, and slips.

All plants propagated, by means of their living principles, the proper and necessary degrees of heat, by which they vegetate, increase, and are enabled to refine the abundant cold or heat, which may at any time surround them; but they differ very materially in this respect, some having a much greater power of doing it than others. There are some which have also a remarkable capability of refining cold in their roots; and others, which are equally remarkable in refining heat. The kidney bean is an example of the former kind, and that of the cucumber of the latter: for if a green leaf of the former vegetable be introduced into the frozen juice of spinach, it quickly becomes thawed; and if a vessel full of water be exposed in a bed of cucumbers, the water speedily becomes warm, but the cucumbers remain cold to the touch; and if one be eaten the stomach is found to be cooled, as if it had been taken ice. And the same thing has been found in respect to fruits, while growing upon the trees. The flake of heat in plants would otherwise seem to proceed from the matter of heat, which is taken from the surrounding air; and hence it is, that the shades of all sorts of trees are so cool in their nature.

Plants, Fossil. Many species of tender and herbaceous plants are found at this day, in great abundance, buried at considerable depths in the earth, and converted, as it were, into the nature of the matter they lie among; fossil wood is often found very little altered, and often impregnated with substances of almost all the different fossil kinds, and lodged in all the shallow strata, sometimes firmly imbedded in hard matter, sometimes loose: but this is by no means the case with the tenderer and more delicate subjects of the vegetable world. These are usually imbedded either in a blackish flat substance, found lying over the strata of coal, or else in loose nodules of ferruginous matter of a pebble-like form, and they are always altered into the nature of the substance they lie among: what we meet with of these are principally of the fern kind: and what is very singular, though a very certain truth is, that these are principally the ferns of American growth, not those of our own climate. The most frequent fossil plants are the polyopody, fปลีน์วิร์ท, of mound, trihomaes, and the several larger and smaller ferns; but beside these there are also found pieces of the equisetums, or horse-tails, and joints of the fossil-plants, as the clivers, madder, and the like; and these have been too often mistaken for flowers; sometimes there are also found complete grusses, or parts of them, as also reeds and other watery plants; sometimes the ears of corn, and not unfrequently the twigs or bark, and impressions of the bark, and fruit of the pine or fir kind, which have been, from their fealy appearance, mistaken for the skins of fishes; and sometimes, but that very rarely, we meet with mosses and sea-plants.

Many of the ferns not unfrequently found, are of very singular kinds, and some species yet unknown to us; and the leaves of some appear yet at regular distances, with round protuberances and cavities. The flones which contain these plants split readily, and are often found to contain, on one side, the impression of the plant; and on the other the prominent plant itself: and, beside all that have been mentioned, there have been frequently witnessed to be found with us ears of common wheat, and of the maize or Indian corn; the first being in reality no other than the common endmost branches of the first, and the other the thicker branches of various species of that and of the pine kind, with their leaves fallen off; such branches in such a flake cannot but afford many irregular tubercles and papillae, and, in some species, such as are more regularly disposed.

These are the kinds more obvious in England; and these are either imbedded in the flaky flone which constitute whole strata, or in flattened nodules, usually of about three inches broad, which readily split into two pieces on being struck.

They are most common in Kent, on coal-pits, near Newcastle, and the forest of Dean, in Gloucestershire; but are more or less found about almost all our coal-pits, and many of our iron-mines.

Though these seem the only species of plants found with us, yet in Germany there are many others, and these found in different strata. A whitish flone, a little harder than chalk, frequently contains them; they are found also often in a grey flaky flone, of a firmer texture, not unfrequently in a blackish one, and at times in many others; nor are the bodies themselves less various than the matter in which they are contained; the leaves of trees are found in great abundance, among which thofe of the willow, poplar, whitehorn, and pear-trees, are the most common; small branches of box, leaves of the olive-tree, and flakes of garden thyme, are also found there; and sometimes ears of the various species of corn, and the larger as well as the smaller mosses in great abundance.

These seem the tender vegetables, or herbaceous plants, certainly found thus imbedded in hard flone, and buried at great depths in the earth: others of many kinds there are also named by authors; but as in bodies so imperfect, errors are easily fallen into, these seem all that can be aertained beyond mere conjecture. Hill’s Hist of Fossils. See Petrifaction.

Plants, Marine. See Sea-Plants.

Planum, Os, in Anatomy, the smooth orbital plate of the ethmoid bone. See Chiasmum.

Plappert, in Commerce, a money of account in Switzerland; 15 plappert, or skillings, being = 12 grochen, or gros = 10 Swiss batzes = 9 good batzes = 1 livre, and containing 36 cretuzers = 90 rappen = 180 pennings.

Plaquet, in Ancient Armour, a plate which was occasionally added to the breast-plate, in order to strengthen it.

Plas, in Biography, two brothers, born in Spain, celebrated performers on the hautbois, who, like the two Bezozzis of Turin, always lived, practiced, and performed together, as one and the same being. They left Madrid in 1752, and arrived at Paris the same year, where their performance excited equal wonder and extacy. Their tone, expression, taste, and execution, were as exactly similar as double flaps on the same instrument.

In 1761 they went into Germany, and were engaged in the chapel of the duke of Wirtzberg, and in his household as chamber musicians.

Plaschken, in Geography, a town of Prussian Lithuanis; 9 miles N.W. of Tilit.

Plasemburg, a town of Transylvania, near Hermantadt.

Plasencia, or Placencia, a town of Spain, in the province of Guipucosa; 20 miles N. of Vitoria.

Plasencia,
PLASENCIA, a town of Spain, in the province of Estremadura, situated in the middle of mountains, in a narrow valley, tolerably fertile, nine leagues long, and watered by the river Xere. The town stands on the banks of this river, and is partly surrounded by it, as if in a peninsula. Its situation is also embellished by an agreeable promenade. Plasencia is a suffranguen of San Jago, and its diocese comprehends a cathedral, chapter, and 152 parishes. This town is the chief place of a corregidore, and contains seven parishes, churches, three convents of monks, and several chapels or oratories. Here is a fine aqueduct, which conveys water from the distance of two leagues, and has upwards of 80 arches; 95 miles W.S.W. of Madrid. N. lat. 40° 3'. W. long. 5° 9'.

PLASH, in Rural Economy, the bough or item which is laid down by means of a nick or cut being made on the upper side of it, in repairing or refolring old hedge-fences. PLASHER, a person of the labouring kind, whose business is the making or repairing of hedge-fences by means of plashing.

PLASHING of hedges, the operation or processes by which this sort of work is performed in refolring old run up open hedges. The usual mode of executing it is as follows: the stronger items are selected, at as regular distances as possible, and generally at about thirty inches apart. These are called the flakes; and are commonly headed over at four or five feet above the surface, according to the general strength of the hedge in question, so as they may all range in line, and at one height. The more pliable branches and small twigs are interwoven, in the basket manner, among the flakes, from top to bottom, as closely as possible. Such as will not bend in a pliable manner, and afterwards remain in due position, are fraged half through with the bill, to make them more obedient. The strong items that cannot be hid in, and are not wanted for flakes, are cut close by the surface. In places where items strong enough, and fit for flakes, are wanting, the deficiency is supplied by dead flakes. After the plashing is finished, the hedge is drest smooth on both sides with the bill, or some other similar instrument. This is a method that is much practised in Hertfordshire and some other counties. See FENCE.

The principal objection to this mode, which is certainly the cheapest and most easily performed, is, that the flakes, or cut-over items, shoot forth strongly to the detriment of the under part of the hedge, which, by over-shadowing, they retard in growth, and keep naked of sprate; and which probably suggested an improvement, which is that of cutting none over at all, but weaving in the tops of the flakes along with the plashes. The propriety of this mode is at once evident; for, besides that the above complaint cannot possibly attach, the items cut by the surface tend up a strong growth, which, intermixing with the plashes, renders the whole more close and impenetrable than would otherwise be the case.

In cafes where two rows of quicks have been planted, according to the common method, at the distance of a foot from each other, the back row being planted in some of the above modes, and the front one being cut down to the flub, the latter would be the most effectual method of preserving the prudent, and producing a new fence. It is, however, conceived, that this operation can only be effectually and handsomely performed in cafes where there is a good portion of sprate and long pliable flakes or branches; and when the edge has, if not youth, at least vigour on its side, to lend forth a luxuriant growth, and cover the naked appearance the plashes would otherwise have. And that for the more handsome performance of this business, there is also a season more suitable than another, which is the fall, or beginning of winter, as at this season the shoots are more pliable than in spring, when the sap begins to rise and circulate; at which time the shoots of all plants are most brittle. After the hedge is plashed, the ditch, provided there be one, should be scoured out, and drest up; and that where the fence is properly attended to, in regard to pruning and cutting, it may last for many years.

The manner of executing this sort of work in the Hertfordshire mode has been fully explained in speaking of the nature of refolring fences. This sort of practice is sometimes necessary to be had recourse to in gardens where the outward fences have been suffered to run up in rude growth, naked and open at the bottom; they being refomed and reduced to order by proper trimming, thinning, cutting, and laying down the general items and branches in a planting manner lengthways, according to the ranges of the hedges, being interwoven between other items which are left upright; the work being performed by suitably nicking, cutting, or gaffing the different parts on their upper sides; and the whole of the smaller lateral branches being plashed in so as to close all the lower vacancies, and thicken every part regularly from the bottom to the top, to the height of from three to four feet, or a little more, according to circumstances.

This process is occasionally performed to any kind of decious common hedges, such as those of white-thorn, blackthorn, elm, poplar, beech, or other sorts; and in proceeding in the work, it is frequently necessary, especially in very disorderly rough edges, previously to trim or lop off much of the outward and over-growing rude branches of them, as well as the large naked wood and obviously superabundant growths, both above and below; carefully bringing down such branches or other parts as are left in an exact and regular manner, plash after plash, until the whole business is finished.

PLASM, PLASMA, is sometimes used for a mould, wherein any metal, or fuch like running matter, which will afterwards harden, is cast to receive its figure.

PLASO, in Botany, Rhede Hort. Mal. v. 6. 29. t. 16. 17. is a very noble papilionaceous and leguminous shrub, or tree, referred by Lamarck to Erythrina, with the specific name of monofermis. Julicius, Gen. 357, mentions it under that genus, with a hint, extremely well founded, of its probably constituting a new one. Of this the celebrated Danish botanist, Koenig, who gathered in India two species of the genus in question, was aware. He named it Butea, after that distinguished lover of botany, the first earl of Bute; either not knowing, or not recollecting, that another genus was called Stauria by Linneus, in honour of this nobleman, and was universally received under that denomination. Dr. Roxburgh has however published the Butea, and it is adopted by Willdenow, Sp. Pl. v. 3. 291, as well as in Ait. Hort. Kew. v. 4. 252, and by the late Rev. Mr. Wood, in our 5th vol. See BUTEA.

The name is altogether inadmissible on the ground above mentioned, one genus being abundantly sufficient to commemorate any one person whatever, nor has there ever been a similar example, among classical writers of the Linnean school. Butea may nevertheless remain as a memorial of the late marchionefs of Bute, who paid much attention to botany, and is mentioned as having introduced several plants from the gardens of Madrid, into those of England.

PLASS, in Geography, a town of Bohemia, in the circle of Rakonitz; 18 miles S.W. of Rakonitz.

PLASSEY, a town of Hindoostan, in Bengal, near

4 P 2
which colonel Clive defeated the troops of Surajah Dowlah in 1757; 25 miles S. of Moorshedabad.

PLASTER, or PLASTER, in Building, a composition of lime, sometimes with hair, sometimes with sand, &c. to paper or cover the nudity of a building.

There is also a platter of a coarser sort than the platter of Paris, which is sometimes used in this country for floors in gentlemen’s houses, and for corn-granaries: it is made of a blue vitre, taken out of quarries, which are generally at the side of a hill, much like the stone of which Dutch terras is made: the stone is burnt like lime, becomes white by burning, and when mixed with water, does not ferment like lime; when cold, it is beat into a fine powder; and when it is used, the quantity of about a bushel is put into a tub, and water applied to it, till it becomes liquid: in this state it is well mixed with a stick, and used immediately; for in less than a quarter of an hour it becomes hard and good for nothing; as it will not bear being mixed a second time like lime. See GYPSUM, and PLASTERING.

PLASTER, in Pharmacy, an external application of a harder consistence than our ointments: there are to be spread according to the different circumstances of the wound, place, or patient, either upon linen or leather.

If the part upon which they are to be laid be naturally hairy, it must be shaven; but that they may stick the better, the natural shape of the part must be confutated, and the plaster spread and formed accordingly, either round, square, triangular, elliptical, or in a lunar form, or in shape of the letter T. Some also are divided at both ends, and others are perforated in the middle: these last are of frequent use in fractures attended with a wound; for by this contrivance the wound may be cleansed and dressed without removing the plaster.

Indeed there is almost no part of the body which a platter of one of these forms may not be made to serve for, if it be notched about the edges with a pair of scissors. See EMPLASTRUM.

The use of plasters is various; they are serviceable in securing the dressings, they also afford the maturation of the pus, agglutinate and heal wounds, unite broken bones, heal burns, allay pain, and strengthen weak parts. In many infirmities they contain acid and stimulating substancies, and operate as rubefacients, or blisters.

The calses or oxys of lead boiled with oils, unite with them into a platter of a proper consistence, which makes the bulbs of several other plasters: but some of them owe their consistence to wax and resin; and others contain no oily or fatty matter whatever: in boiling these compositions, a quantity of hot water must be added from time to time, to prevent the plaster from burning and growing black; but this should be done with care, lest it cause the matter to explode.

Plasters should not adhere to the hand when cold; they should be easily spread when heated; and after they are spread they should remain tenacious and pliant; but they should not be so soft as to run when heated by the skin. All plasters become too confit ent or brittle when long kept; but in this case, those which are unctuous may be remelted by a gentle heat, and some oil added to them. They are usually formed into rolls, each of which is wrapped in paper, and when used, they are melted, and spread on leather, calico, linen, or silk. Those that contain metallic oxys ought to be melted by boiling water, for in a greater degree of heat the fatty matter is apt to reduce the oxide.

PLASTER. Adhesive. See EMPLASTRUM.

PLASTER, Ammoniac, is formed by dissolving 5 oz. of purified ammoniac in half a pint of acetic acid (distilled vinegar), and evaporating the solution in an iron vessel placed in a water bath; constantly stirring it till it acquire a proper consistence. This platter, which is dilatant and resolvent, is applied to eruphous humouris, and white swellings, and sometimes on the scalp, in tinea capitis.

PLASTER, Ammoniac, with Mercury. See EMPLASTRUM.

PLASTER, Anodyne. See EMPLASTRUM, and PLASTER OF OPUS, infra.

PLASTER, Aromatic, is formed, according to the directions of the Dublin pharmacopoeia, of frankincense, 3 oz.; yellow wax, 3/4 oz.; cinnamon bark in powder, 6 dr.; oil of pimento and oil of lemons, of each 2 dr. Melt the frankincense and the wax together, and strain the mixture; when it thickens by cooling, mix with it the powder of cinnamon previously rubbed with the oils, and form them into a platter. This platter is an elegant stimulant, and applied to the region of the stomach in dyspepsia, and increased irritability of that viscus, allaing pain and vomiting, and expels flatus. As the oils are very volatile, it must be spread by the thumb without being melted. It requires to be frequently renewed, and is not very adhesive. See PLASTER.

PLASTER, Atripin, consists, by the Edinb. pharm., of plaster of vitrius oxys of lead, and alafex, of each two parts, and galbanum and yellow wax, of each one part. This platter is sometimes applied over the umbilical region, in flatulence and hysteria.

PLASTER, Blistering, Emplastrum Lyttle of the Lond. pharm., is made by melting 3 lb. of wax platter with a pound of prepared lead, and after removing them from the fire, when the mixture is beginning to be solid, sprinkling in 1/2 lb. of blistering flies reduced to a very fine powder, and mixing the whole together. The emplastrum Mellea vesicatorii, olim, emplastrum vesicatorium of the Edinb. pharm., consists of mutton wax, yellow wax, resin, and blistering flies, of each equal weights. Reduce the infects to a fine powder, and mix them with the other articles, previously melted together, and removed from the fire. The emplastrum cantharidis of the Dubl. pharm., is formed by melting purified yellow wax and mutton wax, of each a pound, and 4 oz. of yellow resin together, and a little before they con crete in becoming solid, sprinkling in 1 lb. of blistering flies in fine powder, and forming the whole into a platter. (See EMPLASTRUM.) Blistering plasters should remain applied at least for twelve hours to raise a perfect blister; they are then to be removed, the vehicle is to be cut at the most adhering parts, and without removing the cuticle, the vesicated part is to be dressed with simple cerate, or spermaceti ointment; and the old cuticle allowed to remain until a new one is formed under it; when it peels off, and the whole is healed in the course of a few days. The application of these plasters is sometimes attended with strangury and bloody urines, from the abolition of the active principles of the infect, and the irritation of the kidneys and uretha; and this effect is much increased, if the blister be applied over an abraded surface, e.g. on the head after it has been immediately shaved, and also if the platter has remained too long applied. To prevent strangury, it has been recommended to mix camphor with the blistering composition, but this has no good effect: it is better obtivated by copious dilution with milk, or mucilaginous fluids, and fomentations of warm milk and water to the blistered part, after the removal of the platter. When the head is to be blistered, it should be shaved at least ten hours before the platter is applied; and in all cases it is expedient to interpose a piece of thin gauze between the vesicated and the skin, wetted with vinegar, and applied smooth and very close over the
parts. When the blistered part becomes a spreading fore, which is sometimes the case in irritate habits, the best local application is a warm emollient poultice, and basting the denuded surface frequently with tepid milk and water; while at the same time cinchona bark is internally administered. See Blister.

Plaster of Spanish flies, compound, of Edinb. pharm., is prepared of 18 parts of Venice turpentine; Burgoody pitch and blistering flies, of each 12 parts; yellow wax, 4 parts; subacetate of copper, 2 parts; white mustard seeds and black pepper, of each 1 part. Melt the Burgoody pitch and the wax, and add to them the turpentine, while the remain still warm, after being melted, sprinkle in the other ingredients reduced to fine powder, and mix them, stirring constantly, so as to form a plaster. This plaster is intended to raise a blister more quickly than the former, and is therefore adapted to cases of gout and cramps of the stomach, in which the effect of the blister must be almost instantly produced. Its operation is attended with much pain and pungent fefee of heat; and it is apt to produce very unpleasant ulceration if allowed to remain too long applied. See Plaster, Cephalic. See Emplastrum Cephalicum. See Plaster, Cumen. See Emplastrum Cymnii. This plaster is stimulant and diuretic; and is applied to the hypogastric region in flatulence and a cold feeling of the bowels, and to indolent tumours.

Plaster, Drying. See Emplastrum Attributum. Plaster of Galbanum, compound, of the Lond. pharm., is composed of powdered galbanum, 8 ounces; plaster of lead, 3 pounds; common turpentine, 10 drachms; and resin of the fyrse or powdered, 3 ounces. Having melted the galbanum and the turpentine together, mix in the refi, and then the plaster of lead previously melted by a flow fire, and mix the whole together. The plaster of galbanum of the Dub. pharm. is prepared by adding 1/6 of galbanum melted by heat, 2 lbs. of litharge plaster, and 4 oz. of yellow wax sliced; and then melting the whole together by a gentle heat. Plaster, Gum, of Edinb. ph., is composed of 8 parts of plaster of semi-vitireous oxyd of lead, and ammoniac gum-refin, galbanum, yellow wax, of each 1 part. See Emplastrum Gummi.

These plasters are stimulant and fuppurative. They are applied with advantage to fcorahulent tumours; to joints which have been long affected with arthritic pains; and to the loins in rickets. As a fuppurative, they are applied to indolent tumours, and to reduce the induration which often remains round abbeffes, after they are discharged. See Plaster, Mercurialis. (See Emplastrum communi cum Mercurio.) The Edinb. pharmace. direct to be prepared of olive oil and-refin, of each 1 part; mercury, 3 parts; plaster of semi-vitireous oxyd of lead, 6 parts; rub the mercury with the oil and the-refin, previously melted together and cooled, until the globules disappear; then add gradually the plaster of semi-vitireous oxyd of lead melted, and let the whole be carefully mixed together. These plasters are powerful diuretics, and are applied to buboes, venereal tumours, nodes when they are not very painful to the touch, and indurations; they are also applied to joints affected with oblitinate syphilitic pains.

Plaster of Opium, consists of hard opium powdered, 1 oz. ; resin of the fyrse or powdered, 2 oz. ; lead plaster, 1 lb. ; melt the plaster and the-refin together, then add the opium, and mix the whole. This plaster is said to be anodyne, and useful in relieving rheumatism and local pains. See Plaster of red oxyd of Iron of Edin. pharm., formerly strengthening plaster, is composed of plaster of semi-vitireous oxyd of lead, 24 parts ; resin, 6 parts; yellow wax and olive oil, of each 3 parts; and red oxyd of iron, 8 parts; rub the red oxyd of iron with the oil, and add the other ingredients melted.

Plaster of Frankincense of Dubl. pharm. is of the form of litharge plaster, 2 lbs; frankincense, 1/6 lb; and red oxyd of iron, 3 oz. ; to the frankincense and plaster melted together add the oxyd, ftrilling them together fo as to form a plaster. These plasters are supposing to be tondic; and are used in muscular relaxations, and weaknesses of the joints from sprains; but they act chiefly in affording a mechanical support to the parts. See Emplastrum Roborans.

Plaster, Compound, of Dubl., is composed of dried pitch, 2 lbs.; frankincense, 1 lb.; yellow resin and yellow wax, of each 4 oz.; and expressed oil of nutmeg, 1 oz. To the pitch, resin, and wax, melted together, add first the frankincense, then the oil of nutmeg, and mix the whole. This plaster is stimulant and rubefacient. It is used in catarrh, and other pulmonary affections, applied to the thorax; and in head-ache, and chronic ophthalmia, applied to the temples. When a ferox exudation takes place, the plaster should be frequently renewed. See Plaster, Head, is prepared by boiling together over a flow fire, of semi-vitireous oxyd of lead, rubbed to a very fine powder, 5 lbs.; olive oil, a gallon; water, 2 pints, ftrilling constantly until the oil and oxyd of lead cohere into the confluence of a plaster. It is necessary, however, to add a little boiling water, if the whole of that which was employed at firl shall be consumed before the end of the process. See Plaster, Litharge, of Dubl. ph., is prepared by mixing 5 lbs. of litharge in fine powder; 7 lbs. of olive oil, and 2 pints of boiling water, at a high temperature, constantly ftrilling until the oil and the litharge unite fo as to form a plaster, suppling occasionally a little water of water that may take place. These plasters are intended chiefly to defend exoriated surfaces from the action of the air, and to form the basis of some other plasters. See Plaster, Refin, is formed of yellow-refin, 3/6 lb.; and lead plaster, 3 lbs.; melt the lead plaster by a gentle heat; then add the-refin in powder and mix. See Plaster, Refinos, formerly ads-free plaster, is composed of plaster of semi-vitireous oxyd of lead, 5 parts; and-refin, 1 part. See Emplastrum Adhipsum. The plaster with Refin, Litharge, is formed by melting 3 lbs. of litharge plaster by a moderate heat, and adding 1/6 lb. of yellow-refin finely pulverized, that it may melt quickly, and form a plaster. See Emplastrum Adhipsum. These plasters are defensive, adhesive, and gently stimulant; they are used for retaining together the lips of recent wounds, when it is proposed to heal them by the first intention; to give support to ulcerated parts; and to affict their granulation and cicatrisation. See Plaster, Soap. (See Emplastrum Soaposis.) The soap plaster of the Edinb. pharm. is composed of 4 parts of semi-vitireous oxyd of lead; 2 parts of gum plaster, and 1 part of soap sliced. Mix the soap with the plasters melted together; then boil them a little fo as to form plaster. Soap plaster is diffusive, and is applied to lymphatic tumours; but it is much less useful than the mercurial plaster. See Plaster. Stomatia. See Emplastrum Stomaticum. Plaster,
PLA

Plaster, **Warm**, is made by melting together, over a gentle fire, one ounce of gum plaster, and two drachms of blistering plaster; or one part of plaster of cantharides, and seven parts of Burgundy pitch, according to the Dublin pharmacopoeia. This is useful in catarrh, hooping-cough, the sciatica, and other fixed pains of the rheumatic kind.

It ought, however, to be worn for some time, and to be renewed, at least, once a week.

Plaster, **Wax**, is formed by melting together of yellow wax and of prepared flux, of each three pounds; and yellow wax a pound; and then straining. The **simple plaster**; formerly **was plaster** of Edinburgh pharmacopoeia, is formed of yellow wax, three parts; mutton flux and rein, of each two parts. These were generally used instead of the meiolit plaster, as a proper application after blisters, and in other cases where a gentle digestion is necessary; but on account of the pain and irritation they occasion, they are now seldom employed.

Plaster of Paris, is a fossil stone, serving many purposes in building; and used likewise is sculpture, to mould and make statues, baffle relieves, and other decorations in architecture.

It is dug out of quarries, in several parts of the neighbourhood of Paris; whence its name. The finest is that of Montmartre. See Gypsum.

Plaster of Paris, among our workmen, is of two kinds, viz. crude, or in the stone, and burnt, or beaten.

The crude is the native plaster, as it comes out of the quarry; in which state it is used as tharsis in the foundations of buildings.

The burnt plaster is a preparation of the former, by calcining it like lime in a kiln or furnace, and then beating it into powder, and diluting and working it. In this state it is used as mortar, or cement, in building.

This, when well sifted, and reduced into an impalpable powder, is used also to make figures, and other works of sculpture; and is, besides, of some use in taking out spots of grease, &c. in fluffs and fikks.

The method of representing a face truly in plaster of Paris is this: the person, whole figure is designed, is laid on his back, with any convenient thing to keep off the hair. Into each nostril is conveyed a conical piece of stiff paper, open at both ends, to allow of respiration. These tubes, being anointed with oil, are supported by the hand of an attendant; then the face is lightly oiled over, and the eyes being kept shut, alabaster freshly calcined, and tempered to a thinnish consistence with water, is by spoonfuls nimbly thrown all over the face, till it lies near the thickness of an inch. This matter grows sensibly hot, and in about a quarter of an hour hardens into a kind of flaky concretion; which being gently taken off, represents, on its concave surface, the minute part of the original face. In this a head of good clay may be moulded, and therein the eyes are to be opened, and other necessary amendments made. This second face being anointed with oil, a second mould of calcined alabaster is made, confisting of two parts joined lengthways along the ridge of the nose; and herein may be call, with the same matter, a face extremely like the original.

If finely powdered alabaster, or plaster of Paris, be put into a bason over a fire, it will, when hot, assume the appearance of a fluid, by rolling in waves, yielding to the touch, teaming, &c., all which properties it again loses on the departure of the heat; and being thrown upon paper, will not at all wet it, but immediately discover itself to be as motionless as before it was set over the fire; whereby it appears, that a heap of such little bodies as are neither spherical, nor otherwise regularly shaped, nor small enough to be below the dimcement of the eye, may, without fusion, be made fluid, barely by a sufficiently strong and various agitation of the particles which compose it; and, moreover, lose its fluidity immediately upon the cessation thereof.

Two or three spoonfuls of burnt alabaster, mixed up thin with water, in a short time coagulate, at the bottom of a vessel full of water, into a hard lump, notwithstanding the water that surrounded it. Artificers observe, that the coagulating property of burnt alabaster will be very much impaired or lost, if the powder be kept too long, especially if in the open air, before it is made ufe of; and when it hath been once tempered with water, and suffered to grow hard, they cannot, by any burning or powdering of it again, make it serviceable for their purpose as before. Boyle's Works Abr. vol. i. p. 133. 313. 341.

This matter, when wrought into veffels, &c. is full of fo lose and pconomy a texture, that the air has easy paflage through it. Mr. Boyle gives an account, among his experiments with the air-pump, of his preparing a tube of this plaster, clofed at one end and open at the other, and on applying the open end to the cement, as is ufually done with the receivers, it was found utterly impossible to exhaust all the air out of it; for fresh air from without prefied in as fast as the other, or internal air, was exhausted, though the fides of the tube were of a confiderable thickness. A tube of iron was then put on the engine; fo that being filled with water, the tube of plaster of Paris was covered with it; and on uifing the pump, it was immediately seen, that the water pafled through into it as easily as the air had done, when that was the ambient fluid. After this, trying it with Venice turpentine instead of water, the thing succeeded very well; and the tube might be perfectly exhausted, and would remain in that state several hours. After this, on pouring some hot oil upon the turpentine, the cafe was much altered; for the turpentine melting with this, became a thinner fluid, and in this flate capable of pafling like water into the pores of the plaster. On taking away the tube after this, it was remarkable that the turpentine, which had pervaded and filled its pores, rendered it transparent, in the manner that water gives transparency to that indulgular stone called osculus mundi. In this manner, the weight of air, under proper management, will be capable of making several forts of glues penetrate plaster of Paris; and not only this but baked earth, wood, and all other bodies porous enough to admit water on this occasion. Phil. Trans. N° 122.

Plaster of Paris, diluted with water into the consistence of a loft or thin paste, quickly sets or grows firm, and at the inflant of its letting, has its bulk increafed; for Mr. Boyle has found, that a glafs vefsel, filled with the fluid mixture, and clofly stopped, bursts while the mixture sets, and fometimes a quantity of water fflies through the cracks.

This expansion of the plaster, in pafling from a loft to a firm flate, is one of its valuable properties; rendering it an excellent matter for filling cavities in fundry works, where other earthy mixtures would shrink and leave vacuities, or entirely separate from the adjoining parts.

It is probable also, that this expansion of the plaster might be made to contribute not a little to the elegance of the impreffions which it receives from medals, &c. by properly confining the loft matter, that its expansion may force it into the minutefll traces of the figure; the expansion of the matter doing the fame office as the preflure by which the wax is forced into the cavities of a fculptor.

Plafler
Plaster of Paris promotes the fusion of forged iron.

This substance is commonly used for taking casts and impressions from figures, buildings, medals, &c. as it is adapted to the double use of making both casts and moulds for forming them. See Impressions of Medals.

Plaster of Paris, in Agriculture, a substance of the calcareous kind, in combination with the vitriolic acid, which has been sometimes made use of as a manure. See Gypsum and Sulphate of Lime.

Plaster, in Gunnery, a piece of greased leather or rag, used by riflemen, &c. to make the ball fit the bore of the piece.

Plaster Floors, in Rural Economy, such floors as are constituted of plaster, prepared from such lime as possesses a strong binding property. They are highly useful in cottages and farm-houses, as affording much security against fire. In constructing them, it is observed, in the first volume of Communications to the Board, that the joists are laid in the usual manner; after which a coat of strong reed, which is found in Huntingdonshire, is nailed on, upon which the plaster is applied; but in order to face it, there is frequently a thin coat of common lime laid on first, to fill up the crevices and inequalities. On this the plaster is then spread out, to the thickness of about two inches, being laid on with as much expedition as possible. The plaster is then, at the kilns in the midland districts, at 6d. the bushel; and the expense of laying it on, if burnt and prepared, is 5d. the square yard; but if to be burnt and prepared by the workmen, about as much more. The floors are laid to be excellent and cheap. Where reeds cannot be procured, laths may be made use of, but they come much higher. Floors of this sort are much in use in Nottinghamshire, as well as in Rutlandshire, at the earl of Winchelsea's, where the upper floors of his farm-houses are made of it.

These kinds of floors should be more attended to, in constructing small houses both of the cottage and other kinds, as being cheap, readily laid, and at the same time secure.

Plastering, in Architecture, is that operation which consists in laying on coats of mortar, variously prepared, on the ceilings and walls, &c. of different buildings. This belongs to a class of artificers called plasterers. See Plaster.

Plasterers' work is of two kinds: namely, ceiling, which is plastering upon laths; and rendering, which is plastering upon walls. These are measured separately. The contents are eliminated either by the foot, or yard, or square of 100 feet. Instructed mouldings, &c. are rated by running or linear measure. Deductions are to be made for chimneys, doors, windows, &c. But the windows are seldom deducted, as the plastered returns at the top and sides are allowed to compensate for the window opening.

It was much to be wished that this art of plastering could be again brought to its ancient perfection. In our best buildings the plastered walls and ceilings crack and fly, and in a little time grow damp, or mould to decay.

The Romans had an art of rendering their works of this kind much more firm and durable, and there is no reason to depair of reviving this art by proper trials.

The ancient plastering of these people preferred to this time, where it has not met with violent blows or injuries from accidents, is still found as firm and solid, as free from cracks or crevices, and as smooth and polished on the surface, as if made of marble. The bottoms and sides of the Roman aqueducts were made of this plastering, and endured many ages without hurt, unless by accidents; witness that whereof some yards are still to be found on the top of the Pont de Gard, near Nîmes, for the support of which that famous bridge was built to carry water to the foid town. The roofs of houses, and the floors of rooms, at Venice are covered with a coat of plaster, made of later date, and yet strong enough to endure the sun and weather for several ages, without cracking or spoiling, and without much injury from people's feet.

The secret of preparing this Venetian plaster is not among us, but it would be worth while to try whether such a substance might not be made by boiling the powder of gypsium dry over the fire, for it will boil in the manner of water; and when this boiling or recalcining was over, the mixing with it reinf, or pitch, or both together, with common fulphur, and the powder of sea-shells. If these were all mixed together, and the water added to it hot, and the matter all kept hot upon the fire till the inftant of its being used, so that it might be laid on hot, it is possible this secret might be hit upon.

Wax and oil of turpentine may be also tried as additions; these being the common ingredients in such cements as we have accounts of as the firmest. Strong ale-woot is by some directed to be used, instead of water, to make mortar of lime; of a more than ordinary strength. It is possible, that the use of this tenacious liquor to the powdered ingredients of this proposed plaster, might greatly add to their solidity and firmness. Phil. Trans. No. 93. See Stucco.

Plastic, Plastic, from plastic, of plasto, or plastis, fasum, fuction, form, &c. imports as much as formative, or a thing endued with a faculty of forming or fashioning a mass of matter after the likeness of a living being.

Some of the ancient Epicureans, and perhaps the Peripatetics too, imagine a plastic virtue to reside in the earth, or at least to have anciently resided therein; and that it was by means of this, and without any extraordinary intervention of a Creator, that it first put forth plants, &c. Nay, some of them, whether serioiusly or not we do not undertake to determine, taught that animals, and even man, were the effects of this plastic power.

Some learned modern writers have strenuously contended for the doctrine of a plastic nature, which they have described to be an incorporeal created fulblance, endowed with a vegetative life, but not with sensation or thought, penetrating the whole created universe, being co-extended with it, and, under God, moving matter so as to produce the phenomena, which cannot be solved by mechanical laws; active for ends unknown to itself, not being conscious of its own actions, and yet having an obscure idea of the action to be entered upon. Dr. Gudworth reasons thus: since neither all things are produced fortuitously, or by the unguided mechanism of matter, nor God himself may reasonably be thought to do all things immediately and miraculously, it may well be concluded, that there is a plastic nature under him, which, as an inferior and subordinate instrument, doth drudgingly execute that part of his providence, which confines in the regular motion of matter; yet so as that there is also, besides this, a higher providence to be acknowledged, which, presiding over it, doth often supply the defects of it, and sometimes over-rule it: for as much as this plastic nature cannot act electively, nor with discrimination. This doctrine, he says, hath had the suffrage of the best philosophers of all ages. Aristotle, Plato, Empedocles, Heraclitus, Hippocrates, Zeno, and the Stoics, and the latter Platonists and Peripatetics, as well as the chemists and Paracelsians, maintained this doctrine.

"If an unintelligent agent," says Dr. Price, "can act with such uniformity, and yet so variously, as to produce the order of the world, and govern its motions; if, for instance, it can..."
can frame the bodies of plants and animals, or so direct its own action as to impel the particles of matter towards one another, in such different directions, and with such different forces in different situations, as to be the constant cause of those laws and powers which obtain in the corporeal universe, and on which depend its form and being; if, I say, this is possible, there is an end of all our reasonings about causes and effects, and of all arguments for the design and intelligence in the author of nature, taken from its regularity and beauty. It avail nothing to say, that this agent acts in subordination to the deity, and only in virtue of powers given it by him. For it is not supposed to be merely an instrument in the hands of the deity, which never acts except in consequence of being first acted upon; but what it does, is supposed to do properly by a power inherent in itself, without wanting any immediate direction from the deity; and the very reasons that have been assigned for supposing such an agent, are, that it is absurd to think that the deity should be continually employed so much in vain, as is necessary to be supposed, if the general laws of the world are derived from his agency; and that it is dishonouring him to conceive of him as acting himself continually on matters, and immediately concerned in framing the bodies of the meanest plants and insects. To as little purpose is it to say, that omnipotence can give such a power to an unintelligent agent: for what has not wisdom, cannot act wisely; and no power can make that to be, which cannot be. If the deity does not do this in any knowledge or design to produce regular effects; then it is in the nature of things possible for such a cause to produce such effects; then design in the cause is not necessary to the greatest conceivable order and regularity in the effect, nor can we certainly infer the one from the other: then, in short, any thing may produce any thing, and no conclusion with respect to the cause can be drawn, in any case, from what we see in the effect. The effects of habits have been very improperly alleged, as affording inferences of regular action, without knowledge of design. For, what is done by habits, is, I think, always done in consequence of some volition or direction of the mind; and our not being conscious of it is in reality no more than not remembering it, the whole effect of a habit on the executive powers consisting in their more easy and ready compliance with the dictates of the mind. But not to insist on this; let it be granted that regular actions are frequently performed in consequence of habits, without thought or design: this, if true, must be owing to certain powers and laws of the animal economy, which must be accounted for in the same manner with other powers and laws which obtain in nature, and cannot be made an argument for such a blind platic force as has been contended for, without begging the question. See the truly great and learned Dr. Cudworth's Intellectual System, hook i. ch. 3, where the opinion on which I have made these remarks is particularly explained and defended. See also an account of a controversy which it occasioned between Mr. Bayle and Le Clerc, in the account of the life and writings of Dr. Cudworth, prefixed to the second edition of the Intellectual System by Dr. Birch. Dr. Henry More and Dr. Grew have likewise maintained this opinion. 19 Intell. System, vol. i. p. 147, &c. Birch's ed. More's Imm. of the Soul, lb. in. cap. 12. Price's Diff.

PLASTICE, PLASTICE, the platic art, a branch of sculpture; being the art of forming figures of men, birds, beasts, fishes, plants, &c. in plaster, clay, fluceo, or the like. The workmen concerned in this art are also called plumas, plumas.

Plasticce differs from carving, because here the figures are made by addition of something that is wanting; but in carving, always by subtraction of what is superfluous. The platic art is now chiefly used, among us, in fretwork ceilings; but the Italians apply it also to the mantlings of chimneys with great figures.

PLASTRON, in Ancient Military Armour, a breastplate of forged iron occasionally put on, under or between the hauberks and gambeson.

Plastron is also a piece of leather fluided, used by fencing-masters, on which to receive the pushes made at them by their pupils.

PLASWIG, in Geography, a town of Prussia, in the province of Ermland; 28 miles N.W. of Heilberg.

PLAT, a popular term, among Mariners, &c. for a fea-chart.

Plat, in Rural Economy, a term provincially applied to the mould-board of a plough.

Plat-Veins, in the Manage, called in French ars, are the veins in which we bleed horses, one in the lower part of each shoulder, when we bleed a horse in the shoulders; and in the flat part of the thigh.

Plats, in a Ship, flat ropes made of rope-yarn, and twined into faxes; they serve to fave the cable from galling in the hawse, or to wind about the flukes of the anchors, to fave the pennant of the fore-sheet from galling against them.

PlATA, PLATE, in Commerce, a Spanish term, signifying silver; as vellon, which they pronounce vellion, signifies copper. These two terms are not only used to express the species of those metals struck in Spain, but also to distinguish between their several monies of account. Plate is reduced to vellon by faying, as 17 is to 32, fo is the given plate to the vellon fought; and vice verfa. See Exchange; see also Maravedi and Real.

Plata, La, or Buenos Ayres, in Geography, a vice-royalty belonging to the Spanish dominions in South America, erected in 1778 (not in 1776, as stated under the article Buenos Ayres, from authorities to which we had then access), is one of the most important divisions, and that by which the chief opulence of the Spanish dominion in this part of the world passes to the parent country, and is interwoven with the commerce and interests of Europe. Including the savage Chiquitos and Molos in the north, and extending to the southern limits of Tuyu and the wide plains called the Pampas, its length from the chain of Villanota to the vicinity of the river Negro, may be asumed from 14 S. lat. to near 38°, that is 24°, or 1440 geographical miles. Eflalla states the boundary between La Plata and Peru to be now the cordilleras of Villanota, dividing the province of Carabaya in La Plata from that of Canes and Canches in Peru.

The breadth of La Plata, which is generally pretty equal, may be computed at 12°, or 720 geographical miles. Esflalla, cited by Pinkerton, computes the extent at 1000 Spanish or rather American leagues (meaning vaguely to include Chili), and the greatest breadth at 350, forming a triangle of 1000 leagues in height, on a base of 350, equal to 75,000 square leagues; which, as he adds, might support 50,000,000 persons, while in fact there is scarcely one million of civilized inhabitants, and some few barbarous nations. Before the establishment of this vice-royalty, the greatest part of the jurisdiction belonged to that of Peru; although the three provinces of Buenos Ayres, Paraguay, and Tucuman, were considered as "Capitanías Generales," that is, the governors had an authority independent of the viceroys of Peru, except in cases of great importance and difficulty. The
PLATA.

The part of Peru now annexed to La Plata was divided into well-known provinces or districts; and the millions of the Chiquitos, Mojos, and Guaranis, formed three distinct governments. The form of government in this new province remained the same, though its title was changed. The ordinance of his Catholic majesty for the sub-division of the vice-royalty was issued in 1782, and appointed nine intendancies. Eftalla says that this vice-royalty is divided into nine intendancies, namely Buenos Ayres, comprising the whole of that bithropic; the bithropic of Tucuman embracing two intendancies, that of Salta, and that of Cordova, to which is joined the province of Cuyo-y Mendoza, which, with regard to spirituals, is subject to the bithropic of Chili: in former Peru, there are five intendancies, Potosi, Plata, Puno or Paucarcolla, La Paz, and Cochabamba on the S.E. of La Paz; and from the remaining description, which is rather confused, it would appear that Santa Cruz de la Sierra forms the ninth intendancy; but there is also an intendant of Paraguay.

Mr. Pinkerton, for the purpose of a geographical description of this vice-royalty, enumerates the principal provinces, proceeding from the south, which are as follow:

1. Pampas, 16. Plata,
2. Tuyu, 17. Santa Cruz de la Sierra,
3. Buenos Ayres, 18. Chayanta,
4. Cordova, 19. Oruro and Paria,
5. Cuyo and Mendoza, 20. Carangas,
6. Charcas, 21. Pacajes,
7. Guarana, 22. La Paz,
8. Paraguay, 23. Cochabamba,
9. Chaco, 24. Sicaico,
10. Salta, 25. Lariaca and Omasuyos,
11. Jujuy, 26. Chucuito,
12. Chicas and Tarija, 27. Puno or Paucarcolla,
13. Lipes, 28. Lampa,
14. Atacama, 29. Afangaro,
15. Poto or Porco, 30. Carabaya, which is the last province of La Plata on the N. of the great lake of Titicaca, separated from the Peruvian province of Canes and Canchas by the grand chain of the cordillera called Vicanota.

Eftalla has briefly described the upper and inferior parts of the vice-royalty, as he calls them. The former part is peculiarly rich in the precious metals, yielding only to Mexico in this respect; and he particularly mentions the cordillera of Lipes; and to Porco belong the celebrated mines of Poto. The metals of Oruro and Paria are also celebrated. The provinces most rich in gold are Lariaca and Carabaya; while those that produce the greatest quantity of silver are Lampa, Puno, Chucuito, Oruro, Chayanta, and Chicas, not to mention Poto. Carangas and Pacajes are famous for the breed of pocos, which are used as beasts of burden. Lampa and Afangaro are noted for the produce of wool, the sheep in the former being estimated at near a million. These districts, together with Chucuito, also rear cattle and herds. In the provinces of Salta and Jujuy mules form a prodigious article of trade, supposed to yield 200,000 dollars annually. Cochabamba produces abundance of wheat and maize, so as to supply Oruro, La Paz, and other upland provinces. Santa Cruz de la Sierra, which ranks among the warm regions beneath the chain of mountains, trades in honey, sugar, and beer. In the lower part of the vice-royalty, Eftalla observes that the province of Buenos Ayres comprehends three other cities besides the capital, namely, Montevideo, Corrientes, and Santa Fe. The chief products of this province are beech and mules. For an account of Buenos Ayres, we refer to that article; here adding some particulars which have come to our knowledge since that article was written. In consequence of the creation of the new vice-royalty, there has been a great increase of commerce and agriculture, and many other advantages have contributed to its progressive prosperity. Formerly its inhabitants had no country-houses, nor any other fruits than a kind of peach; but now every person in easy circumstances has a country cottage and garden, with a variety of fruits, garden plants, and flowers. The houses, though not elevated, are convenient and well furnished. The women are celebrated among the most beautiful in America; and though their dresses are less expensive than that of those of Lima, it is more agreeable and elegant. The cathedral has been lately rebuilt; it has three naves, besides several chapels; and in 1798 it had cost half a million of dollars, and the expense of completing it would be as much more. A college is opened, that of San Carlos, which is said to contain 100 students. The ecclesiastical establishment consists of a bishop and some dignitaries; the parish churches are fix, and the convenants are numerous. Here are two hospitals for orphan children, one of which receives foundlings; and here is also an asylum for women of the town, and in the vicinity are several hermitages and little chapels. The population, which is daily on the increase, is supposed to be about 40,000 persons, of whom the whites or Spaniards compose one half, the other half consisting of negroes, mulattoes, and some few Indians from other parts. Of the Spaniards, some are creoles, born in the country of white parents, and all are chiefly employed in commerce, the arts, and agriculture, while the people of colour are mostly servants. The merchants form the chief part of the population, and of these the greater number is composed of such as are not natives. The inhabitants of Buenos Ayres are, according to Eftalla, of a sedate turn, affable and polite. A theatre is established. Bull fights, which were formerly held in the great square, are abolished. Both sexes are handsome, having agreeable countenances, and wearing the Spanish drefs. The ladies are fond of music, with which they amuse themselves and their company. Their flockings are fancifully embroidered with gold. The religious proccSIONs of this city are numerous and splendid. From Spain, and chiefly from Cadiz, are imported mof of the necessaries, as silks, woollens, cotton, linen, hats, &c. They are disembarked at Montevideo, and carried in boats to Buenos Ayres, whence they may pass to any part of the vice-royalty, paying per cent. on the fad if carried to the frontier provinces, and per cent. in other cafes. The merchants are effeemed men of character and good credit. If Buenos Ayres were not the capital of the province, and at present the great mart of Peruvian commerce, its trade would be inconsiderable, because it has no great branch of native exportation. But the fertility of the neighbouring provinces may in time incline the balance in its favour, and the leather, wool, wheat, tallow, may yield considerable revenues to the vice-royalty. The market of Buenos Ayres is abundantly supplied with all kinds of plants, fruits, meat, bread, fish, flour, milk, &c. Eftalla says, that nearly 1000 head of cattle are slain in the neighbourhood for the daily use of the city; fish is also abundant; but clear water is wanting. The climate is less healthy than that of Montevideo, and the caleatures or fevers are pernicious. The city is not deficient in coffee houses, confectionary shops, and taverns; but ice and snow are wanting. The vicrory is lodged in the fortresses, in which are also the new royal audience, the royal treasury, the chapel, guard-house, and various magazines. The guild-hall is a large building, raised on pillars of brick, where the judges hold the sessions, and underneath
is the gaol. The environs, especially towards Cordova, are pleasant, being full of gardens and groves, diversified with fields of wheat and maize. Cattle are abundant. See BUENOS AIRES. For an account of Montevideo, Santa Fé, Corrientes, Potofi, La Paz, Mendoza, Cordova, Tucuman, Salta, Cuyo, Rioja, the Guaranies, Paraguay, the Pampas, Chucuito, Puno, Oruro, Santa Cruz, Jujuy; see the several articles.

The government of La Plata is entrusted to a viceroy, who has also the title of captain-general, with an aileffor, and a fiscal, and also a secretary. The jurisdiction of the viceroy comprehends the whole political management, except the royal treasury, to which his authority does not extend. In the military department he is commander-in-chief under the sovereign. The aileffor is also auditor, or supreme judge; and his military jurisdiction is that of captain-general of the veteran troops. The salary of the viceroy is 40,000 dollars; but after certain deductions the residue is about 30,000. He is nominated for three years. The salary of the aileffor, fiscal, and secretary, is between 2 and 10,000 dollars each. The viceroy is supreme president of the royal audience of Charcas, and also of the new royal audience, erected in 1785, at Buenos Ayres. He exercises the royal vice-patronage, and as such has a grand feast and canopy in the cathedral, where he is treated with the same ceremonies as are paid to the monarch. The royal treasury acknowledges as its chief the intendant of the army; he has a salary of 10,000 dollars; and he audits all the accounts of the vice-royalty. The essential branches of the administration of the royal treasury at Buenos Ayres are the customes, the deposits of tobacco, the monopoly of which has sometimes yielded 100,000 dollars a-year, playing cards and stamped paper, which are of little consequence.

Similar duties are exacted in the principal cities of the vice-royalty, and a per cent. arises from the sale of merchandise. But the chief branch of the revenue is the duty called fittis, though in fact the tenth only of all metals. There is also a capitation tax from eight to ten dollars, paid by each person. However, the royal expenses are great: the pay of the military, the charges of the fairs, and the salaries of the officers of the customes and of tobacco, are prodigious. The intendants of the provinces manage in their jurisdictions the administration of justice, of the police, of the revenues, and of war. In Paraguay, Tucuman, and Santa Cruz, they have joined the command of the troops. The governors intendants have a salary of 6000 dollars, and 600 for the expense of the secretariat and visiting their province. The intendant of Potofi, who is also director of the mint, and of the bank, has a salary of 10,000 dollars. The aileffor, appointed by the king to aiffit these intendants in the administration of justice, has a salary of 1000 dollars, derived from the law-suits, and 500 from the treasury, thofe of the general intendency excepted, who have 1000.

Besides the nine intendencies there are four governments in the vice-royalty of La Plata, viz. that of Montevideo, political and military; and thofe of the Guaranies, Chiquitos, and Mojos, who have great power military and civil. The estabishments on the Patagunian coast, and the Maluinas, or Falkland islands, are subject to particular instructions. Eftalla computes the population of this extensive vice-royalty at 1,000,000 Spaniards or creoles, and an inconsiderable number of savages. The population of the other two vice-royalties, viz. Peru and New Granada, probably does not exceed 2½ millions. That of Caracas, by the account of Deponls, amounts to 728,000, including whites, negroes, and Indians; and Chilli can fearly exceed the number necessary to complete a million. Brazil, by the best accounts, contains 200,000 whites, and 600,000 negroes, while the natives are little more than sufficient to complete another million. The whole number, therefore, will yield 5½ millions; nor can more, it is thought, than 6 millions be allowed for the general population of the whole of South America.

The internal commerce of this vice-royalty is conducted by means of covered carts or small waggons drawn by oxen, and these form caravans for security against the attacks of the savages. The chief journey is from Buenos Ayres to Jujuy and Mendoza; beyond which itations it is necessary to have recourse to mules, as the country becomes mountainous. This trade supports many individuals, and increases the circulation of money. The freedom of trade, granted in 1778, contributed very much to augment the general commerce of La Plata; and by a royal ordinance of the 10th of April, 1793, it was permitted, that salted meat and tallow might pass to Spain, or the other colonies, free from duties; a privilege, which had before been granted to the trade in negroes, who were found necessary for the cultivation of the country.

The increase of commerce in this vice-royalty has had a beneficial effect on the agriculture of the country. A royal schedule, in 1791, granted to Spaniards and foreigners the right of introducing negroes, and instruments of agriculture; nor is it improbable, as our author (Eftalla) conceives, that this wide and fertile vice-royalty may become, in a few years, not only the granary of the other Spanish colonies, but of the parent country, by the extreme fertility of its soil, and the excellent regulations that are adopted. The climate is singularly benign, and the extent of fertile lands immense, watered by innumerable rivers and rivulets, which join the majestic waves of the Paraguay and the Parana. The farms, villages, and inlets for breeding sheep, hores, mules, sheep, etc. are already so numerous that they may be counted by millions. Salt rivers and lakes, with numberless creeks, afford convenience for loading boats with salted meat, and the natives are distinguished by their activity and industry. Some districts of the missions produce cotton, lint, and flax; and there are mines of gold at Maldonado and San Luis, 200 leagues from the capital. Although agriculture, fishery, the chase, and the mines serve to enrich these provinces, yet no object is more useful than the breeding of cattle, and we may form some judgment of the number by that of the skins imported. In 1792, 825,609 hides of beavers were carried to Spain, besides those sent to the coast of Brazil, and for the purchase of negroes, &c.

The botany of the provinces of this vice-royalty, which formerly belonged to Peru, may be found in the Flora Peruana; and that of the central, southern, and easter provinces, may be supplied from the work of the industrious Dobrizhoffer, who, in his first volume, given a general natural history of Paraguay. For a sketch of the botany and zoology, see PARAGUAY.

The mines form a grand object in the new vice-royalty, and are found chiefly in the provinces formerly considered as Peruvian; for, in fact, Charcas, Tucuman, and Buenos Ayres, were all regarded as dependencies of Peru, before the grand change in the year 1778. The upper part of the vice-royalty of La Plata very justly deserves the appellation given to the vice-royalty, as it is the richest country in silver which has yet been discovered on the globe. The mines of gold and silver may be said to be innumerable. All the northern provinces teem with mineral opulence; while Lariaca and Carabay are distinguished by virgin gold.
PLA

gold. (See Potosi.) Besides gold and silver, copper is found at Arcavoa near Oruro, and in the district of Lipez. A rich mine of tin is wrought in the district of Pariá; and mines of lead abound in the province of Chicas.

The following is the statement of the mines in the new vice-royalty of Buenos Ayres, as reported by Helms.

Pinkerton's Geography, vol. iii. ed. 1827.

**PLATA**

**PLATA**, or **Rio de la Plata**, a river of South America, which is the conjunct flood of the Paraguay, the Pilcomayo, the Parana, and the Uruguay. The main streams are the Paraguay and the Parana, which flow respectively. This river was first discovered by Juan Diaz de Salis, in the year 1515, who sailed upon the same as far as an island, which lies in S. lat. 34° 40'. The mouth, nearly 60 leagues broad, is supposed to have been called La Plata from the great quantity of silver found by those who first visited the countries adjacent to its banks; though it was originally called the river Salis, from its first discoverer, who, oberving some Indian tents as he sailed upon the river, imprudently went on shore with ten men, who were all murdered by the savages. The river Plata, receiving considerable streams, sometimes swells to such a height, that the banks on each side are overflowed, like those of Egypt by the inundation of the Nile, and thus rendered remarkably fertile. The current of the river, where it falls into the sea, is so rapid, that the water is fresh from leagues distant from its mouth. Its water is also clean, sweet, and wholesome. It abounds with great plenty and variety of fish; and its banks are frequented by a number of very beautiful birds. The distance from the confluence of the Paraguay and Parana to the mouth of the river is near 600 miles, and this interval is interfaced with delightful islands, and navigable by the largest ships. See Parana.

**PLATA**, a small island in the Pacific ocean, near the coast of Peru. S. lat. 5° 10'.

**PLATA** or **Sebastian del Oro**, a town of South America, in the province of Popayan; 60 miles E. of Popayan. N. lat. 3° 50'. E. long. 75'.

**PLATA**, a large sand-bank among the Bahamas islands, about 40 miles N. of Hispaniola.

**PLATAE**, a word used by some anatomical writers to express the testicle.

**PLATAEA**, in Ancient Geography, an island of the Mediterranean, on the coast of Lybia, whither, according to Herodotus, the Cyrenians sent a colony. It was situated on the coast of the Giganties, in the midway between that coast and the isle of Aphrodite. Scylax places it on the coast of Marmara.

**PLATAEA**, a town of Greece, in Boiotia. Homer writes this name in the singular ΠΛΑΤΑΕΑ, Platae; but the historians write it ΠΛΑΤΑΙΑ. It was situated on the river 4 Q 2

Afopus;
Afopus; and seems to have derived its name from Platea, the daughter of an ancient king of the country, who had given his own name to the river Afopus.

The first military exploit of the Platæans, of which we have any knowledge, occurred at Marathon, where they effectually aided the Athenians; they afterwards distinguished themselves on many occasions; but after having experienced the calamities of many wars, and having been frequently driven from their city and recovered it, their ruin was accelerated by Philip, after his victory in the battle of Cheronæa. Near the walls of this city was the tomb of those Platæans who had fallen in combating against the Periæans. The other Greeks had also a common sepulchre, whilst the Athenians and Lacedæmonians had another apart for themselves. Jupiter Liberator had an altar near the common burying-place of the Greeks; both the robes and the statue of the god were of white marble. The Platæans instituted games, which they celebrated every fifth year, on which occasion they ran armed before the altar of Jupiter. The temple of Juno was very splendid and highly ornamented; her statue was of an extraordinary size, and executed by Praxiteles of Pentæelic marble. Minerva had also a temple at Platea, which had been erected of the spoils gained from the Periæans in the battle of Marathon. Her statue was the work of Phidias, and was not les in fize, than that of bronze in the citadel at Athens. In this city was also the tomb of Leitus, who was the only Boeotian chief who returned from the siege of Troy.

PLATALEA, the Spoon-bill, in Ornithology, a genus of birds of the order Grallæ. The generic character is this: the bill is long and thin; the tip dilated, orbicular, flat; the nostrils are small, and at the base of the bill; tongue short, pointed; the feet are four-toed and semi-palmate. There are three species.

* LEUCOROMA; White Spoon-bill. Body white; chin black; hind-head sub-crested. The bill is black, brown, or spotted; tongue heart-shaped; irides grey; lores, orbits, and naked dilatable chin black; quill-feathers sometimes tippd with black; the legs are black. There are two varieties of this species, of which the frill has the wings varied with black and white, the legs yellowish; in the second the body is all white; legs flesh-colour. The white or common Spoon-bill weighs about three pounds and a half, and measures two feet eight inches in length. It inhabits from the Fereö islands to the Cape of Good Hope; it is rarely seen in England, but its appearance is sufficiently frequent to justify us in placing it before it the alterilk. It lives on græs, caröces, the roots of reeds, férpents, frogs, mussels, and other shell fish; but especially on fishes, which it often feizes from other birds. It makes its nests in high trees, near to the sea, and lays three or four white eggs, speckled with pale red spots. The fîsh of the young Spoon-bill is reckoned very good, little inferior to that of the goose.

AJAJA; R señal Spoon-bill. Body rofe coloured; tail-coverts scarlet. There is a variety blood-red; neck white; collar black; tail-feathers scarlet. It inhabits South America, and is twenty-four inches long.

PYGME; Dwarf Spoon-bill. Body above brown, beneath white. It is only the size of a full-grown Sparrow, and is found in Guinea and Surinam.

PLATAM, a word used to express a low and smooth rock, just appearing above water.

PLATAMONE, in Geography, a town of European Turkey, in Macedonia, at the mouth of the river Jenicoro; 44 miles S.S.E. of Edessa.

PLATANUS, in Ancient Geography, a town of Aria, in Syria; situated on the western bank of the river Orontes, E. of mount Cæmus, towards N. lat. 35° 30'.—Allo, a town of Phœnicia, placed by M. d’Anville between Berytus and Sidon, in the vicinity of Libanus.

Gen. Ch. Male flowers compound, disposed in a globose catkin. Cal. A few minute segments. Cor. barely discernible. Stam. Filaments oblong, swelling upwards, coloured; anthers square, surrounding the lower part of the filament. Female flowers numerous, forming a globe, on the same tree. Cal. of several minute scales. Cor. Petals several, concave, oblong, club-shaped. Fii. Germanse several,awl-shaped, ending in awl-shaped styiles; stigma simple, recurved. Pericarp one; several fruits are collected together into a globe. Seed roundish, tapering at the base, crowned with the awl-shaped permanent styile, the bottom of the seed being surrounled with copious capillary down.

Obf. Linnæus submits his description of the flowers to the more attentive scrutiny of "some lynx-eyed observer," but no one as yet has taken up the challenge. Mr. Bauer's fine drawing of P. orientalis, for the Flora Graeca, has no male flowers.

1. P. orientalis. Oriental Plane Tree. Linn. Sp. Pl. 1417. Wildl. n. 1. Ait. n. 1. (Platanus; Gen. Em. 1489.) Matth. Valgr. v. 1. 120. P. orientalis varius; Duham. Arb. v. 2. 172. t. 33. —Leaves palmate, five-lobed; wedge-shaped at the base: segments lanceolate, filiate: ribs pedate. Stipulas nearly entire.—Native of the Levant.—A specimen in the Linnæan herbarium was gathered by Hallequin, from a remarkably large tree, in the island of Cos, now Stæichio, the circumference of whose trunk was thirteen and a half Swedish ells, about eight yards and a half. This beautiful species is among the earliest exotic trees recorded to have been cultivated in Britain, being mentioned by Turner in 1648; but the great lord Bacon appears to have been the first who planted it in any abundance. The Greeks and Romans esteemed this tree very highly for its shade, as well as beauty. About the Roman villas it was always planted, and sometimes honoured, rather than benefited perhaps, with libations of wine. Some ancient trees of this kind are reported to have attained a more ample size than the
above. The finest Oriental Plane, we believe, in England, stands at one corner of Chelsea garden, raising its round head far above all neighbouring objects. Miller speaks of this as the Maple-leaved variety, now made a species, see n. 3; and he affirms, that young plants, which sprout from its seeds, proved of the common fort. We have no opportunity at present of investigating this point. An elegant specimen of the Oriental Plane, whose spreading branches are feathered down to the ground, stands near the temple in the arboretum at Kew. In Germany, this species is not hardy enough to attain the size of a tree. The branches of *P. orientalis* are round, smooth, slightly zigzag. Leaves deciduous, alternate, on longish, round, downy stalks, rather deeply palmate, about a span wide, with five lanceolate, more or less deeply or copiously finned, lobes, whose points are callous or glandular, and somewhat incurved; both sides are smooth, with peduncles, and innumerable fine veins; in an early state only, the leaves are clothed with mealy deciduous down. *Stigmas* tubular, surrounding the branch, with a spreading border, more entire in this species than the rest. *Buds*, as in the whole genus, ensheathed in the hollow base of each *footstalk*, ovate, obtuse, compressed, quite concealed till the leaves fall. By their swelling, the buds promote the separation of the footstalks. *Flowers* in three or four globular heads on each long drooping *footstalk*, appearing in April and May. *Stigmas* crimson. Each globe of ripe *fruit* is an inch or more in diameter.

2. *P. cuneata*. Wave-leaved Plane Tree. Willd. n. 2. *Ait. n. 2.* (P. orientalis undulata; *Ait. Hort. Kew. ed. 1. v. 3. 364.);—Leaves three or five-lobed, toothed; wedge-shaped and elongated at the base; triple-ribbed, nearly smooth.—Gathered by Hafelquint in the Levant. Miller is said to have cultivated it in 1739. In some parts this answers to his "Spanish, or Middle Plane Tree!"); but we find great difficulty in applying with certainty the English names of this genus, which are used among nursery-men. The leaves in our wild specimen are remarkably wedge-shaped, and elongated at the base; in consequence of which there are only three principal ribs, of which the lateral ones are seldom precisely opposite; the lobes are three, strongly finned, but not separated so far as the middle of the leaf. *Footstalks* long. Miller describes them short, and covered with short down, in his Spanish Plane, which character answers to another specimen in the Linnean herbarium from Burgundy, resembling the true *orientalis*, except in its short *footstalks*, and strongly toothed *StipUs*.* This specimen may be a undescribed species. The leaf in Duhamel. Arb. v. 2. t. 34. given for the following, represents our plant very well.

3. *P. acerifolia*. Maple-leaved Plane Tree. Willd. n. 2. *Ait. n. 3.* (P. orientalis acerifolia; *Tourn. Cor. 41.);—Leaves heart-shaped, five-lobed, smooth, dimidiously toothed; abrupt and three-ribbed at the base.—Native of the Levant, where it was noticed by Tournefort. The Hort. Kew. mentions this species as cultivated here before 1724. Willdenow says it is hardly, forming a lofty tree, in Germany, and that it is known from all the rest by the leaves being abrupt, not wedge-shaped at the base, and having their two lateral ribs springing from the top of the *footstalk*, accompanied by any leafy expansion beyond them. He adds, that they are extremely like those of the Sugar Maple, *Acer saccharinum*. We have no specimen that answers to this description, nor does Duhamel's t. 34, given as Tournefort's plant, agree with Willdenow's account.

v. 1. 56. t. 56. Duham. Arb. v. 2. 1722. t. 35.—Leaves with five angles, slightly lobed, toothed; wedge-shaped at the base; downy beneath.—Native of the banks of rivers in North America, from Canada to Florida, as well as in Louisiana. Mr. Pursh says this is perhaps the largest North American tree, some individuals, on the fertile banks of the Ohio and Missippis, measuring from ten to sixteen feet in diameter. It is known by the names of Buttonwood, Water Beech, Sycamore, and Plane Tree; in Canada by that of Cotton Tree. This Plane has been cultivated in England about 180 years, and is usually hardy with us, as well as in Germany, flowering like the other species in April and May; but the winter of 1810, or spring of 1811, was fatal or injurious to most of the Occidental Planes in England, owing perhaps to transfect cold, not generally observed, at some critical period of the growth of these trees in particular. The broad, slightly lobed foliage distinguishes this species readily from all the rest. The three or five principal ribs have a concolorable leafy, though scarcely wedge-shaped, expansion below the point of their union. The *Stigmas* are wavy, with blunt shallow teeth. *Footstalks* rather short, downy.

*Platanus*, in *Gardening*, contains plants of the exotic deciduous tree kind, of which the species cultivated are; the oriental plane tree (*P. orientalis*); and the American plane tree (*P. occidentalis*).

Of the first there are two varieties, as the *maple-leaved*, which has not its leaves so deeply cut as those of the eastern plane: they are divided into five segments, pretty deep, but not lobed, like those of the occidental plane. The petioles are much longer than either of the species, and the upper surface of the leaves is rougher, so that they might be taken for different sorts, if it was not known that they rose from the same seeds.

The *spanish* plane, which has larger leaves than either of the sorts, and are more divided than those of the occidental, but not so much as those of the oriental. Some of the leaves are cut into five, and others into three lobes only; these are sharply indented on the edges, and are of a light green; the footstalks are short, and covered with a short down. This is by some called the middle plane tree, from the leaves being of a shape between the two species.

**Method of Culture.**—These plants may be increased by seed, layers, and cuttings; but principally in the two last methods.

The best season for sowing the seed is autumn, if they can be procured, otherwise in the spring, upon a somewhat lightish mellow soil: the ground having been dug and raked, it should be formed into four-feet wide beds, and the seeds then scattered evenly on the surface, and raked in, or with the back of a rake the earth be previously trimmed off the surface near half an inch deep into the alleys; then sowing the seed, and directly with the rake turned the proper way, drawing the earth evenly over the seeds, and trimming the surface smooth, when many of the plants will rise in spring, but probably not generally till the spring following. When they are one or two years old, they should be planted out in nursery-rows, two feet alender, and about half that distance in the lines; to remain till of a proper size for being finally set out.

In the layer method, some stout plants must be planted for foolls, which in a year after must be headed down near the bottom, that they may throw out many shoots near the ground convenient for laying; which, in the autumn after they are produced, should be laid down by flat-laying; and by the autumn after they will be well rooted, and form plants
PLA

plants two or three feet high, which may be separated, and planted in nursery rows, as the seedlings. They succeed very readily in this way.

Most of the forts take tolerably by cuttings of the strong young shoots; but the latter more freely than the former kinds. The most proper season for planting them is the autumn, as soon as the leaf falls, or occasionally in the spring; choosing a moist soil for the purpose, when many of the cuttings will grow, and make tolerable plants by the autumn following.

These lathe methods are the only ones in order to continue the distinct varieties effectually.

These trees have a very ornamental effect in all sorts of plantations, from their large growth and the great size of their leaves.

PLAT-BAND, a border or bed of flowers, along a wall, or the side of a parterre; frequently edged with box, &c.

PLAT-BAND, in Architecture, is any flat square moulding, whose height much exceeds its projection.

Such are the faces, or façades, of an architrave, and the plat-bands of the modillions of a cornice.

The plat-band is signified in Vitruvius, and others, by the words façia, tania, and corfa.

PLAT-BAND of a door or window, is used for the lintel, where that is made square, or not much arched.

These plat-bands are usuall crossed with bars of iron when they have a great bearing; but it is much better to ease them by arches of discharge built over them.

PLAT-BANDS of flutings, the lifts, or fillets, between the flutings of columns.

PLATE, in Commerce, denotes gold or silver wrought into vehicle for domestic uses.

PLATE, in Geography, a town of Hinder Pomerania, on the Reg; 22 miles S. of Colberg. N. lat. 53° 49'. E. long. 15° 17'.

PLATE, in Heraldry, is a round flat piece of silver, without any impress; but, as it were, formed ready to receive it.

The term is used only by the English heralds. In other nations they are known by the name of bejants argent.

PLATE-Mail, in Ancient Armour, see MAIL.

PLATE-Armour, formed of small round plates of iron, like the scales of a fish, was known and used among the ancients. There are many specimens of Roman plate armour in the museums of curious collectors. If the suit of armour, shewn in the Tower of London, be really what it is said to have been, the armour of John de Courcy, earl of Ulster, in Ireland, brought with him to the Tower; it will prove that plate-armour was in use as early as 1204, the date of his confinement. The general prevalence of it was checked by the large sum which a complete suit of plate-armour cost. It was, however, introduced both here and in France into more common use about the middle of the 14th century.

PLATE, a term used by our Sportsmen, to express the reward given to the best horse at our races.

The winning of a plate is not the work of a few days to the owner of the horse, but great care and preparation are to be made for it, if there is any great dependence on the success. A month is the least time that can be allowed to draw the horse's body clear, and to refine his wind to that degree of perfection that is attainable by art.

It is first necessary to take an exact view of his body, whether he be low or high in flesh; and it is also necessary to consider whether he be dull and heavy, or brisk and ready when abroad. If he appear dull and heavy, and there to suppose it is owing to too hard riding: or, as it expresses it, to some grease that has been dissolved in hunting, and has not been removed by scouring, then the proper remedy is half an ounce of diapente, given in a pint of good sack; this will at once remove the caufe, and revive the creature's spirits. After this, for the first week of the month, he is to be fed with oats, bread, and split beans, giving him sometimes the one, and sometimes the other, as he likes best; and always leaving some in the locker, that he may feed at leisure when he is left alone. When the groom returns at the feeding time, whatever is left of this must be removed, and fresh given; by this means the creature will soon become high spirited, wonton, and full of play.

Every day he must be rode out an airying, and every day it will be proper to give him a little more exercise; but not in such a degree as to make him sweat too much.

The beans and oats in this case are to be put into a bag, and beaten till the hulls are all off, and then winnowed clean; and the bread, instead of being chipped in the common way, is to have the crust clean cut off.

If the horse be in good flesh and spirits when taken up for its month's preparation, the diapente must be omitted; and the chief fullnes will be to give him good food, and so much exercise as will keep him in wind, without over-sweating or tiring his spirits. When he takes larger exercise afterwards, towards the end of the month, it will be proper to have some horsetp in the place to run against him. This will put him upon his mettle, and the beating them will give him spirits.

This, however, is to be cautiously observed, that he has not a bloody heat given him for ten days; or a fortnight before the plate is to be run for; and that the last heat that is given him the day before the race, must be in his clothes: this will make him run with greatly more vigour when he is tripped for the race, and feeling the cold wind on every part. In the second week, the horse should have the same food and more exercise: and in the last fortnight he must have dried oats, that have been hulled by beating; after this they are to be wetted in a quantity of white and eggs beaten up, and then laid out in the sun to dry; and when as dry as before, the horse is to have them. This sort of food is very light of digestion, and very good for the creature's wind.

The beans in this time should be given more sparingly, and the bread should be made of three parts wheat, and one part beans. If he should become colicte under this course, he must then have some ale and white of eggs beaten together: this will cool him, and keep his body moist.

In the last week the maff is to be omitted, and barley-water given him in its place; and every day, till the day before the race, he should have his fill of hay; then he must have it given him more sparingly, that he may have time to digest it; and in the morning of the race day, he must have a toast or two of white bread, soaked in sack, and the same just before he is led out of the field. This is an excellent method, because the two extremes of fullnesses and fasting are at this time to be equally avoided; the one hurting his wind, and the other occasioning a faintness that may make him loose. After he has had his food, the litter is to be shook up, and the stable kept quiet, that he may be disturbed by nothing till he is taken out to run. See Racing.

PLATES, in Gunnery. The prize-plates, are two plates of iron on the cheeks of a gun-carriage, from the cap-square to the centre, through which the prize-bolts go, and on which the job-plates rest, when in position to the breech of the piece. Breast-plates are the two plates on the face of the carriage, one on each cheek. Train-plates are the two plates on the cheeks at the train of the carriage. Dudgeon-plates are the fixed plates on the wheel of a gun-carriage, where
PLATE

where the fellows are joined together, and serve to strengthen the dulidges.

PLATES, Copper, in Engraving. See Copper-Plate.

PLATES, Ground, in Building. See Ground-Plates.

PLATES, Pintle. See Pintel.

PLATE-Glafs. See GLASS.

PLATES, Colours of Glas. See Colours.

PLATE-KNEES, in Ship Building, are iron knees, made of flat bars of iron, about one inch thick, and four inches broad; the arms are bolted through the end of the beam, and a chock of oak under the beam, which is first bolted through the ship's side. This method of connecting the beams to the side is an excellent subsitute for wood hanging-knees.

PLATE-Longe, in the MANUFACTURE, a wovenrap, four fathoms long, three fingers broad, and as thick as one. It is used for raising a horse's legs, and sometimes for taking him down, in order to facilitate several operations of the farrier. Some improperly give the name of plate-longe to the martingale.

PLATE, in Ornithology, the name of a bird of the long-necked kind, approaching to the nature of the fowl and heron, and called in English the spoon-bill. See Plate.

PLATED MANUFACTURE, in the Arts. From the valuable properties possessed by silver as a metal, it is much to be regretted that it is not sufficiently plentiful, so as to be used for the fabrication of such articles as are liable to corrosion; more especially such utensils as are employed for culinary purposes. This desirable object has given rise to the deluder of covering some of the cheaper metals with silver, and this art has always been known by the name of plating.

The art of plating with silver appears to have been first applied to articles made of brass, after they were in other respects finished. It is known by the name of French plating, and was formerly much used for brass candlesticks. After the goods were polished, and perfectly free from grease, and indeed any other extraneous matter, the part to be plated was heated to a temperature something short of changing the colour of the metal. Leaf silver was now laid upon the part, and, while hot, was rubbed on with a hardened steel burnisher, perfectly dry and clean. By this means the silver adhered firmly to the brass, which, from the action of the burnisher, assumed a fine polish. These had much the appearance in colour and luster of those of the present day. They possessed but little permanence, owing to the thinness of the covering. This art is scarcely now practised, from the introduction of the superior plan of plating upon ingots of copper, and forming the utensils out of the sheets and wire made from the ingots. This latter is at present carried on to an immense extent in Sheffield, and also at Birmingham, but on a less scale.

The inventor of this method of making plated articles was not aware of its great importance. He began by making it into snuff-boxes, and other triding articles. It afterwards was extended to the manufacture of pins and tacks, and other articles, by a Mr. Hancock, who erected a mill near Sheffield for rolling the ingots. This mill is at present employed for this purpose by the son of the above gentleman.

The plated manufacture is divided into three departments, in each of which a distinct set of workmen is employed. Those workmen employed in making vessels, such as are required to be raised by the hammer, are called braziers, probably from braziers being first employed in it.

The next are called candlestick makers, being exclusively employed in making all the varieties of these articles.

The next and last are called piece-workers: these were originally employed in making articles with ornamental open work, such as bread-baskets, and trays of different kinds.

This open work was formed by piercing the substance with punches of different shapes, by means of a screw-prest called a fly.

This species of work is now become obsolete, since the invention of plated wire. The articles in which piece-work had been made, are now formed by the varied interfections of wires, which give light effects and elegance, with less waste and more expedition. The workmen employed in this department are still called piece-workers.

Previously to deferring particularly the different branches of this art, we shall give the method of preparing the plated sheets and wire of which all the different articles are made.

The ingots on which the silver is laid are not pure copper, but an alloy, consisting of copper and brass; this gives it a degree of fluidness greater than that of copper, which renders it less liable to be deformed when in use.

Fig. 12. in Pl. Plated Manufacture, represents a section of the furnace used for melting the alloy for the purpose of casting. The crucibles are those made at Chelsea with black-lead. The ingot-moulds are of cast-iron, consisting of two pieces, fastened together by two rings, with wedges, the interior being of the shape of a parallelepipedon, about three inches broad, 1½ in thick, and about eighteen or twenty long. The mouth-piece, into which the metal is poured, makes an angle with the length of the cavity; so that when the mould is placed on the ground, with the narrow side uppermost, and makes an angle with the horizon of about ten degrees, the mouth-piece points directly upwards. The inclination of the mould and the length of the mouth-piece are to give a certain head of liquid metal, which determines the impurities of less specific gravity than the metal to rise into the cavity of the mouth-piece, in order to injure the foundness of the ingot. If this were not attended to, the sheets rolled from such ingots would abound with seams and loofe places. It is easy to see that a small hole in the ingot would be the source of a seam by extension, and a larger cavity would have the effect of making hollow places in the substance of the sheet, which frequently peel off with the silver after plating.

The proper heat of the metals, and the temperature of the mould when the metal is poured, are of great importance, as far as regards the foundness of the ingot. When the metal is too cold, and its liquidity of course imperfect, the impurities cannot freely ascend, which causes imperfection in its substance. The same effect may take place from the moulds being cold: this, with the great conducting power of the metal mould, rapidly robs the metal of its caloric, and lessens its liquidity. The proper heat for the moulds is something short of burning the fat with which they are greased on the interior surface. The presence of fat which contains hydrogen has a happy effect in preventing the surface being rough. Its presence is therefore essential, and hence the moulds should never be so hot as to destroy it. On the other hand, the metal should not be too hot, as in this case it remains longer in the liquid state than is proper: this has the effect of allowing the metal to assume a more perfect crystalline arrangement than under ordinary circumstances. When an ingot under such circumstances is broken, the crystals are very distinct. The sheet rolled from an ingot so cast, will be found to exhibit on its surface very thin loofe pieces, which peel off. This is frequently a source of great mischief to the manufacturer. After the pieces are plated and
PLATED MANUFACTURE.

and rolled, this last inconvenience is frequently so great, as to render the whole sheet useless, except to work over again.

It will be remembered, from what we observed respecting the temperature of the ingot moulds, that the proper point at which the metal can only be acquired by practice. Men of some talent and observation should have the management of casting and platting. It is notorious, however, throughout the trade, that the men employed in this essential department are generally taken from the clafs of common labourers.

The best test for the proper degree of heat of the metal is its colour, and the appearance of liquidity. When it first fuses it appears stiff, and of the colour of the red cokes of the furnance: with a greater heat it becomes more liquid, and assumes a blueish colour. This latter is the proper plate for pouring it into the mould. If the heat be greater, the zinc of the brafs, and perhaps the copper itself, begins to burn. This arises from the metal's afluming the form of vapour, which combines with the oxygen of the atmosphere. When the metal has become fluid in the mould, the wedges which keep the two halves of the mould together are flaccened, to prevent the ingot from breaking, by its contraction, during cooling. When it is taken from the mould its surface ought to be smooth and metallic. Its fracture should exhibit a rough uniform crystallization, in which the cryftals prefent small surfaces. If the cryftals appear diffignt, with large faces, the metal will be flally when rolled.

For the ordinary kind of work these ingots are generally cut in two in the middle, being more convenient for plating than longer pieces.

The next process is to draw the face of the ingot for the purpose of receiving the silver, on one or both sides, as it may be intended to be single or double plated. This is effected by filing, which is continued till the surface becomes entirely free from the leaf blemishes. This is fio important, that the naked eye should not be depended upon. A very small hole in the ingot would become a surface on rolling, and the silver would come off in that part. The surface of the copper should, therefore, be minutely examined by a magnifier; before the silver is laid on. The thicknefs of the silver to be laid on the copper will be folt known, when it is understood, that the silver, in single plated metal, or that plated on one side only, is from 8 to 10 pennyweights to the pound Troy of copper; and, of course, double that quantity when plated on both sides. If the ingot of copper be 1/4 thick, the silver plate to be laid upon it, at eight pennyweights to the pound, will be 1/5 of an inch, and a square inch of it will weigh about 90 grains. When the plate of silver is cut to a little less than the fize of the copper plate, made flat, and scraped perfectly clean, the copper surface being equally clean, they are laid together, and the silver plate is tied down with wire. A little of a faturated solution of borax is now infufed under the edge of the silver plate on every side: this fuses at a low red heat, and prevents the oxygen of the atmosphere from acting on the surface of the copper, which would prevent the adherence of the silver. In this plate the ingot is brought to the platting furnance.

In fig. 12. B is an iron door, with a small hole to look through. This furnance has a grate on a level with the bottom of the door. The fuel confifts of cokes. The ingot is laid upon the bare cokes, and the door shut. When it has acquired nearly a proper degree of heat, the plater applies to the hole in the door to observe the proper point, when the procefs is finifhed. When the silver and copper are uniting, the surface of the former begins to be riveted, and this is the sign to remove the ingot from the fire as quick as poifible. If it were allowed to flop longer, the silver would become alloyed with the copper, and completely spoiled.

In this procefs, the silver is, in fact, folded to the copper, although no folder is expressly employed. It is well known to chemifts, that an alloy of silver and copper, as well as many other alloys, is more fufible than either of the fimple metals. From what takes place in the above procefs, it will be easily inferred, that a portion of silver and copper unite at contiguous surfaces, which fusing before the silver or the copper, unite the silver with the copper. The ingot, being now plated, is made perfectly clean, and is ready to be rolled. The firk rollers employed for plated metal are of cast-iron, similar in size and construction to those employed for sheet iron and sheet copper. (See ROLLING MILL.) The metal is rolled cold, and annealed from time to time. When it has gone through the rollers a certain number of times, it acquires a certain degree of hardness, fo that the rollers have not much effect upon it; and if the rolling were continued, the metal would crack. To remedy this evil, the metal is taken to a reverberatory furnace. It is laid upon a hearth of brick or fire-brick, and the flame of coal made to pass over it. The heat, however, is not intense, since the metal is required to be feaftly heated to a dull red. It may now be cooled in the quickest way poifible to fave time, as quenching in water does not affect it, as is the cafe with fteel. It now passes through the rollers, as before, till it becomes hard, and then annealed and rolled again, till it is reduced something fhort of the size required. This being done, it is again annealed and passed through a pair of rollers fuced with cast-iron, and finely polifhed. This gives the surface great smoothness and truth. It is now annealed for the falt time: after this, the sheets are infufed in hot dilute sulphuric acid, then fcorer with fine Calais fand, which fits them for the workmen to fhape into different articles.

Having described the method of preparing the fheet plated metal, we shall now give an account of the method employed for manufacturing plated wire. This is generally a diftinguifhing buinfefs, being unconnected with the buinfefs of making the plated goods.

The pieces of metal to be plated for the purpose of making wire, are forged out of bar copper unalloyed. These pieces are of a cylindrical shape, and about 15 or 20 inches long, and about 1 1/4 inch in diameter. The true cylindrical shape is given to the copper by wire-drawing: it is then made perfectly clean and metallic by scraping. The filver to be laid upon it is much thinner in proportion to the copper than was laid in the fheet metal. The filver is firft formed into a tube, one edge projecting a little over the other. A copper cylinder, a little less in diameter than the tube, and so much longer as to admit one end of it being fastened into a hole, is now heated red-hot, and fastened by one end in the hole. The tube is now flipped upon it, with the seam upwards. A flat fteel burnifier, with rounded polished edges, and a handle at each end, is now rubbed briskly backward and forward upon the overlapped edges of silver, at the fame time urging considerable prejudice. By this means the two surfaces are completely welded together, fo that it would be difficult to find where the union had taken place.

The cylinder of copper intended to be plated, is now made perfectly clean, the inside of the silver tube being the fame. It is now put upon the cylinder, which is about two
two inches longer than the tube; a small groove is made round the cylinder coinciding with the ends of the silver tube. Into this groove the ends of the tube are closely worked, so as to render the space between the tube and the cylinder perfectly air-tight. The necessity of this will be obvious, since the whole is required to be heated red-hot, which would cause the oxidation of the copper, and prevent the silver from adhering to it. When the cylinder and tube are together heated gradually red-hot, the fame burnisher that was used to unite the tube is now rubbed briskly over the tube in a longitudinal direction. This unites the silver firmly to the copper, and makes it fit for drawing into wire of various forms and sizes. The machinery employed for drawing this wire is precisely similar to that employed for brass and copper wire. The great variety of figure and form given to it depends upon the plate through which it is drawn. Some are flat, others half round, some fluted, or with mouldings. It is chiefly used for making bread-baskets, toast-racks, flourers, and many other articles, affording much neatness and elegance, with little manual labour. The wire after drawing, like sheets after rolling, is annealed, and afterwards cleaned with hot dilute sulphuric acid.

We shall first describe the manufacture of sheet metal into various articles. It may be easily conceived, that the nature of this metal is so similar to copper, that the working of it with the hammer into various forms will be very similar to that used by coppersmiths, with the difference of more exact and complete tools, and greater care on account of the value of the metal. Formerly all the different shaped vessels were made with the hammer, which made the price of labour very great. Now, all vessels of simple form, and not of large size, are formed in dies by means of the flanging hammer. This operation is now so general, that some manufacturers employ as many as six or eight of these engines.

Figs. 1 and 2 are two views of the flang. A is a large stone, the larger the better; b, the anvil on which the die, c, is secured by four screws. See ground plan. In fig. 1, a, a, are two upright flanging pillars, with the angles opposed to each other, which work in angular recesses in the hammer d. This admits the hammer to slide freely and truly from top to bottom, by pulling at the rope, f, which passes over the pulley, e. This hammer is let fall from different heights, according to the effect to be produced.

All vessels may be flanged by the flang, with the exception of such as are immediately large, or those of inordinate depth, compared with the diameter. Vessels which are of less diameter at the top and bottom than in the middle, must either be flanged on two pieces, or raised with the hammer by hand.

The dies are, or ought to be, made of cast steel, but it should be as hard as to weld to iron, so that the iron should not be much below the surface of the die. This precaution is necessary only when the die requires to be hardened. In other respects the whole may be cast steel. Those unhardened should be of harder cast steel. No other steel can answer, as it would be liable to abound with flaws, and would not be uniformly hard.

When the die is placed upon the anvil, and the metal cut into pieces of proper size, the next thing is to surround the top of the die with a paste made with oil and clay, an inch or two above the surface. This cavity is now filled with melted lead. The under side of the flanging hammer has a flat face of iron fitted into it, about the breadth and length of the die: this is called the lickerup. When the lead becomes solid, the hammer is raised to a certain height and let fall upon it. The under side of the lickerup, from being cut on the surface into teeth like those of a rasp, firmly adheres to the lead, which afterwards rises with the hammer. The metal is now placed over the die, and the hammer with its lead made to fall upon it, till the impression on the metal is complete. If the flange be flanged be of any considerable depth, two or three dies are often used, one bigger than another, the last being of the proper size and shape. It sometimes happens, that when the vessel has a long conical neck, they are obliged to have recourse to an auxiliary operation called drafting. These in the plate are called embossing punches.

In fig. 11, the punches are made of cast steel, and the cavities turned out in a lathe. The pieces a, b, c, are of lead. This operation is performed by a series of these punches of different sizes, beginning with the largest flint, and gradually going on to the smallest. By this means a hollow cone may be raised out of a flat plate, three or four inches in length, and not more than an inch in diameter at the widest part. The punches are also employed for small articles of too great delicacy for the flang. It frequently happens, that one part of an article is made by the flang, and the rest by the hammer. Sometimes they are rudely formed by the hammer and finished by the die.

Cylindrical and conical vessels are mostly formed by bending and folding. The bending is performed on blocks of wood with wooden hammers, to avoid injuring the plated surface. We shall here recommend a method of turning rings, or any thing in a cylindrical or conical shape. It is already used to great advantage by tin-plate workers. This is done by a machine consisting of three rollers, a portion of which is shown in figs. 5 and 6. A, B, C, are the three rollers, and abcd the piece of metal passed through them to receive the cylindrical or conical shape.

The upper roller, A, can be raised or lowered at pleasure, which has the effect of determining the diameter of the cylinder. When one end of the upper roller is higher than the other, it gives the conical shape. In order to folder the cylinder inwards, the two edges are made very true, and are kept in contact by binding them with small iron wire. The part where the folder is intended to be run must be made perfectly clean by scraping. The folder employed is that called folder. It is an alloy of brass and silver, or rather an alloy of silver, zinc, and copper. The alloy of copper and silver is more fusible than either of these metals, and may be employed as a folder for silver, copper, or plated metal, when the plated metal has no zinc in its composition. It is, however, necessary to employ an alloy of brass and silver as a folder for plated metal. The brass should be the least possible, being no more than what is necessary to give the requisite fusibility to the folder, since too much brass would not only injure the colour, but its malleability is impaired, and the seam would break when it came to be hammered.

The folder is first cast into an ingot, and then rolled thin enough to cut with shears into small shreds. Befides the folder they also employ borax, and a substantia which floats on the top of melted glass, and is taken off as refuse. It is called sundance, and probably consists of fulphat of potash, or nitre. The borax is first calcined, which consists in driving off the water of crystallization. The white powder is then mixed with a little water, a small quantity of the powdered sundance being at the same time added. After the funnel to be foldered has been smeared with this pulpy mass, and the sides of the folder laid on, the whole is exposed to the heat of a lamp with a blowpipe; or if the substance be large, to a charcoal fire, urged with bellows. The borax first

4 R

fuses,
fuses, and defends the parts to be united from the action of the air. The heat is then increased rapidly till the folder melts. The use of the folder is to prevent the iron wire from being foldered to the other metal. It appears that the falt in this fusibility is decomposed by the iron, by which the surface of the lead becomes oxidized, and prevents the metallic unition with the silver or the copper. The folder has no action upon the other metals, and therefore does not prevent their union. When the united part is made clean, and hardened with polished tools, the seam cannot be seen on the silvered side. If a yellow line appear, the folder contains too much brass.

Vessels intended to have other forms are generally foldered, up in a conical or a cylindrical form, according to the width at the top and bottom of the vessel varies. The metal is too malleable, even in the foldered part, that a skilful workman can give almost any form to a vessel with the hammer. 

Moulds are sometimes formed upon the edges of vessels, which serve to give much strength and stiffness, as well as being ornamental. This operation is performed by an instrument called a dawge, see fig. 3 and 4. The part A lifts up a joint, and the metal to be foldered is placed between the dies, as shown in the figures: the part b is held in a vice, while the other rests upon it. By striking on the part A, at the same time shifting the metal forward, the bead is formed. In fig. 3, the part a is a guide to regulate the distance of the bead from the edge. The fame effect is produced in a nearer and more expeditious manner by the rollers, figs. 6, 7, 8, 9. Fig. 10. is a sketch, shewing the form of the bead. The two wheels a, a (fig. 8) are placed upon an axis, which have pinions for the purpose, the lower one giving motion to the upper one. The groove in the upper wheel corresponds with the bead in the lower one, and the metal passed between accuracly the fame figure. This machine, a little varied, may be used as shears to cut the metal into pieces of uniform breadth. A part of the upper wheel a, for this purpose, must be a little larger, and the edges square and sharp. The lower wheel being put on first, the other must be put on to the other axis, till the face of the enlarged part comes up to that of the other wheel, and in this situation secured by nuts. It will be evident, that if a piece of metal be now placed between them, that the metal will be cut by the projecting part of the upper wheel, in a similar manner to that employed for filing iron.

The beading and moulding, however, is not at present much used. When prominent parts like these are merely plated metal, they, from being more expof'd, soon become bare, and the copper surface is preferred. The greatest improvement ever made in this branch of manufacture, is the introduction of silver edges, beads, and mouldings. Without this means of defending the prominent parts which become so soon bare in the old method, the trade must long since have given into disfance, and ultimately to decay. The silver intended to form the prominent and ornamental parts is rolled extremely thin, a superficial inch sometimes not weighing more than 10 or 12 grains.

This is too delicate to have the ornamental form given to it by the swage above described. The two opposite dies being equal, if not very accurately made, would tear silver fo delicate as that used for ornaments. It is necessary, therefore, that the fink part of the die shou'd be equal, and the opposite side lead, as was observed in the flamping, and this is the method generally employed to form these silver ornaments. It seems wonderful, that manufacturers have not thought of doing this by small rollers. It would only require to have the part in which the die is funk a wire ring of cast steel, the concave part being a little conical, and made to exactly correpond with a convex cone on one of a pair of rollers, so that by a little force it may be as firm as a solid roller. A ring of lead, or even a straight piece, might act as a roller, or even be inserted into the die. A much greater number of dies might be made in this way, than by taking dies flat. The dies would co'd colf, and be better executed. The silver would also run less risk of tearing, than by the flamp or the swage.

When these silver mouldings are formed, and the refuse metal poured off, they are laid upon a level plate, with the hollow side upwards. Small bits of resin are put into the hollow parts, and soft folder melted in with a foldering iron, the point of the fame being applied into the groove to keep it in a lathe of fusion. This is continued till the cavity is quite full. To prevent the folder from accidentally adhering to the convex part, it is previously covered with a paint-like compound of size and whitening. The name expedient is referred to in all cases where soft folder is employed, or when it is applied to great heat. The soft folder is formed of equal parts of lead and tin. The former metal has a great an affinity for lead, as to require the greatest care to keep these metals separate when one of them is in a state of fusion.

The silver wheels, thus filled with soft folder, will now admit of being bent into any form. After they are fitted accurately to the place they are to occupy, the part being first made clean and partially tinned, they only require to be secured by temporary fastenings, till the parts can be exposed to a degree of heat capable of melting the folder. This unites the ornament, without leaving any appearance of folder on the outside.

In forming fusibilities which have a massive appearance, such as the feet of tea urns, the handles of vessels, and plated table spoons, no other metal is employed but the facet. The mafs is formed of two shells, which, when put together, form an apparent fold. Each of the concave parts is filled filled with soft folder, they are then fitted accurately together, and heat applied till the mafs fuses, so that the apparently massive article consists of a shell of plated metal filled with soft folder. Bulky ornaments, in the form of shells and flowers, are frequently put on in this way; fame in silver. These have a similar massive appearance to, and strongly imitate, real plate.

All goods formed by hand with the hammer, require great labour in finishing. After hammering the vessel into the proper shape, the marks of the hammer appear like so many flat places. These are removed from the outside of the vessel to the inside, when the inside is concealed, as in tea urns. This is effected by covering either the anvil or the hammer with a piece of the flint called everlasti. The roughness is transferred to that surface in contact with the everlasting. In hammering plated metal from time to time, it requires to be annealed by heating it red-hot: this discolors both the silver and the copper. These are cleaned by boiling in dilute sulphuric acid, and scouring with Caal's sand. The sulphuric acid to the water is in very small proportion. If the silver begins to appear black by boiling, the acid is too much, and must be watered. When the vessels are finished in every respect by the maker, and the surface free from oxyd, it frequently happens that bits of rosin, used with soft folder, adhere to it. This is removed by boiling in a weak solution of pearl ashes. The name is also used for cleaning the face of tinned copper.

The vessels are now ready for burnishing, a process which we shall soon describe.
Our instructions hitherto have particularly applied to braziers' work; we shall next describe the candlestick-making.

In this branch of the business there is great variety. In the commencement of this trade the object was chiefly to imitate those made of silver, and it began with the prevailing taste of imitating the different orders of architecture. The numerous points and prominences thus introduced, were ill fitted for plated metal, as in a very little time their silver disappeared, which gave them the most shabby appearance possible. This obliged the manufacturers to make them more plain and simple, and it was not till the discovery of the silver edges, that candlesticks of plated metal began to gain respect in the world of luxury and fashion. The stems of candlesticks have been made square; some with sharp, others with rounded corners; others oval, but the greatest number with round items, which appear to be the most confin'd and the most permanent. Of these, the patent telescope candlestick has had the greater run. This consists in the cylindrical part lengthening and shortening at pleasure, by one tube sliding into the other. In this case the tubes are drawn by machinery, similar to that used for drawing the tubes of telescopes. The feet of candlesticks, or the base, are generally made in a die by the flax. The neck, which is sometimes small in one part, is also flamed. The diaphragm of the nozzle or socket is made in a die, and the tube part in the same way as the cylindrical pillar. These, for the sake of neatness and expedition, are generally drawn in the wire-drawing machine, whether for sliding or not. Some of these tubes are fluted. The prominent moulding and beads are generally of silver. The different parts are folded together, some parts with hard and others with soft folder. The branches of candlesticks are formed in two halves, like the tea urn feet, &c. In forming such articles as are made of wire, such as bread baskets, toast racks, and caskets, the wire is bent into the given form with a wood block and a mallet. When pieces require to be folded together, the joints must be accurately fitted, in order to prevent the copper from appearing. In these cases hard folder is employed. This branch of plated manufacture admits of extensive application. Wires are capable of great variety of positions. The work lately published by Sir James Hall, seems to prove that Gothic architecture has originated in the fanciful forms of bended twigs. The perusal of this work could not fail to give important hints to an ingenious manufacturer of plated wire work.

Plated goods, particularly tea-urns, and globular vessels for the same purpose, frequently require to be engraved; but it is obvious that, from the extreme thinness of the plate, the graver would lay bare the copper; and if the plate was so thick all over as to admit of engraving, the articles would be very expensive. Both these evils are obviated, by working an extra plate of silver on to the part to be engraved. This is done while the plate, of which the vessel is made, is in its flat form. The part where the engraving will fall is first scraped clean, and a plate of silver, of similar thickness to that employed for silver edges, is cut to the same size, and also scraped clean. The plated fleec is then laid upon a hot anvil, and the plate of silver laid upon the place prepared. It is first rubbed flowly, but with great pressure, with a polished hammer previously heated, but not so as to affect the polish. The plate will begin to adhere, and it may then be slightly hammered; ultimately it will adhere all over, and now may be hammered on a polished stake, till the whole surface becomes plane, and the piece of silver cannot be distinguished from the rest. This proceeds on the same principle as the plating of wire, and is similar to welding two pieces of iron together. It appears practicable that the surfaces of any malleable metals, when clean and heated to acquire a certain degree of softness, are capable of uniting. Most people are familiar with the union of two pieces of lead by pressure, even at the common temperature.

When the different plated goods come out of the hands of the workman, the metal, although clean, is of a dull white colour, polishing no polish whatever.

This last smith is called burnishing, and is generally performed by females in a distinct set of apartments. The burnishing tools are generally made of blood-stone, and some of hardened steel finely polished. The latter are to burnish the minute parts which cannot be touched by the blood-stone, which are employed chiefly for the greater and uninterrupted parts.

The bits of blood-stone are let into little cafes, made of sheet iron, and then finely polished.

The burnishers, if used dry, would adhere to the silver in some places, and would scratch instead of giving the fine polish intended. This is obviated by frequently dipping the burnishing tool into a solution of white soap. After being burnished they are raised, and lastly wiped with clean sheep's leather.

It is a circumstance much to be regretted, that silver, although it is susceptible of fine polish, does not keep its lustre. This is occasioned by the sulphur which comes from the sulphurated hydrogen, a gas always existing in the atmosphere. The thinness coating of any substance will prevent this change. If the surface of silver were coated with a solution of gum arabic or infusgalls, the defence will not be perceived, and the silver will never change colour.

We shall conclude this article with a few remarks upon the present mode of plated the ingots intended for sheets. It will be evident, that since the heat in plating must be equal to forming a portion of an alloy of silver and copper, which by its early fusion unites the two surfaces together, the silver will not be uniform in its quality, and by wearing will present an alloy having more than its proper quantity of copper; and will, in consequence, exhibit a base colour. It will be remembered, that the method used for plating the wire ingots does not admit of this inconvenience. The silver will keep its colour to the last. We shall no doubt hear, for some time when the plated manufacturers employ men of talent as platers, that the ingots for rolling will be plated by the method employed for the wire.

**PLATER, FELIX.** In *Biography*, an eminent physician of the 16th century, was born at Basle in 1536, of the college of which place his father was principal. Here Felix received his early education under his father's eye; and afterwards went to complete his medical studies at Montpellier, where he distinguished himself at an early age, and obtained the degree of doctor in 1566. He then returned to Basle, where he is said to have taken another degree in the following year, and settled in the practice of his profession. His reputation and success were soon equal to the promise of his education; for he was appointed to the chair of medicine in 1560, and became the confidential physician of the princes and nobles of the Upper Rhine. In addition to his medical skill, he possessed an extensive knowledge of anatomy, botany, natural history, and other branches of science, and contributed much by his talents and character to the celebrity of his native university, in which he was a teacher upwards of fifty years. He died in July, 1614, in the 78th year of his age, extremely regretted by his countrymen and his brother-professors. He left the following works: "De Corporis humani structure et usu Libri tres," Basle, 1583 and 1603, folio: "De 4 R". Febribus

Thomas Plater, the brother of Felix, also was a professor
of medicine at Balf, and had two sons, Felix and Francis,
the former of whom occupied successevly the chairs of logic

PLATERNETZA, in Geography, a town of Selavonia,
on the Save; 10 miles from Polzega.

PLATES, a cluster of small islands among the Bahamas.
N. lat. 23° 30'.

PLATESSA, in Ichthyology, a name by which Auto-
nius and fome other authors have called the paler-fish,
or common plaice. See Pleuronectes Plateaffa.

PLAT-FOND, in Architecture, the fame as foftit.

PLAT-FORM, in the Military Art, an elevation of
earth, a floor of wood or flone, on which cannon is placed
to fire on the enemy.

Such are the mounts in the middle of the curtains. On
the rampart there is always a platform, where the cannon
are mounted.

It is made by the heaping up of earth on the rampart, or
by an arrangement of madriers, rising insensibly for the
cannon to roll on, either in a cafeteria, or an attack in
the outworks.

Plat-forms are generally laid sloping towards the parapet,
nine or ten inches; this declivity carries off the rain, pre-
vents the gun from recoiling so much when fired as it would
do if laid level; and, when loaded, it is more easily brought
to the embrasure.

In temporary batteries, the plat-forms are made of planks
laid across ground-timbers or flappers, usually five in number,
and kept ready by flakes at each end; there is usually a
plat-form made to each gun; it is common by about eighteen
feet long, eight feet broad next the parapet, and about
fourteen feet broad at the tail, the intermediate spaces be-
tween the plat-forms serving for the shot and other neces-
farities. When a plat-form is to be laid on marly ground,
first lay a foor or two of falfines; cover thefe with hurdles,
twelve or fifteen feet long, and fix or even broad; on these
lay a floor of three or four inches of earth, and therein lay
the flappers, and over them the planks. When a battery is
built of stone or brick, the plat-form is generally a flat flone
pavement ranging the whole length of the battery; this,
on account of its defiling the injuries of the weather for a long
time, is to be preferred to planks; but in case of bombard-
ment such a plat-form is to be avoided, becaufe the fheilds
will not only break the pavement, but also, by driving
about the broken fones, do much mischief to the troops.

All practitioners are agreed, that no shot can be depended
on, unless the piece be placed on a solid plat-form; for if
the plat-form flakes with the firft impulse of the powder,
it is imposfible but the piece muft likewife flake; which
will alter its direction, and render its shot uncertain. To
prevent this accident, the plat-form is usually made extremely
firm to a coniderable depth backwards, fo that the piece is
not only well supported in the beginning of its motion, but
likefwise through a great part of its recoil. However, it is suf-
ficiently obvious, that when the bullet is feparated from the
piece, it can no longer afected by the trembling of the
piece or plat-form; and by a very easy computation it will
be found, that in a piece ten feet in length, carrying a bullet
of twenty-four pounds, and charged with fixteen pounds
of powder, the bullet will be out of the piece before it has
recoiled half an inch; when loaded it will be sufficiently
folid at the beginning of the recoil, the remaining part of it
may be much lighter, since its unfeadinefs beyond the firft
half inch will have no influence on the direction of the shot:
and hence a more compendious method of constructing plat-
forms may be found out. New Princip. of Gunnery, p. 42.

PLAT-FORM, in Architecture, is a row of beams, which
support the timber-work of a roof, and lie at the top of the
wall where the entablature ought to be railed.

PLAT-FORM is also used for a kind of terrace, or broad,
smooth, open walk, at the top of a building, from whence
we may take a fair prospect of the adjacent country.

Hence an edifice is laid to be covered with a plat-form,
when it is flat at top, and has no ridge.

Most of the oriental buildings are thus covered, as were
all those of the ancients. Cesar was the firft among the
Romans who procured leave to build his house with a
ridge or pinnacle.

PLAT-FORM, in a Man of War. See ONLOP.

PLATIA, in Geography, a small island in the gulf of
Engia; 18 miles N.W. of Engia.

PLATIAMOS, of πλαταῖος, I dilat, formed from πλαταίω, wide, a word used by many authors to express a
fault in pronunciation, owing to a person's opening his
mouth too wide, and thence speaking indistinctly.

PLATICORIA, formed of πλατικέω, wide, and σπυρή, pupil,
a word used by medical writers to express a presbyartical
dilatation of the pupil of the eye, usually owing to a paralytic
disorder.

PLATILLA, in Geography, a mountain of Spain,
N.W. of Molina; celebrated for its mines of copper.

PLATINA, Bartolommeo, in Biography, an historian
who flourished in the 15th century, was born in 1421, at
Piadena, in the Cremonese, from which place he chose to
take his surname, rather than from that of the family to
which he belonged, which was De Sacchi. He was brought
up to the military profession, and bore arms some time before
he engaged in literary studies, which he probably first purfued
at Mantua. He accompanied cardinal Francesco Gonzaga
to Rome, where Pius II. aggregatet him to his new college
of abbreviators. He was deprived of his poft by Paul III.,
who diffolved the college, and turned on the world, without
any means of support, seventy learned men, who had been
employed in it. Platina, who had more spirit than the
others, wrote to the pope, threatening him with an appeal
to a council. This menace enraged Paul to fuch a degree,
that he threw Platina into prison, where he was kept four
months, till he obtained his liberty by the intercession of
cardinal Gonzaga. Three years after this he underwent a
more severe treatment, on occasion of a contile between the
same pope and the Roman academy of Pomponio Leto,
of which Platina was a member. It appears from Platina's
own account of this tranfaction, that he himfelf was apre-
headed while at supper with cardinal Gonzaga, brought
before the pope, and urged with threats to confefs a
fupofed conspiracy againft him; and that he was committed
to prison, because he avowed his perfect innocence of the
crime laid to his charge. He and feveral of his friends
were put to the torture twice, but when nothing could be
found to criminate them, they were gradually liberated.
Platina obtained from Sixtus IV. a recompence for his fuf-
ferings, in the honourable poft of keeper of the Vatican
library, which he held till his death in 1481. In the fol-

...
they appear to be partly attracted by the magnet, which is no

doubt owing to the iron always mixed with them. Their

size varies from that of fine sand to that of a pea. No veins

or considerable masses of pure platina have ever been dis-
covered. Some fragments, however, weighing from 10 to

40 grains, have occasionally been found, and are preferred

as mineralogical curiosities. An extraordinary large speci-
men of this kind, exceeding the size of a pigeon's egg, was
given by Humboldt to the National Museum of France; it weighs 1288 grains, and its specific gravity is
15.6. It was found in 1800, in the mines of Taddo, in the

Platina, in the granular form just described, which is properly

that of an ore, still containing a variety of impurities, fluctuates in its specific gravity between 15 and 17.

In one instance Dr. Wollaston found it weigh 15.7; but this is the heaviest specimen he ever met with. (Phil. Trans. 1805.)

This ore scarcely contains 80 per cent. of the pure metal, and sometimes much less; the remainder being a mixture of a great variety of other minerals, such as gold, silver, mercury, iron, copper, lead, chrome, titanium, (Fournier and Vauquelin, Annales du Mufee, tom. iii.) and, what is very remarkable, no less than four new metals, iodium, omniun, rhodium, and palladium, the existence of which was not even suspected till a few years ago, and which have never been found elsewhere. Various iron impurities, and especially quartz and hyacinth, are also occasionally found mixed with this ore in different proportions. Wollaston, Phil. Trans. 1805.

Purification of the Ore.—Before we describe the properties of platina as a metal sui generis, it will be proper to relate the manner in which it is obtained, in a pure and malleable state, from the granular mixture just described.

Various difficulties occur, not only in separating the platina from the other bodies with which it is mixed in the ore, but also, and principally, in bringing the metal to the state of a consolidated malleable mass.

With regard to the separation and purification of platina, this might be effected in an imperfect manner, by leaching and picking out the grains of platina, which are discernible from the other ingredients by their external characters. This, however, would be a most tedious process, and the grains of platina would still be found to contain various impurities, and particularly iron, which would prevent their subsequent consolidation into a malleable mass. Besides, the great infusibility of platina would render such a mode of consolidation, if not impracticable, at least extremely difficult. After trying a variety of methods, more or less imperfect, for the purification of platina, chemists have generally adopted the following processes.

The first step consists in separating from the platina ore small globules of quicksilver, which are generally found mixed with it, in consequence of a process of amalgamation, which it undergoes in America, in order to separate the gold from it, when it is first collected. These are easily driven off by a moderate heat. A considerable portion of the other impurities may be easily separated, in consequence of their greater levity; thus, by blowing upon a quantity of these grains, spread over an inclined plane, with a common pair of bellows, the lighter particles, such as those of quartz and iron ore, are readily driven off from those of platina.

The gold, some portions of which always escape the process of amalgamation just mentioned, may be next separated by pouring a small quantity of dilute nitro-muriatic acid upon the grains of crude platina. The quantity of gold thus taken up commonly amounts to about a quarter of a
PLATINA.

grain from each ounce of the ore; but as much as 7, or in one instance as much as 13, parts of gold are said to have been obtained from 100 parts of the ore. (Proisst. Ann. de Chim. vol. xxviii.) In this first operation, a small quantity of platina and other ingredients will also be dissolved; but the gold may be easily precipitated from this solution by sulphate of iron, and the platina by muriate of ammonia.

After the separation of the gold, nitro-muriatic acid, being poured on the remaining mafs, will dissolve it, with the exception of a small quantity of black matter (about 3 per cent.,) which was formerly mistaken for plumago, but is now proved to be a compound of olimium and iridium, two of the four new metallic bodies before mentioned, which were discovered a few years ago by Mr. Tennant. See IRIDIUM and OSMIUM; and Phil. Trans. for 1804.

These two metals Dr. Wollaston has since shewn to exist also in the crude platina ore, united in the form of distinct minute crystalls, and dispersed through the other grains, from which they can be distinguished and picked out without difficulty. (Phil. Trans. for 1805.) Muriate of ammonia being now added to the solution, the platina is precipitated in the form of a yellowish powder, which is a compound of muriatic acid, ammonia, and platina, or an ammonia-muriate of platina.

The remaining solutio, after the platina has been separated from it, still contains, besides iron, minute quantities of various other substances, amongst which the two other metallic bodies, palladium and rhodium, were discovered by Dr. Wollaston. Phil. Trans. for 1804 and 1805. See also PALLADIUS and RHODIUM.

Confusion. — Having now brought the platina to the state of a salt, the next object is to restore the platina, thus purified, to its metallic state, and to confolditate it into a malleable mafs. This, from the great infusibility of platina, has long been a matter of considerable difficulty and labour; and although the process has been, of late years, considerably improved and simplified, it still requires from the operator a certain degree of dexterity and experience.

Before we describe the improved process in question, it may be proper to notice the earlier and less successful attempts, which were made for the confolidation of platina.

It had been long discovered that arfenic readily united with platina, and formed with it an alloy of great fusibility. An alloy, therefore, was made of crude platina and arfenic; and the latter metal, being easily volatilized, was driven off by heat: whilst the iron, being oxidated during the process, was also separated from the mafs; so that the platina was left in an impure, but malleable state. This mode of confolidation of the crude ore by means of arfenic, first proposed by Achard and others, was brought to a great degree of improvement by Jeannetty, a working fivermith of Paris (Ann. de Chim. vol. xiv.); and utensils of platina were procured by his method at a reasonable price. But the platina so prepared was far from being pure; for it had a lower specific gravity, and still contained small portions of arfenic, iron, lead, copper, besides the four new metals above mentioned; and it did not, therefore, polish in a sufficient degree those qualities which render platina so useful for its various purposes.

The late improvements in the process confit principally in obtaining the platina, not immediately from the crude ore, but from the ammonia-muriate above mentioned. By applying heat to this salt, the muriated ammonia is gradually expelled, and the metal passes to the state of a fpongy mafs, which, by patient and repeated heating and hammering in a frong mould, is at last brought to a malleable state. Count Moufîn Pouschkin was, we believe, the first perfon who proposed to prepare platina from the ammoniacomuriate (Nichelkon's Journal, vol. ix.); but he used mercury in the process. An amalgam was formed with the fpongy mafs above described; and by succifeively heating and hammering this amalgam, the mercury was driven off, and the metal was confolidated into a malleable mafs. This method was afterwards fooner simplified by other chemifts, the intervention of mercury being altogether difpenced with. One of the earlieft accounts of this laft improvement was published by Mr. Knight. (Phil. Mag. vol. vi.) But the most perfect description of this mode of working platias, that has yet been published, is that given by Mr. Cock, in Aikin's Dictionary, vol. ii. p. 233, which, being scarcely susceptible of abridgment, we shall transcribe verbatim.

"The platina being difolved in nitro-muriatic acid, the liquor is to be filtered through clean white sand, in order to separate the black powder which floats among it. The clear solution being then decomposed by fuf-fermammonie, the yellow precipitate is to be collected, moderately well washed in warm water, and dried. It is then to be distributed into faucers, which are placed in a small oven constructed for the purpofe, where they are exposed for a short time to a low red heat, in order to bring the platina to the metallic state, and drive off by fublimation the greater part of the muriated ammonia. When withdrawn, it is a fpongy mafs of a grey colour. About half an ounce of the platina in this state is to be put into a frong iron mould, about 2½ inches long, by 1½ wide, and is to be comprifed as forcibly as poflible, by friking with a mallet upon a wooden peffle, cut so as accurately to fit the mould; another half ounce is then added, and treated in the fame manner; and fo on, till fix ounces have been forced into the mould. A loofe iron cover, juft capable of flidmg down the mould, is then laid upon the platina, and, by means of a frong fcrew pref, almost every particle of air is forced out from the platina. This is a part of the procefs that requires fpecial care; for if any material quantity of air is left in the mafs, the bar into which it is formed is very apt, in the fubfquent operations, to fcale and be full of flaws. The prefure being duly made, the mould is to be taken to pieces, and the platina will be found in the form of a dense compact parallelopiped. It is now to be placed in a charcoaf forge fire, and heated to the moft intenfe white heat, in order completely to drive off the remaining ammoniacal muriate. This being done, it is to be quickly placed on a clear bright anvil, and gently hammerd in every direction by a clean hammer. This is to be repeated feveral times, at the end of which the mafs will be perfectly compact, and fit to be laminated or wrought in any other manner that the artifi choofes. It is to be oberved, that while the platina is heating, it muft be loofe in the fire; for if it were held by the tongs, they would infallibly become welded to the platina, and thus greatly damage it. By the time that the platina is thus drawn down to a compact bar, it will be covered by a fome what reddih femi-vitreous criff, proceeding chiefly from particles of the fufs melted down upon it, and extended over its surface by the hammer. To remove this, the bar, being made red-hot, is to be sprinkled over with pulverized glafs of borax, and then kept for a few minutes at a white heat. When moderately cool, it is to be plunged into dilute muriatic acid, by which the borax and other vitreous matter will be difolved, leaving the platina with a perfectly clean white surface."

It is by methods of this kind that utensils of platina, though still expensive, have gradually become less scarce, and are now much used in chemical manipulations.
metal may now (1814) be purchased in bars at the rate of 15s. an ounce; whilst a few years ago, its price was between two and three times as great. The price of platina, in grains, fluctuates between 3s. and 4s. an ounce.

**Physical and Chemical Properties of Platina.**—The colour of pure platina is between silver-white and steel-grey; its ductility and malleability are very great; it can be brought to the state of lamina of almost any thinness by being passed between rollers; and it can also be drawn into wire of extreme thinness. In hardness, platina is scarcely inferior to iron, and it is insusceptible of a fine polish; so that coins or medals made of pure platina would admit of very fine impressions, and, like gold, would not be liable to alteration.

The specific gravity of malleable platina is generally found to be about 21.3; never rising to 22 or 23, as some French chemists have erroneously stated; but being subject to flight variations according to the different degrees of density it has received during the process of hammering.

Gold, the next heaviest metal, is 19.3; and therefore the density of platina is much more considerable than that of any other known substance.

In its native state, however, the specific gravity of the platina ore does not, as was observed before, exceed 17.7; whilst that of the grains of iridium and osmium above mentioned is 19.15, which is a higher degree of specific gravity than that of any other known native substance.

The great ductility of platina has been put in a very striking light by some recent experiments of Dr. Wollaston. (Philos. Trans., 1834.) This philosopher, whose dexterity in mechanical operations is no less confinuous than his views in natural science are acute and refined, succeeded, by a new and ingenious process, in drawing platina wire so small as the 72,000th, or even 75,000th part of an inch in diameter; and the tenacity of the latter was still such as to support 11d grain without breaking. The method by which Dr. Wollaston succeeded in obtaining such very fine wire was shortly this: a piece of platina wire, previously drawn, by the usual means, to the 75,000th of an inch, was fixed longitudinally in the centre of a short cylindrical mould of 4d. of an inch in diameter; the mould being afterwards filled with melted silver, a cylinder of this metal was obtained, having the platina wire in its centre. Now it is evident, that by drawing the silver rod to 75,000th, the platina wire was reduced to 75,000th of an inch; and this was repeated, till, by a succession of similar reductions, the extremely small wires above-mentioned were obtained. The silver coating was then removed by dilute nitrous acid, which left the platina wire untouched. Very fine wires of this kind have been employed by Dr. Wollaston to measure the intensity of very small voltaic batteries, and have also been applied to some optical purposes.

But the most characteristic property of platina, from which it derives its great value, is that of being neither oxydizable by the combined influence of heat, air, and moisture, nor capable of being fused by the most powerful furnaces: on this account crucibles and other utensils are made of this metal, which are singularly useful in chemical experiments. In the state of wire, however, it can be fused and reduced to the state of globules by a very powerful voltaic battery; and Dr. Marcet has shewn that the same may be effected with great ease by the flame of a spirit lamp impelled by a current of oxygen gas. (Thomson's Annals of Chemistry, vol. ii.) Platina which has been thus melted, appears to be somewhat more ductile and tenacious; and it was from globules melted by the latter method, that the extremely fine wire above-mentioned was obtained. Platina wire, provided it be exceedingly fine, is also capable, as Tennant and Berzelius have lately observed, of being melted by the common blowpipe; but the globule thus obtained is so minute as to be scarcely ponderable.

Although platina can only be fused in very small quantities, whatever method be employed, it poiffles, at a white heat, the valuable property of welding like iron; so that two pieces, when heated to the proper point, may be forged together and united into one uniform mass. This, however, is not very easily effected, on account of the impurities which arise from the fuel and impede the operation.

Platina is not acted upon by the nitrates of the alkalies, except by the nitro-muriatic acid, or oxymuriatic acid. If two parts by weight of aquafortis of 35°, 36°, be mixed with five parts of muriatic acid of 15°, and digested with this laminie of platina, nitrous gas is given out, and about one part of the metal is dissolved. (Proust, Ann. de Chim. vol. xxxvii.) This solution is of a red-dish-orange colour, and gives an indelible stain to the skin.

The muriate of platina is capable of being crystallized by careful evaporation; and by the application of heat alone, it may be reduced first to the state of oxide, and afterwards to the pure metallic state.

Platina, thus dissolved in nitro-muriatic acid, has the property, (first discovered by Lewis, and already alluded to in describing the purification of platina,) of being precipitated by muriate of ammonia, in the form of a triple salt, or ammoniac-muriate of platina. This salt, if pure and unmixed with other metals, is of a yellow colour; but it is laid to assume a brick-red colour if combined with the oxide of iron, or the other metals which are mixed with crude platina. The ammoniac-muriate of platina is but very sparingly soluble in water; it is decomposed by heat alone, leaving behind about 32 per cent. of its weight of platina; so that, in this influence, the metal passes from the state of salt to the reguline state, without appearing in the intermediate form of oxide.

Both soda and potash, in precipitating platina from its solution, also form triple salts, the general properties of which are analogous to those of the former. There is, however, this remarkable difference between the action of the two fixed alkalies on muriate of platina, that solutions of this salt, however dilute, are instantly precipitated by potash or its compounds; whilst soda does not produce any precipitates from them, the soda-muriate being much more soluble than the two others, both in water and alcohol, and requiring considerable concentration for its crystallization. A solution of platina, therefore, affords an easy test of discrimination between the two fixed alkalies, which are not always easily distinguishable by their other properties.

Solutions of muriate of platina are decomposed by several metallic salts, particularly by solution of muriate of tin, a very minute quantity of which will impart to solutions of platina a bright red colour. Platina, however, is not precipitated by the gallic and profleric acids, or by their compounds. Sulphuretted hydrogen separates platina from its solution in the form of a brown precipitate.

The action of the caustic fixed alkalies on platina, at high temperatures, is considerable. The metal is corroded and partly dissolved, a circumstance which, of course, limits the use of platina crucibles in the analysis of earthy minerals.

Nitre, likewise, as Mr. Tennant has shewn, is capable of acting upon, and partly dissolving platina, at high temperatures.

Platina is capable of combining, by fusion, with most of the metals. It forms alloys with gold, with silver, with lead, &c., many of which have been examined by Mr. Hatchett. (Philos. Transact. 1803.) The alloy of platina and gold, in particular, poiffles properties, especially
in regard to its hardnefs and malleability, which may some day be found useful. The alloy of platina and silver is moderately fusible and very malleable; but when heated to redheat, its surface becomes uneven, and incapable to be wrought. Lead combines readily with platina at a full red heat, forming a malleable and easily fusible alloy. Mercury acts but slowly upon platina in its malleable state; but the triple salt, or ammoniac-muriate, readily combines with mercury by trituration, forming solid and brilliant amalgams.

Platina does not appear to be capable of combining with sulphur; but it unites readily with phosphorus, forming a phosphuret of much greater hardness and fusibility than the metal itself. When exposed to a strong fire, the phosphorus is melted and volatilized; a circumstance which has suggested the idea of purifying platina by the intervention of phosphorus. Pelletier, Ann. de Chim. xiii. 105.

Platina has hitherto been extensively used in the arts on account of its high price; but its utility is becoming every day more generally acknowledged. From its great infusibility and unalterability in particular, crucibles, and other utensils made of this metal, are of incalculable value in analytical researches. Many facts are daily brought to light by means of platina instruments, which, without it, might perhaps ever have escaped notice. The remarkable flow-means with which platina conducts calorific, increases its utility in many chemical manipulations. Thus small tongs or spoons, or thin slips of laminated platina (which often answer the purpose better than spoons) may be held with the hand by one end, whilst the other extremity is exposed to an intense heat, without the heat reaching the fingers. The touch-holes of guns are now generally made of this metal, instead of gold, which was formerly used for this purpose. From the circumstance of platina not being tarnished by air or moisture, nor feared by any chemical agent, mirrors for reflecting telescopes have been made of this metal; and instruments of various kinds might, no doubt, be covered over or plated with it with great advantage.

Guyton Morveau has recommended platina as a substan- chance likely to afford a new and useful means of ascertaining high temperatures, by its dilatations and contractions, which he believes to bear an exact proportion to the changes of temperature. Platina being nearly infusible and unalterable by heat and air, would seem, on these accounts, likely to be a valuable pyrometrical substance. Morveau's contrivance consisted in connecting a bar of platina with a very simple machinery, by which the elongations or contractions of the portion of the apparatus which was exposed to the heat, were rendered conspicuous, and could be accurately measured. Ann. de Chim. tom. xvi.

Platina vessels have, in a few instances, been used upon a large scale in manufactories, especially in the concentration of vitrific acid, which is usually carried on in large glass retorts, containing as much as 50 or 60 pounds of acid. The burning of these vessels, an accident both dangerous and expensive, and by no means uncommon, may be totally avoided by substituting vessels of platina. A vessel of this metal, containing 300 pounds of vitrific acid, has, for many years, been used for this purpose in the manufactury of Mr. Sandmann in the Borough. Still larger vessels have since been used for the same purpose by other manufacturers. The distillation is also more easy, because the vessel is set upon a naked fire, instead of being placed in a band bath.

The metallic glazing, with which some kinds of earthen ware and porcelain utensils have, for a few years past, been coated, is obtained from oxyd of platina. (Klaproth's Dictionary, iii. 382.) This glazing has a brilliant silverly, or rather fleck-grey lustre. The ammoniac-muriate of platina is said to be commonly employed in British potteries for this purpose.

PLATISMA, in Botany, from παστικα, broad, the name of the nineteenth section of Lichens, in the Promordium of Achariae. See LICHENES.

PLATNER, John Zachariah, in Biography, an able physician, was born at Chemnitz, in Mifnia, in August 1694. His father, who was one of the principal merchants of the place, intended to make him his successor in the same line; but resolved to enlarge his mind by a liberal education, and to give him a knowledge of ancient languages and philosophy, before he led him into commercial pursuits. But young Platner professed a delicate constitution; and, partly on this account, and partly in consideration of the rapid progress which he made in his studies, his parents relinquished their original design, and confided that he should direct his attention to medicine, for which he had manifested a strong inclination. He repaired, therefore, to Leipfìc in 1712, where he pursued his studies for the space of three years, when the reputation of the university of Halle induced him to visit its schools. During the following winter, he studied mineralogy and metallurgy in the celebrated mines of Chemnitz; after which he returned to Halle, and received the degree of doctor in September 1716. The pursuit of professional knowledge became his passion, and he spent four years in visiting the most celebrated seats of learning in Europe. At Paris he particularly attended to anatomy and surgical operations, especially to those relative to diseases of the eye, in which he is said by Haller to have acquired such dexterity, as to have succeeded in the cure of some, which the celebrated St. Ives had failed to relieve.

He now determined to settle at Leipfìc, and accordingly fixed himself in that city in 1720; and his great professional acquirements were speedily rewarded by public acknowledgements of their value. In 1721 he was appointed professor extraordinary of anatomy and surgery. In 1724 he obtained the chair of physiology, which had become vacant by the death of Riviònus; in 1737 he was promoted to the professorship of pathology; and in 1747 to that of therapeutics. He was also nominated perpetual dean of the faculty, and confuting physician to the court of Saxony. He did not live long, however, to enjoy these flattering distinctions; for he was carried off suddenly, on the 19th of December 1747, in the fifty-fourth year of his age, by a paroxysm of asthma. He had visited his patients on the morning of that day, and given his lecture after dinner; and upon returning home, about fix in the evening, was seized with the fatal fit.

He left only three different works, the first of which, entitled "Inflations Chirurgicæ Rationalis, tum medicæ, tum manualis," Leipfìc 1749, was published by himself. It passed through several editions. The second, entitled "Opusculorum Chirurgicorum et Anatomicorum Tomi duo; Differentiores et Prolusores," ibid. 1749, was edited by his son, Frederic Platner, a professor of law. And the third, entitled "Ars medendi fugulis morbis accommodata," ibid. 1765, which had been bequeathed by the author to his pupil J. B. Bohmer, upon condition that it should not be published, was printed by a bookseller, Fritsch, into whose hands a copy of it fell eighteen years after the author's death. Eloy Diet. Hîll. de la Meû.

PLATO, a Greek comic poet, who flourished about the close of the fifth century B.C., was contemporary with Aristophanes and Euripides. He is said to have left

PLA

PLA
twenty-eight comedies, of which the titles of many are to be found in Athenæus, Pollux, and other writers. Of his works, only a few fragments remain, none of which are of the epigrammatic kind.

PLATO. See PLATONISM.

We shall here observe, that Plato, Ariototle, Aristoxenus, and Plutarch, were for ever complaining of the corruption and degeneracy of music. The pious Plato, indeed, regarded it as fit only for the gods, and their celebration in religious ceremonies, or as a vehicle for religious and moral lectures in the education of youth; and with a methodical spirit, confined all such as was used in theatres, vocal facility, or domestic amusements: but modern divines might, with equal propriety, declaim against the profane use of bread as an aliment, because it is administered in the most solemn rite of our religion. A line should certainly be drawn between the music of the church and of the theatre; but totally to silence all musical sound, except upon solemn occasions, seems to border upon downright fanaticism.

With respect to perfection and depravity, there is nothing so common among musical disputants, as for the favourers of one sect to call that degeneracy, which those of another call refinement. But Plato seems to have been always too fond of ideal excellence in every thing, to be satisfied with any other. His complaints of the degeneracy of music, may be seen in his third Book of Laws. The poets, indeed, never fail to charge the corruption of music upon its professors, yet Plato throws the blame upon the poets themselves. "The music of our forefathers," says he, "was divided into certain species and figures. Prayers to the gods were one species of song, to which they gave the name of hymns: opposed to this was another species, which, in particular, might be called threnoi; another, psalms; and another, the birth of Dionysus, which I hold to be the dithyrambus; there were also cathartic Motions, so called, as being still another song. These, and some others, being preferred, it was not allowable to use one species of melodies for another. But, in process of time, the poets first introduced an unlearned licence, being poetic by nature, but unskilled in the rules of the science, trampling upon its laws, over attentive to pleasing, mixing the threnoi with the hymns, and the psalms with the dithyrambi, imitating the music of the flute upon the cithara, and confounding all things with all." Plat. de Legibus, as translated by F. H. E. Stiles. Though it was Plato's opinion, that the government of a state, and the morals of a people, would be affected by a change in the national music, yet this was not the opinion of Cicero, who in many other particulars is a rigid Platonist: "Change," says this orator, "the government and customs of a city, and it will certainly change the music." De Legib. lib. iii.

It has been said by many writers, both ancient and modern, that Plato was deeply skilled in the music of his time; but it does not appear that his claims to skill in this art extend further than to mere theory, or a very little more. Plutarch, indeed, in his dialogue, proves his profound musical science; but how? By a long paean from his Timæus, in which he applies musical ratios to the soul.

However this may have been, it is difficult to refrain from numbering this philosopher, together with Aristotle, Aristoxenus, and Plutarch, though such illustrious characters, and, in other particulars, such excellent writers, among the musical grumblers and croakers of antiquity. They all equally lament the loss of good music, without considering that every age had, probably, done the same, whether right or wrong, from the beginning of the world; always throwing musical perfection into times remote from their own, as a thing never to be known but by tradition. The golden age had not its name from those who lived in it.

Aristotle, indeed, complains of degeneracy in a more liberal way: "every kind of music," says he, "is good for some purpose or other; that of the theatres is necessary for the amusements of the mob; the theatrical transitions, and the tawdry and glaring melodies in use there, are suited to the perversion of their minds and manners, and let them enjoy them?"

The complaints of Aristoxenus are more natural than those of Plato and Aristotle; for he was not only a philosopher, but also a musician; and, as a professor, and an author on the subject of music, he must have had rivals to write down. He lists the bad habits that harden ears, and beggars beggars. And it has been the practice for writers on music, in all ages, to treat their contemporaries with severity and scorn. Gaëtan Pintz infests his book a canononet in four parts, in which every rule of composition is violated, and calls it modern; as if error was always new. But besides a natural tendency in human nature, or at least in the nature of authors, towards envy and malignity, Aristoxenus had a system to support, which is usually done at the expense of moderation, truth, and every thing that stands in its way; for, like the tyrant Procrustes, the builder of a system, or the defender of a hypothesis, cuts shorter what is too long, and stretches to his purpose whatever is too short.

The music of the Greeks, in the time of Aristoxenus, was too remote from perfection to be much injured by innovation and refinement; and yet Athenæus gives a passage from a work of this writer, now lost, in which he makes the following complaints: "I, and a few others, recollecting what music once was, and considering what it now is, as corrupted by the theatre, imitate the people of Paphlagonia, who annually celebrate a festival after the Greek manner, in order to keep up the memory of what they once were; and before they depart, with tears deplore the barbarous state into which they are brought by the Tuscan and Romanas."

Though Aristoxenus lived with Alexander the Great, with Plato, and with Aristotle, when all other arts and sciences had arrived at their greatest degree of force and refinement; yet music, from whatever cause, does not seem, at that, or at any time, to have kept pace with other arts in its improvements: at least, it did not in Italy; nor, indeed, in England or France, if we compare the poetry of Milton with the music of Henry Lawes, or the writings of Racine and Boileau, with the compositions of Lully.

PLATOBERG, in Geography, a mountain of France, in the department of Mont Tonnerre; four miles N. of Landau.

PLATONIA, in Natural History, a name given by the modern Greeks to the prox of Aristoxen, and of other ancient writers in that language. This is the cervus puscereus, or broad-horned stag. Some have translated this dama; but they are to be understood in this as meaning the dama of their own times, not that of the ancients; that being the iba, or chamois-goat, not any animal of the stag kind, or by any means meriting that title.

PLATONIC, something that relates to Plato, his school, philosophy, opinions, or the like.

PLATONIC Bodies, are the name with what we otherwise call regular bodies.

PLATONIC Love denotes a pure spiritual affection, fulfilling between the different sexes, abstracted from all carnal appetites, and regarding no other object but the mind, and its beauties; or it is even a sincere disinterested friendship.
fustihing between persons of the same sex, abstiruted from any filthy views, and regarding no other object but the person.

The term took its rise from the philosopher Plato, a fene-
rous advocate for each kind.

The world has a long time laughed at Plato's notions of
love and friendship. In effect, they appear arrant chimeras,
contrary to the intentions of nature, and inconsistent with
the great law of self-preference; into which love and
friendship are both ultimately reducible.

Platonic Year, or the great year, is a period of time de-
termined by the revolution of the equinoctuses, or the
space in which the planets and comets return to their former
places, in respect of the equinoctuses.

The Platonic year, according to Ptolemy Brahe, is
25816; according to Ricciolius, 25920; and according to
Calmus, 25900 years. See Periplus of the Equinoctuses.

This period, which is more than five times the age of
the world, once accomplished, it was an opinion among the
ancients, that the world was to begin anew, and the same series of
things to return again.

Platonism, the doctrine and sentiments of Plato
and his followers, with regard to philosophy, &c.

The founder of this system of philosophy, Plato, the son
of Aristocles, was an Athenian, related by his father to Codrus,
and by his mother to Solon; born in the island of Megara,
where his father retired after it became subject to Athens,
on the seventh of Thargelion, in the first year of the 88th
olympiad, B.C. 428, or, as it may be more accurately
fixed, in the third year of the 87th olympiad, B.C. 430.

He gave early indications of a distinguished genius; and
whilst he was young he was instructed in the rudiments of
letters by the gramianer Dionysius, and trained in athletic
exercises by Arifto of Argos. He applied with industry to
the study and practice of painting and poetry. In the latter
he made such proficiency as to produce an epic poem, which,
however, upon comparing it with Homer, he committed to
the flames; and at the age of 20 years he composed a dra-
matic piece, which he delivered to the performers in order
to its being exhibited on the theatre; but in the mean while
he became acquainted with Socrates, and so much enamoured
of his philosophy that he was the first to have been
represented to the public he withdrew it, and gave up all ideas of
poetical distinction. After having spent his youth in exercises of the body, painting, poetry, and music,
he became, at the age of twenty years, a disciple of So-
crates, and applied himself wholly to the study of wisdom.
It is supposed, that he received the first dictate of philo-
sophy from Cratylus and Hermogenes, who taught the
syllables of Heracleitus and Parmenides. But having become
a skilful disciple of Socrates, he remained with him eight
years. Blending, however, foreign tenets with those of his
master, and grafting upon the Socratic system opinions
which he had taken from some other rock, he occasionally
deployed the followers of Socrates, and sometimes gave
Socrates himself occasion for complaint. Nevertheless, he
retained a zealous attachment to this master, and when he
was summoned before the Senate, Plato undertook to plead
his cause, and began a speech in his defence, which the par-
tiality and violence of his judges would not allow him to
proceed. After the condemnation of Socrates, he pre-
ferred him with money enough for redeeming his life,
which, however, this eminent teacher of wisdom refused to
accept. During his imprisonment, Plato attended him,
and was present at a conversation which he held with his
friends concerning the immortality of the soul, the fab-
flance of which he afterwards committed to writing, in the
beautiful dialogue entitled "Phaedo," intermixing occa-
onally his own opinions and language. Upon the death of
his master he withdrew, with several other friends of So-
crates, to Megara, where they were hospitably entertained
by Euclid, and remained till the ferment at Athens subsi-
ded. Under Euclid he studied the art of reasoning, and
probably increased his fund of disputation. With a
view of furnishing himself with all the knowledge which
the age in which he lived could supply, he travelled into
every country which was likely to answer any useful purpose
for him in this respect. In that part of Italy called Magna
Grecia, there was a celebrated school established by Pytha-
goras, and here he was instructed in the mysteries of the
Pythagorean system, the subtleties of which he afterwards
too freely blended with the simple doctrine of Socrates.
He next visited Theodorus of Cyrene, in order to be in-
ftructed in mathematical science; and he then determined to
study astronomy, and other sciences, in Egypt. Under the
dignity of a merchant, and seller of oil, he traversed the
whole kingdom of Artaxerxes Memon, deriving informa-
tion from the Egyptian priests concerning their astronomical
observations and calculations. In Egypt, it is said, he
acquired his opinions concerning the origin of the world,
and learned the doctrines of the tranmigration and immor-
tality of the soul; but it is more probable, that he learned
the latter doctrine from Socrates, and the former from Py-
thagoras. All things considered, it is not very likely that
Plato derived his system of philosophy from the Egyptians;
but it is more probable, that during his residence in Egypt,
Plato became acquainted with the doctrine of the Hebrews,
and enriched his system with spoils from their sacred books.

The Platonic philosophy appears, in many respects, very
confident with the Mosaic; and a great party of the prir-
mative fathers follow the opinions of that philosopher, as
being favourable to Christianity. Justinus is of opinion, that
Plato could not learn many things which he has said in his
works, from mere natural reason; but thinks he might have
learnt them from the books of Moses, which he might have
read when in Egypt.

Hence Numenius the Pythagorean expressly calls Plato
the Attic Moses, and upholds him with plagiarisms; because
he flos his doctrine about the world and God from the
books of Moses.

Theodoret says expressly that he has nothing good and
commendable about the Deity and his worship, but what he
itole from the Hebrew theology; and Clemens Alexander
calls him the Hebrew philosopher.

Galat is very particular in his proof of the point, that
Plato borrowed his philosophy from the scriptures, either
immediately, or by means of tradition; and, besides the
authority of the ancient writers, he bring some arguments
from the thing itself. As, e. gr. Plato's confession, that
the Greeks borrowed their knowledge of the one infinite
God from an ancient people, better and nearer to God
than they; by which people, our author makes no doubt,
he meant the Jews, from his account of the state of inno-
cence; as, that man was born of the earth, that he was
naked, that he enjoyed a truly happy state, that he con-
verted with brutes, &e. In effect, from an examin of all
the parts of Plato's philosophy, physical, metaphysical, and
eethical, this author finds, in every one, evident characters
of the sacred original.

St. Augustine commends the Platonic philosophy; and
even says, that the Platonists were not far from Christianity.
He adds, that the generality of the new Platonists of his
time embraced the faith; and he expressly acknowledges,
that it was by means of the Platonic sytem he was able to understand the doctrine of the Trinity.

Justus Martyr professes, that Plato's doctrine was of the utmost advantage to him, in helping him to believe the mysteries of the Christian faith. To which it may be added, that it was, in good measure, by Plato's help, that Origen confuted Celsus.

Indeed, the late author of "Platonism Devoide" carries things to an extravagant length, when he contends, that the dogmata of our religion are only the opinions of Plato; that the fathers give us nothing of the mysteries thereof, but what they learnt from him; and that Christianity is only Platonic veiled, or covered over. To which opinion, however, M. le Clerc seems also a little inclined.

The opinion, that Plato borrowed the dogmata of his philosophy from the scriptures, which has been strenuously maintained by several Jewish and Christian writers, has, however, as others maintain, little foundation besides mere conjecture; and it is supposed to have originated in that injudicious zeal for the honour of revelation, which led these writers to make the Hebrew scriptures, or traditions, the source of all gentile wisdom.

The chief grounds upon which the above-mentioned opinion rests are the following; 1. The authority of the Jewish writers, Josephus and Arifolobus, and of the Christian fathers, Justus Martyr, Clemens Alexandrinus, Eusebius, Cyril of Alexandria, Theodoret, Ambrose, and others.

2. The opinion that a Greek version of the Hebrew scriptures appeared in Egypt before the time of Plato, which he might have seen and read, as Clemens Alexandrinus and Eusebius, on the testimony of Arifolobus, assert. 3. The premissum, that the Egyptians borrowed many of their tenets from the Israelites, and communicated them to Plato. And 4. The agreement of the doctrines of Plato with those of the Hebrews. But to these arguments it has been replied, 1. That the testimony of the Christian fathers is, with regard to the present question, of little value; as they had recourse to no authentic memorials or impartial witnesses, but credited the assertions of certain Jewish writers, who, several centuries after the time of Plato, with a view of gratifying their own vanity, and that of their countrymen, pretended that all gentile wisdom had been originally derived from Moses; and particularly, that Plato, during his residence in Egypt, had been instructed in the Hebrew school. This notion was eagerly adopted by several learned Plato- nists, who in the second century were converted to Christianity, but still retained an attachment to their former matter; and from this time it became a common practice among those who affected the credit of Greek erudition, to maintain, that whatever opinions Plato and his followers held, similar to the doctrines of revelation, had been borrowed either from the Hebrews or Christians. 2. A Greek version of the Hebrew scriptures, prior to the time of Alexander, never existed but in the brain of Arifolobus. 3. Equally unconfirmed is the assertion, that the Egyptians, and even Plato himself, converted with the Jews on theological subjects. Lastly, no proof of the point in question can arise from the supposed agreement between the Mosaic and Platonic doctrines; for the agreement is either imaginary, or it consists of such particulars as might be easily discovered by the light of reason. Besides, the true doctrine of Plato was so far adulterated and blended with other systems in the Alexandrian school, that those Christian fathers who had studied Platonism in this school, might easily conceive that there was a greater harmony between the Platonic doctrine and their own creed than in reality existed.

Plato, after having availed himself of all the information which he could receive in distant countries, returned to the Pythagorean school at Tarentum, in Italy, and here he attempted to improve his own sytem by incorporating with it the doctrine of Pythagoras. In recounting the sources of Plato's philosophy, we may observe, that he borrowed his dialectics from Euclid of Megara; the principles of natural philosophy he learned in the Eleatic school, from Hermogenes and Cratylus; and combining these with the Pythagorean doctrine of natural causes, he framed from both his system of metaphysics. In mathematics and astronomy he was instructed in the Cyrenian school, and by the Egyptian priests. From Socrates he imbibed the pure principles of moral and political wisdom, the simplicity of which he afterwards obscured by Pythagorean speculations. At length Plato, with his mind thus richly furnished, settled at Athens, and accomplished the design which he had long meditated, of forming a new school for the instruction of youth in the principles of philosophy. The place he chose for this purpose was a public grove, called the Academy; which see. Here he established his school, and over the door of it, in order to indicate its respect for mathematical studies, and how necessary a preparation he thought them for higher speculations, he placed this inscription, τῦπος ̓ αρτιμάνων ἀνὰ ἱστορίας: "Let no one, who is unacquainted with geometry, enter here." This school became famous, and was crowded not only by young men from every quarter and of every distinction, but by females disguised in men's clothes. Among the most illustrious of his followers we may reckon Dion, the Syracuse prince, and the orators Hyperides, Lycurgus, Demosthenes, and Hierocrates.

Such a distinguished reputation excited among the companions of Plato, formerly the disciples of Socrates, a spirit of emulation, which degenerated into envy, and which terminated in detraction and obloqui. To this natural jealousy it was owing, that Xenophon and Plato, though they related the discourses of their common master, modestly avoided to mention one another. Diogenes the Cynic ridiculed Plato's doctrine of ideas, and other abstract speculations. Nevertheless, the fame of Plato increased, and his political wisdom was held in such high estimation, that several states solicited his assistance in new-modeling their respective forms of government. The Arcadians and the Thebans applied to him for this purpose, but he rejected their applications, because they refused to adopt the plan of his republic, which required an equal distribution of property. He gave his advice to several Grecian states, and furnished them with codes of law for Syracuse. At three different periods he visited the court of Dionysius, tyrant of Sicily, and made several attempts to subdue his haughty and tyrannical spirit. The object of his first visit to Sicily, in the fortieth year of his age, was to survey the island, and to observe the wonderful phenomena of mount Etna. During his residence at Syracuse, he was employed in the instruction of Dion, the king's brother-in-law; and in his efforts to rescue his pupil from the baneful influence of the general depravity, he was not dis- appointed. Dion, infatuated with the love of wisdom, was de- ficient in introducing his preceptor to Dionysius, the tyrant; but his discourse with him being levelled against the vices and cruelties of his reign, the tyrant conceived a prejudice against Plato, and formed a design against his life, which by the assistance of Dion he execrated. Having engaged Pollio, a delegate from Sparta, to take charge of the philosopher, and to lead him safely in his own country, Dionysius attempted to defeat his friendly purpose, and engaged Pollio either to put him to death, or to sell him as a slave, in his passage. Accordingly, Pollio held him in the island of Aegina, the inhabitants of which were at war with the Athe-
PLATONISM.

nians. Here he became acquainted with Anicerris, a Cyrenean
philosopher, who testified his respect for Plato, by purchasing
his freedom for thirty mine, and sending him home to
Athens; and when Plato's relations afterwards wished to re-
pay the money which Anicerris had advanced, he declined
accepting it, alleging, with the genuine spirit which true
philosophy always inspires, that he saw no reason why Plato's
relations should engross to themselves the honour of serving
him.

After much solicitation and delusive promises on the part
of Dionysius, Plato took a second journey to Syracuse,
where he was received by the king with singular respect,
and sacrifices were offered in congratulation of his arrival.
It was not long, however, before Dion was banished into
Italy, and Plato was sent back into his own country. Dio-
nyus again renewed his intrigues for the return of Plato to
his court, who arrived a third time at Syracuse, and for
some time professed the chief influence and authority
there. But finding it impossible to prevail upon Dionysius
to adopt his system of policy, or to recall Dion from his exile,
a mutual distrust arose between the tyrant and the philo-
osopher, and Plato, disinterested with his situation, car-
nearly requested permission to return to Greece. After
some delay permission was granted, and a vessel of convoy
was provided; but the tyrant again changed his mind, and
declined to send Plato to Syracuse on account of his inclina-
tion. The tyrant's seeming respect was converted into rage,
and the philosopher was dismissed from court, and committed
to the custody of soldiers. When his Pythagorean friends at Ta-
rentum heard of his dangerous situation, they dispatched an
embassy to Dionysius, demanding a fulfilment of his pro-
mises; and the tyrant, dreading the conceptions of a re-
fusal, and the disgrace of having banished from his court the
first philosopher of the age, gave Plato a magnificent en-
tertainment, and sent him away loaded with rich presents.

Plato, reclining to his country and his school, devoted
himself to science, and spent the last years of a long life in
the instruction of youth. Having enjoyed the advantage of
an athletic constitution, and lived all his days temperately,
he arrived at 81, or, according to some writers, the 79th
year of his age, and died, through the mere decay of nature,
in the first year of the 108th Olympiad, B.C. 348.

He passed his whole life in a state of celibacy, and as he
had no natural heirs, he bequeathed all his effects by will to
his friend Adamantus. The grove and garden, which had
been his philosophers' real labour, at last afforded him a sepulchre.
Statues and altars were erected to his me-
ory: the day of his death long continued to be celebrated
as a festival by his followers; and his portrait is to this day
preferred in gems: but the most permanent monuments of
his genius are his writings, which have been transmitted,
without material injury, to the present times.

The character of Plato has been differently appreciated.
Whilst some have extolled him with the language of mere pa-
trypugyric, as if he had been free even from human frailties,
others have loaded his memory with unjust obloquy and rep-
touch. Several anecdotes are preferred which reflect ho-
our on his moral principles and character. Such was his
command of temper, that whilst he was lifting up his hand
to correct his servant for an offence, and perceiving himself
angry, he kept his arm in that elevated posture, and said to
a friend, who asked him what he was about to do, "I am
punishing a passionate man." At another time, he said to
one of his lovers, "I would chastise you if I were not angry." At
the Olympic games he passed a day with some strangers,
who were delighted with his affable conversation, and who
merely knew that his name was Plato. When they parted,
he invited them, if they should visit Athens, to take up
their residence at his house; they accepted his invitation,
and were courteously entertained. During their stay, they
expressed a wish to be introduced to his nameake, the fa-
mous philosopher, and to be shown his academy. Plato,
smiling, said, "I am the person you wish to see." The
discovery surprized them, nor could they easily persuade
themselves, that a philosopher, so eminent, would con-
found to converse so familiarly with strangers. When he was
informed that his enemies were industriously circulating re-
ports to his disadvantage, he said, "I will live so, that none
shall believe them." One of his friends remarking that he
seemed no less defers to learn himself, than to teach him,
asked him, how long he intended to be a scholar? As
long," says he, "as I am not ashamed to grow wiser and
better.

Of his merit as a philosopher, we may form the most fa-
satisfactory judgment from his writings. As to his style, it
retained that strong tincture of a poetical spirit, which he
in discovered in his first productions. Hence have proceeded
those encomiaums which ancient and modern critics have puffed
up upon his language; and on this account it was held in high
estimation by Cicero, who says, that "if Jupiter were to
speak in the Greek tongue, he would borrow the style of
Plato, and describes it as "a middle species of dic-
tion, between verse and prose." Moft of his dialogues, in-
depependently of the copious and splendid diction that en-
riches them, are justly admired for their literary merit: the intro-
ductions are pertinent and amusing; the course of the debate,
or conversation, is clearly marked; the characters are ac-
curately supported; every speaker has his proper place, lan-
guage, and manner; the scenery of the conference is painted
in lively colours; and the whole is, with admirable art,
adorned and enlivened by those minute embellishments which
render the colloquial mode of writing fo peculiarly plea-
ing. Even upon abstract subjects, moral, metaphysical
or mathematical, the language of Plato is often clear as
the running stream, and in simplicity and sweetness vies
with the humble violet which perfumes the vale. In
these beautiful parts of his works, it has been conjectured,
and not improbably, that Socrates and Lyfias were his mo-
dels. At other times, his style is turgid and bombast,
puerile or frigid, and his metaphors are harsh, and he is too
fond of introducing new terms, with a bold and unwarrant-
able innovation. Faults of this kind have been noticed
and censured by several ancient critics. His conceptions also
have been charged with an irregularity, similar to that of his
style. Whilft he adheres to the school of Socrates, and dif-
courses upon moral topics, he is much more pleasing, than
when he loses himself with Pythagoras, in abstract specu-
lations.

The Dialogues of Plato are classed by the ancients under
the two heads of "didactic" and "inquisitive." The
former are divided into "speculative," including physical and
logical; and "practical," comprehending ethical and political.
The latter, or "inquisitive," are characterized by terms taken
from the athletic art, and divided into the "gymnastic,"
and the "agonistic:" those termed "gymnastic," suppos-
ted to be similar to the exercises, were subdivided into the
majestic, as resembling the teaching of the rudiments of the
art, and the 

The
The writings of Plato were originally collected by Hermodorus, one of his pupils: they consist of 32 dialogues, and 15 epistles. They were first published, after the invention of printing, by Aldus Manutius, at Venice, in 1515. The editions of Cicero and Serranus are the most valuable; but the notes and interpretations should be read with caution; for Cicero, having formed his conceptions of the doctrine of Plato after the model of the Alexandrian school, frequently, in his "Arguments," misrepresents the design of the author, and in his version obscures the sense of the original; and Serranus, for want of an accurate acquaintance with the doctrine of his author, and under the influence of a strong predilection for the iconoclastic system of theology, sometimes gives an incorrect and injudicious explanation of the text.

Availing ourselves of the excellent work, which has furnished the materials of this article, we shall now proceed to detail the philosophical system of Plato, in order to which some general observations should be premised. Plato, declining the sober method of reasoning introduced by Socrates, left his first master in search of other preceptors. Inclined to speculative refinement, and mired by the celebrity of the Italian school, which abounded in subtleties, he attached himself to the Pythagorean philosophy; and pursuing this bias, he was thrown from the Pythagorean sect to the Egyptian priests, he devoted still farther from the plain path of common sense, which had been pursued in the Sophistic school. Among other errors which he adopted from foreign philosophy, it was not the least that he borrowed the art of concealing his real opinions; and hence his writings became not only relatively, but perhaps desirably, obscure. After the example of Pythagoras, he threw a veil of obscurity over his public instructions, which was removed only for the benefit of those who were admitted to his more private and confidential lectures. This concealed method of philosophizing he adopted partly from a regard to his personal safety, and partly, if not principally, from motives of vanity. For this purpose the colloquial form of instruction, introduced by Socrates in his contests with the Sophists, and adopted in the Dialectic schools, was found by Plato to be peculiarly convenient. Accordingly Cicero, though an enthusiastic admirer of Plato, observes, that "Plato affirms nothing, but after producing many arguments, and examining a question on every side, leaves it undetermined." His language like-wise, occasionally splendid, and at other times ambiguous and equivocal, renders his meaning often so obscure as to be inscrutable; to which we may add, that the obscurity of his writings is greatly increased by the intermixture of mathematical ideas or language with those of metaphysics. After all, the principal cause of the want of perspicuity that characterizes the writings of Plato is the extreme subtlety of his speculations upon abstract and sublime topics. Raising men above his condition and nature, Plato unites him to certain imaginary divinity principles, leads him through various orders of emanation and forms of intelligence to the Supreme Being, and represents these fictions of fancy as the first principles of wisdom. In such a wordless maze of words does Plato involve his notions, that none of his disciples, not even the sagacious Stagirite, could unfold them; and yet we receive them as sacred mysteries, and if we do not perfectly comprehend them, imagine that our intellects are too feeble to penetrate the conceptions of this divine philosopher, and that our eyes are blinded, as Burdock in his "Archeologia," expresses it, by that resplendent blaze of truth, upon which his eagle sight could gaze without injury. Plato, indeed, ambitious of the honour of forming a new sect, and ended by nature with more brilliance of organ than strength of judgment, collected the tenets of other philosophers, which were, in many particulars, contradictory, and could by no exertion of ingenuity be brought to coalesce; and that, out of this heterogeneous mass, he formed a confused syltem, delusive form of confusinity. This, it is said, will be acknowledged by every one, who, in perusing the philosophical writings of Plato, is capable of divesting himself of that blind respect for antiquity, by which the learned so frequently infer themselves to be misled. In confirmation of this judgment, we need only refer to the dialogue entitled "Timaeus," a chaotic mass of opinions, which no commentators have yet been able to reconcile, or to explain. The followers of Plato, instead of striving to diffuse the clouds that envelope his system, seem to have combined in increasing its obscurity. By successive changes in the academy, after the death of its founder, new opinions were introduced, and these increased the difficulty of exploring the true sense of Plato; and when, in a subseuent period, the Platonic philosophy was professed in Alexandria, it was further adulterated by an injudicious and absurd attempt to mould into it, a syltem, the doctrines of Plato, the traditionary tenets of Egypt and the eastern nations, and the forged records of the Jews and Christians; a coalition which will appear, in the sequel of this article, to have proved exceedingly injurious both to philosophy and religion.

All the preceding circumstances considered, it will appear to be no easy task to delineate an accurate sketch of the Platonic philosophy. This philosophy, as he suggests, and his interpreters allow, may be divided into three branches: the first treating of the art of reasoning, or dialectics; the second, of theoretical questions concerning nature, or physics; and the third, of practical subjects respecting life and manners, or ethics.

Wisdom, in the strict Platonic sense of the term, is the knowledge of those things which truly exist, and are comprehended by the intellect, particularly those which respect God, and the human soul as distinct from the body. Philosophy is the desire of divine science, or the liberation of the mind from the body, and its direction towards those real effences, which are perceptible only by the understanding: accordingly, a philosopher must possess a mind naturally turned towards contemplation, an ardent love of truth, a penetrating judgment, and a retentive memory; and he must also be inured to the exercise of temperance and fortitude, and is thereforeCold, intentional, and practical. For the sum of Plato's doctrine on dialectics, as collected from his dialogues, see DIALECTICA. The theoretical philosophy is divided by Plato into three branches, viz. theoretical, physical, and mathematical.

One doctrine, the fundamental doctrine of Plato, as well as that of other ancient philosophers, is, that from nothing nothing can proceed. This universal axiom, applied not only to the infinite efficient, but to the material cause, Plato,
PLATONISM.

Plato, in his "Timæus," lays down as the ground of his reasoning concerning the origin of the world. In this dialogue, which comprehends his whole doctrine on the formation of the universe, matter is so manifestly spoken of as eternally co-existing with God, that this part of his doctrine could not have been mistaken by so many learned and able writers, if they had not been devious of establishing a coincidence of doctrine between the writings of Plato and of Moses. On the other hand, it is observed by the learned Dr. Cudworth, that though some of the ancient fathers impute to Plato the opinion, that matter was an unmade self-existent being, there seems to be no sufficient ground for their so doing; and Porphyry, Iamblichus, Proclus, and other Platonists, do not only professedly oppose the same as false, but also as that which was dissolvent from Plato's principles. However, he acknowledges, that Plato did assert a plurality of gods, meaning animated or intellectual beings, or demons, superior to men, to whom honour and worship are due, and applying the appellation to the sun, moon, and stars, and also to the earth. Nevertheless he affirms, at the same time, that there was one supreme God, the self-originated being, the maker of the heaven and earth, and of all those other gods. He also maintains, that the Pýche, or universal mundane soul, is a self-moving principle, and the immediate cause of all the motion which is in the world, was neither eternal nor self-existant, but made or produced by God in time; and above this self-moving Pýche, but subordinate to the Supreme Being, and derived by emanation from him, which he calls ζ in, and ς αγαθον, the good, he supposes an immovable Nous or intellect, which was properly the Demiurgus, or former of the world.

The first matter of which this body of the universe was formed, he observes, was a rude undigested heap, or chaos; now, adds he, the creation was a mixed production; and the world is the result of a combination of necelcity and understandings, i.e., matter, which he calls necelcity, and the divine wisdom; yet so that mind doth rule over necelcity: and to this necelcity he ascribes the introduction and prevalence both of moral and natural evil; maintaining, however, that the evils resulting from the necelcity of imperfect beings are over-ruled by Mind or God for good.

The principles, or elements which Plato lays down are fire, air, water, and earth.

He supposes two heavens, the empyrean, which he takes to be of a fiery nature, and to be inhabited by angels, c.e.; and the flary heaven, which he teaches is not adamantine, or solid, but liquid and spirable.

Although Plato, in his "Timæus," as other writers argue, calls God "the parent of the universe;" and in his "Sophist," speaks of him as "creating animate and inanimate beings, which did not before exist," yet these expressions do not necessarily imply that no prior matter existed, from which these new beings were formed. Through the whole "Timæus," Plato supposes two eternal and independent causes of all things; one, that by which all things are made, which is God the other, that from which all things are made, which is matter. He distinguishes between God, matter, and the universe; and supposes the architect of the world to have formed it out of a mass of pre-existent matter. According to Plato, matter is an eternal and infinite principle, originally of no form, yet capable of receiving any, and infinitely divisible; but his notion of it is essentially different from that which supposes it to consist of small indivisible particles; and, therefore, Plato is not to be ranked among the Atomic philosophers. Plato also maintains, that there is in matter a necessary, but blind and refractory force; and that hence arises a propensity in matter to disorder and deformity, which is the cause of all the imperfection which appears in the works of God, and the origin of evil. See Evil.

The principle opposite to matter, in the system of Plato, is God, an intelligent cause, the origin of all spiritual being, and the former of the material world; whose nature he thought it difficult to discover, and, when discovered, impossible to divulge. The existence of God he inferred from the marks of intelligence, which appear in the form and arrangement of bodies in the visible world; and from the unity of the material system he concluded, that the mind by which it was formed must be one. God, according to Plato, is the supreme intelligence, incorporeal, without beginning, end, or change, and capable of being perceived only by the mind. Plato ascribes to the Deity all those qualities which modern philosophers attribute to immaterial subsistence, and conceives him to be in his nature simple, unconfined in space, the author of all regulated motion, and, in fine, possessed of intelligence in the highest perfection. Whatever were Plato's notions of the essence of Deity, he ascribed to him wisdom and power sufficient for the formation and preservation of the world, and supposes him possessed of goodness, which inclined him to define, and, as far as the refractory nature of matter would permit, to produce, the happiness of the universe. This great being is distinguished by the appellation Θεός, the Good. "God, that he might form a perfect world," says Plato, followed that eternal pattern, which remains immutable, and which can only be comprehended by reason." But this pattern, or archetype, he has explained so obscurely, that his interpreters and followers have been led to adopt very different opinions concerning it. Some have inferred from various passages that occur in his writings, that the whole of Plato's doctrine, with respect to the formation of the world, amounts to nothing more than that the Deity employed his understanding or reason in planning and executing the system of the universe; and, consequently, that by ideas existing in the reason of God are only meant conceptions formed in the divine mind. But by ideas Plato appears to have meant something much more mysterious; namely, patterns, or archetypes, subsisting by themselves, as real beings, archetypes, in the divine reason, as in their original and eternal region, and infusing thence to give form to sensible things, and to become objects of contemplation and science to rational beings. It is the doctrine of the "Timæus," that άληθεία τε η θεός, the reason of God, comprehends examples of all things, and that this reason is one of the primary causes of things. Plutarch says, that Plato supposes these principles God, matter, and idea. Juvénal Martyr, Plauto-Origen, and others, affirm the same. These ideas Plato defines to be the peculiar natures of things, or essences as such; and affirms, that they always remain the same, without beginning or end. Plato, having been from his youth conversant with Cratylus, a disciple of Heraclitus, and instructed in the doctrine of that school, that all sensible things are variable, and cannot be proper objects of science, reasonably concluded, that if there be any such thing as science, there must exist, besides sensible objects, certain permanent natures, perceptible only by the intellect. Such natures, divine in their origin, and eternal and immutable in their existence, he admitted into his system, and called them ideas. These objects of contemplation and science Plato seems to have found in the school of Pythagoras, whose numbers agreed in many leading characters with the ideas of Plato, and were employed for the same purposes, namely, to furnish objects of true science, and to elevate the human mind.
mind to a resemblance to the divine. Plato compares the
state of the human mind, with respect to the material and
the intellectual world, to that of a man, who, in a cave into
which no light can enter but by a single passage, views,
upon a wall opposite to the entrance, the shadows of ex-
ternal objects, and misinterprets those for realities. See the
article Perception.

It was another doctrine in the Platonic system, that the
deity formed the material world after a perfect archetype,
which had eternally subsisted in his reason, and ended it
with a soul. This Plato supposed to be the animating
principle in the universe, pervading and adorning all things.
This third principle in nature is, in the Platonic system,
inferior to the Deity, being derived from that divine reason,
which is the seat of the ideal world; thus essentially dif-
fering from the Stoical doctrine of the soul of the world,
which supposed the essence of the divine nature diffused
through the universe. The doctrine of a twofold soul of
the world, the one \( \psi\varphi\rho\varepsilon\rho\varepsilon\mu\varepsilon \rho\), predating over it, the other
\( \varepsilon\varphi\kappa \nu\varphi\omega\varepsilon \), refuting in it, is an appendage to the ancient Platonic
system, introduced by the later Platonists, to accom-
modate this system to the notions adopted by many of the
Christian fathers concerning the divine nature. But Plato's
doctrine concerning God and the soul of the world differs
materially from the doctrine of the Trinity, afterwards re-
ceived in the Christian church. Plato did not supposc three
substances in one divine essence, separate from the visible
world; but he taught, that the \( \lambda\varphi\kappa\sigma \), or reason of God, is
the seat of the intelligible world, or of ideas, and that the
soul of the world is a third subordinate nature, compounded
of intelligence and matter. In the language of Plato, the
universe, being animated by a soul which proceeds from
God, is the soul of God; and several parts of nature, par-

cularly the heavenly bodies, are Gods. He probably con-
ceived many subordinate divinities to have been produced at
the same time with the soul of the world, and imagined
that the Supreme Being appointed them to the charge of
forming animal bodies, and superintending the visible world;

a doctrine which he seems to have borrowed from the Py-
thagoreans, and particularly from Timaeus the Locrian,
who says, "the ruler of all alligned the inspection of human
affairs to demons, and committed to them the government
of the world."

On the foundation of the doctrine, above explained,
concerning God, matter, ideas, the soul of the world, and
demons, Plato raised the structure of his physics: thinking,
that the supreme Architect, by uniting eternal and immuta-
ble ideas or forms to variable matter, produced the visible
world; and believing, that the world had a beginning in
time, and not to have existed from eternity.

Other tenets included in the Platonic doctrine of nature
were, that the universe is one animated being, including
within its limits all animated natures; that fire and earth
were first formed, and afterwards united by means of air and
water; that from perfect parts one perfect whole was pro-
duced, of a spherical figure, as in itself most beautiful, and
best adapted to contain all other figures; that the elementary
parts of the world are of regular geometrical forms, the
particles of earth being cubical, those of fire pyramidal,
those of air in the form of an octahedron, and those of
water in that of an icosahedron; that these are adjoined, in
number, measure, and power, in perfect conformity to the
geometrical laws of proportion; that the soul which per-
vades this sphere is the cause of its revolution round its cen-
tre; and, finally, that the world will remain for ever, but
that, by the action of its animating principle, it accom-
plishes certain periods, within which every thing returns to
its ancient place and state. This periodical revolution
of nature is called the Platonic, or Great, year.

Plato's doctrine concerning the human soul, as an eman-
ation from God, is treated obscurely. This emanation
was instantaneous, but through the intervention of the soul of
the world, debased by some material admixture; and conse-

quently the human soul, receding farther from the first intel-
ligence, is inferior in perfection to the soul of the world.
The human soul, in the material part of its nature, is formed
for conversing with sensible objects, and its intellectual
part, capable of spiritual contemplation; but what he meant
by \( \varepsilon\varphi\kappa\nu\varphi\omega\varepsilon \), the material vehicle of the soul, is uncertain.
The relation which the human soul, in its original constitu-
tion, bears to matter, Plato appears to have considered as the
source of moral evil. As to the manner in which the soul
acts on the body, Plato speaks obscurely and inconsistently;
but it is probable, that, as he conceived the soul of the
world to produce the motion of the earth, and the heavenly
bodies, by means of that part of its nature which is mat-
erial; so he supposed the power of moving bodies, which
belongs to the human soul, to be the effect of its material
principles. With regard to the origin and present state of
human souls, Plato supposes, that when God formed the
universe, he separated from the soul of the world inferior
souls, equal in number to the stars, and assigned to each its
proper celestial abode; but that these souls, by some means,
or for some reason or other not explained, were sent down
to the earth into human bodies, as into a sepulchre or pri-
fon; and to this cause he ascribes the depravity and misery
to which human nature is liable; maintaining, at the same
time, that by disengaging itself from all animal pleasures
and rising above sensible objects to the contemplation of
the world of intelligence, the soul of man can be prepared
to return to its original habitation. According to Plato, the
soul consists of three parts, \( \varphi\kappa\sigma \), the seat of intelligence,
that of passion, and that of appetite; and he assigns to each
its proper place in the human body. The first of these
portions or faculties of the soul, under both which denomina-
tions he speaks of them, he conceived to have been de-

erived from God; the second and third from matter. Plato
teaches, in express terms, the doctrine of the immortality
of the rational soul, reiterating the proof of this doctrine, how-
ever, upon arguments drawn from the mere fanciful parts
of his system.

Plato was a zealous advocate for the importance of that
kind of science, which is purely speculative, and though he
had left no direct treatise on mathematics, he requires from
his disciples an acquaintance with the elements of this branch
of knowledge, preparatory to the study of theoretical phi-
losophy. On the subjects of policy and morals he prefers
rules, which are intended for the direction of societies and
individuals in the offices of life, but they are too much
thorough with his theoretical doctrines. The main object of his
political institutions, appears to have been the subjugation
of the appetites and passions, by means of the abstract con-
templation of ideas. The chief heads of his moral doctrine
are as follow: Our highest good consists in the knowledge
and contemplation of the first good, which is mind, or God.
All those things which are called good by men, are really
such only so far as they are derived from the first and
highest good. The only power in human nature, which can
acquire a resemblance to the Supreme good, is reason. The
minds of philosophers are fraught with valuable treasures;
and, after the death of the body, they shall be admitted to
divine entertainments; so that whilst with the gods they are
employed in discerning the fields of truth, they will look
down with contempt on the folly of those, who are con-
tented
PLATONISM.

tested with earthly shadows. Goodness and beauty consist in the knowledge of the first good, and the first fair. That only which is becoming is good; therefore virtue is to be preferred for its own sake; and, because it is a divine attainment, it cannot be taught, but it is the gift of God. He alone who has attained the knowledge of the first good, is happy; the end of this knowledge is, to render man as like to God as the condition of human nature will permit. This likeness confits in prudence, justice, sanctity, temperance. In order to attain this state, it is necessary to be convinced, that the body is a prison, from which the soul must be released, before it can arrive at the knowledge of those things which are real and immutable. Virtue is the most perfect habit of mind which adorns the man, and renders him firm, resolute, and constant, in action and speech, in solitude and society. The virtues are so nearly allied, that they cannot be separated: they are perfect, and therefore neither capable of increase, nor of diminution. The passions are motions of the soul, excited by some apparent good or evil: they originate in the irrational parts of the soul, and must be regulated and subdued by reason. Friendship is, strictly speaking, reciprocal benevolence, which inclines each party to be as fictitious for the welfare of the other, as for his own. This equality of affection is created and preserved by a similarity of disposition and manners. Upon the whole it may be observed, that whilst the writings of Plato contain many just and sublime sentiments on moral subjects, his ethical doctrine, duly examined, will appear to be, in some particulars, defective, and in others extravagant and absurd. The fanciful notions which he entertained concerning the divine nature, the world of ideas, and matter, seem to have given a romantic and enthusiastic turn to his conceptions on morals; a defect, which may be in part ascribed to his connection with the Pythagorean school, but which was, perhaps, chiefly owing to the peculiar propensity of his genius towards metaphysical fiction.

After the death of Plato, two of his principal disciples, Aris- totle and Xenocrates, continuing his office, and teaching, the one in the Academy, and the other in the Lyceum, founded two sects, under different names, though in other respects the same; the one retaining the denomination of Academics, the other assuming that of Peripatetics. The Academic sect fell into general neglect under the Roman emperors; partly because it was treated with contempt by the dogmatists, and partly on account of the reviving credit of the Scipionic sect, in which the peculiar tenets of the Middle Academy were embraced. Nevertheless, the true doctrine of Plato, which had formerly obtained such high esteem among philosophers, and which had been lately restored at Athens by Antiochus, resumed its honours. Among the genuine followers of Plato, we find, at this period, several illustrious names. Under the emperors Augustus and Tiberius, flourished Thrasybulus, a Mendezon, who, though an eminent Platonist, so far conformed to the practice of the Pythagoreans, as to become an adept in the art of astrology. Not long after his time lived Theon of Smyrna; to whose astronomic observations, Ptolemy the astronomer, who flourished under Antoninus Pius, has referred, and whose mathematical treatises, elucidating the writings of Plato, prove that he belonged to the Platonic school. At the same time, his discourses in geometry, arithmetic, music, astronomy, and the harmony of the universe, serve to cast some light upon the Pythagorean system. Aleinous, whose age is uncertain, but commonly placed about the beginning of the second century, wrote an introduction to Plato, containing a summury of his doctrine, which shews him to have been well acquainted with his philosophy. Favorinus, a native of Arles, lived in the reigns of Trajan and Adrian, and was well instructed in the precepts of philosophy by Epictetus, the illustrious ornament of the Stoical school; but none of his writings are extant. Under the reign of Antoninus Pius flourished Calvius Taurus of Berytus, and he is mentioned as a Platonist of some note. He wrote several pieces, chiefly to illustrate the Platonick philosophy; he lived at Athens, and taught, not in the schools, but at his table. Aulus Germanus was frequently one of his guests, and in his "Neces Atticae" has given an account of the manner in which these philosophical entertainments were conducted. The same period produced Lucius Apuleius; see his article. Another Platonist, who flourished under M. Aurelius Antoninus, was Atticus; chiefly memorable for the laudable pains with which he endeavoured to ascertain the exact points of difference between the doctrines of Plato and Aristotle. (See Atticus.) Numenius of Apamea in Syria belonged to the same clafs of writers with Atticus; and MaximusTyrius, though chiefly distinguished by his eloquence, obtained some degree of celebrity as a philosopher, and his elegant Discourses are for the most part written upon Platonic principles, though they sometimes incline towards scepticism. Plutarch and Galen are also commonly ranked among the Platonists. See their respective articles.

In later times, about the first ages of the Christian church, the followers of Plato abandoned the title of "Academics" or "Academiæ," and assumed that of "Platonists." It is supposed to have been at Alexandria, in Egypt, that they first assumed their new title, after having restored the ancient Academy, and re-established Plato's sentiments; many of which, in process of time, had been laid aside. Among the Greek Platonists, those who acquired the greatest reputation were Porphyry, Plotin, Iamblichus, Proclus, and Plutarch; and among the Latins, Apuleius and Chalcidius. Among the Hebrews, Philo Judæus occupied the chief rank. The modern Platonists were Plotin, the founder, at least, the reformer of their sect.

It is certain, that most of the celebrated fathers were Platonists, and borrowed many of their explanations of Scripture from the Platonic philos. In order to account for this fact, we may observe, that towards the conclusion of the second century, a new sect of philosophers, called the modern, or later Platonists, arose of a sudden, spread with amazing rapidity through the greatest part of the Roman empire, swallowed up almost all the other sects, and proved extremely detrimental to Christianity. The school of Alexandria in Egypt, instituted by Ptolemy Philadelphus, renewed and reformed the Platonic philosophy. The votaries of this system distinguished themselves by the title of Platonists, because they thought that the sentiments of Plato, concerning that most noble part of philosophy, which has the Deity and things invisible for its objects, were much more rational and sublime than those of the other philosophers. This new species of Platonism was embraced by the Alexandria Christians as were devout to retain, with the profession of the Gospels, the title, the dignity, and the habit of philosophers.

These Alexandrian philosophers, who became converts to the Christian faith, retained a strong predilection for Platonic tenets, and the highest reverence for the name of Plato; and therefore they carefully credited the report, that the doctrine of Plato concerning the divine nature had been derived from revelation; and hence they thought themselves justified in attempting a coalition between Plato and Jesus Christ. An union of Platonic and Christian doctrines was
PLATONISM.

unquestionably attempted in the second century by Justin Martyr, Athenagoras, and Clemens Alexandria, in whose writings this doctrine closely meet with Platonic sentiments and language; and it is not improbable, that this corruption took its rise at a still earlier period.

Ammonius Saccas was the principal founder of this new Platonic system, and was succeeded by his disciple Platonius, as he was by Porphyry, the chief of those formed in his school. (See Eclectics.) From the time of Ammonius, who, in order to recommend his Eclectic system to the attention of Christians, accommodated his language to the opinions which were then received among them, until the sixth century, this was almost the only system of philosophy that was publicly taught at Alexandria. Origen, and other Christians who studied in his school, were so far duped by the artifice of Saccas, as to imagine that they discovered, in the system of the Platonists, traces of a pure doctrine concerning the divine nature, which, on the ground just mentioned, they thought themselves at liberty to incorporate into the Christian faith. Entering upon the office of Christian teachers, under the bias of a strong partiality for Plato and his doctrine, they tinctured the minds of their disciples with the same prejudice, and thus diffamated Platonic notions, as Christian truths; little aware, without doubt, how far this practice would corrupt the purity of the Christian faith, and how much confusion and dissidence it would occasion in the Christian church.

The Platonic system of philosophy was brought into Greece by Plutarch, who renewed at Athens the celebrated Academy, from whence flowed many illustrious philosophers. The general principles on which this sect was founded, however the partizans of it might differ with respect to particular opinions, was, that truth was to be purfued with the utmost liberty, and to be collected from all the different systems in which it lay divided. None, however, who were ambitious to be ranked among these new Platonists, called in question the main doctrines; thofe, for example, which regarded the existence of one God, the fountain of all things; the eternity of the world; the dependence of matter upon the Supreme Being; the nature of souls; the plurality of gods; the method of interpreting the popular superstitions, &c.

That the reader may be able to trace distinctly the introduction and progress of this new Platonic system in the Christian church, we shall divide the Christian fathers into two classes; namely, those who flourished before and those who flourished after the institution of the Eclectic sect. (See Eclectics.) The first class commences with Justin Martyr, and the second with Origen. Justin Martyr, (see Justin Martyr,) after his conversion, retained a strong attachment to the Platonic system, and applied his knowledge of this system to the illustration and defense of the Christian doctrine. Perceiving an agreement between Platonism and Christianity, he concluded that whatever was valuable in the former, had either been communicated to Plato by inspiration, from the Logos, or by emanation of the divine nature, or by a transmission by tradition from Moses and the Hebrew prophets, and hence therefore be juftly claimed as belonging to divine revelation, and incorporated into the Christian creed. By the term Logos he understood, not the reasoning faculty of the human mind, but, after Plato, the originating reason of the divine nature; and he conceived this principle as having inspired the Hebrew prophets, and to have been the Christ who appeared in the flesh. He moreover apprehended, that it had been participated not only by the Hebrew patriarchs, but by the more excellent Pagan philosophers; and consequently he regarded every tenet in the writings of the Heathens, which he could reconcile with the doctrine of Christ, as a portion of divine wisdom which Christians might justly appropriate to themselves. He had learned from Plato and his followers, in the school of Alexandria, that the knowledge of God is alone to be gained by the contemplation of ideas, which have their primary seat in the divine Logos, and that the human mind, in consequence of its nature as proceeding from the soul of the world, is capable of contemplating those divine ideas by means of which it may ascend to the knowledge of God. Justin was pecculiarly led to conclude, that man can only arrive at divine science through the medium of the Logos. Hence, he referred all Christian knowledge to the perception of the divine reason inhabiting in man; and thus laid the foundation of an error, still retained by some Christian feists. This, or, the Word, is a substantial ray of divine light internally communicated to man. Justin also borrowed from Plato his notion of angels employed in the government of the elements, the earth, and the heavens, and many other tenets that are not to be found in the scriptures. The sentiments and language of Tatian, who, after his conversion from Heathenism to Christianity, became a disciple of Justin Martyr, perfectly agree with those of the Egyptian and Cabalistic philosophy, and were probably derived from those sources.

The whole tenor of his Apology concurs with what is known of his history to prove, that he was a Platonic Christian.

Several things in the Apology of Theophilus of Antioch (see his article), discover his predilection for the Platonic system, and his inclination to adapt it to the Christian doctrine. We may also rank among the Platonizing fathers, Athenagoras. (See Athenagoras.) Another writer of this period, viz. Irenæus, seems to have borrowed his ideas and language from the Alexandrian Platonists. About the beginning of the third century flourished Tertullian, who frequently makes use of Platonic notions and language; but, none of the fathers of this period merit higher distinction than Clemens Alexandria; nor was any one of them led farther astray, by philosophical subtlety, from the simplicitv of the Christian faith. We frequently find him adopting Platonic and Stoic tenets as Christian doctrines, and thus laving the seeds of error in the Christian church. The most celebrated of the Christian fathers, after Ammonius, who, following the idea of Plotinus, framed the Eclectic system, was Origen; and among other names which distinguished this period, the principal arc Arnobius, Lactantius, Eusebius Pamphilus, Didymus of Alexandria, and Augulfine. See their respective articles.

In the fourth century, under the reign of Valentinian, a dreadful storm of perfecution arose against the Platonists; many of whom, being accused of magical practices, and other heinous crimes, were capitally consigned. In the fifth century Proclus gave new life to the doctrine of Plato, and restored it to its former credit in Greece; with whom concurred many of the Christian doctors, who adopted the Platonic system; among the more eminent of whom we may reckon Syncellus, an African bishop. The Platonic philosophers were, in general, opponents of Christianity; but in the sixth century, Chalecius, whose conversion to Christianity has been doubted, gave the Pagan system an evangelical aspect; and those who, before it became the religion of the State, ranged themselves under the standard of Plato, repudiating the doctrine of Christ, without any considerable change of their system. At the beginning of this sixth century appeared Irenæus, who was born at Rome, and sent to Athens to study philosophy. In the school of Proclus he became acquainted with the Eclectic system; and from the
PLATONISM.

mendations which he befalls upon Porphyry, as the best interpreter of Aristotle, he seems to have united the Platonic with the Ariflotelian doctrine. Æneas Gaza, towards the close of the fifth century, in a poem profoundly written against the Platonists, confounds the doctrines of Platonism and Chriftiанity. Under the emperor Julian, who illuftrated a particular edict, prohibiting the teaching of philosophy at Athens, which edict seems to have been levelling at modern Platonism, all the celebrated philosophers of this fect took refuge among the Perfians, who were, at that time, the enemies of Rome; and though they returned from their voluntary exile when the peace was concluded between the Persians and Romans, A.D. 533, they could never recover their former credit, nor obtain the direction of the public schools. Thus, says Mosheim, expired that famous fect, which was distinguished by the title of the modern or later Platonists, and which, for a feries of ages, had produced fuch divisions and tumults in the Chriflian church, and which had been, in other refpects, prejudicial to the interests and progrefs of the Gospel. For a farther account of this fect, fee ELECRITY.

The knowledge of Alexandrian Platonifm was, however, revived in the West by Joannes Scotus, who, in the ninth century, translated the books ascribed to Dionius the Areopagite, or St. Denis, and laid the foundation of the mythical fystem of theology, which afterwards fo generally prevailed. Thus philofophical enthusiasm, born in the East, nourfhir of Plato, educated in Alexandria, matured in Asia, and adopted into the Greek churches, found its way, under the pretence and authority of an aperture name, into the western Churches; and there produced innumerable mi-chiefs.

The firit Greek who gave occasion to the revival of Platonifm in Italy, was Gemilius Plettha, a native of Constantinople, who was born in 1390, and lived 100 years. He was a zealous advocate for Platonifm, and maintained a violent contoverfy with the Ariflotelians. In his "Expositio Oracorum Magorum Zoroaftri," he exhibits twelve fundamental articles of the Platonie religion, and gives an elegant comprehension of the whole Platonie philosophy. A more moderate adherent to Plato, who maintained his fystem without cafeing contempt on the philosophy of Aristotle, or trefpassing upon the doctrine of Chriftiianity, was Belfario, a learned bishop of Nice, who was appointed by the emperor Michael Paleologus, about the year 1440, together with other Greek divines, to treat with the Latin church concerning an union. He died at Ravenna in 1472. He wrote a defence of the Platonie fystem against George of Trebizond. Under the patronage of Cofmo de Medici, Mar-•fius Ficinus, a Florentine, born in 1433, was educated by Pleftho, for the express purpose of translating the writings of Plato. It appears, however, from the execution of the task assigned him, and his other writings, that he was deficient in strength of judgment and correctness of taste. His Latin style wants that richness and dignity which are requisite in a version of Plato. A fellow labourer with Ficinus, in the task of editing and translating the writings of Plato, was Joannes Picus of Mirandola, born in 1460; who, for his successes in reviving the Platonie philosophy, was honoured with the title of the phoenix of his age. Picus was a zealous supporter of Platonifm, after the model of the Alexandrian school; but not without blending with its doctrine a large portion of Cabalifical mewy, and confounding with both thefe the doctrine of divine revelation. About this period, a body of Greek scholars avowed themselves zealous advocates for the genuine Ariflotelian philosophy; and employed their time and learning in editing and translating the writings of the Stagirite. The principal of them who engaged in this undertaking were Theodore Gaza, George of Trebizond, and Georgius Scholarius. Between these philosophers, on the one part, who followed Plato, and those on the other who followed Aristotle, a dispute arose concerning the merits of the two systems, which was carried on to a molt ridiculous and extravagant height. It was begun by Pletho, whose veneration for Plato led him to oppose with great violence the univalved dominion which Aristotle had for ages polifhed in the schools. Georgius Scholarius, on the other hand, zealously defended Aristotle, and strenuously maintained that his opinions are confonnant to the truf! and helt doctrines of the Chriflian religion, and are even more true; and that the tenets of Plato, differing from thefe of Ariflotle, are therefore false. George of Trebizond supported Scholarius; and Pletho was ably seconded by Gaza. Other combatants also engaged in the contest, and in the prosecution of it exposed themselves to ridicule. The partifans of the Platonic fystem, who, under the patronage of the Medicean family, for a long time maintained their ground against the Ariflotelians, declining with the fortune of their patrons, the advocates for the Peripatetic philosophy proportionably increased, and after a violent struggle, established a victory.

The doctrines of the later Platonifls having been revived by the Greek exiles in Italy, their further spread is chiefly to be imputed to the averter mentioned many good men entertained against the Peripatetic philosophy, on account of the shameful impurities to which it had given birth. Perceiving that they could not commit themselves to the direction of Aristotle, without hazarding their religious principles; and not having strength of mind sufficient to form a fystem of opinions for themselves, they adopted the philosophy of Plato in the corrupted flate in which it had been transmitted, through the Alexandrian and Chriftian schools, to modern times. This philosophy was the more readily embraced, because it was believed, that the mysteries of Pythagoras, than which none appeared to approach nearer to thefe of true religion, had been long since united with the wisdom of Plato. In this school they expected to find much divine instruction; more especially as they were led to believe, that its doctrines had been, mediatel or remotely, derived from divine revelation. And as one error generally produces another, thrfe learned men united with this fystem the secret or cabalifical philosophy of the Jews, which, for want of due examination, they conceived to have been the pure doctrine of the ancient Hebrews. Hence arose a new compound of tenets, sufficiently mystical and paradoxical, which was received by this chie of philosophers as the fum of ancient wisdom. While Ficinus was reviving the Platicine philosophy in Italy, and Faber the Ariflotelian one in France, John Reuchlin, otherwise called Caprius, born at Pforzheim, in Swabia, in 1455, professed and taught a mystical fystem, compounded of Platonic Pythagoric, and Cabalifical doctrines. George Venet, an able and enthusiastic writer, pursued a similar course, and blended fundry Peripatetic notions with the Platonic and Cabalifical systems. The mystical fystem of Cabbalifical Platonism was ably supported by Henry Cornelius Agrippa. A very different mode of reforing the Platonic philosophy was pursued by Francicus Patricius, born at Chifa, in Hyllyricum, in 1529. In the schools of Italy he professed to unite the doctrines of Ariflotle and Plato, but in reality undermined that of the former. Being appointed by pope Clement VIII. a preceptor in philosophy at Rome, he openly discovered his aversion to the Ariflotelian fystem, and advised the pope to prohibit the teaching of this philosophy in the schools; and to introduce the doctrine of Plato, as more confonnat.
confonant to the Christian faith. In the 17th century, Platonism found many advocates in Great Britain, owing, in a great measure, to the desire which many able and learned divines at this time entertained of refuting the tenets of Hobbes; and this they thought could not be more effectually done, than by reviving an attention to the doctrine of Plato, both in his own works, and in those of his followers. Of those who ranged themselves under the banners of Plato, the most celebrated are Gale, Budworth, and More. Brucker's History of Philosophy, by Enfield, vol. i. and ii. Mohemn's Eccl. Hist.

PLATONISTS. See Platonism and Academicians.

PLATONOPOLIS, in Ancient Geography, a city which Plotinus requested the emperor Galienus to build in Campania. This city had been formerly razed, and Plotinus used his intercess with the emperor, not only to have it rebuilt, but to obtain a grant of the neighbouring territory, that it might be inhabited by a body of philosophers, and governed by the laws of Plato, under the name of Platopopolis. He promised, at the same time, that he and his friends would lay the foundation of this philosophical colony. The emperor was diffused by his friends from acceding to this proposal.

PLATOON, or Plottoon, formed, by corruption, of the French pétaon, a bottom, or clus, of thread, in War, formerly denoted a small body of men, drawn out of a battalion of foot, and placed between the squadrons of horse, to sustain them; or in ambuscades, straits, and defiles, where there is not room for whole battalions or regiments.

Platoons were also used when they formed the hollow square, to strengthen the angles.

The grenadiers were generally posted in Platoons.

A battalion was generally divided into sixteen Platoons, exclusive of the grenadiers, which formed two or four platoons more, as occasion required. At present the battalion is generally divided into wings, grand divisions, divisions (or companies), subdivisions, and sections; and the word platoon is seldom used, except to denote a number (from 10 to 20) of recruits assembled for the purpose of instruction, in which case it may be considered as synonymous with company. See Battalion.

PLATOON Exercice. See Battalion.

PLATOON Firing. See Battalion and Firing.

PLATOON Rifles. See Platoon.

PLATE, or Shallow River, in Geography, a western branch of the river Missoury, remarkable for its quick-fands and bad navigation. Near the confluence of this river with the Missoury, dwells the nation of the Otoes, or Otoes, consisting of about 200 warriors.

PLATTE, La, a smaller river of America, in the state of Vermont, which runs into lake Champlain, at Shelburn.

PLATTE Forne, La, a cape on the W. coast of St. Domingo. N. lat. 10° 36'. W. long. 74° 2'.—Also, a town on the S. side of the N. peninsula of St. Domingo; 13 leagues S.E. by S. of the Mole.

PLATTEN, a town of Bohemia, in the circle of Leitmeritz; 4 miles E. of Kamnitz. — Also, a town of Bohemia, in the circle of Elnbogen; 27 miles N.E. of Eger. N. lat. 50° 23'. E. long. 12° 45'.

PLATTENBURG, a citadel of Brandenburg, in the Mark of Pretzeng; 4 miles E. of Willnach.

PLATTS, a small island in the Indian sea. S. lat. 5° 55'. E. long. 55° 20'.

PLATTS, on board a Ship. See Plats.

PLATTSBURG, in Geography, a post-town of America, in Clinton county, New York, on Lake Champlain; 5 miles W. of Ticonderoga. N. lat. 44° 41'. W. long. 73° 27'. Here are a house for public worship, a courthouse, and a gaol. The court of for common pleas and grand juries sit here twice a-year; and in the town are artisans of almost every kind, who furnish among themselves all the materials for building, glafs excepted. Here also are found polite circles. The number of inhabitants is 1409.

PLATNUM, in Botany, from πλατύνω, to dilate or enlarge, in allusion to its large spreading calyx; a genus described by Jullien, in the Annales du Musée, v. 7. 65, with which we are unacquainted. De Théis. 371.

PLATYCEROS OVIS, in Zoology, the name given by Géfenier and some others to a species of sheep, commonly called ovis laticauda, or the broad-tailed sheep. See Ovis.

PLATYCEPHALUS is also a name given by Pliny to the Cervus Dama, or fallow deer.

PLATYCEROS, in Entomology, a species of Lucanus. See Lucanus Alces, and Lucanus parallelepipedus. See also TENEBRIO Caraboides.

Gen. Ch. Cal. Perianth inferior, of one leaf, bell-shaped, two-lipped; the upper lip rounded, very large, divided half way down into two obovate segments; the under much smaller, in three equal, awl-shaped, white segments. Cor. papilionaceous. Standard heart-shaped, large, ascending, twice as long as the upper lip of the calyx, with a short, linear, convex claw. Wings half the length of the standard, obvate, each with a plait, and prominent tooth, at the base on its lower side, and a narrow claw. Keel the length of the wings, of two obovate, concave, converging petals, each with a tooth on its upper edge at the base. Stam. Filaments ten, united into one foot for about half their length, separate only at the upper edge, ascending; anthers simple, roundish. Pik. Germin on a short stalk, oblong, compressed, filiform, recurved; stigma simple. Peric. Legume flanked, oblong, compressed, almost flat, of one cell, its upper edge dilated into a flat longitudinal wing, the valves membranous. Seeds several, oval, compressed, each on a curved white flake, with a tamarind appendage.

Eff. Ch. Calyx two-lipped; the upper lip cloven, rounded, very large. Stamens all connected. Legume flanked, compressed flat, membranous, winged at the back, of one cell, with many seeds.

1. P. formentum. Orange Flat-pee. Sm. Bot. of New Holl. 177. t. 6. Willd. n. 1. Ait. n. 1. Curt. Mag. t. 469. Venten. Malmant. t. 3. — Leaves ovate, somewhat heart-shaped. Germin all over hairy. Stalk of the legume shorter than the calyx. Bractea silky.—Native of New South Wales, from whence specimens, drawings, and seeds, were early sent by Dr. White and others. It is rather difficult to raise and to prefer, but when in perfection proves a great ornament to the greenhouse from June to August. The flum is erect, but very slender, and rather weak, hairy, with numerous, opposite, spreading branches, all of reddish-brown, hairy and round. Leaves opposite, on short stalks, acute, entire, convex, rigid, smooth, about an inch long; glaucous beneath. Stipulae in pairs, lanceolate, membranous, brownish. Flowers numerous, inodorous, large, on short, simple, axillary, crowded flanks, with a pair of bracteas under the
the calyx, which like them is silky. *Standard* and *wings* of an orange yellow, the former crimson at the back, as well as at the centre in front; wings pale, tipped with crimson. *Legume* an inch and a half long, and half as broad, obtuse, with a little sharp point, somewhat hairy all over. 2. *P. parviflorum*. Small-flowered Flat-pea. Sm. Bot. of N. Holl. 18. Willd. n. 2. Curt. Mag. t. 1520.—Leaves lanceolate-ovate. Germin nearly smooth. Stalk of the legume longer than the calyx. Bracteas smooth.—From the same country. Sent to Kew by Br. J. Banks in 1792. It blooms in the summer, amongst other greenhouse shrubs.

3. *P. triangularis*. Triangular-leaved Flat-pea. Brown MSS. At. n. 3. Curt. Mag. t. 1528.—Leaves somewhat triangular or heart—shaped, with spiny angles. Flower—stalks bracteated at the base and furnished, naked in the middle. *Legume* several times longer than the calyx. Gathered by Mr. Brown in Van Diemen's island, and sent to Kew in 1825. It is kept in the greenhouse, and flowers from June to September.

**PLATYPHthalmus.** A name given by force to antinomy, from its use among the ladies of old time, to make their eye—brows broad and black.

**PLATYPUS,** Duck—billed Flat—pea, in Zoology, a genus of the clafs and order Mammalia Britta, of which the generic character is; mouth shaped like the bill of a duck; the feet are palmate. There is but a single species.

**Aartonius.** This extraordinary animal is placed by Dr. Shaw next to the genus Myrmecophaga. The description of this naturalist, who has taken much pains in investigating the characters of the genus, we shall transfer, as being the only satisfactory account we have of it. Of all the mammalia yet known, it seems the most extraordinary in its conformation, exhibiting the perfect resemblance of the beak of a duck engraved on the head of a quadruped. So accurate is the imituation, that, at first, view, it naturally excites the idea of some deceptive preparation by artificial means; the very epidermis, proportion, ferratures, manner of opening, and other particulars of the beak of a fowler, or other broad—billed species of duck, presenting themselves to the view; nor is it without the most minute and rigid examination that we can persuade ourselves of its being the real beak or frount of a quadruped.

The body is depressed, and has some resemblance to that of an otter in minute: it is covered with a very thick, soft, and beaver—like fur, and is of a moderately dark brown above, and of a subferrugineous white beneath. The head is flattish, and rather small than large; the mouth or frount, as before observed, so exactly resembles that of some broad—billed species of duck, that it might be mistaken for such. The skin of the beak is a flat circular membrane, somewhat deeper or wider below than above, viz. below near the fifth of an inch, and above about an eighth. The tail is flat, furry like the body, rather short and obtuse, with an almost bident termination; it is broader at the base, and gradually tapers to the tip, and is about three inches in length; its colour is similar to that of the body. The length of the whole animal, from the tip of the beak to that of the tail, is thirteen inches; of the beak an inch and a half. The legs are very short, terminating in a broad web, on which the fore feet extend to a considerable distance beyond the claws; but on the hind feet reaches no farther than the roots of the claws. On the fore feet are five claws, straight, strong, and sharp—pointed; the two exterior ones somewhat shorter than the three middle ones. On the hind feet are fix claws, longer and more inclining to a curved form than those on the fore feet; the exterior toe and claw are considerably shorter than the four middle ones; the interior, or sixth, is seated much higher up than the rest, and resembles a strong, sharp spur. All the legs are hairy above; the fore feet are naked both above and below; but the hind feet are hairy above and naked below. The internal edges of the under mandible (which is narrower than the upper) are ferratured and channelled with numerous filrips, as in a duck's bill. The nostrils are small and round, and are situated about a quarter of an inch from the tip of the bill, and are about the eighth of an inch distant from each other. There is no appearance of teeth; the palate is removed, but seems to have resembled that of a duck; the tongue also is wanting in the specimen. The ears or auditory foramina are placed about an inch beyond the eyes; they appear like a pair of oval holes of the eighth of an inch in diameter, there being no external ear. On the upper part of the head, on each side, a little beyond the beak, are situated two smallish oval white spots, in the lower part of each of which are included the eyes, or at least the parts allotted to the animal for some kind of vision; for from the thick—ness of the fur, and the smallness of the organs, they seem to have been but obscurely calculated for distinct vision, and are probably like those of moles, and some other animals of that tribe; or perhaps even subeaneous; the whole apparent diameter of the cavity in which they were placed not exceeding the tenth of an inch. When we consider the general form of this animal, and particularly its bill and webbed feet, we shall readily perceive that it must be a reptile in watery situations; that it has the habits of digging or burrowing in the banks of rivers, or under ground; and that its food consists of aquatics, plants, and animals. This is all that can at present be reasonably guessed at; future observations, made in its native regions, will, it is hoped, afford us more ample information, and will make us fully acquainted with the natural history of an animal which differs so widely from all other quadrupeds, and which verifies, in a most striking manner, the observations of Buffon, etc., that whatever was possible for nature to produce, has actually been produced.

Dr. Shaw observes, in a subsequent volume, as the result of more accurate experiments, that "on laying open the parts beyond the base of the bill, it appears that the platypus, like the ant—eaters, is furnished with small bony processes resembling grinding—teeth, imbedded in the gum, but not fellenned or rooted in the jaw; of these processes, there are two on each side both of the upper and under jaw." Shaw's Gen. Zool. vol. 1. and ii.

**PLATYRINCIOS.** In Ichthyology, a name given by some to the naus, or nase, a fresh—water fish, caught in the Danube, and most of the large rivers in Germany, and much resembling the chub. See Cyprinus Nafas.

**PLATYSMA MYOIDES.** In Anatomy, the thin stratum of muscular fibres placed immediately under the skin in the neck. It is described in the article DEGLUTITION, under the name of latissimus coeli.

**PLATYSTERNOS.** A word used by the old physicians to express a periton with a very broad chest or sternum.

**PLATYZOMA.** In Botany, from παλαι, broad, and ζομα, a belt, a genus of Fìllets in Mr. Brown's Prod. Nov. Holl. v. 1 166, nearly allied to Gleichenia, from which the author says he was induced to separate it, rather on account of its undivided filaments, which in Gleichenia are forked, than for the slight difference in the fructification. The latter seems principally to consist in the revolute margins of the leaflets forming a sort of involucre.
The only species mentioned is

Stalks undivided. 

Folios pinnate; leaflets extremely numerous, dilated, orbicular, entire, minute, beneath with sulphur-coloured powder. Capsules few together in each dot. Seed very large. Some from, from the same root, are compressed, nearly thread-shaped, and undivided.

See GLEICHENIA.

PLATZ, in Geography, a town of Bohemia, in the circle of Bechin; seven miles W. of Prüflitz.

PLAUZAT, in Geography, a town of the duchy of Mecklenburg, 15 miles E. of Parchim. N. lat. 53° 50'. E. long. 12° 23'.

PLAVA, a town of Berwia; 10 miles S.W. of Jenesbafar.

PLAUEN, a town of Saxony, in the county of Schwartzbarg, on the Gera; 16 miles N.W. of Schwartzbarg. N. lat. 50° 45'. E. long. 12° 21'. — Allo, a town of Saxony, in the Vogtland, on the Ellter, which is a manufacture of cotton and cloth; 22 miles S.W. of Zwickau. N. lat. 50° 24'. E. long. 12° 8'. — Allo, a town of Brandenburg, in the Middle Mark, seated on a lake formed by the Havel, which gives name to a canal that runs from thence to the Elbe. This town has a manufacture of porcelain; six miles W. of Brandenburg. N. lat. 52° 29'. E. long. 12° 30'.

PLAUER See, a lake of the duchy of Mecklenburg, about 20 miles in circumference; E. of Plau.

PLAUSCHNITZ, a town of Bohemia, in the circle of Boleslaw; three miles E.S.E. of Turnau.

PLAUSEN, a town of Prusia, in Ermeland; 14 miles E. of Heilberg.

PLAUZUS, among the Romans. See Acclamation.

PLAUTEN, in Geography, a town of Prusia, in Oberland; 16 miles S.E. of Marienwerder.

PLAUTUS, Marcus Accius, in Biography, a celebrated Latin writer of comedy, was a native of Sarina, a small town in Umbria. He was thought not only to have been of mean parentage, but the son of a slave. Few facts have come down to us that at all illustrate his life. He came to Rome, and obtained not only fame but emolument from his dramatic compositions, which were represented about a century and a half before the Christian era. Plautus is said to have acquired considerable property, and to have been tempted, in order to increase it, to engage in trade, but that, like many other literary speculators, he succeeded so ill, that he was reduced to so great poverty, as to hire himself as a labourer to grind in a mill. Yet even in this toilful situation his mind remained undepressed, and he composed three comedies. He died in the year 184 B.C. Anciently a great number of comedies were current under the popular name of Plautus, but of these the greater number was merely retouched by him, and the best Roman critics admitted only about twenty-five of his genuine compositions. Twenty of these are still extant, but some of them are in a mutilated state. Of the character they bore among his countrymen we have the most decided testimony. The learned Varro said, if the Muses were to speak Latin, they would use no other style than that of Plautus. By Cicero the wit of Plautus is called elegant, refined, ingenious, and facetious. "To a modern reader," says an able critic, "the humour of Plautus will often appear strong and genuine, but coarse and indelicate, and intermixed with quirbles and witticifms. His plays are, however, lively, and generally entertaining, and the language is a rich treasury of the Latin tongue. Many of his pieces, like those of the other dramatists, are professed translations from the Greek, and it is probable that all his plots are borrowed from the Grecian theatre." The best editions of Plautus are the Variorum by Gronovius.

PLAUZAT, in Geography, a town of France, in the department of the Puy de Dôme; 10 miles S. of Clermont Ferrand.

PLAY, Lucas. See Game, and Gaming.

PLAY, in the Doctrine of Chances, is used for the probability of the play's ending in a given number of games.

PLAY, in Poetry, &c. See Drama, Tragedy, Comedy, &c.

PLAYFORD, John, in Biography, a stationer and musician, seller of musical books and instruments, and clerk of the Temple church.

In 1655 he published the first edition of his "Introduction to the Skill of Musick," a compendium compiled from Morley, Butler, and other more bulky and abstruse books, which had so far a sale, that, in 1683, ten editions of it had been circulated through the kingdom. The book, indeed, contained no late discoveries or new doctrines, either in the theory or practice of the art; yet the form, price, and style, were so suited to every kind of musical readers, that it seems to have been more generally purchased and read, than any elementary musical tract that ever appeared in this or any other country.

John Playford was born in the year 1613, and feems, by what means is now not known, to have laid in a considerable stock of musical knowledge, previous to becoming the vender of the chief productions of the principal composers of the time. As he was the first, so he seems the most intelligent printer of music during the seventeenth century; and he and his son Henry appear to have acquired the esteem of the finest masters of the art; and without a special licence, or authorized monopoly, to have had almost the whole business of furnishing the entire nation with musical instruments, music books, and music paper, to themselves; as, during more than the first fifty years of the last century, Wallis and his son had afterwards.

In 1655, this diligent editor also published, in two separate books, small 8vo. "Court Ayres, by Dr. Charles Colman, William Lawes, John Jenkins, Simpson, Child, Cook, Rogers, &c."

These being published at a time when there was properly no court, were probably tunes which had been used in the masques performed at Whitehall during the life of the late king.

It was honest John Playford who first strung the harp of David, and published, in 1671, the first edition of his "Psalms and Hymns in solemn Musick, in four Parts on the common Tunes to Psalms in Metre used in Parish-churches. Also fix Hymns for one Voice to the Organ," folio. The several editions of this work published in various forms, at a small price, rendered its sale very general, and psalm-singing in parts, a favourite amusement in almost every village in the kingdom.

PLAYFORD, Henry, the second son of John, succeeded his father as a music-seller, at first at his shop in the Temple, but afterwards in the Temple Exchange, Fleet-street.

The music books advertised by him were but few compared with those published by his father. Among them were the Orpheus Britannicus, and the ten sonatas and airs of Purcell.

Henry Playford published, in 1701, what he called the second book of the "Pleasant Musical Companion, being a choice collection of catches for three or four voices; published chiefly for the encouragement of the musical societies which
which will be speedily set up in the chief cities and towns of
England."

We know not what effect this advertising title-page had
upon the nation, but believe that the publication of Purcell's
catches in two small volumes of the elder Walsh in queen
Anne's time, was the means of establishing catch clubs in
almost every town in the kingdom, where tobacco, ale, and
psalm-singing were to be found.

It is conjectured that Henry Playford survived his father
but a short time, for we meet with no publication by him
after 1710.

PLAY-HOUSE. See Theatre, Amphitheatre,
&c.

The most ancient English play-houses were the Curtain in
Shoreditch, and the Theatre. In the time of Shakspere,
who commenced a dramatic writer about the year 1592,
there were no less than ten theatres open, four private houses,
and one that were called public theatres. Moff, if not all
of Shakspere's plays, were performed either at the Globe,
which was an hexagonal building, partly open to the weather,
and partly covered with reeds, on the southern side of the
river Thames, called the Bank-side, and a public theatre,
where they always acted by day-light; or at the theatre in
Black-friars, which was a private play-house, and where plays
were usually represented by candle-light. Both these
belonged to the same company of comedians, viz. his majesty's
servants, which title they assumed after a licence had been granted
to them by king James, in 1603; having before this time been
called the servants of the lord chamberlain. The
exhibitions at the Globe feem to have been calculated chiefly
for the lower clafs of people, and those at Black-friars for a
more select and judicious audience. The former was a sum-
mer, and the latter a winter theatre. Many of our ancient
dramatic pieces were performed in the yards of carriers' ins,
in which, in the beginning of queen Elizabeth's reign, the
comedians, who then first united themselves in companies,
erected an occasional stage. The form of these temporary
play-houses feems to be preferred in our modern theatres.
Many circumstances concur to render it probable, that our
ancient theatres, in general, were only furnished with curtains,
which opened in the middle, and a fingle scene compos'd of
tapestry, fometimes ornamented with pictures. In the year
1605, Inigo Jones exhibited an entertainment at Oxford, in
which moveable fcenes were us'd; but they were not then us'd
in the public theatres. When sir William Davenant
firt opened, by virtue of his patent, the duke of York's theatre in Lincoln's-inn-fields, in the spring of the year 1662, with one of his own plays, the Siege of Rhodes, then
scenes made their first appearance upon the English stage;
and about the same time atfrcles were also introduced, prob-
bly by him, in imitation of the foreign theatres; and Mrs.
Betteton is faid to have been the firft woman that appeared
on the English stage. Before this time, female characters
were reprefented by boys or young men. In the time of
Shakspere plays began at one o'clock in the afternoon, and
the exhibition was usually finifh'd in two hours; and so late as 1607, they commenced at three o'clock. See Ma-
alone's Supplemental Observations to Stevens' edition of
Shakspere.

If any perfon shall play in plays, &c. jellingly or prophanely
ufe the name of God, they shall forfeit 10/. (Stat. i Jac. I.
cap. 21.) And playing speaking anything in derogation of
religion, &c. are liable to forfeitures and imprisonmert.
(1 Eliz.) Also acting plays or interludes on a Sunday is
subject to penalties, by i Car. i. cap. 1. No perfon shall
act any new play, or an addition to an old one, &c. unless
a true copy thereof, signed by the maker of the play-house,

be sent to the lord chamberlain fourteen days before it be
acted, who may prohibit the representing any stage play;
and perfons acting contrary to such prohibitions shall forfeit
50l. and their licences, &c. (Stat. to Geo. II. cap. 28.)
And by this statute, no licence is to be given to act plays,
but in the city and liberties of Westminster, or places of his
majesty's residence. Ibid.

PLAZIA, in Botany, a genus in the Flora Peruviaina,
p. 92, named after John Plaza, a Spanish botanist,
mentioned respectfully by Clusius. De Thes. 371.

PLEA, in Law, that which either party
allegeth for himself in court, in a cause then depending to be
tried.

Ples are either of the crown, or common pleas.

PLEAS OF THE CROWN comprehend all crimes and midle-
manners, in which the king, on behalf of the public, is the
plaintiff. Such are treasons, felonies, misprisions of either,
and mayhem.

PLEAS, Common, include all civil actions depending be-
 tween subject and subject. The former of these were the
proper object of the jurisdiclion of the court of king's bench;
the latter of the court of common pleas.

pleas are of two sorts; viz. dilatory pleas, and pleas
to the action. For an account of dilatory pleas, see DILA-
TORY.

pleas to the action, are such as dispute the very cause of
fuit.

A plea to the action is to answer to the merits of the com-
plaint; which is done either by confessing or denying it.
(See Confession of action.) To this head may be referred
the practice of what is called a "set-off," by which the
defendant acknowledges the justice of the plaintiff's demand
on the one hand; but on the other, sets up a demand of his
own to counterbalance that of the plaintiff, either in the
whole or in part; as if the plaintiff sues for ten pounds due
on a note of hand, the defendant may set off nine pounds due
to himself for merchandise sold to the plaintiff, and in
cafe he pleads such set-off, must pay the remaining balance into
court. This answers very nearly to the compenfatio, or
flage, of the civil law (Fl. 1. 2. 1.), and depends on the
statutes 2 Geo. II. c. 22. and 8 Geo. I. c. 24. which
cajil, that where there are mutual debts between the
plaintiff and defendant, one debt may be set against the other,
and either pleaded in bar, or given in evidence upon the
general issue at the trial; which shall operate as payment,
and extinguish to much of the plaintiff's demand.

pleas that totally deny the cause of complaint are either
the general, or a special plea, in bar. The general issue,
the general plea, travels, shovrs, and denies at once the whole
declaration, without offering any special matter whereby to
 evade it. Thus, in debt on contract, it is, nihil debet, he
owes nothing; in debt on bond, non est ipsis, it is not his
deed; in action of the cause upon a promife, non assumpt, he
had not promis'd; in trespass upon the cause, not guilty;
in covenant, performance of covenants, &c. In real actions,
nulla, no wrong done; nulla, non efficat, no effe effe; and in a
writ of right, that the tenant has more right to hold than
the demandant has to demand. These pleas are called the
general issue, because they amount at once to an issue, or a
fact affirmed on one side, and denied on the other. For-
merly the general issue was seldom pleaded, except when
the party meant wholly to deny the charge alleged against
him. But when he meant to disingenuously, deny, or palliate
the charge, it was always usual to set forth the particular
facts in what is called a special plea; which was originally
intended to apprise the court and the adverse party of the
nature and circumstances of the defence, and to keep the law
and
and the fact distinct. And it is an invariable rule, that every defence which cannot be thus specially pleaded, may be given in evidence, upon the general issue at the trial. Of late, on account of the chicanery and delay that have attended special pleading, the courts have, in some instances, and the legislature in many, more, permitted the general issue to be pleaded, thus leaving every thing open, the fact, the law, and the equity of the case, and have allowed special matter to be given in evidence at the trial.

Special pleas, in bar of the plaintiff’s demand, are very various, according to the circumstances of the defendant’s case. As, in real actions a general release, or a fine, both of which may defray and bar the plaintiff’s title. Or, in personal actions, an accord, arbitration, conditions performed, monage of the defendant, or some other fact which precludes the plaintiff from his action. A justification is likewise a special plea in bar; as in actions of assault and battery, for assault and battery, that it was the plaintiff’s own original assault; in trefpafs, that the defendant did the thing complained of in right of some office which warranted him to do it; or, in an action of slander, that the plaintiff is really as bad a man as the defendant said he was. A man may also plead the statutes of limitation in bar. (See Statutes of Limitation.) An estoppel is likewise a special plea in bar. See Estoppel, Bar, and Abatement.

The conditions and qualities of a plea are, 1. That it be single, and containing only one matter; for duplicity begets confusion. But by statute 4 & 5 Ann. c. 16, a man, with leave of the court, may plead two or more distinct matters or single pleas; as in an action of assault and battery, three, not guilty, for assault demijfs, and the statute of limitation. 2. That it be strict and positive, and not argumentative. 3. That it have convenient certainty of time, place, and persons. 4. That it answer the plaintiff’s allegations in every material point. 5. That it be so pleaded as to be capable of trial. Special pleas are usually given in the affirmative, sometimes in the negative, but they always advance some new fact not mentioned in the declaration; and then they must be averred to be true in the common form; “and this he is ready to verify.” This is not necessary in pleas of the general issue; those always containing a denial of the facts before advanced by the other party, and therefore putting him upon the proof of them.

It is a rule in pleading that no man be allowed to plead specially a plea as amounts only to the general issue, or a total denial of the charge; but in such case he shall be driven to plead the general issue in terms, whereby the whole question is referred to a jury. But if the defendant, in an afflue or action of trespass, be defers to refer the validity of his title to the court rather than to the jury, he may flate his title specially, and at the same time give colour to the plaintiff, or suppose him to have an appearance or colour of title, bad indeed in point of law, but of which the jury are not competent judges. When the plea of the defendant is thus put in, if it does not amount to an issue, or total contradiction of the declaration, but only evades it, the plaintiff may plead again, and reply to the defendant’s plea; either traversing it, that is, totally denying it; or as if on an action of debt upon bond, the defendant pleads foras ad dem, that he paid the money when due, here the plaintiff in his replication may totally traverse this plea, by denying that the defendant paid it; or he may allege new matter in contradiction to the defendant’s plea; as when the defendant pleads no award made, the plaintiff may reply, and set forth an actual award, and assign a breach; or the replication may confess and avoid the plea, by some new matter or distinction, consistent with the plaintiff’s former declaration; as, in an action for trespassing upon land of which the plaintiff is seized, if the defendant shews a title to the land by descent, and that therefore he had a right to enter, and gives colour to the plaintiff, the plaintiff may either traverse and totally deny the fact of the defendant; or he may confess and avoid it by replying, that true it is such descent happened, but that since the descent the defendant himself demised the lands to the plaintiff for term of life. To the replication the defendant may join, or put in an answer called a rejoinder. The plaintiff may answer the rejoinder by a fur-rejoinder; upon which the defendant may rebut; and the plaintiff answer him by a fur-rebutter; which pleas, replications, rejoinders, fur-rejoinders, rebutters, and fur-rebutters, answer to the exceptio, replica, duplicatio, triplicatio, and quadruplicatio of the Roman laws. Inft. 4. 14. Draft. l. 5. tr. 5. c. 1.

The whole of this proceeds is denominated the pleading; in the several flates of which it must be carefully observed, not to depart or vary from the title or defence, on which the party has once infilled. For this (which is called a departure in pleading) might occasion endless altercation, therefore the replication must support the declaration, and the rejoinder must support the plea, without departing out of it. As in the case of pleading no award made, in consequence of a bond of arbitration, to which the plaintiff replies, setting forth an actual award; now the defendant cannot rejoin that he hath performed this award, for such rejoinder would be an entire departure from his original plea, which alleged that no such award was made; therefore he has now no other choice, but to traverse the fact of the replication, or else to demur upon the law of it. Yet in many actions the plaintiff who has alleged in his declaration a general wrong, may, in his replication, after an evasive plea by the defendant, reduce that general wrong to a more particular certainty, by aligning the injury alread with all its specific circumstances in such manner as clearly to ascertain and identify it, consistently with his general complaint; which is called a new or novel affimation. Although duplicity in pleading must be avoided for various reasons, yet it is often expedient to plead in such a manner, as to avoid any implied admission of a fact, which cannot with propriety or fact be admitted af affirmata. And this may be done by what is called a protestation; by which the party interposes an oblique allegation or denial of some fact, protending (by the gerund, protesud) that such a matter does or does not exist; and at the same time avoiding a direct affirmation or denial. The use of this protestation is to save the party from being concluded with respect to some fact or circumstance, which cannot be directly affirmed or denied without falling into duplicity of pleading; and which yet, if he did not thus enter his protest, he might be deemed to have tacitly waived or admitted.

In any flates of the pleadings, when either fide advances or affirms any new matter, he usually avers it to be true, “and this he is ready to verify;” on the other hand, when either fideทราverses or denies the facts pleaded by his antagonist, he usually tenants an issue, as it is called; the language of which varies with the party by whom the issue is tendered; for if the traverse or denial comes from the defendant, the issue is tendered thus, “and of this he puts himself upon the country;” whereas submitting himself to the judgment of his peers; but if the traverse lies upon the plaintiff, he tenders the issue, or prays the judgment of the peers against the defendant in another form; thus, “and this he prays may be inquired of by the country.” But if either fide (e. g. the defendant) pleads a special negative plea, not traversing or denying anything that was before alleged,
alleged, but disclosing some new negative matter; as when the suit is on a bond, conditioned to perform an award, and the defendant pleads negatively, that no award was made, he tenders no issue upon this plea; because it does not yet appear whether the fact will be disputed, the plaintiff not yet having asserted the existence of any award; but when the plaintiff replies, and sets forth an actual specific award, if then the defendant traverses the replication, and denies the making of any such award, he then, and not before, tenders an issue to the plaintiff. For when, in the course of pleading, they come to a point which is affirmed on one side, and denied on the other, they are then freed to be at issue; all their debates being as at last contracted into a single point, which must now be determined either in favour of the plaintiff or defendant. Blackf. Com. b. iii. 

Plea, in Equit. may be either to the jurisdiction, shewing that the court has no cognizance of the cause; or to the person, shewing some disability in the plaintiff, as by outlawry, excommunication, and the like; or in bar, shewing some matter, wherefore the plaintiff can demand no relief, as an act of parliament, a fine, a release, or a former decree. And the truth of this plea the defendant is bound to prove, if put upon it by the plaintiff. 

Plea in Indictment, is the plea of the prisoner, or defendant, matter alleged by himself in his arraignment, if he does not confess, or plead, a false matter. Wanting the plea of bar, which is now abrogated (see SANCTUARY); there are five pleas of this kind. 1. A plea to the jurisdiction, which is when an indictment is taken before a court that hath no cognizance of the offence; as if a man be indicted for a rape at the Sheriff's term, or for treason at the quarter-sessions; in these, or similar cases, he may except to the jurisdiction of the court, without anwering at all to the crime alleged. (2 Hal. P. C. 256.) 2. A demurrer to the indictment. (See DEMURRER.) 3. A plea in abatement, which is principally for a misnomer, a wrong name, or a false addition to the prisoner. But the prisoner derives little benefit from dilatory pleas of this kind; because, if the exception be allowed, a new bill of indictment may be framed, according to what the prisoner in his plea avers to be his true name and addition. 4. A special plea in bar, which affects the merits of the indictment, and gives a reason why the prisoner ought not to answer it at all, nor put himself upon his trial for the crime alleged. These pleas are of four kinds: a former acquittal, a former conviction, a former attainer, or a pardon. Here we may observe that, though in civil actions, in which a man may sue where plea in bar to make, he is concluded by that plea and cannot recur to another; in criminal prosecutions, when a prisoner's plea in bar is found against him upon issue tried by a jury, or adjudged against him in point of law by the court; still he shall not be convicted or convicted thereon, but shall have judgment of relict ante posterius, and may plead over to the felony the general issue, not guilty. (2 Hal. P. C. 239.) For the law allows many pleas by which the prisoner may escape death; but only one plea, in consequence of which it can be indicted, viz. on the general issue, after an impartial examination and decision of the facts, by the unanimous verdict of a jury. 5. The general issue, a plea of non guilty, upon which plea alone the prisoner receives his final judgment of death. 

Plea in Bar of Execution, may be either infancy, pregnancy, the king's pardon, an act of grace, or diversity of person, viz. that he is not the same that was attainted and the like. In this last case a jury shall be impanelled to try this collateral issue, viz. the identity of his person, and not whether guilty or innocent; for that has been decided before. In these collateral issues, the trial shall be infallible, and no time allowed the prisoner to make his defence, or produce his witnesses, unleas he will make oath that he is not the person attainted; neither shall any peremptory challenges of the jury be allowed the prisoner, though formerly such challenges were held to be allowable, whenever a man's life was in question. 

Pleas of the Sword. Ranulph earl of Chester, 2 Hen. III. granted to his barons of Cheshire an ample charter of liberties, "exceptis platis ad gladium meum pertinentibus." The reason of the exception was, that William the Conqueror gave the earldom of Chester to his half-brother Hugh, commonly called Lupus, ancestor of this Ranulph. "Teneat is libere ad gladium, fictum ipse rex tenetur Angliam & coronam." 

Accordingly, in all indictments for felony, murder, &c. in the county palatine, the form was, "Contra pacem domini comitis, gladium & dignitatem suam:" or, "Contra dignitatem gladii Erfriedi." Such were the pleas for the dignity of the earl of Chester. 

Plea: Court of Common Pleas, called also common bench. See Court of Common Pleas. 

PLEADING, Placitatio, a discourse spoken at the bar, in defence of the cause of a party. From the time of the Conquest, all pleading was performed in French till the time of Edward III.; when it was appointed, that the pleas should be pleaded in English, but that they should be entered, or recorded, in Latin. But now by 4 Geo. I. cap. 26. it is enacted, that all proceedings in courts of justice shall be in English. 

At Athens, and even in France and England, it was prohibited to have any formed, or prepared pleading, or to annull the court with long artificial harangues; only, in important matters, it was the settled custom to begin the pleadings with a paflage in holy scripture. It is but of late years that eloquence was admitted to the bar, where it has been much practised and encouraged. Among the Athenians, an equal time was allowed both parties to plead, which was measured by a water-hour-glass; and in order to see justice done in this respect, there was an officer appointed to dilute the water to each, whence he was called ephydor. 

Pleadings, in the strictest sense, are all the allegations of the parties to a suit, made: after the count, or declaration, till issue is joined: or, more generally, pleadings are the mutual alterations between the plaintiff and defendant; which at present are set down and delivered into the proper office in writing, though formerly they were usually put in by their counsel or tenor, or vice versa, in court, and then minuted down by the chief clerks, or prothonotaries; whence in our old law French, the pleadings are frequently denominated the parol. The fault of these is the declaration, which fee. When the plaintiff had stated his case in the declaration, it is incumbent on the defendant within a reasonable time to make his defence, and put in a plea or else the plaintiff will at once recover judgment by default, or nihil dicat of the defendant. (See DEFENCE.) After defence made, the defendant must put in his plea. But, before he defends, if the suit is commenced by capias or beati, without any special original, he is entitled to demand one impression, or licentia rogandi; and may, before he pleads, have more granted by consent of the court; to see if he can end the matter amicably without farther suit, by talking with the plaintiff: a practice which is supposed to have arisen from a principle of religion, in obedience to the precept of the gospel (Matth. v. 25.) which
which preceptor has a plain reference to the Roman law of
the 12 tables, which expressly directed the plaintiff and
defendant to make up the matter, while they were in the
way, or going to the priest. There are many other
previous steps which may be taken by a defendant before
he puts in his plea. When these proceedings are over, the
defendant must then put in his excuse or plea. For an ac-
count of the different pleas, and the further proceed by
pleading; see Plea, supra.

PLEASANT, in Geography, a town of Clermont county, in
Ohio, containing 1245 inhabitants.—Alfo, in Fairfield
county, containing 968 inhabitants.

PLEASANT, Mount. See Mount Pleasant; adding in
that article after Pennsylvania, containing, in 1810, 1105
inhabitants.—Alfo, Mount Pleasant in Washington county,
containing 1105; and Mount Pleasant in Westmoreland,
containing 1780 inhabitants, both in the fame state.—Alfo,
in Jefferson county, Ohio, containing 846 inhabitants.

PLEASANT Point, a N.E. headland in Merrimack
bay, Lincoln county and flate of Maine.—Alfo, the eastern
boundary of Hawk's, or Sandwich river, in the harbour of
Chebucto.

PLEASANT River, a small village, with a poft-office, on
the sea-coast of Washington county, in Maine, at the head
of Narragansett bay; 16 miles N.E. of Goldborough.

PLEASURE, the effect of a fenfation, or perception,
agreeable to the mind, or of the gratification of some
appetite.

Pleasures may be diftinguished into two kinds. The firft,
thofe which anticipate, or go before the reafon: fuch are all
agreeable fenfations. These are popularly called pleasures of
felf, or of the body.

The fecond are thofe which do not precede, or antici-
patc, either the fensations or reafons. Thofe we call pleasures of
the mind. Such is the joy arifing from a clear perception of
fome future good, or the confufed fenfation of a prefent
one.

For an infance of each. A man frequently finds plea-
ure in eating a fruit he was before unacquainted with; this
is anticipating pleasures, which he feels before he knows the
fruit to be good. On the other hand, a hungry hunter ex-
pects, or perhaps actually finds viuitals; where the joy he
conceives is a pleafeure that follows from the knowledge of
his prefent or future good.

Pleasure and pain feem to be no other than engines in na-
ture's hand, by which we are directed to confult our own
prefervation, and avoid our ruin. To things that may con-
trbute to the one, as food, &c. he has annexed pleasure;
and to thofe that may conduce to the other, as hunger,
difeafe, &c. pain.

Among the multiplicity of things to be done, and to be
avoided, for the prefervation of animal life, &c. how should
we have diftinguished between the one and the other, but
for the fenfation of pleafure or pain? These are not only
spurs to urge us on, but also guides, to direct us when-
we are to go. Wherever nature has fixed a pleafure, we
may take it for granted, fie there enjoins a duty; and
fhofe that is there done, either for the individual, or
for the fpecies.

Hence it is, that our pleafures vary at different flages of
life; the pleafures, e. gr. of a child, a youth, a grown man,
an old man, &c. all tending to thofe particular things
required by nature in that particular flate of life, or for
the prefervation, simply, or, jointly, for that and pro-
pagation, &c.

Hence, from the different conftitutions of the body, at
different ages, it were very easy to account for all the par-
ticular fatisfactions and pleafures thereof: not by deducing
the pleafures mechanically from the difpofition of the organs in
that flate, but by confidering what is neceffary for the per-
fection and well-being of the individual in that flate, and what
is to con tribute to that of the fpecies. In a child, e. gr. mere
p prefervation in the prefent flate is not enough, it muft like-
wise grow: to bring this to pafs, nature has made the
returns of hunger, &c. more frequent, as well as more acute,
and the pleafures of feeding more exquifite. And that the
complex of aliment, in proportion to the bulk of the body,
may be difpelled with, she has made one of the great ple-
afures of the flate to confift in a feries of sportive exer-
cices; by means of which the parts of the body come to be
opened and expanded, and arrive at maturity. This done, the ple-
afures that conduced to it disappear; and others, suited to the
new flate, succeed.

In the Hartleyan fylla, the capacity of pleafure and
pain is one of the faculties of the human mind, by which a
man becomes capable of action, enjoyment, or fuffering.
Our affections, or paffions, are feelings arifing from the per-
ception of pleafure or pain, or, in other words, of natural
good or evil, according to the circumftances in which they are
placed. "By the affections," fays Dr. Hartley, "we are excited to pursue happinefs and all its means, and to
flee from misery and all its apparent caufes." The primary
affections in his fylla are ten; five grateful, and five un-
grateful: the former are love, defire, hope, joy, and plea-
sing recollection: the latter are hatred, averfion, fear, forrow,
and difpleafing recollection. (See Affection and Paffion.)

The eftence of this capacity of pleafure and pain we
drive from confciousfae, and what pleafure and pain
we learn from experience; thofe being feelings which
cannot be expreffed by definition. Natural good produces
pleafure, and that which produces pain is natural evil. Our
pleafures and pains are either fenfible or intellectual, that is,
they are the effect of other fenfations or ideas. The plea-
surable and painful fenfations he thus explains by his theory
of vibrations. Moderate vibrations are the caufes of plea-
ure, whilst violent vibrations occasion pain; hence the fame
fenfation, which in a moderate degree is pleasurable, may,
by increafing beyond certain limits, become exquifitely pain-
ful, as in the caufe of heat. Dr. Hartley conjectures, that
the precife limit between pleafure and pain is the flolution
of conftituency in the nerve that vibrate. Hence, Hartley
and his disciples also account for the pleafure which accom-
panies the recovery from painful diforders, and from the
recolefction of part pains, dangers, and troubles. The
vigorous vibrations, which occasion pain, fubfide by length
of time within the limits of pleafure. Hence, it has been
suggested, we may account, at leaft in part, for the
exifence of evil in the universe, and are able to affign a reafon,
why a flate of probation, or beings conftituted like our-
selves, fhould be in a confiderable degree a flate of fuffer-

Pains the most exquisite and durable, it has been said, may ultimately fall within the limits of pleasure, and may be even essential to the production of the greatest good.

Dr. Hartley, in the sequel of his "Treatise on Man," has shown how, upon his system of association and vibration, our five senses, viz. feeling, taste, smell, sight, and hearing, produce intellectual pleasures and pains, or the different affections, which are modifications of pleasure and pain.

Arranging the affections under five general classes, viz. imagination, emulation, self-interest, sympathy, and the moral sense; he traces them up to the association of ideas, and deduces them either from sensible pleasures or pains, which are evidently original, or from the combination of other intellectual pleasures or pains, which are derived from sensible ones. The pleasures and pains of imagination arise from the perception of natural or artificial beauty or deformity; and these he distinguishes into seven kinds. The pleasures and pains of ambition arise from the opinions of others concerning us; the sense of honour and of shame.

Those of self-interest arise from the possession or want of the means of happiness, and security from a subjection to the hazards of misery. (See Self-interest.) For the pleasures and pains of sympathy, theopathy, and the moral sense, see their several articles. See also Mental Philosophy.

Pleasure Boat, among the Ancients. See Thalamegus.

Pleasure Garden, in Ornamental Gardening, is that sort of garden which is formed near to, or that surrounds a country-house or residence; and which is contrived for the purpose of curiosity, ornament, or entertainment. This sometimes comprehends the whole pleasure ground, but at other times is totally distinct from it. Pleasure gardens should compactly be laid out according to the nature and situation of the particular places where they are to be formed, being of greater or less extent as circumstances may direct. They are mostly planted either wholly or in the greatest part with flowers and shrubs of the more beautiful and ornamental kinds, that they may afford as much beauty and variety as possible. In their forms they may be square, oblong, or somewhat circular, and have the boundaries of the divisions formed by the arrangements of curvilinear figures, embellished with collections of the most rare, beautiful, and curious flowering shrubs; the interior parts being divided into many narrow compartments, either in the parterre method with straight beds and borders, or into plain four-foot beds arranged parallel, with two-foot wide alleys between each, walks being carried all round next to the outer boundaries, after which borders surrounding the whole divisions, and within these the different divided parts for the beds, as already noticed, which should in general be raised in a gently rounding manner, the edges being let with dwarf-box, thist.f, and pinks by way of variety, and the alleys and walks laid with the box and fine gravel.

In these divisions may be planted the most curious and valuable hyacinths, tulips, polyanthos-narcissi, jonquils, ranunculuses, anenomes, as well as mottler other sorts of rare, hardly, bulbous, and tuberous-rooted flowers, each kind mostly in a separate manner, especially those of the more choice sorts, as being necessary, not only for the sake of distinction, but for the convenience of occasionally giving them protection from severe and inclement weather. In these situations, there may likewise be put out curious collections of the finest descriptions of fibrous-rooted flowering plants, such as carnations, polyanthuses, auriculas, and many other kinds, some of which being placed in separate beds, as those of the more valuable sorts, and others divided in different compartments, in order to give the greatest possible degree of variety. Still further, in other compartments, there may be exhibitions containing great varieties of all the different kinds of both the bulbous and fibrous-rooted sorts of flowering plants.

Gardens of this kind should confinitely, in every part, be kept clean, neat, and perfectly in order.

Pleasure Ground, in Gardening, any fort of ornamented ground round a residence. It comprehends all the ornamental compartments or divisions of ground and plantation; such as lawns, plantations of trees and shrubs, flower compartments, walks, pieces of water, &c., whether situated wholly within the space generally considered as pleasure ground, or extended over hills or, by other communications, to the adjacent fields, parks, paddocks, or out grounds.

In designs for pleasure grounds, modern improvements reject all formal works, such as long straight walks, regular interlacements, square grafts plots, corresponding parterres, quadrangular and angular spaces, inclosed with high clipped hedges, &c., as well as all other uniformities; instead of which, open spaces of grafts ground of varied forms and dimensions, and winding walks, all bound with plantations of trees, shrubs, and flowers, in various clumps and other distributions, are exhibited in a variety of imitative rural forms, as curves, projections, openings, and cloisings, in imitation of a natural alleviagae, having all the various plantations open to the walks and lawns. A spacious open lawn of grafts ground being generally built exhibited immediately in the front of the mansion, or main habitation, sometimes widely extended in open space on both sides to admit of greater prospect, &c., and sometimes more contrived towards the habitation, widening gradually outward, and having each side embellished with plantations of shrubbery, groves, thickets, &c., in clumps, and other parts, in sweeps, curves, and projections, towards the lawns, &c., with breaks or openings of grafts spaces at intervals, between the plantations; and serpentine gravel walks winding under the shade of the trees; extended plantations being also carried round next the outer boundary of the ground, in various openings and cloisings, having also gravel walks winding through them, for shady and private walking; and in the interior divisions of the ground serpentine winding walks exhibited, and elegant grafts openings, arranging various ways, all bordered with shrubberies, and other tree and shrub plantations, flower compartments, &c., disposed in a variety of different rural forms and dimensions, in easy windings, concaves, projections, and straight ranges, occasionally; with intervening breaks or openings, of grafts ground between the compartments of plantations, &c., both to promote rural diversity, and for communication and prospect to the different divisions; all the plantations being so variously arranged, as gradually to discover new scenes, each furnishing fresh variety, both in the form of the design in different parts, as well as in the disposition of the various trees, shrubs, and flowers, and other ornaments and diversities.

So that in these designs, according to modern gardening, a tract of ground of any extent may have the prospect varied and diversified exceedingly, in a beautiful representation of art and nature, so that in paling from one compartment to another, new varieties present themselves in the most agreeable manner; and even if the figure of the ground be irregular, and its surface has many inequalities, in windings and fallings, and other irregularities, the whole may be improved without any great trouble of squaring and levelling, as by humouring the natural form, even the very irregularities may be made to conceal their natural deformities, and carry along with them an air of diversity and novelty.
In these rural works, however, we should not entirely abolish all appearance of art and uniformity; for though, when properly applied, give an additional beauty and peculiar grace to all natural productions, and yet nature in the fairest and most advantageous point of view. One principal point in laying out a pleasure ground, is for the designer to take particular care that the whole extent of his ground be not taken in at one view, as where the contrary is the case, there is a tameness and want of proper effect produced.

It is impossible to give any directions for planting a pleasure ground; as the plan may be varied exceedingly, according to the natural figure, position, and situation of the land, and taste of the designer.

In respect to the situation, it must be immediately contiguous to the main house, whether high or low situated; however, a somewhat elevated situation, or the fide or summit of some moderate rising ground, is always the most eligible on which to erect the chief habitation, arranging the pleasure ground accordingly; such an exposure being the most desirable, both for the beauty of the prospect and healthfulness of the air; a low level situation neither affording a due prospect of the ground, nor the adjacent country, besides being liable to uninhabitable dampness, and sometimes inundation in winter; there are, however, many level situations, forming plains or flats, that possess great advantages both of soil and prospect, and the beauties of water without too much moisture; there are also sometimes large tracts of ground, confining both of low and high situations, as level plains, hollows, eminences, declivities, and other inequalities, which may be so improved as to make a most desirable pleasure ground, as the scene may be varied in the most beautiful manner imaginable; but as the choice of situation and scope of ground is not always attainable, every one must regulate his plan in the most commodious manner possible, agreeable to the nature of the particular situation, extent of ground, and plan which has been adopted.

The extent of pleasure grounds may be varied, according to that of the estate or premises, and other circumstances, as from a quarter or half an acre to thirty or forty or more.

The ground for this purpose should previously be well fenced in, by a wall, palis, hedge, or parts of each fort, and in some parts a folie or hah, where it may be necessary to extend the prospect, either at the termination of a lawn, walk, or avenue; and the clofe fences should generally be concealed withside, particularly the wall and palis fences, by a range of clofe plantation, unless where the wall may be wanted for the culture of wall fruit. But sometimes, when the pleasure ground adjoins to a fine park, paddock, or other agreeable prospect, the boundary fence on that side is often either a low edge, or a hah; but many prefer the latter, especially at the termination of any spacious opening, both to extend the prospect more effectually, and give the ground an air of greater extent, than it really has, at a distance; the hah being fink, nothing like a fence appears, so that the adjacent park, fields, &c. appear to be connected with the grounds.

The arrangement of the several divisions, both internal and external, must be wholly regulated by the nature and extent of the ground.

And in whatsoever mode such grounds are laid out, the whole of the different quarters, walks, and other parts, should be kept in an exact and neat order.

According to Mr. Loudon, the pleasure ground may consist of scenes of different expressions of avowed art, as those of gardening; and of nature, as those of picturesque improvement, such as tranquil or sequestered glades, romantic glens, flowery meads, fuzzy heaths, tangled dingles, wooded dells, rocky steeples, and numberless others, which are to be met with in a varied or picturesque country, and are either to be heightened in effect, or preferred from cultivation by the improver. Wherever the pleasure ground is not under some of the particular scenes of ornamental gardening, it should be fed at least by thyme, and often by horaces, cattle, &c., which should be allowed to come close to the terrace wall that separates the lawn from the mansion; for what can be more dull and unnatural, than the modern method of surrounding a house by a naked lawn totally delibute of animation?

A hollow winding dell or dingle, containing a brook or rill overhung with wood, and its banks diversified by broken ground presenting various coloured earths, and among the low growths old trunks of trees, roots, and flones, or dells of a grander character, containing bold, perpendicular, projecting, or irregular, massive rocks, overhung with huge trees, bushes, ferns, and creepers, grouped and combined in an infinite diversity of ways,—the stream, interrupted by the rocks, tumbling over in roaring cataracts, foaming cascades, or interrupted only by gentle falls,—and perhaps in some places, where the dell widens into a valley, spreading itself into a crystal lake, varied by little islands and woody projections, all heightened by the usual appendages of animation, the fingring of birds, the fragrance of flowers, from what is considered to be among the most enchanting kinds of recluse pleasure ground scenery. When a place is fortunate enough to have such a romantic chain of picturesque beauty as this, it should seldom be touched by the hand of art. It may happen, that some improvement may be made, by frowning, in a partial manner, rocks, roots, or flones, that are perhaps totally concealed; by augmenting a natural cascade, or by supplying ivy, or some other creepers, or evergreens, &c.; but in general more little can be attempted with propriety. The principal operation, that in any case can be undertaken in such a scene, is, where it may be requisite to lead through a walk, or road, either to observe its beauties, or as an approach to some other part of the residence. The difficulty of executing either of these will be great to those, who think of nothing but undulating sweeps, shaven lawns, and serpentine gravel walks; but by those accustomed to admire this kind of scenery, the operation will easily be accomplished. See Residence.

Pleasure of the King, in Lake, is used in connection with the infliction of punishment for any crime, not to signify any extrajudicial will of the sovereign, but such as is declared by his representatives, the judges in his courts of justice: “voluntas regis in curia, non in camera.” — Hal. P. C. 375.

PLEAU, La, in Geography, a town of France, in the department of the Corrèze, and chief place of a canton, in the district of Tulles; 18 miles E. of Tulles. The place contains 655, and the canton 6535 inhabitants, on a territory of 2258 square kilometers, in 8 communes.

PLEAUX, a town of France, in the department of the Cantal, and chief place of a canton, in the district of Mauriac; 8 miles S.W. of Mauriac. The place contains 2584, and the canton 10,667 inhabitants, on a territory of 1824 square kilometers, in 12 communes.

PLEBANUS was anciently the title of a rural dean.

The denomination arose hence, that these deanserie were then affixed to the plebania, or chief mother-church within such a district; which, at first, was usually ten parishes.

PLEBANUS seems also to have been used for a parish-priest of such a large mother-church, as was exempt from the jurisdiction of the ordinary; so that he had the authority of a rural
PLEBEIAN Games, were games celebrated by the Roman people, in remembrance, as some say, of their reconciliation with the senators, after the expulsion from the city, in the year of Rome 261; or, according to others, in token of their public rejoicing, when the kings were driven from Rome, A.U.C. 245; and the people enjoyed their liberty. These games were celebrated in the circus for three days, and commenced on the seventh of the calendar of December. Adrian instituted plebeian games in the circus, A.U.C. 874.

PLEBISCITUM, among the Romans, a law enacted by the common people, at the request of the tribune, or some other plebeian magistrate, without the intervention of the Senate.

PLEBISCITUM is more particularly applied to the law which the people made, when, upon some misunderstanding with the Senate, they retired to the Aventine mount.

PLECH, in Geography, a town of Germany, in the principality of Culmbach; 21 miles S. of Pegnitz.

PLECHAS, a word used by Hippocrates to express that region of the body which is terminated backward by the anus, forward by the pudenda, and sideways by the hips.

PLECTANAE, a word used by some to express the cornua uteri, and by others, for any plexus of vessels.

Gen. Ch. Cal. Perianth inferior, of one leaf, somewhat heart-shaped, short, two-lipped; upper lip obtuse, broad, with five, four, or five-lobed acute; the two lower segments rather the longest. Cor. of one petal, ringed, revolved; tube compressed, longer than the calyx; one lip, which is turned upward, broad, long, three-cleft; its middle segment very large, conspicuous; lateral ones small: the other, directed downwards, narrower, entire, ovate, concave. Nectary a spur or prominence, from the base of the tube of the corolla, pointing upwards. Stam. Filaments four, declining, awl-shaped, two of them rather the shortest; anthers simple. Fig. Genus four-lobed; style thread-shaped, the length and position of the stamens; stigma, lobed, acute. Peric. none, the calyx containing the four roundish seeds.

Such are the characters of this genus, as originally defined by its author, who considered the reversed corolla, or flower; the spur or prominence of the tube; and the simple stamens, as essential marks. The two latter especially were supposed to distinguish it from Ocimum; see this article. Mr. Brown however, looking more deeply into this latter genus, and finding several of its species without any tooth or appendage to their filaments, has referred such to Plectranthus, varying the consideration of the spur. He therefore gives the following character of Plectranthus.

Sepals two-lipped, spirated, the lower lip divided; the base tumid beneath in fruit. Upper lip of the corolla three-cleft, the middle segment two-lobed; lower lip longer, undivided, (modily concave.) Stamens declining; their filaments without teeth, (sometimes united at the base;) anthers of one cell, bearded.

This includes, not only the Plectranthus of other authors, and the toothed species of Ocimum, but also the Denudata and Coleus of Lour＼4eiro. Mr. Brown does not admit Lavandula carnosa into this genus, from which he says it differs in calyx and inflorescence, though agreeing in corolla, stamens and stigma, constituting, in his opinion, a genus by itself. (See Lavandula, at the end.) All the six New Holland species of Mr. Brown's Plectranthus are deficient of a spur. As the question is rather doubtful, while the whole genus of Ocimum requires to be critically examined, we shall here exhibit only such species of the genus before us as we conceive to answer to its original idea.

1. P. fruticosus. Shrubby Plectranthus. L'Herit. Stirp. 85. t. 47. Willd. n. 1. Air. n. 1. (Germana urticifolia; Lamarck Dict. v. 2. 692.)—Nectary spurred. Clusters compound. Flower-flanks three-cleft. Stem shrubby, downy.—Found at the Cape of Good Hope, from whence Mr. M"affon sent it in 1774 to Kew. This is a greenhouse shrub, flowering copiously from June to September. Every part has a fragrant scent. The stem is clothed with fine short down, unspotted. Leaves opposite, stalked, ovate, strongly serrated like those of a common nettle, vein, rough. Flowers copious, in pale violet clusters.

3. P. nudiflorus. Naked-flowered Plectranthus. Willd. n. 3.—Nectary gibbous. Panicle racemose, naked. Leaves heart-shaped, rugose; the upper ones clasping the stem.—Supposed to be a native of China; Willdenow having seen it in gardens under the name of Ocimum elatum. Root perennial. Stem erect, square, downy, scarcely six inches high. Lower leaves stalked, two or three inches long, coarsely toothed, rugose, smooth, except the veins at the back. Panicle a foot or more in length; each of the four clusters an inch long, turned one way, with two small heart-shaped bracteas. Corolla small, cloved, downy.

PLEEAE. See Conichthyodontes.

PECTRUM, a machine of wood or ivory used by the ancients in playing upon the lyre, crooked and pointed at both ends, in using which there was more spirit given to the tone, and less danger of hitting the wrong string by using the finger. The quill used in playing on the mandoline, is in miniature what we may suppose the plectrum to have been with respect to the lyre.

PLEDGE, in Law. See VADUM.

PLEDEE. See Process.

PLEDE, Pledge, a surety, or gage, either real or personal, which the plaintiff, or demandant, is to find, for his prosecuting the suit.

The word is sometimes also used for frank pledge.

To Pledge, in Drinking, denotes to warrant, or be surety to one, that he shall receive no harm while he is taking his draught.

The phrase is referred, by our antiquaries, to the practice of the Danes, heretofore, in England; who frequently used to flab, or cut the throats of the natives while they were drinking.

PLEDGERY, or PLEGGERY, surethip, or an undertaking, or answering for another.

The appellant shall require the confable and marefchal to deliver his pleggs, and to discharge them of their pledgey; and the confable and marefchal shall ask leave of the king to acquit his pleggs, after that the appellant is come into the lift to do his devor. Orig. Jur. ex Vet. Cod. Mss. in Bibl. Selden.

PLEDS of Goods for Money, &c. See PAWN and BAILMENT.

PLEDBET, in Surgery, a kind of flat tent, made not to enter a wound, but to be laid upon it, to imbibe the superfluous humours, and keep it clean and dry.

PLEEIA, in Botany, a name of Michaux's, which seems intended to express the superabundance of itamens compared with others of its kindred, from πλήθος, more. Mich. Boreal. Amer. v. i. 247. Pursh Am. Sept. v. i. 275.—Clas and order, Encyndria Trigynia. Nat. Ord. Tripetalinae, Linn. June, Jaff.

PLEEAE. See Conichthyodontes.

PLEEAE, a loan, to which the name is given by Linnaeus, which is not so good as Burmann's.

Differing from the leaf, according to Vahl, in its flaky leaves, and in having ovate membranous bracteas.

6. P. punctatus. Dotted Plectranthus. L'Herit. Stirp. 87. t. 42; not 41. Willd. n. 6. Ait. n. 3. (Ocyismum punctatum; Linn. Suppl. 275.)—Neptary gibbous. Clus- ter dense. Stem herbaceous, tumid, hairy.—Native of Africa, where it is said to have been found by Mr. Bruce the famous traveller. This species is biennial, flowering in the greenhouse from January to May. The tumid, flaky, purple-dotted, hairy stem distinguishes it. The footstalks are short. Corolla very pale blue.

7. P. carnosa. Dense-spiked Plectranthus. (Lavandula carnosa; Linn. fil. Diff. 9. 1. 2. Am. Acad. v. 10. 52. t. 3. Ait. Hort. Kew. v. 3. 188. Katu-Kurka; Rheede Hort. Malab. v. 10. 79. 52. Nepeta indica, rotundifolium; Morif. Seet. 11. t. 6. f. 7.)—Neptary gibbous. Spikes ovate, dense. Leaves ovate, somewhat heart-shaped, flaky, wavy or serrated.—Found by Koening, on dry walls and rocks, at Sadras in the East Indies, flowering in the hottest season, after which the foliage appears. The stem is shrubby, but succulent, finely hairy. Leaves flaky, ovate or slightly heart-shaped, wavy, or more or less deeply serrated, very flaky, minutely hairy, varying greatly in size. Spikes generally three or four to each branch, flaky, foliary and simple, ovate, thick, very much crowded, the calyces singularly reflexed, or imbricated downward. Corolla yellowish. Rheede speaks of this plant as aromatic, and useful against the bite of some serpents.

It was sent to Kew in 1788 by Sir Joseph Banks, and is kept in the flow, flowering in June and July; but the root is said to be only biennial.

Gen. Ch. Cal. Perianth superior, of one leaf, turbinate, with five flight teeth, the mouth closed with five hairy scales, permanent. Cor. Petals five, lanceolate, tellous, inserted into the mouth of the calyx. Stam. Filaments five, very short; anthers two-lobed, roundish, each sheltered by one of the scales of the calyx. Fil. German inferior; style thread-shaped, shorter than the calyx; stigma ovate. Peric. Berry oblong, of two cells. Seeds foliary, oblong, compressed.

Eff. Ch. Petals five, inserted into the mouth of the calyx, which is closed by five hairy scales. Berry inferior, with two seeds.

1. P. tenusfolia. Linn. Mant. 52. (P. corymbosa; Burm. Prodr. Cap. 6. Rhannus folis subrotundato-acuminatis, tenui racemoso; Burm. Afr. 257. t. 94.)—Native of woods at the Cape of Good Hope, flowering in September; a stranger, as yet, in our gardens. This is a tree, whole trunk and principal branches are armed with very considerable, long, tapering, simple, opposite pinnas. The leaves are opposite, stalked, elliptical, acute at each end, entire thick-edged, somewhat wavy and revolute, smooth on both sides; polished above; paler and opaque beneath; with one rib, and many traversing veins. Flowers small, yellow, in compound, axillary, dense clusters, about twice the length of each footstalk; their stalks opposite, angular, rather downy, with opposite, minute, deciduous bracteas under their subdivisions.

We are at a loss for the meaning of the specific name given by Linnaeus, which is not so good as Burmann's.

The tree is said to be well calculated for making hedges. The habit and appearance of every part seem rather to justify the opinion of Linnaeus than of Jaffreu, respecting the natural order to which this plant belongs, but the inferior germen, if it be really so, is adverse to both.
Pleaides, in Mythology, were the seven daughters of Atlas, called Maya, Elektra, Taygeta, Aeternia, Alcione, Celene, and Merope. These Atlantides, it is said, were translated to the heavens, and formed the Pleiades; the meaning of which fable is, that Atlas first observed these stars, and called them by the names of his daughters.

Pleaides, Poetical, is a name which the Greeks gave to seven celebrated poets, flourishing under the reign of Ptolemy Philadelphus.

In imitation of the Greeks, Ronard formed a Pleiades of French poets under the reign of Henry II. It consisted of Daurat, Ronard, du Bellay, Bellon, Bai£, Tyard, and Jodelle.

On the same model, some of their authors afterwards projected a new Pleiades of the Latin poets of the last century; but they were not agreed about the names of those that should compose it; much less on him who should be the Lucida Pleiad. M. Baillot named F. Rapi, F. Commune, F. de la Rue, M. de Santeuil, M. Menage, M. du Perier, and M. Petit.

Plein River, in Geography, the northern head-water of Illinois river; it interlocks with Chicago river, a water of lake Michigan, and five miles below Dupage lake, through which it passes; it joins Theskiwi river, which comes from the caftward. Thence the united stream takes the name of Illinois. The land between these branches is rich, and intermixed with swamps and ponds.

Pleinfeld, or Blankfeld, a town of Bavaria, infulated in Anspach; 22 miles S.E. of Anspach. N. lat. 49° 37'. E. long. 10° 55'.

Pleinfoeureres, a town of France, in the department of the Ille and Villaine, and chief place of a canton, in the district of St. Malo. The town contains 2726, and the canton 12,878 inhabitants, on a territory of 167.5 kilometres, in 11 communes.

Pleinting, a town of Bavaria, on the Danube; 5 miles S.S.E. of Osterhof.

Pleiske, a river of Brandenburg, which runs into the Oder; 9 miles above Francfort.

Pleisnitzen, a town of Hungary, 25 miles W. of Caflchir.

Pleissa, a river of Saxony, which runs into the Elter, near Leipzig.

Pleissen, or Pleissa, a lordship of Germany, in the principality of Heffe Rhinefl, infulated in the duchy of Brunswick. It takes its name from an old castle situated on a mountain.

Pleisvedel, a town of Bohemia, in the circle of Leitmeritz; 8 miles S.W. of Leypa.

Plelan, a town of France, in the department of the Ille and Villaine, and chief place of a canton, in the district of Montfort; it falls into E.N.E. of Vannes. The place contains 2917, and the canton 13,316 inhabitants, on a territory of 323.5 kilometres, in 8 communes.—Also, a town of France, in the department of the Northern Coasts, and chief place of a canton, in the district of DÌman; 6 miles E. of Loudeac. The place contains 834, and the canton 3903 inhabitants, on a territory of 1223 kilometres, in 9 communes.

Plemmyrium, in Ancient Geography, a promontory on the eastern coast of Sicily, over-against Syracus, of which it was the port, according to Thucydides. It is also mentioned by Virgil.

Pleummyros, a word used by the old Greek writers to express a redundance of honour. Its proper figurative sense is the flowing in of the tide.

Pleumpius, Vorsches Pontentaus, in Biography, an eminent physician, was born at Amsterdam, of a distinguished family, in December 1604. He received his classical education at Gant, and studied philosophy at Louvain, whence he repaired to Leyden, and commenced his medical studies. He subsequently travelled into Italy, and passed the principal portion of his time at Padua and Bologna, having the advantage of pursuing his anatomical investigations under the direction of Spigelius at the former place, and of taking his degree of doctor at the latter. On his return to Holland, he settled in the practice of his profession in his native city, where he acquired a high reputation; and was induced to accept the invitation of Isabella, princess of the Low Countries, to the vacant profeship of
PLENEUF, in Geography, a town of France, in the department of the North Coasts, and chief place of a canton, in the district of St. Brieuc; 20 miles W.N.W. of Dinan. The place contains 1243, and the canton 6502 inhabitants, on a territory of 1155 square miles, in 5 communes.

PLENILIUM, composed of plenus, and in Latin Plenus, and Lunae, in Astronomy, that phase of the moon, properly called the full moon.

PLENIPOTTENTIARY, compounded of plenus, full, and potentes, power, a person who has full power and commission to do any thing.

The word is chiefly understood of the ministers or ambassadors sent from princes or states to treat of peace, marriages, and other important matters.

The first thing done in conferences of peace, is, to examine the power of the plenipotentaries. See Treaty.

PLENITUDE, Plenitude, the quality of a thing that is full, or that fills another.

In physic, it is chiefly used for a redundance of blood and humours.

Physicians reckon two kinds of plenitude. The one called ad locos, when the abundance of the blood oppresses the patient's strength.

The other ad usus, when it fills the vessels too much; swelling them to a degree of bursting.

PLENNA, a word used by some writers to express any mucous humour.

PLENUM, in Physics, a term used to signify that state of things, in which every part of space, or extension, is supposed to be full of matter. It is used in opposition to a vacuum, which is a space supposed devoid of all matter.

The Cartesian adhere firmly to the doctrine of an absolute plenum. This they do on this principle, that the essence of matter consists in extension; and hence, indeed, the consequence is very easy, that wherever there is space or extension, there is also matter. But this principle we have elsewhere shewn to be false; and therefore, the consequence drawn from it falls to the ground. See Matter.

That there is a real vacuum, in the nature of things, is likewise demonstrated by arguments a posteriori, under Vacuum.

PLEONASM, Pleonasmus, formed from πλεονασμός, q. d. superabundance, in Rhetoric, a figure of speech, by which we make use of words, seemingly needless or superfluous, in order to express a thought with the greater force and energy.

Such is, I saw it with my own eyes; or, he heard it with his own ears, &c.

The pleonasm is called by the Latins redundatio.

Pleonasm, by grammarians, is usually defined a fault in discourse, wherein we say more than is necessary.

M. Vaugelas will not allow the phrase, I saw it with my own eyes, to be a pleonasm; insomuch as there are no superfluous words in it; none but what are necessary to give a stronger assurance of the thing affirmed. It is sufficient that one of the phrases shew somewhat more than the other, to avoid the imputation of a pleonasm.

In effect, though we give the same pleonasm to any thing that is not necessary, or that enters the discourse independently of the sense or construction, yet there are frequently words which, in that view, would be pertinent, and even are used to good purpose, to give a greater force or grace to discourse, and to ascertain the truth of what is said. He spake with his mouth, is a pleonasm in English; it is none in Latin: Virgil says, hic ore locutus. Some French authors deny unir ensemble, to write together, to be a pleonasm.

PLECOSTIAS, a word used by the old Greeks to express the reflexion or reflexing the body to its natural state, after it has been emaciated by sickness.

PLERETICS, Pleurotics, formed from πλευρής, I fall, in Medicine, a kind of remedies, otherwise called incumbratives, and forotics.

PLES, in Geography, a town of Ruffia, in the government of Koftron, on the Volga; 16 miles S. of Koftron.

N. lat. 57° 15'. E. long. 41° 14'.
PLESHY, a village and parish, situated in the hundred of Dunmow, and county of Essex, England, though now containing, according to the parliamentary returns of 1818, only 45 houses, and 221 inhabitants, was a place of distinguished confluence in ancient times. Gough and Morant are both of opinion that it was the site of a Roman station, from the number of urns and Roman bricks which have been dug up here, and from the boulders and regularity of the entrenchment surrounding the village. The valley of this work is still very perfect on three sides, and appears to have had four original entrances through it into the inclosed area. These circumstances, however, though plausible reasons for assigning to Pleshy a Roman origin, are not conclusive evidence. In the Saxon era no mention is made of this place; indeed its authentic history does not commence till the reign of King Stephen, when we are informed that it was vested in the crown by the king's marriage with Maud, granddaughter of Eulalce, earl of Boulogne, by whom it is probable the castle here was first erected. Stephen granted it to William de Magnaville, high constable of England, who procured licence to fortify the castle from Henry II. Hence we conjecture that he was the person who constructed the fosse, as well as the immense keep, which remains to this day a proud monument of the ancient grandeur and strength of this once majestic fortress. The keep is oval-shaped, and measures about 890 feet in circumference, and forty-five feet in breadth at the top.

Humphrey de Bohun, earl of Hereford, having succeeded to the estates and honours of the Magnavilles, obtained leave of Edward I. to enlarge his park at Pleshy, by inclosing 150 additional acres. In this family the castle and manor continued till the year 1372, when Thomas of Woodstock, afterwards duke of Gloucetlcer, became possessor of them, and of the dignity of high constable, by his marriage with Eleanor, eldest daughter, and co-heiress of Humphrey, the last male heir of the Bohuns. This nobleman, whose busy life and tragical fate form conspicuous features in the history of England, was decoyed from the castle by his nephew, king Richard II., and treacherously put to death. Pleshy, after that event, devolved to Edmund, earl of Stafford, in right of Anne, the duke's daughter. It afterwards fell to the crown, and was annexed to the duchy of Lancaster. From that period the castle seems to have been totally neglected, but the date of its demolition is not mentioned. Lebien says that this place was anciently called Tumbledown, and that Pleshy is a corruption for Caulef de Placocto. A college for a master and eight secular priests, two clerics, and two choristers, was founded here by Thomas of Woodstock in 1353. The original endowments were subsequently augmented by various benefactors: and at the time of the dissolution its revenues were valued at £ 39 13s. 10d. per annum clear. This house was granted by Henry VIII. to Sir John Gate, who razed all the old buildings, the college-church excepted, which he however also partly destroyed. It continued in a ruinous state till the beginning of the last century, when bishop Compton, having been promoted to the see of London, repaired such portions of it as were standing, and added a neat body of brick. The principal monuments here are those of Sir William Jolliffe, knt., and his nephew, Samuel Tuffnell, esq., whose family here possessed the manor for upwards of half a century. Some memorial of the former confluence of Pleshy appears in the election of a mayor annually from among the freeholders of the village, at the court-leet for the manor. This custom is singular, and seems to indicate that Pleshy was at one time a corporate town. Beauties of England and Wales, vol. iv., by John Britton and E. W. Brayley, from Morant's "History, &c. of Essex," folio; and Gough's "History and Antiquities of Pleshy," 4to.

PLESNONE, a word used by the ancients to signify plenteous or fatity.

PLESEVITZA, in Geography, a mountain of Croatia; 12 miles N.W. of Bihae.

PLESSOW, a town of the duchy of Holland; 8 miles W. of Kalisch.

PLESTIN, a town of France, in the department of the North Coasts, and chief place of a canton, in the district of Lannion; 7 miles S.W. of Lannion. The place contains 4862, and the canton 9460 inhabitants, on a territory of 105 kilometres, in 7 communes.

PLESUR, a river of the Grisons, which runs into the Rhine at Coire.

PLESZ, or Plese, a town and fortresses of Silesia, and capital of a lordship, in the principality of Katibor, on the borders of Poland, surrounded with walls, flanked with towers, and containing two churches; 17 miles N.N.E. of Teplitz. N. lat. 49° 57'. E. long. 18° 50'.

PLETCHEBERG, a mountain of Switzerland, in the canton of Berne; 22 miles S.S.E. of Thun.

PLETHORA, πλέθωρα, in Medicine, from πλεθέω, imped, fullness of habit, or an abundance of blood.

Every increase of the fluids is sometimes called plethora; but the medical authors, who speak distinctly, limit the term to a superabundance of good blood. (See Van Swieten, Comment. ad Aph. 106.) This, then, is fearfully to be considered as itself a disease, but a degree of high health, bordering upon disease; a condition which predisposes to disease, and renders the person liable to be disordered by any exciting cause, by which the equilibrium of the circulation may be accidentally disturbed.

The mechanical physicians ascribed many of the morbid actions of the system to plethora; and they remarked, that an abundance of blood was inconvenient to the animal economy in a relative manner only, in different cafes, viz., relative to the quantity, to the space occupied, to the bulk, and to the patient's strength. The first, plethora ad molem, or ad vasa, signifies the absolute over-abundance of blood, as seen by the florid dilatation of the minute vessels, and detected by a full, oppressed, and laboured pulse. This occurs generally in vigorous constitutions, where the digestive powers are strong and active, and the vaile from exercise disproportioned to the supply. The second, or plethora ad spatum, is produced when the quantity of the circulating fluids remaining the same, the capacity of the vessels is diminished; as may be exemplified in the state of circulation in cold weather, or in the cold fit of fevers. The third, or plethora ad volumen, implies the contrary condition, or that in which the quantity remaining the same, the bulk is augmented; as by external heat, inflammatory differences, stimulating food and drink, violent pellagous, &c. The blood, however, is not capable of much expansion; and both this and the preceding condition are occasioned rather by a change in the distribution of the blood, than by any actual variation in its condition. By cold, it is driven from the extreme vessels to those of the interior; by heat, it is admitted into the relaxed vessels of the external parts. The last, or plethora ad virens, signifies only a comparative weakness of the circulating powers; so that although the quantity of blood be not superabundant, yet it is greater than the vessels are enabled to distribute freely.

After all these refinements of pathology, it will be obvious that there is, in fact, but one kind of actual plethora, which is a real superabundance of blood, and is therefore the cause of a predisposition to disease, especially to fevers, to
to all inflammatory affections, such as gout and pleurisy, to apoplexy, lethargy, palsy, and the rupture of blood-vessels. This plethoric state is produced by a vigorous digestive power in the stomach, especially in certain constitutions, which peppers a lax constancy of the venuous system; and its production is favoured by taking copiously of food that is nutritious and easy of digestion, by quietness and composure of mind, by much sleep, and by obedience and inactivity as to muscular exertion. (See Corpulence.) The symptoms by which the existence of this plethoric state are indicated, are thus enumerated by Van Swieten:—we know that it is present, he says, if there be a great redness over the whole body, especially where the cuticle is fine and delicate, as in the corners of the eyes, the inside of the eyelids, nose, mouth, lips, and throat; if the veins are distended, and the pulse at the same time is full and strong; and if upon unusual motion, or exposure to heat, or taking of wine, a tene of fullness and distention is felt throughout the body, and this is followed by dullness and drowsiness. Comment. loc. cit.

The cure of this plethoric state is not always easy. Blood-letting is attended with temporary relief; but it is apt to be followed by an increase of the fullness, if other circum-
stances are not attended to. But with it should be combined a diet of milder kind, more cooling and fragile, and of less nourishing substances, of regularity and freedom in the relaxation of the bowels, and a gradual attainment of the power of corporeal exertion, by taking exercise at first by way of gentle walking, and subsequently by the more active use of the muscles, even by bodily labour, if that prove requisite.

PLETHRON, a Grecian measure, by some said to contain 1444, by others 10,000 square feet. As蝙abnot.

PLETENBERG, in Geography, a town of Germany, in the county of Mark, on the Elbe and the Oeller, governed by its own magistracy. The parih-church belongs in common to the Lutherans and Calvinists. The inhabitants are employed partly in agriculture and breeding of cattle, and partly in the manufacture of coarse cloths and smith’s work, particularly fectes; beside other handicrafts; 28 miles S. of Hamm.

PLETENBERG’S Bay, a bay on the S.E. coast of Africa, Cape Seal, at the southern extremity of the bay, is in S. lat. 34° 6’. E. long. 23° 48’. Variation of the compass 27° 12’. W. The tide flows at full or change 3° 10’, and rises five or six feet perpendicularly. This bay scarcely seems capable, by any expense, of being rendered secure, even for small craft, in the winter months; but, in the summer season, ships may remain without any danger. Wellward of this bay, at the distance of about eighteen miles, is Knysna, which see. Plettenberg’s bay is a division of the district of Zwelbordan, which begins at the Kayman’s river, and continues to the inaccessible forests of Sitikamma. The whole of this tract of country is very beautiful, agreeably diversified by hill and dale, and lofty forests. Within seven miles of the bay are large timber-trees, and the surface is almost as level as a bowling-green, over which the several roads are carried. The peafanry who inhabit this district are mostly wood-cutters, who earn a very hard subsistence. The great divince from the Cape of Good Hope, being 400 miles of bad road, allows them little profit on a load of timber, when sold at the dreased rate in the Cape market, so that they prefer disposing of it at the bay for a mere trifle. Plank of thirteen or fourteen inches in width, and an inch thick, may be purchased on the spot at the rate of 3d. per foot in length. The bark of several of the creeping plants in the forest might be employed as substitutes for hemp; and the iron oars, near the base of the mountain, might be worked

by clearing away the wood, of which there is an inexhaustible supply. Barrow’s Africa, vol. ii.

PLETZDORF, a town of Bavaria, in the bishopric of Bamberg; six miles W.N.W. of Burg Eberach.

PLETZKY, a town of Saxony; two miles W. of Gommern.

PLEVEN, a town of European Turkey, in Bulgarla, on the Vid; 28 miles S. of Nicopolis.

PLEUGLIA, a town of European Turkey, in Servia; 43 miles W. of Jembefar.

PLEVIN, Plevina, in Laos, a warrant or allowance, the same with pledge. See Pledge, Pleven, &c.

PLEUMANGAT, in Geography, a town of France, in the department of the North Coasts; 13 miles S.S.W. of Dinan.

PLEUMARTIN, a town of France, in the department of the Vienne, and chief place of a canton, in the district of Chatellerault. The place contains 1205, and the canton 7143 inhabitants, on a territory of 86 kilometres, in 12 communes.

PLEUMAUDAN, a town of France, in the department of the North Coasts; six miles S.S.W. of Dinan.

PLEUNOS, a town of Africa, in Barea. N. lat. 31° 40’. E. long. 25° 20’.

PLEURA, in Anatomy, the serous membrane, which lines the cavity of the thorax. See Lung.

PLEURISY, Pleuritis, in Medicine, an inflammation of the pleura, or membrane surrounding the lungs. The pleurisy has been generally distinguished by medical writers from the peripneumony, or inflammation of the sub-
stance of the lungs; by the greater acuteness of the pain in the side, increa.ed on inspiration, the greater hardness and strength of the pulse, the dryness of the cough, and the greater violence of the fever. It is in fact, however, only a modification of the same disease with the pneumony; whence Dr. Cullen gave the same generic name pneumonia to both. We shall, therefore, refer the reader to the former article, where all the modifications of pneumonic inflammation are discussed at length. See Pneumony.

PLEURITIS, the pleurisy.

PLEUROCYSTUS, in Natural History, the name of one of the general arrangements of the echini marini. The word is derived from the Greek πλευράς, the side, and οιανς, the anus. The echiuri of this division are distinguished from the others, by having their anus neither on the funnulor, nor in any part of the bafe, but in some part of the superficies of one of the fides.

PLEUROYDNE, in Medicine, from pleura and ήνος, pain, signifies a pain of the side, independent of inflammation, as pleuritis denotes the pain arising from inflammation. A fitch or pain in the side often occurs, independently of any acute inflammation of the lungs, pleuris, or contiguous organs, and it is generally increa.ed by the action of breathing. It has been often denominated a falle or pneumous pleurisy. The pain, however, is seldom leated in the membrane called the pleura, but often in the muscles of the chief, sometimes in the other membranous parts; and it may arise from rheumatis affecting those parts, from fepsis or disiph, from a plethoric condition, or from a nervous and hydrophic state, in which the circulation is languid and irregular; it may also be connected with a gouty, lyphalitic, or locubitor habit. Sauväges has distributed the pleurodyne into eighteen species, according to its origin from one or other of these caufes. (See his Nofol. Method. chfs. v. gen. ii.) The term is now most commonly applied to rheumatic pains affecting the muscles of the ribs and the diaphragm. See Rheumatism.

PLEURON, in Ancient Geography, the name of two
bony fish that are demarcated flat-fish. The structure of this fish is considered as one of the most curious deviations from the general uniformity or regularity observed by nature in the external figure of animals, in which, with a few exceptions, both sides of the body are perfectly similar; but in the genus Pleuronectes, the animal is so constituted, that one side appears to represent the back, and the opposite side the abdomen. They swim obliquely or on their sides, and the two eyes are always placed on one side, and it is from this circumstance that the sections into which the species are divided, are constituted; that is, according as the eyes are on the right or the left side. The fish of this genus refite at or near the bottom of the water, owing to their having no air-bladder; they often bury themselves in the sand as far as the head, by which means they escape the jaws of the more rapacious tribes; the eyes are covered with a nitid membrane; the nostrils are double and contiguous; the belly is without ribs; the fins are soft, and mostly with simple rays; the ventral and pectoral long, the tail generally rounded, with biff rays.

A. Eyes both on the right Side of the Head.

TRICHODACTYLYS. Body rough; pectoral fins filiform. This is only known from the description of Artedi, who says that it is rough, of a grey colour, with dusky variegations. It is a native of the Indian seas, and found about Ambona.

ZEBRA. Body with numerous transverse bands. This is reckoned a very elegant species, and readily distinguishable by its colours, the upper part being white, with a brownish cast towards the back, and marked from head to tail by numerous, double, deep brown, transverse bands, passing across the fins themselves. It is rather larger than the common sole. It is a native of the Indian seas, and in considerable esteem as an article of food.

PLEGNANA. Body oblong, somewhat rough; dorsal and anal fins joined to the tail. It inhabits Carolina; the body is pale and cinereous.

OCELLATUS. Body with four dark brown ovalate spots; the irides are white. Found in the sea about Surinam.

* HYPOGLOSSUS; Holb hut. The body of this species is perfectly smooth; the tail is lunar. This species not only exceeds in size all the rest of the present genus, but may be considered as one of the largest of fishes, properly so called, having been found of the weight of three or four hundred pounds. It is a native of the Mediterranean and Northern seas, but appears to arrive at its greatest size in the latter; it is the most voracious of the whole tribe, preying on a variety of other fishes, as well as upon different kinds of crabs, shell-fish, &c. It is of a longer or more slender form than most other flat-fish. It is not much regarded as an article of food.

CYNOGLOSSUS. Body oblong, smooth; teeth obtuse; tail a little rounded. It is extremely allied to the preceding, and has been regarded rather as a variety than a distinct species.

It is a native of the Northern seas, and found in considerable numbers in deep bays about the coasts of Greenland.

* PLATESSA; Plaite. Body smooth; behind the left eye there is a row of six tubercles reaching to the lateral line. The plaice is easily distinguished from the others of the genus by its shape and colours, being very broad and flat; of a fine palish brown above, marked both on the body and fins by pretty numerous orange-coloured spots; the under side is white. It is an inhabitant of the Mediterranean, the Baltic, and Northern seas, and is found in considerable plenty about our own coasts.

* RENUS; Rofe-coloured Flounder. Body roly; fins pale yellow-brown. It is frequently taken in the Thames.

* LIMANDA; Dab. Scales very small, ciliate; spinules at the root of the dorsal and anal fins with obtuse teeth. It inhabits the European seas; is less and thinner than the flounder; feeds on worms and insects, especially small crabs, it spawns in June; the fish is reckoned very good.

* LEVIS; Smear-dab. Brown, with obscure yellow spots, beneath white, with five large dusky spots; scales smooth; the dorsal fin has seventy-nine rays. It is about eighteen inches long, and the flesh is reckoned good for food.

LIMANDOIDES. Body oblong, rough; lateral line straight, broad. It is found in the Northern seas; it resembles the plaice; the flesh is very good.

SOLEA; Sole. Body oblong, rough; the upper jaw is longer. The sole is an inhabitant of the Northern, Baltic, Mediterranean, and American seas, and grows to the length of two feet or more, and to the weight of six or eight pounds; its general size is, however, very much smaller. It is covered with small rough scales of an oblong form, each terminated by numerous spines, and very strongly fastened to the skin. These scales, from the elegance of their structure, have long since formed objects for the microscope; an erroneous idea sometimes prevails that the spine end of the scale is that by which it is inserted into the skin. This fish delights in lying at the bottom of the coasts which it frequents, preying on small shell-fish, infish, sea-insects, &c.; it is generally taken by the trawl-net. The chief fishery is said to be at Brixham, in Torbay.

* ARNOCLOERUS; Smooth Sole. Thin, pellucid, white, smooth. It is found, though but seldom, on the coasts of Cornwall.

LINGUATULA. Vent on the left side; the teeth are very sharp.

GLACIALIS. Very smooth; above brown, beneath white; middle rays of the dorso and anal fins rough, with small spines. It inhabits sandy places in the Frozen sea, and is about nine inches long.

PLATESSOIDES. Body above with brown spots. It inhabits sandy places in the mouths of rivers in Greenland; it is scarcely a foot long; feeds on small worms and fish; in shape it resembles the R. linguatula; in its scales, the sole; and in its spots, the plaice.

B. Eyes both on the left Side of the Head.

LINEATUS. Body rough, barred with black; it has no pectoral fins. It inhabits North America.
**PLERANTHUS.** Lateral line double, and also without pectoral fins. It is a native of China.

**PUNCTATUS.** Body broad and very rough. It inhabits the deep sandy places of the Northern sea. It is reckoned a great delicacy in Denmark.

*Rhombus;* Pearl. Body smooth. It is found in European seas, and is the broadest of its size, except the turbot; the body is covered with small scales, deep brown, with dirty yellow spots, beneath white; the flesh is very good, but inferior to the turbot described below.

**DENTATUS.** Body oblong, smooth; teeth extending out of the mouth. It inhabits Carolina.

*Maximus,* the Turbot. Body rough. This fine fish, so highly prized by epicures, inhabits the European and Mediterranean seas; grows sometimes to thirty pounds weight; it is very voracious, and feeds on inlets, worms, and teataceous animals; the body is squarer than any other species; it is covered with obtuse, unequal, spiny tubercles; above it is brown, variegated yellow; beneath it is white, spotted with brown; the flesh is firm and excellent. For the method of catching turbot, see the article TURBOT.

*Passer;* Whiff. Lateral line much curved, prickly.

It is a native of European seas, and is about a foot long; the flesh is good.

**PAPILLOUS.** Lateral line curved; body papillous. It inhabits America, and is supposed to be a variety of the last.

**MANCUS.** Head tuberculate; pectoral fins unequal. It inhabits the sandy bottoms of the Balsal and Pacific seas.

**ARGUS.** Body variegated; tail rounded; jaws equal. It is found in the neighbourhood of the Caribbea islands; the body is covered with small soft scales, and variegated with yellow spots, which are dotted with brown, and edged with blue; the body is sprinkled with brown points.

**LUNATUS.** Body with scattered, blue, half ocellate spots.

It is a native of the North American seas; the tail is lunate.

**JAPONICUS.** Tongue rough. It is a native of the Japanese seas. It is about fix inches long; the colour is brownish above, and whitish beneath; rays of the dorsal and anal fin so extremely numerous as to be counted with difficulty.

**PLEURO-PERIPNEUMONY** or **PLEURO-PNEUMONIA,** in Medicine, a term employed to denote the most common form of pulmonary inflammation, in which both the pleura and the lungs are involved in the disease at the same time. See PERIPNEUMONY.

**PLEUROORTHNOPCEA,** a term used by medical writers to express that kind of pleurisy in which the patient cannot breathe, unles in an erect posture.

**PLEUROTTHALIS,** in Botany, from πλης, the side, and ἐκλεις, a bough or friend, apparently in allusion to the lateral insertion of the inflowence, the whole plant often consisting of but a simple leaf with its flalk; and at the side, where both unite, the flowers are produced.—Brown MSS. Ait. Hort. Kew. v. 5. 211. —Clavis et order, Gym. and Hort. Kew. Eff. Ch. Lip. of the nectary connected, by a joint, with the base of the column. Two lower calyx-leaves combined underneath. Masses of pollen two, without a furrow. Br.

1. P. rufifolia. Butcher’s-broom leaved Pleurothallis. (Dendrobiun rufiflorum; Swartz Orchid. 94. Willd. Sp. Pl. v. 4. 135.) Epidendrum rufiflorum; Jacq. Amer. 226. t. 133. f. 3. Linn. Sp. Pl. 1353. Helleborine rufi majoris folio; Plum. Ic. 171. t. 176. f. 2.)—Stem elongated. Leaf solitary, ovato-lanceolate. Flowers aggregate, at the base of the leaf.—Native of Woods in the Weit Indies. It flowers in the flore in May and June. The perennial roots consist of numerous long simple fibres, growing parasitically on the branches or stems of trees. Planta several, about a span high, forming a tuft, like small lilies of the valley, but the flowers are not much elevated. Their form we have not had an opportunity of seeing.—We presume the two other species in Plumer’s tab. 176, belong to the same genus; but the above is alone mentioned in Hort. Kew.

**PLEURS,** Plurs, or Piuro, in Geography, a town of Switzerland, which was formerly large and flourishing, and subject, as well as Chiavenna, to the Grisons. It is laid to have contained three churches, many large houses, and a stone bridge over the Maria; and that its population amounted to at least 1500 inhabitants, who carried on an inconsiderable commerce. But it was totally overwhelmed by the fall of mount Conto, which terrible catastrophe happened on the 25th of August, 1618. The valley in which it was situated is very narrow, and the whole town was buried in one undistinguishable ruin. A contemporary account relates, that the cloud of dust and rubbish was so great as to cover the heavens like smoke, and even to extend as far as Chiavenna; the inhabitants of which place, alarmed at the phenomenon, were still more terrified at the sudden disappearance of the river Maria, the course of which was stopped by the fallen fragments of rock, and apprehensive that the torrent had undermined Chiavenna, they precipitately fled in great numbers to the mountains. A part of the ancient walls, and the ruins of a country house, belonging to the richest family in the place, are the only remains of its former existence.

**PLEURTUIT,** a town of France, in the department of the Ille and Villaine, and chief place of a canton, in the district of St. Malo. The place contains 6596, and the canton 10,973 inhabitants, on a territory of 75 kilometres, in 4 communes.

**PLEUVAULT,** a town of France, in the department of the Côte d’Or; 12 miles S.E. of Dijon.

**PLEXUS,** in Anatomy, a term applied to various parts of the body, and particularly where several nerves or bloodvessels are united together. The plexus choroides is situated in the lateral ventricle of the brain. (See Brain.) The plexus pampiniformis is made up of the ramifications and unions of the spermatic vessels. (See Generation.) In the nervous systemplexuses are frequent, particularly in the great sympathetic. See Nervous System.

**PLEYBEN,** in Geography, a town of France, in the department of Finlêtre, and chief place of a canton, in the district of Chateaulin; five miles N.E. of it. The place contains 3572; and the canton 14,493 inhabitants, on a territory of 475 kilometres, in 9 communes.

**PLEYBERG,** a town of the duchy of Carinthia, formerly called “AuffenReim;” 20 miles E. of Clagenfurt.

**PLIANT MEALY TREES,** in Gardening, a common tree in plantations. See Viburnum.

**PLICA,** in Medicine, commonly mentioned with the epithet Polonica, because the disease is endemic in Poland, and the neighbouring countries, is an affection of the hair, which becomes matted together, and thickened, so as to form masses which cannot be unravelled, in consequence of the deposition of a morbid matter in and about the hair.

The disease is called Kolam, or Kolcz, in Poland; and by the Germans Weichfel-sepp, on account of its prevalence in the region watered by the Weichsel, or Vistula. Sauvages and the zoologists have denominated it Trichoma. As the disease is never seen in this country, except by the accidental visit of a person affected with it from the country.
where it prevails, we can only describe it after the writers who have witnessed it. The most clear and concise account of it is given by M. de la Fontaine, surgeon at Warsaw, in his surgical and medical treatise on various subjects respecting Poland, published in German, from which we shall extract the following history.

The symptoms which precede the morbid affection of the hair are various, and often put on the appearance of other diseases. Thus pseudo-rheumatic pains are sometimes the antecedents of the malady: and it is said that apoplexy, mania, and various nervous diseases are apt to occur, as well as inflammations, particularly of the eyes, indurations of the glands, gangrene, and caries, more particularly of the nasal bones and cranium. Sometimes, however, the plica comes on without any previous symptom, even in the course of one night; and violent pinnions of the mind, especially rage and terror, are said to have caused it instantaneously. The most common symptoms of its approach are, a sense of weight and torpidity in all the limbs, pains in the back, giddiness, difficulty of breathing, ringing in the ears, with an increased secretion of cerumen, dull pains in the orbits of the eyes and lacrymal glands, with an augmented flow of tears, head-ache, violent itching and pricking in the hairy scalp, pain in the precordia, and depression of spirits. In many patients there is a remarkable change in the appetite, a craving for spirituous liquors, and for new and strange kinds of food, while they loathe the things which they used to relish most. But the most certain sign that a plica will soon be formed, are clammy sweats about the head, with a diminution of pains, and a febrility of tigtheses, as if the upper parts of the head were drawn together.

The hairs now begin to grow greasy, and emit a remarkably disagreeable smell. The patient has frequent alternations of shivering and heat, and feels an unpleasant pricking cold under his nails. Under these circumstances, a sort of crisis takes place, upon the deposition of the morbid matter upon the hair and nails, and the symptoms of ill health immediately disappear, except in some rare cases, where a new deposition is to take place, and the crisis is therefore imperfect. The matter is deposited in the hairs, and sometimes in greater quantity than they can contain; they then burst, and a prodigious quantity is poured out between them, gluing them together. It is not true, that the hairs extend so much that blood flows out of them, as has been affirmed, or that they bleed on being cut. Occasionally the matter is not only deposited in the hairy scalp, but upon the hair of the pubis, of the arm-pits, or upon the nails. If the symptoms continue, a second plica will certainly be formed, but not until the first has separated from the head, and new hair has grown: it is never certain, however, that a second will not be formed; for the disease often takes on a kind of periodic form. A constant fever of cold about the head, and particularly at the temples, is a sure sign of its returning.

Sometimes the whole matter is deposited in one half of the hair, the other half remaining found: in which cases, the previous symptoms attack only one side of the body. The peculiar form of the matting depends upon the previous fashion of the hair: most of the men cut it short, while the women, on the contrary, have uncommonly long and beautiful hair. The morbid matter is first deposited in the rete Malpighii, from whence it penetrates into the hair, sometimes slowly, sometimes rapidly. The moisture oozing out from the hairs bind them together, and the same is impossible to separate them again: if the whole hair be affected, it forms a kind of cap: if it flows out more partially, several tails or rope-like plicae are produced. Some days after the mass of disease has been formed, it begins to emit an odour like that of rancid fat; and when it is touched, it excites a prickling unpleasant sensation in the fingers. M. Fontaine described a patient, in whom the plica had come on just before death, and he found the bulps of the hair larger than natural, from which he pressed out a pale yellow clammy mucus. In another, in whom the plica was already old, he found nothing remarkable. The plica is apt to be productive of prodigious numbers of lice, from which the patient suffers even more from than from the disease.

All writers have divided the plica into several species, according to the various forms which it assumes. Sauvages has described three species. 1. Trichoma cirriforme, or what the French call plica en cordons, is the most common form, when it appears in long tails or cords, as before mentioned. It was called abusively enough by Schultz, plica mus, or the male plica. 2. Trichoma villosum, the plica feminina of Schultz, when the disease is more generally diffused. And 3. The Trichoma Polonium, when it suddenly extends to a great size, and forms a cap over the head. M. Alibert, in the treatise "Sur les Maladies de la Peau," which he has not mentioned, has also divided la plica into three species, and points out several varieties under each. His first is Plica multiforme, or Plica caput-medusa, which applies to the tail-like or serpentine agglutinations, which may not be inapparently compared to the fabulous head of Medusa. His second species is Plica à queue, ou foliaires, or Plica longi-cauda, in which the plicae are not divided, as in the former species, but reunite and form one tail-like mass, not unlike the tail of a quadruped, often acquiring a great length. And bis third is Plica en maffes, or Plica asphyza, in which a conglomerated mass is formed over the head, without any tail-like divisions. These arbitrary classifications afford at least some distinct notion of the varieties of appearance which the diseased assumes.

The proximate cause of the plica, according to M. de la Fontaine, is a peculiar morbid matter, which is clammy and acrid, has its seat in the lymph, and is deposited critically upon the hair or nails. When it is deposited upon the nails, either of the hands or the feet, they become larger, thicker, prominent, deformed, horny, and ill-coloured, but not black.

The exciting causes are altogether uncertain; for neither the air, water, nor food, seems to have any influence in producing it; nor are cleanliness and regular combing the hair any defence against it. Excessive shews, however, that it is a contagious disease, and very often concerns; at the same time, those to whom it is communicated by contact are said to have it slightly, and to be easily cured. It affects no sex, age, or condition, nor even newly arrived strangers, and some infants bring it into the world with them: the lower classes of the people, however, suffer most from it; and those who have soft brown hair are most frequently affected, though no colour escapes. The plica is never white; but when it drops off in old people, it is sometimes succeeded by white hairs. Poles, who travel, are sometimes affected with it in other countries, and even their children. There is no accurate history of its origin: the Greeks, Romans, and Arabs have not mentioned the disease; but some modern writers affirm that it was imported from Tartary in the year 1387. It now prevails in Tartary, White and Red Russia, Lithuania, and from the source of the Vistula to the Carpathian mountains; but is more frequent in some districts than in others.

The method of cure recommended for plica varies with the circumstances of the case. When fever is present, moderate evacuations
écavations must be referred to; but blood-letting is to be employed with great caution. M. de la Fontaine compares the disease with the small-pox, in which, when the febile action is too feeble to produce the eruption, it must be increased; when it is too violent, it must be diminished. Hence the patient must be, in some instances, supported by generous diet; while, in others, a purgative regimen must be adopted. In order to bring about the crisis, the famous writer recommends the use of fudorifics, and appears, indeed, to consider antimony as a specific in this disease. The older physicians praise the Lycopodium as poiffelled of specific powers, but without any good grounds; and the common people believe in a great number of specific remedies, but the disease has not become less frequent, notwithstanding these supposed means of cure. Mercurials, especially when carried to the extent of exciting salivation, are said to be highly detrimental in every case; but if the disease be complicated with yphills, the corrosive muriate of mercury is very beneficial.

External remedies are almost always necessary; such as the application of warmth to the head, in the form of vapour, warm bath, or fomentations made with the decoctions of various plants: a decoction of soap is oftentimes beneficial when the head-ache is severe. Sinapisms and blisters are likewise applied with advantage. The plica may, or may not, be cut off according to circumstances. After a complete crisis, it separates from the head, and remains attached only by a hair. This may take place in a few days, weeks, or months. If it has lost its peculiar fineness and greasy appearance, has become dry, and all concomitant symptoms have ceased, it may be cut off by dividing the found hair: for it is remarkable, that even an old plica cannot be cut in the middle without giving pain. The new hair may be washed with warm water, and combed out. If, however, the plica be new, fit fast on the head, cause a prickling in the fingers when touched, and the general symptoms have not subsided, it must not on any account be cut off. The most dreadful accidents often immediately ensue from such practice. Some have become instantly blind, or have died from apoplexy, or in epileptic convulsions. The people are so much afraid of this, that they will seldom permit the plica to be cut off, even when it may be done with safety. If bad conseqences follow the cutting off of the plica, the most certain and speedy remedy is to apply it in its former situation. This must be done before it becomes dry; and it is almost incredible, says M. de la Fontaine, that, after one, two, three, or more days, it will again adhere to the head. He does not maintain that it grows to the flumps of the hair; but that innumerable examples prove, that a kind of callus is formed, as in a fractured bone. If the plica be not brought to adhere again, the patient, if he furvive, remains excessively sick, until the hair grow, and a new plica be formed. The Jews, who are bigoted to their own customs and methods of cure, never permit it to be cut off, and nothing can be more disgusting than one whose beard and whiskers are affected with this disease.

If the morbid matter be deposited on the surface of the body, it is said to occasion malignant and obdurate fomes, which give a great deal of trouble. If it has a tendency to deposit itself in the nails, it must be encouraged by the application of stimulants, such as tincture of cantharides, blisters, or by touching a fresh plica with the fingers. The nails do not separate so readily as the hair, and can only be safely cut off when new nails have begun to grow; and this often does not happen. The Poles believe, that keeping their hair short, or even shaving the head, is a preferreive

against this disease; but, on the contrary, the men suffer much more than the women, whose hair is long; and it at last affects the hair on other parts of the body.

M. de la Fontaine recommends a mild, attenuant, and corrective diet, as in other diseases proceeding from acrimony of the fluids, with the use of ripe fruits. The correctness of his advice, however, may be justly questioned, since he informs us, that the diet of the common people in Poland consists abnoln, if not entirely, of vegetables, which are generally made four. He concludes by this singular observation, that, if all these means be inadequate to produce the crisis, insculation of the disease will often effect it; and that this is performed by putting on a cap, which has just been worn by one who has a recent plica. See Duncan's Annals of Medicine, vol. i. sect. 1. Haller, Diffutationes Med. tom. i. art. 16, 17. Alberth, Précis Théorique et Pratique sur les Maladies de la Peau, p. 92, et seq. Memoirs of the Literary and Philosophical Society of Manchester, vol. iv. part 2.

PLICARIA, in Botany, a name used by some for the club-mofs.

PLICATED LEAF. See LEAF.

PLIGHT, in our old Law Books, a term which signifies the estate, with the quality of the land; though sometimes it extends also to the rent-charge, and the possibility of a dower. Coke's Inq. fol. 221.

Obf. Every botanist, who has attended, in any manner, to the subject, is aware of the great obscurity that envelops this genus, which depends chiefly on the authority of Plu-

mier, and which no succeeding botanist has been able to verify; except perhaps Allamand, from whose communications Linnaeus corrected the generic character as above. Some have suppos'd Plumier to have been totally mistaken, as to the genus being superior, and that Plinia is no other than...
than an *Eugenia*. Linnaeus, and Allamand possibly, confounded these genera in their ideas; for their *P. rubra* is, as every body knows, *Eugenia uniflora*. See Wild. Sp. Pl. v. 2. 562, where its multifarious synonyms are correctly cited; see also our article *Eugenia*. We subjoin all we can find upon record of the original and only species of *Plinia*, of which we have never been so fortunate as to see a specimen.

1. *P. crocea.* Orange-fruited *Plinia*. Linn. Mant. 24.4. Wildl. n. 1. (P. pinnaata; Linn. Sp. Pl. ed. 1. 516. ed. 2. 735. P. pentapetala; Linn. Mant. 402. P. fruticu croceo, odorato; Plum. Lc. 219. t. 225.) By Plummer's figure, which is our only guide, this appears to be a *tree*, with round alternate branches. The leaves are opposite, nearly sessile, ovate, pointed, entire, about three inches long and one broad, apparently smooth, with one rib, and many transverse incurved veins. *Flowers* clustered over the larger branches, nearly sessile, solitary, scarcely so big as a hawthorn blossom, the tapering *calyx* projecting beyond the numerous *flamentos*, which are themselves longer than the *petals*. *Fruit* globular, saffron-coloured and fragrant, according to Plummer, the size of a large gooseberry, deeply furrowed and wrinkled. Not more slightly furrowed, or rather quite globular and only fruited, large, with a thin shell, and full kernel.

Burmann, the editor of Plummer, misconceived the *fruits* to be abruptly pinnate, taking the whole branch for a leaf. Linnaeus adopted this error, and having once made a false step, he floundered deeper and deeper in trying to correct himself, altering the specific name time after time, and contradicting the plant with one of a different genus; into which last mistake he was indeed led by his correspondent Allamand. We do not presume to throw any new light on this obscure point of botanical history, but what we have collected may serve to afford those who may be so fortunate as to meet, in some part of the West Indies or of South America, with the plant Plummer described. Dr. Swartz, who investigated the former with great industry, seems never to have seen the *Plinia*; nor has he, in his *Observations Botanicae*, 203, done more than indicate the generic confusion, to which we have sufficiently adverted.

*Plinia*, in *Gardening*, comprises a plant of the exotic shrubby kind for the *rove*, of which the species cultivated is the red-fruiting *plinia*, or myrtle (*P. pedunculata*).

*Method of Culture.*—It is increased by the seeds, which should be procured from abroad, and which should be sown in pots, filled with rich mould, plunging them in a bark hotbed, when they appear in the fame leaon. They may also be increased by planting cuttings of the young shoots, in the later spring and summer months, in pots filled with good earth, covering them, with sand or bell-glaucies, and watering them occasionally. They may be so rooted as to be fit for removing into separate pots the same year. It is a plant highly ornamental in flower collections, from its flowering in the winter leaon.

**PLINIANA**, in *Geography*, a town or rather village of Italy, in the department of the Lario; six miles N. of Como. This place is remarkable for a singular fountain, which is still to be seen in the fame *lake* as described by Pliny, *lib.* iv. ep. 30. This spring bursts from a rock, and falls in natural cascades into the lake of Como. It ebbs and flows three times a day; gradually rising until it forms a considerable stream, and then as gradually subsiding till it becomes almost dry.

**PLINLIMMON**, a mountain of Wales, in the N. part of the county of Cardigan, on the borders of Montgomeryshire.

**PLINTH**, from *pars*, brick, in Architecture, a flat square member, in form of a brick: sometimes, also, called the *sitter*.

The plinth is used as the foot, or foundation of columns: being that flat square table, under the mouldings of the base and pedestal, at the bottom of the whole order, seeming to have been originally intended to keep the bottom of the primitive wooden pillars from rotting.

The plinth is also called the *orlo* or *orlo*.

Vitruvius also calls the Tuscan abacus, plinth, from its resembling a square brick.

**Plinth of a Statue**, &c. is a base or stand, either flat, round, or square, serving to support a statue, &c.

**Plinth of a Wall**, is a term for two or three rows of bricks advancing out from the wall; or in the general for any flat high moulding, serving in a front wall to mark the floors; or to sustain the eaves of a wall, and the larnier of a chimney.

**PLINTHITIS**, a kind of alum found in some of the islands of the Archipelago, and called also *placitius*, from its usually being found in thin cakes.

**PLINTHUM**, a name given by the ancients to a machine invented for the making extension of dislocated or fractured limbs. Orfobius describes several kinds.

**PLINY, the elder, CAIUS PLINIUS SECUNDUS**, in *Biography*, a distinguished Roman writer, was born, it is thought, at Verona, in the reign of Tiberius, A.D. 23. He was descended from an illustrious family, and served in the army during the wars in Germany. He rote to various public employments under the emperors Nero, Vespasian, and Titus. It is said that there is a scarcely a man of bu- nes who was so devoted to study, or comprehended such an extent of literary research. The following is the mode of his spending his time at Rome, when he was high in the possession of the imperial favour. Before day-break he waited upon Vespasian, who was also an early rifer, and then proceeded to execute the emperor's orders. On returning home he employed the rest of the day in study. After taking a light repast, he reclined in the sun according to the Roman custom, while a book was read to him, from which he took notes. He never puted any work without making extracts, as he was accustomed to say "that no book was so bad as not to afford something valuable." He then bathed, flumbered a little, and rising fresh, as it to a new day, studied till supper time. Even during that repast a reader was at his side, as there was upon all his journeys; and a vacant hour never occurred which he did not employ in reading and writing. Of his absence of time, his nephew, the younger Pliny, gives the following instance: one of his friends having obliged the reader to repeat something that he had pronounced improperly, "Did you understand him?" said Pliny, "I did," he replied. "Why then did you stop him? We have lost more than ten lines by the interruption." He always went from place to place in a sedan, that he might read on his road, and reproved his nephew for walking as so much time lost. The plan thus adopted by the philo- sopher, it might be supposed, would have precluded all original observation and reflection; but he was diligent in natural pursuits, and it was his ardent curiosity and thirst of knowledge that occasioned his death. He had the com- mand of the fleet stationed at Milawa, when, in the month of August, A.D. 79, a great eruption of Vesuvius broke out. On its first appearance he steered directly to the spot, as well for the humane purpose of giving assistance to the fugitives, as for viewing the progres of the eruption. The volcano raged with the utmost fury, and spread alarm through all the vicinity. While others were flying he ordered his pilot
Pliny, the younger, C. Plinius Cæcilius Secundus, born at Como, in the reign of Nero, A.D. 62, was the son of L. Cæcilius, by a sister of the elder Pliny. He was sent to Rome for education, and after perfecting himself in the Greek language, he was placed under the tuition of Quintilian and Nicetes. His disposition and talents caused him to be adopted by his uncle Pliny, and defined to be the heir of his name and fortune. He was in the eighteenth year of his age when the eruption of Mount Vesuvius took place, which proved fatal to his uncle. He had imbibed so much of his uncle's ardour for study, that he chose to remain reading the history of Livy, rather than accompany his uncle to a nearer view of the interesting but fatal phenomenon. He began to plead causes soon after his uncle's death, but his labours in this way were soon interrupted by a campaign into Syria, with the rank of military tribune. He did not, however, wholly abandon his literary pursuits in that situation, but availed himself of the presence of the philosophers Euphrates and Artemidorus, who had been banished Rome, with the other professors of philosophy, by Vespasian. After his return his reputation for eloquence rose so high, that when he was likely to harangue the people, vast crowds attended, and he was sure to be greeted with the loudest applauses, in which even the judges sometimes joined. In the reign of Domitian he was raised successively to the offices of questor, tribune of the people, and praetor. Under Nerva he was appointed to the office of prefect of the Saturnian treasury. In the third consulate of the emperor Trajan, Pliny was one of the honorary consuls termed iuvenal, and on this occasion he returned public thanks to the emperor in an oration, which he afterwards enlarged to the panegyric of Trajan. After this the care of the channel, and the banks of the Tiber, was next conferred upon him, with the augurate; and then he was appointed proconsul; whence he wrote to Trajan that curious letter concerning the primitive Christians, which is extant among his epistles. Pliny's letter is esteemed as almost the only genuine monument of ecclesiastical antiquity, relating to the times immediately succeeding the apostles, it having been written within about forty years after the death of the apostle Paul. It has been preferred by Christians themselves, as a clear and unanswerable evidence of the purity of their doctrine and practice, and is frequently appealed to by the early writers of the church against the unprovoked calumnies of their adversaries. It is not known what became of Pliny after his return from Bithynia; antiquity is also silent as to the time of his death; but it is conjectured, that he died either a little before or soon after Trajan; that is, about the year 116.

It appears that he left his first wife in the beginning of Nerva's reign, and that soon after he married his beloved Calpurnia: he never had any children. He was one of the greatest wits, and one of the worthiest men among the ancients. He had fine parts, which he cultivated with great care. He wrote and published a great number of pieces; but nothing has escaped the wreck of time except the books of Letters, and the panegyric upon Trajan. This has ever been regarded as a master-piece of excellent composition. It is an elaborate specimen of true eloquence, chiefly of value as containing enlarged views of the duties of a sovereign. Some writers have said, that no panegyrist was ever possessed of a finer subject, and on which he might better indulge in all the flow of eloquence, without incurring the suspicion of flattery and falsehood; but others observe, that as it was composed at the very beginning of Trajan's reign, it has but little weight as a testimony to the merits of that excellent emperor. It might perhaps have been the happy means of fixing his character, and it is no small praise if it produced this feat of effect, and that the youthful emperor was determined by a life of virtue to deserve all the encomia paid to him. His epistles, in ten books, are much to be prized for the anecdotes with which they abound, of the characters and incidents of the times, and likewise for the purity and elevation of their moral sentiments, which imparts a favourable idea of the writer. They were no doubt intended for the public. Every epistle is a kind of historical sketch, in which we have a view of him in some striking attitude either of active or contemplative life. They strongly mark that love of applause which was unquestionably his ruling passion, and afford some curious facts relative to the modes of feeding a writer's vanity in those times. They exhibit the writer as a professed orator, entertaining and perhaps wearing his friends with long and laboured orations and recitations, commanding confluent plaudits by virtue of his rank, his wealth, and his truly estimable qualities; but he was probably in some influences the dupe of adulation. The best editions of Pliny the younger are the Variorum by Veenhuis; and that by Longinus. His epistles have been translated into English by lord Orrery and Mr. Melmoth; the version of the latter is singularly elegant. Pliny contributed largely to the maintenance of a public professor for the instruction of youth in the place of his nativity; affixed an annual revenue for the support of children of both sexes, whose parents had been reduced to poverty; and founded a public library.

PLISIA, in Geography, a town of Lithuania, in the palatinate of Mink; 21 miles E. of Mink.

PLITE of Lowen, in our Old Writers, seems to be an ancient measure, as a yard or ell, at this time; it is mentioned in the Stat. 3 Ed. IV. cap. 5.

PLIVA, in Geography, a river of Bosnia, which runs into the Verbas.

PLIUSA, a river of Russia, which runs into the Baltic, between Nerva and Ivanгород.

PLIUSKINA a town of Russia, in the government of Irkutsk; 20 miles N.E. of Verchnei-Udinsk.

PLIWISCHEN, a town of Prussia, in the province of Samland; 28 miles E. of Königberg.

PLOCAMA, in Botany, so named by Dr. Solander, from προκαμία, a head of hair, in allusion to its long pen-
PLO

PLOEUC, a town of France, in the department of the North Coasts, and chief place of a canton, in the distrito of St. Brieuc; 10 miles S. of St. Brieuc. The place contains 5073, and the canton 12,800 inhabitants, on a territory of 170 kilometres, in six communes.

PLOGASTEL, a town of France, in the department of Finisterre, and chief place of a canton, in the distrito of Quimper; seven miles W. of Quimper. The place contains 1047, and the canton 10,809 inhabitants, on a territory of 230 kilometres, in 13 communes.

PLOK-PENIN, in Commeres, a term used in the public fates at Amsterdam for a little lump given by the late bidder. The plok-penin is a kind of earthen, by which it is signified, that the commodity is adjudged to him.

The plok-penin differs according to the quality of the commodity, and the price of the lot. Sometimes it is arbitrary, and depends on the pleasure of the buyer; and, sometimes, it is regulated by the ordinances of the burgomasters.

PLOMBIERES, in Geography, a town of France, in the department of the Voges, and chief place of a canton, in the distrito of Remiremont; six miles S.W. of Remiremont. The place contains 1109, and the canton 9947 inhabitants, on a territory of 215 kilometres, in five communes.

PLOMNITZ, a town of Silezia, in the county of Glatz; two miles N.W. of Habelschwerdt.

PLOMO, in Metalurgy, a name given by the Spaniards, who have the care of the silver mines, to the ore of that metal, when it is found adhering to the surface of stones, and incruting their cracks and cavities in the form of small and loose grains of gunpowder. Though these grains be but few in number, and the rest of the stone have no silver in it, yet they are always very happy in meeting with it. As a certain token there is a very rich vein somewhere in the neighbourhood. And if in diggings forwards they fall meet with these grains, or the plomo in greater quantity, it is a certain sign that they are getting more and more near the good vein.

PLONCOUR, in Geography, a town of France, in the department of the Finisterre; eight miles S.W. of Quimper.

PLONE, a river of Pomerania, which runs into the Dammeich, at Danne.

PLONEVEZ de Foues, a town of France, in the department of the Finisterre; eight miles W. of Carhaix.

PLONGEON, in Ornithology. See COLUMBUS.

PLONKETS, in our Old Writers, a kind of coarse woollen cloth. 1 Ric. III. cap. 8.

PLONSK, in Geography, a town of the duchy of Warsaw; 22 miles N. of Plucko.

PLOSAWO, a town of Poland, in the canton of Belez; 28 miles W.S.W. of Belez.

PLOSS, a town of Germany, in the principality of Culmbach; six miles N.W. of Bayreuth.

PLOT, Robert, in Biography, a natural philosopher and antiquary, was born, in 1641, at Borden, near Sittingbourne, in Kent. He was educated at Magdalen Hall, Oxford, where he took his degree of L.L.D. in 1671. Soon after this he became distinguished for his zeal in philosophical and natural science, and was made a fellow of the newly constituted Royal Society, of which learned body he was elected one of the secretaries in 1682. In the following year he was appointed the first Keeper of Ahamole's museum at Oxford, and at that same time professor of chemistry in the university. Antiquities were the leading objects of his pursuit, and in 1687 he was made regifter to the earl marshall's court, and in 1695 the Movbray-herald extraordinary.
nary. He died in 1696. He is principally known in the literary world by his two county natural histories, which were the first of the kind published in England, and were exemplifications of a great plan which he had formed for a natural history of the whole kingdom. The "Natural History of Oxfordshire" was published first in 1677, and again in 1705, with additions and corrections by Mr. Burman. That of "Staffordshire" was published in 1679, and reprinted in 1686. It was decorated with views of the feats of the nobility and gentry. It is at present extremely scarce. Both these county histories include not only all that properly belongs to the natural history, but whatever relates to arts, manners, and antiquities, and all other meritorious. As secretary to the Royal Society, he conducted the publication of their Transactions from No. 143 to 166 inclusive, and he communicated to it some papers of his own. Since his death two letters of Dr. Plot's have been published relative to antiquities in Kent and Thanetford. He left a number of manuscripts, among which were large collections for a natural history of Kent. Brit. Birg. Brit.

Plot, or Plott, in Gardening. See Grass-plat, &c.

Plot, in Dramatic Poetry, the fable of a tragedy or comedy; or the action represented therein.

Plot is more particularly used for the knot or intrigue which makes the difficulty and embarrass of a piece.

The unravelling puts an end to the plot.

Plot, in Surveying, the plan or draught of any parcel of ground, e. g. a field, farm, or manor, surveyed with an instrument, and laid down in the proper figure and dimensions. See Plotting.

Plotile, in Geography, a town of Samogitia; 25 miles N.N.W. of Miedniki.

Plotinopolis, in Ancient Geography, a town of Thrace, upon the river Hebrus; 22 miles from Trajano-polis, according to the Itinerary of Antonine.

Plotinus, in Biography, a Platonic philospher, was born at Lycopolis, a city of Egypt, in or about the year 204. In very early life he began to show a great singularity both in taste and manners. He began to study philosophy at about the age of twenty, and for some time he attended the lectures of different famous professors, who then abounded in Alexandria, but he was dissatisfied with all their systems, and attached himself to Ammonius, who attempted to reconcile the different opinions then subsisting among the philosophers, and founded a distinct eclectic school, in which he taught his disciples certain sublime doctrines, and mystical practices, which he communicated to them under a solemn injunction of secrecy. With the instructions of such a preceptor, Plotinus, whose mind had a strong tincture of enthusiasm, was highly delighted, and he told his friend, that he had now met with a tutor in all respects suited to his wishes. Under this master he prosecuted his philosophical studies during eleven years, and became a deep proficient in the abstruse subtleties, and mystical flights of his system. Upon the death of Ammonius, he determined to travel to Persia and India, to learn wisdom of the Magi and Gymnosophists. In this resolution he was encouraged by the example of Apollonius Tyanaeus, whose pretensions to the magic arts were said to be derived from these sources. For some time Plotinus confided himself to be under an obligation not to disclose the doctrines which he had learned in the school of Ammonius, in consequence of the injunction of secrecy to which he had submitted, but two of his fellow-pupils having publicly taught the mysteries of their master, he thought himself abjured from his engagement, and became a lecturer in philosophy upon eclectic principles. During ten years he confined himself to oral discourse, but at length he found it necessary, as well for the convenience of his pupils, as for himself, to commit the substance of what he delivered to writing. The novelty of his plan of instruction drew after him a crowd of auditors, among whom were persons of high rank of both sexes. To the intrigues of those who were willing to become his auditors he devoted himself with the greatest ardour and affection. He frequently prepared himself for his sublime contemplations by watching and fasting; hence his enthusiastic affections were sometimes raised to a pitch, that he believed he was under the immediate protection of a genius, or familiar spirit, of the most eminent order, who was not merely a demon, but a god. The superiority which he fancied belonged to his tutelar genius, inflamed him with a degree of pride, that bordered upon impiety, or perhaps insanity. He, however, enjoyed to a high reputation for wisdom and integrity, that many private quarrels were referred to his arbitration, and several persons of high rank, having upon their deathbeds, sent for him to take upon him the care of their effects, and the guardianship of their children. Such offices he never refused, and he discharged them in a manner that gave the highest satisfaction to the parties concerned. His excellent character secured to him the esteem of many persons of high rank, and particularly of the emperor Galienus, and his empress Salonina. The romantic turn of his mind was sufficiently shown, by the use which he made of his interest at court. (See Platonopolis.) He died in the year 270, when he was in the 66th year of his age. When he found his end approaching, he said to Eutychius, "the divine principle within me is now halting to unite with that divine being which animates the universe;" expressing by these words a leading principle of his philosophy, that the human soul is an emanation from the divine nature, and will return to the source whence it proceeded. By his disciple and biographer, Porphyry, he is represented as having possessed the power of working miracles; this was probably said with a view of depreciating the Christian religion, of which Porphyry was a great enemy. The treatises of Plotinus, which are fifty-four in number, were distributed by his biographer under six classes, called Euneads. Proclus wrote commentaries upon them. At the request of Cosimo de' Medici, Marfilus Ficinus made a Latin version of them, which was first published at Florence, under the title of "Plotini Opera ex interpret. Marfilii Ficini, cum commentariis, necnon Vita Plotini a Porphyrio confcripta 1492." The Greek text was afterwards published at Bafil, from a manuscript slated by Lambecci to be in the Imperial library, accompanied with the version of Ficinus in 1580. Dr. Enfield, in his abridgment, &c. of Brucker's Phil., speaking of Plotinus, says "that he made it the main scope and end of his life to dazzle his own mind, and the minds of others, with the meteors of enthusiasm, rather than illuminate them with the clear and steady rays of truth. How much that is to be regretted that such a man should have become so great a degree, the preceptor of the world, and should, by means of his discourses, have everywhere disseminated a species of false philosophy, which was compounded of superlition, enthusiasm, and imposture. The muddy waters sent forth from this polluted spring, were spread through the most celebrated seats of learning, and were even permitted to mingle with the pure stream of Christian doctrine. Not only at Rome, where Plotinus taught, but first in Alexandria, and afterwards in many of the principalities of Asia Minor, and even at Athens, the ancient seat of wisdom, the fyltem of Anc. monius Vol. XXVII.
monius and Plotinus was embraced and propagated by men, who, in learning and abilities, were greatly superior to its founders."—Enfield's Hift. Phil.

PLOTTING, among Surveyors, the art of describing or laying down on paper, &c. the several angles and lines of a tract of ground surveyed by a theodolite, or the like instrument, and a chain.

In surveying with the plain-table, the plotting is needlefs; the several angles and distances being laid down on the spot as fault as they are taken.

But in working with the theodolite, femicircle, or circumferentor, the angles are taken in degrees; and the distances in chains and links. So that there remains a subsequent operation, to reduce those numbers into lines; and so to form a draught, plan, or map. The operation is called plotting.

Plotting, then, is performed by means of two instriments, the protractor and plotting-scale. By the fift, the several angles observed in the field with a theodolite, or the like, and entered down in degrees in the field-book, are protraced on paper in their jufv quantity.

By the latter, the several distances measured with the chain, and entered down, in like manner, in the field-book, are laid down in their jufv proportion.

Under the articles Protractor and Plotting-scale, is found, severally, the ufe of thofe refpective instruments in the laying down of angles and distances; we fhall here give their ufe conjointly, in the plotting of a field, surveyed either with the circumferentor, or theodolite.

Plotting, Method of, from the circumferentor. Suppose an inclofeure, e. gr. A B C D E F G H K (Plate VI. Surveying, fig. 10.) to have been surveyed; and the angular, as taken by a circumferentor in going round the field, and the distances, as measured by a chain, to be found entered in the field-book, as in the following table.

1. On a paper of the proper dimensions, as L M N O (Plate VI. Surveying, fig. 11.) draw a number of parallel and equidistant lines, reprefenting meridians, exprifed in dotted lines. Their ufe is, to direct the pofition of the protractor; the diameter of which muft always be laid either upon one of them, or parallel thereto; the femicircular limb downwards for angles greater than 180°, and upwards for thofe lefs than 180°.

The paper being thus prepared, affume a point on one meridian, as A, whereon lay the centre of the protractor, and the diameter along the line. Consult the field-book for the firft angle, i. e. for the degree cut by the needle at A, which the table gives you 191°.

Now fince 191° is more than a femicircle or 180°, the femicircle of the protractor is to be laid downwards; where, keeping it to the point with the protracing pin, make a mark againft 191°; through which mark, from A, draw an indefinite line A B.

The firft angle thus protraced, again consult the book for the length of the firft line A B. This you find ten chains 75 links. From a convenient fcale therefore, on the plotting-scale, take the extent of 10 chains 75 links between the compafs; and letting one point in A, mark where the other falls in the line A B, which protrufe in B: draw, therefore, the full line A B for the firft fide of the inclofeure.

Proceed then to the second angle; and laying the centre of the protractor on the point B, with the diameter as before directed, make a mark, as e, againft 297°, the degree cut at B; and draw the indefinite line B e. On this line, from the plotting-scale, as before, let off the length of your second line, e.g. 6 chains 83 links; which extending from B to the point C, draw the line B C for the second fide.

Proceed now to the third angle or flation: lay then the centre of the protractor, as before, on the point C; make a mark, as d, againft the number of degrees, cut at C, e.g. 216° 30': draw the indefinite line C d, and therein set off the third distance, e.g. 7 chains 82 links; which terminating, e. gr. at D, draw the full line C D for the third fide.

Proceed now to the fourth angle D; and, laying the centre of the protractor over the point D, against 325°, the degree cut by the needle, make a mark e; draw the occult line D e, and thereon set off the distance 6 chains 96 links; which terminating, draw E D for the fourth line: and proceed to the fifth angle, e.g. E.

Here the degrees, cut by the needle, being 12° 24' (which is lefs than a femicircle), the centre of the protractor must be laid on the point E, and the diameter on the meridian, with the femicircular limb turned upwards. In this fention make a mark, as before, against the number of degrees, e.g. 12° 24', cut by the needle at E; draw the line E f, on which set off the fifth distance, e.g. 9 chains 71 links; which extending from E to F, draw the line E F for the fifth fide of the inclofeure.

After the fame manner proceed orderly to the angles F, G, H, and K; then placing the protractor, making marks againft the refpective degrees, drawing indefinite lines, and setting off the refpective distances, as above, you will have the plot of the whole inclofeure, A B C G, &c. Such is the general method of plotting from this instrumtnt; but it must be obferved, that in this procefs, the stationary lines, i. e. the lines in which the circumferentor is placed to take the angles, and in which the chain is run to measure the distances, are, properly, the lines here plotted. When, therefore, in surveying, the stationary lines are at any distance from the fence or boundaries of the field, &c. off-fets are taken, i. e. the distance of the fence from the stationary line is meafured at each flation; and even at intermediate places, if there prove any confiderable bends in the fence.

In plotting, therefore, the stationary lines being laid down, as above, the off-fets must be laid down from them; i. e. perpendiculares of the proper lengths muft be let fall at the proper places from the stationary lines. The extremes of which perpendiculares, being connected by lines, give the plot defcribed.

If, instead of going round the field, the angles and distances have been all taken from one fation, the procefs of plotting is obvious, from the example above; all here required, being to protrufe, after the manner already described, the several angles and distances, taken from the fame stationary point in the field; from the fame point or centre on the paper. The extremities of the lines thus determined, being then connected by lines, will give the plot required.

If the field has been surveyed from two stations, the stationary
tionary lines are to be first plotted, as above; then the angles and distances taken from each to be laid down from each respectively.

Plotting, Method of, where the angles are taken by the theodolite, i.e. by back-fight and fore-fight (as it is called) is somewhat different. To prepare the angles for plotting, the quantity of each must first be found, by subtracting the degrees of the fore-fight and back-fight from each other: the remainder is then the angle to be protracted. The use of parallel lines is here excluded; and instead of laying the protractor constantly on, or parallel to meridians, its direction is varied at every angle. The practice is thus:

Suppose the former inclosure to have been surveyed with the theodolite, after the manner of back-fight and fore-fight; and suppose the quantity of each angle to be found by subtraction.

An indefinite line is drawn at random, as A K, (fig. 11.) and on this the measured distance, e. gr. 8 chains 22 links, is set off, as in the former example: if now the quantity of the angle A have been found 140°, the diameter of the protractor is to be laid on the line A K, with the centre over A; and against the number of degrees, viz. 140, a mark made, an indeterminate line drawn through it, and the distance of the line A B laid down from the scale upon it.

Thus we gain the point B; upon which laying the center of the protractor, the diameter along the line A B, the angle B is protracted, by making a mark against its number of degrees, drawing an occult line, and setting off the distance B C, as before.

Then proceed to C, laying the diameter of the protractor on B C, the centre on C protracts the angle C, and draw the line C D: thus, proceeding orderly to all the angles and sides, you will have the plot of the whole inclosure A B C, &c. as before.

Plotting-Scale, a mathematical instrument usually of box-wood, sometimes of brass, ivory, or silver, and either a foot, or half a foot long, and about an inch and a half broad.

It is denominated from its use in plotting of grounds, &c.

On one side of the instrument (represented Plate VI. Surveying, fig. 12.) are seven several scales or lines, divided into equal parts. The first division of the first scale is subdivided into ten equal parts, to which is prefixed the number 10, signifying that ten of those subdivisions make an inch; or that the divisions of that scale are decimals of inches.

The first division of the second scale is likewise subdivided into 10, to which is prefixed the number 16, denoting that sixteen of those subdivisions make an inch. The first division of the third scale is subdivided in like manner into 10, to which is prefixed the number 20. To that of the fourth scale is prefixed the number 24; to that of the fifth, 30; that of the sixth, 40; and that of the seventh, 48; denoting the number of subdivisions equal to an inch, in each, respectively.

The two half scales are broken off before the end, to give room for two lines of chords, marked by the letters C C.

On the back-side of the instrument is a diagonal scale, the first of whole divisions, which is an inch long, if the scale be a foot, and half an inch, if half a foot, is subdivided, diagonally, into 100 equal parts; and at the other end of the scale is another diagonal subdivision, of half the length of the former, into the same number of parts, viz. 100.

Next the scales, is a line divided into hundredths of a foot, numbered 10, 20, 30, &c. and a line of inches subdivided into tenths, marked 1, 2, 3, &c.

Plotting-Scale, Use of the. Any distance being measured by the chain, to lay it down on the paper.—Suppose the distance to be 6 chains 50 links. Draw an indefinite line; set one foot of the compasses at figure 6 on the scale, e. gr. the scale of 20 in an inch, and extend the other to five of the subdivisions, for the 50 links: this distance being transferred to the line, will exhibit the 6 chains 50 links, required.

If it be desired to have 6 chains 50 links, take up more or less space, take them off from a greater or lesser scale, e. i.e. from a scale that has more or fewer divisions in an inch.

To find the chains and links contained in a right line, at that just drawn, according to any scale, e. gr. that of 20 in an inch. Take the length of the line in the compasses, and applying it to the given scale, you will find it extend from the number 6 of the great divisions to five of the small ones; hence the given line contains 6 chains 50 links.

Plotting-Table, in Surveying, is used for a plain table, as improved by Mr. Beighton, who has obviated a great many inconveniences at two. See Phil. Trans. N° 461, 1st. 1800.

PLOTTNITZ, in Geography, a lake of Silesia, in the principality of Oels; four miles E. of Militsch.—Also, a town of Silesia, in the principality of Neisse; three miles W. of Patchkau.

PLANTUS, the Darter, in Ornithology, a genus of birds of the order Anseres. The generic character is, bill straight, pointed, toothed; the nostrils have a slit near the base; face and chin naked; legs short; all the toes are connected. The birds of this genus, of which there are three species, have a small head, and long slender neck; they are chiefly Seen in southern climates; they live chiefly on fish, which they take by darting forwards the head while the neck is contracted like the body of a serpent.

Species.

AINGA; White-bellied Darter. The head is smooth, and the belly white. It inhabits Brazil, and is about 34 inches long. It builds on trees, and is hardly ever seen on the ground; which at times it loses, with the neck drawn in between the shoulders. The flesh, though sometimes eaten, is reckoned rancid and oily. The bill is cinereous, yellowish at the base; irides golden; head, neck, and breast reddish-grey; body above black, the scapular feathers with a white spot in the middle; it has 12 tail-feathers, which are broad and long; its legs are of a yellowish ash colour.

MELANOGASTER; Black-bellied Darter. Head smooth; belly black. It is about three feet long, and found in Ceylon and Java. There are three varieties of this species:
1. Above brown, beneath black; streaks on the scapulars and oval spots on the wing-coverts white. Between the breast and belly is a rufous band. It is a native of Cayenne.
2. Black; back and scapulars spotted with white; wing-coverts yellowish-white; tail rufous at the tip. 3. Black; head, neck, and wing-coverts streaked with rufous and brown. It is found at Senegal.

SURINAMENSIS; Surinam Darter. Head crested; belly white. Found, as its name imports, in Surinam; is about 15 inches long, and is domesticated. It feeds on fish and insects, especially flies, which it catches with great dexterity.

PLOTEKAN, in Geography, a town of Germany, in the duchy of Anhalt-Bernburg; five miles S.S.W. of Bernburg.

PLOUGAGAT, a town of France, in the department 4 Y 2 of
of the North Coasts, and chief place of a canton, in the
district of Guingamp. The place contains 2034, and the
canton 7259 inhabitants, on a territory of 172½ kilometres,
in seven communes.

PLOUARET, a town of France, in the department of the
North Coasts, and chief place of a canton, in the
district of Lannion. The place contains 4276, and the
canton 14992 inhabitants, on a territory of 250 kilometres,
eight communes.

PLOUAY, a town of France, in the department of the
Morbihan, and chief place of a canton, in the district
of L'Orient; seven miles N. of Hennebon. The place
contains 3586, and the canton 12304 inhabitants, on a
territory of 215 kilometres, in seven communes.

PLOUABALAY, a town of France, in the department of the
North Coasts, and chief place of a canton, in the
district of Dinan; nine miles N. of Dinan. The place
contains 1385, and the canton 6208 inhabitants, on a
territory of 92½ kilometres, in eight communes.

PLOUDALMAZEAU, a town of France, in the de-
partment of the Finistere, and chief place of a canton, in
the district of Brest; 10 miles N.N.W. of Brest. The
place contains 2890, and the canton 14588 inhabitants, on
a territory of 17½ kilometres, in 12 communes.

PLOUDERY, a town of France, in the department of the
Finistere, and chief place of a canton, in the district of
Brest; five miles E.N.E. of Landerneau.

afford much assistance, by enabling them to execute the
work with greater regularity in the depth, and more even-
nets in the surface. But from the nature of the machinery
with which they are loaded, they are evidently more expen-
sive in their construction, more liable to be put out of order,
and from the friction that is thus produced require more
strength in the teams that are employed in drawing them.
Besides, they have the disadvantage of being more apt to be
put out of order in their course, by the occurrence of stones,
clothes, and other surface inequalities, than those of the
former kind.
A convenience attending these ploughs is also noticed by
lord Somerville in the Communications to the Board of
Agriculture, which is, that with wheel-ploughs
workmen are apt to set the points of their shares too low, so
as by their inclined direction to occasion a heavy pressure
on the wheel which must proceed horizontally. Of course he
conceives the effect of this struggle to be an increased weight
of draught infinitely beyond what could be imagined, on
which account he thinks that the wheel is to be considered as
of no consequence in setting a plough for work; but that
paling lightly over the surface it will be of material use in
breaking old lays, or lands where flints, rocks, or the roots
of trees are present, and in correcting the depression of the
share from any sudden obstruction, as also in bringing it
quickly into work again, when thrown out towards the sur-
face. It is however believed on the whole, by the writer of
the report just mentioned, that in comparing two extensive
districts, one of which is managed with wheel-ploughs, and
the other with those of the fwing kind, taking every
description of ploughmen that are met with in them, the
wheel-ploughs were found to have the advantage in point of
neatness of work.

But the great weight of the carriage parts for the wheels,
and the time and trouble which they require in adjusting and
fixing them, are great objections to the use of this sort of
plough in most cases, and particularly for the general pur-
poses of husbandry.

Therefore, in the forming of all sorts of ploughs, the less
they are encumbered with machinery of the wheel or other
kinds, the more useful they will probably be found.

All around Kelvedon, in the county of Essex, it is stated
in the agricultural survey of that district, that they make
use of both fwing or foot, and wheel-ploughs, and that it
is much disputed which is preferable. In favour of the
fwing-plough, it is contended that it is better calculated for
fallowing, as the soil can be broken up to a greater depth,
and it does not rise at the headlands, which is the case with
the wheel-plough; the ends of the furrows being shallower,
from the wheels, as soon as they get upon the headlands,
throwing the share up. The fwing, or foot-plough, is
easier of draught, the prime coat is less, and it is kept in
repair at a smaller expense.

The wheel-plough, on the other hand, keeps a more re-
regular depth, and will turn a shallower furrow, when the
fallow are put upon the ridge, or formed into ridges; the
work can be done with more regularity, the wheels being
put out to the exact width at which furrows are to be
made; this is of material consequence. And further,
wheel-ploughs about the above place, can be worked when
fwing ones will cack on flubbles, and they are varied in
pitch with more exactness, as well as go deeper than the
others; but fwing-ploughs are better, if the land be at all
wet.

It may be noticed, however, that when the men are ac-
customed to ridge-ploughing, they will do it as well with the
fwing or foot-plough as with the wheel, but they cannot
block up hard land in the summer so well with it.

And in respect to the depth of this sort of work, some
contend that very deep ploughing can hardly be effected
without the assistance of wheels to the ploughs. Besides,
if the land is to be broken up for fallow late in the spring,
and the soil comes up in large blocks, which is sometimes
the case in wet land and late fallowing, the fwing, or foot-plough,
is apt to be thrown out of the furrow, and does not perform
its work so well as the wheel-plough.

It is found a matter of great importance in the con-
struction of the fwing-plough, that the beam should have the
length of about six feet, or six feet and a half. The rule
or reason for which, according to Mr. Arbuthnot, is that
the line of traction from the tug at the horse's shoulder to
the centre of gravity and resistance, is a little behind the
point of the share.

In the Rural Economy of Yorkshire, after noticing the
similarity of the principles that are requisite in the con-
struction of the ship and the plough, and considering the
difficulty of fixing and reducing them to a regular theory,
as nearly the same, it is observed, that the art of construc-
tion in either case is principally attained by practice. In this
district, says the writer, the ploughs of different makers pas
through the soil, with various degrees of facility and execu-
tion; nevertheless, though he has paid some attention to
the different makes, he finds himself entirely incapable of
laying down such particular rules of construction as would
do his country any service, or his work any credit. Even
the general principles of construction he must mention with
diffidence.

The great difficulty in the construction of a plough is
that of adapting it to all soils, in all seasons, and to all
depths. If the soil break up in whole furrows, every inch of
depth requires, in strictness, a separate plough, or a se-
parate regulation. Here rests the main objection to the
winding mould-board, which admits no regulation in respect
depth. If the semi-arch, or hollow of the hind part of
the mould-board, be raised sufficiently high to turn a thick
furrow completely, it is of no use in turning a thin one.
On the contrary, if it be brought down sufficiently low to
turn a shallower furrow properly, it is impossible to turn a
deep one with it in a workman-like manner. There is not
room for it within the hollow, or semi-archway of the
mould-board. The inevitable effect of this is, either the
furrow is forced away wholly by the upper edge of the
mould-board, and set on edge; or the mould-board rides
upon the furrow, raising the heel of the plough from the
ground, the bad effects of which need not be explained.
An upright flerm, with a moveable heel-plate to turn the
furrow at any given depth, is, in this point of view, much
preferable to a hollow mould-board; and if its use in raising
a crest of mould, for the purpose of covering the feed, be
added, its preference is still more conspicuous. But some
of these inconveniences have been obviated by the invention
of moveable mould-plates, as will be seen afterwards.

Yet in the construction of all sorts of ploughs, there are,
notwithstanding, a few points or circumstances that ought
to be particularly, and in all cases attended to; such as the
following: that part which perforates the soil, and breaks
it up, and which is usually termed the throat or breast, should
have that sort of clean, tapering, sharpened form, that is
introduced with the greatest readiness, and which affords
the smallest resistance in its passage through the ground.
According to some, this part should be long and narrow,
making an acute angle with the beam, as the length of the
breast is supposed to have a tendency to predispose the flag
from being broken, on account of the surface for it to support
being longer; which is a circumstance of consequence in the
ploughing
ploughing of old lays for wheat, pea, and other similar crops; as, by such means, the growth of weeds through the broken ground is prevented. And the resistance of the earth against the break is likewise lessened, in proportion to the acute angularity of that part against the beam of the plough. The mould-board should also have that fort of curved, twisted, or hollowed-out form, which is best calculated to lessen resistance, and at the same time give the furrow-slice the proper turn. And the beam and muzzles of these implements should likewise have such a construction, as that the team or moving power may be attached in the best and most suitable line of draught, as this is a circumstance of great importance, when several animals are made use of together, that the draught of the whole may coincide in the most perfect manner, and with the utmost exactness.

Likewise, in the construction of every fort of plough, much regard should be paid to the weight, so that they may have sufficient strength for the purpose, without being unnecessarily heavy. Much may be done in this intention, by lessening the quantity of wood in those parts where there is no particular necessity, while it is retained so as to have full power in the others. This has been much less attended to in the making of ploughs than its importance would seem to demand.

It is noticed in the Agricultural Survey of the County of Essex, that the 'oharat at the fore end or neb of the plate or break in the Norfolk, and most other ploughs, with the exception of the Rotherham, rises from the upper surface of the share too perpendicularly, and too much at right angles to the line of friction, or pressure of the earth, the plate has constantly to act against: working thus abruptly in the ground, the slice or furrow is violently torn, or burst from off the ground, broken and imperfectly turned over, instead of being gradually cut, raised whole, and whelmed over; as will always be the case, when the plough enters the ground obliquely, and at a proper angle; and that the plate or mould board is properly turned for raising up, and turning the slice completely over.

It is a clear position, proved by experiment, that a semi-elliptis is the true form of throat which is necessary in ploughs, which is the part or space from the share point to the junction or approach of the break to the beam; and that there is found a remarkable variation in the form of the break, or mould-boards of the ploughs throughout the northern parts of the same district, and which is chiefly in the degree of concavity or convexity. Some wheelwrights and farmers prefer a form rather concave, a flatness in the fore part, which joins the share, and which gradually fills up as the sweep recedes; others like it neither concave nor convex; and there are many ploughs in which the convexity is extremely great.

The great length of the break, in some ploughs, is a circumstance which gives flatness to the Implements; but, at the same time, it is probably the means of increasing the draught to the horses in a great degree.

The shortness of the break, if the curve or sweep be in perfection, or wears equally every where, may lessen friction, and certainly does, if the earth be loose; but it probably may not have the same effect in the first earth, upon a stiff layer. It is, however, a pretty general opinion, that it lessens it in all cases.

A great variety of breaks, of different forms and constructions, are represented in the plates upon ploughs, in the Agricultural Survey already referred to, which are well worth consulting by the inquirer on this subject; and in the ploughs which are given here, there is also a very great diversity in the shape of the same part, as will be seen by attending to the figures of the different plates.

Some cultivators in this district use a break which is very convex, and contend that such a degree of roundness and flatness in the bottom is necessary on heavy lands; also, that the foil sticks adherently to the plough, if it be not thus rounded all the way; as well as that it turns the furrow better.

On the great variety of the breaks of ploughs, which appear in the plates of the above Survey, all of which are more or less distinct and different from each other, it is observed that they will all, on certain soils, and moments or times of tillage, make very good work; but it does not hence follow, that the form is a matter of indiscernence; such a conclusion would be very erroneous. There is a considerable difference between a break passing freely through the foil without loading, and driving the earth before it, or preffing it after the furrow is turned, and another that has either of those faults, not visible perhaps in the work when finished, but to the great fatigue of the horses. In the construction of the plough, as has already been seen, there is not a point of more importance.

One of the most extraordinary circumstances in these breaks is, that of their all, with the exception of one, having more or less convexity, and in many, as has been seen, to a very extraordinary degree, especially in those about Birch Holt and South-End. But, in that furnished by his excellency Mr. Jefferys, the late president of the United States of America, and which was sent to the Board of Agricultural, and first tried by C. C. Werden, efq., at Felix Hall in this district, the formation was made on the idea, that as the bottom cut of the furrow is, or ought to be, perfectly flat, the break, which comes in direct contact with it, should be flat also; so that there should be no disposition in the mould to sink into any depression or concavity of the break; nor any projection from a right line in the break, to prevent or force into the furrow-slice, as it is turning. The idea is new and excellent; but what, on such principles, can be said to the convexity in some instances, the shape in the breaks of which must constantly have a tendency to groove that furrow-slice, from preffing in the centre. It should seem as if this must, on every principle, be erroneous. The retaining of it, in the case of Mr. Duckett's plough, is supposed, more apparently than really, an exception, in consequence of the soil he had to work on, as it was invented for a very loofe land only; and on such a foil the straight break is much more admissible than any other. This plough was seen at work on his farm many years ago, and it made excellent work: the convex addition to the flat surface, on the lower part, was properly made to divide the weight of the moving land, and to keep enough of it in a due degree of elevation.

The objection to so much concavity or flatness in the fore part of the break, as appears in that supplied by the American president, is that of the loose earth of the furrow loading there, which in some cases it is very apt to do.

Another point in which the ploughs here, as well as in other places, seem to be deficient, is in the height of the break from the ground; they are, for the most part, too low behind; they should be, therefore, somewhat raised in this respect. In turning over a furrow of loose mould with rolling clods, the hind corner of the break should be high enough to sweep them over, but without preffure.

In the next place, that part which is called the plough-heel may be examined, which comprises the position of the break behind, and forms, together with the end of the reef, that wedge which fills up the furrow. There are two principal...
PLOUGH.

equal questions, it is supposed in this district, in relation to the form of it:—What ought to be the breadth at bottom, or, more properly speaking, the heel? and, what should be the breadth at top? Some think the heel should not be more than seven inches wide at bottom, which is the common width in some places. In examining the ploughs, in some cases, it appears that the breast clothe at the heel gradually, being a termination of that convexity of breast, of which so many farmers in this district are fond. Improvements have been made, in which this narrowing at the heel has been retained, without the convexity before, and but slightly behind. Some ploughs are found to be faulty at the top of the breast behind; it overhangs the furrow too much, and seems to the eye to be in a position to serve. In concluding the subject, it is remarked, that when the ploughs in a single county can vary so much in the breast, or earth-board, and that in a district, too, not at all remarkable for diversity of soil, which might call for considerable variations, it must afford a strong proof how very undetermined the true mechanism of this most necessary of all tools still continues to be. And this, it is contended, ought to excite the endeavours of every scientific farmer to multiply experiments, to reduce the construction to plain and fixed principles.

In regard to the pitch of ploughs, it is noticed, that in the operation of working wheel-ploughs with improperly turned plates, or mould-boards, it will frequently happen, from the refinance produced against the plough by rocks, the tenacity or compreッション of the earth, that they are obliged to be let down below the corresponding line of level, so materially necessary to the equal bearing between the pitch of the plough, and to the inclination which is thus given to the point of the share downwards, and which ought always to be, as nearly as possible, in a line drawn parallel to that of the draught, and with the breast-work, which forms the fulcrum for the beam to rest on. When a plough is so constructed, and set to work, that it bears unequally in these points, the end of the share will be roasting or digging with its point downwards, kicking up and sideways at the heel, and rendering it utterly impossible to plough the ground clean, or in anywise to lay the work uniform, or even in a tolerable manner; notwithstanding an excessive and unnecessary degree of labour is thereby produced to the ploughman and horses. This description is not so very clear, but there can be no doubt that not going close at the heel is a very common fault in wheel-ploughs, and often seen in Norfolk, as well as in other counties, in cases in the former, which have not the least reference to the breast; and it is a just observation, that the horses suffer much by it. The draught-chain in some ploughs, which draws by the hammer, between the counter and the tuck, is not so parallel with the horizon as it would be, were it thrown more backward, which is the case in other tools of this kind, and forms a much better position.

In each of the above descriptions of ploughs there are several varieties in common use in different districts of the kingdom; but it is only necessary here to describe such as have been found to answer in the most perfect manner in practice. In the facing form, those most in use are the Rotherham plough, which is a light useful plough for all the heavy forts of soil, and which, probably from its next simple construction, is in more general use than any other, especially in all the more northern districts of the kingdom. It has certainly much superiority where one plough is only required, and where the advantageous and economical method of performing the work with one man and two horses without a driver is had recourse to. It is in much estimation in all the

Well Riding of Yorkshire, and is said in the Survey of that district to have been invented by Mr. Joseph Foljambe, of Eastwood, about seventy years ago. As constructed in that part of the island, the dimensions are as follow:

<table>

It has also a cope rack, or hoe with teeth, to admit of more land being given to the plough, or the contrary, which is particularly useful in many cases.

It is noticed, that with a few trifling alterations it is made use of over the whole district, and from that being often called the Dutch plough, it is supposed to have been originally brought from Holland by the inventor.

But since its introduction it has received various improvements by different cultivators. In Mr. Bailey's attempts upon it, the mould-board, which is of cast-iron, is so formed, that the fod to be raised presses equally against it, in every part, from the fod point to the place where it leaves it; and it varies from other mould-boards, in not beginning to take its rife from the bottom of the heel, but at least twelve inches farther forward towards the socket, and in being cut away at the bottom opposite the heel, about three inches high, from the sole, by which the turning of the sod or furrow-slice is said to be much facilitated. Thus improved, these ploughs have been found to answer perfectly in different trials, and have been allowed by those who have seen them at work to go with more ease to the teams than those of any other construction.

And it has been supposed that the beam, from its crooked form, which is obvious in some of its improvements, by being fixed so low down in the part next to the handles, makes the plough require less force, and to go in a more sliding manner. And that from the fore end of the beam being so much higher than the hinder part, the holder of the plough has more power, as the draught does not oppose so much resistance to him; for if the beam were fixed to the handles much higher, as is usually the case in other ploughs, this plough would be constantly rippling on the point, and in that way increase the weight of draught. And where it meets with any resistance, such as a stone, it is liable to rise up, while in this form it proceeds in a sliding manner, which affords a lighter motion, and renders it more easily held. Besides, it is much stronger; as in the part where the left handle and the beam are joined, underneath the mortise where the tenor of the beam, by which the bearing of the ploughman on the handles does not in the least affect that part, which in other ploughs is the weakest. In this improvement of the Rotherham plough, the mould-board is so constructed at the breast as to have a slight degree of convexity, instead of being concave, as it often the case, by
by which the furrow-flice is supposed to be prevented from
flipping down; and by the keeping the lower part from
the ground, when it comes to the turn of the breast, it falls
off; consequently, as the furrow-flice has rested on or by
the side of the breast, when the plough has advanced twelve
inches the work is finished. By this improvement it is sup-
posed that the plough will turn a furrow of any extent,
from four to eighteen inches, where requisite, and the fame
in depth; as the plough that will produce a wide furrow
and turn it well, is capable of ploughing deep: the
convexity of the breast also causes it to clean itself better,
which is a desirable property, as it is thereby rendered less
heavy, and less resistance afforded by one portion of earth
being prevented from rubbing upon another, and at the same
time the work performed in a more perfect manner. The
counter has likewise a position so as to cut in a slanting
manner, which causes any resistance to rise up more expedi-
tiously, and the land to be opened with more facility than
where it has a more perpendicular direction.

It may be noticed, that where this improved plough is
employed with more than two horses abreast, the additional
ones must be put before the pair, as it has not land
enough to follow single horses.

Thus improved, it has the excellent property of being
small and light, while it is sufficiently strong to resist any
power that may be applied to it. It is capable of ploughing
any fort of land, and in larger proportion than any other
except the Norfolk and Suffolk ploughs. The chief
improvements which have been effected in the form of this
plough, are isted to be in the breast, and in fixing the beam
to the handles or flints. There is also a cock, or a fort of
crank, fixed by a screw and nut, to as to keep the share in
its proper situation when the plough is drawn backwards.

A representation of an improved plough of this kind may
be seen in Plate XXX. Agriculture, on Swing-ploughs, at
fig. 1.

Wheels have sometimes been added to these ploughs as
a fort of improvement for particular purposes; and with
either one or two fixed near the points of the beams, with
out any carriage parts, they have been found to pass through
the soil in a very light, easy, and handy manner, and where
there are two wheels, to require no holder in many cases,
except in tending in turning out of the work at the ends of
the ridges. As swing-ploughs, they are probably, however,
capable of the most general application.

The Northumberland or Cumberland plough is an improved
plough of this nature, which is held in very high estimation
in most of the northern districts, and which performs its
work in a very excellent manner, being light, and of little
draught. It ought to be much more generally employed
than is at present the cafe on most kinds of soil.

Small's Chain plough is another plough of the swing
kind, that is a very useful implement, and capable of very
extensive application. It has its name from that of the
inventor, who constructed it about forty years ago. It is
nearly formed, and very light in its appearance, but at the
same time, from the addition of the chain, possessing great
strength. It is, therefore, capable of being employed in
strong rough forts of soil, where other forts of ploughs are
liable to be destroyed, as when the thare, or when the
counter, in this implement, meets with any sudden impediment
or obstructing cause, the share is immediately thrown upon
the chain instead of the beam. The sock is also formed
with a fin or feather, by which the firm earth in the bottom
of the furrow is cut and moved more readily, and in a more
complete manner than could be done by the sock in the
common plough. In this plough the mould-board is mostly
made of call-iron, having a gentle curve, by which the
furrow-flice is thrown off with the least possible resistance.
It is supposed by Mr. Donaldson to be on the whole one
of the best contrivances for ploughs for all sorts of soils,
in a proper state of cultivation, in common use in the isle.

It is capable of ploughing, with one man and two horses
yoked abreast without any driver, more than an acre a
day with the greatest ease. An improved plough of this fort
is shown at fig. 2, in the same plate on swing-ploughs.

The Somerville plough is also an improved plough of
the same fort, in which the throat has a more clean
hardened form, and the mould-board is rendered moveable
in the manner that will be noticed in speaking of the
Double Furrow plough. It is capable of being made ufe of with
advantage in breaking up deep stiff soils, as from the move-
able nature of the extreme part of the mould-board the
furrow-flice can be laid more or less flat, according to the
particular circumstances of the cafe. It is consequently
capable of a pretty general ufe in most forts of soils.

This fort of improved plough is represented at fig. 5,
in the same plate on different kinds of swing-ploughs.

The Suffolk Iron Swing-plough is another plough of
this class, which is found useful in different cafes. It was,
according to the author of the Agricultural Report of Suff-
folk, improved by an ingenious blacksmith in that district
of the name of Brand, and made wholly of iron. It has been
found to answer well in practice, in fuch lands as are of a
strong heavy tenacious quality, and where much obstruction
is afforded by the roots and fibres of different forts of plants
and vegetable productions. Its useful properties have been
fully experienced in breaking up strong heavy rooty lands
on his majesty's farm in the Great Park at Windsor,
according to the author of the Agricultural Survey of Berks,
as it performs its work not only with more facility,
but in a better manner than most of those ploughs that are
made ufe of in such descriptions of land. The cops by
which it is drawn are said to have been constructed by Mr.
Brand, and are extremely well contrived for the purpofe.

An improved plough of this description is seen at fig. 4,
in the plate on swing-ploughs.

Ducket's Skin-scuttler plough is another very useful imple-
ment of this fort, which is capable of being employed with
great advantage where the surface is coarse or gravelly, in
order to bury it to such a depth as may prevent any incon-
venience from its rising to injure the crops that may be
fown upon such lands. The principle upon which this
plough operates is extremely simple, and of course of a very
useful nature, being merely taken from that of trenching
ground in the practice of gardening, or that of depositing
the surface spit of earth in the bottom of the preceding fur-
row, and placing the second, or that taken from below, upon
it, by which means it is evident that that which was first
turned down remains in a state of decay, without any risk
being incured of the gravelly material rising fo as to produce
inconveniences in the operations that may be going on upon
the surface. It is capable of performing its work to a con-
 siderable depth, where the soils are sufficiently deep for the
purpofe.

And it has been remarked by lord Somerville, in a little
tract on ploughs and oxen, that the skin requires a perpen-
dicular direction, and that the counter-hole should be re-
moved further from the throat and thare, as in the common
position it would choke when in work.

By this fort of plough the ground may be opened to
any depth in separate horizontal portions of earth; and
as the weeds or gravelly surface are turned down in the firft
operation, and covered by fresh earth or mould from beneath,
a larger
a larger proportion of nourishment is supposed to be provided for the crop, while at the same time it is rendered more clean, and the inconvenience of the roots of the grasses or other plants wholly got rid of. It requires a strong team in the heavier forts of soil, but this is in some degree counterbalanced by the circumstance of one furrow ploughing being mostly sufficient for the crop. It is consequently evident, considering the number of ploughings generally given in the ordinary way of preparing lands for a crop of barley or turnips, and under the following system for wheat, and the labour and expense in the latter cafe, in raking, picking, and burning weeds, that the advantages of this plough are probably greater than are generally supposed.

It has also advantages in another point of view, which are, that the soil is increased in depth, and the parts of it loosened and broken down, that the fibrous roots of the crops strike and extend themselves more readily in it, and of course are better fed and supported. The noble writer just mentioned, thinks, that in thin and sandy soils it is more particularly useful, because it cuts off all which is on the surface, at the depth of an inch, or an inch and a half, in order to its being laid in a state of decay for a future crop, by which an increased depth of soil is given to every subsequent course of crops, and which often acts as a pan or support, to keep up manures in circulation, as their running through such soils too quickly is considered a great misfortune and disadvantage in such soils.

A figure of this valuable implement is given in the plate on swing-ploughs, at fig. 5. Besides, it is also capable of being made use of without the skim-coulter as a common plough. When well made, it cuts from three to five pounds.

And there is a fort of plough of this nature which has a double share, the one being fixed directly over the other. It is made use of in some of the southern districts with advantage, in putting in one crop immediately after another, as by it a narrow furrow is removed from the surface, and another from below placed up the furrow as may be thought most proper, it being capable of acting ten inches or more. In this manner many sorts of crops, such as rye and other green crops that have much height of stem, may be turned down without any inconvenience of any of the parts sticking out through the seams of the furrow-slices, by which the farmer has a clean surface of mould for the reception of the grain.

Another plough of this sort, which differs much in the nature of its construction, having a strengthened couler, and an application of lord Somerville's mould-board made to it, is not unfrequently made use of in some of the southern districts of the kingdom.

This very useful form of skim-coulter plough is indeed much had recourse to in the neighbourhood of Eneatellone, in the county of Effe. And a further variety of this kind of plough is made use of in some parts of Oxfordshire. Mr. Kimber, of Little Tet in that county, both makes and employs this sort of tool, and finds it to be extremely useful for certain purposes. The skim in this implement is fixed to a fore couler, by which means it is found to do the work much better, than when attached to the common couler, in which way some have found that it could not work well at all. Upon hollow land, it is, however, not at all approved of, as facing the surface of such ground is supposied by Mr. Kimber to be much worse than turning it over in the usual manner, and letting the surface-vegetables be laid into the diagonal position, with an edging of them sticking, perhaps, out of the seams. But it is supposied by Mr. A. Young, that in this notion Mr. Kimber is in an error; as he contends that the vegetable growth upon the surface is to be rotted in some way, for it is ploughed in every mode of tillage, and the only question is, how to rot it in such a manner as to convert it into the food of plants, so as they may be able to avail themselves of that food.

This surely is the means of loosening, in the greatest degree possible, that additional hollowness which must be caused in a measure, plough it in how you will. The furrow of common ploughing four, five, or six inches, is so shallow, that the warmth of the sun, the moisture of rain, and the influence of the atmospheric air, act to the bottom of it, and will convert vegetable substances into gaseous matter sooner than if exposed to the immediate action of the sun and air, which in all dry weather reserve them, and must occasion a greater hollowness than in the other case, in which they are sooner consumed. And further, the great successe which has attended the system counter to that of Mr. Kimber would not have taken place if his theory was just. Good farmers, when they have skim plough, or common plough hollow land, will adapt the operation to the soil the crop is to be put in, and the season of tillage; and by these means provide a remedy for the expected evil; this as is clearly applicable to a skim as to no skim at all.

This skim-coulter plough does not answer in some management, or where the soil is of a flinty nature, but till many farmers in this district approve it highly; and some think it excellent, especially for ploughing turnip land for barley, when the weather and treading have made it a little soft, also, if the fallow for turnips has become a little weedy; but do not use it on layers for wheat, as they plough their lays for that crop deep. Particular farmers, however, find that it makes neat and perfect work on clover lays for wheat crops, not going more than three or four inches deep, and yet skimming off sufficient to bury every thing, and leaving the teams without any vegetable growth to be seen. Shallow ploughing clover land for wheat, is thought essential on these flinty soils.

There are still some other modes of constructing these kinds of ploughs, as when they have skim plough or common plough, and some other Reports of the Board of Agriculture.

There is also a very great difference in the construction of the common swing-ploughs of this diocese. The swing-plough with an improved breadth, which is employed by Mr. Welford, is of a very beneficial kind, and is held in much esteem in several different places.

About South-End, in the same county, they have also a swing-plough, which is pretty generally in use, but which has an uncommon degree of convexity in the fore-part of the breadth.

And a very good swing-plough, which has an extremely effective addition for the purpose of keeping the couler fixed steadily in its place, has been long in use upon all the estates of the late lord Petre.

The Miner is an implement of the plough kind, that is very useful for the purpose of loosing the soil to a great depth without bringing it up to the surface, a mode of operation which is particularly useful for various sorts of tapp-rooted plants, as well as for extirpating the roots of such weeds as strike deep into the ground. For these purpuses it may be employed in the bottom of the furrow after the common plough. It is constructed in a very strong manner, having only a share without any mould-board.

The Beverston plough is another sort of useful tool of this kind, which was invented by Mr. Tugwell, and has been employed in some districts in the more heavy kinds of land. It has its principle of draught given it in a very effective manner by an ingenious contrivance of iron work, in which,
PLough.

According to lord Somerville, the point of draught is perpendicularly above the point of action, or the throat or breaf where the flare fits on. A plough of this nature is fhown in Plate XXXI. Agriculture, on Wheel-ploughs, at fig. 1, in which its dimensions are as follow:

Heel to tuck-hole of share
Tuck-holes to point of share

The Double Furrow plough is a kind of implement of this fort, which has, at least in its improved form, been found highly useful and advantageous. Ploughs of this fort have been conftucted in various ways, as with a double beam, and with a single beam only, which is the manner in which they are ufually made at prent. But the most improved plough of this nature is that conftucted by lord Somerville, and for which he has taken out a patent. It is advantageus in performing more labour in a given time with a certain strength of team, than other forts of ploughs, as producing two furrows at a time. It has been found useful on the lighter forts of land where the ridges are ftrait and wide, though many think it more confined in its work than thoſe of the fingle kind. A principal advantage in which it excels other forts of ploughs, is in the faving of the labour of one perfon, and in doing nearly double the work with but little more strength in the team, in the fame time. It is remarked by his lordhip, in speaking of this fort of plough, in the fecond volume of Communications to the Board of Agriculture, that the clean and fharpened conftuction of the breaf and throat will warrant their breaking deep fift land with infinite fuccéfs; in this cafe the coulters fhould be f¢ nearly ftrait with the throat and flares; in crofs ploughing, or fliring, they may be fet three-quarters of an inch towards the land, by which greater dispatch will be obtained in feed time. Should they carry too deep a furrow, the ftraihouette of their flares is obvious; Should they cut too much to the land, or go unready to the ploughman, it muft absolutely proceed from a want of fetting them true, relatively to each other, and from an undue regulation of the cogs; here a nice attention is required; their powuer alfo of cutting a furrow level at the bottom fhould afterwards be proved on a level floor. The want of this practive in the mallers has condemned many a good plough, when the fault was in the ploughman only. It may fuggelt itfelf, that two-furrow ploughs are unfit for hilly ground, but the very reverse is the cafe. The effect of ploughing across the inclined plane, or hill, is that of carrying the foil in time to the bottom of the field, which muft be carried bodily up again at a great expence; let fuch land be worked from the top to the bottom, it be carried with the hindmost or land ffare up the hill, and two down, fo will the power be apportionate to the weight with which it has to contend, and needlefs toil to the team will be faved. That power which was required to carry two furrows up would be fuperfluous in carrying the furrow down the hill, and the effect will be as 3 to 4, that is an acre and a half, instead of two acres per day.

A plough of this improved conftuction may be fenn in the plates on fwing-ploughs, at fig. 6.

In regard to the improvement of thefe ploughs, his lordship obferves, in his tract juft noticed, that from the defign, which repreffents a fide view, it may be obferved that, besides the moveable plates, there are coulters, ifays, &c. and how firmly the plough is put together, and how little waife there is of timber and iron work. And after noticing its conftuction in the breaf fo as to leffen refifiance, it is added, that the double-edged coultor is formed fbo to produce this effect; in frength and fubftance it is equal to the common or narrow coultor, and being lefs broad, preffes fo much lefs for refifiance: when in work, the ifay gives a headnefs to it, the coultor being fubject to frequent derangement, to correct which much occafion frequent fops, alteration of the wedges, and lofs of time. And it is afterwards flated, that an economical and fpirited ftylen of farming labour already prevails in fonie diftricts; in none more eminently, with refpect to ploughing, than in Effex, on both banks of the Tweed, in Suffolk, Yorkshire, and Norfolk. Here it would be no object to inveade the ftylen already elabified, for innovation is not palatable to farmers; nor fhould the firft deep ploughing in Kent give way to any novel ftylen; there can be no better husbandry: but, except for beams and tap-rooted plants, fubfquent deep ploughings are injurious, both as to expence and effect. Dr. Hunter, in his Essay on the Roots of Wheat, points out the depth needful for the fupply of feminal roots in wheat and wheat corn in general; that which is turned down then, in the firft deep ploughing, fhould be rotting for the fucceeding crop: Let not the bottom know what the furface is doing! Here two-furrow ploughs, even admitting them incapable of carrying a deep furrow, which is far from true, muft come into admirable effect, for a twofold advantage can be taken,—of the feafon in fowing, and the work being done at half the expence. But where men are chained down by long ufage, and perhaps, for the convenience of confiant road work, to teams of heavy corn-eating cart-hores, two-furrow ploughs become, he fuppofes, objects of extreme importance, becaufe their hores will not feel the difference between their own single furrow, working one acre, and the well conftucted two-furrow furrow, with two acres per day: here is no ftylen deranged, and double work done.

The counties of Leicefter and Stafford have profitted much by their use under thefe circumftances, although their two-furrow ploughs, in other refpects good, have never been fo conftucted in the throat and breaf as to destry the means of refifiance. Without doubt, obstinacy in these particulars muft add incommensurably to the weight, muft break the furrow, and fo spoil the work; moreover, let it not be forgotten, that removing refifiance not only diminishes the labour of the cattle, but is also of equal advantage in increasing the strength of the implement;—the refifiances with a well conftucted, and with an ill conftucted plough, in performing the fame work, are as different as the refifiances of
of a well constructed king's cutter, and of a floundering Dutch merchantman, sailing with equal velocity.

And the noble inventor adds, that in his own county these ploughs have met with a reception more favourable than could be expected in so short a period. On the 16th of October, 1798, two-furrow ploughs were not thought capable of breaking up ley-ground, although in constant use for following, but from their construction requiring fix oxen. On the 16th of October, 1799, a very large and respectable farming society gave a premium for two-furrow ploughs, working ley-ground only. On the day following, in the presence of many members of this society, one acre and a half of ley-ground was broken up by four oxen, with infinite ease to themselves, in three hours and fifty-five minutes, they having, as part of a continual course of work, ploughed seventeen perches short of an acre of ley-ground the same morning; this was done to prove the effect of movable plates at the extremities of the mould-board, that the furrows might be laid more or less flat; for mould-boards, formed to lay furrows in ley, so as to give the mould foil to harrows, cannot be of that form best calculated to make good work in flitting earths, more especially the last, which ought to be thrown up in small heaps, as it were, that the seed may be duly buried. It has hitherto been held necessary to rip off the plate for this purpose, and drive in wedges, by which the mould-plate must be injured. From the trouble attending this operation, it has for ever been omitted, and the land, of course, imperfectly worked. But this inconvenience may be remedied, and the mould-board be adjusted with great facility and expedition, by the following means: when the mould-board is formed, and its plate fitted as usual, let the parts marked $a$, $a$, be cut off, and again connected with the fixed part of the mould-board by means of flat hinges, or of thin flexible plates of tempered steel, or of hard hammered iron, so as to admit of those parts being let to have different inclinations with the fixed part of the mould-board: by means of two screws passing from the inside through the lower parts of the handle of the plough, opposite the backs of these moveable pieces $a$, $a$; those screws may be made to keep them at any desired degree of inclination, according to the nature of the work to be performed. It is flatted farther, that ley-grounds cannot be laid too flat, or feed-earths too much on an edge; and by this improvement of the mould-board the plough may be infinitely adjusted for either purpose: when these moveable parts are screwed outwards, it will cause a proportionate convexity in the bafe of the furrow, and so give more earth to cover the feed. That plough which can give most mould to the harrow is the best for a ley crop. That part of the mould-plate that is marked with the dotted line $c$ being found most liable to wear, should be made of a double thickens, that is, twice the thickens of a new crow-piece; it will then last nearly as long as the plough. The increased weight of draught, when these moveable parts were extended, did not appear, in a two-furrowed plough, to be by the cops more than twelve pounds, in ley-ground, at six inches depth. It is needless to state the successe of these alterations; the friction in furrows required to be laid flat was less than could be supposed, probably not more in both furrows than from twelve to fix pounds.

With regard to the moveable mould-plate, and its operation on the furrow. If the break of a plough be obtuse, the whole struggle lies there,—there is the furrow turned, and the hindmost part of the mould-plate has little or nothing to do: the furrow may be well laid for one particular sort of work, but the break of the common plate can only be of one form, therefore can only turn one description of furrow; and this must be done at an increased weight of draught: this is beyond all contradiction. In these moveable plates, the furrow is not turned until it reaches the remotest point of action, at a distance of two feet from the point where the furrow is cut off from the land. By the gentle and progressive turn of the mould-plate, the earth hangs balancing, as it were, in the air, and the slightest pressure of the moveable plate lays it over. The principle of this plate is, as has been seen, to deposit the furrow at any angle required, and to qualify it thereby for the different purposes of husbandry. There is another principle in ploughing equally well established; namely, that the base or bottom of the furrow must be cut level and true, or the surface of the work will be untrue, and the crop derive other wise material injury. To effect this, the plough must go close at heel, and upright in its work, therefore the furrow must assume one form only. A third principle equally certain, is, that in ploughing ley-ground, or for sowing on one earth, the furrow should be laid far more flat than is advisable in the last flitting or feed earth. As for barley, &c. hitherto, we have obtained one of these objects at the expense of the other. No two-furrow plough could, for an instant, make work, except in an upright direction; for if it did, the land or left share would be buried too deep, and the furrow, or right share, would be thrown out of work. But still farther the writer will be bold to say, that no single-furrow plough, whether constructed in China, in France, or in England, has ever yet, or ever will be able to answer all these purposes, without the aid of a moveable plate; and therefore, however good for a limited purpose it may be, it cannot be called a perfect implement; it is incapable of doing all that is for ever required of it to do. It would be the height of folly and extravagance to construct two implements where one would do. He therefore fits contentedly in the conviction, that these plates must be reformed to.

And in many cases, the moveable plate will probably furnish the use of the turn-plate equally certain. His lordship adds, that it cannot be deemed irrelevant to the subject, here to state the result of a challenge given to the owner of these ploughs, to plough 24 days work successively, on his majesty's farm, either at Kew or Windsor, on the 10th of March. The challenge was accepted, and it is a matter of regret that this challenger did not venture to appear, although repeatedly urged to do so: because a trial for such a length of time, and between two breeds of cattle so distinguished for their powers in labour, must, his lordship supposes, have thrown great light on a subject of such importance to the farming world. That something, however little, might be proved, his majesty was pleased to allot the only piece of land then untiared, 17½ acres, statute measure, which was ploughed by a two-furrow plough, four Devonshire oxen, six years old, a man and a boy driver, in fix days and a few hours: the oxen were in good order at the commencement of their work, and finished it in higher order, as well as in flesh, than when they began. This is a strong fact; but numbers in the vicinity of London know it, and are ready to prove the fact. Those oxen, and that custom in their county, never tailed corn.

Mr. Perrott of Evesham, speaks of these ploughs as doing their work well, and as being on the best construction he ever saw. And Mr. Weitphaling of Radvale, near Rofs, in Herefordshire, observes, that this plough certainly makes exceeding good work, and turns the furrows remarkably well. The time of its arrival was not the most favourable, as their soil, in general light and clay, is now, by the wet and fine, caked, and works with great difficulty; notwithstanding which, not one farmer but says it will be of great use.
PLOUGH.

Mr. Tweed’s land is strong and stiff in quality, and not a turnip has been sown there for more than twenty years past: it is what we term bean and wheat land. The practice of that country has been to allot 100 acres of land in tillth to four horses; therefore let it be remembered, that the saving of expense obtained by the use of the two-furrow plough does not arise from a comparison on lands, expensively cultivated with four or five horses, incurring a charge of twelve, sixteen, or twenty shillings per acre; but in the county of Ellex, and in the vicinity of Chelmsford, where it has long been a system to work these strong soils with two horses and no driver: and where this art is allowed to be as well understood, and practised with as much skill and economy as in any part of Europe, Flanders not excepted. Mr. Tweed’s account of the business in a letter to his lordship, is this:

"In answer to the letter I have just had the honour to receive, I take the liberty of stating the experiments I have made with your two-furrow plough upon strong land, as well as the result of the only match I have yet been engaged in. I put my first plough to work with three horses and one man, against two of my own, and four horses, held by two remarkable good ploughmen, who are very much averse to any new implements: after exerting themselves to the utmost every day for a month, upon clover layes, bean and pea etches, for wheat, they allowed, very much against their inclinations, that it performed the work bett, which is entirely owing to the superior form of the beam, and the great advantage derived from the moveable plates. This trial having perfectly convinced me that there is an absolute saving of five shillings a day every day they are used, I ordered a second, and soon after a third, and have ever since had all my work done with them, nine horses, and three men, which before employed fix ploughs, twelve horses, and fix men, causing a reduction of one-fourth the horses, and one-third of the men, and is, in my opinion, one of the greatest improvements that ever was made in agriculture, for which I conceive the public and myself highly indebted to your lordship. Being at Mr. Lovibond’s rent dinner (the gentleman I live under), I made a proposal to the company, who were all farmers, to plough, for a wager, two acres of any land with the two-furrow plough and three horses, as well, and in the same time, as one acre could be ploughed by a single one and two horses. This was accepted by Mr. Gibling of Hatfield, and a field of his fixed upon that had been sown with rye directly after harvefft, (flubbly) upon a wheat etch, and being fed by bullocks and sheep in wet weather, poached a great deal; and when the ploughing took place, was extremely dry and bound. A great number of spectators attended; at flarting, the odds were three and four to one against the two-furrow plough, as it was supposed not able to break up and turn hard work; after a fair contest, five farmers were appointed umpires, who were unanimous in their decision, that the two-furrow plough, having executed the work foundett and left, and in the least time, was entitled to the wager.

Sandown, 1802. I remain, &c.

"In a second trial, the sweepstakes were adjudged by the umpires to the double-furrowed plough of Mr. Thomas Little Tweed, of Sandon. A double-furrowed plough was allowed, by the articles, to have four horses; but Mr. Tweed’s was worked with only three, and ploughed two roods, not only in the best agricultural manner, but within considerably shorter time than the other common plough did their one rood." The noble writer adds, that in addition to this testimony he has only to say, that it has not been his ill-fortune to verify the old adage, which says, ‘a prophet is no prophet at home;’ for these ploughs are spreading, with unexampled rapidity, over the county in which they originated; and at a very large meeting of farmers, held there lately, no ploughs of any other description appeared, and the prize given by subscription was contested for by these ploughs only.

It has been argued, that a two-furrow plough, with the double mortifed beam, has an advantage over that of the curved single beam, inasmuch as, by a screw, the beams can be brought nearer, or set more apart, for the purpose of cutting a wider or narrower furrow. In common ploughing, no great benefit was contended to result from this power, but in following under furrow, great things were to be expected. Now let us look round, and see where the tillage husbandry is reputed to be good, and single-furrow ploughs in use; conseqently, the size of the furrow is optional; let us see whether the wide or the narrow furrow is preferred. We can in a moment infalnke the usage of the country round Weltham, in Ellex, and Peterham in Moulsey, in Surrey. In both infalnses the land is level and good, and the broadcast husbandry very high in reputation, as their crops, on an average of years, are ready to sellify. Here the feed is ploughed in at a ten or sometines at an eleven inch furrow. We are not, however, to establish a general system on two or three inss—if twenty or thirty might, perhaps, be adduced; but they are worth, at least, one attention. It has been his determination to avoid, as much as possible, any comparison of other implements with his own; but he may say, that he hears from one, who is as good a judge of husbandry as any among us, and has compared the double-beam two-furrow with that of the curved single beam in mortifing and iron-work, and consequent tendency to derangement, there is an absolute difference of one horse in four in favour of the patent plough.

And if land is inclined to be wet and stiff, the lefs trod it is, the better. Here Mr. Tweed’s mode is to work three horses, one on the land, and two in the furrow, one before the others, instead of three abrealt; and it appeared by the regulation of the cops, that is, an iron feer, acting through the end of the beam to regulate the depth of work, how little he has added to the weight of draught. It is almost needless to say, that the true point of draught should be exactly in the centre noth of the cops; any deviation to the right or left can only be for the purpose of counteracting a false fricition or pressure, which must have added to the weight. The size of a furrow, provided it be ofjust proportions, is optional; that which he has preferred is nine inches and a quarter, and for every purpose of husbandry he knows of none better. It will give as much mould,
mould, or "crumb," (as we term it, provincially) to the harrow, as any other furrow whatever; this is the best object in ploughing for a ley crop. If ley peas are to be fown, every other furrow, at nine inches and a quarter each, there will be an interval of eighteen inches and a half between the rows; a distance as much approved of as any we know. At every third furrow for beans, the interval will be twenty-seven inches, three quarters; at every fourth furrow, thirty-seven inches; and it must be allowed, that if any implement be attached to a plough for the delivery of pulp, or white grain in drills, the upright position necessarily belonging to the two-furrow plough, when in work, will qualify it admirably for the purpose.

Upon the whole, these observations place the utility of double ploughs in a point of view, that seems to deserve the notice of the practical farmer in a much greater degree than has hitherto been any where done.

Norfolk Plough.—This is a kind of plough, that is held in much esteem in that, as well as some other light districts, as performing the work in an easy and expeditious manner without any great strength of draught. The carriage and wheels in all ploughs of this nature, however, form objections to them, and at the same time render them awkward, clumsy implements. An improved plough of this sort is drawn in the plate on wheel-ploughs, at fig. 3.

The head and beam are short; while the carriage part and wheels stand very high in this sort of ploughs, of course the fore end of the beam is much elevated, by which advantage is gained in driving the horses or team, as it is usually drawn by two horses yoked abreast, the ploughman directing them by reins, by which there is a saving of one perfon in the business.

In the county of Essex, Mr. Rogers prefers the Norfolk plough, in two circumstances, to the common wheel-plough of that district: the point of the share is nearer to the points in the wheels, where they touch the earth, a shortness which, in his opinion, eases the draught; and the mould-iron or plate, as it is called in Norfolk, turns the furrow better.

The common Essex wheel-plough is said, however, to be a very good tool of this sort, and which is used extensively all around the town of Kelvedon. It has the carriage part for the wheels somewhat in the form, and the beam raised up at the point much in a similar manner to that in the Norfolk plough.

Kentish Turn-plough.—This is another sort of strong plough, much used in the strong heavy, flinty or rocky soils in that district. It is a very powerful implement in such sorts of land, but extremely clumsy, heavy, and awkward. The expense of it, when complete, is mostly about five or six guineas. A representation of it is given in the plates on wheel-ploughs, at fig. 4.

In the survey of that county, it is described as consisting of a beam of oak ten feet long, five inches deep, and four broad, behind which is a foot five inches by three and a half, and three feet and a half long, on the top of which the handles are placed; the foot is tenoned to the end of the beam, and morticed at the bottom to the end of the chep. Through the beam, at two feet five inches distance from the foot, is a sheath of oak seven inches wide, and one and a half thick, which is mortised into the chep in an oblique direction, so that the point of the share is twenty-two inches distant from the beam. The chep to which the share is fixed is five feet long, four inches wide, and five inches deep. The share is of hammered iron, weighs about thirty-two pounds, is twenty inches long, and from four inches and a half to seven inches wide at the point. The upper end of the beam rests on a carriage with two wheels, three feet two inches high. On the axle-tree is a gallows on which is a sliding bolster to let up and down. Through the centre of the axle is a clasp iron, to which is fixed a strong chain called a tow, that comes over the beam, so fixed, as by means of notches (or a pin called a check) to let the whole plough out a greater length from the axle, thereby letting it down to a greater depth.

A different kind of turn-plough or revolving plough has been lately invented by Mr. Lumbert, in which there are two shares, one of which at the end of each furrow, or every length of the field, turns round, and lays another flag by the side of the last, differing it all the same way, in a somewhat similar manner to that which has been described above. Figures of this implement may be seen in the Corrected Report of Oxfordshire.

And besides these different sorts of ploughs, there are various other kinds in use in different districts, as the Single and Two-furrow Ploughs, both of which are good ploughs for particular purposes, but any of the light swing-ploughs, may readily be converted into wheel-ploughs simply by the addition of that apparatus.

Also the Hampshire Patent Iron Plough is a very useful plough in some cases. It is seen at fig. 2. in the plate on wheel-ploughs.

A plough has likewise lately been invented, in Berkshire, by Mr. Berriman of Speen, which is denominated a Pelling Plough, and which is held in much esteem by many pertons, who have given it a sufficient trial, especially upon clover lays. It is constructed under a patent, and costs about twelve guineas. It is stated by the inventor and patentee, that it is intended to be drawn over the land recently ploughed, in order to press in the grips or channels made by the common ploughs, that in no hollow places may remain for the feed to be buried too deep, and that every kind of grass, fluff, or any thing else, may be pressed into the ground. After the field has been pressed, almost any kind of seed may be sown by broad-cast; and it will, by rolling into the channels of the pressing wheels, be evenly and equally buried at a proper depth, after being harrowed, and consequently be kept out of the way of birds, and will come up more regularly. It is evident, therefore, that there is no necessity for sawing so much feed to an acre, as in the common broad-cast husbandry; thus combining the advantages of the drill and the broad-cast systems. This machine is also of such a construction, that in the most uneven ground, every wheel acts as fully and amply as if it were drawn over a level surface. One of the pressing wheels, with or without the line before it, may be put before a common hand drill, and drawn by one horse, by which means any ground, however foul, may be drilled; or a drill may be added to the pressing machine, which has been described, with three wheels, so as to throw the corn into the channels.

Tools of the plough kind have likewise been contrived with more than one coulter, in order to reduce the surface more effectually; but these have in modern practice given way to implements of the harrow kind, such as cultivators, flailers, &c. &c.

Double Mould-boarded Plough.—This is a kind of plough often used with advantage in making the furrows in setting potatoes, cabbage, and other similar crops, and earthing up such as are planted in wide rows. Thofe whose mould-boards move on hinges, and may be set wider or narrower at pleasure, are the most convenient.

Single Hoe Plough.—This is also often useful in striking the mould in the intervals of different sorts of crops, and laying
laying it to the roots of the plants, and thereby preventing the growth of weeds. The mould-board in this plough is so constructed, that it can be raised or depressed at pleasure according to the nature of the crop, and the intention with which it is used.

The Single-Horse Plough, too, is extremely useful for several purposes in tillage husbandry. This fort of tool is very common on the farms in the county of Norfolk, but they are made upon a very different and much inferior construction to this, which is in use upon the estate of Mr. Welton in Essex, and found to work extremely well, but without a wheel. The different parts have the following proportions in his ploughs of this kind.

Ploughs have likewise been invented and constructed entirely without coulters: of this kind is the Argyleshire plough, contrived by the Rev. A. Campbell, on which it is observed, that as the common plough is very liable to be choked by an accumulation of rubbish, &c. in the narrow angle under the beam before the coulter, and, not unfrequently, is thrown out of the ground, by taking small stones or shells between the points of the coulter and stock, both these inconveniences have therefore been attempted to be obviated by throwing aside the coulter altogether, and supplying its place by an upright feather attached to the land side of the stock, and which serves the purpose of stoning off the furrow in the same manner as a coulter; on being laid off on the same angle, it is found, in practice, to succeed to admiration. Small ploughs of this fort employed in horse-hoeing turnips, beans, cabbages, &c. of which the weight of the wooden part is about forty pounds, and of the iron-work about thirty-six, and coil about two pounds ten shillings each, are made in a very accurate manner, by Meffrs. Brown and Co., coach-makers, Abbeyhill, Edinburgh, who have made several, and can supply any number of them on demand. This plough is found to answer extremely well, more especially in taking the earth away from the sides of a drill crop; for which purpose it is conceived to have attained absolute perfection; as its broad upright feather, which operates as a coulter, completely shields the plants from all risk of earth falling on them from the left side of the plough, while, at the same time, the ploughman correctly afferts, that the part of the plough below ground, approaches no nearer to the roots of the plants, than the upper part does to their leaves; so that he can bring the plough to face off the earth cloche in upon their sides, where necessary.

In point of draught, it is precisely the same as the common plough. It obtained the premium from the Highland Society.

And the same gentleman has invented a very curious and useful muzzle or cephe for ploughs, which, by a single twist of a ferre, gives both earth and land or depth and breadth at the same time, or either, as may be requisite, even in the most minute degree. It weighs from ten to thirteen pound according to the size of the plough it may be used for, and costs from nine to thirteen shillings. It is strong and durable, and may be had at the above manufactory.

There are still a few other kinds of ploughs, which are contrived and constructed for the purpose of accomplishing different views and intentions in husbandry, such as those for paring or taking off the surface or scurf of the land, in different circumstances; for the removing of the wetness with which it may be impregnated or faturated in its more superficial parts, and for the forming and improving of roads in different cafes, &c., as may be seen under their several proper heads.

In the first of these intentions, the common paring plough, and the improved paring plough, which is in use in the county of Chester, are extremely good tools, especially the latter, which is very much employed in different parts. See Paring and Burning, and Paring-Plough.

In the second view, there are different forts of ploughs made use of in different places, and according to the different circumstances and soils in which they may be employed. The common draining plough is had recourse to in some of the midland districts of the kingdom for the more general purpooses with great success, for which it is said to be a good, and not very expensive tool. The drain or gutter plough, which has been recommended by the duke of Bridgewater, is also an useful plough of this kind. It has been found beneficial in forming at once gutter drains on farms lands, which are retentive of moisture, but it requires a great strength of draught in all cafes. The common mole plough, and the improved mole plough, by Lumbert and others, are likewise very good implements in many cafes especially those of the latter kinds. There are also some others, which answer different purpooses of the draining kind in a very efectual manner. See Mole-Plough.

In the last intention, a very usefull plough has been invented by a blacksmith of the name of Brand, which will be described under the head of roads. See Road.

PLough, among Book-binders, is a tool with which they cut the leaves of books smooth. See Book-Binding.

Plough, or Plow, in Navigation, an ancient mathematical instrument made of box or pear-tree, and used to take the height of the sun, or stars, in order to find the latitude.

It admits of the degrees to be very large, and has been much esteemed by many artists; though now generally difused amongst us.

Plough-Alive, a duty anecently of a penny, paid to the church for every plough-land, or hide of land.

"De qualibet carucata: juncta inter Particle & Pentecosten unum denarium, qui dicitur plou-almes." Monalt. Ang.

Plough-Bote, in our Old Writers, a right of tenants to take wood to repair ploughs, carts, and harrows, and for making rakes, forks, &c.

Plough, Gallows of a. See Gallows.

Plough, Handles of a, the name given by farmers to the two pieces of the plough followed to the earth-board, and to the planes, and serving the ploughman to rest his force upon in the guiding of the plough. When they are considerably long, the plough is always guided the better, and the land is better tilled; but the lazy ploughmen are apt to cut them off shorter, that by bearing their whole weight upon them, they may, in a manner, ride, instead of walking. If they should ride, in this manner, on the long handles, they would tilt up the end of the beam, and raise the plough out of the ground.

Plough-Head, a name given by the farmers to the fore-
moist half of the plough, or that part containing the two wheels and their spindles, the box, the crow-flakes, the pillow, the wilds, the tow-chain, and bridle-chain, and the flake. See Plough.

Plough-Land, carricata terre, in our Ancient Cyloms. See Carri cate.

Plough-Monday, the next Monday after Twelfth-day. The ploughmen, in the north-country, on this day, draw a plough from door to door, and beg plough money for drink.

Plough-Tail, a name given by the farmers to that part of a plough which contains the beam, the coulter, or coulters, the flake, the shaft and under-shaft, the earth-board and handles, as also the drock, the ground-wrists, and the rachets. See Plough.

Plough-Logger, a term provincially applied to a ploughman of the more ordinary kind: a sort of barger in the work of ploughing.

Plough-Wright, a term applied to a person whose business it is to make ploughs, and other implements of husbandry. Workmen of this sort are most commonly very common in all country situations.

PLOUGHING, the act of breaking up, and leveling the soil by means of a plough and proper teams. This or some other mode of looseness and turning up the upper parts of soils, is in all cases necessary to render them more suitable for the reception of the feed and the growth of the crops, and they have been constantly in practice since the very infancy of the art. As it is only by some such method that a proper bed for the roots of the young plants can be prepared, and a proper condition of the land for supplying them with nourishment be provided; in performing the operation it is a matter of great utility for the farmer to have particular attention not only to the state and nature of the soil, but also to the season of the year, and kind of crop that is to be cultivated, as in this way the preparation of his land may be rendered more perfect and suitable, and at the same time some of the natural defects which have been removed. In almost every sort of soil it has been observed that ploughing them up before the latter end of the autumnal or beginning of the spring season commences, renders them capable of imbibing and retaining a large portion of moisture for the succeeding summer; while the turning them up during the spring and summer, causes much waste and discharge of moisture by evaporation and other means.

In cases where the soil in its natural state is too dry, and possesses too little tenacity for the growth and support of such crops as are necessary to be put into the earth in the spring months, the land, by being fully brought into a state of preparation for the crop in the autumn, and the seed introduced without any additional ploughing in the spring season, may be preferred in a more moist and adhesive condition, consequently in a more proper state for the growth of such crops; but where the soil is naturally moist, and the crops that are to be cultivated require that it should be dry and mellow, when they are put into the ground, the ploughing, by being deferred for the winter, and performed as late as possible in the spring months, when it becomes a good deal dried, will be the more advantageous for the crops that are to be grown upon it. But there are other circumstances that constantly demand attention in the process of ploughing land. In all the flint, heavy, and more adhesive kinds of soils, that are much disposed to the retention of moisture, whether they be perfectly clayey or have more of a loamy quality, it should be a common rule never to plough or turn them up when wet in any degree, except where the nature of the crop requires it: as when such sorts of lands are ploughed under such a condition, the parts of which they are composed are very apt to cake and run together into hard lumps, that require much trouble and difficulty to be afterwards reduced into a fine flake. And further, great injury is produced by the treading of the team, as well as a much greater power necessary in performing the operation. They should not, however, be suffered to become in such a flake of dry mud as to oppose too much refistance before the work is undertaken. It, however, has been suggested, that in all such lands where the clayey material is the most predominant, the ploughing may be performed when the ground is wet without injury, where the work is executed before the commencement of the frosts in the winter, while in the spring the team should not be suffered upon the ground until it be in a properly dry condition. Communications to the Board, vol. iii.

But in all those sorts of land where there is a considerable depth of vegetable earthy matter, as those of the moor, moor, peat, and fen kinds, the ploughing of them, when under the state of tillage, should be executed when they are in a favourable condition in respect of dryness, as under the contrary circumstances they can rarely be ploughed with benefit, and in many cases not at all.

However, in most of the more light dry sandy or gravelly sorts of land, and perhaps in some of the more mellow descriptions of the loam less kinds, the work of ploughing may be had recourse to, especially in putting in the crops, when they are in a considerable degree impregnated with moisture, without any disadvantage being sustained, and sometimes even with benefit, as they are liable to part with their moisture in too quick a manner. This circumstance should indeed direct the farmer in such sandy sorts of land, to till them as little as possible, where the season is hot and dry, so as only to keep down the weeds, as much mischief may otherwise be done by the exhalation of moisture that may be caused. These sorts of lands are of course managed with much less trouble and expense of teams, as well as with less difficulty in respect to the state of the weather, than most other sorts.

The depth to which lands should be ploughed, should in some degree vary according to the nature of the soil, and the crops that are to be grown. It would likewise seem proper that the seed furrows should have less depth than those ploughings that may have preceded it; and perhaps, in general, deep ploughing is not so necessary as has been supposed, except in the cases of tap-rooted plants. It has, indeed, been well remarked by Mr. Kent, in his Hints to Gentlemen and Farmers, that though deep ploughing has been much advised by different writers lately, on such sorts of land where the bottom and surface are of opposite qualities, and neither of them good; a mixture may in such cases be advantageous, and may be effected by going below the usual depth; but where the top and bottom, to the extent of eighteen or twenty inches, are similar, he does not think it ever proper to exchange the surface part, which has been gradually for a great length of time increasing in fertility, for the under part, which has only the property of being more fresh. He has stated that ploughing deep, except for certain sorts of crops above, is never requisite or advisable. The growth of the common crops of corn or of grass does not require any great depth. He likewise remarks, that where ground is ploughed to a great depth, the roots of weeds are only turned over, without being removed or thrown upon the surface to decay, while clean light or shallow ploughing dislodges them in a perfect and effectual manner. In some districts, as that of Cornwall, where
where the foil is extremely shallow, a large produce is afforded; and in several other counties the land is found to be injured by deep ploughing, or going below the usual depth, to which the lands have been ploughed. It is added, that hand-hoeing is known to every one to be more effectual in cleaning land than a ploughing; and the procefs of paring and burning renders land perfectly clean, though it be only two inches in depth. All these tend to fhow that ploughing to a great depth is by no means neceffary in cleaning of land; and it cannot but be generally admitted, that the longer the manure is kept within three or four inches of the surface the better, especially on light foils, through which it is apt to sink and escape too quickly.

It is, however, itated in the Calendare of Husbandry, that in some of our well cultivated counties, the shallowness of the ploughing is remarkable; when almost every other point of management is very spirited and complete, a deficiency in this may not be at once perceived in the crops; but no doubt failures are often caused by it, though attributed to other circumstances. Therefore the following hints are thrown out: 1. An additional depth should firt be gained in autumn, that a consequent change fof fasons may take effect in atmospheric influences before any feed is ventured in the raw furfum brought up. 2. The quality of that furfum should be examined; it is fometimes feril by reafon of an acid, discoverable by boiling in water, and putting that water to the test of blue infufions. 3. Animal and vegetable manures cannot be buried: at whatever depth they are deposited, their conflant tendency is to ftre the atmosphere.

4. Poffile manures are extremely liable to be buried, having a conflant tendency downwards. Chalk marle and clay are sufficiently foble, or fo miscible with water, as to fink in a regular fift; and are fometimes found much below the path of the plough. 5. In foils of a poor hungry quality, there fhould be fome proportion observed between the depth of ploughing and the quantity of manure fublimly spread; but this doe not hold good on better foils. 6. Soils are rarely found that ought not to be ploughed, in common, fix inches deep; many ought to be flurred eight inches, and fome ten. 7. One deep ploughing (to the full depth) fhould, if it is conceived, be given once in twelve, eighteen, or twenty-four months; if this be ferured, shallow tillage by fealing, fcarifying, fcufling, firiming, or broad-fharing, is in many cafes preferable to deep working offers, and especially for what which loves a firm bottom.

But with regard to the depth of breaking up grafs-land it fhould be considered according to the manner of performing the bufinesfs, as by the procefs of paring and burning, and by that of merely ploughing. In regard to the firft, it is nearly a general opinion in almost every part of the kingdom, that the firft ploughing after the operation fhould be shallow. It cannot, however, be admitted, that though the notion be far spread, it is therefore juft, as the fame thing prevails every where with refpect to dung and the fleep-fold; in which cafes there is great reaon to think it erroneous. Manures that purify, and of course become volatile, cannot be buried, as have been fecn above: plough as deep as you please, they all rife sooner or later into the atmosphere; but with foffle bodies, and probably with the ashes of paring and burning, the cafe may in a great measure be different, and the good effects of the ufual management affords reaon to fhew the principle on which it proceeds. It may, therefore, be deemed a fafe maxim not to plough after this operation for the firft time, more than three, or at moft, four inches in depth. In the other mode of breaking up grafs-land after much experience, the writer has not found much difference either in the produce or effects on gravelly, clayey, or fandy foils when executed in either way. In diftricts where they usually plough as deep as fix or eight inches, he has observed (and it has been his own practice) that they plough up old grafs-land shallow, that is not above four inches deep, or at moft five; the crop being every where put in upon this earth, except in the cafe of summer-fallowing peaty or moory lands. By not ploughing deep, the atmosphere has a more effectual influence in affifting the putrefaction of the fod covered, as it is with the crop which is probably one of the fmoother kind.

But that two circumstances are here to be attended to, which are the ufe of the fkhm-couler plough, and that of fowing on a fable furrow.

This plough he considers as one of the molt effectual and applicable implements for breaking up this fort of land. It is well known that when this is done by a common plough, there is a feam between every furrow-like of grafs and weeds that grow through the fummer to the injury of the crop; but which is wholly prevented by this plough, which is applicable in all cafes, except where there are roots or foones.

In regard to fowing on a fable furrow, it is a good practice in breaking up old ley, when done in foils that are not ticklish to get upon. On wet clays and foils, where not well drained, the bufinesfs of fowing is often obliged to be delayed too late in the fpring, if ploughed in the winter, in which cafes it is faper to plough and dibble at once; but on other forts dry enough, fuch as dry foils, fands and chalk, it is better to plough in autumn and plant early in the fpring; the frofts and fucceffive variations of weather, sweeten the frefly turned up foil, and crumble the surface enough to give a little mould, and not fo much as to impede the perfon em-ployed in dibbling.

But in all the heavy strong forts of land a great improvement has been effected by ploughing the lands in the early autumn, fo as to avoid as much as poiffible all fpring tillage. In this way the fummer fallows inted for barley and oat crops; the pea, bean, and tare ftubbles which are to receive the fame forts of crops, as well as the white corn ftubbles which are defignfed for any fort of fpring crops, fhould at this fefon be ploughed in a careful manner in the proper form, fo as to be the future feed earth, no further ploughings being admiffible on any account. In this method, it is itated, in the Calendare of Husbandry juft noticed, that the crops are much larger and the expence considerably leffened. The leading principle is this; if the fand is laid in autumn, on to ridges of that exact breadth which fuits the tools, (whatever they may be, whether harrows, fcarifiers, fcuflers, or drills,) so that the horfes which draw them may walk only in the furrows, the fofts will have left fo fine and friable a surface, that any of these operations may be performed long before the land in the common system would be ploughed. The feed is ufually in the ground before the old fashioned farmer thinks of moving. If he ploughs, he turns down a dry crumbling furface, and brings up the fift wet fprung bottom; if rain comes, then he is in the mire, and must wait for a fean; if a drying sharp north-eaft wind comes, his furrows are converted to oblong strips of a flony hardfafts. In one cafe he is plagued with mud, in the other with impenetrable clofs; he was pof-ffed of juft the furface he wanted, and which, once loft, is not often regained. This furface may be fcuflered, and immediately drilled fecurely. In this practice the lands or ridges fhould be laid out with great exacnefs and attention.

There are also other points that require attention in the ploughing of land; the furrow-flices fhould be difposed in a different manner, according to the nature of the grounds; the
the views of the farmer and the crops to be grown upon them, circumstances which have been already noticed in speaking of ploughs. The feed furrows, and those where advantage is to be derived from the effects of the atmosphere, should be laid much flatter than in other cafes. The breadth of the furrow must likewise be regulated by similar circumstances. And there is another point that has been noticed by Mr. Kent, which is, that, on all the lighter forts of soils, it is essential to perceive at the depth of from six to eight inches below the surface of the land, what in the language of farmers is denominated a pan, which is an unbroken bottom at such depth; in consequence of which, it is suppoed, that manure may be kept longer in the top part; and that in such feasons as are very dry, the less deep this pan is, the less liable the grain will be to burn, especially where it consists of earth and not of rock, as the roots of the grain will find more moisture by striking against a body of compact earth, than in a greater depth of hollow earth, as the former obviously prefers more moisture in such dry feasons. There is also another advantage in this pan, which is, the having a less proportion of mould to work and keep in a state of fertility. In such cafes, where deep ploughing is had recourse to, this compact bottom or pan must be broken and destroyed, for which a great deal more manure will become requisite to keep the land in proper condition for the supporting of crops. On these accounts, care should be taken in such cafes, not to go so deep with the plough as to injure this firm earthy crust, and increase the difficulty of cultivating such soils. See PAN.

In regard to the frequency of ploughing lands, it must, in a great measure, be directed by the state or condition in which they are, and the nature of the crops which are to be grown upon them. It has been observed, in a late System of Practical Husbandry, that the fluff, clayey, loamy, and even chalky soils, in general, stand in need of more frequent tillage, either by means of the plough, harrow, or some other implement, in order to separate and break down their tenacious particles, than those of the sandy or gravelly, and more light kinds, in which there is much less adhesion. Besides, where lands have been in a course of tillage for some length of time, whether they are of a clayey, loamy, or even sandy quality, they may require less frequent tillage than where the contrary is the case. And where the method of putting the feed into the ground by means of drill machines is to be had recourse to, a fine state of tilth will, in general, be indispensably necessary. But, the nature of the crop that is to be cultivated must, in most cafes, direct the number of ploughings that may be necessary, as some demand a much finer state of tillage than others; though in most cafes a well reduced earth is favourable. It has, indeed, been affected by Mr. Tull, in his Horse-hoering Husbandry, that the finer land of any kind is made by tillage, the richer, and more capable of supporting plants it becomes. A proof of which may often be met with in lands where a part has, from accident or other causes, been better tilled than the rest, as, though they be afterwards constantly managed in precisely the same manner, the part so treated always affords better crops than that which have had no such advantage of such tillage.

And where the nature of the crop is such as to be greatly retarded and injured in its growth, by the occurrence of other plants, as in wheat and barley, the land will constantly require to be rendered fine and mellow, either by frequent tilling by the plough, or the growing of such preparatory crops as have a tendency to bring it into a friable and clean state, by the shade which they produce, and the repeated tilage and culture which they receive while growing. Also, where such plants as produce large, knobby, or tap roots, in or upon the soil, are to be grown, it will be necessary to have the land well broken down, and rendered mellow by repeated turning over, in order that they may more readily put down, or extend themselves in other directions. It has likewise been found, that a finer state of tilth is always the most favourable for affording the nourishment and support of crops in a free and equal manner, both on account of its admitting the fibrous roots of the plants to spread and extend themselves with more facility, and the manures to become more mutually divided, and more intimately blended with the soils; as well as from the substanences that constitute the food of the plants being more readily and more copiously formed by the chemical combinations and decompositions that take place under such circumstances. And further, by means of such degrees of pulverisation and mellowness, the feed, especially when it is of the smaller kind, is not only more equally and more perfectly covered, but its vegetation more quick, from its becoming more fully in contact with the mould, and from the moisture being more minutely diffused and retained in the ground, which is an advantage of much importance in the cultivation of many forts of crops.

The work of ploughing may, in most cafes, be well performed with any of the light well formed ploughs that have been described, with two horses without a driver, being managed by reins by the ploughman; and where double ploughs are employed, three horses may mostly be sufficient for effecting the purpose, being directed in the same manner; though in the usual method of performing the work, with the common awkward ill-formed ploughs, that are so frequently met with in practice in many places, three, four, or more horses are in general in use of, and the business executed with more difficulty and less dispatch. The advantage of having recourse to the improved forms of ploughs in this expensive fort of work, muff, of course, be extremely obvious. It has been itated, in the third volume of Communications to the Board of Agriculture, that it has been lately found in Lancashire, that in a light loamy fort of soil, Small's plough with two horses abreast, and the ploughman driving them by means of reins, is capable of executing its work with equal expedition, and to a better depth when necessary, than the common ploughs of the district with four horses, a ploughman, and a boy as driver. This great advantage is considered as depending upon the excellence of its construction, and the team possessing the greatest purchase in the draught, by being placed so near the plough; the least variation in the formation or proportional distances of the different parts being, however, capable of destroying the effect. The Northumberland or Cumberland, and the Rotherham ploughs are also found equally valuable.

Having taken this view of the nature of performing this important operation in the cultivation of land, it may be useful to state the facts as they have been collected in the fertile parts of the kingdom, by the surveyors employed by the Board of Agriculture. In East Norfolk, as stated by the secretary to the Board, there is much difference in performing the work. On some farms he has remarked, the furrow to be cut level and clean; but, on others, swifl-banked, by tilting the plough to the left, which, raising the flare-fin makes that inequality, and is partly the occasion of his having found so many ploughs at work, which would not go a single minute without holding. In Earl Norfolk, Mr. Marshall has observed, that the ploughman, to prevent the soil when moist from turning in whole glossy furrows, which they term "scoring," ties a piece of strong rope round the plate or mould-board, which by these means
PLoughing.

means is prevented from acting as a trowel upon the soil.
And Mr. Young found this the practice at present; but was
informed, that it was not so generally wanted as formerly,
which they attributed to better constructed plates or mould
boards.

And in relation to the depths of ploughing, he states,
that Mr. Thurtell, at Gorildone near Yarmouth, has a great
opinion of deep ploughing. Three or four inches are a
common depth about him, but when land is clean he al
ways ploughs five, and sometimes six or seven; he is care
ful, however, not to do this on foul land; he has no appre
hension of breaking the pan, having many times gone deep
enough for that without any inconvenience, and so to bring
up a dead foil he has not seen any ill effects from it.
The land on which this practice has been pursued, is a good
fandy loam on a clay marle or gravel bottom. But Mr.
Everitt, of Caillor, is of a different opinion; he is not fond
of deep ploughing; he thinks four inches deep enough:
his ideas on this subject, however, refer, Mr. Young lays,
to have been chiefly the result of a trial made by his father,
who broke the pan by trench-ploughing a piece of land,
which has ever since been full of charlock, &c. The dif
ference of their foils will not, he thinks, account for this
opposition of sentiment. Gorildone is a very good fandy
loam at 20r. or 25r. an acre, though certainly inferior in
depth and goodness to the land at Caillor. In discourse
with these two gentlemen on this subject, Mr. Everitt re
marked to Mr. Thurtell, that if he ploughed deeper than
common, he ought to add manure proportionally to the
quantity of foil flirred; an old idea of his, and he remem
bers well, combated by his friend Arbuthnot. It is added,
that Mr. Francis, of Martham, ploughs four or five inches
deep; and Mr. Cubit, of Honing, on a fine sandy loam,
always as shallow as possible; and at East Ruston, where
the soil is exceedingly good, the same; he thinks a smaller
quantity of muck by this means answers.
But they do not
plough four inches deep at Scotto; Mr. Dyble remarked,
it is observed, that a piece was there ploughed five or six
inches deep, and damaged for seven years; three inches
enough; the soil much of it a fine sandy loam, manifesting
no want of depth. Mr. Palgrave, at Cellilial, however,
applications deep ploughing in one cafe with singular judgment;
he brings by water from Yarmouth large quantities of sea
ozone, or hawn mud; this, on dry felling gravels and fands,
he trench-ploughs in without fear of burying, and finds,
on experience, the eftect very great, forming thus a
cool bottom, so that the surface buries no more. And
Mr. Johnson, of Tarning, thinks that it is common to
plough too shallow; nor does he believe that any mischief
results from depth. He has made a ditch one year, and
thrown it down again the next, and the benefit was seen for
seven years, without the foil being acted on by draining, or
wanting it; nor is he nice to have his muck ploughed in
shallow, having no fear of burying it. By ploughing a
good pitch for turnips, they come flow to the hoe, but
when they do get hold, thrive much fatter than others. He
also finds Mr. Reeve, of Wight, an advocate for deep
ploughing; he goes five inches deep; if he did not he
should get no turnips. And Mr. Durlagte approves of deep
ploughing; remarking, that he breaks up his loands deeper
than most people. Mr. Willis observing the mark on his
land was sunk below the common path of the plough,
turned it up again by going a deeper pitch, and found it to
answer nearly as well as a new marking; and he suffered no
inconvenience. It is added, that the two-furrow work
about Holt, &c. is to turn a furrow on lay or allond; the
plough then returns and throws it back with the untouched
land that is under it, into the former open furrow, and over
lapping that, rests on the baulk left before it. It is also ob
served, that Mr. Money Hill, in breaking up the strongest
land he has, ploughs deeper than on the lighter; that is,
four inches, and on light three and a half; and on that
deep drills on flag; if twitch in the land, ploughs only
three and a half; if beyond the usual depth, would hurt
the crop and give weeds. Waterden is a thin and fitly
foil. It is remarked, that Mr. Hill's father lived for many
years at Gateon, and was succeeded in the farm by Mr.
Parker. Mr. Hill's last crop yielded 400 laths of corn,
above 320 of which were barley. He generally ploughed
four inches deep, and never more than four and a half.
Mr. Parker in the first year ploughed the second barley earth
seven inches deep, fowing about eight score acres (the
common quantity twelve score.) He told that year but
twenty hawks; the fees also were worse than usual; the
wheat that followed, good; but in general, he had indif
ferent crops for fourteen or fifteen years. And in March
he applies what he calls one-furrow work to a foul fubble,
if he has fuch by chance; the land slde hore (that on the
left land) always, after the first furrow, returns in it; it
is left open; harrowed down with a heavy harrow; then
the weeds gathered and burnt, and the next ploughing given

The Agricultural Report of Hertfordshire states, that the
common depth of ploughing about Welmill is four or
five inches; but Mr. Greg ploughs as deep as the flape will
admit; which account of his bailiff implies, that five
inches are not the depth of the flape. The crops in that
vicinity are fo great, that the writer should fuppofe that
there cannot be any material error in the basis of their prac
tice. And Mr. Whittingham remarks, that winter tillage
is but of little use; he avoids it as much as poifible, and has
found that the application of a break, or a large four-horse
harrow, is a good fubstitute for some ploughing.

With regard to the flrength of team which is necessary,
it is flated by the author of the Norfolk Report, that Mr.
Thurtell, through the fummer, ploughs with three horses
two acres a day, one always reiling: this from finishing
fowing fping corn to the end of the turnip tillage. There
is no doubt of their ploughing with cafe an acre in four
hours and a half. And in the clays of Marlheald, all are
foot or fiving-ploughs; never more than two hores used;
they do an acre a day, and in fummer one and a half at two
journeys. And at Remby, each pair of hores two acres a
day at two journeys.

About thirty years ago, the common price of ploughing was
2 r. 6d. an acre, in every part of the district, except
Marlheald; it is now 4r.; in some places 3r. 6d. Mr.
Young adds, that the farmers in every part of it get more
land ploughed in a day, by their own men and hores, than
on any fimilar foil in any other part of the kingdom; which,
he thinks, is not altogether to be attributed to the merits of
the plough, thouf it is certainly a good one, nor to any
inferior activity in the hores: the exaie is more in the men,
who have been accustomed to keep their hores and them
elves to a quick ftep, instead of the flow one common in
almost every other district of the island.

And the Suffolk Report states, that in every part of the
county this fort of work is done with a pair of hores, con
ducted with reins by the ploughman; and the quantity of
land usually turned in a day is an acre upon fliff foils, and
from one and a quarter to one and a half on fands. And it
is added, that the ploughmen are remarkable for ftraight
furrows, and also for drawing them by the eye to any ob
ject, ufually a flick whitened by peeling, either for water
PLoughING.
cuts, or for new laying out broad ridges, called there ftratches; and a favourite arrangement is ploughing fuch fur-
rows, as candidates for a hat, or pair of breeches, given by ale-houfe keepers, or subscrib’d among themselves, as a
prize for the dirhghted furrow. The skill of many of them
in this work is remarkable. Such a mode should be prac-
ticed in other diftricts of the kingdom.
In the Hertfordshire Report it is remarked, that the price
of ploughing about Hatfield amounts to 11s. and 12s. an
acre; twenty years ago, 7s. were paid; all is done with four
horses and a driver; 2s. per acre have been paid in the
new inclofure at Cheflhurt. And that in the 17 acres of
experiment ground of the Marchionefs of Salifbury, the
cultivation was began by a powerful trench ploughing,
18 inches deep. Mr. Senhonfen, the manager, who, hav-
ing been bred a gardener, had the farmers’ bel education,
knew that her ladyship intended to cultivate parnips, car-
rrots, cabbages, and other plants demanding deep tillage,
and very wifely began on garden principles. He remarks,
that in general, in Hertfordshire, there is a deficiency in not
ploughing to a greater depth: they have a prejudice again-
it, and think land ruined that is ftrirred deeper than common.
It is admitted that the first crop will fometimes fuffer in
spots, but the fucceeding ones make ample amends. Barley
has been fown on trench-ploughing, and with fucces; in a
dry fefon it grew well, while that for which the land had
been indifferently prepared fowed ill.
Mr. Pratchet of Hatfield having aleried that he would
readily give for ploughing his land once over 12s. per acre,
and that he would fave it, call it him more, put down the par-
ticulars on which he founded his opinion, and his calcula-
tions are as folows:

<table>
<thead>
<tr>
<th>Expences per Week.</th>
<th>£  s. d.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Four horfes, seven buhels of oats, at 4s.</td>
<td>1 8 0</td>
</tr>
<tr>
<td>Eight fruftles of hay, at 5l.</td>
<td>1 2 2</td>
</tr>
<tr>
<td>Ploughman</td>
<td>0 15 0</td>
</tr>
<tr>
<td>Driver</td>
<td>0 12 0</td>
</tr>
<tr>
<td>Wear and tear, plough and harnes</td>
<td>0 6 0</td>
</tr>
<tr>
<td><strong>Total</strong></td>
<td>4 3 2</td>
</tr>
</tbody>
</table>

It is added, that they plough five roods per day, when
they break up their land, and one acre and a half when they
give it a fsecond, or any fubfquent ploughing; and that at
seven acres and a half per week, the expence amounts to 11s.
and 1d. per acre, besides the wear of the horfes; at nine
acres, it amounts to 9s. 2½d. But the above estimate of
Mr. Pratchet is drawn from the consideration, that this in-
cludes none of the time when the horfes are unemployed,
which is a very/material point, and adds largely to the ex-
penfe when they work; on a wet-land farm particularly,
the time thus loft is considerable.

Mr. Cook, from near Colchafher in Essex, bailiff to the
duke of Bridgewater, is of opinion, however prejudiced in
 favour of two-horfe ploughs, that they could not break up
for a fallow the flinty clayey loams of this county; but
that, after one ploughing, they are fully equal to the fol-
lowing tillage. And that about Hitchin, they break up with
the common Hertfordshire plough; but in furrowing, use the
fwing-plough with three horfes, and fometimes with two.
And that at Mortgrave, near Hitchin, where Mr.
Green is settled, who came from near Clare, in Suffolk,
about four years ago, this farmer never ufe more than two
horfes in a plough, and does his work juft as well as the
natives with four: he succeeds, and is fuppofed to be a
very thriving man. Some of his Suffolk ideas, however,
are, Mr. Young obferves, faid not to have anfwered fo well,
particularly the making comfits with ditch earth: this he
has given up, and now goes to London for manure, like
others. And Mr. Sedgwick recommends a practice in
ploughing broad lands with the common plough, to leave
two or four furrows for the small narrow plough, to fuit the
lands; by which means, there are channels on the flopes
of the great thorrath to catch fees; whereas, with the
great plough, the feds pool in the hole thorraths. But
Mr. Parker of Mundes ufe the foot-plough in Middlefex,
as preferable to the great Hertfordshire wheel-plough,
and can break up flinty strong land with it as well as the other
performs it. Cales very rarely happen, in which the county
plough has the advantage. He has a great opinion of deep
ploughing; never has the leaft objection to any depth, nor
ever yet checked his men for going too deep. His common
depth is nine inches. This he has practiced 23 years on
good loamy land in Huntingdonshire, and here on the
gravels and flints of Hertfordshire. He has never loft a crop
by it, but met with an unvarying fucces; and is clearly of
opinion, that at this time of day it ought not to be made a
queftion, but received as an admitted fact. He does not
limit his ploughs to nine inches, for he would like twelve
better, if easily attainable. It is added, that he has no idea
of buying dang, but ploughs it in nine inches deep, and
would plough it in deeper; for he is well afurred from ex-
perience, that nothing is loft; and a great advantage of
depth is, that one ploughing, given deeply and clean, is of
more effect and better than two, or even ten, fuch
fcratching as are called ploughings often in this county;
but the harrows in cleaning fould, in loamy foil, be as deep
as the ploughing. Mr. King of Barkway, it is remarked,
who has Suffolk connections, ploughs with a pair of horfes
and no driver, and does as much and as well as his neigh-
bours with four.

On their moft retentive clays at Albury they are ex-
 tremely attentive never to go on in wet weather: the foil is
fliff and ticklih, and if touched when too moift, is greatly
injured. This is a fact which is very general in moif parts
of the kingdom, on fuch lands.

In every part of Hertfordshire they have a method of
ploughing, of which they are very fond, called combing, or
backing. A field that lies on flat or broad lands is half
ploughed across, by beginning with a furrow, and return-
ing; the plough doubles the breadth of it by a fsecond fur-
row, the contrary way from the former, leaving a very small
bault, juft fufficient to give the ploughmen a little
space to work, by a combe against the unploughed land, which is equally well
effected by leaving no bault, but by going two inches
dereper on the land fide. Then the plough, returning for
the third time, throws back the half turned furrow, taking
up earth enough under it to clean plough the whole land, it
wanted, or to do it at fuch spaces as to whole plough, or
half plough the field; but if combed clofe, the surface is
left in regular narrow ridges, called combs. This opera-
tion, with a little difference in the execution, is called rib-
bling in Suffolk. It appears a good hold for the harrows.
The writer of the Hertfordshire Report faid it well executed
at Sir John Seabright’s, at Beechwood, who understands the
Hertfordshire tillage well. And bonting, as it is called, is
the lapping of two furrows together, by forming narrow
ridges, a bout in each; then they are reverfed in the fame
manner by fplitting; after that, they plough down by one
furrow in the centre of the ridge, and fo leave it for har-
rowing:
rowing: some time elapses between each operation. In breaking up, they do an acre a day, and sometimes more.

It is stated in the Corrected Report of the County of Essex, that the ploughs which are employed there are both those of the swinging and wheeled kind; the latter generally on dry land, and the former on wet; but that in some districts, swinging-ploughs are used on all soils. That in general the plough-team is two horses, driven by the ploughman by means of a cord; and that a common addition is a perpendicular iron faftened to the beam, with two holes to keep the cord from entangling with the plough or whiffletrees. But that upon strong land, three horses abreast are not uncommon, when the work is hard, though still without a driver. Further, that the usual day's work is an acre; at busy fairs, and for good managers, five roods are sometimes done. Scarcely any common farmers use oxen; there are such cases, but they are very few: some gentlemen have them. The ploughing is in general extremely well performed in this county, which abounds with fruitful and accurate ploughmen. The reporter has walked over 40 acres of wheat fresh put in, tilling the land carefully, and not discovering a single false furrow; no variations in the breadths of the flitches, or of the furrows; no depressions, nor any variations in the curvatures of the flitches. But they do not plough so deep as in Kent, nor so flat as in Norfolk; nor is it their wish to do so. The number of ploughings for different crops are in most places great, as from four to eight, or more; and as to the depth of ploughing, some prefer it when done deep, others when more shallow. In the island of Foulness, they break up for fallows six to seven inches deep; but some farmers shallower. Mr. Vaffal of Eastwood, in Rochford hundred, ploughs eight or nine inches deep; and Mr. Wood, who managed Rochford-hall, after the death of the late Mr. Wright, trench-ploughed several fields, which were the worse for it, relative to the wire-worm. The present Mr. Wright ploughs his fallows only a fair depth, and is convinced that it is better, as he has had much better crops from shallow tillage. A neighbour of his, after ten years of deep ploughing, got at first nothing from it but weeds and wire-worm. Wild oats abounded much. He left off the practice, and then got much better crops.

At Little Wakering, Dr. Aplin, and many others, plough the first inch of a fallow very shallow, and get deeper every time; other earths, not in fallowing, shallow. But as to the depth of ploughing for fallows, it must depend upon the soil; but the best farmers like to go deep enough to chip up the dead soil now and then, and chew it a little upon the surface, after all is finished.

In the work of ploughing here, some think the laying the furrows flat the best; but others prefer feather-edged furrows, as covering the seed better in harrowing: and this is the more general opinion. At Burnham, Mr. Ketcher does not approve of feather-edged ploughing; and he thinks flat furrows best on wet land, as well as on dry. But Mr. Tabrum, at Margarettng, not only approves feather-edged work, but thinks it essential for giving moulds to cover the feed.

In regard to the expence of ploughing in this district, in all the strong rich clays at Bradfield, and around by the coast to Clacton, it is 8s. an acre. On the wet loams at Dunmow, three horses, a man, and boy, for the first and second earths of a fallow, by the acre, 7s. At Snorrm, from 9s. to 9s. each ploughing; the soil very stiff. Mr. Ruff, at Latchington, gives 9s.; at Rochford, 10s. 6d.; at Raleigh it was formerly 5s., is now 8s.; at Thorndon, 10s.; at Margarettng, the common hiring price is 10s. 6d.; and at Toppsfield, Mr. Eley reckons it worth 8s. with three horses; 6s. 6d. with two. They plough barley-fallow five or six times.

At Little Wakering, Dr. Aplin used formerly to contract with one labourer for all the tillage of his farm, at 2s. an acre for ploughing, 6d. for harrowing, and 2d. for rolling. More work was done, always five roods ploughed per day, but he left it off on account of the shallowness and wide furrows.

At Jetworth, in Oxfordshire, according to the report of that district just published, they plough with four horses, and do an acre a day. In the south-eastern division of the county, a party of farmers agreed that an acre is the general quantity that should be ploughed in a day by a team; but many ploughs go out for three roods. The expense was thus reckoned.

However, on calling up the account, they observed that it was too low, for an acre of land could not be ploughed under 14s.

At Wormley, &c. horses are allowed 20lb. of hay per diem, and a bushel of oats per week; more for extra work. They plough with three or four, and do an acre a day. Three and four horses are likewise employed in most other places, but some have tried two, though this is only seldom done. The same quantity of land is usually ploughed in the day.

About Adderbury, it has been agreed by several very good farmers, that it is right to plough a fluke in autumn for a fallow, deep; five inches considered as deep ploughing. Also at and about Thunley, they are of the same opinion, when they break up for the first time in May. Mr. Edmonds thinks, that beans do best on deep ploughing; but the after crops may suffer for want of due tillage being given to such additional depth. If deep, it should be continued. Mr. Cozens, of Golder, ploughs eight inches deep for beans, and also in the first ploughing for a fallow. Mr. Newton, of Crownarth, likewise ploughs deep for beans and turnips; but thinks that clover land cannot be ploughed too shallow for wheat. At Mungwold, the bishop of Durham ploughs for the most part according to the flake of the ground, which is very shallow. He generally goes as deep as the flake will admit. His lordship gained exceedingly by ploughing one inch deeper than the farmer before him had done; and which has gradually become an addition to the flake and the foil.

Mr. Percey thinks, that they are apt to plough too much; the less they plough their land the better. A good farmer will plough enough to keep it clean, and all beyond that is bad. Hence, it is supposed, that land may be ploughed too much.
On the rich lands at Adderbury, they do not plough more than four inches deep at any time, except on the little clay land they have, at the first breaking a fallow. Mr. Davy of Dorchester ploughs as deep as he can for beans; but as shallow as possible on clover lays for wheat.

The rates of ploughing in most of the other districts, both in the south and the northern parts of the kingdom, stand equally high with these; and in some they are considerably higher, as more strength of team is employed.

There are many other modes of ploughing practised in different counties, but it is not necessary to describe them here. See Tillage.

Ploughing in Green Crops, the process of turning down various sorts of vegetable crops in their green or mott succulent condition. It is a method of practice that has been employed for a great length of time on the continent, though little practised here by the farmers. The reason of which is probably, that the soils are in most districts too wet and heavy for its being had recourse to with advantage; the light and more friable kinds of land are moat adapted for improvement in this way, as in such the green materials undergo decomposition much more readily, and become more quickly in the proper state for affording the support of crops. In some clayey soils, the putrefaction of such materials is retarded in such a way, that little or no benefit can be derived from their use. But in suitable soils, crops of the green kind, such as buck-wheat, taro, clover, rape, and where sown for the purpose, pease or beans, &c. may be used with advantage, being turned in as a preparation for wheat-crops, without the expense of a fallow. Where employed in this way, the crops, as observed above, should always be turned down when in their most luxuriant state of growth, and the foil rather dry, in order that a speedy decomposition and decay may be undergone. It has been suggested, that advantages may be gained in this view, by the application of small proportions of calcareous substances in their cautious or more active state over them before they are turned down.

And that the economy of this practice much chiefly depend upon the savings in cartage, and the labour of preparation, which in other sorts of manure is often very heavy. Mr. Young, in his Survey of Lincolnshire, states, that this practice, after having been attempted, appears to have been given up from its not fully answering the purposes for which it was intended, probably for the reasons stated above. But it is a mode of husbandry that Mr. Donaldson states to have been had recourse to with success in Warwickshire, and which he considers as, beyond all others, the most economical. The expense of the seeds is almost the whole of what attends the practice. It is now little had recourse to any where.

In the county of Essex, Mr. Hardy, of Bradfield, had a field of clover, part of which was mown twice, and part but once; the second growth being kept until it was in blossom before mowing, when hogs, &c. were turned in, who trampled down five times as much as they ate, which was ploughed in for wheat; and where this latter management took place, gave by far the flouter wheat; and it is said, that it should be remarked that through all the parts of Tendring hundred, this husbandry of trampling second crop clover apparently to waste is very general, and the opinion entertained of its merit is high. Lord Braybrooke favours cole for ploughing in November, and his bailiff, Mr. Nookold, affirmed the reporter that he could see in an inch in the barley where this management takes place. If the crop be high he mows it first, but this is for want of a flimcooler, which would do it better standing. Mr. Chyden, a very spirited tenant on the Audley-End estate, is in the same hulbandry. Corrected Agricultural Report of the County of Essex.

Ploughing in green crops is frequently practised by some of the best farmers bordering on the White-horse hills, in Berkshire, and found much less expensive than carrying along from the yard. Vetches, buck-wheat, rye, &c. are there chiefly employed for this purpose. Corrected Berkshire Report.

PLOUGHMAN, in Husbandry, the person who guides the plough, in the operation of tillage or tillage.

PLoughman's Spikeboard, the English name of a genus of plants called by the botanists concyza; it is likewise called by us flea-bane. See CONVYZA.

PLouguenast, in Geography, a town of France, in the department of the North Coasts, and chief place of a canton, in the district of Loudeac; 7 miles N.N.E. of Loudeac. The place contains 3189, and the canton 12,503 inhabitants, on a territory of 132.5 square kilometres, in 5 communes.

PLouguerneau, a town of France, in the department of the Finisterre, and chief place of a canton, in the district of Brest; 13 miles N. of Brest. The place contains 6430, and the canton 15,033 inhabitants, on a territory of 175 square kilometres, in 6 communes.

Plouha, a town of France, in the department of the North Coasts, and chief place of a canton, in the district of St. Brieuc; 12 miles N.N.W. of St. Brieuc. The place contains 4145, and the canton 10,376 inhabitants, on a territory of 215 square kilometres, in 8 communes.

Plouzevede, a town of France, in the department of the Finisterre, and chief place of a canton, in the district of Morlaix; 8 miles S.W. of St. Pol de Leon. The place contains 2564, and the canton 11,436 inhabitants, on a territory of 190 square kilometres, in 6 communes.

Plowman's Islands, a cluster of islands, forming a part of the Chu-fan islands (see CHU-SAN), which are inhabited, and contain several spots of beautiful verdure, but not a single shrub, except a very few fruit-trees, oak, and Weymouth pine. The rocks on these islands are of the same nature with those of the Ladrones, with the addition, in some parts, of perpendicular veins of white, and of blue and white spar. The Lion, one of the ships belonging to Lord Macartney's embassy, moored between the Plowman and Buffalo's Nile islands; and found a most excellent harbour, secure from the sea, and the holding ground so good, that it required the whole strength of the ship's crew, with the assistance of every purchase, to weigh the anchors: the depth of water being from 12 to 22 fathoms. The tide ricks about 12 feet, and runs at the full and change of the moon, 2 1/2 miles an hour. Its latitude is 29° 45' S., and longitude 121° 26' E. The ship was supplied from these islands, at moderate rates, with bullocks, goats, and fowls; and from some of the surrounding boats with a variety of excellent fish. Stavon's Emb. to China, vol. i.

Plows, in Agriculture, a provincial term signifying ploughed ground, either in clover or open fields.

Pluche, Antoine, Abbé, in Biography, an elegant writer, was born at Rheims in 1688. Having passed through the usual course of education, he was appointed professor of humanity in the University of his native place, and two years afterwards of rhetoric, at which time he entered into holy orders. Some years afterwards he went to Paris, where he gave lectures in geography and history. In that capital he acquired a name among men of letters, by his popular work entitled "Speculum de la Nature," of which the first volume appeared in 1734, and which was carried on to nine volumes. It contains a view of the most interesting facts in natural history,
The writings of many of the ancient philosophers were translated into various languages. His next publication was "Histoire du Ciel," in two vols. 12mo., of which the first volume is chiefly mythological; the second relates to the formation of the world, and contains a confirmation of the Mosaic account of the creation. In 1753, he published a treatise, entitled "The Truth of the Gospel demonstrated." As a philologist, he is distinguished by his "Mecanique des Langues, et l'Art de les Enfeigner," which is said to be a very useful and judicious treatise. He died in 1761, at the age of 73, leaving behind him the character of a truly virtuous and respectable man. Two of his posthumous pieces were published after his death, entitled "Concorde de la Geographie des differens Ages"; and "Harmonie des Pleasures, et de l'Evangile."

PLUCKART Bay, in Geography, a S.E. branch of Loch Ewe, on the W. coast of Scotland. N. lat. 57° 45'. W. long. 5° 34'.

PLUCKENIN, a town of America, in Somerset county, New Jersey; 25 miles N. of Princeton. It carries on some trade.

PLUDENTZ, a town of Germany, and capital of a county of the same name, situated on the II. In 1533 it was almost destroyed by an earthquake, and in 1638 was wholly burnt down; 62 miles W. of Infruck. N. lat. 47° 3'. E. long. 9° 8'.

PLUDENSCH, a town of Germany, in the county of Pludenz; 6 miles N. of Phudentz.

PLUE, L., or Rainy Lake, a lake of Upper Canada, lying W. by N. of lake Superior, and E. by S. of the lake of the Woods. The Narrows are in N. lat. 40° 3' 4", Fort la Cane in 48° 35' 49", iland Portage, 50° 7' 31", at the Barrier, 50° 7' 51". W. long. 95° 8' 30'.

PLUG, Lat. a river forming a communication between lake Plue and the lake of the Woods.

PLUG, a large wooden peg, with which to stop the bottom of a siltern, eske, pipe, or the like.

PLUGs, in Ship Building. Hauge-plugs are pieces of timber trimmed to the size of the haule-holes, so as to keep out the water. Shot-plugs are formed like the frustum of a cone of various sizes, in proportion to the haule-holes made by the different sizes of that which may penetrate the ship's sides in time of action. The latter are sometimes made of tallow and junk, or oakum, made hard together, and are thrust or driven into these shot-holes, to prevent leaking; accordingly they are always ready for this purpose.

PLUKENET, LEONARD, in Biography, "a learned, critical, and laborious botanist," as Dr. Pulteney justly denominates him, was the contemporary and rival of Petiver, fec that article; and laboured, with still more ardent, as well as exclusive, affinity, to collect and to delineate the vegetable productions of nature. His origin and native country, as well as the place of his education, are unknown. He has indicated 1642 as the date of his birth, and we know that he survived the sixty-third year of his age, but there is no precise record of his decease. A handsome portrait of him, at the age of forty-eight, is prefixed to his "Phytographia," with the title of Doctor of Physic, and his arms; formerly, a bandelier engraved, gulls. It is not known where he took this degree. His name seems to betray a French extraction, plus qu'amitie. He resided in Old Palace-yard, Westminster, where he appears to have had a small garden; but as Dr. Pulteney fought in vain for his name, in several lights of the College of Physicians, printed in the first of the 18th century, as well as in those of the Royal Society, of the same date, it should seem that he was not then eminent, either as a medical practitioner, or a natural philosopher. His motto, an anagram of his name, ut pent creatis est arde, well expresses the zeal with which he devoted himself to his favourite study; while another motto in the same page, over a burning candle, alias inferendo confusor, and a subsequent one, to the fourth part of his work, nihil nisi præmia defunt, evince that his worldly recompense was not adequate to his wishes or expectations. Dr. Pulteney has discovered that Plukkenet had a son Richard, who was a student at Cambridge in 1665; and the Almagest contains some verses written by another son, Robert, at Eton school; which is all we know of his family or connections. He published his early works at his own expense, but was afflicted afterwards by trifling subscriptions. Towards the close of his life he is said to have experienced royal patronage, to have obtained the superintendancy of the garden at Hampton-court, and the title of Royal Professor of Botany; all from the favour of Queen Mary. Three of the sections of his Phytographia are severally dedicated to Bishop Compton, the first Earl of Portland, and King William III. That he enjoyed the friendship of Uvedale, who was his fellow-student; and the high commendation of Ray; are sufficient proofs of his personal and scientific merits. The beginning of the Almagest testifies his elevated piety, which at the end degenerates into the orthodox style of the day. That he was skilled in the learned languages, and that his correspondence was very extensive, appears from almost every page of his works; and there are many particular parts which shew his researches have been deep, and conducted with considerable ability. It is to be lamented that some of his latter pages betray a severity of spirit, on the literary labours of Sloane and Petiver more especially, of which we have already spoken in the life of the latter, and of which mere may be said hereafter when we come to speak of Sloane. Plukkenet was, apparently, a man of more solid, learning than either of those distinguised writers, and having been less prosperous than either, he was perhaps less exposed to the errors of his age.

There are all the circumstances we can find, illustrative of the life and character of Plukkenet. We shall now offer a few remarks upon his works.

Having collected a vast Herbarium, for the time in which he lived, not only by means of his various correspondents, but also from the treasures that were then daily pouring into the gardens about London, his object was to publish a catalogue of the whole, accompanied by figures of the new or rare species. The first part of this design was executed in his Almagest Botanicum, which, like all his other publications, is in quarto, making a handsome volume of 404 pages, dated 1696. Its arrangement is alphabetical, according to the generic names at that time received, and adopted from Bauhin and other old authors, though not without many corrections and alterations made by himself in this department. Each plant is distinguished by a specific definition, either adopted in like manner from his predecessors, or new-modelled by himself; and all the synonyms could be collected are subjoined. No idea of systematic arrangement seems to have entered into his contemplation, at least in the plan of this work. There are passages in his writings which shew he had occasionally thought on that subject, nor could it altogether escape a man of so much reading; but it was by no means one of his primary objects. These were rather specific dilutions of plants, their synonyms, and their history. This work is

s

f

aid
fied to contain about 6000 species, of which its author supposed 5000 to be new. Of these 6000, many are now considered as varieties, being merely differences founded upon colour, or on double or single flowers; but if Plukcnct erred in these particulars, lie erred in common with all the botanical world at that period.

The Phytographia of our author was anterior in date to the above work, and yet is rather to be considered as an accompaniment to the Amagetium. It consists of 350 plates, engraved by various hands, each plate containing figures of five or more flowers, chiefly, if not altogether, done from dried specimens, with various degrees of merit. If these figures seldom rise to any great excellence of botanical precision, they are at least original, and not only free from the faults of copies, so copiously displayed in the plates of Morison and such authors, but also tolerably exempt from gross blunders of their own. Of their beauty little can be said, but the work improves as it advances. Being so generally cited by succeeding authors, especially Linnaeus, it is indispensable to every botanic library. This book came out in four parts, of which the first and second were published in 1691, the third in 1692. The plates of these have the names, and many synonyms, of each plant engraved at the bottom. The fourth part, which commences with tab. 251, and was published in 1696, wants this useful appendage, and most of its figures are delineated of any reference. They are however cited in the Amagetium, and some of them likewise refer to that work; but in so obscure and difficult a manner, that few persons take the trouble of searching them out, or of citing them correctly in their own publications. Those who investigate the matter, will find several plants, supposed to be of recent introduction and hitherto nowhere delineated, which were known to Plukcnct; though his references are often so faulty, as to damp our admiration of enquiry, by the needleless difficulties they throw in our way.

In 1700 appeared the Manifolia, or appendix to the Amagetium, consisting of 192 pages, with a copious index to both works. This publication comprehends above 1000 new plants, with numerous observations and corrections relating to the former. Some of Plukcnct's corrections display great learning; as what concerns the Gopher, or Juniper tree, of the bible, first book of Kings, chap. xix. ver. 4; though he errs in referring the Barbadoes Juniper to this oriental plant; see his Mant. 109. Commentators have not been sufficiently attentive to botanical geography, on many occasions.

In 1705, Plukcnct published his last work, the Amuletum, which is a supplement to the other two, and composed on the same plan, consisting of 216 pages, with an index, and 103 plates, some of which illustrate the plants of the Manifolia. All these works were reprinted, with new title-pages, in 1720, and again, with a re-impression of the letter-press, in 1769, making four volumes all together. Gikeke published a very incomplete Linnaean index to them at Hamburg in 1779. The herbarium of Plukcnct, containing about 8000 plants, having been bought by Sir Hans Sloane, is now in the British Museum. The original manuscript of his works was given by the late Mr. Hudfon to the writer of the present article. Pulteney's Sketches of Botany. Plukcnct's Works. S.

Female, on the same plant, Col. Perianth inferior, of one leaf, in four deep, ovato-lanceolate, acute, equal, spreading, persistent segments. Cor. none. Pill. Germen superior, four-lobed, depreelled, smooth; style very long, cylindrical, declining, four-lobed at the summit; stigmas four, capitate, globose. Peric. Capsule four-lobed, coated, depreelled, smooth, with dilated angles, of four cells, and eight elastic valves. Seeds solitary, large, compressed, with vein wrinkles.

Female, Calyx in four deep segments. Corolla none. Germen superior. Style pillose. Stigmas four, capitate. Capsule four-lobed; cells elastic, with solitary seeds.

P. volubilis. Twining Plukcnetia. Linn. Sp. Pl. 1423. Wild. n. 1. Ait. n. 1. (P. scandens, hedez bulbus ferratis, fructu tetragono; Plun. Gen. 47. t. 13. f. 2. l. 220. t. 226.)—Angles of the capsule compressed, keeled. Native of the West Indies. Miller appears to have cultivated it at Chelsea, in 1739, but it had long been lost, till the late Hon. Mrs. Barrington received a living plant from Jamaica, which bloomed in her stove at Mungewell, near Wallingford, in 1795. The stem is twining, branched, round, leafy, smooth; the young branches alternate, axillary, downy in their upper part. Leaves alternate, falcate, simple, heart-shaped, pointed, about three inches long and half as wide, minutely ferrated, dark green, rather roughish to the touch, naked, except a short downy line on the ribs at the back, reticulated on both sides with copious veins, and furnished with a pair of glands at the base. Foot-talks about one-third the length of the leaves, channelled above, downy near the extremity. Stipules in pairs at the base of the foot-talk, very minute, triangular, acute, smooth. Flower-flanks axillary, solitary, racemose, downy, square at the base, round above, generally bearing one female flower at the base; copious for its quadrangular stem, thick style, above an inch long, and large globose stigma; and above it a long compound downy effiguier, of numerous small male flowers. Some branches terminate in a cluster of partly axillary, female flowers only. All the flowers are green, and more singular than beautiful. The bracteae, scattered through the clusters, are small, ovate, acute, smooth, membranous. Fruit the size of a small walnut, green, depreelled, with four spreading, dilated, compressed, rounded angles, the valves separating elastically at the base. Seeds pale brown, large, greatly compressed, lenticular, somewhat bordered, rugged with elevated veins.

2. P. veerania. Warty Plukcnetia. Sm. in Aet. Upfl. n. 2. Wildl. n. 2. (P. volubilis; Linn. Suppl. 421. Am. Acad. v. 8. 261.)—Angles of the capsule terminated by two tubercles. Native of Surinam, from whence our specimens were sent to Linnaeus, who inadvertently referred them.
them to the above original species. The leaves indeed fearfully differ, except in being very minutely and doubtfully tattered, rather than ferrated. The flowers are somewhat smaller. The capsulæ differ most essentially, in being but one-fourth as large as the former, their lobes each tipped with a pair of warts, and not dilated nor keeled. The seeds more-where are obovate, not lenticular nor compressed.

3. P. corniculata. Horned Plukentia. Sm. in Aët. Upf. n. 5. Willd. v. 3. (Sajo volubilis, fruticous corniculata; Rumph. Amboin. v. i. 193. t. 79. f. 2.)—Angles of the capulse composed, tapering, pointed.—Rumphius describes this as found wild in the woods of the district of Baguala, in Ambon, where it is known by the name of Uuta Poli, or Uuta Tala. The Dutch were accustomed to cultivate it, for the sake of its leaves; which, when boiled with the milk of the cocao-nut, prove an agreeable and delicate vegetable. Their name for the plant was Sajo-Maccou. The stems are long and flender, twining about the trunks of trees, and sending off short lateral alternate branches. Leaves much like both the foregoing, but according to the plate and description, very evidently and distinctly ferrated. Their stems are strong like elder, but their taste sweet; at least when boiled, for the natural affinities of the genus lead us to presume that none of its species can be eaten without such preparation. Flowers small and green. There seem to be sometimes two female ones, with a small cluster of numerous hairs above them. The fruit is very well described by Rumphius, as resembling the flary anide, Illicium, except in having but four cells, sometimes only three, instead of six. “Each segment,” says he, “is the size of the seed of Ricinus, with a very thin point, and these fruits, when ripe, fly asunder, like the Ricinus, with an explosion, throwing out their round, compressed, or lenticular sharp-edged seeds.” Nothing can more precisely answer to the character of Plukentia, and Linnaeus actually confounded the plant in question with his P. volubilis.

PLUM ISLAND, in Geography, an island on the coast of Massachusetts, about nine miles long, and half a mile broad, extending from the entrance of Ipswich river S., nearly a N. course to the mouth of Merrimack river, and separated from the main land by a narrow sound called Plumb island river, which is fordable in many places at low water. It consists for the most part of land blown into ludicrous heaps, and covered with bushes bearing the beach plum. On the N. end the land the light houses, and the remains of a wooden fort, built during the war for the defence of the harbour. On the sea-flore of this island, and on Saltbury beach, the Merrimack Humane Society has erected several small houses, furnished with fuel and other conveniences, for the relief of mariners who may be shipwrecked on this coast. The N. end lies in N. lat. 42° 4', and W. long. 72° 47'.

PLUM TREE, in Botany. See Pruens.

PLUM, American black cocoa. See Chrysobalanus.

PLUM, Bay. See Guayaba.

PLUM, Jamaica, or Hog. See Espandias.

PLUM, Indian date, pigamin, perfume, or pigchum. See Diospyros.

PLUM, Maiden. See Camocladia.

PLUMAGE, the feathers, or covering of birds; for the mechanism of which, see Feather.

PLUMAGE, in Falconry, is particularly underflow of the feathers under a hawk's wing.

The falconers also give their hawks parcels of small feathers to make them call; and these they call plumage.

PLUMARTIN, in Geography. See Pluàrtart.
Ceylon leadwort (P. zeylanica); the rose-coloured leadwort (P. rosea); and the climbing leadwort (P. scandens).

Method of Culture. — The first fort is increased by parting the roots in the autumn, when the stems decay, and planting them in a dry soil. They should afterwards be kept clean from weeds, and have proper support.

The three other forts should be raised from seeds, which should be sown in pots in the spring, and plunged in hot-beds. They likewise may sometimes be raised by planting slips and cuttings in pots, and plunging them in the frame of hot-beds.

These are all ornamental flowering plants; the first in the pleasure-grounds, and the others in pots among hot-house collections.

Plumbago, in Metalurgy, a metalline decrement, separated in the purification of gold or silver with lead, and sticking to the sides of the furnace.

This is otherwise called molybdana; and has the same virtue with litharge. See Molybdana.

Plumbago seems to have been used, among the Ancients, for Black Lead (which see), and employed in making pencils for designing, &c.

The black lead used for this purpose, called “plumbago,” and also “carbon of iron,” by Werner “graphite,” and the “black carbon” of Halyot, is a species of coal, or mineral carbon (see Coal), of a dark iron black colour, passing into steel-grey, and occurring in mafs, in kidney-shaped lumps, and disseminated. It has a glintening metallic lustre; its fracture is small, somewhat curved foliated, approaching to scaly, or granular uneven: in the great it is flaty. It occurs generally in granular or scaly distinct concretions; takes a polish by cutting or rubbing; gives a dark lead-grey streak, and is inconstant to the feel, soft, and not very brittle. Spec. grav. 1.98 to 2.26. It does not change when heated, nor can it by itself to support combustion. After long exposure to a high heat in a muffle, its carbon is burnt off, and its earthy and metallic parts remains behind. If one part of plumbago, and two of very caustic dry alkaline, be heated in a retort with the pneumatic-chemical apparatus, the alkaline becomes effervescint, hydrogenous gas is obtained, and the plumbago disappears. This experiment proves, that the small quantity of water contained in the falt is decomposed, and that its oxygen, by combining with the carbon of plumbago, forms the carbonic acid. The sulphuric acid does not act upon plumbago, according to Scheele, Pellletier has observed, that 100 grains of plumbago, and four ounces of oil of vitriol, being digested in the cold for several months, the acid acquired a green colour, and the property of congealing by a very slight degree of cold. The sulphuric acid distilled from plumbago passes to the flate of the sulphureous acid; at the same time that carbonic acid is obtained, and an oxyd of iron is left in the retort. The nitric acid has no action upon plumbago, unless it be impure. The muriatic acid dissolves the iron and clay which containe native plumbago. Meffrs. Berthollet and Scheele availed themselves of this method to purify it. The liquor being decanted after digestion upon the plumbago, the residue is then washed and submitted to distillation to separate the sulphur. The muriatic acid alone has no action upon plumbago, but the oxygenated muriatic acid dissolves it; the result being a true combustion effected by the oxygen of the acid, and the carbon of the plumbago. If ten parts of the nitrate of pot-ash be fused in a crucible, and one part of plumbago be thrown upon it by a little at a time, the falt will dissolve, and the plumbago will be dissolved. The matter which remains in the crucible consists of very effervescint alkali.
alkali, and a small portion of martial ochre. If plumbago be distilled with muriate of ammonia, the muriate sublimes, coloured by the iron. All these facts prove that plumbago is a peculiar combustible substance, a true charcoal combined with a metallic base. The purer kind of plumbago, according to Scheele and Berthollet, consists of about 90 per cent. of carbon and 10 of iron. An impure kind from Pluffier afforded Vauquelin.

23 carbon
2 iron
37 alumine
38 flex

100

The brilliant charcoal of certain vegetable substances, more especially when formed by distillation in close vessels, possess all the characters of plumbago; and the charcoal of animal substances possesses characters still more peculiarly resembling it. When animal sublimes are distilled by a strong fire, a very fine powder sublimes, which attaches itself to the inner part of the neck of the retort. This sublimate may be made into excellent black-lead pencils. Carbon may be formed in the earth by the decomposition of wood, together with pyrites; but the origin of plumbago, says M. Chaptal, is principally owing to the lignonous, and truly indecomposable, part of the wood, which refines the destructive action of water in its decomposition of vegetable substances. This mineral is found in primitive and ancient rocks in England, Scotland, France, Spain, Germany, America, &c. Besides its use for pencils, the best for this purpose is that from Borrowdale, in Cumberland; it is sometimes used to lubricate machinery instead of oil, and to protect iron from rust. The hearths and plates of chimneys and other utensils, which appear very bright, owe their colour to plumbago. For this purpose Honberg, long ago, viz. in 1669, directed 8 lbs. of hog's bladder to be melted with a small quantity of water, with the addition of 4 oz. of camphor. When this last is fused, the mixture is taken from the fire; and while it is yet hot, a small quantity of plumbago is added to give it a leaden colour. When this is to be applied, the utensils must be heated to such a degree that the hand can fearlessly bear to touch them. In this state the composition must be rubbed on them, and afterwards wiped when the piece is dry. Those who prepare small shot, use black lead to polish or glaze it, by rolling or agitating them together with a quantity of plumbago. It is likewise useful to make razor strops.

When kneaded with clay, it makes excellent crucibles. One part of plumbago, three of argillaceous earth, and a small quantity of cow's dung very finely chopped, form an excellent lute for retorts; this lute is a refractory substance and the glaze will melt with the coverings changing its form. Aikin's Dict. Chaptal's Chem. vol. ii.

Pomet says, that plumbago was the fast-lad, plumbum marianum, of the ancients; who, he notes, took black-lead for a production of the earth, not a mineral, as it really is; but this is scarcely credible.

Plumbago, in the History of the Gems, a word used by the Roman authors to express a bluish common to their works, and greatly debasing their value. It was a sort of blue-flint or blackish dead-earth in the floor, which mixed itself with the other colour, be that what it would, and rendered it dull and dead. The emerald was of all the gems the most subject to this fault; and in this case, its fine green colour was always rendered cloudy and blueish; and in some lights the stone appeared of a dusky greyish-blue, with no green at all in it. The Bactrian emeralds, which were in great esteem with the ancients, were often subject to this imperfection; and those of Cyprus, taken out of the copper mines, though subject to many other imperfections, were usually quite free from this.

Plumbago, in Mineralogy, a name given by many authors to a sort of fossil, having very much the appearance of a lead-ore, but not such in reality.

It is called also galena, blede, and mock-lead. It is usually of a plated texture, and dark blackish-blue colour, like the lead-ores; but on trial it yields no metal. See GALENA and BLENDOR.

Plumbaria, in Ancient Geography, an island situated on the coast of Spain, near the promontory Diumium, according to Strabo.

PLUMBASTE, among the Ancients, a kind of scoure, the thongs of which were armed with lead.

Plumbatae, likewise signified leaden balls, used by soldiers to annoy the enemy with; whence the soldiers were called martiobarbari.

PLUMBERY, formed of plumbeum, lead, the art of casting, preparing, and working lead; and of using it in buildings, &c. See LEAD.

The lead used in plumbery is furnished from the leadworks in large ingots, or blocks, called pigs of lead, ordinarily weighing about a hundred pounds apiece.

As this metal melts very easily, it is easy to cast figures of it, of any kind, by running it into moulds of brats, clay, plaster, &c. But the chief article in plumbery is the sheet, and pipes of lead. They are those which make the bars of the plumber's work in building; the pieces of these, therefore, we shall give a description of.

Method of casting large sheets of lead.—The lead defined for this use is melted in a large cauldron or furnace, usually built with free-flue and earth, fortified on the outside with a muffle of bricks and plaster. At the bottom of it is a place sunk lower than the rest, in which is disposed an iron pot, or pan, to receive what may remain of the metal after the sheet is run. The furnace is so raised above the area of the floor, that the iron pot just rests on it.

To use the furnace, they heat it with wood laid within it; that done, they throw in the lead at random with the burning coals, to melt.

Near the furnace is the table or mould, on which the lead is to be cast. This consists of large pieces of wood, well jointed, and bound with bars of iron at the ends. Around it runs a frame, consisting of a ledge, or border of wood, two or three inches thick, and one or two high from the table, called the flanges. The ordinary width of the table is from three to four feet; and their length from eighteen to twenty feet.

This table is covered with fine sand, prepared by moistening it with a watering pot, then working it with a rick; and at last, to render it smooth and even, beating it flat with a mallet, and planing it with a flap of brats, or wood.

Over the table is a flake or rake of wood, which bears and plays on the edges of the frame, by means of a notch cut in either end of it; and is so placed, as that between it and the sand is a space proportional to the intended thickness of the sheet. The use of this flake is to drive the matter, while yet liquid, to the extremity of the mould.

At top of the table is a triangular iron pole or shovel, bearing, before, on the edge of the table itself, and behind, on a trestle somewhat lower than the table. Its use is in conveying the metal into the mould; and the design of its oblique disposition, is, that it may by that means be able to retain the metal, and keep it from running off at the fore-side, where
where it has no ledge. Some of these leads are big enough to hold fifteen or sixteen hundred weight of lead, and even more.

Things being thus disposed, with a large iron ladle they take out the melted lead; coals and all, out of the furnace; and with this, mixed as it is, they fill the iron peel. When full, they take out the coals, and close the lead with another iron spoon, pierced after the manner of a hammer.

This done, they hoist up the lower part of the peel by its handle; upon which the liquid matter running off, and spreading itself on the mould, the plumber conducts and drives it to the extremity of the table, by means of the strike, which the workman pushes along the edges, and thus renders the sheet of an equal thickness.

The sheets thus cast, there remains nothing but to edge them, i.e., to planish the edges on both sides, and to render them smooth and straight.

Method of casting thin Sheets of Lead.—The table or mould here used is of a length or breadth at discretion, only several inches thick, and it is fastened to the table by a piece of woollen stuff, nailed down at the two ends, to keep it tight; and over this they lay a very fine linen cloth. The feet of the table are uneven, so that it does not stand horizontal, but moderately inclined.

Great regard is, in this process, had to the lead while melting, that it have the just degree of heat, so as it may run well, yet not burn the linen. This they judge of by a piece of paper; for if the paper take fire in the liquid lead, it is too hot; and if it be not shrunk and scorched a little, it is not hot enough.

Being then in its just degree, they have a strike, but different from that described in the former article; as serving both for peel and strike; both to contain and to conduct the liquid lead. It is, in effect, a wooden case without any bottom, only closed on three sides. It is pretty high behind, but the two sides, like two acute angles, still diminish to the top, from the place where they are joined to the third or middle piece, where they are of the same height with it; viz. seven or eight inches high. The width of the middle makes that of the strike, which again makes that of the sheet to be cast.

The strike is placed at top of the table, which is before covered in that part, with a peaceboard, that serves as a bottom to the case, and prevents the linen from being burnt while the liquid is pouring in. The strike is fast disposed on the table, as that the highest part looks to the lower end of the table, and the two sloping sides to the higher end.

The strike is now filled with lead, according to the quantity to be used; which done, two men, one at each side the table, let the strike descend down the table, or else draw it down with a velocity greater or less, as the sheet is to be more or less thick; the thickness of the sheet still depending on the promptitude with which the strike slides down the inclining mould.

The fine smooth sheets of lead, thus made, are sometimes used between the joints of large floors in great buildings, &c.

For the method of casting pipes, without foldering, see Pipe.

The folder which the plumbers use is a mixture of two pounds of lead with one of tin. See Solder.

Plumber's work is commonly estimated by the pound or hundred weight; but the weight may be discovered by the measure of it, in the manner below stated. Sheet lead used in roofing, guttering, &c. is commonly between seven and twelve pounds weight to the square foot; but the following table shews by inspection the particular weight of a square foot for each of several thicknesses.

In this table the thicknesses are set down in tenths and hundredths, &c. of an inch; and the annexed corresponding numbers are the weights in avoiding pounds, and thousandths of a pound. So the weight of a square foot of 13 or 15 of an inch thick, is 5 pounds and 899 thousandths of a pound; and the weight of a square foot of 6 of an inch thickness is 6 pounds and 198 of a pound.

Leaden pipe of an inch bore is commonly 13 or 14 pounds to the yard in length.

Examples.

1. How much weighs the lead which is 39 feet 6 inches long, and 3 feet 3 inches broad, at 8.12 lbs. to the square foot?

   Answer 1091.7 lbs.

2. What cost the covering and guttering of a roof with lead, at 18s. the cwt.; the length of the roof being 43 feet, and the breadth or girth over it 32 feet, the guttering 35 feet long, and two feet wide; the former 0.831 lbs., and the latter, 7.373 lbs. to the square foot? Ans. 1155.62. 13d. Hutton's Measured.

Plumbing, among Miners, a term used to express the using a mine dial, in order to know the exact place of the work where to sink down an air shaft, or to bring an adit to the work, or to know which way the lead inclines when any flexure happens in it.

It is performed in this manner: A skilful person with an affilant, and with pen, ink, and paper, and a long line and a fun-dial, after his gauges of the place above ground, descends into the adit or work, and there fastens one end of the line to some fixed thing in it; then the worked needle is let to rest, and the exact point where it rests is marked with a pen; he then goes on farther in the line still fastened, and at the next flexure of the adit he makes a mark on the line by a knot or otherwise; and then letting down the dial again, he there likewise notes down that point at which the middle flanks in this second position. In this manner he proceeds from turning to turning, marking down the points,
and marking the line till he comes to the intended place; this done, he ascends, and begins to work on the surface of the earth what he did in the adit, bringing the first knot in the line to such a place where the mark of the place of the needle will again answer its pointing, and continues this till he comes to the desired place above ground, which is certain to be perpendicularly over the part of the mine into which the air-shaft is to be sunk.

PLUMBUM. See Lead.

PLUMUUM, Calla also Saturnus cornus, in Cleemijry, is a metallic salt, formed by the precipitation of lead from its solution in nitric acid with the marine acid, and all the neutral salts which contain it. It is thus called from its resemblance to the luna cornes. This salt may be made by other methods, and particularly by dispersing the volatile alkali of sal ammoniac by lead. In this way Mr. Margraef makes the plumum cornum, which he employs in the preparation of phosphorus. See Lead.

PLUMERIA. See Burnt Lead.

PLUME, A tet or bunch of ootrich feathers, pulled out of the tail and wings, and made up to serve for ornament in funerals, &c.

PLUME, formed of pluma, feather, in Faleover, is the general colour or mixture of the feathers of a hawk, which fhears her constitution.

When a hawk fakes her prey, and diftiles it of its feathers, he is said to plume it.

PLUME, in Botany. See PLUMULA.

PLUMES, La, in Geography, a town of France, in the department of the Lot and Garonne, and chief place of a canton, in the district of Agen; 7 miles S.S.W. of Agen. The place contains 1,888, and the canton 6,033 inhabitants, on a territory of 127½ kilometres, in 10 communies.

PLUME ALUM. See Alum.

PLUMENAU, or PLUMARIA, in Geography, a town of Moravia, in the circle of Olmutz; 4 miles W. of Profnitz.

PLUMENTAAL, a town of Austria; 4 miles W. of Zitterdsdorff.

PLUMERIA, in Botany, was so named by Tournefort, in honour of its discoverer, the celebrated Father Plumier. (See PLUMIER, CHARLES.)—Tour n. Inf. 659. t. 439.

Gen. Ch. Cal. Perianth inferior, small, in five deep obuete segments. Cor. of one petal, funnel-shaped; tube long, gradually dilated upwards, naked at the mouth; limb spreading, in five deep, ovate-oblong, oblique segments. Stam. Filaments five, awl-shaped, from the middle of the tube; anthers converging. Filr. German superior, oblong, clove; styles scarcely any; stigma double, pointed. Peric. Follicles two, long, pointed, tumid, bent downwards, drooping, each of one cell, and one valve. Seeds numerous, oblong, imbricated, winged with a membrane. Receptacle separate, cylindrical.

1. P. rubra. Red Plumeria. Linn. Sp. Pl. 366. Willd. n. 1. Ait. n. 1. Curt. Mag. t. 279. (P. flore rosec odo- ratiflum; Tour n. Inf. 659. Trew. Ehr. t. t. 41. Jahn. indicum; Merian. Inf. Surinam. t. 8.)—Leaves ovate-oblong. Flower-flalks downy, even.—Native of Jamaica and Surinam, where it is cultivated on account of the beauty and fragrance of its blossoms, which come out before the leaves. Merian says it is readily propagated, and grows rapidly. In our flos it blooms in July and August. The flem is thick and fleshy, forming a tall shrub, or small tree, in the course of a few months, and abounding with milky juice. Leave deciduous, fattered, falked, a span long, and one or half or two inches wide, oblong, somewhat ovate or elliptical, pointed, entire, smooth, with one thick rib, and many tranverse veins, connected by a submarginal line. We find no traces of the two glands on the flower-flaks, mentioned by Linnm., after Browne. The flowers are numerous, in a terminal cymose pante, whose flalks, in all the specimens we have seen, are denfely downy. The corolla expands near two inches, and is rofe-coloured, with a yellow mouth.

2. P. acuminata. Sharp East Indian Plumeria. Ait. n. 2. (Flos convolutus; Rumphi. Amboin. v. 4. 85. t. 38.)—Leaves lanceolate, flat, taper-pointed. Flower-flaks smooth, even.—Native, as well as cultivated, in various parts of the East Indies, being much admired for its beautiful and fragrant white flowers. These, according to Rump., are sometimes candied with sugar. It was introduced at Kew, about 1790, by Mr. Joseph Banks, and flowers there from June to September. The habit of the plant is like the fale, but the corolla is white with a yellow mouth; the flower-flaks smooth; and the leaves much more pointedit. The tapering leaves, and fefs tumid or rugged flower-flaks, dilligent this from the following, which the flowers most nearly resemble.

3. P. alba. White West Indian Plumeria. Linn. Sp. Pl. 366. Willd. n. 2. Ait. n. 3. Jacq. Amer. 36. t. 174. f. 12. (P. flore niveo, foliis longis angustis et acuminatis; Tour n. Inf. 659. Plum. 1c. 227. t. 231.)—Leaves lanceolate, revolute. Flower-flaks smooth, knotty above.—Native of the West Indies, on rocks by the sea side. Jacq. It flowers in our flos in July and August, but is more rare than the fervis. Nothing can exceed the fragrance of the large and elegant white flowers, whose infinity, at the mouth of the tube, is yellow, as in the two preceding.

4. P. obtusa. Blunt-leaved Plumeria. Linn. Sp. Pl. 307. Willd. n. 3. Ait. n. 4. Aubl. Guian. v. 1. 259. (P. flore niveo, foliis brevioribus obtusis; Tour n. Inf. 659. Plum. 1c. 228. t. 231. Catef. Carolina, v. 2. t. 93.)—Leaves obovate, obtuse, with a short point; Native of South America and the West Indies. It flowers in the flos in July, according to Mr. Ait. Our specimen is from Aublet. The shape of the leaves, as above defined, is very diferent from any of the foregoing, with much more diftant, fefs parallel, veins; in which respect Plumier's plate is altogether unlike our plant. Our flower-flaks too are much more elongated, zig-zag, and copiously jointed. Aulet says it is as large as a pear-tree of the largest fize. Burnmann has very improperly confounded the fynonyms of P. rubra with this, and Willdenow, like Linnm., erroneously cites under it Rumpius's Flos convolutus; see n. 2. 5. P. padica. Virgin Plumeria. Jacq. Amer. 37. Willd. n. 4.—Leaves oblong, flat. Limb of the corolla clofed.—Jacquin says he faw this plant cultivated in the gardens of Curacao, where it was highly clemenced for its flowers, known there by the name of Donzellas, or Virginis, because they are never expanded. Their colour is entirely yellow, and their scent, in the opinion of the author we quote, greatly exceeds every other Plumeria, and is fanned superior to all the flowers with which he was acquainted. The fewith is five fets high, milky, with unbranched, oblong, flat venous leaves. Flowers faling, in abundant fuccedion, for two months,
months, their corolla always rolled up, like the 
Arbënia Malabatejus.

5. P. cunata. Wedge-leaved Plumeria. Linn. fil. MSS. 
(P. alba; Aubl. Guian. v. 1. 259, excluding the syno-
nyma.)—Leaves ovate, somewhat wedge-shaped, rounded, 
pointed; veins divergent.—Cultivated at Cayenne, according 
to Aublet, who took it for the Linnaean P. alba. We 
have numerous leaves from his own herbarium, given by sir 
J. Banks to the younger Linnaeus, who justly remarked 
that this must constitute a distinct species, though he had 
seen merely these separate leaves. Another specimen, ap-
parently from the same herbarium, and likewise without 
flowers, is marked P. laurifolia; but it looks to us like a 
leafy plant variety of Aublet's obtusa.

The French name of this genus, Frangipanier, is rather 
remarkable. It is said to allude to its fragrance, Frangi-
pani being a sort of perfume, so called in France from its 
inventor, an Italian, of the Frangipani family, so copi-
cious in the Roman diffusions of the twelfth century.

PLUMERIA, in Gardening, contains plants of the four-
leaved, flowering, exotic kind for the flower, of which the species 
cultivated are the red plumeria, or jasmine (P. rubra); the 
white plumeria (P. alba); the bluish-leaved plumeria (P. ob-
tula); and the close-flowered plumeria (P. pjudic.).

Method of Culture.—These plants are capable of being in-
creased by seeds and cuttings of the young branches. The 
seeds should be procured from the native situation of the 
plants, and be sown in pots, filled with a light sandy com-
po t, plunging them in a hot-bed, covered by glass, or in 
the dark-bed in the flower, when they readily vegetate; and when 
the plants have attained a few inches in growth, they should 
be removed into separate pots, of a small size, which must 
be plunged in beds of the same kind as above.

The cuttings should be made from the young branches, 
and after being laid in the flower or some other dry situation, 
to dipel their succulence, and heal over the wounds, he 
planted out during the summer months, in pots, filled with 
light dry mould, plunging them in the dark-bed of the 
flower, giving occasional shade and very light waterings, till 
they have thriven fresh root, and when they have become 
well rooted, they may be removed into separate pots, being 
managed as other flower exotics.

They afford much ornament and variety among collec-
tions of flower plants; especially the red rose; and when set 
out with other potted plants in the flower, have a delightful 
fragrance.

PLUMER, Charles, in Biography, a French botanist 
and eclectician, of the most respectable character, was born in 
1646. He belonged to the religious order of Minims, 
and is described as of a simplicity of character becoming 
his monastic profession, if not invariably associated with it. 
To this he added the most enthusiastic love of botany, and a 
degree of accuracy and penetration rarely excelled in that 
science. He was sent, at the expense of the French king, 
on three different voyages to the West Indies; and was 
about to undertake a fourth, when he died of a pleurisy at 
Càdiz in 1704, aged 58.

His first publication is entitled Description des Plantes de 
l'Amérique, avec leurs figures, a splendid folio of above 100 
pages, with 108 plates, which issued from the Louvre pres, 
at the king's expense, in 1693. The text is French; the 
plates are outlines, drawn by Plumier himself, with a mat-
terly hand. In the preface he relates, that he first imbibed 
a taste for botany at his convent of Trinita dei monti at Rome, 
from the lectures of Father Sergeant, a French 
monk, and of de Onuphris, a Roman physician. By this 
taste he was insensibly diverted from the mathematics, which 
have always been much studied in that convent, even to our 
own times. Being ordered to his native country, he ob-
tained the permission of his superiors to botanize on the 
shores of Provence, and the mountains of the Alps. Here 
he meditated a general Pinax, or System of Botany, with 
figures, of which he actually had drawn a considerable 
number, when he found at Marseille an opportunity of 
falling to America. Begun, intendant of the French navy, 
furthered his views, and procured for him the patronage and 
support of government; by which action alone, if by no-
thing else, the intendant may be said to have merited his 
own botanical honours. (See BECQUEREL.) Of the plates of 
this book, 50 are devoted to the fern tribe, and contain 
many curious species, previously unknown to botanists.

The rest of the engravings consist of many species of Piper, 
Arum, and Pafijflora, with other climbing plants. Their 
parts of fructification are not critically detailed; but that 
defect was supplied in the author's Nova Plantarum Ameri-
canarum Genera, a thin quarto, published in 1703, after his 
third voyage. In this book 159 genera are established, and 
illustrated with plates. The manner and principles of 
Tournefort are adopted throughout. In his nomenclature, 
Plumer is profuse in honouring botanists, as well as in 
adopting the most uncostly words of barbarous origin; 
scarcely constructing one original name, of Greek or Latin 
derivation, except perhaps paviflora, a genus now sunk in 
the more ancient Piper. Haller justly complains, that Plu-
mer falls into the imperfections of Tournefort, with respect 
to his superficial mode of considering the parts of the flower, 
and his inattention to number in their description. He hints 
also that some of the delineations have a doubtful or 
supicious aspect. That some of these figures are erroneous 
in parts, cannot be denied; as the flaves of Fuchia, the 
ligmas of Plumeiua, and the whole flower of Matthiola; 
besides abundance of slight negligences or inaccuracies; but 
we must not try the performances of one of the fathers 
of scientific botany, by the test of our present advanced 
knowledge.

The Ferns of Plumer's first publication were reprinted 
with a great number of additional figures of the same tribe, 
very finely executed, in another splendid folio, containing 
172 plates, with Latin as well as French descriptions. In 
the preface he investigates all that had been said relative to 
the flowers of these plants; and though he attributes to 
Tournefort a sentiment of Pliny's, he proves himself suffi-
ciently conversant with botanical writers. The more 
conformity to his favourite pursuit, he very com-
methodically enlarges on the benefits which medicine may de-
rive from the study of the vegetable world: but as Rouf-
seau's Swiss herbalis died of a pleurisy, whilst employed in 
gathering a sovereign Alpine remedy for that disorder; so 
it is not improbable that Plumer was extolling the Polyri-
chium, see his preface p. 2, as 'un antipiureticque des plus 
alure,' when he himself fell a victim to the very same dif-
temper; leaving his half-printed book to be his monument. 
So much easier is it for an ardent botanist to catch a pleu-
ry, we write from the conviction of experience, than to 
cure one!

The above works contained but a small part of the pro-
ductions of Plumer's pencil. Vast treasures of his draw-
ings, in outline, have remained in the French libraries, for 
the most part unpublished. The late earl of Bute obtained 
copies of a great number of these, which after his lordship's 
death paled into the hands of sir Joseph Banks. Boerhaave 
had previously procured copies of above 500, done by the 
accurate Aubriet, under Vaillant's inspection, which were 
afterwards, in great part at least, published by John Bur-
mann at Amsterdam, between the years 1755 and 1760. These plates are executed with tolerable, but by no means infallible, accuracy, being far inferior in neatness and correctness to what Plummer himself published. The well-meaning editor has overloaded the book with descriptions of his own, needlessly made from the figures, and therefore entirely superfluous. They are indeed not uniquely founded in misapprehension; rather, it has been very happy to the adaptation of his materials to Linnaean names and principles. He ought rather, as Lamarck observes, to have given Plummer's materials without alteration or addition. A careful reader may, nevertheless, avoid being misled; as the original names and definitions of the author are subjoined. It is a pity that nothing is preferred of the native country, history, properties or colours of each plant.

Father Plummer wrote, in the Journal des Scavans for 1694, and elsewhere, on Cochineal, and some subjects connected therewith; proving that valuable article of commerce to be an animal, and not any thing of a vegetable nature. His opinion was, in every essential point, confirmed, as well as more precisely illustrated and established, by Richter, in his rare little treatise de Cochinitis, published at Leipsic in 1701.

Our author left no herbarium of his own, his collection of dried plants having been lost at sea; but he had, on various occasions, communicated dried specimens to Toursfort; and these still remain, with his hand-writing annexed, in the collections at Paris. Léllier, who visited Plummer in his cell at the convent of Minims in that city, speaks of his obliging and communicative manners, and of his "delights and paintings of plants, birds, fishes, and insects of the West Indies, all done by himself very accurately." It appears that, notwithstanding the royal favour, he was obliged to soliciet repeatedly, and most finely, for the publication of his drawings at the king's printing-press; so imperfect is government patronage for science on all occasions, and in all countries. See Léllier's Journey to Paris. Plummer's Works. Héller Bibl. Bot.

PLUMMER'S ETHOPS. This medicine is composed of the sulphur auratum antimonii and calomel, commonly in equal parts, e. g. of three drams; but this may be varied occasionally, according to the physician's discretion. These two powders must be well leviugated together, by which the bright red colour of the sulphur is changed into a dusky brown; afterwards, add two drams of the extract of liquorice; and the mass, with a sufficient quantity of the mixture of gum arabic, may be made into pills. We refer to the Medical Essays of Edinburgh for the dose, regimen to be observed, and effects of this medicine; as also for the manner of preparing the sulphur of antimony according to Angelus Salus, which is said to be preferable to the common method. See Med. Ell. Edinb. abridg. vol. i. p. 265. vol. ii. p. 455.

This medicine has been found greatly beneficial in cutaneous eruptions, and is said to have completed a cure after salivation has failed, in scrofulous infections, and in gleet remaining after the cure of a gonorchia. It operates by carrying off the excrements of distempers by indigible perspiration or sweat. It has also been found useful in obliterating glandular swellings; or two or three pills of an ordinary size may be taken night and morning, the patient keeping moderately warm, and drinking after each dose a draught of the decoction of the wood, or of farfaparilla.

PLUMMET, Plumb-rule, or Plumb-line, an instrument used by masons, carpenters, &c. to draw perpendiculars; in order to judge whether walls, &c. be upright, planes horizontal, and the like.

It is thus called from a piece of lead, plumbum, fastened to the end of a thread or chord, which usually constitutes this instrument.

Sometimes the string depends along a ruler of wood or metal raised perpendicularly on another; in which case it becomes a level.

A plummet is used by the pilot to find the depth of the water.

PLUMOSE ANTENNAE, in Natural History, a term used to express the antenna, or horns of certain moths and butterflies, which are formed in the manner of feathers, being composed of a stem and fibres lying on each side from it; these are jointed and moveable any way; and even the smallest fibres, at their sides, are jointed at their bottom, and are moveable, but they move all together. See FEELERS.

PLUMSTEAD, in Geography, a post-town of Pennsyl vania, situated on the west side of Delaware river; 36 miles N. of Philadelphia.

PLUMULA, in Botany and Vegetable Physiology, so called from its resemblance to a little feather, is the expanding embryo of a seed, just sprouting, which soon becomes a tuft of young leaves, elevated by the protruding item. See EMBRYO and COTYLEDONES.

PLUNDER, in Sea Language, a name given to the effects of the officers or crew of a prize, which are pillaged by the captors.

PLUNGE, in the Minde. See EXTRAFADE.

PLUNGER, in Mechanics, a solid brass cylinder used as a former in forcing pumps.

PLUNGER is also a large vessel, intended to act as a counter-plate for raising the water in a lock, in some of the schemes for raising water. See CANAL.

PLUNOS, in Ancient Geography, a port of Lyibia, at the extremity of the country of the Adynamichides; mentioned by Lycephon and Herodotus.

PLUQUET, Fransc ANDREWS, in Biography, a French abbe of some celebrity in the 16th century, was born at Bayeux, in Normandy, in 1716. He was educated for the church, and obtained some preferment in it; after this, he was nominated to fill the chair of professor of history in the university of Paris. By his lectures he acquired a considerable share of reputation, the claim to which he ably supported by several useful and well-written works. He died in 1750, at the age of 74, having maintained through life the character of a truly virtuous good man. His principal publications are: "An Examination of the Doctrine of Fatalism," in 3 vols. 12mo.; "A Dictionary of Heresies," in 2 vols. 8vo.; "A Treatise on Society," in opposition to the fyllem of Hobbes, and to prove that man is dippod to benevolence and religion; "The Critical Books of the Church Empire," in 4 vols. 12mo., translated from the collection of father Noël; and "A philosophical and political Treatise on Luxury," in 2 vols. 12mo.

PLURAL. PLURALIS, in Grammar, a particular inflexion of nouns and verbs, whereby they come to express a plurality, or number of things.

The Latin, English, &c. have only two numbers, singular and plural: the Greeks and Hebrews have three, singular, dual, and plural.

In Latin, &c. both nouns and verbs have usually distinct terminations to their different numbers; in English, nouns substantives usually become plural by the addition of an an or to the singular.

Nouns adjective are the same in both numbers; and in verbs, the number is distinguished by that of the pronouns.

PLURALITY, PLURALITES, a discrete quantity, consisting of two, or a greater number.

A plurality
A plurality of worlds is a thing which Mr. Huygens has endeavoured to prove in his Colmotheoros. And the same is likewise contended for in a very pretty treatise of M. Fontenelle under that title.

See the chief argument for a plurality of worlds under Moon, Planet, and Earth.

The greatest absurdity in the pagan theology is the plurality of gods.

Plurality of Benefices, or Livings, is where the same clerk is poissfed of two or more spiritual preferments, with cure of souls. See Benefice.

Plurality of benefices is a thing too much tolerated in the church, but never approved of.

It was the smallness of some benefices that first gave occasion to pluralities; for an ecclesiastic, not being able to subdivide on a single one, was allowed to hold two; and at length the number increased without bounds.

The abuse was endeavoured to be remedied at the council of Lateran, under Alexander III. and Innocent III., in the year 1215, when the holding more than one benefice was expressly forbidden by a canon, under the penalty of deprivation: but the same canon granting the pope a power to dispense with it in favour of person(s) of distinguished merit, there were so many found a title to this merit, that the prohibition became ineffectual.

Pluralities were also restrained by Statute 11 Hen. VIII., cap. 13, which enacted, that if any person, having one benefice with cure of souls, of the yearly value of £L. or above, (in the king's books,) accept any other with cure of souls, the first benefice shall be adjudged in law to be void. &c., though the same statute provides for dispensation in certain cases. For other provisions of a later date, see Chaplain and Curate.

In order to procure a dispensation, the benefice must obtain of the bishop, in whose diocese the livings are, two certificates of the values in the king's books, and the reputed values and distance of such livings; one certificate for the archbishop, and the other for the lord chancellor. And if the livings lie in two dioceses, then two certificates, of the same kind, are to be obtained from each bishop. He must also exhibit to the archbishop his presentation to the second living; and bring with him two papers of testimonials from the neighbouring clergy, concerning his behaviour and conversation, one for the archbishop, and the other for the lord chancellor; and he must also exhibit to the archbishop his letters of orders of deacon and priest, and a certificate of his having taken the degree of master of arts at the left, in one of the universities of this realm, under the hand of the regifter of such university. And in case he be no doctor or bachelor of divinity, nor doctor of law, nor bachelor of canon law, he is to procure a qualification of a chaplain, which is to be duly registered in the faculty office, in order to be tendered to the archbishop, according to the statute. And if he hath taken any of the aforesaid degrees, which the statute allows as qualifications, he is to procure a certificate thereof as already mentioned, and to exhibit the same to the archbishop; after which his dispensation is made out at the faculty office, where he gives security according to the direction of the canon. Afterwards he must repair to the lord chancellor, for confirmation under the broad seal; and then he is to apply to the bishop of the diocese where the living lies, for his admission and institution. By 48 Geo. III. c. 149, for every skin, or paper, or parchment, &c. on which any dispensation to hold two ecclesiastical dignities or benefices, or a dignity and a benefice, shall be engrossed or written, there shall be paid a stamp duty of 30l., when either of them shall be above the yearly value of 10l. in the king's books; and in all other cases 20l.

We have also a regulation in regard to pluralities; but it is often dispensed with; for, by the faculty of dispensation, a pluralist is required, in that benefice from which he shall happen to be most absent, to preach thirteen sermons every year, and to exercise hospitality for two months yearly.

In Germany the pope grants dispensations for poissling a plurality of benefices, on pretence that the ecclesiastical princes there need large revenues to bear up against the Protestant princes.

Plurie in Law, a writ that issues in the third place after two former writs have been disfayed: for first goes out the original writ or capias, which, if it has no effect, then issues the alijs; and if that also fails, then the pluriis. Old. Nat. Br. 33.

It is used in proceedings to outlawy, and in great diversity of cases. Tabl. Reg. Writs.

Plurs, in Geography. See Pleurs.

Plur, in Algebra, a term commonly used for major, or more; denoted by the character +.

Thus 4 + 10 = 14, is read, four, plus, or more, 10, is equal to 14.

Plush, in Commerce, &c., a kind of stuff having a sort of velvet nap or fag on one side; composed regularly of a wool of a single woollen thread, and a double warp, the one wool, of two threads twisted, the other goats' or camels' hair; though there are also some pluses entirely worked, and others composed wholly of hair.

Plush is manufactured, like velvet, on a loom with three treadles. Two of these separate and deprefs the woollen-warps, and the third raises the hair-warp, upon which the workman throwing the shuttle, pafles the wool between the woollen and hair-warp; and afterwards laying a brafs broach, or needle, under that of the hair, he cuts it thereon with a knife defined for that ufe, conducting the knife on the broach, which is made a little hollow, all its length; and thus gives the surface of the plush an appearance of velvet.

Some affcribe the invention of plush to the English; others say it was first made in Holland, and particularly at Haerlem. Be this as it will, it is certain the French are the people who make the moft of it; there being several very coniderable plush manufactures at Amiens, Abbeville, and Compiengne.

There are other kinds of plush, all of silk; some of which have a pretty long nap on one side, and some on both.

Plush, among Botanists, is a name given to the middle of roths, anemones, &c., called also thrown or thrummy beads; by others, hairy beads, buttons, knops, tufts, or swort.

This is properly the flamma of the flower.

Plutarch, in Biography, an eminent biographer, was born at Chaeronia in Boeotia, of a family that had long filled the offices of magistracy in that city. The time of his birth is not exactly ascertained, but it was probably about the commencement of the reign of Nero. He studied under a philosopher of the name of Ammonius, whose particular sect is not known. After he had completed the usual course of academical education, he travelled for improvement; and it is said that he visited Egypt; there, however, no other evidence of this fact than that he wrote a treatife on Isis and Osiris. His attachment to study did not prevent him from engaging in public business. While he was a very young man, he went on a deputation to the Roman proconsul; and it was probably in some public capacity that he first visited Rome, and other parts of Italy; for
for he says, he had not leisure at that time to learn the Latin language, on account of the number of commisions with which he was charged, and the numbers who referred to him in order to be instructed in philosophy. He either revisited Rome, or made it his continued abode for a considerable time, since we find him in reputation there during the reign of Trajan, who is supposed to have been one of his auditors. That fame emperor is said to have raised Plutarch to the consulary dignity: this, however, was probably only a titular honour. He finally retired to his native place, in which he fixed his residence, giving this as a reason, that being born in a little city, he would not make it lefs by deserting it. Here he was chosen to the office of archon, or chief magistrat, and was afterwards admitted into the college of priests of the Delphic Apollo. He is thought to have died about the year 120. He was married, and had several children. Two sons survived him, viz. Plutarch and Lamprias; the latter probably imitated his father in his studies, as he drew up a catalogue of his works, and is supposed to have collected his apothegms. He had a nephew, Sextus, who was preceptor in the Greek language to the emperor Marcus Antoninus. The name of Plutarch is popularly known by his "Lives" of illustrious men, one of the most interesting remains of ancient literature, and to which, in our biographical articles, we have had frequent recourse. A vein of pure morality runs through them, with a spirit of piety, occasionally deviating into superlativity. From the list of his writings it appears that several of his biographies are lost. Plutarch's moral treatises are numerous and valuable; the author does not excel in depth and sagacity, but his sentiments are commonly marked with good sense and candour. In kindnets of heart and humanity few philosophers have surpassed him. It appears from his son's catalogue, that more of his works of the moral and critical class have been lost than preferred. Of the complete works of Plutarch, the bell editions are those of Mauzac and of Reiske. There are numerous editions of the Lives, and other detached works, translated into various languages. In our own language we have a great number of different editions.

Though no dictionaries or biographical accounts in our country, or in France, seem to have taken notice of his knowledge and love of music, or of his writings on the subject, M. Burette, in the 8th vol. 4to., and 11th abridgment, of the Memoirs of the Acad. des Inscriptions et Belles Lettres, in 1726, took up the subject of ancient Greek music, and, with a true critical spirit, laid open all its arcana, after a long study of modern music, and the Greek writers who have treated of it ex professo, or incidentally; letting us know nearly all that is to be known with certainty of this myserious subject.

After denying to the ancients, in the most formal terms, the knowledge of counterpoint, he proceeds to the examination of Plutarch's "Dialogue on Music," first removing all doubt of its having been written by him, which had been disputed, and then proceeds to a close, and, in general, faithful translation, which he gives opposite to the original text; and proves from that work itself, that the ancients were perfectly ignorant of composition, or music in parts. And what gives greater force to this proof is, that Plutarch was thoroughly versed in the subject which he treats. He writes of the nature of sound, to far as was then known; of its generation and proportions; of the genera, intervals, modes, rhythm, melopoeia; explains the musical technics of the Greeks, (not the notation,) but neither quotes nor mentions any practical musician, except Aristozenus. Of poet musicians, from Homer to the time of Alexander the Great, he makes honourable mention, but of none after.

He speaks frequently of music having been corrupted by the theatre, particularly in his "Dialogue," where he says, "If we look back into remote antiquity, we shall find that the Greeks were unacquainted with theatrical music. The only use they made of this art was in praising the gods, and educating youth. The idea of a theatre had not then entered their thoughts, and all their music was dedicated to sacrifices, and to other religious ceremonies, in which they sung hymns in honour of the gods, and canticles in praise of great and good men."

It should be remembered here, that Plutarch was a priest of Apollo; and, moreover, that what he, Plato, and Aristoxenus say, concerning the injuries which music had received from the theatre, favours very much the cant and prejudice. Athenæus, on the contrary, tells us, that notwithstanding the complaints of Aristoxenus against theatrical corruption, others were of opinion, that music derived its principal improvements in Greece from the theatre; and it seems natural, that the hope of applause, and the fear of cenfure, should operate more powerfully on the industry and faculties of a composer or performer, than the idea of private praise or blame. And, if we may judge of ancient times by the present, the theatre seems the place to develop all the powers of music, and to expand the talents of its professors: for it is at the musical theatre, the modern temple of Apollo and the muses, that perfection of various kinds is more frequently found than anywhere else. But old things do get violently praised, particularly music, after it ceases to give pleasure, or even to be heard; and old people exclusively praise what pleased them in their youth, without making allowance for their own want of judgment and experience at that time, which, perhaps, joined to the disposition of youth to be easily pleased, occasioned their former delight.

It is natural to suppose as Greek music, like other arts, and other things, must have had its infancy, maturity, and decrepitude; that in second childhood, as its effects were more feeble, its pursuits would be more trivial than before its decline. Few great actions were achieved by the Greeks after their total subjection. However, they cultivated music under the Roman emperors, under their own, and are still delighted with it under the Turkish government; but their music is now so far from being the standard of excellence to the rest of the world, that none but themselves are pleased with it.

Plutarch treats the subject of music in a manner less dogmatical than histerical. The two principal branches of the art, upon which he lays the most stress, are the harmonic and rhythmical; that is, tone, or melody, and time.

In M. Burette's notes, he gives a biographical account of all the ancient poets and musicians mentioned in the course of the Dialogue; which serves his readers much trouble in seeking them, dispersed as they are through all literature; and greatly enlivens the translation of many parts of the treatise, that are now either unintelligible or useless.

Upon the whole, however, there is more to be learned from this Dialogue, concerning the history, and indeed practice, of ancient music, thus illustrated and explained, than in Melbonius, Ptolemy, and all the philosophers and mathematicians, who only treat of the monochord, ratios, and harmonics, without giving us a single passage of ancient music, or telling us what it was in practice.

PLUTEI, in the Roman Art of War, were engines contrived for the defence of soldiers, consisting of the same materials
PLU

materials with the vine, but of a different figure; being shaped like an arched fort of waggon, and having three wheels, so conveniently placed, that the machines would move either way with equal ease.

PLUTO, in Mythology, the son of Saturn and Rhea, and sovereign of the empire of darknefs. Statius calls him the black Jupiter; and he is represented by the poets as seated on a throne, holding his sceptre in his hand, which had two points by way of distinguishing it from Neptune's trident, which had three, with a veil over his head, which, as well as his complexion, should be dark and terrible.

He is sometimes called by the name of Dis.

The fable of Pluto's having had hell or the empire of darknefs affigned him for his lot is thus explained by Diodorus Siculus. He says, that it arose from his being the first who rejected the custom of burning the dead, of transferring them into sepulchres, and ofabbetting other services upon them, which before him had been neglected.

But Banier, not thinking it probable that duties so natural would have been neglected till the time of Pluto, is of opinion, that he was reckoned the king of hell, because he lived in a very lone country in respect of Greece, where Jupiter had fixed his empire. This country was the extremity of Spain, where he bullifly employed himself in working at the gold and silver mines, which were very common near Cadiz, where he fixed his residence. Spain was anciently reckoned a country abounding with rich mines; and near Tartusus, at the mouth of the river Betis, it is said there was a mountain of silver; and from this name of the island Tartusus, Tartarus is supposed to have been derived. This circumstance induced Pluto to fix his residence in this island, and hence he obtained the name of Pluto, the god of riches, and has been sometimes confounded with Plutus. Befides, Pluto's kingdom was not only low in respect of situation compared with Greece, but as Pluto employed labourers in the mines, and the custom of burying the dead was abandoned, they came into the Mount of Pluto and penetrated, as it were, to the gloomy mansions of the men, alov, or hell, in search of hidden treasures, he was reckoned king of the dead. Befides, the ocean, on the coaft of which he reigned, was accounted a place overspread with darkness, and this, as Banier imagines, was the foundation of all the fables that were invented concerning Pluto and his realms of darknefs. Tartarus he supposes to have been derived from Tartusus near Cadiz, and the river Lethe from Guadalhorce, which runs over-against that city, and the lake Avernas from the word Abaron, importing at the extremities, a name given to that lake, which is near the ocean; accordingly Pluto was particularly worshipped at Cadiz, under the name of Death, as Philostratus has observed; of which there can be no doubt, since the Phcenicians, whose language was established at Cadiz with the colonies planted there by Hercules, called Pluto Math, their name for Death. We might also add, that all the names given to him, or the countries where he was worshipped, have a relation to this title, "god of the dead." For the Fertility of Fruits by Pluto, see Pherephine.

PLUTUS, the god of riches, reckoned amongst the number of infernal deities, because riches are derived from the bowels of the earth. Hefoil makes him to be a descendant of the Cereus and Jasion in the ile of Crete, probably because these two perfons applied themselves to agriculture, which is the means of obtaining the most subftantial riches. Plutus had a statue at Athens, placed in the temple of Minerva, where the public treasures were deposited; at Thebes, in the temple of Fortune, this goddefe holds Plutus in her arms as an infant, nourished by her; Vol. XXVII.

and at Athens, Plutus is in the arms of the statue of Peace, as the symbol of riches, which give peace.

This Plutus, having been observed to dispence his favours very unequally, was therefore repreffed as blind: and Aristophanes in his "Plutus" adds, that he was lame, because whenever he had a mind to enrich the good, he came to them very slowly; and when it was his intention to favour them, he was very clear-sighted, and said to have good eyes. Pindar, Aristophanes, and Lucian inform us, that Plutus was a faftidly god, on which circumstance Erasmus has founded one of his proverbs; but Plutus indicates himself from that imputation, in the comedy above cited, and says, that as thieves and robbers never could eat him, that is, never could acquire great riches, they hence conftructed his precaution and foresight to he true. St. Jerome, followed by several ecclesiastical writers, alleges that the Syracusian or Chaldaic word "Manmona" was the fame with the Plutus of the Greeks.

PLUVIAL, PLUVIAL, anciently signified a hood or cloak; which ecclesiastics, chiefly religious, wore in the country, to shelter themselves from the rain; by the Latins called pluvialis lacerna.

The word is now ufed, in the Romifh church, for a large hood worn by the chanter and subdeacon at masses and vepers, &c. It covers the whole man, and is fixed before with two clasps.

PLUVIALIS, in Ornithology. See PLOVER.

PLUVIALIS Major, a name given by some authors to the limosa, a bird in some respects resembling our red thax, but larger and longer legged.

This bird is also called the glottis. See Scopax Glottis.

PLUVIALIS Levus, a name given by many to the common green wood-pecker, the picus viridis of authors, called also in English the rain-fowl, from an observation of its always being moist clamorous when rain is coming on. See Picus Viridis. See also CICULUS Pluvialis.

PLUVIGNIER, in Geography, a town of France, in the department of the Morbihan, and chief place of a canton, in the district of L'Orient; 14 miles E. of L'Orient. The place contains 4800, and the canton 12,476 inhabitants, on a territory of 252½ kilometres, in seven communes.

PLUVIUS, in Antiquity, an attribute of Jupiter; impliciting him the author of rain; q. d. he that sends rain. Among the bafio relieves of the Antonine column, in the place where the miracle of the thundering legion is represented, we fee a flying man in the air, his arms spread out, and with a very long beard, which seems to dissolve into rain. He learned this to be a representation of Jupiter Pluvius. The Athenians worshipped him under this name, as we learn from Pausanias in Attia.

Plyers, in Fortification, denote a kind of balance used in raising or letting down a draw-bridge. They consist of two timber levers, about twice the length of the bridge they lift, joined together by other timbers framed in the form of a St. Andrew's cross, which serves as a counterpoise. They are supported by two upright jauns, on which they swing; and the bridge is raised or let down by means of chains joining the ends of the plyers and bridge.

PLYING, or Plying to Windward, in Seamanship, the act of making, or endeavouring to make, a progress against the direction of the wind. Hence, a ship that advances well in her course in this manner of sailing, is said to ply well, or be a good plyer. See BEATING, in Navigation.

Plying is also used by ferrymen to denote their waiting for a fare.
PLYMOUTH. in Geography, a town having separate jurisdiction, in the hundred of Roborough, at the western extremity of Devonshire, is 218 miles W.S.W. from London. It is situated at the head of a capacious haven, formed by the conflux of the rivers Tamar and Plym with the sea, and is probably the largest corporate town in the county, as well as one of the most important maritime places in England. Within a circuit of two miles, including its appendages of Stonehouse and Dock, there is a population of between 60,000 and 70,000 people, exclusive of seamen and soldiers. Plymouth is of considerable antiquity, and was called, in the time of the Saxons, Tannoworthy: after the Conquest it acquired the name of South-Town, or Sutton; and in the reign of Edward I. of Sutton-Prior, and Sutton-Vallort, the north part of the town being situated on the land of the revival of trade and enterprise. In the 18th year of Henry VI. it was incorporated as a borough, and on the dissolution of monasteries, in the reign of Henry VIII., the entire lordship of the borough, together with the patronage of the religious establishments within or near the town, were given to the mayor and commonalty, and these advantages they still retain. In the reign of queen Elizabeth, through the means of Sir Francis Drake, various privileges were granted to the town, and at the private expense of the same gallant admiral, a stream of water was conveyed to it from springs on Dartmoor, by a winding channel of twenty-four miles in length. In the year 1579, Plymouth was visited by a dreadful plague, supposed to have been introduced with some cotton-wool, landed from a Smyrna ship, without first being properly aired. Upwards of 600 persons fell victims to its ravages; and so general was the fear of its spreading, that the annual election for mayor was held in the open air, on Cat-down, some distance from the town. In 1581 the plague again broke out, and continued several months; and many of the inhabitants became victims to its violence. At the period of the expected invasion by the Spanish Armada, in 1588, a British fleet of 120 ships was assembled in Plymouth Sound, under the command of lord Howard, and the admirals Sir Francis Drake and Sir John Hawkins. This fleet failed for Torbay to join the Exeter ships; and soon afterwards the grand Spanish armada, which papal arrogance had pronounced invincible, appeared in the form of a crescent, and lay to off the harbour of Plymouth; but proceeding to the eastward, it was affailed by the British fleet, and a destruction thus commenced was completed by a violent storm, which utterly frustrated the expedition. In 1595, the landing of the Spaniards in Cornwall, (for which see Penzance,) threw the inhabitants of Plymouth into much alarm, and caused the adoption of various precautions to ensure their safety. From this period till 1625, nothing material occurred, when Charles I. with his whole court, 120 ships, and 6000 troops, came from Portsmouth, and remained here ten days, fumptuously entertained by the mayor and corporation. In the following year, Plymouth was a third time infested by a plague, which raged with incredible fury, till nearly 2000 persons were destroyed. About 1637, in consequence of a petition to that effect from the mayor and commonalty, the town was divided into two parishes, and in 1640, an act was obtained for the erection of a new church; but the civil wars, which soon after ensued, occasioned the suspension of this latter design. At the breaking out of the civil war, Plymouth very early declared in favour of the parliament, and the year 1643 forms a memorable era in the annals of its history, from the spirited resistance made by the inhabitants against the forces of prince Maurice, who besieged it from September till the close of the year without success. What the citizens wanted in means of defence, was made up to them in enthu.siasm, and they held out till the parliamentary forces, under the earl of Effex, approached to their relief. On the surrounding eminences are still to be traced the remains of various works, constructed both for the defence and reduction of the town. The different attempts of the royalists, under the king in person, and his general, Sir Richard Grenville, successively proved abortive, and they were finally compelled to raise the siege, and entirely withdraw their forces. In the year 1683 the charter of the town was surrendered to the king, on the requisition of judge Jefferys, and a new one granted at an expense of 417l. 19s. 4d. This vested the power in ten aldermen and twelve affiliates only, and continued in force till the latter end of the year 1697, when the old charter was restored, though not before upwards of 600l. had been ineffectually expended.

Various fortifications have been at different times erected for the security of Plymouth, and it is now in a state of respectable and formidable defence. Several smaller block-houses and forts were demolished on the building of the citadel on their site, in the time of Charles II., in 1670. This strong fortresses consists of three regular, and two irregular bastions; and the curtains of the regular bastions are further strengthened by two ravelins and hornworks. On the east, north, and west sides is a deep ditch, countercarp, and covered way, palfio. In the time of war the parapets are mounted with a great number of heavy ordnance, and the garrison consists of a regiment of militia. A lieutenant-governor, and other officers, reside here. The view from the ramparts is exceedingly beautiful, and comprehends a great variety of interesting objects. There is a lower fort, connected with the citadel, and chiefly intended for the defence of the found. Besides these works, several batteries and block-houses are raised on different points of the harbour; on mount Batten, Staddon-heights, and at Maker; but its chief security is St. Nicholas's lighthouse and its formidable batteries. This island lies nearly in the centre of the sound, between the Plymouth shore and Mount Edgecumbe. Between the latter and the island is a ridge of rocks, great part of which is visible at low water, and renders the entrance into the sound, or harbour, difficult and dangerous.

The Victualling office, under the eastern walls of the citadel, is an extensive range of buildings, where the ovens for supplying
PLYMOUTH.

Supplying the navy with bread, and the ingenuity exercised in the baking and preparations, present interesting objects: though there are but two bakehouses, each containing four ovens, yet they are heated eight times a day, and in the course of that time bake a sufficient quantity of bread for 16,000 men. The granaries are large and well constructed; and the whole process of converting the grain into bread is simple and ingenious.

The town itself has very few claims either to elegance or neatness; the streets are in general ill constructed, irregular, and badly paved, but a better taste characterizes the improvements which are taking place. Amongst the public buildings the most ancient is the parish church, which consists of a nave, side aisles, and chancels, with a tower at the west end, ornamented with pinnacles. This structure contains several curious and ancient monuments. The precise period of its erection is not known, but it is mentioned in a general survey in the year 1291. The tower is of more recent date, having been built, in 1440, by Thomas Yogge, a merchant of the town. The other church, begun in 1646, is consecrated to the memory of Charles I., and called Charles's church. Seculars are numerous, and here are various meeting houses, chapels, and a synagogue for Jews. The Guildhall, lately rebuilt on the site of a more ancient one, is a very indifferently edifice. It contains a few portraits of some of the English sovereigns and other illustrious personages. Adjoining the guildhall, and connected with it, are the public prisons of the town; they consist of a room for debtors, and several cells for prisoners, all very small and inconvenient. There are twenty-one charitable institutions in Plymouth, some of them established and supported by the town, others by voluntary contribution, and the rest from the annual income of donations by individuals. Of the former are the workhouse, which is a very useful and well-regularized institution; St. Andrew's almshouses, in which twelve widows are permitted to live gratis, with a small weekly allowance; and the workhouse almshouses, of a similar nature with the last. Those supported by voluntary contributions are the Public Dispensary, House of Faith, Female Asylum, Grey and Yellow School, School of Industry, Public School, on the new plan of instruction designed by Dr. Bell and Mr. Lancaster; Misericordia, Lying-in-Charity, and Merchants' Hospital, for maintained and disabled men, and the widows and orphans of such as are killed, slain, or drowned in the merchants' service. Those maintained by private bequests are, Hele's charity, Lanyon's charity, Orphan's aid hospital and grammar-school, Charles' almshouses, Jory's almshouses, lady Rogers' school, Kelway's trust. The Presbyterians have a very extensive seminary for educating girls in the tenets of their sect, supported by the contributions of their members. Among the other public buildings are to be noticed the public library, a new and elegant edifice erected by the subscribers. It is capacious and convenient, and the architectural part executed with taste and judgment by Mr. Fennelon; the front in imitation of a temple at Athens. The theatre and hotel, covering with their appendages nearly an acre of ground, have just been completed by the mayor and commonalty, at an expense of nearly 40,000/.: the front is very noble and has a portico, the largest in this country, containing eight columns of the Ionic order forty feet in elevation. The theatre is the handomest country theatre in England, and is constructed almost entirely of iron. The roof is sixty-four feet span, and was made at Bristol of wrought iron bars. There are three tiers of boxes formed of cast-iron, the fronts thinly cased with wood to preserve the found. Plans for a new public exchange have been adopted, and are about to be acted upon, as well as are those for a new parish church. Government has several military establishments here, such as barracks, hospitals, and prisons. The latter have lately been rebuilt, and are capable of containing 3000 men; they are placed under the direction of a captain of the navy, and used as a depot for prisoners of war, from whence they are sent to Dartmoor and other inland prisons.

Plymouth was constituted a borough in the eighteenth year of Henry VI., and has sent two members to parliament, without intermission, since that period. It is governed by its own magistrates; who are a mayor, jurists, and the two senior members of the bench of aldermen. In addition to the mayor and jurists, the corporation consists of twelve aldermen, twenty-four common-council men, a town clerk, and a coroner. A general election of the peace is held here four times in the year, where all offences, which extend to transportation for seven years, are tried, and those of minor importance are determined by the mayor at his weekly sitting in guildhall. There is a considerable trade carried on at Plymouth independently of the importation of coal, salt, corn, iron, timber, and articles for town consumption, and during war, at which times a vast deal of busses arises from the sale of prizes and their cargoes, which attract purchasers from all parts of the kingdom. During peace an active trade is carried on with Newfoundland. A new and convenient pier was erected in 1720, at the expense of government, which secures the vessels lying in the pool, or inner harbour, from the violence of the waves. The market days are Mondays, Thursdays, and Saturdays. The market-place has lately been erected at an expense of 10,000l., and is very extensive and commodious, comprehending three acres of ground, with an open area for a cattle market. The revenues belong to the corporation, and are considerable. Here are held two annual fairs.

The borough of Plymouth and its suburbs, according to the population report of 1811, contains 5732 houses, and 56,000 inhabitants. Of these it is specified that 12,339 were resident within the parish of St. Andrew.

This town has not acquired much literary character. Joseph Glanville, a celebrated divine and philosopher, was born here in 1636. (For an account of his life and writings, see vol. xvi. art. GLANVILLE, JOSEPH.) The brave admiral Sir John Hawkins, who commanded the rear of the fleet which defeated the Spanish armada, was a native of this town (see vol. xvii.); and it was long the residence of the celebrated Sir Francis Drake, who was a member of the corporation, representative to parliament, and the author of many valuable improvements in Plymouth, and its vicinity. (See vol. xii.) In the east parts of the town are the remains of the priory of White Friars, granted in the 38th year of Henry VIII. to Giles Welham. The principal gateway or entrance is in a very dilapidated state, but the ruins of the priory itself are almost extinct, and their site occupied by a smith's shop. The hospital of the Grey Friars is still remaining, and is now a private house. An abbey of Cistercian friars is still standing south of St. Andrew's church, and is denominated the abbey wine vaults, the vaults being occupied for that purpose.

PLYMOUTH Port and Harbour is conveniently adapted for the purposes of trade, and affords an excellent road for ships of war, their prizes, and merchant vessels. The harbour is divided into several ramifications, which are distinguished by different appellations. Sutton-pool immediately adjoins the town, the buildings of which nearly encircle it. The entrance to the pool is between two large piers, erected by
parliamentary grants in 1791–1799. It is surrounded with public and private quays, and all ships entering it are obliged to pay certain dues on landing their cargoes. The port is under the management of a company, by whose management it has been benefited with important improvements.

Catwater harbour is formed by the eftuary of the river Plym, and is capable of protecting from the south-west gales, which are prevalent, upwards of 500 ships. Part of this harbour is under the jurisdiction of the mayor and commonalty of Plymouth, the other part is subject to the control of the present lord Boringdon, who has been at much expense in laying down moorings, buoys, &c. On the banks of the Catwater are several small villages. Cat-down, on the northern side, is famous for its lime-stone quarries: it has a shipwright's yard, various store-houses, wharfs, &c. for commercial transactions. Turnchapel, on the opposite bank, is the property of the Boringdon family, and is principally inhabited by shipwrights employed at the dockyard. Here, where large ships of war are frequently repaired, and merchant and armed vessels con frec tured. Orelton is a populous village on the eastern banks, principally inhabited by sea-faring men. In this neighbourhood are the beautiful villages of Upper and Lower Turnchapel. Catwater enters into that part of the harbour denominated the Sound, which is a large and capacious bay peculiarly adapted for a naval rendezvous. One disadvantage, however, attends it, of no incon siderable kind, which is its exposure to south-west gales, that occasion a tremendous swell. To obviate this objection, and render it safe as well as commodious, the lords of the admiralty determined to erect a pier or breakwater, and applied to Mr. Rennie, a gentleman well fitted, from his extensive architectural knowledge, to prepare an efficient and practicable remedy, and render them a plan for the purpose. The report of this gentleman has been put in execution, and the work is in a state of great progress. The plan of its construction is this: it is a mass of punken stone, in length 500 fathoms, extending from about 60 fathoms of St. Carlo's rocks, on the efl, to about 500 fathoms west of the Shovel, on the west. Another pier is made from Andurn Point towards the before-mentioned breakwater, about 400 fathoms in length, having an inclined kant, forming an angle of about 120°. Of the first, about 500 fathoms in the middle are straight, and 150 fathoms at each end inclined to the straight parts in an angle of 120°. These inclined ends prevent the influx of the sea from agitating the water, and shelter a greater extent of theSound. The two kants of the eastern end of the breakwater, and western end of the pier, repel the waves in such a manner as to prevent them from palling in any material degree through the opening between. The improvements are constructed of large blocks of stone, thrown promiscuously into the Sound in the line of the breakwater, leaving them to find their own base, which is about seventy yards broad, and the top is intended to be about ten yards in width, at the level of ten feet above the low water of an ordinary spring tide. The principal part of the stone used for the works is brought from quarries at the head of Catwater, in small vessels, of from 50 to 100 tons, with a crane fixed in their decks to take out the stones, and throw them into the water. The expenses necessary to complete the undertaking were estimated at 1,150,000l.: the quantity of stone required was 350,000 tons. The work of the first year was calculated at 500,000l.: 170,000 tons of stone have been deposited, and 500 yards in length of the mole are already apparent above low water, and the expense so far has been considerably within the estimate presented by Mr. Rennie to the lords of the admiralty. At a more advanced state of the business, it is contemplated to erect a cut-stone pier on the top of the great breakwater, and build two light-houses on each extremity, to assist ships entering the Sound.

The Eddystone light-house, at the mouth of the Sound, five leagues south of Plymouth, is necessarily an appendage of the most important kind to the harbour, without which the entrance to it would be extremely dangerous. There is a duty payable by ships palling the light-house, which is collected at all the neighbouring ports. Merchant ships only are subject to this tax, those belonging to the king are free. For an account and history of the Eddystone light-house, see vol. xii.

Stonehouse is a populous town, containing about 5000 inhabitants, situated on the road leading from Plymouth to Plymouth-dock, and almost connecting the latter with the former by the continuation of buildings. The streets are generally irregular, but most of them paved, and the houses handsome and convenient. Stonehouse bridge, erected over a small creek of the same name, is a neat stone fabric of one arch. The revenue arising from its toll is considerable, and bafes to the lords of the manor. Stonehouse has ever been the property of individuals; as early as the 27th of Henry III. it belonged to Joel de Stonehouse, and has since, by various marriages, passed into the family of Mount Edgecombe. By the last census the number of houses was found to be 566, and the population 5714. There are a chapel, work-house, and market-place; but the most important public buildings are the Royal Marine barracks, a handsome range of uniform granite edifices, in the form of a quadrangle, and capable of containing upwards of 1000 men, with their officers. At Stonehouse, and connecting it with the town of Plymouth, is the Royal Naval hospital, which is an immense establishment, under the superintendence of a governor, lieutenants, and medical officers. Besides the chapel, dispensary, and officers' residences, there are several large, commodious buildings surrounding the town, each containing six wards, and capable of accommodating 959 persons, officers and sailors. The sick and wounded are brought in boats from their ships, and landed at a quay immediately adjacent to the hospital. The Royal Military hospital, of a more recent erection than the former, is situated on the opposite bank of the river, and consists of only four distinct buildings. Its government is similar to the other. Adjacent to Plymouth are several inland towns and villages of minor consequence. St. Budeaux, about five miles north of Plymouth, is a pleasant village, formerly the property of Sir William Gorges, the only descendant of whom is said to be the celebrated Gorges, who commanded the Chouans in Brittany during the latter part of the French revolution. The church is a plain simple edifice, erected in the 14th century, with the materials of an older structure. Buckland-Monochorum is entitled to notice for its handsome church, consisting of a nave, side aisles, transepts, a tower, with turrets and pinnacles. The remains of the Drake family are deposited here, with several handsome monuments to their memory, as well as to that of Lord Heathfield, the brave commander at the famous siege of Gibraltar. There are also the villages of Lifpon, Weyde, Tamerton, Crabtree, and Compton. Polwhele's History of Devonshire, folio. Beauties of England, vol. iv. Picture of Plymouth.

Plymouth-Dock, sometimes denominated Dock, in the hundred of Roborough, and parish of Stoke-Damerell, Devonshire, is situated west of Plymouth, with the town of
PLIMOUTH.

of Stonehouse only intervening. It is placed on the easter
crn bank of Hamoaze. The manor, excepting a part
of the dock-yard, is the property of the St. Aubyn family,
who inherit it from Sir William Morice, secretary of state to
Charles II., and mentioned by Clerendon as instrumental
to the restoration. In this family the presents to
the living of Stoke-Damerell. The streets are regular,
interfecting each other at right angles, and generally well
built. The pavement is of the marble with which the
neighbourhood abounds, and after a shower its veins have
a beautiful appearance. Though of such considerable
magnitude, it is wholly of modern date, and owes its or-
igin and rapid increase to the establishment of the dock-yard
and naval arsenals. It was made a king's yard in the latter
part of the reign of William III., before which it was a
mere hamlet or a few houses. The greater part of the
town has been erected since 1760. The number of inhab-
ients in Dock is about 25,000, and the houses 24,000. They
are erected by the inhabitants on leaves for ninety-nine
years, subject to a small annual quit rent. The town
and the dock-yard are defended by lines. They were com-
menced in the reign of George II., but the works have been
much improved under an act made in the 21st of his
prent majesty, George III. On the north-east and south
sides the town is bounded by a solid wall, about twelve feet
high, which was built in 1787. The western side is skirted
by the walls of the dock-yard and gun-wharf. Without
the lines is a ditch from twelve to eighteen and twenty feet
deep, excavated from the solid slate and lime-flint rock.
In this line of fortification are three barrier gates; the
North barrier, the Stoke barrier, and the Stonehouse bar-
rrier. Round the whole extent are planted pieces of ord-
ance, at regular distances. The other fortifications are a
battery on mount Wife; another at the Obelisk hill; and a
redoubt commanding the entrance to the town, and one
third of a mile distant from the dock-yard, which is called
the royal dock. It is commanded by a line of the
which command the whole. It is in contemplation
to fortify the town regularly, and the bastions is actually
begun; but the dock-yard may be commanded from many
of the adjacent eminences, all of which must be fortified
also, at an expense that would erect several distinct yards!
The town, being circumscribed by these defensive works,
does not admit of any increase of building within it. A
new town without the lines, named Morice-town, is also
the property of the St. Aubyn's family. Dock has two
chapels, and several meeting-houses for sects of different
denominations, which are very numerous. The parish
church is situated about a mile from the town. There are
few charitable institutions, perhaps in consequence of the
recent growth of the town. The poor-houses is extensive,
and will contain nearly 300 persons: picking oakum for
the dock-yard affords constant employment to its inmates.
The town, not being incorporated, is under the juridiction
of the county magistrates, who hold their sessions quarterly
here. The inhabitants are supplied with water from the
springs and wells, by an aqueduct similar to that of
Plymouth. Markets are held three days in the week in the
new market place, lately erected by Sir John St. Aubyn.

The government house is a handsome building, erected when
Lord Lennox commanded here; it is appropriated solely to
the dispatch of military business, court-martials, &c. and
has in front a grand parade. Here are eight different
barrack establishments, which afford conveniences for
3000 men. The naval department consists of an admiral
and rear admiral, deputy judge advocate, and com-
missioner for the payment of seamen's wages. Near the
grand parade stands the telegraph, by which a commu-
nication is kept up with the Admiralty in London,
through thirty-six different stations. Influences have oc-
curred of a short mileage being transmitted to London,
and an answer returned, in fifteen minutes. (See Post
and Telegraph.) The dock-yard, even in its present un-
finished state, is acknowledged to be one of the finest
in the world. When it was first used as a naval arsenal is
uncertain; but as the bason and dock are the most an-
cient, and were not made till the reign of William III., it
seems evident that this was a place of little confluence
before that period. The wall, which separates the yard
from the town, is of slate and lime-flint, and in some places
thirty feet high. The area within the wall is seventy-one
acres and thirty-six poles; including the projecting parts of
the jetties. The entrance to the dock-yard from the land
side is from Fore-Street, by a large gate for carriages, &c.,
and a small one for foot passengers. No permit is required
to enter, unless well known, or in uniform, without an
order from the commissioner. Immediately within the gates
is the master porter's house; and close by is the chapel, the
tower and one side of which are as old as 1700, the other
aisle is of much more recent date. In front of the chapel
is the military guard-office, and over that the navy pay-
office. From the gates, a flat paved road, skirted with
els, leads to the officers' dwelling-houses, which are of
brick, and thirteen in number. From hence to the lower
part of the yard, which has been levelled from the solid
rock, is a defile by a flight of steps, leading to two hand-
some buildings, the northernmost of which is the joiner's
shop, the other is used as an office. Directly in front of
these is the bason and dock, made in the reign of William
III. The bason is a large excavation, in which all the boats
belonging to the yard, as well as the launches employed
in moving ships, are kept; the water flows into it through an
aqueduct about seventy feet wide. Within the bason is a
dock, sufficiently capacious for a seventy-four gun-ship, its
length is 157 feet 3 inches; its width, 65 feet 10 inches;
and its depth, 23 feet 1 inch. The bason is bounded on
each side by jetty-heads, which are platforms projecting
over the sea, supported by wooden pillars driven full of nails,
to prevent the winds from perforating them. Ships of all
sizes lie alongside these jetties without grounding, and here
all vessels are brought to be fitted out. On the fourth jetty
is a landing place, called the master attendant's slips, where
all vessels returned from ships are landed, and thence to be
sent to them shipped off. Adjoining this jetty is the rigging
house, a handsome building, 480 feet long, and three stories
high, forming one side of a quadrangle. This building is of
lime-flint, with the cornices and cornices of Portland stone.
Within it the rigging for the ships of war is kept in such
a state of forwardness, as to be fit for use at a very short
notice. Over the rigging is the sail loft, where all the sails
are cut out and made. The remaining three sides of the
quadrangle are flore-houses, in which the various articles
necessary to equip the fleets are kept. Advancing south-
ward is a slip for hauling up and graving the bottoms of
small vessels, such as boats of war, cutters, &c. Beyond
this is the Camber, a long canal, about seventy feet wide,
terminating at the upper end in a bason, where boats lie;
on the north side of which is the boat-house, where
boats are built and repaired. Here, before the year
1768, were the bounds of the yard; all thence to the
southward is called the "new ground." The black-
smith's shop is situated south of the canal; it is a spa-
cious building, about 210 feet square, and contains
forty-eight forges. The largest anchors made here weigh
five tons; they are made of iron bars forged together, and
are moved in and out of the fire by the aid of cranes.
PLYMOUTH.

The quantity of coals burnt in 1802 was 876 chaldrons and 23 bushels. The anchor-wharf fronts the blacksmith's shop. Near this wharf are three slips, whereon large ships are built; and adjoining them is a boiling-house, in which the plans that are to receive a particular curve are boiled in water for a considerable time, and being afterwards applied hot to their places are immediately fastened. Northward of the slips are the mast-house and pond; in the former the different masts and yards are made of many pieces of bark, formed to fit into each other, then rounded and pressed together with iron hoops driven on red-hot. The pond is a large piece of water, inclosed from the sea by a very strong wall, of at least 10 feet in thickness, and about 380 feet long; the top of which is laid flat with large flags of coarse granite. The water flows in through two openings about forty feet wide, over which are light wooden bridges. An immense number of masts, yards, &c. are always kept in this pond, to prevent their cracking, from exposure to the sun. Near the south end of the mast-house is a small mount, generally called "Bunker's Hill," on the summit of which is a watch-house and a small battery. Under this hill is a small powder magazine, and near it a slip for building sloops, brigs, and small vessels. Returning to the interior of the yard, the rope-houses first engage the attention. These are two buildings of lime-bone, two stories high, and twelve hundred feet long, running parallel to each other. In the upper stories twine is made, and yarn prepared for the cables, which are laid (twisted together) below. The largest cables that are made are 25 inches in circumference, and 100 fathoms long; they weigh 116 cwt. 1 qr. and 16 lb., and contain 32,400 yarns. One of these buildings was partly confounded by an accidental conflagration in June 1812. The whole of the machinery was destroyed, and only 400 feet of the rope-house saved. The loss was estimated at 15,000l. In 1776 confederate alarm was excited from an attempt of John Aitken, commonly called " Jack the painter," to destroy the dock-yard with fire; he was afterwards detected in a similar endeavour at Portsmouth, and hanged. (See PORTSMOUTH.)

The mould or model loft, where the different parts of ships to be built are laid down according to plans sent from the Navy Board, is in front of the rope-house, and is divided by a building of brickwork in that part of the yard fourth of the basin. On the north jetty is a landing place, called the North-flairs, where officers not on duty generally land. Near it is a house where pitch is continually boiling, to be applied to the bottoms and seams of ships. The double dock is the first of three, very near each other, for line of battle ships, and so denominated from its capability of containing two ships at the same time. The dock gates, by which the water is kept out of the docks, form, when closed, the segment of a circle, with its convex side toward the sea; they are made of timbers strongly put together and hung on each side of the mouth of the dock. As soon as a ship is taken into dock, which is always at high water, the gates are shut and locked; the water within the dock then runs out through sluices made for the purpose, till the ebb tide has ceased; the sluices are then shut, and the water which may still remain is thrown out by engines on the plan of pumps, worked by horses. The ship is taken out by opening the sluices, and suffering the water to attain an equal height within as without, when the gates are opened without difficulty. The second dock, called the Union, or North dock, is 239 feet 4 inches long, 86 feet 7 inches wide, and 26 feet 10 inches deep, and is faced with Portland stone. The New Union, or North New dock, 259 feet 9 inches long, 85 feet 3 inches wide, and 27 feet 8 inches deep, was made in the year 1789, and is on the same plan. Near the head of this latter dock is the burning place for old copper; and further northward, are the plumbers', braziers', and armourers' shops, and the bricklayers' and stone cutters' yards. Behind all this side of the yard, the rock, having never been levelled, rises very high and irregularly; on it are a few sheds and storehouses. Every person belonging to the dock-yard is under the command of the commissioner, from whom all orders are received, and who has in his power to discharge workmen for neglect of duty. The gun-wharf is separated from the dock-yard by North-corner fleet; it was begun in 1718 or 1719, and completed about 1785. The buildings are in general good, but very heavy, and in the Dutch style. They were projected by the late sir John Vanburgh, who was then attached to the ordnance department. The quantity of ground within the walls is four acres and three quarters. Here are two principal flour-houses, of three stories high, for 30,000 bushels of flour, and other small flours; a number of sheds for gun-carriages, &c. are kept there. The magazine, and a cooperage. The dock-yard, as well as the gun-wharf, is rated to the poor, and pays house and window-tax for the dwellings; but neither tithes, church rates, nor land-tax. The diversity of employments, ingenuity, and manual activity, exhibited in the various departments of the dock-yard, present a very interesting spectacle to those who have not been accustomed to appreciate the effects of human industry on a large scale. The bay or estuary of Hamoaze, on which the dock-yard is situated, is a commodious basin about four miles long, and half a mile wide, where in times of peace a very considerable part of the English navy is laid up in ordinary. The port admirals, hospital and prison ships, are always stationed here, and those that have undergone, or are about to receive repair in the dock. The ships are moored by large chains of iron, sixty fathoms long, confining 120 links, and having at the end a large anchor. On the banks of this harbour are other establishments of government: the powder magazine, higher up, consists of several detached stone buildings; the powder-kilns, erected for drying damaged powder; and near the bank of a creek of the bay, but not in it, the S.W. is the South-down brewery, where all the beer for the fleet is brewed. In the vicinity of Dock is several small towns, of which Stoke is the most important. It is an ancient village, and has considerably enlarged itself within a few years. The church is situated at a short distance from the town, confining of three aisles and a tower: the period of its erection is unknown. Morice-town, on the north side of Dock, near the ferry which crosses the Tamar, is increasing very fast in size and consequence. There are other villages in the neighbourhood, which will be treated of in our description of Saltash. Immediately opposite to Dock is the delightful peninsula of Mount-Edgecumbe, the seat of the earl of Mount-Edgecumbe. The manor was completed in the reign of queen Mary, and is antiquated in its appearance. It contains a few good paintings and portraits, and is pleasantly situated on the site of a wooded hill, from whence the prospect is variegated and comprehensive. The grounds occupy an area of about three miles in circumference, and are divided into parks, lawns, woods, terraces, kitchen and flower gardens. The estate became the property of the present family about the beginning of the 17th century from an intermarriage; by which connection they also became the proprietors of Stone-house. On the heights bordering the park of Mount-Edgecumbe stands Maker-church, the tower.
tower of which is used as a medium for conveying signals from the admirals' ships in Hanozoe to ships in the Sound, and also to forward the information of any fleets or vessels of war in the offing, or palling up or down Channel. Polyhyle's History of Devon, folks. Beauties of England, vol. iv. Picture of Plymouth and Dock.

PLYMOUTH, a maritime county, in the eastern part of the state of Massachusetts, containing 35,169 inhabitants, and subdivided into 18 townships, of which Plymouth is the chief. Within the counties of Plymouth and Bristol there were, in 1796, in actual work, 14 blast and six air furnaces, 20 forges, seven flitting and rolling mills, besides a number of nail shops, and others for common smithy. These furnaces, supplied from the neighbouring mines, produce annually from 1500 to 1800 tons of iron-ware. The forges, at an average, manufacture more than 1000 tons annually, and the flitting and rolling mills at least 1500 tons. The manufactures of these mills have given rise to various others dependent upon them, such as cut and hammered nails, pins, and, though, card teeth, saws, sheaves, metal buttons, cannon-balls, bolts, rifle-arms, &c. In these countries are also manufacturers of hand-bellows, combs, sheet-iron for the tin-manufacture, wires, linseed oil, flax, hemp, and earthen ware. The iron works, called the Federal furnaces, are seven miles from Plymouth to the harbour. Plymouth, the capital of the above county, is a poft-town and port of entry, 42 miles S. from Boston, to which belongs an extensive township, more than 80 square miles, is about 16 miles in length, and more than five in breadth, containing, by the census of 1791, 2495 inhabitants, and in 1810, 4228. The town, or principal settlement, containing more than two-thirds of the inhabitants, lies on the N.E. part of the township, near a stream, called the "Town brook," which flows from a large pond, bearing the name of "Bellington brook." The principal street crosses the stream, and is interfaced by three crois streets, extending to the shore; another street runs westerly on the N. side of the brook. The town is compactly built, and contains about 200 dwelling houses, a handsome meeting-house, court-house, and gaol. Here are two precincts, one including the town and the district of Hobbs Hole and Eel river; the other at Monument Ponds, a village about seven miles E. from the town, beyond the highlands of Monument. The soil near the coast is generally good; the residue of the township is barren, and remains confiding partly of pine and partly of oak. The harbour is spacious, but shallow; formed by a long and narrow neck of land, called "Salt-houfe beach," extending furtherly from Marshfield and terminating at the Gurnet head, and by a smaller beach within, running in an opposite direction, and connected with the main land near Eel river, about three miles from the town. On the Gurnet is a light-house, and on Salt-houfe-beach is placed one of the two, erected and maintained by the Humane Society of Massachusetts, for the reception and relief of shipwrecked mariners.

The principal busines of the town is the cod-fishery, employing about 2000 tons of shipping and about 300 men annually. Many of the fishing vessels make voyages to the southern states in the winter season. The exports in 1795 exceeded 70,000 dollars, and in 1796 amounted to near 130,000 dollars. The produce of the fishery was formerly sold at Boston, or Salem; but it is now wholly exported from the town. The proceeds of the foreign voyages are generally conveyed to Boston for a market. During the war for independence, Plymouth suffered much, and was reduced to a state of great distress; but it has since revived, and both the town and its environs have been improved. A taffe padises to Bolton twice a week, and an aqueduct is constructed for bringing fresh water to the inhabitants. The township abounds with ponds (amounting to more than 100) and streams. Bellington sea covers near 300 acres, about two miles from the town, and from it runs a stream, which supplies the aqueduct. South pond is much larger. Many of the ponds abound with white and red perch, pike, and other fresh-water fish, and in the numerous brooks which run into the sea are found excellent trout. These ponds and streams are frequently scenes of amusement for parties of both sexes. In the summer season. At the villages of Monument Ponds and Eel river, and in some other parts of the township, many of the inhabitants are farmers; and in the town the gardens are numerous and well-cultivated, and assisted by the aqueduct will furnish a supply adequate to the wants of the inhabitants.

The situation of the town is pleasant and healthful, but the easterly winds of the spring are noxious. Although the market is not regularly supplied, fowl, fish, poultry, and wild fowl are plentiful, and cheaper, perhaps, than in any other sea-port of the same size. The people are sober, industrious, and friendly. Plymouth is the first settlement in New England, in 1620, but is peopled, principally, by the descendents of the ancient stock, intermixed with a few foreigners. The rock on which their forefathers first landed, was conveyed, in 1774, from the shore to a quay in the centre of the town. Although fishing and foreign commerce engage at present almost the whole native capital of the town, a variety of circumstances will probably render it, at some future period, a considerable manufacturing town.

PLYMOUTH, a town in Litchfield county, Connecticut, containing 1882 inhabitants. Alfo, a port and half-thire town in Grafton county, New Hampshire, on the S. side of Baker's river, at its mouth, where it falls into the river Pembigewasset; 45 miles N. of Concord; incorporated in 1763, and containing 937 inhabitants. Alfo, a town of New York, in Onondago county; lying about 12 miles S.E. of Geneva, on a beautiful declivity on the E. side of Seneca lake, and commanding a view of the whole lake. The situation is healthful and pleasant, well watered by numerous springs: more than twenty houses were built here in 1796. The new road leading to this town, and here is a ferry across the lake to another thriving town on the opposite side. Alfo, the name of two townships in Pennsylvania, one in Luzerne county, and the other in that of Montgomery; the former has 765, and the latter 895 inhabitants. Alfo, a town of North Carolina, about 20 miles from Edenton, and a place of considerable trade; the navigation is free and open, and the two places have a constant communication across Albemarle sound. Alfo, a settlement on the S. peninsula of St. Domingo, in the dependence of Jeremie. Alfo, a township in Windor county, Vermont, formerly Saltash, 12 miles W. of Windor; containing 834 inhabitants.

PLYMOUTH Town, a town in the island of Tobago. N. lat. 10° 16'. W. long. 60° 3'.

PLYMOUTH Marble, among our Artificers, a term used for a sort of marble dug in great plenty about Plymouth, and in some parts of Devonshire, where it lies in very thick strata, and whence it is brought in large quantities to us; and when wrought looks little less beautiful than some of the Italian marble.

It is very hard and firm, and of a beautiful texture; its ground is a blueish-white, and its variegations are principally pale red, and in smaller quantities brown and yellow: these
PLYMPTON, or EARLS-PLYMPTON, a
borough and market town in the hundred of Plympton, and
county of Devon, England, is 216 miles W.S.W. from the
metropolis, and 39 miles S.W. from Exeter. According
to the population returns of 1811, it contains 92 houses,
and 715 inhabitants. It is one of the flannary towns, and
formerly constituted part of the honour of Plympton, to
which no fewer than eighty-nine knight's fees were appur-
rent, when it was granted by Henry I. to Richard de
Rivers, or Redverfe, earl of Devonshire. That nobleman
built here a magnificent castle, and made it the capital seat
of his barony. He and his successors likewise conferred
upon the town considerable privileges. Baldwin de Rivers
granted it a charter of incorporation, which was succe-
Sively confirmed and extended by Edward III., Richard II.,
and Henry V. and VI. Queen Elizabeth granted a new
charter, under which the town is now governed by a mayor,
depository, eight aldermen, a bailiff, and a town clerk. The
mayor is invested with the powers of a justice of the peace,
and holds a court of record at stated intervals.

Plympton sends two members to parliament, and has done
so, though irregularly, since the reign of Edward I. These
are elected by the mayor and free burgesses, who are eli-
mated at one hundred in number. The mayor is the return-
ning officer. The market day here is Saturday every
week; besides which there are four annual fairs. The
houses are chiefly disposed in two streets, extending at right
angles with each other in the form of the Roman letter T.
The church is only a chapel annexed to the church of
Plympton St. Mary, an adjoining parish and village. The
living is held by one of the trustees of Eliezeus Hele, esq.
of Fardel, who bequeathed 1500l. per annum, to be expended in charitable purposes. Of this school, the father of Mr Joshua Reynolds was master for many years, and in the master's house belonging to it the
celebrated artist himself was born on the 16th July 1723.
See Reynolds.

PLYMPTON St. Mary, above-mentioned as adjoining to
Plympton-Ears, is a village and parish of very considerable
antiquity. The church was formerly collegiate for a dean
or provost, and four prebendaries with other ministers.
This college is said to have been of the foundation of one
of the Saxon kings. It was dissolved by William War-
well, bishop of Exeter, on the refusal of its religious to
discard their wives in obedience to the decrees of the synod,
held in London A.D. 1102, by which celibacy was enjoined
upon the clergy. That prolocutor settled here a prior and
canons regular of the order of St. Augustin. The
benefactions conferred on this priory by earl Baldwin and
others were immense, and rendered it the richest mona-
sity institution in the diocese of Exeter. Its revenues at the
time of the dissolution were valued at 912l. 12s. id. per
annum. The site was granted by queen Elizabeth to
Arthur Champernon, esq. Here was also an hospital for
lepers. The parish of Plympton St. Mary, exclusive of

PLYMPTON-Ears, contains, according to the parliamentary
returns of 1811, 272 houses, 1727 inhabitants.

Near Plympton is Boringdon, the ancient seat of the
Parker family, and now the property of their representative
John Parker, earl of Exeter. The mansion which was built
in the fourteenth century has been converted into a farm-
house, and has consequently undergone great alteration
and diminution since the removal of the family seat to Salt-
tram, in the neighbourhood, by lady Catharine Parker.
Salttram is remarkable for the beauty of its situation; for
exclusive of the diversity of landscape displayed by the
surrounding pleasure grounds, the prospects which it commands "of
Plymouth found, the town, citadel, Mount Edgecumbe,
and the endless variety of effects peculiar to the sea and
harbour, are extremely interesting and amusing." The house
is the largest in the county, and contains a valuable collec-
tion of paintings by ancient and modern masters. Beauties
and E. W. Brayley.

PLYNTeria, Plynteris, in Antiquity, a festival in
honour of Aglaurus, the daughter of king Cercops, or
rather of Minerva, who had from that lady the name of
Aglaaurus. These were the holidays of Minerva, which
was reckoned unlucky, at which time, according to Xenon-
phon, they shut up the temples of that goddess. It was
expressly forbidden to perform any work whatever on the
day of this festival, even in cases of necessity. It was then
allowable by the law of Solon to sewear by the three names
of Jupiter Propitious, Expiator, and Defender. For the
ceremonies observed at this solemnity, see Potter, Archael.
Greece, lib. ii. cap. 20. tom. i. p. 325.

Pneuma, Pνεύμα, in Hippocrates, sometimes imports
spirit, air, or vapour, and frequently it signifies the breath,
that is, the air drawn in by inspiration, and expelled
during expiration. But pneuma, by the above quoted author,
is often used to express a difficult, short, and laborious respi-
ration.

Pneumatica, Pneumatica, called also Pneuma-
tology and Pneumatophy, the doctrine and contemplation
of spirits, and spiritual substances.
The word is formed from the Greek πνεῦμα, spiritus, breath; whence, from the different acceptations of that word either
as an incorporeal substance, or as air, there arife two forts
of pneumatica.

Pneumatica, in the Schools, is frequently used for the
document of spirits; as God, angels, and the human soul.
See Spirit.

In this sense pneumatica coincide with what we otherwise
call metaphysics.

Pneumatica is more commonly used among us for the
document of the air; or that part of natural philosophy
which treats of the nature, properties, and effects of the
air.

Some make pneumatica a branch of mechanics; because
it considers the air in motion, with the effects of it. It
is certainly a filter of hydrostatics; the one considering
air in the same manner that the other does water.

Wolfius, in lieu of pneumatica, uses the word aerometry,
q. d. the art of measuring the air.

The doctrine and laws of pneumatica will be found under
Air, Atmosphere, Elasticity, Gravity, Compression,
Condensation, Rarefaction, Expansion, &c.

Pneumatic Engines, Machinae or anthes pneumatica, denotes
the air-pump.

Pneumatic Sec. of physicians, a subdivision of the
methodic sect, which took place at Rome, and is ascribed to
two or three different persons, who are severally esteemed its
founders.
founders. The chief distinction of the pneumatic fea, consisted in referring to a particular spirit, or pneuma, which they considered to arise from the heart and arteries. See Medicine, History of.

**PNEUMATOCLE, from ψυγης, wind, and ςυρες, a tumour, in Surgery, a swelling containing air: also a wind rupture; a complaint which is spoken of by many surgical writers; but has no real existence. Hernial tumours do, indeed, sometimes include air, which is combined within the protruded bowel, or else produced in the cellular membrane from pustulation in the flowing state of the disease. Yet it is not the accidental presence of such air that constitutes the rupture or hernia; but the protrusion of some of the visera from the cavity of the abdomen.**

**PNEUMATODES, a word used by Hippocrates to express a person who fetches his breath short and quick: and sometimes for one who has his belly or head much distended by flatulences. Pneumata is also used in the same double sense.**

**PNEUMATOMACHY, from ψυγης μάχης, in Ecclesiastical History, ancient heretics, so called, because they opposed the divinity of the Holy Spirit, placing him in the number of creatures.**

**PNEUMATOMPHALOS, from ψυγης, wind, and ροικας; the navel, in Surgery, a rupture of the navel, containing air, or supposed to be produced by wind.**

**PNEUMATOSIS, in Medicine, from ψυγης, air, a term denoting large accumulations of air in any cavity of the body. It may include, therefore, not only tympanites, but emphysema. In this sense Sauvages employs the term, and describes four species of pneumatosis; the first he calls spontaneous, as it arises without any evident cause; the second, traumatica, which originates from wounds of the lungs, whence the air is permitted to escape into the cellular membrane of the whole body; the third, venenata, arising from poisons; and the fourth, hysterica, when the air is confined to the stomach and intestines. (See his No. Fol. Method. clas. x. gen. 5.) See also Emphysema.**

**PNEUMONANTHE, in Botany, a name given by many botanical writers to a species of gentiana, called also by some the calathian violet.**

**PNEUMONIA, in Medicine, from ψυγης, the lungs, signifies an inflammation of the lungs and its involving membrane. It includes, therefore, both the forms of the disea, perniosis and pleurisy. See Peripneumonia.**

**PNEUMONICS, ψυγης νίκης, medicines proper in diseases of the lungs, in which respiration is affected. The word is formed from the Greek ψυγης, lungs; or ψυγης, spiritus, breath.**

Of this number are sulphur, lung-wort, hyssop, ground ivy, and colt’s foot; they are used in phthises, asthma, perniosis, pleurisy, &c.

**PNEUMORA, in ENATOMOLOGY, a genus of insects of the order Hemiptera. The generic character is; body ovate, inflated, diaphanous; head inflated, armed with jaws; thorax convex, carinate beneath; wing-cases deflected, membraneous; legs formed for running. There are three species of this genus, and they all appear to consist of a mere hollow inflated membrane; by rubbing together their ferrate or toe-rotted legs, they make a shrill kind of noise morning and evening; and they follow a light; they are so nearly allied to the cricket tribe, that they have been ranked by Fabricius with the Gryllus genus.**

**Species.**

**IMMACULATA. Green spotted with white; wing-cases imbussa.**

**IMMACULATA. Wing-cases green, with square white spots.**

**IMMACULATA. Wing-cases green, with three white spots on each side. This is found at the Cape of Good Hope.**

**IMMACULATA. In Fabricius it is the Gryllus papillosus.**

**MACULATA. Wing-cases green, with square white spots.**

**MACULATA. Wing-cases green, with two white spots; abdomen with three white spots on each side. This is found at the Cape of Good Hope.**

**MACULATA. In Fabricius it is the Gryllus papillosus.**

**PNIKTIS TERRA, in the Materia Medica of the Ancients, a name given at different periods of time to two different species of earth: the terra pnikitis of Dioscorides and Pliny being a grey marle, and the pnikitis of Galen a black clay.**

The last of these is said to be a very valuable allargent, and is found in many parts of this kingdom, particularly in the neighbourhood of London, and well deserving to be introduced in the practice of physic.

**PNIGMOS, from ψυγης, πυγματε, in Medicine, a kind of suffocation, from whatever cause: it is very often used to express that of hysterical fits in women.**

**PNIX, a word used by physicians to express the suffocation from hysteric fits, or any other cause.**

**PO, in Geography, Padus, (which is), a river of Italy, which rises in mount Viù, at the N.W. part of the marquisate of Saluzzo, seven miles N. of Chateau Dauphin, traverses a part of the marquisate of Saluzzo, the province of Chieri, the duchy of Montferrat, the Milanese, Mantua, and Ferrarese, and runs into the gulf of Venice, by a great number of mouths.**

**PO, Department of; one of the fix departments into which Piedmont was divided, after having been united to the French republic, Aug. 26, 1802, the other five being, Dauphine, Seine, Marengo, Tanara, and Stura. This department is formed of the district of Turin, quatre-vallois, and the marquisate of Susa, in N. lat. 45°, lying between Doire and Stura, and on the W. and N.W. bounded by the Alps, containing 254 square leagues, and 395,193 inhabitants. It is divided into three circles, viz. Susa, including 61,240 inhabitants; Turin, 232,913, Pinerolo, 101,634. Situated at the foot of the Alps, and broken into vallies, hills, and plains, the soil of this department is of various qualities. The plains and vallies, in general, are fertile. In the mountains are mines of copper, lead, iron, quarries of marble, stone, flate, &c.**

**PO, Lower, a department of the new kingdom of Italy, composed of the duchy of Ferrara, and the valley of Comachio.**

**PO, Upper, a department of Italy, formed of the Cremonae, the Cremasco, and the Lodesan.**

**PO, the Vale of the, one of the four regions into which Italy may be divided; it extends about 300 miles in length, and in breadth, where it is widest, 150. It is bounded by the Alps and Apennines on the N., W., and S., and on the E. by the open to the Adriatic. The second region is the tract included by the Apennines, forming the Roman and Tuscan territories. The third is confined to the Campania Felix, and its immediate dependences, such as the borders and the island of the bay of Naples, and of the plains of Padua. The last consists of Abruzzo, Apulia, Calabria, and the southern extremities of Italy.**

The first of these has been represented by many, as perhaps the most fertile and the most delicious territory in the universe. It owes this fertility to the many streams that descend from the bordering mountains, and furnish a constant supply to the adjacent river that intersects it. Mr. Euclide, in the second volume of his "Classical Tour," avoids the name frequently given to the plains of the Po or of Milan. Lombardy (which is), he says, a barbarous word.
appellation, derived from one of the fiercest tribes that invaded and wasted this delicious region. After more than two centuries of devastation and refills warfare, they were exterminated by Charlemagne; and our author does not see why their name should survive their existence, or why a barbarous term should displace a Latin appellation.

P. panthers, a city of China, of the second rank, in Kiang-kan; 260 miles S.S.W. of Peking. N. lat. 33° 15'. E. long. 113° 14'.—Alto, a town of China, of the third rank, in Chan-tong; 262 miles S. of Peking. N. lat. 35° 48'. E. long. 115° 14'.

Gen. Ch. Cal. Glume of two ovate, pointed, awnless valves, collecting the numerous florets into a two-ranked ovate-oblong spikelet. Cer. of two ovate, sharpish, concave, compressed valves, rather longer than the calyx, membranous at the edges. Neoty of two acute or torn leaflets, gibbous at the base. Stam. Filaments three, caudate; anthers forked at each end. Pfii. Germen inferior, roundish; stylus two, reflexed, villous; ligulas feathery. Peric. none, the corolla unites itself to the seed, and does not separate. Seed one, oblong, pointed, compressed at each side, covered by the corolla.

Obif. In some species the florets are connected at the base by a fine web of folded silky threads.

Of this large and valuable genus the 14th edition of Sppt. Veg. contains 35 species; Willdenow reckons up 61; but we feel the last of these, P. plumosa, not to be different from his n. 38, the Linnaean tenella. The British species are 18, which we shall particularize, along with a few of the most remarkable exotic ones. Mr. Brown describes 21 Poe, mostly new, in his New Holland Prodromus.

P. aquatia. Reed Meadow-grafs. Linn. Sp. Pl. 98. Willd. n. 1. Engl. Bot. Dr. 1315. Curt. Lond. fabe. 5. t. 12. Knapp. t. 44. (Gramen aquatimum major; Ger. Em. 6.)—Panicle erect, branched, lax. Spikelets fixed, flowered, linear. Florets obtuse, with seven ribs.—In ditches and about the banks of rivers, perennial, flowering in July, conspicuous for its large size and reedy aspect. Its colour is a light, not at all glaucous, green. Stem five or six feet high. Leaves flat, acute, broad, straight, rough at the edges and keel, with a nearly smooth sheath, and a short, entire, very blunt ligula. Panicle very large and numerous, languidly, the subdivisions rather zigzag, rough. Calyx almost equal, whitish, polished. Florets from five to eight, scarcely more, nearly cylindric, somewhat distant, obtuse, rough, purplish at the outer part.

Cattle are said to be fond of this grass, though coarse. It usually makes a principal part of marsh-land hay.

P. fluitans. Floating Meadow-grafs. Scop. Carn. ed. 2. v. 1. 73. Fl. Brit. n. 2. Ait. n. 2. Engl. Bot. t. 1520. Knapp. t. 45. (Felluca fluitans; Linn. Sp. Pl. 111. Curt. Lond. fabe. t. 7. Mart. Ruff. t. 113. Willd. Sp. Pl. v. 1. 426. Glyceria fluitans; Brown Prod. N. Holl. v. 1. 179.)—Panicle branched, divericated. Spikelets close-prefled, cylindrical, many-flowered. Florets obtuse, with seven ribs, and intermediate ones at the base.—In ditches and flow rivulets, perennial, flowering throughout the summer, in most parts of Europe. Mr. Brown found it at Port Jackson, New South Wales, the seeds probably having been carried from England by accident. This writer has separated it as a genus from Poe, chiefly because the ligulas being repeatedly branched, and the neoty a solitary feathery scale. But the neighbouring species of Poe, wanting these characters, seem too strictly akin to this to allow of such a separation. The root creeps extensively. Stamens spreading widely, floating for the most part, with their lower leaves, on the still surface of the water. Spikelets long, compressed, flattened, smooth. Spikelet short, triangular, jagged. The larger branches of the panicle spread widely, and are accompanied by short more erect ones. The short intermediate ribs, at the bottom part of each floret, afford a peculiar character.

P. dylans. Reflected Meadow-grafs. Linn. Mart. 32. Willd. n. 55. Ait. n. 22. Engl. Bot. t. 986. Knapp. t. 47. (P. retroflexa; Curt. Lond. fabe. 6. t. 10. P. falina; Pollich. Palat. v. 1. 89.)—Panicle branched, spreading; the branches at length reflected. Spikelets of five, very obtuse, slightly five-ribbed, shining florets.—In meadows, and amongst rubbish, chiefly near the sea, in various parts of England. Jacquin found it in Austria. The root is fibrous, perennial. Stamens several, about a foot high, decumbent at the lower part, flattened, smooth to the touch. Leaves glaucous, flat, with long sheaths, and a blunt emarginate ligula. Panicle erect, with branches of various lengths, several together, remarkable for being strongly bent downwards as they advance in age. Florets much like the aquatius in their form and arrangement, but with only five ribs. Vahl in his Symbola, v. 2. 19, most unaccountably confounds this grass with Gouan's P. divaricata, Willd. n. 56.

P. dura. Hard Meadow-grafs. Scop. Carn. ed. 2. v. 1. 70. Sm. Prodr. Fl. Grasc. Sibth. n. 181. Schrad. Germ. v. 1. 284. Holl. Grum. Audr. v. 2. 53 t. 73. (Cynogurus durus; Linn. Sp. Pl. 105. Willd. Sp. Pl. v. 1. 413. Pollich Palat. t. 1. t. 1.)—Spikelets nearly simple. Spikelets fleshy, alternate, crowded, rigid, obtuse, compressed, all turned one way, of about five elongated ribbed florets.—Native of sandy waste ground in the south of Europe, flowering in May and June. Root annual, of many long simple fibres. Stamens numerous, two to four inches high, spreading in every direction, leafy, rigid, sometimes branched at the base. Leaves glaucous. Spike ovate, an inch long, rigid, its zigzag smooth stalk visible at the back only. Spikelets about a dozen, linear-oblong, glaucous, all their glumes strongly ribbed, and each bordered with a broad white membrane. This species is closely allied to the preceding and the following ones, nor has it any character of Cynogurus. It has not been found in Britain.

POA.

Bock. Muf. 135. t. 95. — Panicle lanceolate, denfe, rough, turned one way; common falk round. Spikelets cylin-
drical, of about five bluntifh, ribbed florets.—Native of
fandy inundated wafte ground, near the sea, in England,
Holland, and Sicily, flowering in fummer. The root is
annual. Whole plant much like P. duraf, but more fnder,
taller, and fels rigid, with a doubly compound panicule, not
a fpike, and far more numerous, fmalier, cylin-drical
fpikelets.

Engl. Bot. t. 197. — Panicle lanceolate, denfe, smooth,
twobranced, turned one way; common falk bordered.
Spikelets of seven cylindrical, ribles florets.—Common
on the tops of dry walls, and in barren fandy ground, annual,
flowering in June. The whole plant is four or five inches
high, of a peculiarly rigid, elafic, wiry habit, and pulpi-
brown hue. Every part is fmalier than in the laft.

P. divaricata. Straggling Meadow-grafs. Gouan lu-
ltr. 4. t. 2. f. 1. Willd. n. 56. Desfont. Atlant. v. 1.
75. (Gramen phalaroides, fparfa panicaul, minimum an-
gulifolium; Barrel. Ic. t. 44. f. 1.) — Panicle capillary,
divariated, with corymbofe branches. Flower-falks club-
shaped. Florets four. Leaves brittle-shaped.—Native of
the south of France and of Barbary. A small, delicate,
fnder, annuaf gras, with the habit of Astra caryophylla,
for which the plate of Barrelier has been quoted, a circum-
fance that has caufed fome confusion. It flowers in the
spring, and has a very elegant aspect. The thickened
flower-falks, and the crowded little finning fpikelets, are
characterifical of this species.

Grec. Sibth. v. 1. 57. t. 73. Cavan. Ic. t. 92. (P. megaf-
tachyia; Schrad. Germ. v. 1. 288. Briza Eragrofis;
Gram. t. 30. G. eranthis, feu agrigerae; Barrel. Ic.
t. 43.) — Panicle eref, branched, spreading. Spikelets
linear, many-fwered. Florets tymid, with three keels.
Stipula brifly.—Native of Grecce, Barbary, Italy and
Switzerland, though not known to Haller as a Swifs plant;
fee the following species. A very elegant annuaf gras,
with numerous fjes, from one to two feet high, quite
smooth. Leaves spreading, grasf-green; their tipula of
many fine hairs. Panicule ample, loofe, much branched.
Spikelets linear, alternate, falked, green or purplifh, ffining.
Florets from ten to thirty-fix, imbricat, ovafe, tymid,
roughifh, with three diftant ribs or keels. The abofe two
plants of Limneus are certainly one and the fame, differ-
ing merely as to number of florets. The ripe feed being
unconfecrated with the corolla, makes the plant a Pof, not a
Brisia.

P. elegantifima. Elegant Meadow-graps. (P. Eragrofis;
Gramen phalaroides, fparfa Briza panicaul minus; Barrel.
Ic. t. 44. f. 2. G. paniculcis elegantifima, minimum;
Schreich. Ager. 192. t. 41. f. 2.) — Panicle erif, branched,
capillary, fpreading. Spikelets lanceolate, fcarafly ten-
flowered. Florets compressed, keeled, three-ribbed. Stip-
ula brifly.—Native of Switzerland, France, and Italy.
About one-third the fize of the foregoing, with fharper
leaves, dark purple tapering fpikelets, and about a quar-
naturally three or four inches high; in a garden they rise to a above a foot, and the leaves are long in proportion. The ferrated foliage, the bulbs, the woolly web connecting the florets, and their broad veined leaves, clearly ascertain this species. The panicle is small, hoary or silverly and purplish.

We have gathered this grass for the most part in a viviparous state, on the open ground near St. John Lateran, at Rome, in the early spring. This is probably the variety $\beta$ of Schrader and other German authors; but the $\beta$ of Linnaus is a very different, much taller, and greener grass, with long and extremely narrow leaves, an elongated panicle, of numerous viviparous flowers, and peculiarly rough flower-flats. Oriental specimen are in the Linnaean collection, apparently sent by Haffelquist. This is what Scheuchzer has described in his Agrographia 211, and what Morison has figured, fol. 8 t. 5 f. 14, after Bauhin's Theatrum 52. But the whole representation is in Barteri, t. 703 f. 2. We are afraid to describe this as a species, without seeing some spikelets in a natural state; but we are persuaded it is perfectly distinct, and that there are, besides, other bulbous Poa, hitherto confounded with the true bulbous.

P. cefia. Sea-green Meadow-grasfs. Fl. Brit. 103. Engl. Bot. t. 1719. Ait. n. 7.—Panicle spreading. Spikelets ovate, five-flowered. Glumes lanceolate, filky-edged, unconnected by any web. Stipula very short and blunt. Native of the Highlands of Scotland, flowering in June and July. It seems unknown in every other country. The root is perennial, fibrous, tufted. Whole plant very glaucous. Stems erect, about a foot high, round, smoothish, with two joints near the bottom. Leaves bluntnish, flat, rough to the touch, except on the back near the base. Sheaths roughish, about as long as the leaves. Stipula sometimes variable in shape and size. Panicle much branched, rough. Flowers variegated with purple, white, and green, each outer valve marked with a silky line of hairs, near the edges, and on the keel; but there is no complicated web connecting the florets. The doubtful reference to Withering is to be struck out of Fl. Brit., as belonging to our glauca, hereafter mentioned, which Mr. Knapp has by mistake figured for cefia.

P. trivilata. Roughish Meadow-grasfs. Linn. Sp. Pl. 99. Willd. n. 6. Ait. n. 8. Curt. Lond. facie. 2 t. 6. Knapp. t. 54. Engl. Bot. t. 1072. (P. dubia ; Leers Herborn. 28. t. 6 f. 5.)—Panicle spreading. Spikelets three-flowered. Glumes lanceolate, five-ribbed, connected by a web. Stem roughish. Stipula elongated.—Very general in meadows and pastures throughout Europe, particularly where the soil is moist, flowering from June to September, and forming perennial tufts of valuable herbage for the food of domestic cattle. The florets are a foot and half high, rough when drawn through the hand, by which this species is known from the equally common and useful P. pratensis. The leaves are grass-green, pliant, with sheaths of their own length, crowned with an oblong pointed stipula. Panicle ample and spreading. Florets with five strong ribs, wanting in many of the last described. The web which connects them is copious and long. P. setacea of Hudson's first edition is a mere variety, with narrow involute leaves.

P. pratensis. Smooth-Halked Meadow-grasfs. Linn. Sp. Pl. 99. Willd. n. 8. Ait. n. 9. Curt. Lond. facie. 2 t. 5. Knapp. t. 55. Engl. Bot. t. 1073.—Panicle spreading. Spikelets four-flowered. Glumes lanceolate, five-ribbed, connected by a web, stem smooth. Stipula short and blunt.—Equally common with the last, but it will grow in much drier situations. It flowers rather earlier, comes sooner into leaf, but Mr. Curtis remarks that the trivilata produces a better crop as the season advances. That excellent observer found the smoothness of the florets the chief criterion for distinguishing this from the last; which Hudfon and Ehrhart have likewise noted. The panicle of the present species is most inclined to assume a purple hue; and the web connecting the florets is peculiarly long and complicated. P. angustifolia, Linn. Sp. Pl. 99, is a trifling variety, whose lower leaves are narrower and more rigid, with roughish sheaths, and the panicle is smaller. This variety is described in Leers, t. 6 f. 3.

P. humilis. Short Bluef Mein Meadow-grasfs. Ehrh. Calam. n. 115. Sm. Fl. Brit. 1587. Ait. n. 10. (P. sub-ceruela; Engl. Bot. t. 1004. P. ceruela; Knapp. t. 118.)—Glaucous. Panicle spreading. Spikelets ovate, of about three acute florets, connected by a web. Stipula very short and blunt.—Native of mountainous pastures in Weftmoreland, Cumberland, and Anglesea, flowering in June. Root perennial, creeping, with villous fibres. Stem from four to six inches high. Whole plant glaucous. Florets ribbed, green at the base, purple and brown in the middle, white and membranous at the margin. Schrader, who directs us to strike out the synonyms of Willdenow, Haller, and Scheuchzer, quoted in Fl. Brit. (as belonging to his spina, Fl. Germ. v. 1. 289.) thinks the present plant differs from pratensis in its glaucous colour only. We agree that this is the chief distinction, but it seems to us essential. Hudfon made our plant a variety of pratensis, but he mislabels it for the Linnaean alpina, a widely different species.

P. annua. Annual Meadow-grasfs. Linn. Sp. Pl. 99. Willd. n. 16. Ait. n. 11. Curt. Lond. facie. 1 t. 6. Mort. Ruff. t. 98. Engl. Bot. t. 1141. Knapp. t. 52.—Panicle widely spreading. Spikelets ovate. Florets a little remote, five-ribbed, delittit of a web. Stem oblique, compressed.—Common everywhere in waste as well as cultivated ground throughout Europe, flowering at all times of the year when the weather is mild. In gardens it is a troublesome weed; in pastures it affords excellent food for cattle, and is rather improved than damaged by being trodden. Though the roots are annual, the lower part of the florets spread by numerous fibres, and thus the plant extends itself widely during summer, as well as by scattering abundance of seed. The herbage is bright green, not glaucous. Leaves flat, with a crumpled appearance here and there. Sheaths compressed, crowned with a sharp stipula. Spikelets ovate, variegated with green and white, rarely redish. Floret a little filmy at the back, membranous at the edge, delittit of a web at their base.

P. glauca. Slender Glaucous Meadow-grasfs. Fl. Dan. t. 964. With. 138. Sm. Fl. Brit. 1388. Engl. Bot. t. 1720. Ait. n. 19. (P. cæfia ; Knapp. t. 56. P. n. 1468 ; Hall. Hist. v. 2. 224. Feltuca aroides ; Lamarck Dict. v. 246, excluding the reference to Haller's n. 1459, which is Feltuca pumila of Willd. Sp. Pl. v. 1. 420.)—Panicle glaucous, slender, erect. Spikelets ovate, of about three flowers. Glumes bluntish, filky-edged, unconnected by any web. Stipula very short.—Found on the loftiest mountains of Wales and Scotland; perennial, flowering in June. The whole plant is very glaucous, and of a much more slender habit than any of the foregoing, in which last character it approaches the following. Schrader indeed supposed it to be a mountain variety of the nemoralis. The spikelets however are more ovate and close, and we believe the glaucous colour to be an important distinction. If however the proximity of this, in other respects, to nemoralis, and of our humilis to pratensis, should be thought to invalidate that character, we submit our opinion to the test of cultivation by feed, which alone can decide the question.

POA.

— Panicle and leaves flender. Spikelets lanceolate, of about three flowers. Glumes acute, oblongely five-ribbed. Stipula very short, notched.—This grass compiles the tall thin herbage in woods or groves in the north of England, as well as rather mountainous woods throughout Europe. In lowlands it is less frequent, except on chalk. It is perennial, flowering in July and August. The whole plant is extremely flender, gravis-green, one or half, or two feet high. Stem smooth, flattish. Leaf—touched to the touch, taper-pointed. Sheaths smooth, tight, compressed, shorter than the leaves. Stipula very short, notched, or torn. Panicle nearly erect, loose, capillary, zigzag, rough. Spikelets small, pale green, lanceolate rather than ovate. Glumes rough at the keel. Florets from two to four, thinning, lanceolate, silky at their backs and hairy at the base, but not connected by a web.

There is a flouther variety, Hudson's P. angustifolia, the true nemoralis being his β.

P. decumbens. Decumbent Meadow-grasses. Scop. Carn. v. 1. 69. With 147. Sm. Fl. Brit. 107. Ait. n. 24. Schrad. Germ. v. 1. 305. Engl. Bot. t. 792. Knapp. t. 59. Hort. Gram. Aultr. v. 2. 52. t. 72. P. rufescens decumbens; Linn. Sp. Pl. 110. Willd. Sp. Pl. v. 1. 424. Fl. Dan. t. 162.)—Panicle nearly simple, condensed, erect. Spikelets ovate, of four florets, scarcely exceeding the calyx. Stipula bristly.—Native of pungy bogs, in barren sandy or mountainous situations, flowering in July. This species is perennial, of a remarkably hardy and rigid habit, lying close to the ground, except when in flower, and of no agricultural use. The roots creep moderately, and are very strong. Stems about a foot long. Leaves straight, tapering, acute, rather glaucous, with long hairs; blade, and a bristly tuft of hairs in the place of the usual membranous sheath. Panicle zigzag, of a very few large purplish-glaucescent flowers, of so ambiguous an appearance, that botanists have differed much about the genus of the gravis in question; some making it a Melica, to which, as Linneus remarks, it has a degree of affinity in habit as well as structure. Koder ekeems it a Bromus, and Bernhadi, like Decandolle, cuts the knot, by making it a new genus, we know not by what essential character. Mr. Brown is inclined to refer this puzzling plant to his own Triodia, Prodr. Nov. Holl. v. 1. 182.

The extra-european species of Poa afford a wide range for the botanist, too extensive for our present purpose. They require a more general investigation than they have yet received, though abundance of particular species have been described with sufficient care. Thos of American growth agree best, as might be expected, with ours. Some tropical ones have so different an aspect, that it is to be wished they possessed some generic division. Many of them are singularly elegant when minutely examined. We apprehend that a great number still remain undescribed.

Poa, in Agriculture, a genus of grasses, which principally forms the green covering of the fields: the meadow-grasses.

There are several species, some of which are highly useful as field-grasses.

Poa angustifolia, the narrow-leaved meadow-grass, which Mr. Sole says is a very sweet grass, especially for hay, but like the triticial, is liable to go off after mowing. It is more sparingly in the meadows about Hinton Abbey.

Poa annua, the dwarf or white meadow, or Suffolk grases, which, according to Mr. Sole, is the quickest in growth of all the grases, coming up, blooming, and ripening its seeds in the course of one month. It ought therefore to be called mensual; but as it will keep time with no other grases, it is not worth fowing. It is always leaving the ground bare in patches, except there happens to be an agrostis to fill its place. It is however a very sweet grass, and very generally liked by animals of most forts.

Poa aquatica, the reed meadow-grasses, which, Mr. Sole says, is an excellent grass in its native soil, the fens of the Isle of Ely, growing to the height of six feet. It is usually cut when about four feet in height, and when dry, is bound into sheaves; and it mosty undergoes a heat in the stack that improves its quality. It is found an excellent fodder for milch cows, but horses are not fond of it. In that place it is cal led fodder hayway of eminent, other forts of coarse hay being denominated flower, which signifies coarse stuff, and it is cal led white leed, from its drying of a white colour.

Poa bulbosa, the bulbous meadow-grasses, which Mr. Sole finds to have all the good qualities of the pratenis, in so far as its size will admit, and it is proper for hilly dry grounds and poor soils, where it delights to grow. It is found in the hilly dry pastures about Newton St. Loe.

Poa bulbosa, the campressed, or flat stalked meadow-grasses, which Mr. Sole thinks an excellent grass for parks and heep-walks, as both deer and sheep are fond of it; and as it is a dwarf grass, the blades seldom exceeding two inches in height, it forms a fine turf, and caustes the flesh of the animal to cut short, and be fine flavoured. It is found in bloom in some places about Claverston Down, and probably on the down itself, but the sheep there never suffer a bent of it to blow.

Poa bulbosa, the ten meadow-grasses, which Mr. Sole finds an exceedingly sweet grass, affording very rich milk, but it is difficult to cultivate, as it delights in miry situations. It grows in moist meadow-marshes, and abundantly about Cottenham, and the fens of Cambridge.

Poa bulbosa, the hard or durnel meadow-grasses, which Mr. Sole thinks the most insignificant of all the poas, but which has one good property, that of growing where no other grasses is capable of living, as in the drier parching fens.

Poa bulbosa, the sea meadow-grasses, which the fame botanist considers as a fine nourishing grass, being the principal one of our bell flat-marshes; but from its delighting in salt, is difficult of cultivation.

Poa bulbosa, the marsh meadow-grasses, which Mr. Sole thinks a fine exuberant grass, and probably the bell ditch grass. It grows in the rich marshes in all parts of the land, particularly those that are frequently refreshed by the occasional overflows of rivers. It is valuable for laying down pungy lands. It has often the height of four or five feet; and the panicle, when full blown, is extremely fine and flowing.

Poa bulbosa, the great or smooth-stalked meadow-grasses, which for the purposes of agriculture, is considered by Mr. Sole as the most noble of all the grases. Its foliage begins to shoot and put on a fine verdure early in the spring, but not so soon as some other grases. Every animal that eats grass is fond of it; while it makes the bell hay, and affords the richest pasture. It abounds in the bell meadows about Laycock and Chippewham, and it has the valuable quality of abiding in the same land, whilst most other grases are continually changing. According to some, it delights in rather a dry than a moyst soil and situation, on which account it keeps its verdure better than 1,000 others in dry seasons; but it thrives most luxuriantly in rich meadows. It has been objected to by some from its creeping roots, which are difficult to extirpate, of course it is probably the most suited
suit to permanent grs lands. According to Curtis it is distinguished from the rough-stalked meadow-grs, by the stem being smooth when drawn between the finger and thumb, and while in that the membrane at the base of the leaf is long pointed, in this it is short and blunt. And besides, it only throws up flowering stems once in the feason, and is of course well suited for lawns, &c.

Poa Setacea, the fine meadow-grs, which Mr. Sole considers as a fine rich grs for upland pastures, as it delights in a dry foil. It is found in the hilly pastures about Newton, in Somerfethire. It is likewise an abiding grs.

Poa Trivialis, the common or rough-stalked meadow-grs, which Mr. Sole thinks a fine grs for hay as well as pastures, but inferior to the pratenis. It delights in moist and sheltered situations, on which account it is tender though productive. In rich land it grows tall; its height however is about two feet. It is said by some to be well suited to good found moist loams. It is much esteemed on the continent for dry pastures and watered meadows, as it multiplies by seed as well as the root. It is of course proper to let the seeds fall. Its fattening property is considerable for cattle. It is, however, apt to go off after mowing, being overpowered by those grs of the bent kind. Its radical leaves, as well as those on the stem, grow much larger in the pratenis. In sowing it the seeds should be carefully separated.

POAKE Root, in Virginia, is used to denote the folium bacciferum. The Indians use it for a purge, though commonly deemed a poison. Phil. Tranf. N° 453. p. 1.

POBEDA, a town of Prufiia, in the province of Samland; 16 miles N.W. of Konigberg.

POBIANITZA, a town of the duchy of Warsaw; 33 miles E.N.E. of Siradiz.

POBINDEN, a town of Prufiia, in the province of Samland; 15 miles N. of Konigberg.

POBLA, a town of Spain, in Catalonia; 25 miles N.W. of Saloua.

POBLA de Lillet, a town of Spain, in Catalonia; 20 miles E.S.E. of Urgel.

POBLACION, a town of Spain, in Navarre; 12 miles W. of Estella.

POBEDA, a town of Spain, in Old Catife; 21 miles S.W. of Calahorra.

POBNIITZ, a river of Bohemia, which rife near Cumbbach, on the borders of Silesia, and runs into the Elbe, near Tetschen.

POCAHONTAS, a town of Chelford county, in Virginia, within the jurisdiction of Peterburg, in Dinwiddie county; probably deriving its name from the famous princesse Pocahontas, the daughter of king Powhatan. Morfe.

POCAR, a town of Naples, in Principato Citra; 7 miles W. of Salerno.

POCATSJETTI, H. M., in Botany, the name of a small shrub which grows in Malabar. The leaves powdered and sprinkled upon ulcers, repel Ixotrit in and fungous flet; and taken internally, they excite a sweat, and diminish the paroxysm of an intermitting fever.

Of the bark and root, powdered, and mixed with oil, an unguent is made, said to be good for the itch, and other cutaneous disorders.

POCOON. See Puccoon.

POCHARD, in Ornithology, the name of a species of wild duck, called by some the penelope and rat habls, and by many in English the red-headed widgeon. It is larger than the common widgeon, and is shorter and thicker bodied. This is the Anas ferina of Gmelin. See DUCK.

POCHERRY, in Geography, a town of Hindooflan, in Maravar; 5 miles S. of Ramanapdorun.

POCK. See POX.

POCK-Wood. See Guiana.

POCKESO, in Geography, a populous and commercial town of Africa, in the district of Axim, on the Gold Coast.

POCKET SHERIFFS, in Law, sheriffs nominated of the sole authority of the crown. See SHERIFF.

POCKET, in Rural Economy, a large fort of bag, in which hops are packed up, in order to be fold; being formed of a particular kind or quality of tacking. See HOPS.

POCKET of Wool, is half a sack. See SAC of Wool.

The pocket contains usuall twenty-five hundred weight of wool.

POCKET Instruments, in Surgery, are such as a surgeon ought always to have in his pockets, and may conveniently carry about him in a proper case: there are two lancets of different sizes; the one proper to open abscences, the other smaller, for bleeding; a pair of straight scissors, useful on many occasions; a pair of crooked scissors, proper to be used in dividing flitures, and in several other cases; a pair of forceps, with teeth at one end, to remove dressings, and upon occasion to extract splinters or thorns; these are also serviceable to the surgeon in his anatomical exercises; they are commonly made of steel, but those of silver are much neater; a razor; a straight incision-knife; a crooked incision-knife; a straight double-edged incision-knife; a probe with one end broad and thin, proper for discovering a fliture in the cranium, and for many other uses; and the other end rounded, to examine the depth and situation of wounds and ulcers. The neateft probes are made of silver, though they are frequently made alfo of steel, ivory, or whalebone; a grooved probe or director, to direct the edge of the knife or scissors in opening sinufes, or flitures, that by this means the subjacent veffels, nerves, and tendons, may remain unhurt. The upper end of this instrument sometimes is ornamented, and serves only for a handle; sometimes it is made in form of a spoon, to contain powder to sprinkle upon wounds or ulcers; sometimes also this is made forked at the end, to divide the cranium of the tongue; a fpatula to depress the tongue, in order to examine the state of the tonsils, uvula, and fauces, when they are affected with any disorders; it is also used to unfed the tongue when the cranium is to be divided; for which purpose it is to be made with a fliture at its extremity, and should therefore rather be made of filver than of any other metal. Besides these, there should be an ordinary fpatula for spreading plasters, ointments, and cataplasm; and sometimes, by means of their fuleated extremity, they are of service in raising up fratured bones of the cranium; several needles muff also be kept here, some ftraight and others crooked, for the ftitching up of wounds, taking up of arteries, and many other uses. Heifler's Surg. p. 12.

POCKET Medicines. See MEDICINE.

POCKLINGTON, in Geography, is a market town and parish, situated partly within the liberty of St. Peter, York, and partly in Wilton-Beacon division, in the wapentake of Harthill, Earl Riding of Yorkshire. The town is distant from York 13 miles E. by S., and from London 197 N. by W. The market-day is Saturday every week, and there are four fairs annually. Here are held the petty feifions for Wilton-Beacon division of the wapentake of Harthill. The living is a vicarage in the patronage of the dean of York.

According to the parliamentary returns of 1841, the
houses in this town were estimated at 396, and the inhabitants at 1539 in number.

Several places in the vicinity of Pocklington merit the notice of the topographer and antiquary. The Roman road, called the Ermine-street, passes within two miles to the west of the town. Londesborough-park, which it intersects at the distance of three miles, is suppos'd by Drake, the historian of Yorkshire, to be the ancient Delgovita, but the circumstances upon which he founds his opinion are by no means conclusive. This place was for many centuries a seat of the ancient and celebrated family of the Clifords.

It is now the property of the duke of Devonshire, as descendent from the daughter and heir of Henry Clifford, the fifth and last earl of Cumberland. The house is situated on elevated ground, and is surrounded by an extensive and well wooded park. At Melburn, five miles to the south-west of Pocklington, is the seat of Sir Henry Valfavour, bart. The mansion is a large modern edifice of brick, and commands some fine views of the western acclivities of the wolds. Stamford-bridge, eight miles to the north-west, Drake receives to be the site of the Derventio, but Camden fixes that station at Aldby, about a mile and a half to the northward. Here was fought, in 1666, one of the most bloody battles recorded in the history of England, between the forces of Harold II. and those of Tofti his brother, the banished earl of Northumberland, assisted by Harfagar, king of Norway. The contest lasted from seven in the morning till three in the afternoon, when the Norwegians and rebels were routed with immene slaughter. Beauties of England and Wales, vol. xvi. by John Bigland.

POCKREKESKO, a river of North America, in New-Britain.

POCO Allegro, in the Italian Mufes, is not so fast as allegro.

Poco Largo, intimates to play or sing a little slow. See Largo.

Poco meno Allegro, is used to signify that the part it is joined to should be played or sung in a little less gay manner than allegro requires.

Poco Piu, serves to let us know that we ought to sing or play that part to which it is annex'd, not quite so quick as primo requires it should.

POCOCCK's ISLAND, in Geography, an island in the East Indian sea, S. lat. 6° 2'. E. long. 118° 12'.

POCOCCK, EDWARD, in Biography, a celebrated orientalist, was born at Oxford in 1624; he received the early part of his education at the free school of Tame, and in 1618 was entered a commenner of Magdalen Hall, Oxford. In 1620 he removed to Corpus Christi college, in which he obtained a scholarship. He now began to apply himself to the study of the oriental languages, and the ardour which he manifested in the pursuit,caused him to make extraordinary progress in a comparatively short time. In 1627 he began to prepare, from a MS. in the Bodleian library, a Syriac version of four epistles, which were yet wanting to a complete translation of the New Testament into that language. This work he finished in 1628, and in the same year he was admitted probationary fellow of his college; and the epistles coming to the knowledge of Gerard John Volfius, he carried them to Leyden, where they were printed under the inspection of Lewis de Dieu. Pococck was ordained priest in that year; and having been appointed chaplain to the English factory in Aleppo, he arrived at that city in 1630. He instantly took advantage of the situation; engaged a master in the Arabic tongue, and was a servant of the nation for the purpose of familiar converse in it. As a skillful guide, he undertook the translations of several Arabic books, among which was a collection of 6000 proverbs. Having received a commission from the famous Dr. Laud, bishop of London, for the purchase of Greek coins, and Greek and Oriental MSS., he was eager in obtaining them; though more than once the zeal which he shewed for his employer exposed him to imminent danger from the plague. In 1636 he was nominated by the bishop first proctor of the Arabic lecture founded by that munificent prelate at Oxford. He accordingly returned to take possession, and in August of the same year he opened his lectures with an eloquent Latin oration, on the nature and use of the Arabic tongue. Having commenced his official duties, he obtained leave of absence to embark with a learned mathematician, in 1637, for Constantinople. Here he flaid till 1640, and, passing through Paris on his return, he had an interview with the illustrious Grotius, who was much gratified on being consulted by him on the Arabic translation of his celebrated work, " De veritate Christianae Religionis."

On his arrival in England, he had the mortification and misery to find his patron, bishop Laud, a prisoner in the Tower. In 1643 he was presented by his college to the rectory of Coldrey, in Berkshire, and immediately set himself to perform the functions of a parish priest with the modesty and simplicity of his character. In the following year, the salary of his professorship being seized by the sequestrators as part of the archbishop's estate, Pococke was reduced to his country living. He thought it now suitable to his situation to marry, and in 1646 he formed an union with the daughter of Thomas Burdett, esq. of Hampshire. Soon after this, by the intercess of the learned Selden, he obtained the restoration of his salary, and was at the same time completely protected from the violence of the soldiery.

In 1648, the Hebrew professorship at Oxford, with the prebend of Chrift-church annexed, was given to him: but as he readily refused to subscribe the engagement, he was not deemed eligible. Attempts were made to deprive him of his prebend and both his professorships; the former he actually lost, but by the intercession of powerful friends, he was allowed to retain the latter. In 1650 he published his " Specimen Historie Arabum;" and in 1652 he engaged to afford his assistance to the editors of the Polyglott Bible, his talk being the collation of the Arabic pentateuch. In 1654 he was in danger of being ejected from his living on account of his ignorance and insufficiency; at least those were the charges preferred against him by Cromwell's committee. Some of his Oxford friends, however, particularly Dr. John Owen, so warmly reprezent the disgrace which would follow the rejection upon such grounds, of a man more eminent than almost any other in Europe for sound learning, that the prosecution was abandoned. In 1655 he published " Porta Mosis," being six preatory discourses of Moses Maimonides, containing an account of the Jewish doctrine and discipline. Mr. Pococck added a Latin version, with a large appendix of miscellaneous notes, and this was the first specimen of the Hebrew prefs at Oxford. In 1659 he published, according to his promise made to Selden, the annals of the patriarch Eutychius, in Arabic and Latin, with Selden's preface and notes. On the restitution of Charles II. he obtained the restitution of his prebend and canony of Chrift-church, and in that year, 1660, he took his degree of D. D. He had the mortification to find, that in the new reign oriental literature fell into dis discouragement, nevertheless he continued through life to perform the duties of his professorships. His other publications after this were " Carmen Abu Ismaelis Tigrai," Arab. et Lat.; " Gregorii Abul Faraji Hijloria Dynastarum," Arab. et Lat.; " Commentaries upon Micah, Malachi, Hosea, and Joel;" in thefe is he a defender of the purity of
of the Hebrew text against the objections of several learned men, and he takes great pains to set in a strong light the predic-
tions of the Old Testament, generally impugned by Christians
to relate to Jesus Christ. The last of these he published in
1691; and if he intended, which is not certain, to pursue the
same plan with the other minor prophets, he was prevented
therein by his death, which happened on the 10th of Sep-
tember, in that year, being in the 87th year of his age.
A gradual diminution of strength and bodily vigour had for
some time, previously to this, indicated his approaching dif-
solution, but his intellect and memory were continued almost
unimpaired to the last. His body was interred in the cathed-
ral of Chrift-church, and on the north wall there is a monu-
ment, with an inscription, from which the following is an
extract, "Edwardus Pococke, S.T.D. cujus nomen audias,
nihil hic defama defideres." To the excellence of his private
character, Mr. Locke bears the most ample testimony.
He repreffes him as free, open, and intelligent in his conver-
sation; sincere, modest, humble, and tranquil, singularly charitable, and forgetful of injuries. He adds, "his life
appeared to me one continuant calm. To conclude, I can
fay of him what few men can fay of any friend of theirs, nor
I of any other of my acquaintance; that I do not remember
I ever once faw in him one action, that I did, or could in
my own mind blame, or thought amifs in him."

As a scholar, his knowledge of language comprifed all
the principal oriental tongues, with fome European, besides
the Latin and Greek. He was father of a numerous fa-
mily, of whom the eldest son, Edward Pococke, published
under his father's direction, in 1671, an Arabic work, with a
Latin version, entitled "Philofophus Autodidactus; five Epif-
tola Abu Jaafir Ebn Tophail de Hai Ebn Yokhdan." The
design of the author Abu Jaafir Ahn Tophall, who was a
Mahometan philosopher, is to fhew, by an ingenious fiction,
how human reafon, by observation and experience, without
any affifiance, may arrive at the knowledge of natural
things, and from thence rise to supernatural, particularly to
God and a future life. For this purpofe he impofes a per-
fon, Hai Ebn Yokhdan, brought up by himself, where he
was altogether diftinct from instruction, but what he could
get from his own observations. Mr. Pococke had alfo pre-
pared an Arabic history, with a Latin version, and actually
fent it to the prefs; but this performance, not being worked
off when his father died, was withdrawn by him upon a difguift
at his being difappointed of fucceeding him in the Hebrew

Pococke, Richard, a distinguished traveller, and a pre-
late of the Irish church, son of a clergyman of Southam-
ton, was born in 1704. He was educated at his native place,
whence he was removed to Corpus-Christi college, in Ox-
ford. In 1731 he took the degree of bachelors of laws, and
in 1733 that of doctor. About this time he made a tour on
the continent, probably as tutor to some young man of rank.
In 1736 he made a second tour, in which he took his coure
through Holland, Germany, Hungary, and Italy, to Leg-
horn. In 1737 he embarked for Egypt, in which country
he purfued his travels till the following spring. In the
month of March, 1738, he embarked at Damietta for Pa-
leffine, and then took his road through Syria, Mesopotamia,
Cyprus, Candia, and Laffier Afia, to Conftantinopol. He
returned by fea from Cephalonia to Medifina, whence, through
Italy, Germany, and Flanders, he proceeded homewards.
He returned in 1741, having been abfent five years. The
results of his obervations and refearches were given to the
public, under the title of "Description of the East, and
fome other Countries," of which the first volume, entitled
"Observations on Egypt," dedicated to Henry, earl of
Pembroke and Montgomery, appeared at London in 1743;
and the second, entitled "Observations on Palestine, Syria,
Mesopotamia, Cyprus, and Candia," dedicated to Philip,
earl of Chelfterfield, in 1745. These publications were well
received; his remarks chiefly relate to buildings, infcrip-
tions, and other remains of antiquity, but he has likewise
many obervations refpefting manners and cuftoms, and the
products of nature and art, in the countries which he visited.

When the earl of Chelfterfield was appointed lord-lieute-
nant of Ireland, in 1745, he carried Dr. Pococke with him
as one of his dometical chaplains, and he soon appointed him
archdeacon of Dublin. In 1756, the duke of Devonshire,
then lord-lieutenant, promoted him to the bishopric of Offord.
He was tranfiated to Meath in 1765, in which he died. Dr.
Pococke, besides being an Oriental traveller, made a tour
in Scotland, and gave a description of the baftafe rock in
the harbour of Dunbar, refembling the Giant's caufeway,
which was printed in the Philof. Tranf. vol. 32; also of fome
antiquities found in Ireland, printed in the fecond vol. of the
Archeologia, vol. ii. Several MSS. which he prefented to
the Britifh Muufeum, are preferved in that repofitory.

Pococke's Travels.

POCOGNACA, in Geography, a town of Italy, in the
department of the Mincio; four miles N. of Mantua.

POCOKOLIGO, a village of South Carolina; 15
miles from Combacce ferry, and G7 from Charlefon.

POCOMOCK, a river of the iflate of Maryland, which
difcharges itself into the Chefapeake bay, forming a large
bay at its mouth, called "Pocomock bay." N. lat. 37° 50'
W. long. 75° 50'.

POCONA, a town of Peru; 60 miles S. of Cuzco.

POCUMMA, in Botany, a name given by the people of
Guinea to a species of plant which they fee as an afrin-
tent. Their manner of taking it is very fingular; for they
put the leaves among their dough, and bake them into a
mafs with the bread, and then eat the whole togethcr in

POCUTIA, or POKETIA, in Geography, a province of
Poland, annexed to Aultria, and included in the kingdom
of Galicia.

POD, in Botany and Vegetable Physiology, has been con-
fidered as fynonimous with the Latin legumen, as well as
with filica; but it is now reftricted to the latter, legume
being used for the former. See Legume and Silica.

PODAGRA, from pod, foot, and aitia, captura, feizure, in Medicine, the gout in the feet.

PODAGRA Dentium, sometimes, though with impropriety
enough, is used for the tooth-ach.

PODAGRA Linii, in Botany, a name given by fome of the
later Greek writers to afeuica, or dodder, when found grow-
ing on the limus of flax. The Latins have called this epil-
nium, as they do the dodder growing on thyme epithymum;
the earlier Greeks called this linoepile. Where this dodder
takes root in a field of flax, it generally occupies many
plants, and when it twines round them it caufes protuber-
ances and dwelling, and has therefore been refemblcd to
the gout on that plant.

PODAGRARIA, a name given by many authors to the
leffer wild angelica, called also herba Gerardi.

PODALA, in Geography, a town of Hindooftan, in the
Carnatic; 18 miles W. of Ongole.

PODALIRIUS, in Biography, an illuftrious phyfician,
and reputed fon of Aecipulus, is celebrated by Homer as
having accompanied the Grecian army in the Trojan war,
together with his brother Machaon. He appears to have
been the younger brother, and to have been on the whole
legs

2
distinguished than Machaon; though, like him, he was married to the daughter of a king. On his return from the siege of Troy, he was shipwrecked on the coast of Caria, where he was hospitably received by a shepherd, who, having learned that he was a physician, took him to king Damethis, whose daughter had accidentally fallen from the top of a house. Podarhrius bled her in both arms, after which the recovered, which so delighted the king, that he gave him his daughter in marriage, with the Cherefones as a portion. Here Podarhrius built two cities, the one of which he called Syrnum, from his wife, Syrna, and the other Bybaulus, which was the name of the shepherd who had received him when shipwrecked. Among other children, he had a son, called Hippolochus, from whom, in a direct line, Hippocrates considered himself as descended. See Le Clerc. Hist. de la Medecine, p. i. chap. 18. See Machaon.

PODALYRIA, in Botany, a well-foundning name, which seems its chief recommendation; for we do not perceive what title the brother of Machaon, however famous a physician, has to botanical honours. The etymology of the original seems to be τοδαληπεια, lily-footed. The Hindos at this day vfe lotus-footed as a compliment.—Lamarck Illutr. t. 327. f. 3. 4. Wild. Sp. Pl. v. 2. 501. Ait. Hort. Kew. v. 3. 6.—Clafs and order, Decandria Monogynia. Nat. Ord. Papilionaceae. Linn. Leguminosae, Jull.

Gen. Ch. Cal. Perianth inferior, of one leaf, short, bell-shaped, in five unequal segments; its base externally concave. Cor. papilionaceous, of five petals. Standard twice as large as the rest, kidney-shaped, with a thick claw. Wings two, shorter than the standard, half-ovobate, converging at their upper edges. Keel shorter than the wings, and covered by them, of two oblong converging petals. Stam. Filaments ten, awl-shaped, ascending, equal, inferted into the base of the calyx, permanent, cohering at the bottom; anthers roundifh, small. Pet. German fefilo, ovate; ftyr longer than the flaminis, ascending; stigma fimple, obtufe. Peric. Legume ovate, turged, coriaceous, of one cell. Steds several, kidney-shaped.

Eff. Ch. Calyx in five unequal segments; fowly externaUy at the base. Corolla papilionaceous; the standard largeft. Stamens permanent, combined at the base. Legume inflated, with many seeds.

This genus is limited by Mr. Saltbury and Mr. Brown to the simple-leaved species of Lamarck and Willdenow, to which only the above characters apply. They are shrubs, natives of the Cape of Good Hope, with a very fhiUy habit, and confounded by Linnaeus and Thunberg under Sophora. The ternate-leaved species of Lamarck and Willdenow confume the Baptifla of Venetan, and Hort. Kew.; for thofe with pinnate foliage, fee VIRGINIA.

1. P. myrtillifolia. Bilberry-leaved Podalyria. Willd. n. 13. Ait. n. 1. (Genift arborefca africana, ifyraco fajo, flore carcello; Herm. Lugd.-Bat. 270. t. 271.)—"Leaves oblong-ovobate, fviky on both fides. Calyx fiky. Starks fingle-flowered, nearly as long as the leaves."—A greenhouse plant, flowering from April to July, introduced at Kew in 1795, but cultivated at Leyden more than a century earlier. Hermann fays it grows at the Cape, in wetty places. The flem is buufy, with hoary branches. Leaves numerous, alternate, coriaceous, rather pointed, clothed on both fides with white fiky down. Flowers axillary, generally folidary, blue-cr. The specific name is not happy.

2. P. fericea. Silky Podalyria. Ait. n. 2. (Sophora fericea; Andr. Repof. t. 440.)—"Leaves oblong-obovate, fiky on both fides. Calyx fiky. Starks fingle-flowered, many times shorter than the leaves."—Found at the Cape.

3. P. biJora. Two-flowered Podalyria. Lamarck f. 3. Willd. n. 12. Ait. n. 3. Curt. Mag. t. 753. (P. argentea; Salif. Parad. t. 7.)—Leaves ovate, pointed, fiky on both fides. Calyx clothed with dene rigid down. Starks two-flowered, much longer than the leaves. —Native of the fame country. Mr. Mallon fent it to Kew in 1789. It flowers in May and June, and occasionally at other feafons. The leaves are rather lefs decidedly obovate than in the two former. Flowe-flats fount, twice or thrice as long as the leaves, each bearing two, rarely three, large, handifome, sweet-fcented, white or pale purplifh flowers, whose calyx is of a rufUy hue, rough with rigid fhort down, that is moft deufe in the wild specimens. Linnaeus doubtfes comprifed this plant under his Sophora biJora, but he confounded with it two or three others, fo that he cannot, with precifion, be quoted for any.

4. P. calyptra. Reticulated Podalyria. Willd. n. 11. Ait. n. 4. (Sophora calyptra; Retz. Obf. falc. 1. 36. Crotalaria; Seb. Muf. v. 2. t. 99. f. 3. good. Willd.)—Leaves somewhat obovate, reticulated beneath; downy when young. Starks fingle-flowered, about equal to the leaves. Calyx villous; its limb membraneous, reflexed.—From the fame country; fent to Kew in 1792. It flowers during fummer. The smoothnefs of the adult leaves, and their ftrong coriaceous reticulations beneath, mark this species at firft sight. The flats, shorter than the leaf, bear one flower, accompanied, as in the refl, by a decifious bract. Corolla purplifh.

5. P. biflora. Hairy Podalyria. Willd. n. 14. Ait. n. 5. (P. ifyracifolia; Sims in Curt. Mag. t. 1582.)—"Leaves villous, fikked; the upper ones ovate; the lower roundifh. Starks fingle-flowered. Calyx villous; its segments the length of the fings."—Sent by Mr. Mallon from the Cape, in 1774. The flowers are more copious than in any of the former, but not of frequent occurrence. Leaves in our wild fpecimen nearly orbicular; the adult ones almoft smooth above. Flowe-flats about the length of the leaves. Corolla pink, large and handifome. The foliage in the Botanical Magazine is drawn more ovate than we have seen it, but answers the better to Mr. Brown's specific character given above, and we are therefore more inclined to refer Dr. Sims's plant to the principal than to the laft species. He fpeaks of it as a beautiful shrub, requiring an airy greenhouse, propagated by cuttings, and blooming from May to July. No wonder that it has pafled unexamined, under the name of biflora, as it fo rarely produces flowers. Linnaeus applied the fame to a fpecimen of this, pafled with one of the calypttrata, on the fame paper.

(Podalyria; Lamarck f. 4. Sophora biflora; Retz. Obf. fac. 1. 35. S. pedunculata; Thum. Prodr. 79.)—Leaves elliptic-obovate; smooth above; fiky beneath. Starks fingle-flowered, longer than the leaves. Calyx downy, coloured, acute.—Native of the Cape, but not yet known in our greenhoufes. We have seen no fpecimen. The leaves are reprefented about the fize and fhape of Box, scarcely half, or one-fidh, the length of the flowe-flats; but Retzious defcribes the latter as no longer than the leaves. The calyx is hairy within, as well as without; its segments acute. Corolla purplifh, with paler wings.

5 E. (Sophora)
POD

(Sophora cordata; Thunb. Prodr. 79? Brown.)—"Leaves heart-shaped, rounded, nearly felted, extremely villous. Stalks two-flowered. Calyx villous, its segments shorter than the wings. Sent by Mr. Maillon from the Cepæ to Kew, in 1793. It flowers there from May to July. We have seen neither specimen nor figure. Willdenow omitted Thunberg's plant, because the character was not sufficient to identify it, but described it.

Lamarck represents, at his fig. 5, another supposed species; a small shrub, with inversely heart-shaped leaves, and solitary, nearly felted, flowers; the legume small, ovate, hairy, single-feeding. This seems unnoticed by any subsequent writer, nor are we acquainted with the plant.

PODANA, in Geography, a town of Hindoostan, in the circar of Condappilly; eight miles from Mafulpatan.

PODANG-MEW, a large and populous city of the Birmian empire, not far from the city of Prome.

PODARIA, in the History of India, a classical name comprehending all such insects as have limbs, but no wings. See APTERA.

Of this class there are two subdivisions. 1. Such apterae poharias as have oblong bodies with numerous legs, or more than six pairs: these are the julus, or galliformes; the collopendra, or centipides, and the oniscides, or wood-loups.

2. The apterae podarian with shorter bodies, and fewer legs, or fewer than six pairs. This subdivision contains numerous genera, as the pulax; the podura or puceron, the pediculi of various kinds, the monoculi, the acari, the aranei, the scorpions, and a great many others. See GALLY-WEET, SCOLIOPODA, &c.

PODEM, in Geography, a town of Asia Minor, in the government of Trebizond; 30 miles E. of Trebizond.

PODEMNO, a town of Russia, in the government of Tobolstok; 44 miles E. of Kemski.

PODENDA, a town of Asia Minor, in the province of Adana; 33 miles N. of Adana.

PODENSEE, a town of France, in the department of the Gironde, and chief place of a canton, in the duchy of Bourdeaux; five miles N.W. of Cadillan. The place contains 1425, and the canton 15,688 inhabitants, on a territory of 250 kilometres, in 13 communes.

PODENISE, a town of Austria; eight miles W. of Tuilin.

PODENTES, a town of Portugal, in the province of Beira; 10 miles N.E. of Coimbra.

PODENZA, a town of the duchy of Piacenza or Placentia; five miles S. of Piacenza.

PODERADOS, in Ancient Geography, an episcopal town of Phoenicia, the episcopal being dependent on Thebes, the second metropolis of the patriarchate of Antioch.

PODERIS, from ποδερις, from ποδός, podes, and αίμα, apto, in Antiquity, a robe hanging down to the feet; but it is chiefly used to express a linen garment, a surplice, a shirt. The Jewish priests were covered with this kind of long garments during the time of their attendance in the temple; and this was the proper habit of their order.

PODESTA, or PODESTA, a magistrate, or officer of justice and policy, in a free city.

The name is originally Italian, podesta; and is chiefly applied to certain magistrates of Venice and Genoa, whose function is to administer justice in those republics.

The podesta in Venice corresponds to the prato in ancient Rome, though appeals he from his decisions to the new auditors, or the new civil quaryant. See QUARANTIA.

PODESTANA, in Geography, a town of Italy, in the Veronese; 15 miles N. of Verona.

PODETUM, in Botany, from ποδή, a foot, a name appropriated by Acharius to the peculiar footstalk of the taberlches in the cup lichens. See LICHENES.

PODEX, in Anatomy, &c. the fame with anus, or fundament.

PODGINOCK, in Geography, a town of Russia, in the province of Ulling; 100 miles E.S.E. of Uit Sifolsk.

PODGORODKOI, a fort of Russia, in the government of Usha, on the Ural; 92 miles E. of Orenburg.

PODGURZA, a town of the duchy of Warsaw, on the Vihilka, opposite to Thorn.

PODHORSAN, a town of Bohemia, in the circle of Saatza; eight miles S.S.W. of Saatza. N. lat. 50° 12'. E. long. 13° 29'.

PODIECEPS, in Ornithology, a name given by many to the several kinds of columbii, or divers, as they are also called in English arfe-foot; from their legs being placed very backward on their bodies, by which means they have great advantages in swimming and diving. See COLUMBUS Podieps.

PODIEBRAD, in Geography, a town of Bohemia, in the circle of Kunigingratz; 14 miles S.E. of Biecov.

PODISMUS, among the Greeks, a certain space or number of feet laid out by surveyors; it was the fame with what the Romans call pedemura.

PODIEUM, in the Theatre of the Ancients, the wall that separated the orchestra from the scene. Mem. de l'Acad. vol. i. p. 196.

PODKAMIEN, in Geography, a town of Austrian Poland, in Galicia; 56 miles E. of Lemberg.

PODKAMEN, a town of Russia, in the government of Tobolstok, on the Tchulim; 32 miles N. of Atchenick.

PODLACHIA, a county or patrinate of Poland; bounded on the N. by Prussia and Lithuania, on the E. by Lithuania, on the S. by the patrinate of Lublin, and on the W. by Mafovia; annexed by the conquest of Poland in 1596. It is also called the "Patrinate of Bislet," from its capital.

PODAMESCHNAIA, a town of Russia, in the government of Archangel; 48 miles S.W. of Mezen.

PODOK, a town of Poland, in the patrinate of Bracław; 30 miles N.W. of Bracław.

PODOI, a town of Bohemia, in the circle of Chrudim; five miles W.S.W. of Chrudim.

PODOLAPIS, in Botany, aptly so named by Labillardiere, from ποδός, a foot, and λαπείς, a leaflet, in allusion to the numerous feet 5, which clothe the flower-flanks.—Labill. Nov. Holl. v. 2, 56. Brown in Hort. Kew. v. 5, 82. (Scalina; Sims in Curt. Mag. v. 24, 956; a name adopted from Theophrastus, whose ποδήλατος appears to belong to the same tribe.)—Clasf and order, Syngenesia Polygamia superflua. Nat. Ord. Compositae capitati, Linn. Cymboplena, Jull.

Gen. Ch. Common Calyx hemispherical, imbricated, with numerous falcate membranous scales. Cor. compound, radiated. Florets of the disk numerous, tubular, all perfect, with five equal spreading segments; those of the radius female, ligulate, with from two to four oblong segments. Stam. Filaments. In the florets of the disk only, five, capillary; anthers united into a rather prominent tube. Fib. in all the florets. Gynoec., ovary inferior, obovate; style cylindrical, scarcely so long as the stamens; stigma two, blanched, spreading. Todic, none, except the permanent calyx. Seeds solitary, oblong, compacted. Down fellose, capillary, roughish. Receptor, naked, dotted.

Eff. Ch. Corolla of nine petals. Calyx of three leaves, deciduous. Berry of one cell, crowned with the stigma.

1. P. pelatum. Duck's-foot, or May-apple. Linn. Sp. Pl. 723. Wildl. n. 1. Ait. n. 1. Trev Ehret, t. 290. (Anapodophyllum canadense; Cateb. Car. v. 1. t. 24. Acontifolia humilis, flore albo unico campanulato, fructu cynoebati; Mentz. Pugill. t. 11.)—Native of North America, from New England to Carolina, in shady woods, generally where the ground is moist, growing in large patches, and flowering in March and April. The fruit is the size of a common plum, green, edible, known by the name of May-apple; the root is sometimes used as specula- anha. Pujio. This is a hardy perennial herbaceous plant, known time out of mind in our more curious gardens. The root creeps, and resembles that of the Helchurus niger. Stems solitary, fimbred, round, smooth, about a foot high, crowned with two large, flaked, peltate, lobed, and jagged, smooth leaves, between whose footstalks grows a solitary, flaked, drooping white flower, an inch and a half broad, whose petals are curiously reticulated with veins.

The other species of Linnaeus, P. diphyllum, Sp. Pl. 723, is separated from this genus by Barton, Michaux, and Pursh, and is thus distinguished.

Calyx of five leaves, deciduous. Petals eight, incurved. Capular obovate, somewhat flaked, of one cell, burting below the funnuit. Seeds several, oblong, tumidated at the base.—This has received the name of Jeffersonia diphylla. It belongs to Oiandria Monogynia, and appears to us a tolerably distinct genus, though retained in Podophyllum by Wildedenow, and consequently in Hort. Kew. See Pursh v. 1. 286.

Podor, in Geography, a fortress of Africa, on the Senegal, built by the French, and ceded to the English in 1763; afterwards retaken by the French, and kept by them in the peace of 1783. N. lat. 17° 1'. W. long. 14° 20'.

Podostemum, in Botany, derived from πως, a foot, and στυμων, a flamen; so named by Michaux on account of the flaments being situated on a base or foot, which is divided into two branches.—Michaux Boreal-Amor. v. 2. 164. Willd. Sp. Pl. v. 4. 156. Pursh. v. 1. 3.—Clas and order, Monocia Diandria. Nat. Ord. . . . . .

5 E 2 Female.
White, clofely 44. 34', 28 Blueifh flyle running, ftigmas On about that 1. 'van; is and the POE, fpring Germen blue town leaflets It the Male, abdomen tail much undivided infefts, thirty davia nus. infefts, tho. Gmelin.

1. P. Ceratophylum. Michaux t. 44. Willd. n. 1.
Native of rocks about the falls of the river Ohio.—Stem a finger's length, thread-shaped, floating. Leaves pinate, alternate; leaflets alternate, bristle-shaped, much cloven. Flowers axillary, solitary, the miles infected at the base of the females.

We are unable to trace any affinity to this curious genus. It has certainly no relation to Ruppia as Michaux has suggested. Mr. Pursh places it in Monandria Digitia.

PODRELSKOI, in Geography, a town of Ruffia, in the government of Viatka; 32 miles N.N.E. of Viatka.

PODRUS, a river of Walachia, which runs into the Syl, about three miles E. of Motrul.

PODSPUSNOI, a fort of Ruffia, in the government of Kolivan; 220 miles S.W. of Kolivan. N. lat. 51° 20'.
E. long. 78° 34'.

POSTEPNOI, a fort of Ruffia, in the government of Kolivan; 196 miles S.W. of Kolivan. N. lat. 52° 10'.
E. long. 77° 40'.

PODULLUNG, a town of European Turkey, in Moldavia; 28 miles S.W. of Jaffi.

PODURA, the Spring-tail, in Entomology, a genus of insects of the order Apta. The generic character is, lip bilab; feelers four, fuscavate; two eyes, composed of eight facets; the antennae are bifid; the body is fuscay; tail forked, bent under the body and acting as a spring; it has fix legs that are formed for running. There are about thirty species enumerated by Gmeini. They are all small insects, which, in general, are found in damp places, under stones, on the bark of trees, &c. When disturbed they suddenly spring to a small distance by the help of a long fork, which is doubled under the abdomen, and which is suddenly thrown out during the act of leaping. They feed on the leaves of various plants; the larva and pupa are fix-footed, nimble, and resemble the perfect insect.

SIGNATA. Sub-globular, brown; abdomen with fulvous spots at the sides.

* Viridis. Sub-globular, green, with a yellowish head. Found on the leaves of the Polygonum fagopyrum.

* Polyopoda. Sub-globular, black; antennæ as long as the body, and tippet with white. Found on various plants, in this and other countries of Europe.

* Atra. Globular, shining brown or black; antennæ long, comosed of many articulations. It is found on the bark of trees.

* Plumea. Round, brown, with a blue glos. It is found in similar situations with the last.

* Minuta. Oval, yellow, with two ferruginous spots on the back. This and the four following are found on plants in many parts of Europe.

* Nivalis. Oblong, yellow, with two ferruginous spots on the back. It is frequently found in the winter on the snow in the footprints of men and other animals.

POD

* Vaga. Oblong, black; abdomen and antennæ with a white band.

* Arborea. Oblong, black, with white legs and forks.

* Villosa. Oblong, villous, variegated with brown and black.

CINETA. Cylindrical, grey, with a black belt, which is white on the fore-part. This and the next are found chiefly in woods.

ANNULATA. Vivid, with black wings.

LIGNORUM. Lead-colour, with pale head, thorax, legs, and fork. This is an European insect, very small, and found in old wood.

PUSILLA. Cylindrical, bronzed with a white fork. It inhabits woods.

* Aquatica. Black, aquatic. This is one of the most common species of the genus, measuring fearfully the one-twelfth of an inch in length, and entirely of a black colour. It is a gregarious species, and is occasionally seen assembled in vast numbers, particularly near the brinks of ponds, covering the ground to the distance of several feet, and sometimes even the surface of the water itself. On the ground its numbers are so great, as to have the appearance of scattered grains of gunpowder; and if closely examined, will be found in an almost perpetual skipping motion.

* Pimeta. White, terrestrial. This perfectly resembles the larva except in colour, and in that the specific difference of parts. It is found early in the spring in fresh earth, and also in damp places.

**AMBLANS. White, with a bifid extended tail. Found among moss in different parts of Europe.

**MONURA. Whitish, with an undivided conic tail. It inhabits Austria, and found with the larvæ, which it resembles, but is much less.

**Fufescens. Reddish-yellow, villous; eyes black; fork whitish. A native of Austria, and found among stones.

VIRIDIS. Sub-cylindrical, yellow-green, with black eyes. This is found in Norway.

MOTITANS. Long, red, with an extended tail; antennæ and legs hyaline. This and the eight that follow inhabit Denmark.

SYLVA. Cylindrical, grey-brown; tail pointed and unarmèd.

FEMORALIS. Oblong, cinereous; tip of antennæ and legs white; tail of a sulphur colour.

AQUATILIS. Cylindrical, yellowish, with black eyes, back, and sides of the abdomen.

**CRYSTALLINA. Body entirely hyaline.

**LONGICORNIS. Cylindrical, yellowish; antennæ as long as the body, and with legs cinereous.

**PALLISTRIS. Yellowish, with black eyes and line down the back; the fork is white.

**LANUGINOSA. Silvery-gilt covered above with blue wool; antennæ recurved.

**CRASSICORNIS. Dull blue, cylindrical and growing thicker towards the tail.

**HUMICOLA. Blue-brown; antennæ short, thick; body cylindrical, and growing thicker towards the tail. Inhabits Greenland, as does the next.

**MARITIMA. Bluish-black, with a whitish abdomen; body nearly round, and growing thicker towards the tail.

PODERA is also a species of Cercaria in the clafs of Vernim Infusoria.

PODURUEVA, in Geography, a town of Ruffia, in the government of Irkutsk, on the Lena; 12 miles N.N.W. of Vercholensky.
POE, a river of the county of Tyrone, Ireland, which rises in the south-western part, and joins the Cameron a little below Omagh.—Allo, a town of Africa, in Boi; five miles S. of Portudel.

POEANOPSIS, οὐς.οὐλος, in Antiquity, a name sometimes given to the mythical Pyanepia.

POEILAS, in Ancient Geography, a town situated on the southern coast of the island of Crete. Potency,

POEDICULI, or Poedici, the name of one of the three peoples who composed the nation of the Liburni. They came originally from Illyria, about the 16th century B.C.; settling at first between the Alps and the Athies, when they retired towards the south of Italy into Iapygia. The Poediculi, Apuli, and Calabri spoke the same language, which they retained. Strabo.

POEJANNY, in Geography, a town of Bengal; seven miles S. of Koonda.

POEL, an island in the Baltic, near the coast of Pomerania, irregular in its figure, and about fix or seven miles in circumference, containing several villages; two miles N. of Wilimar. N. lat. 53° 57'. E. long. 11° 26'.

POELEMBURG, Cornelius, in Biography, was born at Utrecht in 1586, where he became the disciple of Abraham Bloemart; but he quitted that master as soon as he had made a reasonable proficiency in the art, and travelled to Rome. His first determination was to imitate the manner of Elflerimer; but he found himself so affected while he contemplated the works of Raphael, that he resolved on endeavouring to emulate the grace of that incomparable master, particularly in the naked.

He formed for himself a style that was entirely new, and in many respects preferable to the Flemish gufo; but it did not resemble the style of any Italian master, except in the ruins of the antique buildings, with which he adorned his landscapes; and which he had with great care copied after nature. He surpassed all his contemporaries in the delicacy of his touch, in the sweetness of his colouring, and in the choice of agreeable objects and situations. His skies are clear, light, and transparent; his back-ground, ornamented sometimes with the vellages of magnificent Roman edifices, which always contribute to the harmony of the whole composition; and his female figures, which he generally represented naked, are beautiful and elegant forms. His greatest excellence appeared in the small pictures of his hand, for in the larger fize he is not fo dexterous of commandment.

The Italians were excessively pleased with the works of Poelemburg; and some of the cardinals at Rome, of the finest talents, attended him frequently while he was painting, to observe his manner of working, and express their admiration in the strongest terms.

It was not without regret that he left Rome to return to his own country; though he afterwards found sufficient caufe to be pleased with the honours he received from the grand duke of Florence, and the respect shewn to him in every city through which he travelled, as well as in his native city Utrecht. For, not long after his arrival, Rubens paid him a friendly visit, and having expressed a singular pleasure in examining the works of Poelemburg, he purchased several for his own cabinet, and bespoke others; by which generous conduct, so familiar to that of Apelles towards Protogeones of Rhodes, he instructed the lovers of the art to estimate the merit of Poelemburg as highly as they ought; and at the same time advanced the fortune and the reputation of that artist.

By King Charles I. he was invited to the court of London; where he painted many curious pictures, for which he was nobly recompensed; and that monarch endeavoured carefully to induce him to continue in England; but his fondness for his own country prevailed over all other considerations, and he returned to Utrecht, where he acquired an affluent fortune, and lived in universal esteem. Several very eminent artists procured him to paint the figures in their works, particularly Steenwyck and Kierings; and the excellent perspectives of the former are sometimes rendered still more embellished by the pencil of Poelemburg.

The genuine work of this master are exceeding scarce; but his disciple, John Vander Lis, imitated his manner so successfully, that the paintings of Lis are very often taken for the works of his master. Fuseli's Pilkinson.

POELSROICK, in Geography, a town of Holland; seven miles S.E. of Gouda.

POEM, Poëma, ποημα, a composition in verse, of a due length and measure.

Poems, Carmina, are of various kinds; some denominated from the persons who first invented, or most used them; as the Archilocal, Sapphic, &c. Others from their composition, as the monocolon, consisting of one kind of verse; dicola, of two; and tricola, of three kinds. Others from their entire or deficient; as brevicaletiatus, which in very verse wants two syllables; catalectic, which wants one; acatalectic, none; and hypercaletiatus, which hath a fillable too much, which, if cut oft at the beginning of the next verse, the verse is said to be hypermeter. (See Acatalectic, &c.) Others are denominated from the subject matter; as the apobateiur, epibantes, epiphanes, epithalaeum, genialis, preceptum, elegia, satirica, epieicus, episthe, threnos or lamentation, encomiastic, panegyric, satiric, lyric, psalmod, &c. Others from the manner of narration; as exegetic, which relates a thing under the author's own person, dramatic, and epic. See each on its proper head, Epic, Drama, &c. To these may be added, odes, eclogues, and idylls.

To this head must also be referred several other poetical compositions of a less serious kind, which the idle-labouring vein of little poets has produced into the world, and which, though frequently admired by persons of low taste, are justly ranked by Mr. Addison in the class of falfy wit. Such are the acrostic, enigma, anagram, cento-chronogram, proteus, echo, &c.

PENITENTES, in the church of Rome, a designation given to heretics, who being admonished by the ecclesiastical judge, have abjured their errors, and given sufficient satisfaction to the bishop or inquisition. Condemnation of goods is a punishment common to all heretics; but if they confefs and absolve of their own accord, without being formallyプロセイント, this part of their punishment is usually remitted. See Inquisition.

POEROU, in Natural History, a name given at Otaheite in the South-seas to the hibiscus tiliaceus of Linneus, of the bark of which they make matting, coarse cloth, and ropes and lines from the thickens of an inch to the size of a small packthread. Hawkeworth's Voyages, vol. ii. p. 217.

POGESTUM, in Ancient Geography, called also Posidonie, a city of Italy, on a gulf of the same name, at some distance to the S. of the mouth of Silurus. Obscurity hangs over, not only the origin, but the general history of this city, though it has left such magnificent monuments of its existence. According to the learned Mazzocchi, Pechum was founded by a colony of Dori, from Dora, a city of Phoenicia. It was first called Pechum, or Pechum, which in the Phoenician language signifies Neptune, to whom it was dedicated. It was afterwards invaded, and its primitive inhabitants expelled by the Sybarites, who event is suppo-
Pestum.

Pestum to have taken place about 500 years B.C. Under its new masters Pestum affumce the Greek appellation "Pofidonia," of the fame import as its Phcnician name, became a place of great opulence and magnificence; and it is supphosed to have extended from the prior ruins southward to the hill, on which lands the little town still called, from its ancient delineation, "Acropli." The Lucanians afterwards expelled the Sybarites, and checked the prosperity of Pofidonia, which was in its turn deserted, and left to moulder away imperceptibly. Vejiges of it are still visible all over the plain of Spinzzo or Saracino: the original city then recovered its frst name, and not long after was taken, and at length colonized by the Romans, U.C. 480. From this period Pestum is mentioned almost solely by the poets, who, from Virgil to Claudian, feem all to expatiate with delight amid its gardens, and grace their composition with the bloom, the sweetness, and the fertility of its rocks. But unfortunately the flowery retreats, "Victoria rofaria Pefi, " feem to have had few charms in the eyes of the Saracens, and, if possible, felt fewer in those of the Normans, who, each in their turn, plundered Pestum, and at length compelled its few remaining inhabitants to abandon their ancient feat, and take shelter in the mountains. To them "Capaccio Vecchio" and "Nyro" are supphosed to owe their origin: both these towns are situated on the hills: the latter is the residence of the bishop and chapter of Pestum.

The edifices which still subsist owe their origin, as it is most reasonably supphosed, to the Dorians; and their form seems to indicate that they are the oldest specimens of Grecian architecture now in existence. In fact, the temples of Pestum, Agrigentum, and Athens, appear to be inffances of the commenceinent, the improvement, and the perfection of the Doric order. The frst temple that presents itself to the traveller from Naples is the smallest; it consists of six pillars at each end, and thirteen at each side, counting the angular pillars in both directions. The architrave is entire, as are also considerable remains of the pediments at the W. and E. ends. The "cella" occupied more than one-third of the length, and had a portico of two rows of columns, the shafts and capitals of which, now overgrown with grafs and weeds, encumber the pavement, and almost fill the whole area of the temple. The second temple has frx columns at each end, and fourteen on each side, including those of the angles: the whole entablature and pediments are entire. The "cella," the interior of which is adorned by a double row of columns, supporting each other row of small pillars, had two entrances, one at each end, with a portico formed of two pillars and two antae. The whole of the foundation and part of the wall of this "cella" still remain; under it was a vault. The third edifice is the largest: it has nine pillars at the ends, and eighteen on the sides, including, as before, the angular columns. A row of pillars, extending from the middle pillar at one end to the middle pillar at the other, divides it into two equal parts, and is considered as a proof that it was not a temple. Some supphose it to have been a curia, others a basilica, and others a mere market or exchange. In common to all these edifices it may be observed, that they are raised upon substructures, visible in all the Doric temples of Italy and Sicily, forming three gradations, intended solely to give due elevation and relieve to the superstructure; that the columns in all rest on altars; that the capitals near the bases are of a fluted form, and almost intersect each other; that the columns are all fluted between four and five diameters in height, and taper as they ascend, about one-fourth; that the capitals are all very flat and prominent; that the inter-

Pestum stands on a fertile plain, bounded on the W. by the Tyrrhene sea; about a mile distant on the S. by five hills, in the midst of which Acropolis sits embosomed; on the N. by the bay of Salerno and its rugged border; while to the E. the country swells into two mountains, which still retain their ancient names "Callimara" and "Cantena," and behind them towers "Mount Alburnus" with its pointed summits. A stream called the "Solofone" flows under the walls, and by spreading its waters over its low borders, and thus producing pools that corrupt in hot weather, continues, as in ancient times, to infect the air, and render Pestum a dangerous residence in summer.

Mr. Watkins has given accurate and minute delineations, and meffurations of these celebrated temples; and he, as well as other travellers, supposes, that the pillars of Pestum were covered with a fort of plaster, or stucco, which, by its long duration, seems to have acquired the hardnefs and durability, as it certainly has the appearance, of stone. Near Pestum there are four mineral springs, to which is ascribed considerable efficacy in different complaints: from these springs flow as many streams, that form the "fiume falso" which falls into the Solofone close to the walls of
of the city. Beyond the ruins, and separated from them by a little stream, now called "Putea," rises the hill of the Acropolis, which merits the examination of the naturalist. As the plains that extend for some way on each side of the Silurus are very thinly inhabited, and at the same time covered with woods and thickets, they are become the resort of banditti and outlaws. At the mouth of the Silurus is the seite of the temple of Juno Arvina, of high antiquity, and attributed even to Jafon. Euticle's Classical Tour through Italy, vol. ii.

POE, POESY, POESIS. See Poetry.

The word is formed from the Greek poesia, of poiein, facie, fabricar, fan, face, make, I frame, I invent.

Hence alchemy, or the art of making gold, we anciently called poesi, chrysopeisi, &c.

POET, POETA, an author who compiles poems or discourses in verse.

Cicero relates it as a saying of Democritus and Plato that there could be no good poet sine afflata in ventors, without a mixture of madness; and Aristotle calls poets expressly, mania, mania, madness.

M. Spanheim tells us that the Arab authors are more poetically given than those of any other people; and adds that there are more verses among the Arabsians than among all the other nations of the world put together.

The Greek word poesia, poet, signifies maker, from poiein, I make; whence the poets were anciently also called poets. The name they were properly denoted by among the Romans, was poetis, which signifies also prophet.

By a law of the emperor Philip, inserted in the Code, lib. x. tom. ii. poets are expressly excluded from the immunities granted the professors of all other sciences.

Homer, Virgil, Milton, and Tasso, are the chief, almost the only, epic poets. Sophocles, Euriptides, Shakspeare, Otway, Corneille, and Racine, are the best tragic poets. Ariophanes, Menander, Plautus, Terence, Fletcher, John- fon, Moliere, &c. are the chief comic poets. Horace, Cowley, Malherbe, and Rousell, excelled as lyric poets. And Juvenal, Perius, Regnier, Boileau, Dryden, and Oldham, as satiric poets.

Poet laureate. See Laureate.

This title, says Mr. Gibbon, is perpetuated by custom, rather than vanity, in the English court; and he adds, "From Augustus to Louis, the muse has too often been false and venal; but I much doubt whether any age or court can produce a similar establishment of a hereditary poet, who, in every reign, and at all events, is bound to furnish, twice a year, a measure of praise and verse, such as may be sung in the chapel, and, I believe, in the presence of the sovereign. I speak the more freely, as the best time for aboliishing this ridiculous custom, is when the prince is a man of virtue, and the poet a man of genius." Decl. and Fall of the Rom. Emp. vol. xii. Svo. 1790.

Poet, Provençal. See Provençal, and Troubadours.

Poet's Céphi, or Poet's Renewary, in Botany. See Osier.

Poetical, perturbing, something that relates to poetry or poets.

In this sense we say, a poetical genius, a poetical phrase, poetical licence, poetical fury, &c.

Poetical Epithet. See Epic, Poetical.

Poetical Subject, is chiefly used in respect to the drama, to denote a distribution of rewards and punishments to the several persons, at the catastrophe or close of the piece, answerable to the several characters in which they have appeared. See Character.

Whatever difficulties and difficulties the virtuous and innocent may labour under, and how prosperously ever it may go with the wicked, in the course of the piece; the poet usually takes care to give each of them their due before he parts with them. But it is controverted whether this piece of justice be indispensable, and whether it may not be allowed to leave virtue oppressed, and vice flourishing.

Poetical Language, is that language or style, which acquires a peculiar elevation and ardour from the sentiments of a mind, supposed to be inspired by some interesting object that fires the imagination and engages the passions of the poet; and this language is very different from that mode of expression which is natural to the mind in its calm ordinary state. This language of passion or imagination is formed, most commonly, into regular numbers; because, though verification be, in general, the exterior diversion of poetry, yet there are some forms of verse so loose and familiar, as to be hardly distinguishable from prose, such as the verse of Terence's comedies; and there is also a species of prose, so measured in its cadence, and so much raised in its tone, as to approach very near to poetical numbers, such as the Telemaque of Fenelon, and the English translation of Ollan. The origin and first use of poetical language, says Dr. Lowth, are undoubtedly to be traced into the vehement affections of the mind. For what is meant by the regularity and frequency of poems, which the Greeks, ascribing to divine inspiration, discriminated by the appellation of chrysopeisi, but a style and expression directly prompted by nature itself, and exhibiting the true and permanent image of a mind violently agitated? Hence proceed sudden exclamations, frequent interrogations, apostrophes, even to inanimate objects; for, to those who are violently agitated themselves, the universal nature of things seems under a necessity of being affected with similar emotions. Every impulse of the mind has not only a peculiar style and expression, but a certain tone of voice, and a certain gesture of the body adapted to it. Some, indeed, not satisfied with that expression which language affords, have added to it dancing and song; and as we know there existed in the first ages a very strict connection between these arts and that of poetry, we may possibly be indebted to them for the accurately measured versets and feet, to the end that the modulation of the language might accord with the music of the voice, and the motion of the body.

Most languages have their poetical words, which are seldom, if ever, used on other occasions. These words are of great use to the poets, who are thus enabled to raise their style and distinction to the poetical character, with the greater ease. The French lament the want of such appropriate words in their language; from a defect of which the style of their poetry is not sufficiently distinguished from the common language. It is too referred, not being allowed any boldness or flights, but such as might pass in prose. To this circumstance is attributed, in a considerable degree, the little success which their authors have met with in epic compositions. Phrases also, as well as words, which might originally have been in common use, are now restricted to poetical compositions. The language of Homer differs materially in the mode of inflexion, the syntax, and even the words, from that which was written and spoken in Greece in the days of Socrates; after an interval of 200 years. Homer, however, must have written in a dialect that was intelligible, though not perhaps in familiar use at the period in which he wrote. Notwithstanding the change that must have taken place, during so long an interval, in the style both of discourse and writing, the Iliad continued to be the standard of heroic poetry, and was considered as affording a specimen of the most perfect poetical language; though

Aristotle
Aristotle had doubts about the correct meaning of particular expressions. If Chaucer had ranked so highly as a poet as Homer did, and the English language under Edward III. had been as perfect as the Greek was in the second century after the Trojan war, his style would probably have been the model of poetical language at this day; as Petrarch, his contemporary, sets even now the standard for the best Italian poets. Many words and phrases, used by Ennius, a Latin poet, but not adopted by any prose writer now extant, are to be found in Lucretius and Virgil, and by them transmitted to succeeding poets. These form part of the Roman poetical dialect, which, as the writings of Virgil, where it is found in perfection, testify, was very copious. The style of this charming poet is so different from prose, and so peculiar, that it cannot be analyzed on the common principles of Latin grammar; and yet no author can be more periphrastic or more expressive; or knew better, according to the judgment of Quintilian, to improve even Greek, and old words by which he seems to be attached, into decoration.

The poetical dialect of modern Italy is so different from the profaic, that Petrarch or Tasso can scarcely be confounded by those who are well acquainted with the common language of that country; and yet it is not probable that Petrarch, whose works furnish a standard of the Italian poetical diction, made any material innovations in his native tongue. The French poetry, in general, is distinguished from prose rather by the rhyme and the measure, than by any old or uncommon phraefology. Nevertheless, the French, on certain subjects, imitate the style of their old poets, particularly of Marot, and may therefore be said to have a poetical dialect, though less extensive than that of the Italian, or even of the English. The English poetical dialect is not characterized by any peculiarity of inflexion, nor by any great latitude in the use of foreign idioms. Words and phrases, however, occur in English poetry that are not to be found in prose writings. Several of them will occur to the readers of our poets. The introduction of such words and phrases serves to render the poetical style more melodious; and when they are known to be ancient, more solemn, and by association more elegant and sublime. The following lines afford a specimen of poetical words, which no one can read without perceiving their effect:

“
The breezy call of incense-breathing morn,
The swallow twittering from the straw-built shed,
The cock's shrill clarion, and the echoing horn,
No mortal sound can measure but their lowly bed.”

We may add, that tropes and figures serve very much to improve poetical language. They render it more pleasing, and greatly contribute to its effect. They supply the unavoidable defects of common language; they are also favourable to delicacy of expression; they promote brevity, which, without interfering with periphrasis, is very pleasing; they give strength and energy to language, and make a deep and durable impression on the mind; they are the appropriate language of emotion and passion. See Figure and Threpe, and each figure under its proper name, as Apollrope, Hyperbole, and Prodogopoeia; which see. The found of words ought also to be regarded in poetical language; as it contributes to harmony of composition, without which no poet can be popular. See Verse and Rhyme.

Poetical Licence. See Licence.
Poetical Numbers. See Numbers.
Poetical Rising and Setting. See Rising and Setting.
The ancient poets, referring the rising, &c. of the stars to that of the sun, make three kinds of rising and setting, viz. coérical, acronical, and heliacal.

Poetical Theology. See Theology.

POETICS, Poetice, the doctrine of poetry, or the laws and rules of conducting pieces, or compositions of poetry. Aristotle's Poetics is a work very highly valued; and M. Dacier's comment upon it is one of his best pieces. Horace, Vieta, Voltaire, and Scaliger, have likewise published Poetics in Latin; the duke of Buckingham in English; and Menardiere, Hedelin, and Defpreaux, in French.
